P. australe. Botany-bay Stork's-bill. Willd. n. 81.—Umbels many-flowered, capitate. Leaves heart-shaped, crenate, slightly lobed; most downy beneath. *Nectary* very short.—Native of New South Wales.—This is one of those species found in New Holland, and not at the Cape of Good Hope, all which have a general resemblance among themselves, and are not much like any of the African species, except perhaps *althæoides*, Willd. n. 41, and *capitatum*, n. 83, hereafter described. Their habit is downy; *flowers* generally small, pale purple, in numerous, dense, hairy *umbels*; *leaves* heart-shaped, crenate, but slightly lobed; *nectary* very short. We hope to see them well distinguished in the second part of Mr. Brown's Prodromus. In the mean while we would remark that Willdenow's n^o 40, *anceps*, Jacq. Coll. v. 4. 184. t. 22. f. 3, is one of these New Holland species, and not, we believe, found in Africa. It is less hairy than the rest, but not entirely smooth. As far as we know this tribe, they have none of the aromatic scent, usual in their genus, nor much beauty. We have specimens of four very distinct ones from Port Jackson.

P. capitatum. Rose-scented Stork's-bill. Willd. n. 83. (*Geranium capitatum*; Linn. Sp. Pl. 947. Cavan. Diff. 249. t. 105. f. 1. *G. africanum, folio malvæ*; Riv. Pentap. Irr. t. 99.)—Umbels many-flowered, capitate. Leaves heart-shaped, lobed, wavy, crenate, soft and downy. Stem diffuse.

PELARGONIUM.

diffuse. Nectary very short.—The old favourite rose-scented Stork's-bill was among the first brought from the Cape, and is still preserved in collections, though far less frequently than formerly. The delicate scent of rose-water, which its herbage exhales when touched, is less powerful than that of the *graveolens*, of which we shall presently speak. The flowers are pale purple, with dark veins, and, having very short partial stalks, are crowded into a dense head. One of our New Holland species agrees with them in this respect, and vies with them in size. Indeed though L'Heritier distinguished the latter by the name of *P. extraneum*, we can scarcely think it different from *capitatum*, and if we are right, the species before us is therefore a native of New South Wales as well as of southern Africa.

P. tomentosum. Penny-royal Stork's-bill. Willd. n. 86. Jacq. Ic. Rar. t. 537. Curt. Mag. t. 518.—Umbels many-flowered, somewhat panicled. Leaves heart-shaped, five-lobed, rather hastate, ferrated, very soft and downy. Nectary very short.—Remarkable for its strong scent, like pepper-mint or penny-royal. It has been introduced from the Cape, since the first edition of Hort. Kew. was published. The stem is much branched, widely spreading and brittle. Flowers numerous, but not showy, white, with crimson lines, and *filaments* of the latter colour.

P. graveolens. Ottar of rose Stork's-bill. Willd. n. 89. L'Herit. Geran. t. 17. (Geranium terebinthinaceum; Cavan. Diff. 250. t. 114. f. 1.)—Umbels many-flowered, capitate. Leaves palmate, seven-lobed, their segments oblong, obtuse; revolute and very rough at the margin. Nectary about half as long as the calyx. Our readers would hardly recognise, under the names of *graveolens* and *terebinthinaceum*, the deliciously fragrant "Ottar of rose Geranium," as it is commonly called, which has supplanted the old *capitatum*, being far more powerful, though perhaps less delicate, in its scent. This perfumed kind, however, though now so common, is, it seems, but a variety of one less agreeable, and is first mentioned as such by Cavanilles. The shape of the leaves readily distinguishes this *Pelargonium* from every other. If we were to indulge our imagination in guessing at hybrid species, the present might be supposed an offspring of *capitatum*, impregnated by *Radula*, and that its scent varies according as it partakes more of the constitution of one parent or the other. We find it not much inclined to produce seeds. Willdenow mentions a rose-scented variety of *Radula*, impregnated by *graveolens*, and a less agreeable one of *graveolens* impregnated by *Radula*.

P. Radula. Rap-leaved Stork's-bill. Willd. n. 92. L'Herit. Geran. t. 16. (Geranium Radula; Cavan. Diff. 262. t. 101. f. 1. G. revolutum; Jacq. Ic. Rar. t. 133.)—Umbels of few flowers. Leaves digitate, doubly pinnatifid, toothed, linear, revolute, very rough. Nectary nearly as long as the calyx.—Introduced from the Cape in 1774, and now frequent in collections. The narrow linear segments of the deeply divided rough leaves, and their strong mint-like scent, are enough to determine this species, of which we greatly suspect Willdenow's *asperum*, n. 90, and *denticulatum*, n. 93, to be varieties.

Section 6. *Stem shrubby. Leaves either three-cleft or ternate.*
Seventeen species.

P. bicolor. Two-coloured Stork's-bill. Willd. n. 94. Curt. Mag. t. 201. (Geranium bicolor; Jacq. Hort. Vind. v. 3. 23. t. 39. Cavan. Diff. 248. t. 111. f. 1.)—Umbels many-flowered. Leaves heart-shaped, deeply three-cleft, wavy, hairy; their segments obtuse, three-lobed, cut and toothed. Nectary nearly as long as the flower-stalk.—The native country of this elegant species seems not to have

been ascertained, for we do not find its name in Thunberg's long list of Cape Geraniums, nor has it been heard of but in gardens. Jacquin and Curtis say the seeds are scarcely ever perfected; yet we know not to what particular kinds it is sufficiently allied for us to guess at its hybrid birth. The petals are deep crimson, with a white edge, not unlike the pretty *Silene quinquevulnera*. The leaves are sometimes so deeply divided as to become ternate.

P. scabrum. Rough Stork's-bill. Willd. n. 96. L'Herit. Geran. t. 31. Jacq. Ic. Rar. t. 542. (Geranium scabrum; Linn. Sp. Pl. 946. Burm. Geran. 34. n. 39. t. 1. Cavan. Diff. 247. t. 108. f. 1.)—Umbels of few flowers. Leaves wedge-shaped, deeply three-cleft, acute, coarsely ferrated, rough. Nectary the length of the calyx. Messrs. Kennedy and Lee are said to have introduced this from the Cape in 1775. Its shrubby, much branched stem, as well as the leaves, are extremely harsh to the touch, especially in wild specimens, whence Burmann chose the name. The segments of the foliage vary in breadth. The scent is not remarkable. The flowers are rose-coloured and variegated, but few, small, and inconspicuous, nor is the plant entitled to such general favour as many others.

P. crispum. Curled-leaved Lemon Stork's-bill. Willd. n. 99. L'Herit. Geran. t. 32 and 33. (Geranium crispum; Linn. Mant. 257. Cavan. Diff. 252. t. 109. f. 2. G. hermännifolium; Linn. Suppl. 305. Herb. Linn.)—Stalks one or two-flowered. Leaves stalked, two-ranked, roundish-heart-shaped, three-lobed, wavy, plaited, toothed, rough. Stipules heart-shaped. Nectary the length of the calyx.—A pretty species, sent from the Cape by Mr. Masson, in 1774, and valued more particularly for its lemon-scent, resembling that of *Verbena triphylla*. There are two varieties, one with leaves about half an inch in diameter, the other above an inch; in both they are three-lobed, more than half way towards the base, and stand on footstalks about their own length, occasionally more or less. Flowers large in proportion, rose-coloured, with a purple-eye-like spot on each of the broad upper petals, standing, usually solitary, on long slender, axillary stalks, about the upper part of the branches. The ribs of the leaves, especially in wild specimens, are extremely rough, with minute hooked bristles. The larger-leaved variety has more generally two, or even three, flowers on a stalk.

P. hermännifolium. Hermannia-leaved Stork's-bill. Willd. n. 100. Jacq. Ic. Rar. t. 545. (Geranium hermännifolium; Linn. Mant. 569. Cavan. Diff. 240.)—Stalks two-flowered. Leaves sessile, two-ranked, wedge-shaped, slightly lobed, wavy, plaited, toothed, rough. Stipules heart-shaped. Nectary rather longer than the calyx.—The Linnæan herbarium has no specimen of this species, nor do we know it but from the books quoted. It seems to differ from the last chiefly in the want of footstalks.

P. adulterinum, Willd. n. 101. L'Herit. Geran. t. 34, a soft-leaved plant, is acknowledged to be a hybrid production, and we are disposed to doubt whether *femitrilobum*, Jacq. Hort. Schonbr. v. 2. 3. t. 130, notwithstanding Willdenow's opinion, be more than a variety of some of the last described species, but we have not examined specimens of either.

P. fulgidum. Celandine-leaved Stork's-bill. Willd. n. 104. (Geranium fulgidum; Linn. Sp. Pl. 945. Cavan. Diff. 253. t. 116. f. 2. G. africanum folio alceæ, flore coccineo fulgidissimo; Dill. Elth. 156. t. 130.)—Umbels in pairs, many-flowered. Leaves downy, in three deep segments; the middle one largest; all pinnatifid and cut. Calyx oblique. Nectary pouched at the base.—An old, but rather tender, and not very common, species in our greenhouses or stoves, distinguished

PELARGONIUM

distinguished from all others by the intense brilliant scarlet of its *petals*, to which we know nothing comparable in the vegetable kingdom. The *flowers* however are inelegant in form, far from abundant, and the whole plant rather unsightly, like something starved or abortive. The *nectary* is not quite so long as its flower-stalk; its base inflated and almost globose; its top funnel-shaped; hence the segments of the *calyx* are turned to one side, or rather vertically.

P. gibbosum. Gouty Stork's-bill. Willd. n. 105. (*Geranium gibbosum*; Linn. Sp. Pl. 946. Cavan. Diff. 265. t. 109. f. 1. *G. africanum*, foliis aquilegiæ; Riv. Pentap. Irr. t. 100.)—Umbels many-flowered. Leaves ternate, smooth; leaflets obtuse, notched; the middle one largest, three-cleft. Nectary cylindrical. Stem with knotty joints.—This also was very early brought from the Cape into the gardens of Europe. Yet its succulent *stem* renders it not one of the easiest to cultivate. The glaucous smooth *leaves* are well compared by Rivinus, whose plate is excellent, to those of the Columbine. The *calyx*, and partial *flower-stalks*, are finely downy, and rather hairy. Nectary nearly as long as the *stalk*, its termination not defined, except by the increasing downiness below it. *Flowers* of a dull yellowish or tawny green, exquisitely fragrant at night, like those of *triste*, &c.

P. exilipulatum. Soft-leaved Trifid Stork's-bill. Willd. n. 106. L'Herit. Geran. t. 35. (*Geranium exilipulatum*; Cavan. Diff. 253. 271. t. 123. f. 1.)—Umbels of few flowers. Leaves heart-shaped, hoary, in three deep, lobed, toothed segments. Stipulas scarcely any.—Sent from the Cape of Good Hope in 1779, by Lieut. Col. William Paterson, at that time engaged there in a botanical expedition. This species bears a considerable resemblance to *crispum*, *adulterinum*, &c. in general habit. The *leaves* are small, fragrant, on longish stalks. Stipulas hardly to be seen but on the youngest most luxuriant *branches*, where they are awl-shaped and minute. *Flowers* from three to five on each stalk, rose-coloured, with spots on the two upper *petals*, rather small. Nectary twice the length of the *calyx*.

P. ternatum. Ternate Stork's-bill. Willd. n. 107. Curt. Mag. t. 413. Jacq. Ic. Rar. t. 544. (*Geranium ternatum*; Linn. Suppl. 306. Cavan. Diff. 255. t. 107. f. 2.)—Stalks with few flowers. Leaves ternate, rough, rigid; leaflets linear-wedge-shaped, three-cleft, toothed. Stem rough. Anthers five.—Of the same tribe with the last, but the herbage is rough and harsh to the touch; *flowers* larger and handfomer; *stipulas* ovate, pointed. It came to England in 1790.

P. fragile. Brittle-stalked Yellow Stork's-bill. Willd. n. 109. (*Geranium fragile*; Andr. Repof. t. 37.)—Umbels many-flowered. Leaves ternate, smooth, fleshy; leaflets wedge-shaped, cut; the middle one largest and three-cleft. Nectary as long as the flower-stalk.—Procured from the Cape by Messrs. Lee and Kennedy in 1792. A tender, succulent species, with buff or yellowish *petals*, striped with crimson. In these particulars it differs from the rest of those which close this section in Willdenow, though it agrees with them in the form and division of their *leaves*.

Section 7. *Stem shrubby. Leaves either pinnatifid or pinnate.* Four species.

P. carnosum. Fleshy-stalked White Stork's-bill. Willd. n. 111. (*Geranium carnosum*; Linn. Sp. Pl. 946. Cavan. Diff. 266. t. 99. f. 1. *G. africanum carnosum*, petalis angustis albicanibus; Dill. Eith. 153. t. 127.)—Umbels many-flowered. Leaves sinuated, pinnatifid; segments oblong, obtuse, cut and toothed at the extremity. Petals linear. Stem thick and fleshy.—This appears to have been

cultivated in Chelsea garden, so early as 1724. It is now not frequently to be met with. The *stem* is tall, erect, thick and juicy below; much branched and finely hoary above, terminating in numerous small *umbels*, of inconspicuous white *flowers*. The *nectary* is almost twice the length of the *calyx*, and above half as long as the *flower-stalk*, its base tumid, somewhat like that of *fulgidum*. The *style* is much elongated beyond the hairy rudiment of the beak.

P. ferulaceum, Willd. n. 112. Burm. Afr. t. 36. f. 1, we have not seen, but it has the appearance of a narrow-leaved variety of the last. With *P. alternans*, Willd. n. 113, we are also unacquainted. It occurs in the Hortus Cantabrigiæ of the late Mr. Donn.

P. ceratophyllum. Horn-leaved White Stork's-bill. Willd. n. 114. L'Herit. Geran. t. 13. Curt. Mag. t. 315.—Umbels many-flowered. Leaves distantly pinnatifid, fleshy, rather cylindrical; segments channelled, three-cleft or pinnatifid.—Native of the fourth-west coast of Africa, from whence it was sent to Kew in 1786, by Mr. A. Hove. Like all the fleshy kinds, it is best preserved in a stove. Its habit and *flowers* much resemble the *carnosum*, but the *nectary* is only as long as the *calyx*. The *leaves* are smooth, glaucous, peculiarly thick and fleshy, with almost cylindrical segments, that are generally simple, and but slightly toothed towards their extremities; but we have a specimen in which they are deeply pinnatifid, so that this species connects the present section with the following, being indeed nearly akin to *crithmifolium*.

Section 8. *Stem shrubby. Leaves twice or thrice compounded.* Six species.

P. crithmifolium. Samphire-leaved White Stork's-bill. Willd. n. 115. Smith Ic. Pict. t. 13. (*P. paniculatum*; Jacq. Hort. Schonbr. v. 2. 6. t. 137.)—Umbels many-flowered, panicled. Leaves doubly pinnate, fleshy; segments dilated and cut. Petals obtuse; the upper ones crisped at the base.—Seeds of this noble species were brought from the Cape of Good Hope by the celebrated captain Riou of the Guardian, and being raised in the stove of the marchioness of Rockingham, the plants flowered in April 1792. It greatly exceeds the last in size, and has more compound and dilated *leaves*. The *stem* is very fleshy, resembling a cabbage-stalk, leafy below, crowned at the summit with an ample *panicle*, composed of numerous *umbels* of white *flowers*, which resemble those of *carnosum* and *ceratophyllum*; but the *petals*, instead of being oblong and acute, are obovate and obtuse, the two uppermost bluish-coloured, and remarkably crisped on each side at the base. We have therefore no doubt of the species being perfectly distinct.

P. abrotanifolium. Southernwood-leaved Stork's-bill. Willd. n. 117. Jacq. Hort. Schonbr. v. 2. 6. t. 136. (*Geranium abrotanifolium*; Linn. Suppl. 304. Cavan. Diff. 256. t. 117. f. 1.)—Umbels of few flowers. Leaves in many cylindrical, channelled, compound, hoary segments. Nectary as long as the flower-stalk. Calyx very hairy.—Gathered by Thunberg at the Cape. We have not heard of it amongst our collectors. The *stem* is woody, bushy, much branched, not fleshy. *Leaves* like those of *Artemisia Abrotanum*, numerous, crowded, somewhat aromatic, even when they have been many years dried. *Umbels* on longish stalks, each of about three light-purple, striped, smallish *flowers*, whose *calyx* is clothed with long horizontal hairs.

P. fruticosum. Willd. n. 118. (*Geranium fruticosum*; Cavan. Diff. 263. t. 122. f. 2.) appears to be a smooth-leaved variety of the foregoing. The name is not one of the most discriminative.

P. tenuifolium.

PELARGONIUM.

P. tenuifolium. Fine-leaved Pink Stork's-bill. Willd. n. 120. L'Herit. Geran. t. 12. (*P. hirtum*; Jacq. Ic. Rar. t. 536. Willd. n. 119. *Geranium hirtum*; Burm. Geran. 48. n. 64. t. 1, excluding the reference to Linnæus. Cavan. Diff. 258. t. 117. f. 2.)—Umbels many-flowered. Leaves oblong, pinnate, thrice compound, hairy, with linear segments. Stem fleshy. Nectary the length of the calyx.—Native of the Cape. Introduced into England by Mr. W. Malcolm, in 1768. We do not hesitate to unite, in this place, two supposed species of Willdenow; and it is fortunate that his and Burmann's name of *hirtum* here becomes superfluous, that very fine appellation having been inadvertently applied by Willdenow to his own ninth species, the *filosum* of Cavan. Diff. 273. t. 199. While we thus, as in other instances, attempt to correct the imperfections of our laborious predecessor, we cannot withhold our testimony to the merit of his performance, concerning the present genus. His arrangement of the species is the best we have met with, and he appears to have practically studied and understood most of them; having been misled now and then, chiefly by a deference to other writers. We hope to find this beautiful and favourite family of plants still further illustrated and enriched, in the fourth volume of the second edition of Mr. Aiton's Hortus Kewensis, of which Willdenow's labours will, in this instance, with advantage, lay the foundation. S.

PELARGONIUM, in *Gardening*, contains plants of the fine-shrubby, under-shrubby, evergreen, and herbaceous perennial kinds, for the green-house, of which the species cultivated are; the lady's-mantle-leaved crane's-bill (*P. alchemilloides*); the sweet scented crane's bill (*P. odoratissimum*); the gooseberry-leaved crane's-bill (*P. grossularioides*); the coriander-leaved crane's-bill (*P. coriandrifolium*); the fleshy-stalked crane's-bill (*P. carnosum*); the horn-leaved crane's-bill (*P. ceratophyllum*); the gouty crane's-bill (*P. gibbosum*); the multifid-leaved crane's-bill (*P. radula*); the butterfly crane's-bill (*P. papilionaceum*); the scarlet-flowered crane's-bill (*P. inquinans*); the common horse-shoe crane's-bill (*P. zonale*); the two-coloured crane's-bill (*P. bicolor*); the balm-scented crane's bill (*P. vitifolium*); the rose-scented crane's-bill (*P. capitatum*); the clammy crane's-bill (*P. glutinosum*); the hooded crane's-bill (*P. cucullatum*); the heart-leaved crane's-bill (*P. cordatum*); the prickly-stalked crane's-bill (*P. echinatum*); the square-stalked crane's-bill (*P. tetragonum*); the birch-leaved crane's-bill (*P. betulinum*); the spear-leaved crane's-bill (*P. glaucum*); the sorrel crane's-bill (*P. acetosum*); the rough-leaved crane's-bill (*P. scabrum*); the ternate crane's-bill (*P. ternatum*); and the three-coloured crane's-bill (*P. tricolor*).

The first has a variety with a dark circle in the middle of the leaves.

In the eighth sort there are two varieties, a larger and a smaller; and as it is readily raised from seeds, it affords many femal varieties.

The eleventh sort contains a variety with fine variegated leaves, and the flowers vary much in colour from purple, through the different shades of red to high scarlet.

In the fifteenth, several varieties have been produced from seed.

In the seventeenth there are several varieties.

The eighteenth also varies with petals of a rich purple colour, in which the spots are similar, but not so conspicuous.

In the nineteenth there is a variety with beautifully coloured leaves.

And in the twentieth there is a variety with scarlet flowers raised from seed.

Method of Culture.—All the sorts may be increased by seeds, which should be sown in the early spring in pots filled with kitchen-garden mould, plunging them in a moderate hot-bed. The plants soon appear; when they should have fresh air as much as possible, to prevent their being drawn up weak. When the plants have attained some growth, they should be removed into separate small pots filled with the same sort of earth, replanting them in the hot-bed till fresh rooted, and giving proper shade. They should afterwards be gradually inured to the open air, in order to be placed out in it, in the summer season, in a sheltered situation.

They may also be raised in the open ground without the hot-bed, but not so well.

But they are more commonly increased, especially the shrubby sorts, by cuttings of the young branches, which should be planted in a shady border in the summer, or in pots, and plunged in any hot-bed; which is the better method. When well rooted they may be taken up, and planted into separate pots, placing them in the shade till they have taken new root; after which they may be removed into a sheltered situation, and be treated in the same manner as the seedling plants. The fifth, seventh, and fifteenth sorts have more succulent stalks than the others; the cuttings should therefore be planted in pots filled with the same sort of earth, and plunged into a very moderate hot-bed, where they may be shaded from the sun in the heat of the day; and have but little water; for these are very apt to rot with much moisture. When these are well rooted, they may be removed, and planted in separate pots filled with the same sort of earth, and placed in the shade till they have taken new root; then they may be removed into a sheltered situation, where they may remain till autumn. These sorts should be sparingly watered, especially in the winter season, as they are apt to take a mouldiness with moisture, or in a damp air. They thrive much better in an airy glass-case than in a green-house, as in the former they have more sun and air than in the latter. But all the other shrubby sorts are proper for the green-house, where they only require protection from frost, but should have a large share of free air when the weather is mild. They require water every week, in mild weather once or twice; but it should not be given them in too great plenty, especially in frosty weather. These plants should be hardened in the spring gradually, and towards the middle or end of May be taken out of the green-house, and at first placed under the shelter of trees, where they may remain a fortnight or three weeks to harden; and then be removed into a situation where they may be defended from strong winds, and enjoy the morning sun till eleven o'clock, where they will thrive better than in a warmer situation. And as these sorts grow pretty fast, they soon fill the pots with their roots; and when they stand long unremoved in summer, they frequently put out their roots through the holes at the bottom of the pots into the ground, when the plants grow vigorously; but if suffered to continue long in this manner, it is difficult to remove them; as if their roots be torn off, all the younger branches decay, and the plants are frequently killed. The pots should therefore be moved once in a fortnight or three weeks, in the summer months, and the roots which may then be pushing through the holes cut off, to prevent their striking into the ground.

They require also to be new potted at least twice in the summer; the first time after they have been three weeks or a month out of the green-house; the second towards the end of August, or beginning of September, that the plants may have time to establish their new roots before they are removed into the green-house. When this is performed, all the roots on the outside of the balls of earth should be carefully

fully pared off, and as much of the old earth drawn away from the roots, as can be done with safety to the plants; then, where they require it, they should be put into pots a size larger than those out of which they were taken, putting a quantity of fresh earth into the bottom of each pot, placing the plants upon it, being careful that the ball about the roots of the plant be not so high as the rim of the pot, that some room may be left to contain the water which may be given to them. Then the cavity all round the ball should be filled up with fresh earth, be gently pressed down, and the bottom of the pot beaten upon the ground, to settle the earth; the plant being then well watered, and the stem fastened so as to prevent the wind from displacing the roots before they are fixed in the new earth.

Where such mould as has been mentioned cannot be procured, fresh hazel loam from a pasture, mixed with a fourth or a fifth part of rotten dung; or, where the earth is inclinable to bind, a mixture of rotten tan; and, where light and warm, a mixture of neat's-dung may be employed. This compost should be mixed three or four months before it is used, and be turned over three or four times, that the parts may be well incorporated.

The shrubby forts require to be looked over frequently during the winter, while they are in the green-house, to pick off all decayed leaves from them, which if left on will not only render the plants unhealthy, but by their falling off make a litter among the other plants; and if they are suffered to rot in the house, they occasion a foul, nasty, damp air, which is very prejudicial to all the plants.

The first fort, from having herbaceous stalks, is best increased by seeds, though cuttings of it will take root.

And the second fort may not only be propagated by seeds, but also from heads slipped off from the short fleshy stalk; which should have their lower leaves stripped off, and be then planted single in a small pot; or where the heads are small, two or three may be put into one pot; plunging them into a very moderate hot-bed, shading and refreshing them gently with water. They take root in a month or five weeks; when they should be hardened gradually to the open air, where they may remain till autumn, when they must be removed into shelter, as in the other kinds.

The sixth kind is capable of being increased both by seeds and cuttings, but it is found to be more tender than many other forts, and more liable to be injured by damps. The eighth species is readily increased by cuttings; but the twelfth is more difficultly to be raised in this way. The fifteenth is easily raised by cuttings, and sometimes by seeds; and the seventeenth readily strikes from cuttings; the eighteenth produces seeds, but is more usually increased by cuttings; and the nineteenth and twentieth are readily propagated in the same way; the twenty-first is likewise raised from cuttings, but they are not very free in striking; the twenty-fourth is raised in this manner without difficulty; but in the twenty-fifth, from the branches running out speedily into flowering stalks, few are formed proper for cuttings, and these are struck with difficulty.

All these plants are highly ornamental, and afford considerable variety in collections of green-house plants.

PELASGIANS, in *Ancient Geography*, the most ancient people of Greece, according to Thucydides, Strabo, and Herodotus. The last author says, that the whole country, which in his time was called "Hellas," was in a former period denominated Pelasgia. These people, as some say, were denominated Pelasgi, because they were an unsettled wandering people, who often changed their habitations. Others, among whom we may reckon Hesiod, take them to have been Autochthones, which was the designation given

to the natives of the country, or rather to all whose original was unknown. If we admit Apollodorus's authority, in which Servius (on the 2d *Æneid*) acquiesces, the Pelasgi derived their name from one Pelasgus, a person of great antiquity, and several persons of this name are mentioned by ancient writers. The ancient Scholiast on Apollodorus Rhodius, makes Pelasgus to have been the son of Inachus, and this is the same who, according to Hesiod, was the father of Lycaon, king of Arcadia. According to Pausanias (in *Arcad.*) Pelasgus was the first man who appeared in the country, and surpassed all others in the faculties both of his body and mind. As soon as he began to reign, he taught the Arcadians to erect cottages to shelter themselves from the injuries of the weather, and to clothe themselves with bear's skins. Till that time they had lived upon leaves of trees, herbs, and roots; but instead of these he recommended the use of acorns, or rather a kind of fruit which grew upon the beech-tree; and this food became so common, that long after Pelasgus, the Arcadians were represented as a people who lived only upon acorns, and who on this account were terrible and invincible in war. See *GRÆCIA*.

The writers first cited in this article say, that the Pelasgians were first known in Thessaly, and that from thence they extended their migrations through all the other countries of Greece. However, Dionysius of Halicarnassus says, that they derived their origin from Peloponnesus, and that they sent from hence colonies into Thessaly. This author adds, that these people left Thessaly, and spread themselves through Epirus, Italy, Thrace, the isles of Asia Minor, under the reign of Deucalion. M. de Gebelin says, that the Pelasgi were the possessors of the whole country, which extended from the banks of the Danube to the sea of Peloponnesus; that some of them peopled Thrace, Getia, Macedonia, Illyria, Epirus, Thessaly, the Phocids, the Peloponnesus, and Attica; and that others crossed the Danube, and bore the appellation of Dacii and Getæ. They are said to have replenished all these countries with celebrated cities, and an immense population; to have extended cultivation wherever they went, and to have sent out numerous colonies. On account of these emigrations they were reckoned a wandering people, without arts and sciences.

If we may credit Herodotus, the Pelasgi, having settled in Samothracia, introduced thither the worship of the Cabiri and their mysteries, which they afterwards communicated to the Athenians, among whom they fixed their residence when they quitted that island; but he does not inform us from whom they derived their knowledge of these gods and of their mysteries. We learn from Dionysius Halicarnassensis that some of the Pelasgi, who departed from Thessaly, were received at Dodona; and that in obedience to an oracle they passed into Italy, and settled at the mouth of the Po. Those of them that were least able to bear fatigue, were entrusted with the care of their vessels, and others of them advanced into the country, traversed the mountains, and descended into the country of the Umbrians. Among these people, they obtained some cities, till they were forced to retire among the aborigines, who were the neighbours of the Arcadians; and in process of time they conciliated the aborigines, and were allowed to settle among them. But the country being too small for their accommodation, the Pelasgi induced the aborigines to join them in making an irruption into Umbria, where they took possession of Crotona. Here they founded other cities, which were afterwards occupied by the Tyrrhenians. The Pelasgi founded the town of Larissa, in Campania, of which country they possessed a part after having expelled from it the Aurunci.

In Italy the Pelasgi, after the departure of the Siculi, enjoyed

enjoyed a large and beautiful territory, so that they became rich and powerful. Those who had been left to guard their vessels, built a town to which they gave the name of the river, and gradually became masters of the sea. They sent to the temple at Delphos tithes of their marine profits; at length, however, they were attacked by their neighbours and obliged to abandon their city. The Pelasgi, who were associated with the aborigines, were overpowered by their barbarian neighbours, so that only a few remained among the aborigines, the greatest part having been dispersed in Greece, and among the Barbarians. According to Dionysius Halicarnassensis it was about two generations before the war of Troy, that the Pelasgi experienced these misfortunes. All the towns which they inhabited were demolished, excepting Crotona; but it changed its name and its inhabitants, and in the time of this historian was called Cothornia.

According to the relation of Herodotus, the Pelasgi, under the reign of Deucalion, were in possession of the part of Thessaly called Phthiotis, where they remained till the reign of Dorus, grandson of Deucalion. They then migrated to another part of Thessaly called Esfizotis, situated at the foot of mount Ossa and mount Olympus. From thence they were driven by the Cadmæans, and they established themselves at the foot of Pindus, and were denominated Macedonians.

Dionysius of Halicarnassus says, that about two generations before the war of Troy, some of the Pelasgi, driven from their cities, returned into Greece. These settled in Attica, the Athenians assigning to them a territory at the foot of mount Hymettus, on condition of their building a wall to encompass the citadel. Their ingenuity excited the jealousy of the Athenians, and they expelled them from Attica. They then dispersed in different places, and one party settled in the isle of Lemnos. When they were established in this island they determined to avenge themselves on the Athenians; and for this purpose armed their vessels and made a descent on Attica. Here they seized a number of females, who were celebrating the feast of Diana, and taking them to Lemnos, made them their concubines. The offspring of these females being instructed in the language of the Athenians, and in their mode of life, conceived an aversion to the legitimate children of the Pelasgi; and this occasioned the murder of the illegitimate children and of their mothers. The Athenians, under the command of Miltiades, drove the Pelasgi from Lemnos; and they then established themselves, according to Herodotus, in the town of Aclé, a territory separated from the continent of Thrace by a canal; by degrees they extended themselves to the continent, and occupied Crestonia.

Dionysius informs us, that when some of the Pelasgi, under the reign of Deucalion, passed into Italy, the isle of Crete, and the Cyclades, Bœotia, the Phocide, and Eubœa, others migrated into Asia. According to Strabo, the Lesbians claim the honour in behalf of their ancestors of having been in the war of Troy, under the conduct of Pylæus, a chief of the Pelasgi. All the towns of the maritime coast of Ionia had been at one time inhabited by the Pelasgi; the inhabitants of the isle of Chios also pretend that the Pelasgi of Thessaly were their founders; nor indeed is there a country of Greece, Thrace, and Asia Minor, in which the Pelasgi have not left traces of their power. Soon after the war of Troy, the name of Pelasgi began to sink into oblivion. Those who existed till the time of Herodotus, near the Hellespont, and on the coasts of Thrace, were subject to foreign dominion; and the language which they spoke was the only evidence of their ancient origin. Thucydides says, that the chief cause of the ruin of this nation was the confederation of

the Hellenes, who sprang from the Pelasgi themselves. The Hellenes made a league, formed among themselves a separate body, and made conquests. After separation from the Pelasgi, their parents, they estranged themselves from their names and habits, and by little and little changed their language, in consequence of the commercial intercourse which they had with colonies from the east. Those at length who were originally Pelasgi joined this league, surrendered the name of Pelasgi, and adopted that of Hellenes. Herodian relates, that the Athenians, though reckoned to be Pelasgians at the time of the famous emigration of these people, were become Hellenes, when the Pelasgi, driven from Italy, returned to Greece. About the same time the Lacedæmonians, the Argians, and the Arcadians, who had been also known under the name of Pelasgians, laid aside the barbarism of their progenitors, and assumed the name of Hellenes. The Pelasgi, according to Herodotus, established at Dodona the most ancient and the most respectable of the oracles of Greece. He adds, that they had no other idols nor temples; that they offered their sacrifices to the gods, and gave neither name nor surname to the deities whom they worshipped.

Dionysius Halicarnassensis, in speaking of the antiquity of the Pelasgians, inhabitants of Falerii and Fescennia, two ancient cities of Etruria, built in the Grecian form, says, "the manner of their religious ceremonies was the same as those of Argos. Holy women served in the temple, and a girl unmarried, called canephoros, or basket-bearer, began the sacrifice, besides chorusses of virgins, who hymned the goddess in songs of their country." Now as the Romans had an earlier communication with the Etruscans than with the Greeks, this passage renders it very probable that they were obliged to the people of Etruria for their religious ceremonies, and for vocal music.

Strabo, (de bello Punico,) says in express terms, that the public music, especially such as was used in sacrifices, came from Etruria to the Romans. See also Livy, lib. xxxix.

PELASGICUS SINUS, a gulf of Thessaly, on the coast of the Phthiotide. This gulf had Magnesia on the east, and the Phthiotide on the west; its entrance was a wide strait, between the town of Antron to the south, and the promontory Æantium to the west.

PELASGIOTIS, or PELASGIS, a country of Thessaly, the extent of which is variously assigned by different authors. The epoch of the arrival of the Pelasgi in Thessaly is fixed by some writers to the year 1883 B.C. It is probable, that they established themselves in the centre of the country, to the S. and N. of the Alpheus; but some say that this province had for its boundaries to the N. Aliacmon and the Peneus to the S. But if the Pelasgiotide be considered as comprehending three parts, viz. Perrhæbia, Pelasgiotide proper, and the delightful valley of Tempe, the country must have extended to the S. of the Alpheus. From W. to E. its extent was limited by the mountains.

PELATÆ, Πελαταί, in *Antiquity*, a particular kind of servants among the Athenians.

The pelatæ were free-born citizens, who by reason of their indigence, were forced to serve for wages. They had no suffrage in public affairs, as not being masters of an estate proper to qualify them for giving their votes; but this restriction was not perpetual. They were otherwise called *thetes*, and continued in the condition of servants only during their own pleasure and necessities; for they had power either to change their masters, or (if they became able to subsist themselves) wholly to release themselves from servitude.

PELCHILLEN, in *Geography*, a town of Prussia, in Natangen; 25 miles S.S.E. of Königberg.

PELECANUS.

PELECANUS, *the Pelican*, in *Ornithology*, a genus of birds of the order *Anseres*. The generic character is, bill straight, hooked at the point, and furnished with a nail; the nostrils have an obliterated slit; the face is rather naked; the legs balance the body equally; the four toes are connected by a membrane.

The birds of this genus are gregarious, fond of fish, and in general remarkable for their extreme voracity. For the most part they keep out at sea, but some of them are found in the interior parts of continents. They have a long bill, in a lateral furrow of which lie the nostrils. Several of the tribe are rendered useful to mankind, by being taught to fish for them. There are thirty-one species, divided into sections according to the structure of the bill.

A. *Bill without Teeth.*

Species.

ONOCROTALUS, or *White Pelican*. The birds of this species are, as the name imports, white; the gullet is pouched; the bill is red, and from fifteen to sixteen inches long; the upper mandible is depressed and broad, the lower forked; bag at the throat flaccid, membranaceous, capable of great distension; the irides hazel-coloured; the gape of the mouth wide; the head is naked at the sides, covered with a flesh-coloured skin; the hind head is somewhat crested; the body is faintly tinged with flesh-colour; the spurious wings and first quill-feathers are black; the legs are of a lead colour. It is larger than a swan, and about five feet long. It inhabits Asia, Africa, and South America. In fishing, this bird does not immediately swallow its prey, but fills its bag, and returns to the shore to devour at its leisure the fruits of its industry. As it has a very quick digestion, it has generally to fish more than once in a day. At night it retires to rest, a little way on the shore, with its head resting on its breast. In this state it remains almost motionless, till hunger calls it to break its repose. It then flies from its resting-place, and raising itself 30 or 40 feet above the surface of the sea, turns its head with one eye downwards, and continues to fly in that posture till it sees a fish sufficiently near the surface, when it darts down with astonishing swiftness, seizes it with unerring certainty, and stores it up in its pouch. It then rises again, and continues the same manœuvres, till it has procured a competent stock. The female feeds her young with fish, macerated a long time in her bag. The pelican is susceptible of domestication, and may be trained to fish for its master. The pelican generally builds in marshy and uncultivated places, particularly in islands and lakes, making its nest, which is deep, a foot and a half in diameter, of carices, and lining it with grass of a softer texture. It lays two or more white eggs, which, when harassed, it sometimes hides in the water. When it builds in dry and desert places, it brings water to its young. It walks slowly, flies in flocks, and lives in society with other birds.

ROSEUS; *Rose-coloured Pelican*. This species is of a rosy colour; the gullet is pouched; the bill and legs are black; the area of the eyes is naked; the pouch yellow. It is about the size of a goose, and inhabits Manilla.

FUSCUS; *Brown Pelican*. This, as its name imports, is cinereous brown; the gullet is pouched. It inhabits America, and is four feet long.

MANILLENSIS; *Manilla Pelican*. Entirely brown; gullet pouched. It inhabits, as its name shews, Manilla, and is very like the roseus.

PHILIPPENSIS; *Philippine Pelican*. White; crest varied with white and brown; the gullet is pouched. It is about

four feet and a half long, and is found in the Philippine islands.

RUFESCENS; *Red-backed Pelican*. Reddish; crested head and neck reddish-white; tail dusky; the gullet is pouched. It is four feet long, and inhabits Africa.

CAROLINENSIS; *Charlestown Pelican*. Dusky above, beneath white; gullet pouched. There are two other varieties: 1. One is reddish-white beneath; the upper mandible is rounded at the base. 2. The other is on the lower part of the back striate and dusky-white. It inhabits America; is above three feet long; the pouch is very large.

ERYTHORHYNCHOS; *Rough-billed Pelican*. Crested; white; gullet pouched, and streaked with black. It inhabits North America, and is four feet and a half long.

AQUILUS, or *Frigate Pelican*. The tail is forked; body ferruginous, and orbits black; the bill is red; belly of the female white. It is three feet long; and the extent of the wings is full fourteen feet. It inhabits within the tropics. It is mentioned by Dampier, and other navigators, as the frigate bird. From its great expanse of wing it is capable of flying very smoothly, and so high as to be scarcely visible, seldom coming to land. It feeds on fishes, particularly flying fish, on which it darts with the greatest velocity. It builds on trees or on rocks, and lays one or two eggs of a flesh-colour, and spotted with red.

MINOR; *Lesser Frigate Pelican*. The tail is forked; body ferruginous; bill and orbits red. It resembles the last, but is less, being only about three feet long.

LEUCOCEPHALUS; *White-headed Pelican*. The tail of this species is forked; the body brown; head, neck, breast, and belly white; bill dusky.

PALMERSTONI; *Palmerston Frigate Pelican*. Tail forked; body glossy green-brown, beneath white; throat varied with black. It inhabits Palmerston's island in the South Pacific ocean; is about three feet two inches long. The bill is black; the temples feathered; the legs blackish.

*** CARBO**; *Corvorant*. Tail rounded; body black; head somewhat crested; bill blackish; the base of the lower mandible covered with a yellowish skin, extending under the chin, and forming a pouch; irides green; chin white, surrounded with a yellowish arch; tail long and lax, consisting of fourteen feathers; thighs with a white spot, dotted with black; legs black. Three feet long; size of a goose, but more slender, and weighs about seven pounds. Inhabits Europe, Asia, and America. Common on many of our sea-coasts, building its nest on the highest parts of cliffs that hang over the sea, and laying three or more pale green eggs, about the size of those of a goose. In winter these birds disperse along the shores, and visit the fresh waters, where they commit great depredations among the fish. They are remarkably voracious, and have a very quick digestion. Though naturally extremely shy and wary, they are stupid, and easily taken when glutted with food. Their smell, when alive, is more rank and offensive than that of any other bird; and their flesh is so disgusting, that even the Greenlanders will hardly taste it. It is not uncommon to see twenty of these birds together, on the rocks of the sea-coast, with extended wings, drying themselves in the wind. In this attitude they sometimes remain for nearly an hour, without once closing their wings; and as soon as the latter are sufficiently dry to enable the feathers to imbibe the oil, they press this liquor from the receptacle on their rumps, and dress the feathers with it. It is only in one particular state that the oily matter can be spread on them, namely, when they are somewhat damp; and the instinct of the birds teaches them the proper moment. Corvorants were formerly sometimes trained in this country, as they still are in China, for the purpose

PELECANUS.

purpose of catching fish for the table. With this view they were kept with great care in the house, and when taken out for fishing, they had a leathern thong tied round their neck, to prevent them from swallowing their prey.

GRACULUS; Shag. Tail rounded; body black, brown beneath; tail-feathers twelve; head and neck black, with a green gloss; back and wing-coverts purple-black, glossy at the edges; middle of the belly dusky; legs black. Weighs about four pounds. Length twenty-nine inches. The female weighs about three pounds and a quarter, and is only twenty-seven inches long. Inhabits the northern seas of Europe. Swims with its head erect, and the body under water. On perceiving the flash of a gun, dives instantaneously, and rises at a considerable distance. Has the manners and habits of the preceding, and devours a prodigious quantity of fish. There are two other varieties of this species: in the first the chin is yellow, and the tail wedged. It is found in the Cape of Good Hope. The second is blackish, but beneath it is brown; the feathers above are edged with black. It inhabits Cayenne, and the Caribbee islands, and is about twenty-six inches long.

PYGMÆUS; Dwarf Shag. The tail is wedged, the feathers twelve in number; the body is black, with a few scattered white spots. It inhabits the Caspian sea, and is about the size of the garganey, a species of the *Anas* genus. The female is brown, without spots. A variety has its chin of a mouse colour, and its legs black.

PUNCTATUS; Spotted Shag. Crested; black; tail rounded; wings dark ash, spotted with black; sides of the neck with a white line. It inhabits New Zealand, and is nearly two feet long.

* **CRISTATUS**; Crested Shag. This is found in many parts of the north of Europe, and in our own country. It is of a shining green, beneath it is dusky; bill and legs dusky; head crested; the bill is blackish; irides green; feathers each side the head long, forming a crest; the tail-feathers twelve in number, and of a dusky green; the head often not crested.

VIOLACEUS; Violet Shag. Crest erect; body shining violet-black. It inhabits Kamtschatka, and the neighbouring islands.

URIEL; Red-faced Shag. Shining green; throat and orbits white; face naked, blueish-red; wings and tail dusky; legs black. It inhabits Kamtschatka, and is about thirty-four inches long.

CARUNCULATUS; Carunculated Shag. Black, beneath white; face naked, carunculate, red; orbits elevated, blue; wings with a white band. It inhabits New Zealand, and is about twenty inches long.

MAGELLANICUS; Magellanic Shag. Black, beneath white; temples and chin naked, reddish; head turned, temples with a white line; tail wedged. It inhabits Terra del Fuego and Staten land islands, at the extremity of South America. It is about thirty inches long.

VARIUS; Pied Shag. Brown, beneath white; rump, wings, and rounded tail black; eye-brows pale; area of the eyes naked, yellow. It inhabits New Zealand; two feet and a half long; it builds in trees; the eggs are of a pale greenish-white.

CIRRATUS; Tufted Shag. Black, beneath white; crown crested; wings with a white band; tail rounded; bills and legs yellow. It inhabits New Zealand, and is thirty-four inches long. The orbits are naked; the crest turned back; tail-feathers fourteen; bill and legs yellow.

AFRICANUS; African Shag. Brown-black, beneath varied with white and blackish; chin white; wing-coverts

blue-grey, edged and tipped with black. It is found in Africa and is about twenty inches in length.

B. *Bill ferrate.*

Species.

THIAGUS; Saw-billed Pelican. Brown; tail rounded; gullet pouched, and covered with short cinereous feathers. It inhabits Chili; is the size of a turkey; extends its wings about nine feet. The bill of this species is about a foot long, each mandible is hooked; the pouch is very long, and the legs black.

* **BASSANUS**; Gannet or Soland Goose. Tail wedged; body white; bill and quill-feathers black; face blue; irides yellowish; tail-feathers twelve; eyes surrounded with a naked skin of fine blue; legs black, and greenish on the fore part; the feet long. Weighs seven pounds, and inhabits Europe and America. This species of pelican haunts the Bass island in the frith of Edinburgh, Ailsa on the coast of Ayrshire, the island of St. Kilda, and hardly any where else in Europe. It arrives at these spots in March, and continues till September. As it must let itself fall before it takes wing, it requires a steep and precipitous breeding station. It makes a rude nest of sticks, grass, sea-plants, and lays one egg. While the female is occupied with incubation, the male brings her food, which consists almost entirely of herrings and sprats. In the bag under their bill they are able to fetch four or five herrings at a time, and a great number of sprats, which the young bird extracts from the mouth of the old one with its bill, as with pincers. The young begin to be taken in August, and by some are relished as an exquisite morsel; but the old ones are tough and rancid. The fowler, who seizes the young, is let down by a rope from the top of a cliff, and is sometimes stationed on the slippery projection of a rock, with the perpendicular precipice of four hundred feet or more beneath him. The young are of a dark grey colour, and continue so for a year or more, when they gradually become white, except the tips of their wings, which are always black. In September and October the old birds leave their breeding places, and migrate southward, following, as is alleged, the shoals of herrings. In December they are often seen off Lisbon, plunging for sardinæ; but after that period, it is not well known what becomes of them till March. They are common on the coasts of Norway and Iceland, and are said to be met with in great numbers about New Holland and New Zealand. They also breed on the coast of Newfoundland, and migrate southward along the American shores, as far as South Carolina. Of this species there are two varieties: the first is brown, spotted with white, and white beneath, with naked and blackish. The second is brown, with triangular white spots, whitish, and spotted with brown beneath; the bill, wings, tail, and legs brown.

PISCATOR, or Lesser Gannet. Tail wedged; body whitish; all the quill-feathers black; face red. It inhabits the Chinese, Indian, and American seas; and is about thirty inches long.

SULA; Booby. Tail wedged; body whitish; primary quill-feathers tipped with blackish; face red. It inhabits South America, and the neighbouring isles, and is about thirty inches long.

FIBER; Brown Booby. Tail wedged; body brownish; all the quill-feathers blackish; face red. It inhabits America and Africa, and is rather more than two feet in length.

SINENSIS; Fishing Corvorant. Tail rounded; body brown, whitish, and spotted with brown beneath; throat white; bill yellow; irides blue. It inhabits China, where

it is tamed for the purpose of catching fish. The bill of this bird is yellow, and the irides blue.

PARVUS; Lesser Booby. This species is black, beneath it is white; the face downy. It inhabits Cayenne, and is about eighteen inches long.

PELECANUS, a name given by some authors to the *platea*, or spoon-bill; a bird very different from the pelican, being of the stork or heron kind. See **PLATALEA**.

PELECHUCO, in *Geography*, a town of Peru, in the diocese of Cusco; 36 miles N.N.W. of Carabaya.

PELECINUS, in *Botany*, a kind of vetch, or leguminous plant, mentioned by Pliny, book 21. chap. 12. l. 45, as "growing in corn-fields, and having small shrubby stalks, with leaves like *Cicer*. It bears its seeds in pods (or legumes), which terminate in a hooked point, and grow three or four together, &c." This description accords well with the Linnæan *Coronilla Securidaca*, which is certainly the ἰνδοῦρον of Dioscorides; and Gesner, as well as Bauhin, rightly so understood it. Pliny says "the seeds are bitter, and good for the stomach." It is remarkable that the modern Greeks, at this day, know the plant by the name of πικροπόδι, or *bitter-pod*. The seeds of a very similar plant, *Trigonella Fanumgræcum*, always enter into the composition of curry-powders in Hindoostan, and are supposed to possess a stomachic quality. Such a near coincidence is frequent between the medical opinions of the most ancient nations.

This being the true *Pelecinus*, we cannot account for Tournefort's having adopted the word as the name of the Linnæan **BISERRULA**, see that article; to which it is certainly misapplied, nor does he give any reason or explanation concerning it. This, however, led Linnæus, as it seems, to retain it for the specific name of that curious plant.

PELECOID ANGLE, in *Geometry*. See **ANGLE**.

PELECOIDES, from πέλεκυς, *hatchet*, and εἶδος, *form*, a figure in form of a hatchet.

Such is the figure **BCDA**, (*Plate X. Geometry, fig. 16.*) contained under the inverted quadrantal arcs **AB** and **AD**, and the semicircle **BCD**.

The area of the pelecoides is demonstrated to be equal to the square **AC**; and that, again, to the rectangle **EB**. It is equal to the square **AC**, because it wants of the square on the left hand, the two segments **AB** and **AD**, which are equal to the two segments **BC** and **CD**, by which it exceeds on the right hand.

PELEE, in *Geography*, a small island in the English channel, near the coast of France; three miles N.E. of Cherbourg. N. lat. 49° 41'. W. long. 1° 28'.

PELEGRINI, VALERIO, in *Biography*, an eminent singer, who was in the service of Spain in 1700.

PELEGRINI, PIETRO, a native of Brescia, and some time organist of the Jesuits' church in that city. He was a very neat player on the harpsichord, and a lively composer for that instrument. Bremner published a book of lessons of his composition, and several books were published at Paris, where, in 1742, he set a drama to music, translated from Stampiglia, called *Cirene*.

We heard him perform at Calais in 1766, at a concert for his own benefit. He was then in years, and in the last stage of a consumption; but the Duc de Montpensier, then governor of Calais, coming into the room during the performance, the poor man was obliged to rise and finish his concerto standing. We saw with uneasiness the difficulty with which he supported himself, and executed difficult passages: but no performer was to sit in the presence of the ducal governor, any more than in that of any of the royal family.

PELEGRINI, FERDINANDO, a Neapolitan composer and performer on the harpsichord. According to M. Gerber, the

continuator of Walter's Musical Lexicon, he published a Paris and in London several works for the harpsichord. There is some mistake in the christian names of these two harpsichord-composers, and the works of one are indiscriminately ascribed to the other; nor are we certain of there having been two composers of the same time, of the same name, and in the same places, of similar professional abilities.

PELEGRINO, in *Geography, an island in the Pacific ocean, discovered by Quiros in 1606. S. lat. 14°. W. long. 162°.—Also, a mountain on the N. coast of the island of Sicily, near Palermo, in which is a celebrated sanctuary dedicated to St. Rosalia.*

PELENGON, or **GELENGON**, a town of Persia, in the province of Laristan; 66 miles N.E. of Lar.

PELES, a town of Sweden, in the province of Savolax; 48 miles E. of Nyflot.

PELEW ISLANDS, or **PALAOIS**, a group of islands in the western part of the Pacific ocean, or in that extensive division of the globe, called *Polynesia*, situated between the Philippine islands and the Caroline islands. The first discovery of these islands has been attributed to some Jesuits of the Philippines, viz. the fathers Duberon and Cortil, who left the Philippines for this purpose on the 14th of November, 1710. Before this time, it was only known, that the largest island, which is the most northerly, was called Panlog, and that the royal residence was in Falu or Pelew. After a voyage of fifteen days these fathers discovered land towards the north-east, and the two isles that were seen were called those of St. Andrew, as having been discovered on the day of that apostle. From some Pelewan, whom they accosted, they received information that the true name of these isles was Sonfrol: that Panlog was to the N.N.E. and Pulo to the S.S.E. Panlog was afterwards discovered about fifty leagues from Sonfrol, in lat. 7° 14'. This seems to be the island now called Babelthouap, and the largest of the group, the S. extremity of which in Arrowsmith's maps is about lat. 7° 25'. Father Cantova's letter, dated 1722, and contained in the collection, entitled "Lettres Edifiantes," gives a brief account of the Pelews, and very unjustly represents the natives as cannibals. By his account, the group called the Palaos, or Pelews, consisted of seven principal isles, situated from N. to S. Their names were Pelilieu, Coaengal, Tagaleten, Cogcal, Yalap, Mogulibee, and Nagarrol: the king was called Yaray, and resided in Yalap. The natives were described by the Jesuits as naked cannibals, who were regarded with horror by the people of the Carolines. It was not till the year 1783, that we were able to obtain a just account of these islands, and of their inhabitants. When captain Wilson, commander of the Antelope packet, in the service of the East India Company, was wrecked on Oroolung, one of these islands, he derived that information which was communicated on his return to Mr. Keate; and this ingenious writer, indulging perhaps in some degree the glow of his feelings and imagination, drew up that very pleasing and interesting account, which, from its first publication, has passed through several editions. The whole group is said to contain eighteen islands; but those which Mr. Keate mentions are Oroolung, Artingall, Pelelew, Emilligue, Emunga, Aramalorgoo, Artaguy, Caragaba, and Pethoull: but the names of all were not discovered: and it was but lately known that Pelew was only the name of the capital of the island called Cooroora; and the residence of the king. From Mr. Keate we learn that the natives of these islands, so far from being savage cannibals, were remarkably mild, hospitable, and humane. These islands are in general of a moderate height, and covered with wood; and encircled on the W. side by a reef of coral, from two to six leagues from the shore, and of

PELEW ISLANDS.

great length. Cooroora, the capital of which is Pelew, bears the marks of industry and good cultivation. All the islands which the English saw were covered with trees of various kinds, and some of them of large size, which appeared from their canoes, made of their trunks, and capable of carrying twenty-eight or thirty men. Among the trees in the forest, they observed the ebony, and also a tree which, when pierced with a gimblet, yielded a juice of the consistence of cream; a species of the machinal tree; a tree in size and its branches resembling the cherry-tree, and in its leaves the myrtle, and having, instead of bark, an outward coat of the thickness of a card, darker than the inside, though equally close in texture: the colour of the interior part being nearly that of mahogany, and so extremely hard, that few of the tools which the English had could work it without breaking their edges. Here were also the cabbage tree, and a tree whose fruit resembled an almond: the carambola, and the wild bread-fruit, called by the natives "riafnall." Yams and cocoa-nuts being the chief means of subsistence, are objects of particular attention. Of the beetle-nut, which abounds, the natives make great use: and their islands also afford plantains and bananas, Seville oranges, and lemons. They furnish some sugar canes, great abundance of the bamboo, and likewise the turmeric, used as a dye, and employed by the women for staining their skins. None of the islands which the English visited afforded any kind of grain, nor any sort of quadruped, except some rats which were found in the woods, and three or four meagre cats, found in the house, and which were probably drifted ashore from some wreck. Of birds, pigeons were the most numerous; and they had plenty of cocks and hens, undomesticated and running wild in the woods, of which they had made no use as articles of food till they were instructed by the English to eat them. Several birds of beautiful plumage were observed to fly about, and some of a small size, whose notes were very melodious, and particularly one, which used to sing every morning and evening, with a pipe as sweet as a flageolet. Of fish they had great variety.

These islands, when seen from the sea, exhibit high rugged land, covered with wood; the interior parts were in many places mountainous, but the vallies were extensive and beautiful, and presented many agreeable prospects. The soil was in general rich; the grass, as no cattle ate it down, grew high, and was burnt up with the heat of the sun. The English saw no river in these islands; their supplies of fresh water were derived from small streams and ponds, of which there were many. They had no salt, or any kind of seasoning with their food, which consisted chiefly of fish, and they had also a kind of sweet-meats, which they prepared from the sugar-cane, which seemed to be indigenous. The milk of the cocoa-nut was their usual beverage. As soon as they rise, which is commonly at day-light, they immediately go to bathe in fresh water. They had no method of measuring time, but by the height of the sun; and they divided their seasons, like the inhabitants of other tropical countries, into wet and dry. They appeared to have some knowledge of the stars, to several of which they gave names. Those islands that were visited by the English appeared to be populous, but the account of their population was not ascertained. Their houses were placed upon large stones, and raised about three feet from the ground; being constructed of planks and bamboos, and having the fire-place in the middle, secured with hard rubbish. For public meetings they had large mansions. Their fishing-hooks were of tortoise-shell: their twine, cord, and fishing-nets, were well manufactured from the husks of the cocoa-nuts. The mats on which they slept, and which they threw

over them at rest, were formed of plaintain-leaf. At their meals they used a plaintain-leaf instead of a plate, and the shell of a cocoa-nut served them as a cup, which they sometimes finely polished. Their best knives were of mother-of-pearl, and others of a large muscle-shell, or split bamboo. They had also vessels of an oval shape and reddish-brown colour, which were a kind of earthen ware, and which they used for heating their water, and for boiling their fish, yams, &c. The principal weapons used in their battles were spears, about twelve feet long, formed of the bamboo, having its pointed end of very hard wood: these were barbed transversely, nor could they be drawn from the body without lacerating the flesh. Another weapon was the dart and sling; the sling was a piece of wood about two feet long, with a notch made in it, wherein the head of the dart was fixed. The dart was of bamboo, pointed with extremely hard wood. Their canoes were formed of the trunks of trees, and neatly ornamented. The natives of these islands are a stout, well-made people, rather above the middling stature; their complexions are of a far deeper colour than what is understood by the Indian copper, but not black. They are mild, affable, and industrious, and, like the inhabitants of Otaleite, they form an exception to the general rule of savage existence. Their hair is long and flowing, rather disposed to curl, which they mostly form into one large loose curl round their heads: some of the women, who wore remarkably long hair, let it hang loose down their backs. The men were entirely naked: the women wore only two little aprons, or rather thick fringes, one before and one behind, about ten inches deep and seven wide: these were made of the husks of the cocoa-nut stripped into narrow slips, which they dyed with different shades of yellow: this, which was their only dress, they tied round their waists, commonly with a piece of line, though such as were of higher rank used a string of some kind of beads. Both men and women were tattooed, or as they called it "melgothed;" an operation which is supposed to have taken place at a certain period of youth, children of either sex not being marked by it. The men had their left ear bored, and the women both; a few of the first wore beads in the perforated ear; the latter put either some leaf through, or an ear-ring of tortoise-shell inlaid. The cartilage between the nostrils was also bored in both sexes, through which they frequently put a little sprig or blossom of some plant or shrub that accidentally caught their fancy. When the men and women grew up, their teeth were blacked, which was done by means of some dye; and the operation was tedious and painful. For this purpose they used groundsel, with four other herbs, bruised together, and mixed with a little clinam into a paste, which was applied to the teeth every morning, in order to dye them black: the patients lying with their heads upon the floor, and letting the saliva run out of their mouths. At night the paste was taken away, and they were permitted to eat a little. The same process was repeated the day following, and five days were necessary to complete the operation. This occasioned great trouble, and made them extremely sick.

Persons of both sexes were very expert at swimming, and appeared to be as perfectly at ease in the water as on land. The men were admirable divers. Their marriages were probably no more than a civil contract, but at the same time the contract was regarded as inviolable. They allowed a plurality of wives, but in general had not more than two: the king had five, though not living together. They did not appear to be in any degree jealous of them, permitting them to partake of all their diversions. When a woman was pregnant, she always separated from her husband at night; and it was observed that the utmost attention was paid

paid to women in that situation. Their children are named soon after they are born; and probably without any ceremony. Some peculiar circumstances attended their funerals. At the place of interment, an elderly woman was observed to get out of the new made grave, who was supposed by those who attended to be the mother, or some near relation, who had been drawn by affection to the melancholy scene, in order to be satisfied that every thing was duly prepared. When the corpse was laid in the earth, the lamentation of the women that attended was very great. These last sad offices seemed to be wholly left to the tenderness of the weaker sex; the men only assembled round the body, before it was carried to the grave, where they preserved a solemn silence. They had places appropriated to sepulture. Their graves were made like ours in country church-yards; having the mould raised up in a ridge, over the place where the body was deposited, some flat stones raised above them, with a flat one laid horizontally over, and surrounded by a kind of hurdle-work, to prevent any one from treading over them. There seemed to be no religion of any kind among these islanders, though they have an idea that the soul survives the body. The government is in the hands of a king, under whom there are "rupaks," or chiefs, who also constitute a kind of nobles. The property of all the land is supposed to be vested in the sovereign, while that of the people is only personal, as a canoe, weapons, or rude articles of furniture. The king of Pelew entertained so great an esteem for captain Wilson, that he entrusted his second son, prince Lee Boc, to his care, to accompany him to England. This young man was of a most amiable disposition, desirous of information, and possessed a capacity for receiving it; he died of the small-pox at captain Wilson's house in London in the year 1784, at about twenty years of age. N. lat. between $6^{\circ} 54'$ and $8^{\circ} 12'$. E. long. between $134^{\circ} 5'$ and $134^{\circ} 40'$.

PELHAM, a township of America, in Hampshire county, Massachusetts; 12 miles N.E. of Northampton; incorporated in 1742, and containing 1144 inhabitants.—Also, a post-town of Rockingham county, in New Hampshire, on the S. state line, which separates it from Dracut, in Massachusetts; 30 miles S.W. of Exeter; incorporated in 1746, and containing 918 inhabitants.—Also, a township in West Chester county, New York, bounded S. and E. by the Sound, N. including New City, Hart, and Appleby's islands; containing 943 inhabitants.—Also, a township of Lincoln county, Upper Canada, S. of Louth, watered by the Chippewa or Welland.

PÉLHÉSTRE, PETER, in *Biography*, a considerable French writer, who flourished in the 17th and early part of the 18th centuries, was a native of Rouen, where he was born about the year 1645. At an early age he was inspired with the love of learning, and from thenceforward he devoted his life to studious pursuits. At the age of seventeen or eighteen he came to Paris, when the archbishop of that see sent for him, and said, "I am informed, sir, that you read the works of heretics; are you sufficiently learned to venture on such a dangerous practice?" To which the young man replied, "Your question, my lord, embarrasses me: for were I to answer in the affirmative, you might charge me with presumptuous vanity; and should I say that I have not sufficient learning, you would prohibit me from reading such books." Pleased with the ingenuousness of the answer, the prelate laid him under no restriction. For some time M. Pelhestre officiated in the clerical character, and was zealous as a missionary for the conversion of Protestants to Catholicism: he afterwards resumed the habit of a layman, which he did not change upon his appointment to the place of sub-librarian in the great convent of

the Cordeliers at Paris. His motive for accepting of this post, was the unrestrained access which it gave him to a valuable library. He became intimately acquainted with father Mabillon, and several other of the most learned persons of his time. He visited most of the religious solitudes in France, and said, if he were to seclude himself from the world, he should make choice of one of the principal monasteries on mount Athos, for the advantage of consulting the numerous Greek MSS. which they possess. When he had any particular object in view, it was usual for him to shut himself up in a room from which day-light was excluded, where he applied himself night and day, excepting when nature called for refreshment. Father Le Long was told that he had been seen frequently in this situation. He died suddenly in 1710, when he was sixty-five years of age. He was a man of prodigious reading, and particularly conversant in theological controversy, and the knowledge of ecclesiastical authors. He wrote a severe criticism on various passages in M. Dupin's "Bibliothèque des Auteurs Ecclésiastiques," and filled all the margins of Cave's "Historia Literaria" with notes. The manuscripts of these performances are said to have fallen into the hands of the Benedictines, to whom they would prove useful in their critical researches. He was the author of the numerous additions and valuable notes to the second impression of father Bonaventure's "Treatise on the best Method of reading the Fathers of the Church," in 1697. Moreri.

PELIALA, in *Ancient Geography*, a town of Aſia, in Mesopotamia, between Rhæſana and Alvanis. Ptolemy.

PELIAS, an island on the coast of Sicily, in the vicinity of the promontory of Drepanum.

PELIAS, in *Zoology*, a species of *Coleber*; which see.

PELICAN, in *Chemistry*. See PELLICAN.

PELICAN, in *Ornithology*. See PELECANUS.

PELICAN Island, in *Geography*, a small island near the S. coast of West Florida. N. lat. $30^{\circ} 14'$. W. long. $33^{\circ} 6'$.—Also, a small island near the N.E. coast of Antigua. N. lat. $17^{\circ} 14'$. W. long. $61^{\circ} 24'$.—Also, a small island near the S.W. coast of Antigua. N. lat. $17^{\circ} 10'$. W. long. $61^{\circ} 35'$.

PELICAN Islands, a cluster of small islands near the coast of West Florida. N. lat. $29^{\circ} 48'$. W. long. $88^{\circ} 55'$.

PELICAN Key, Great, a small island near the S. coast of Jamaica. N. lat. $17^{\circ} 49'$. W. long. $76^{\circ} 48'$.

PELICAN Key, Little, a small island near the S. coast of Jamaica, a little N. of the former island.

PELICAN Rocks, rocks on the N.W. coast of Antigua, lying under water, and dangerous.

PELICAN Shoals, sand-banks about half a mile from the shore, on the S.W. coast of the island of Barbadoes.

PELICARE, a town of Cochin; 50 miles E. of Cochin.

PELICARO, a town of Naples, in the Basilicata, at the mouth of a river that runs into the Adriatic; 10 miles E.N.E. of Tarfi.

PELICONDA, a town of Hindoostan, in the circar of Cicacole; 25 miles N.W. of Cicacole.

PELIGNI, in *Ancient Geography*, a people of Italy, between the Marmeni and the Marfi; sometimes comprehended under the name of Marfi. They were immediately descended from the Samnites, but owed their first origin to the Sabines. They are mentioned by Ovid, Faſt. l. iii. v. 95. As they inhabited the high mountains which formed a part of the Apennines, it is probable that they derived their name from the primitive *pal*, elevated. They are said to have constructed a temple to Jupiter Palenus. Their chief town was Corfinium; Salmo also was within their dominion.

PELIJARVI, in *Geography*, a town of Sweden, in the government of Kuopio; 100 miles S.E. of Kuopio.

PELIKANI, a town of Lithuania, in the palatinate of Wilna; 16 miles S.S.W. of Breslaw.

PELIM, a town of Russia, in the government of Tobolsk, on a lake of the same name; 72 miles N. of Turinsk. The lake is about 56 miles in circumference. N. lat. $59^{\circ} 10'$. E. long. $63^{\circ} 56'$. This lake receives a river, called also Pelim.

PELING, an island near the coast of Corea, in the Hoang-Hai, or Yellow sea; ten miles long, and four broad. N. lat. $38^{\circ} 24'$. E. long. $124^{\circ} 28'$.—Also, a small island in the East Indian sea, near the E. coast of Celebes; 50 miles long, and 14 broad. S. lat. $1^{\circ} 45'$. E. long. $123^{\circ} 20'$.

PELION, MOUNT, in *Ancient Geography*, a portion of that long chain of mountains which lay on the eastern coast of Thessaly, and which extended from the peninsula, inclosing towards the south the greatest part of the country called Magnesia, as far as the mountains that separated it from Macedonia. The portion which bore the name of Pelion commenced at the summit of Rhifus, and reached almost from the sea in advancing towards the N.W. In a kind of angle which this mountain formed in its return towards the E. at the bottom of the mountain flowed the small river Amyrus. The coast, in the direction of the mountain, formed in this place a small gulf, in which was Melibœa. From Melibœa, to the right bank of the mouth of the Peneus, the chain of mountains, which approached very near to the sea, was called Ossa. On the other side of the Peneus, in ascending towards the north, it formed two chains of mountains, one of which took the course of the sea very exactly, and the other inclined a little from the S.E. to the N.W. These two mountains were connected with the mountains which separated Thessaly from Macedonia. They were these two chains of mountains which the ancients comprehended under the name of Olympus. When the giants are said to have piled Ossa upon Pelion, the meaning seems to be, that they had fortified these two mountains, whither they retired after their excursions, and kept Jupiter's garrison upon mount Olympus in awe.

PELIOSANTHES, in *Botany*, from *πελιος*, *livid* or *lurid*, and *ανθος*, a *flower*, a recently established East Indian genus, so named by the late Mr. George Jackson, in Andrews's Repository, in allusion to the pale lead-colour, for which the flowers are remarkable. Andr. Repof. v. 9. 605. Ker in Curt. Mag. v. 32. 1302.—Class and order, *Hexandria Monogynia*. Nat. Ord. *Sarmentaceæ*, Linn. *Asparagi*, Juss.

Gen. Ch. *Cal.* none, unless the corolla be taken for such. *Cor.* inferior, of one petal, permanent; tube cylindrical; limb wheel-shaped, in six equal, obovate segments. Nectary of one leaf, globular, contracted at the mouth, one-third the length of the petal. *Stam.* Filaments very short, equal, inserted into the inside of the nectary; anthers oblong, of two lobes and two cells, projecting just beyond the nectary. *Pist.* Germen superior, enveloped in the nectary, globose; style scarcely any; stigma of three obtuse furrowed lobes. *Peric.* Berry ovate, of three cells. *Seeds* two in each cell, some of them frequently abortive.

Eff. Ch. Corolla tubular; limb wheel-shaped, in six segments. Stamens inserted into the globular nectary. Berry with three cells, and six seeds.

1. *P. Teta*. Grey-flowered Teta. Andr. Repof. t. 605. Curt. Mag. t. 1302.—Flower-stalks taller than the leaves. Corolla obtuse.—Gathered by Dr. Roxburgh in Bengal. Living plants were sent by him to the late Lady Amelia Hume, in whose stove they flowered in the following spring,

for the first time in England. *Root* fibrous, perennial. *Stem* none. *Leaves* several, radical, erect, a foot or more in height, on channelled stalks, elliptical, pointed at each end, entire, rather rigid, evergreen, smooth, plaited, with many longitudinal ribs, and fine transverse veins. *Flower-stalks* several, taller than the leaves, erect, round, simple, smooth, somewhat glaucous, each bearing an upright cluster of numerous inodorous small flowers, scattered or in tufts, of a livid purplish lead-colour, intermixed with dull green. *Braçæas* scattered, ovate, pointed, concave, membranous, pale. The flowers fall off even before they wither, without producing any fruit in this country. The natives of Bengal know this plant by the name of *Teta*, but we find nothing recorded of its qualities or virtues.

2. *P. humilis*. Dwarf Teta. Andr. Repof. t. 634. Curt. Mag. t. 1532.—Flower-stalks shorter than the leaves. Cluster simple. Corolla acute.—Introduced from Prince of Wales's island, about the year 1808, by Mr. Evans of Stepney, in whose hot-house it blossomed in November. This differs from the former in its much humbler stature, the leaves being not more than three inches high, and the flower-stalk hardly two inches, bearing an ovate, dense, simple cluster of flowers, whose segments are acute, green with a white edge.

Mr. Jackson has recorded, in Andr. Repof. v. 9. 605, that he had seen two species in Mr. Evans's collection just imported from Prince of Wales's island, one of which had the leaves nearly of a blue colour. The other probably was our *humilis*. Mr. Evans's collector declared that he had found five or six distinct species of this genus, growing wild in the island just named, though he did not succeed in his attempt to bring them alive to England.

PELL, JOHN, in *Biography*, a divine of the church of England, was born at Southwick, in Suffex, in the year 1610. He was educated in grammar-learning at the free-school of Steyning, in the same county, and made so rapid a proficiency in the Latin and Greek languages, that at the early age of thirteen he was fully qualified for entering upon academic studies, and was sent to Trinity college, Cambridge. Here he exhibited a wonderful facility in acquiring languages, and at the same time shewed a peculiar turn for mathematical learning; so that, in 1629, when he was only eighteen years of age, he drew up "A Description and Use of the Quadrant, in Two Books." In the same year, he held a correspondence with the celebrated Mr. Henry Briggs upon the subject of logarithms, and in the following year he wrote "Modus supputandi Ephemerides Astronomicas (quantum ad motum Solis attinet), paradigmata ad ann. 1630, accommodato;" and "A Key to unlock the Meaning of Johannes Trithemius, in his Discourse of Steganography," which he communicated to Mr. Samuel Hartlib and others. He had been admitted to the degree of B. A. at the usual period, and in the present year he proceeded M. A. During this year he wrote "A Letter to Mr. Edmund Wingate, on the Subject of Logarithms." In 1633-4, he finished his "Astronomical History of Observations of Heavenly Motions and Appearances;" and soon after his "Ecliptica Prognostica, teaching how, by Calculation, to foreknow and foretell all Sorts of Eclipses of the Heavenly Lights." By these and other works, which it is not necessary to enumerate, Mr. Pell's reputation for mathematical knowledge was so well established, that he was considered to be deserving of a professor's chair in that science. When, therefore, a vacancy took place in one at Amsterdam in 1639, interest was made to procure Mr. Pell the appointment. The vacancy was not, however, filled up before the latter end of the year 1643, when Mr. Pell was chosen to it. Of the estimation in

in which he was held in Holland, a good opinion may be formed from what was said of him by his colleague, Gerard John Voffius, who styles him a person of various erudition, and a most acute mathematician, and he greatly applauds his lectures upon Diophantus.

In 1644, Mr. Pell published at Amsterdam, in two pages, a refutation of Longomontanus's pretended quadrature of the circle, which obtained for him a high degree of credit among the most learned mathematicians in Europe. Two years afterwards, Mr. Pell was called to the display of his talents on a new scene; for the prince of Orange, having founded a *Schola illustris* at Breda, invited him to be professor of philosophy and mathematics in the new institution, with an annual salary of a thousand guilders. This offer he accepted, and he filled the mathematical chair at Breda with the same reputation and success which attended him at Amsterdam, having, among his pupils, several who were afterwards distinguished as eminent algebraists.

In 1652 he returned to England, and in 1654 Cromwell appointed him agent to the Protestant cantons in Switzerland, which character he retained till the death of the protector. After the restoration, he was encouraged to enter into holy orders; and, having been ordained deacon and priest in 1661, he was immediately instituted to the rectory of Fobbing, in Essex, with the chapel of Battlefen annexed, on the presentation of the king.

In 1663 he was presented by Dr. Sheldon, then bishop of London, to the rectory of Laingdon, in Essex, and about the same time he was created doctor of divinity. Scarcely had he been honoured with this degree, before his patron was translated to the see of Canterbury, and Dr. Pell became one of his domestic chaplains. Such an appointment is generally considered to be a step to higher preferment, but Dr. Pell was so intent on his studies as to neglect his own interest, and it is said he was so imprudent, with respect to the management of his worldly affairs, that he would have disgraced the station of a dignitary. Anthony Wood says, "that he was a shiftless man, and his tenants and relations dealt so unkindly with him, that they cozened him of the profits of his parsonages, and kept him so indigent, that he wanted necessaries, and even paper and ink to his dying day."

In the mean time he distinguished himself as a fellow of the Royal Society, to which he had been elected in the year 1663. He published several other works in mathematical science, and was the inventor of some algebraical signs, of which a few have obtained a general reception, *viz.* \div for division; \odot for involution, and \therefore for ergo, or therefore. In the midst of his incessant application to his studies, owing to the neglect of his pecuniary affairs, his embarrassments increased, and he contracted debts which occasioned him more than once to be thrown into the king's bench prison. He died in 1685, in the 74th year of his age. Besides the various labours already noticed of this gentleman, he wrote a demonstration of the second and tenth books of Euclid, and also of Archimedes' *Arenarius*, and the greatest part of Diophantus' *Arithmetic*. He left behind him a great number of manuscripts, which were, after a considerable time, obtained for the Royal Society: the collection contains not only Dr. Pell's mathematical papers, letters to him, and copies of those sent by him, but also several manuscripts of Mr. Walter Warner, an eminent philosopher and mathematician in the reigns of James I. and Charles I.

PELLA, in *Ancient Geography*, a town of Macedonia, near the sea, on the confines of Emathia. This city became the capital of the kingdom when Edeffa was annihilated according to Ptolemy, and owed its grandeur to Philip, who

had been educated there, and to his son Alexander, who was born in this place. Livy describes it as situated on an eminence surrounded by marshes, in the midst of which was a fortress, appearing like an island, and at a distance seeming to be joined to the city; it was, however, separated from it by a river, which ran between their walls, and over which there was a bridge of communication. This river was called Lndias, Luedias, and Lydius. Pella became a Roman colony. Alexander derives from this city the appellation of Pellæus.—Also, a town of Greece, in Thessaly.—Also, a town of Judea, in the half tribe of Manasseh, on the other side of Jordan; situated on the torrent of Hieromaces, and forming one of the boundaries of Peræa. This town is placed in Cœlesyria by Steph. Byz. and in the Decapolis by Pliny.—Also, a town of Greece, in Achaia.—Also, a town, and a mountain of Ethiopia.

PELLA, in *Geography*, a town of Russia, at the junction of the Tofna and Neva; 20 miles S.E. of Petersburg.

PELLA, in *Ornithology*, a species of *Trochilus*; which see.

PELLACK, in *Zoology*, the name of a young spout whale, often found in Zetland; where they run into creeks, and so entangle themselves among the rocks, that they are cast on shore, or easily taken. Phil. Trans. N^o 473, sect. 8.

PELLACONTA, in *Ancient Geography*, a river of Asia, in Mesopotamia. Pliny.

PELLACOPAS, a river of Asia, in Mesopotamia. Arrian de Exped. Alex.

PELLAEUSPAGUS, a name which Alexander gave to the district in which was situated the town of Alexandria, which he built at the mouth of the Tigris.

PELLAGE, in our *Old Writers*, a custom or duty paid for skins or leather.

PELLAGRA, in *Medicine*, probably from *pellis*, the skin, and *agria*, scabies fera, a sort of cutaneous disease, which was first described about the year 1771 by some Italian physicians, as occurring in many persons in the neighbourhood of Milan and Venice.

The disease appears to have been a species of *lepra* or *psoriasis*; since, in common with these diseases, it commenced about the head and on the extremities with small red patches, upon which scales were afterwards formed, and sometimes chaps and fissures succeeded. This eruption is said to appear first in the spring or summer, and to disappear with the return of cold weather; but it recurs with renewed violence in the following spring. Subsequently, it is affirmed, though the cutaneous affection ceases to be very troublesome, the nervous system becomes greatly deranged; languor, syncope, depression of spirits, and ultimately melancholy, and actual insanity, in which the patients have a particular tendency to drown themselves, ensue, and they sink under a failure both of the mental and corporeal powers.

There is something bordering upon the marvellous in this history of the pellagra; and as we have heard nothing of the disease in later times, when credulity is diminished and observation improved, it may perhaps be concluded, that the disease, to which this new name has been given, is nothing more than the common *lepra* or the *psoriasis*, and that the nervous affections, said to be connected with it, were in reality accidental and independent of it. A full account of the disease may be found in Frapolli, "Animadversiones in Morbum, vulgo Pellagram dictum," Milan 1771, (the first writer who noticed it); and in an essay by W. X. Janfen, "De Pellagra, Morbo in Mediolanensi Ducatu endemio," Leyden 1787. (This essay was reprinted in Dr. Frank's "Delectus Opusculorum Medicorum," vol. ix. art. 9.) See also

also a long list of references to Italian writers on the subject, under the article *Pellagra*, in Dr. Parr's London Medical Dictionary. See *LEPROSY* and *PSORIASIS*.

PELLANA or **PELLANE**, in *Ancient Geography*, a town of Laconia, S.E. of Belemina. It was washed by the Euratas; and is thought to have been very ancient. In the time of Pausanias it had a temple of Esculapius and a fountain called "Pellanide."—Also, a town of the Peloponnesus, in Arcadia.

PELLEGRIN, **SIMON JOSEPH**, in *Biography*, a French poet and ecclesiastic, was born at Marseilles. He obtained, in 1704, the prize of the academy for his "Epistle to the King on the Success of his Arms." He entered into the religious order of the Servites, but afterwards he obtained leave to remove into that of Cluny. He wrote several pieces for the theatres, and dramatized the history of the Old and New Testament, the Psalms of David, &c. He is also known as the translator of the works of Horace into the French language. He died in 1745.

PELLEGRINI, **CAMILLO**, a learned historian and antiquarian, was born in 1598 at Capua. He was educated at the Jesuits' school at Naples, where, besides the usual studies, he acquired an accurate knowledge of civil and ecclesiastical law and theology. He entered into the clerical order, and having been sent to Rome, he diligently consulted the archives and libraries of that capital, and formed the design of collecting all the ancient documents relating to his native place, and to the whole kingdom of Naples. For this purpose he made many journies, and was at great expence in procuring copies of records and manuscripts, and in forming a collection of antiquities. The first fruit of his labours was "L'Apparato alle Antichità di Capua," printed in 1651, in which he minutely describes all the parts of Campagna Felice, and relates its history and several revolutions. He afterwards published a work entitled "Historia Principum Longobardorum," containing the chronicle of the Anonymus Salernitanus, and several other historical pieces which had not yet seen the light, illustrated with learned annotations and dissertations. This publication was of great service in elucidating of the history not only of those provinces of Naples which were under the sway of the Lombard kings, but of Italy; it was therefore republished in the collections of Burmann and Muratori, and has been re-edited, with various additions, at Naples, 1749, by Sig. Fr. Moria Pratiini. This learned writer published other works on different subjects, and had a great collection of MSS., as well of his own writing as others, which were unfortunately lost to the world by the following incident. Being in a bad state of health, he had given orders to a female domestic, that when he should be near his end, she should burn a large bundle of papers which he pointed out. One day overhearing the physicians prognosticate that he had not many hours to live, she too faithfully executed his commands, to his own great regret, after he was somewhat recovered. He died at Naples in 1660, at the age of 65.

PELLEGRUE, in *Geography*, a town of France, in the department of the Gironde, and chief place of a canton, in the district of Le Réole; 12 miles N.N.E. of Réole. The place contains 1882, and the canton 6487 inhabitants, on a territory of 145 kilometres, in 17 communes.

PELLEN, a town of Prussia, in the circle of Natanen; 16 miles S. of Brandenburg.

PELLENA, in *Ancient Geography*, a town of the Peloponnesus, in the Argolide.

PELLENDORF, in *Geography*, a town of Austria; 10 miles W. of Zitterdorf.—Also, a town of Austria; 8 miles S.E. of Vienna.

PELLENE, in *Ancient Geography*, a town of the Peloponnesus, in Achaia, S. of Aritionautæ. It was built round a mountain, and formed a beautiful amphitheatre. The inhabitants pretended that it took the name from Pallas, one of the Titans; but the Argians with greater probability ascribe its name to Pellené, the son of Phorbas, and grandson of Triopas, who came from Argos to this place. Water was conveyed to this city by a beautiful aqueduct; and at a small distance was a gymnasium. In this city were the statues of some famous athletes. Charon was one of them, and he, seduced by Alexander, assumed the sovereign authority, so that his country detested him as a tyrant, whilst they honoured and crowned him as a victorious athlete. Near this town was a temple, on a spot consecrated to Neptune. About two leagues towards the S.E. from Pellené was a famous temple of Ceres the Mysian. In its vicinity feasts were celebrated for seven days, and after the third day no male could be found within the precincts of the temple. During the night the remaining females offered sacrifices, and performed other ceremonies. The men afterwards returned and associated with high satisfaction after this separation. Pellené was defended by a fortress called Olurus towards the S.E., and by the valour of its inhabitants long maintained its liberty; at length it became a part of Sicyonia, retaining its liberty to the time when the Romans took possession of Greece.

PELLENÉ, in *Mythology*, an epithet of Diana, given to her by the inhabitants of Pellené; and upon this occasion Plutarch tells us (in the life of Aratus), when her statue was carried in the processions, her aspect became so terrible that no one durst look upon it.

PELLENINKEN, in *Geography*, a town of Prussian Lithuania; 9 miles N.E. of Insterburg.

PELLERIN, **JOSEPH**, in *Biography*, an eminent medalist, born at Paris in 1683, was commissary-general and first clerk of the French marine. Having obtained his dismissal after forty years' service, he devoted the remainder of his life to the study of antiquity. His collection of medals was the richest and most valuable that was ever made by a private individual. It was purchased by the king in 1776. He contributed to the promotion of the numismatic science by a publication in nine volumes 4to. enriched with a great number of plates. It consists of a collection of medals of kings hitherto inedited or little known; a collection of medals of people and towns, inedited or little known; miscellaneous medals, supplements to the above, and letters on medallic subjects. It is reckoned a very valuable work, not only on account of the beauty of the engravings, but of the learned and judicious explanations subjoined. The author died at Paris in 1782, in the 99th year of his age.

PELLERIN, **Le**, in *Geography*, a town of France, in the department of the Lower Loire, and chief place of a canton, in the district of Paimbœuf; 12 miles S.E. of Paimbœuf. The place contains 1456, and the canton 837 inhabitants, on a territory of 152½ kilt. metres, in 7 communes.

PELLETS, in *Heraldry*, a name given to those roundlets which are black, called also *ogresses* and *gun stones*.

PELLICAN, or **PELICAN**, among the *Chemists*, a kind of double vessel, ordinarily of glass: used in working on liquors, by circulation.

It has a tubulated capital, from which two opposite and crooked beaks pass out, and enter again at the belly of the incurbit. Two marasses, the mouth of one of which is inserted into the mouth of the other, answer the same purpose with this vessel.

PELLICAN also denotes an instrument used by surgeons, &c. to draw teeth.

PELLICAN.

PELLICAN, again, is the name of an ancient piece of ordnance, carrying a ball of six pounds; by the French made eight feet and a half, and by the Dutch nine feet long. See CANNON.

PELLICER, JOSEF DE OSSAU, SALAS Y TOBAR, in *Biography*. a man of considerable eminence in the literary history of Spain, was born at Saragossa April 22, 1602, and inherited a disposition to letters from his father D. Antonio Pellicer de Ossau, who left in MS. an epitome of Garibay's Great History, and a poem, entitled "Batavia Rebelde." He took an honorary degree at Alcalá, and from thence removed to Salamanca, and at the age of 22 took up his residence at Madrid, and in 1629 he was made chronicler or historiographer of Castile. The states of Arragon named him to the same office for their kingdom; but as it was already held by Francisco Ximenez de Urrec, it was decided that the reversion could not be granted; Philip IV. made him amends by creating him arch-historiographer for the kingdoms of the crown of Arragon; the duty attached to this office was to revise and correct the works of the chroniclers of the particular kingdoms. As a farther token of respect, the habit of the order of Montesa was given him, and afterwards exchanged for that of Santiago. These honours were far from profitable to the wearer, and Pellicer was all his life poor. He died at the age of 77, worn out, according to the reports of his biographers, by incessant literary application. He was author of a great number of works, the titles of which, some time previously to his death, filled five folio pages. His learning is generally acknowledged, and his learned works are still consulted by the literati of different countries. Gen. Biog.

PELLICULA, in *Vegetable Physiology*, is a fine skin, which closely adheres to the proper *testa*, or skin, of some seeds, constituting an additional integument, concealing their proper colour and naturally polished surface. Gærtner improperly calls it *epidermis*; a name appropriated to the whole cuticle of the vegetable, as well as animal, body. This part is either membranous, and often downy, as in *convolvulus*; or mucilaginous, and not perceptible till the seed is moistened, as in *Salvia verbenaca*. The latter is a curious instance of such a pellicle; and the seed is, in consequence, endowed with the, often very useful, property of extracting any small irritating body from the human eye. One seed, introduced under the closed eyelids, soon becomes, by the absorption of moisture into the pellicle, enveloped with a mass of jelly, that usually entangles and sheathes the obnoxious substance. We cannot but consider the *utriculus* of Gærtner, which covers the seed in *Cbenopodium* and some of its allies, as no other than a *pellicula*.

PELLISSON, FONTANIER PAUL, in *Biography*, an eminent French writer, born at Beziers in 1624, was descended from a family of great respectability in the profession of the law. The subject of this article lost his father at an early age, and he was left to the care of his mother, who educated him in the principles of the Protestant religion. He studied successively at Castres, Montauban, and Toulouse, and acquired an intimate knowledge of the best authors in the ancient and modern languages. He applied himself professionally to the study of the law, and had already appeared with distinction at the bar, when he was seized with the small-pox. This cruel disease left a permanent weakness in his eyes, and so disfigured him, that he became a model of ugliness. He quitted the bar and retired into the country for some time; afterwards he came to Paris, and made himself known as a man of letters. In 1652 he obtained the place of a king's secretary, and applied with diligence to the affairs of the council, with which

he became intimately acquainted. In the same year he read before the French academy an history which he had composed of that institution, and which was so much approved that a resolution was made to admit him a member on the first vacancy, and in the mean time to give him the privilege of being present and speaking at the meetings of the academy. His history was printed in 1653, and many successive editions of it were given. It is upon the whole a curious and interesting performance. M. Pellisson was brought into a conspicuous situation in the year 1657, by being appointed first clerk to the celebrated intendant Fouquet. The financial business into which he was now plunged did not impair either the disinterestedness of his character, or the amenity of his disposition. His services were recompensed in 1660 by admission into the council of state, but in the following year he was involved in the fall of his patron, and, as having been one of his principal confidants, was committed to the Bastille. As it was found impossible to corrupt his fidelity to his former master, attempts were made to worm out his secrets by means of a German, a supposed fellow prisoner, who concealed craft under a gross and simple exterior. Pellisson was soon aware of his artifices, and treated him with so much politeness, that he converted him into a friend, and by his means kept up a constant correspondence with mademoiselle de Seuder. During his imprisonment, he composed three memoirs in favour of Fouquet, which are reckoned among the most eloquent and best-written pieces of the kind in any language, and have conferred a lasting honour on his memory. They were, however, the immediate cause of increased rigour in his confinement. He was prohibited the use of pen, ink, and paper, and was reduced to write with the lead of his casement upon the margins of books, or to use a kind of ink which he made with burnt crust tempered with wine. His whole company was a Basque, whose only talent was playing on the bagpipe. With vast pains he trained a spider to come out of his hole at the sound of this instrument, and take flies from his hand. Books of controversy were another employment of his solitary hours, and he received in the Bastille those impressions which afterwards produced a change of religious profession. He preserved many friends in this forlorn situation; and Tannequi le Fevre had the courage to dedicate to him, while in his dungeon, his "Lucretion," and his translation of Plutarch's treatise on "Superstition." At length, after a confinement of four years and a half, he obtained his liberty, and thenceforth passed his life in lavishing praises upon the sovereign who had previously deprived him of it. He was taken into favour, obtained a royal pension and a brevet of entrèe, and was made king's historiographer. His public recantation of the Protestant religion is supposed to have been one of the conditions of this favour. He soon after took the order of sub-deacon, and was presented to an abbacy and a rich priory. It was with some reason, therefore, that he annually celebrated his reconciliation with the church of Rome. He gave a more interesting proof of the excellence of his disposition by commemorating the anniversary of his liberation from the Bastille with the annual release of some of the prisoners.

In 1671, Pellisson delivered at the French academy a "Panegyric on Lewis XIV." which was translated into several languages, and even into the Arabic, by a patriarch of mount Lebanon. He accompanied his royal master in his campaigns, and for some time was the only man of letters engaged in writing his history; but some offence which he gave to madame de Montespan induced the king to transfer the appointment of historiographer royal to Boileau and Racine. Although Pellisson was thus deprived of his office,

he was ordered to proceed in his own historical labours; and he produced a "History of Lewis XIV., from the Death of Cardinal Mazarin in 1661, to the Peace of Nimeguen in 1678," in three vols. 12mo. It is more the work of a courtier than that of a faithful historian, yet it has been spoken of with applause by Voltaire and others. He totally disapproved of the dragooning system of proselyting, and he seems to have relied much more on the judicious distribution of the third of the savings destined by the king for rewards to such as should conform to the established religion. He also employed his pen in controversy, and wrote "Reflexions sur les Differences de la Religion," and "Traité de l'Eucharistie," which were composed with much art, and in a laudable tone of moderation.

After this Pellisson was made master of requests, and passed all the latter part of his life in great credit and prosperity. He died in February 1693. Besides the works above-mentioned, he wrote several pieces in verse and prose, among which were an "Abridgment of the Life of Anne of Austria;" "Lettres Historiques," being a journal of the king's journeys and encampments; "Recueil des Pieces galantes;" "Poésies Chrétiennes et Morales." Moreri. Bayle.

PELLITORY of Spain, in *Botany*. See ANTHEMIS.

PELLITORY, *Baslard*. See ACHILLEA.

PELLITORY, *Double*. See ACHILLEA, and YARROW.

PELLITORY of the Wall. See PARIETARIA.

PELLONIA, in *Mythology*, a goddess invoked at Rome, when her votaries wished to be delivered from their enemies, or from any thing that annoyed them.

PELLOUTIER, SIMON, in *Biography*, pastor of the French Protestant church at Berlin, member and librarian of the academy in that capital, and ecclesiastical counsellor, was born at Lepsic in the year 1694. He filled with high reputation the posts confided to him, and obtained a high character for erudition by his work entitled "Histoire des Celtes, et particulièrement des Gaulois et des Germains, depuis les temps fabuleux jusqu'à la Prize de Rome par les Gaulois." Of this work, which is replete with learned and curious research, the best edition is that of M. de la Bastide, in eight vols. 12mo. and two vols. 4to. Pelloutier likewise enriched the Memoirs of the Berlin academy with a number of valuable papers. He died in 1757, highly respected and beloved for his learning and beneficence.

PELLS, *Clerk of the* PELLs. See CLERK of the Pells.

PELLS, *Comptrollers of the*. See COMPTROLLER.

PELLUCID, formed of *pelluceo*, or *perluceo*, I shine through, a term of the same import with diaphanous, or transparent.

Pellucid stands opposed to opaque.

PELLUCIDITY, diaphanetty, or transparency, &c.

PELODES, in *Ancient Geography*, a port of Epirus, between the gulf of Buthrotori and the promontory of Thyamis. Ptolemy.—Also, a gulf of Asia, in Sufiana.

PELONTIUM, a town of Spain, in the Tarragonensis and country of the Lingones. Ptol.

PELOPE, a town of Asia Minor, in Lydia, on the confines of Phrygia. Steph. Byz.

PELOPIA, *πελοπια*, in *Antiquity*, a festival celebrated by the Elæans, in honour of Pelops, for whom that nation had more veneration than for any other hero.

PELOPIDAS, in *Biography*, an illustrious Theban leader, was the son of Hippoclus, of a distinguished family in Thebes. Though brought up in affluence, he adopted a frugal and simple mode of living, and emulated, in private and public virtue, his noble friend Epaminondas, though he had less mental cultivation than that hero. He married and

had several children, but was more intent upon serving the state than improving his fortune. He made a campaign with the Theban auxiliaries, who marched to the aid of the Spartans in the Peloponnesian war, and in a battle fought at Mantinea, he received several wounds, and would have been killed, had he not been protected by Epaminondas. After this period, the citadel of Thebes being betrayed to the Spartans, Pelopidas with many of his friends saved their lives by flight. They took refuge in Athens, whence they kept up a correspondence with those of their friends who remained at Thebes. Pelopidas, animated with the love of liberty and his country, was continually urging his fellow exiles to attempt the recovery of their native city out of the hands of foreign and domestic tyrants, and at length a plan was formed to collect the exiles, and to endeavour to effect a revolution. Pelopidas undertook to be the leader of this bold enterprize; and accordingly, with only eleven associates, he left Athens on a certain day in the middle of winter, and proceeded to Thebes. The party were in the habits of peasants, with dogs and hunting poles, as if they were from the country on an hunting expedition. Thus disguised, they entered Thebes in the midst of a heavy fall of snow, which kept the mass of the people within doors; here they were immediately joined by about thirty or forty others, who were apprized of their approach. The two Theban rulers were at an entertainment given purposely by Phylidas; and although they received an intimation of the entrance of some exiles they paid little or no regard to the fact. A letter disclosing the whole conspiracy was received by Archias, one of the rulers, from an Athenian friend; but although he was told that it contained matter of great importance, he threw it under the bolster of his couch, exclaiming "Business to-morrow!" which afterwards became a proverbial saying. Whilst these persons, half intoxicated, were easily dispatched by some of the conspirators, who entered the room in female habits, Pelopidas and his party had the more difficult task of breaking into the houses of two others of the supporters of tyranny and overpowering them. When this was effected, they sallied out into the streets, proclaiming liberty to all the Thebans, and arming all who joined them out of the shops of the armourers. On the next morning, they were joined by the body of exiles from Athens, and Epaminondas, who had obtained from the bloody scenes of the night, having collected all the most respectable citizens, put an end to the confusion and avowed the common cause. Pelopidas, who was universally hailed as the deliverer of Thebes, was placed at the head of affairs, and at his intigation measures were taken to recover the citadel from the Lacedæmonian garrison. The fortress was surrounded, and compelled to surrender for want of provisions. The date of this revolution, which was the commencement of the Theban glory, is fixed at the first year of the 100th olympiad, or the year B.C. 380. In the subsequent war with Sparta, Pelopidas exercised all the talents of a brave and able general. He defeated the enemy at Tanagra, in which he slew their general with his own hand. Pelopidas is considered as the first who inspired the Thebans with the ambitious desire of rising to distinction among the states of Greece, and extending their power by conquest. His military fame was of an earlier date than that of Epaminondas, though the latter came in time to be superior. It is, however, to the honour of both, that they lived in perfect amity, and concurred in every measure for the advancement of their country. Before the battle of Leuctra he supported with his voice the advice of Epaminondas for an immediate engagement, and at the head of the sacred band he greatly contributed to the success of the day. He was joint-commander with that chief

in the expedition into the Peloponnesus, in which the city of Messene was restored, and partook with him the danger of a charge made against them on their return, for having illegally prolonged their command.

The Thebans having requested the aid of the Thebans against the tyrant Alexander of Phœæ, Pelopidas was sent with an army into that country, and brought the king to terms. He afterwards marched into Macedonia, as arbitrator of a dispute in the royal family of that country, and the opinion entertained of his equity was such, that he was entrusted with a number of noble hostages for the purpose of securing tranquillity, among whom was Philip, father of Alexander the Great. He went a second time into Macedonia, where new tumults had arisen; and obliged Ptolemy, the usurper of the throne, to give his own son, with fifty others, as hostages for performing the conditions enjoined him. Returning through Thessaly with a small escort, he met with Alexander the Phœæan at the head of his army, and with his colleague Ismenias went to him unarmed, trusting to the sacredness of their character as ambassadors. The tyrant, however, seized their persons, and took them with him as prisoners to Phœæ. The spirit of Pelopidas supported him under this misfortune, and he even sent messages of defiance to Alexander, telling him that he acted very absurdly in putting to death so many of his own innocent subjects, and at the same time sparing him, who, he might be sure, would severely punish him for his perfidy, should he ever get out of his hands. Alexander, in return, asked "Why is Pelopidas in such haste to die?" "In order," the hero replied, "that by my death thou mayest become the sooner hateful both to gods and men, and thus brought to destruction." Soon after this, Epaminondas was placed at the head of an army, with orders to invade Thessaly, and proceed against the tyrant. It was the object nearest his heart to extricate his friend from the peril that threatened him; therefore he forbore pushing the Phœæan to extremities, and by alternately acting upon his hopes and fears, brought him to consent to a truce, with the condition of releasing Pelopidas and Ismenias; after this was performed, he marched with them back to Thebes. The Thebans having discovered that the Athenians and Lacedæmonians were negotiating a treaty against them with the king of Persia, sent Pelopidas to counteract it. He was received with great honour at the Persian court, and completely succeeded in confirming the former friendship between it and the Thebans, and in obtaining a declaration in favour of the liberty and independence of Greece.

Alexander continuing to oppress his neighbours, deputies were again sent to Thebes, requesting that forces might be sent to their aid, with Pelopidas to command them. An army was levied for the purpose; but as it was about to march, an eclipse of the sun struck a superstitious terror into the minds of the Thebans; and Pelopidas, not choosing to proceed with a disheartened army, took with him only 300 volunteer cavalry, and entered Thessaly, disregarding the warnings of the soothsayers. When he arrived at Pharfalus, he assembled all the Thebans who were the opposers of the tyrant, and marched in quest of Alexander. The latter, knowing that he had few Thebans with him, did not hesitate to meet him with a very superior force. The battle commenced, and while the event was still dubious, Pelopidas saw Alexander at some distance, rushed forwards, and loudly challenged him to single combat. The tyrant, however, thought it more prudent to shelter himself among the thickest of his troops, than to risk the trial. The noble-minded Theban, hurried away by an inconsiderate thirst of revenge, followed him almost alone, and beat down a number of his

opposers; at length, covered with darts, and pierced through with spears, he fell dead, a victim to unrestrained ardour. The Thebans lamented him as their father, saviour, and instructor, and the Thebans and allies joined in their expressions of sorrow. They, however, revenged his death by a total and bloody defeat of the enemy. His body was met in procession by the magistrates of the towns, the priests and young people bearing trophies and garlands; and the Thebans made an urgent request to be allowed to give it a funeral in their own country, which was granted, and performed with great solemnity and splendour. This event took place B.C. 364. Plutarch. Univer. Hist.

PELOPIS, in *Ancient Geography*, a name given to seven small islands, situated on the coast of the Peloponnesus, over-against Methuna, according to Pausanias.

PELOPONNESUS, a peninsula in the south part of Greece, joined to the continent by an isthmus, formerly denominated the isthmus of Corinth, and in later times Examili. The peninsula now bears the name of Morea. The ancients called it by different names, of which the most known are Apia, the Argolide, and Pelasgia. The Peloponnesus was divided into several parts, which formed separate states; these were Laconia, Messenia, the Argolide, the Elide, Achaia, Sicyonia, Corinth, and Arcadia in the centre; all the others were washed by the sea. Its form was very irregular; its length from N. to S. was about 125 geographical miles; and its breadth about 150 miles. The ancients compared it to a plantain leaf, and some of its inhabitants have represented it under this form on their coins. The medals of the Peloponnesus had for their type a tortoise. The name of Peloponnesus signifies the isle of Pelops; and accordingly the Greeks ascribed its origin to a hero named Pelops, who migrating from Asia took possession of this part of Greece, and gave it his name.

The Greeks were divided into two nations, viz. the Dorians and Ionians. In the best days of Greece, the Dorians had under their dominion the greatest part of the Peloponnesus, and a column was erected in the midst of the isthmus, upon which was engraved, towards the side of Athens, "this is not the Peloponnesus, but Ionia," and on the side towards Corinth, "this is Peloponnesus, and not Ionia." Notwithstanding its small extent, the Peloponnesus was, for a long time, the most considerable portion of Greece. The principal gulfs in its circuit were, the "Sinus Corinthiacus," or gulf of Lepanto; the "Sinus Cyparissus," or gulf of Arcadia; the "Sinus Messeniacus," or bay of Coron; the "Sinus Laonicus," or gulf of Colochina; the "Sinus Argolicus," or gulf of Napoli; and the "Sinus Saronicus," or gulf of Eugia. The chief promontories were, the "Promontorium Scyllæum," or cape Skilleo; the "Promontorium Malea," or cape Malio; and the "Promontorium Tænarium," or cape Motapan. See the article GRÆCIA.

PELOPS, in *Ancient History*, the son of Tantalus, king of Lydia, who is said to have been the last foreigner who arrived in Greece before the destruction of Troy. This prince, forced to fly from his country on account of the war which Tros had waged with him, to revenge the rape of Ganymede, retired into Greece, where he married Hippodamia, the daughter of Oenamaus, king of Pifa, ascended the throne, after the death of his father-in-law, and communicated his name to that part of the peninsula, which was from that time called *Peloponnesus*, (which see.) But his dominion extended also to Ætolia, and by his immense wealth he became one of the most powerful kings of Greece. The era of Pelops's arrival in Greece must have been about the 110th or 120th year before the Trojan war. Among other

fatalities of Troy, it is said that it could not be taken by the Greeks, unless they had the bones of Pelops; and they therefore sent for them to Pifa where he had been interred. The vessel was shipwrecked in its return, and some time after a peasant found upon the shore the shoulder of that prince, and hid it under the sand. The Elæans having gone to the temple of Delphos to consult the oracle, in order to be delivered from the plague, the priests ordered them to go and dig up the bones of Pelops; and perhaps, in memory of this event, they made an ivory shoulder, which they consecrated to Ceres, and the Pelopidæ bore it afterwards upon their ensigns. Some of the ancient fathers contend that the palladium of Troy was made of Pelops's bones. The fable says, that the horses which drew Pelops's chariot had wings, and that they had been given to him by Neptune, the meaning of which is, if we believe Pindar and Palæphatus, that Pelops made use of a ship with sails to carry off Hippodamia.

PELORIA, in *Antiquity*, feasts instituted by Pelorus, and celebrated by the Thesalians. They had a considerable affinity with the Saturnalia; for in these the masters served while their servants sat at table, as in the Chronia celebrated at Athens, in honour of Chronos or Saturn. At the festival of the Peloria, public entertainments were made for strangers and even for slaves, who were served by their masters: and it is said, that the practice, as well as the feast, originated from this circumstance, that Pelorus was the person who first gave intimation to Pelasgus, that by means of an opening in the valley of Tempé the waters of Deucalion's deluge were removed, which intelligence gave that prince so much joy, that he regaled Pelorus in a magnificent manner, and insisted upon serving him at table.

PELORIA, in *Botany*, so named by Linnæus, from *πελορ*, a monster, is a remarkable variety of the common Yellow Toadflax, *Antirrhinum Linaria*, in which the flowers, naturally ringent, with two long and two short stamens, and one simple nectariferous spur, become regularly five-cleft, with five spurs, and five equal stamens. Linnæus published a dissertation on the subject, reprinted in *Am. Acad.* v. 1. 55, with a plate. He gives an interesting history of the first discovery of this flower, by a young student of botany little aware of its curiosity, who gave it to Olaus Celsius; and by the latter it was shewn to Linnæus, who at first thought a trick had been played, by affixing flowers of some other plant to the Toadflax. But when these flowers themselves could not be referred to any thing, his curiosity was strongly awakened. This monster, in short, overthrew not only his own system, but that of every other teacher, if we except the sober *frustrists*; who, no doubt, had they seen such a prodigy, would thence have deduced no small matter of triumph over their adversaries, who contended for the importance of the flower in classification, above other parts; for the pistil and fruit are not affected by the above metamorphosis. How might Linnæus in his turn have exulted, in exhibiting the latter parts changed to a real leaf, in the double-blossomed cherry!—Exultation, however, does not justly belong to those who attempt to measure their own powers with the wisdom of Nature. A little further enquiry discovered other species of *Antirrhinum* subject to the same change; nor are similar instances wanting in different genera of the *Didynamia Angiosperma*, which by this means are transferred to the *Pentandria Monogynia*. Both sorts of flowers are often found on the same plant of *Bignonia radicans*, and have likewise been observed, for many successive seasons, by the writer of this, on the *Antirrhinum* in question, an approach towards which is drawn from the life, in *Engl. Bot.* v. 10. t. 658. The seeds from such altered flowers, nevertheless, do not appear more disposed to pro-

duce the *Peloria* than others. Indeed if all their progeny be not carefully rooted out, the garden will soon be overrun with genuine *A. Linaria*, to the exclusion of the less vigorous plants that bear monstrous flowers, though the latter, if kept clean from weeds, continue in general true to their first metamorphosis, and increase considerably by root.

PELORIDES, in *Natural History*, a name given by some to a peculiar species of chama. Bellonius, who first used the word, never gives it alone as the name of the shell, but only uses it as an epithet derived from *Peloro*, the name of the place where a particular species of chama was very frequent.

PELORUM, in *Ancient Geography*, a river of Asia, in Iberia. Dion Cassius.—Also, a promontory in the N.W. of Sicily, near the cape of Faro.

PELOS, in *Geography*, a town of Italy, in the Cadurin; seven miles N.E. of Cadora.

PELOW, a town of Ava, on the left branch of the river Ava; 15 miles from Prome.

PELT-ROT, in *Agriculture*, a disease in sheep, which is often very destructive. See ROT.

PELT-wool, wool stripped of the skin or pelt of a dead sheep.

PELTA, *πελτα*, in *Antiquity*, a kind of buckler, used among the ancients.

The pelta was small, light, and more manageable than the parma.

It appears from Virgil, and other authors, that the pelta was the buckler used by the Amazons: and Xenophon observes, that the pelta of the Amazons was shaped like a leaf of ivy. Pliny, speaking of the Indian fig-tree, says its leaves are of the width of the Amazonian pelta. Servius on the *Æneid* says, the pelta resembled the moon in her first quarter.

PELTA, in *Botany*, a name happily adopted by Dillenius from the Latin language, (in which it means a short, somewhat crescent-like, shield or buckler,) for the peculiar shields of one tribe of Lichens, first separated as a genus by Hoffmann, under the appellation of *Peltigera*, and now retained by that of *Peltidea*; see that article, and LICHENES.

Pelte, or targets, are almost always situated towards the margin or extremity of the frond, either on the upper or under side, being closely attached to its surface, and each consisting of a flattish, or slightly convex, brown smooth disk; the border being accessory, and hardly distinguishable, originating from the frond.

PELTÆ, in *Ancient Geography*, a town of Asia, in Phrygia. This town was well peopled, and situated at the distance of 10 parasangs from Celenes. Cyrus sojourned here three days, and was a spectator of the Lupercalia which Xenias of Arcadia celebrated by sacrifices and games, at which the prizes were currycombs of gold. This town is not mentioned by Xenophon, Strabo, Ptolemy, and Stephanus of Byzantium.

PELTAN, THEODORE ANTHONY, in *Biography*, a learned Jesuit in the 16th century, was born at Peltis, in the diocese of Liege, whence he derived his surname. He became a member of the Society of Jesus in the year 1552, and acquired celebrity by his proficiency in the Latin, Greek, and Hebrew languages, and his knowledge of philosophy and divinity. When Albert, duke of Bavaria, founded the university of Ingolstadt in 1556, he was appointed professor of Greek and Hebrew literature in that seminary, and discharged the duties of his office with uncommon assiduity and success. He was admitted, at different periods, to the several degrees, and in 1562 he proceeded doctor. Immediately afterwards he was called to the theological chair,

chair, which he filled with great reputation till the year 1574, when he retired to the college belonging to his order at Aufsburg, where he spent his time in laborious study and writing till his death, which took place in the year 1584. He was the author of a work entitled "Theologia Naturalis, et Theologia mystica." He was also author of many other works, chiefly on moral and theological subjects. Moreri.

PELTARIA, in *Botany*, so named by Jacquin, from *pelta*, a shield or target, in allusion to the shape of the seed-vessel. Jacq. Enum. Stirp. Vind. 260. Linn. Gen. 336. Schreb. 439. Willd. Sp. Pl. v. 3. 471. Mart. Mill. Dict. v. 3. Gært. t. 141. (Clypeolæ species; Juss. 240. Lamarck Illustr. t. 560. f. 2.)—Class and order, *Tetradynamia Siliculosa*. Nat. Ord. *Siliquosæ*, Linn. *Crucifera*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of four ovate, concave, erect, coloured deciduous leaves. *Cor.* cruciform, of four obovate, entire, flat petals, whose claws are shorter than the calyx. *Stam.* Filaments six, awl-shaped, the two opposite ones shortest, and equal to the calyx; anthers simple. *Pist.* Germen roundish, compressed; style short; stigma simple, obtuse. *Peric.* Pouch roundish, compressed almost flat, entire, of one cell, not bursting. *Seeds* from one to three, roundish, compressed, emarginate.

Eff. Ch. Pouch nearly orbicular, entire, compressed, of one cell, not bursting, with from one to three seeds.

Obf. Jussieu reduces this genus to *Clypeola*, and he is followed by Lamarck; but the only genuine species of the latter, which is *Ionthlasi*, has toothed stamens, like *Alyssum*; and Gærtner observes, that the valves of its pouch are really distinct and separable, which is not the case in *Peltaria*. He therefore retains the latter, for this particular reason more especially. In assenting to this however we can only insist upon the original species. *P. Garcini*, Willd. n. 2, appears by Burmann's figure, Fl. Ind. t. 46. f. 1, to be, as Mr. Brown has suggested to us, probably an *Isatis*. *P. copensis*, Linn. Suppl. 296, has, as Willdenow well observes, a pouch of two cells, with distinct valves and a membranous partition. Its habit is like a *Heliophila*. Whatever it may be, it is no *Peltaria*.

1. *P. alliacea*. Garlic-scented *Peltaria*. Linn. Sp. Pl. 910. Jacq. Austr. t. 123. (Bohadschia; Crantz Stirp. Austr. fasc. 1. 2. t. 1. f. 1. *Clypeola pereunis*; Arduin. Spec. 1. 16. t. 6. *Thlaspi montanum primum*; Clus. Hist. v. 2. 130. *T. pannonicum Clusii*; Ger. Em. 266.)—Native of itony mountainous places in Austria, near the lofty Schneeberg. It was introduced into our gardens in the time of Clusius, as he himself mentions, and is still preserved, for the sake of curiosity, in Botanical collections, flowering in May, and ripening seed a month or six weeks later. The root is perennial. *Plant* like some species of *Thlaspi*, as *perfoliatum* and *alpestre*, but larger. The leaves are ovate, entire, smooth, of a light glaucous hue, clasping the stem with their arrow-shaped base. *Flowers* white, rather small, in several terminal slender-stalked *corymbs*, which at length become racemose. *Pouches* orbicular, but very irregular in their outline, about a quarter of an inch broad, reticulated with prominent veins, the cavity of much less diameter than the whole pouch.—The herb when bruised has an unpleasant garlic scent, somewhat like that of *Erysimum Alliaria*. The seeds are bitter and acrid.

PELTASTES, πελταστες, among the *Ancients*, one who used the buckler called *pelta*.

PELTATUM FOLIUM, in *Botany*, a peltate leaf, is so called from the insertion of the footstalk into some part of its disk, whether towards the centre or near the margin, which mode of attachment is compared to a shield presented

at arm's length. Such is the leaf of the *Tropæolum*, whose insertion is nearly central, and that of *Pelargonium peltatum*, in which it is nearer the base, sometimes, if we mistake not, gradually disappearing, or varying, into the common mode of attachment. See **PELARGONIUM**.

PELTIDEA, in *Botany*, so named by Acharius, from *πέλις*, a target, see **PELTA**, and *εἶδος*, form or shape; a genus of the natural order of **LICHENES**, for whose characters, with mention of some principal species, we refer the reader to that article, n. 18. The genus is divided, in the *Methodus* of Acharius, into four sections.

Section 1. **EMPROSTEA**. *Targets nearly marginal, on the upper surface of the frond.*

This section consists of ten species, of which *venosa*, Engl. Bot. t. 887, and the common *canina*, t. 2299, are examples; and from which is now excluded by its author the *chlorophylla*, n. 7, as being a variety of *Cetraria sepincola*. To this point we cannot speak; but *collina*, Engl. Bot. t. 1834, is now admitted by Dr. Acharius, as possibly distinct from *rufescens*, t. 2300, so that the number of species in this division remains unaltered.

Section 2. **OPISTERIA**. *Targets nearly marginal, at the back of the frond.* Two, which Acharius considered as certain species, form this section; *polaris*, (Jacq. Misc. v. 2. t. 10. f. 1.) and *resupinata*, Engl. Bot. t. 305. To these are subjoined as doubtful, what we can aver to be no less certain and distinct than the others, *parilis*, Engl. Bot. t. 2360, and *cellulosa*, a curious species brought by Mr. Menzies from the straits of Magellan.

Section 3. **PLEUROTHEA**. *Targets lateral, scattered over the upper surface of the frond.* The beautiful *crocea*, Engl. Bot. t. 498, is the only example.

Section 4. **PEROPHORA**. *Targets lateral, sunk into hollows in the upper surface.* The only certain species is *saccata*, *ibid.* t. 288. Two doubtful ones, unknown to us, are *esculenta* and *velleiformis*; the former described in Pallas's Travels, t. 1. f. 4: the latter by Bellardi, in his Appendix to the Flora Pedemontana.—The plants of these two sections are now referred by Acharius to his genus *Arthonia*, a measure from which we have already, under the article above referred to, presumed to express our dissent.

PELTUINUM, in *Ancient Geography*, a town of Italy, in the territory of Samnium.

PELUA, a town of Illyria, on the route from Sirmium to Salonæ, between Salva and Æquum, according to the Itinerary of Antonine.

PELVIS, in *Anatomy*, is a large irregular bony cavity, open above and below, and forming the inferior end of the trunk. At the upper and back part its parietes support the vertebral column, and they are sustained below and towards the front by the thighs, to which they transmit the weight of the body; thus a well-marked space, which measures the immediate base of support of the trunk, is left between the plane of the limbs and of the spine. In a well-formed individual the pelvis divides the body into two equal halves: that is, if a line be drawn across its middle, the upper and lower portions of the body have the same length. This rule, however, is subject to some exceptions: the lower limbs are imperfectly developed in the fœtus; and, in unusually tall or short adult individuals, the lower extremities or the trunk exceed the just proportion.

The pelvis is symmetrical, but of a figure not easily defined. It forms, by its upper portion, a cavity nearly oval in the transverse direction, expanded at the sides, and hollowed out in front, communicating by an elliptic opening, called the superior aperture (*détroit supérieur*), with its lower portion, which is much smaller in size, and ends below

PELVIS.

low by an opening called the inferior aperture (*détroit inférieur*).

Lines drawn from one side of the pelvis to the other are horizontal, because, on account of the symmetry, the parts on the two sides are exactly on the same level.

The position of the pelvis is oblique, the back part being considerably higher than the front: this obliquity is well seen in the superior aperture, which slants very manifestly from above downwards and forwards: the inferior aperture looks downwards and backwards. Soemmerring states, that in the erect attitude, the last bone of the coccyx is an inch higher than the inferior edge of the symphysis pubis; and that the promontory of the sacrum is higher than the same point, by the whole depth of the sacrum and coccyx. (*Orteologia*, § 432.) The symphysis pubis is oblique, from before backwards and downwards; and the upper part of the sacrum slants in the same direction. The axis of the upper or broad part of the pelvis (the *greater pelvis*) is nearly perpendicular: that of the lower or smaller division (the *lesser pelvis*) slants from above downwards, and from before backwards. It is said to correspond to a line drawn from the apex of the os coccygis to the umbilicus. This line would cut the level of the pelvis nearly at a right angle: that is, the meeting of the two lines would form an angle of 75 degrees in front, and of 105 behind. The weight of the trunk being obliquely transmitted to the thighs, in consequence of this inclination of the pelvis, it follows, says Bichat, that the latter is the seat of a decomposition of motion in this transmission, proportioned to the degree of inclination, which is about thirty-five or forty degrees at the upper part, where we can easily estimate it by the line, which extends from the sacro-vertebral articulation to the upper edge of the symphysis pubis.

The capacity of the pelvis differs remarkably in man and woman. It is manifestly larger in the latter in every direction: thus the two iliac crura, the two anterior, and the two posterior spines, the cotyloid cavities, the tuberosities of the ischia, &c. &c. are further apart. These are all transverse measurements, and those from before backwards are greater, as we may see in measuring from the sacrum to the pubes, from the anterior to the posterior spine, from the sacro-iliac articulation to the foramen ovale, &c. The oblique measurements, from one side to the other, are also larger in the female. The superior aperture often exhibits deviations from the accustomed arrangement, in the diminution of its diameters subsequently to birth; and these are generally caused by rachitis, which exerts its effects more on the antero-posterior, than on the transverse or oblique diameters, because the weight of the upper parts, transmitted by the spine, is the principal exciting circumstance.

The breadth of the pelvis in the female produces some difficulties in progression; but the passage of the child in parturition is facilitated. It performs an important part in this function, besides having the same offices as in man, *viz.* those of forming the basis of support to the trunk, and of containing and protecting the viscera.

The comparative height of the pelvis in the male and female is exactly the inverse of the breadth. The measurement from the crista of the ilium to the tuberosity of the ischium, the depth of the symphysis pubis, and the length of the canal formed by the smaller pelvis, are considerably greater in men than in women.

There are some individual varieties in the dimensions of the pelvis, but they depend very little on stature. Parturition is as easy in small as in large women, although the former frequently produce very large children.

The pelvis is formed of few but very broad bones, united

in such a manner, as not to admit of motion on each other: it can be moved therefore only altogether, and not partially. Four bones enter into its composition; two posterior, symmetrical, and placed on the middle line, are the sacrum and coccyx; two anterior and irregular, transmit to the thigh bones the weight of the trunk, which they have received from the sacrum; they are the *ossa innominata*. The sacrum and coccyx, placed at the back of the pelvis, form a continuation of the vertebræ, and are constructed in a mode similar to that of the vertebræ. In most quadrupeds this prolongation of the spine is much more extensive, and forms the tail, which goes considerably beyond the anus, while in man, that opening is situated a little farther than the end of the coccyx. The sacrum and coccyx are described under the article *SPINE*; the *ossa innominata* under *EXTREMITIES*.

Articulations of the Pelvis.—The relations of the vertebral column to the pelvis are maintained by the articulation of the last vertebra to the sacrum, and to the *os innominatum*. The coccyx is articulated to the sacrum. The two *ossa innominata* are joined to the sides of the sacrum, and to each other in front.

1. *Sacro-vertebral Articulation.*—It is formed by two articular surfaces, belonging to the lumbar vertebra and the sacrum, and resembling, in every respect, those by which the vertebræ correspond to each other. The uniting media are also the same with those described in the account of the vertebral column; *viz.* anterior and posterior vertebral ligaments, which are prolonged to the sacrum, a fibro-cartilage between the latter and the body of the vertebra, a yellow ligament between the laminae of the latter and the back of the orifice of the sacral canal, an interspinal ligament uniting the middle ridge of the sacrum to the spinous process of the vertebra; and the supra-spinal ligament, which ends here upon the sacrum. The disposition and structure of all these, as well as of the synovial membranes belonging to the articular processes, are exactly the same as those of the corresponding parts in the spine. (*See SPINE.*) This articulation has however one ligament peculiar to itself, extending from the lower and anterior part of the transverse process of the vertebra, obliquely outwards and downwards to the sacrum, decussating the anterior fibres of the sacro-iliac articulation. It is short and strong, covered by the psoas in front, by cellular tissue and ligaments behind.

2. *Sacro-coccygeal Articulation.*—This is analogous to the joints of the spine: it is formed by two oval surfaces of the sacrum and coccyx, strengthened by a fibro-cartilage, and by an anterior and posterior fibrous band.

The fibro-cartilage is analogous to those of the spine, but much thinner, and allows much freer motion of the connected parts. The three smaller pieces are connected to each other and to the first piece by fibro-cartilages analogous to this. The little tendency of these fibro-cartilages to ossification explains why the four pieces of the coccyx remain so long separate.

The anterior ligament is very thin, and often scarcely perceptible. It consists of some parallel fibres, varying in length continued from the pelvic surface of the sacrum to that of the coccyx. Sometimes there are two more strongly marked lateral fasciculi.

The posterior is a much more considerable ligament, and, besides strengthening the articulation, has the office of completing behind the end of the vertebral canal. It is fixed above to the edges of the excavation, which terminates the canal, and descends perpendicularly to the spinal surface of the coccyx, on which it is expanded. It is covered by the skin behind, and has a few fibres of the *gluteus magnus* adhering to it. In front it corresponds, first, to the end of the

PELVIS.

the sacral canal, then to the surface of the sacrum within the excavation at the end of the canal, and lastly to the coccyx.

3. Connection of the last lumbar vertebra to the os innominatum: (*vertebro-iliac articulation*).

A ligament, called ilio-lumbar (*lig. pelvis anticum superius et inferius*) is the medium of connection. It is fixed to the point of the transverse process of the last vertebra, and sometimes of the fourth also, goes horizontally outwards, and is fixed to the posterior and superior spine, and to the crista of the os innominatum.

Its fibres are often divided into several fasciculi, separated by cellular tissue, of which the superior are longer than the inferior ones. It is a strong ligament, covered in front by the psoas, behind by the vertebral muscles, corresponding above to the quadratus lumborum, and below to the sacro-iliac ligaments.

4. *Sacro-iliac articulation*,—sacro-iliac symphysis, or posterior symphysis of the pelvis.

The broad and irregular opposed surfaces of the sacrum and os innominatum are covered by a crust of cartilage, which has been generally represented as single, and common to the two bones. Bichat considers that each surface has its own covering, and that the investment of the sacrum is rather the thickest. When the bones are torn asunder, the two surfaces are rough; and Bichat describes a soft yellowish substance between them, which he regards as analogous to synovia. In the child this is white and really fluid, and the cartilaginous surfaces are much smoother and more distinct. The bones are tied together by the following ligaments.

The posterior or great sciatic ligament (*ligamentum tuberoso-sacrum*) is thin, flattened, nearly triangular, and situated at the lower and back part of the pelvis. It arises from the end of the crista ilii, and from the sides and back part of the sacrum and coccyx, being at first very broad; it becomes narrower and thicker, and passes obliquely outwards and downwards to the tuberosity of the ischium; in which it is inserted, growing again a little broader. A little prolongation runs beyond the tuberosity, and is fixed to the edge of the bone in front. This ligament is composed of fibres more oblique in their direction in proportion as they are higher, converging from the sacrum to the os innominatum, and often separated by intervals occupied by a fatty cellular substance and vessels. It is covered behind by the *gluteus magnus*, of which the fibres are inserted in it. In front it corresponds, on the inside, to the lesser sacro-sciatic ligament, to which it is united; on the outside to a triangular aperture separating it from that ligament, and traversed by the *obturator internus*, and the pudic vessels and nerve.

The anterior or small sacro-sciatic ligament (*lig. spinoso-sacrum*) is placed in front of the former, and resembles it in form, but is less oblique. Its attachments to the sides of the sacrum and of the coccyx are confounded with those of the former. Thence it passes outwards and forwards, becoming narrower and thicker, and is fixed to the apex of the spinous process of the ischium. Its fibres are more nearly transverse in proportion as they are higher, separate into distinct fasciculi, and leaving cellular and vascular intervals between them. It corresponds behind to the former ligament, and to the pudic vessels and nerve. In front it contributes, as well as the posterior ligament, to complete the sides of the pelvis, of which the bony parietes are here interrupted. Its fibres are mixed with those of the *coccygeus* muscle.

A very strong flattened perpendicular ligament (*ligamentum posticum ossis coxæ*, *lig. sacro-épineux*) passes from the posterior and superior spine of the os innominatum to the lateral and back part of the sacrum. The

superficial fibres are the longest, and they become shorter as they are more deeply seated. It is a very strong compact ligament, and holds the two bones together nearly motionless in the natural state. A fasciculus, situated more deeply than the former, (*lig. posticum breve*), goes obliquely from the posterior inferior spine to the sacrum, and rather decussates with the former, to which it is much inferior in length and strength.

The *sacro-iliac ligament* is a large assemblage of dense, short, and close fibres, occupying the irregular space left between the sacrum and os innominatum, behind their articular surfaces. It passes transversely from one bone to the other, and is attached to the rough unequal part behind the point of contact of the two bones. Its form is irregular, like that of the space which it occupies. The posterior fibres are the longest, whitest, and most distinct, and form a particular layer: in front they are shorter, in proportion as they are nearer to the articulation. Their resistance is so considerable, either in consequence of their number or shortness, that, when the sacrum is forcibly detached from the os innominatum, the ligamentous fibres are not torn, but detached from one or the other bone, leaving the surface bare.

Besides the two ligaments just described, several fibres of different length and direction pass over the sacro-iliac symphysis, from one side to the other, on its upper and anterior parts. They strengthen the joint, but do not require a particular description.

5. *Symphysis Pubis*.—Before we describe it, we shall notice a ligament, not belonging to it, but requiring, from its situation, to be considered in this place.

The *obturator* ligament occupies the foramen ovale, which it shuts up almost entirely. It is a thin plate, fixed to the circumference of the foramen, except at the upper part, where a groove is left, completing the channel through which the obturator vessels and nerve pass. Its fibres are interwoven in every direction, and form in many parts prominent fasciculi, which are particularly distinct near the groove. It corresponds, by its two surfaces, to the two obturator muscles, which are inserted in it.

The ossa innominata are joined in front by two opposed oval surfaces. Numerous fibres pass from one to the other: they are transverse, and more dense and close in the male than in the female. They may be seen by tearing the bones apart from behind, when they are ruptured in the middle, and not detached from the surfaces, as in the sacro-iliac symphysis. They form concentric laminæ, which decussate, and the most superficial of which extend round the joint, while the others occupy only the upper or lower portion. In some subjects the fibrous laminæ arise from the whole breadth of the articular surfaces; but in most, particularly in women, those surfaces present behind two small cartilaginous incrustations, contiguous to each other, moistened by a whitish or yellowish fluid, but not furnished with a distinct synovial membrane. Sometimes these cartilaginous incrustations occupy nearly the whole breadth of the surfaces in women, and then the fibres are in smaller quantity. The latter and the cartilaginous incrustations are in an inverse ratio to each other, and the proportions are very variable. According to these varieties the bones are more or less strongly tied together.

This and the sacro-iliac symphysis form a kind of connection intermediate between the moveable and immovable articulations.

The following ligaments strengthen this articulation.

A thick and distinct fasciculus of triangular shape (*lig. fous-pubien*) occupies the upper part of the arch of the pubes,

PELVIS.

pubes, which it completes, being fixed to the oblique ramus of each bone at its upper and internal part. Its fibres are long below, and correspond to the cellular tissue about the urethra: they are shorter above, and continuous with the interarticular fibres.

The anterior ligament is not so distinct as the last. It is decussated and covered in front by the aponeurosis of the abdominal muscles, under which it forms several strata. The most superficial consists of oblique fibres, which arise at the upper part of the articulation, separate from each other as they descend, and form two fasciculi, which are lost on the front of the two branches of the arch. The others have an oblique or transverse direction, are much stronger, and go from one bone to the other, confused below with the interarticular laminae.

The articulation is surmounted above by various fibres, which strengthen it: the interarticular laminae project behind towards the pelvis, and this prominence, which is most considerable in the female, marks the middle of the junction.

General Description of the Pelvis.—The pelvis, taken altogether, is a cavity of conical form, of which the basis is turned upwards, and the apex downwards. We have to consider in it the external and internal surfaces, and the superior and inferior circumferences.

The *external surface* comprehends four regions: an anterior or pubic, a posterior or sacral, and two lateral or iliac.

The anterior is the least extensive, and exhibits, 1st, on the median line, the symphysis pubis, which is longer in men than in women, and covered by ligamentous fibres; 2dly, on each side, and from within outwards, the quadrilateral surface, to which the adductors are fixed, the foramen ovale, and the cotyloid cavity.

The posterior region, longer but sensibly narrower than the preceding, offers, 1st, on the middle line, the series of sacral spinous processes, or the continued ridge, which supplies their place; the triangular excavation, which terminates the sacral canal; a furrow indicating the union of the sacrum and coccyx; and the spinal surface of the latter. 2dly. On each side, and from within outwards, the sacral channels, and their foramina; a deep depression corresponding to the sacro-iliac symphysis, which is covered by a thick layer of ligamentous fibres; and the posterior prominent tuberosity of the os innominatum.

The lateral regions are formed by the broad external surfaces of the ossa innominata, bounded below by the ischiatic notches.

The *internal surface* is manifestly divided into two portions: a superior broader one, or the great pelvis; an inferior, which is narrower, and forms a kind of canal, called the smaller pelvis, or simply the pelvis.

The great pelvis presents, behind, the sacro-vertebral articulation; and on the sides the internal iliac fossae. The superior portions of the ossa innominata are expanded horizontally, and sustain the principal weight of the abdominal contents. This arrangement is connected with the erect attitude of the human subject. For a further explanation of the differences between the pelvis of man and animals, see the article MAN. The bony parietes are not continued towards the front, where there is a large excavation, filled by the abdominal muscles.

The superior aperture of the pelvis is the more or less prominent line, beginning from the sides of the sacrum, extending obliquely downwards and forwards along the middle of the os innominatum, where it is called linea ilio-pectinea, to the upper and front part of the pubes, and forming the

communication between the great and the small pelvis. It describes an oval, with the long axis placed laterally, and is much more strongly marked in front than behind.

The small pelvis, much narrower, but longer than the great, forms a kind of canal, wider in the middle than at the ends, and filled by the bladder and rectum in man; and by the same parts, with the addition of the uterus and vagina in women. We observe, in front of it, two surfaces corresponding to the bladder, separated by the symphysis pubis, and bounded by the thyroid foramina; behind, the concavity of the sacrum, with its foramina, terminated by the lines which mark the sacro-iliac symphyses; on the sides, the sciatic notch completed by the ligaments of the same name, and the quadrilateral surface, which separates the notch from the foramen ovale.

The *superior circumference* forms a very irregular line, slightly inclined forwards, and very much expanded in the female. It presents, behind, the sacro-vertebral articulation, bounded on each side by a marked depression, in which we observe the trace of the sacro-iliac symphysis; in front, the large excavations already noticed, formed by the anterior portions of the upper edges of the ossa innominata; on the sides the two iliac crista.

The *inferior circumference*, called also the inferior aperture, is directed downwards and backwards, and is remarkable for three eminences separated by three notches. The two anterior prominences are the tuberosities of the ischia: the posterior and middle one is formed by the coccyx, which does not descend so far as the tuberosities; so that, in the sitting attitude, the latter alone support the weight of the body. The notches have an arrangement exactly inverse of that of the prominences: two are posterior, and one anterior. The latter is called the arch of the pubes. The oblique and oblong portion, which bounds the foramen ovale in front, contributes on each side to its formation. It is terminated above by an angle, nearly acute in man, rounded in women, occupied almost entirely by the generative organs and urethra in both sexes. The posterior notches lie between the sacrum and the tuberosities of the ischia. The sacro-sciatic ligaments divide each into three portions: the superior is a large hole, through which the pyramidalis muscle, the sciatic nerve, and the gluteal, sciatic, and pudendal vessels pass. The second is a less extensive hole than the former, giving passage to the obturator internus, and the pudendal vessels. The third is the general opening, placed in front of the coccyx, and between the sacro-sciatic ligaments, in which the termination of the rectum is placed, surrounded by much cellular tissue.

We have stated already, in general terms, that there are great differences between the male and female pelvis; that the latter is wider in all its dimensions, and deeper from before backwards, while the former measures the most in the perpendicular direction. Hence the cavity of the pelvis is more capacious, and fitted to receive the uterus and vagina, in addition to the parts which it contains in the male, and to give passage to the child in parturition. The distinctions of the two sexes, in this respect, are to be traced through all parts of the pelvis. The ilia are more horizontally expanded, the sacrum more convex, the arch of the pubes much wider and more rounded above in the female than in the male. The superior aperture in the latter has a contracted triangular figure, with the basis turned backwards, and the apex forwards: the inferior aperture is remarkably small, when compared to that of the female. In consequence of this great width of the pelvis in women, that is the broadest part of their trunk, while in man the shoulders are the broadest, and the pelvis the narrowest.

PELVIS.

The following is a comparative view of the dimensions of the male and female pelvis, taken from Soemmerring's Osteology, § 446. The measure is probably Rhyland, of which the foot is to the English as 1033 to 1000.

	In the Male.	In the Female.
The distance between the superior spines of the ossa innominata	9 in. 0 l.	11 in. 0 l.
The superior aperture between the ossa innominata	4 6	5 6
The smaller or conjugate diameter of the same aperture, that is, from sacrum to pubes	4 to 5 in.	4 8
The oblique diameters, from the sacro-iliac symphysis to the pubes	4 in. 2 l.	5 0
Between the tuberosities of the ischia	3 2	4 0
From the apex of the coccyx to the pubes	3 0	4 6
From the tuberosity of the ischium to the superior aperture	4 10	3 6
The depth of the symphysis pubis	1 10	1 6
From the margin of the sacrum to the apex of the coccyx	4 10	5 0
Angle of union of the ossa pubis	60° to 80°	90°

Progressive Development of the Pelvis.—The fœtus, the adult, and the old subject, present essential differences in this part.

In the fœtus it is small in proportion to the rest of the body; it follows, in its growth, nearly the same laws as the lower limbs. This disproportion contributes to the marked prominence which the abdomen of the fœtus presents. The smallness of the pelvic cavity leaves no room for the intestines in that part; even the urinary bladder is in the abdomen, which is moreover dilated in consequence of the great bulk of the liver. The size of the abdomen, which is very considerable from the causes above-mentioned, becomes more striking in consequence of the pelvis being so very small.

The upper part, or great pelvis, which belongs to the abdomen, is more developed than the lower, which contains the generative organs, and affords the point of support to the lower limbs. The iliac fossæ are not so much expanded horizontally, nor so deep. All the dimensions of the pelvis are very small at this time; but the transverse measurements are particularly contracted. The direction of the cavity is more inclined.

The middle of the sacrum, which is concerned in forming the vertebral canal, is already much advanced, but the lateral portions are more backwards; since the foramina are proportionally nearer to the sacro-iliac symphyses. The posterior prominences hardly exist. The pieces corresponding to the bodies of the vertebræ, like those bodies, are rounded and imperfect in front, more developed behind, where they form the canal. The coccyx is small, and contains only osseous rudiments.

The three portions composing the ossa innominata are developed towards their middle; but the circumference, and all the prominences, are cartilaginous. The cotyloid cavities are almost entirely in this state, and not capable of affording

to the thighs a degree of resistance sufficient for the purpose, of standing and walking.

As age advances, the pelvis is more developed to fulfil the important functions, which it has to execute in locomotion and standing, as well as in regard to the generative functions. It becomes less inclined in its position, and gradually acquires those proportions and dimensions which we have already indicated in the general description. Its development is earlier in the female than in the male, so that in many individuals the cavity is so far formed as to answer the purposes of parturition at the age of nine or ten years. The pieces which compose the sacrum and os innominatum, are consolidated about the age of puberty. The cartilage between the rami of the pubes and ischium disappears sooner. The cristæ, and the tuberosities of the ossa innominata, remain to a later period, and the former are the last in their completion.

The pelvis experiences very little change in old persons; its bones are very seldom ankylosed, except the sacro-coccygeal articulation. Their unions, however, are more dense and solid. The general direction of the cavity is altered, the obliquity being lessened.

Mechanism of the Pelvis.—We must consider it as it is concerned in four principal functions; 1st, as the support of the trunk in standing and sitting; 2dly, as the point on which the thighs are moved; 3dly, as executing itself various motions; and 4thly, as forming a large cavity, lodging various important viscera.

In standing, the pelvis is placed between two opposite forces; viz. the weight of the body transmitted to it by the vertebral column, and the resistance opposed by the thighs; hence it would be carried backwards on the thighs, if the powerful muscles extending from the latter to the front of the vertebral column, did not maintain it in the horizontal position. The basis of support of the trunk then occupies the space included between the line of the spine, and of the hips. This space is narrower in the fœtus and child, because the greater obliquity of the pelvis brings the thighs nearer to the line of the sacrum; hence standing is more difficult, and becomes easier in proportion as the elevation of the pubes widens the base of support. The figure of the sacrum, which is received like a wedge between the ossa innominata, is well calculated for the office which it serves, of transmitting to the latter the weight of the trunk, and for preventing it from being depressed between them.

The pelvis rests on the tuberosities of the ischia in the sitting attitude; so that the basis of support is rather enlarged towards the front, the line of these tuberosities being rather anterior to that of the cotyloid cavities. The horizontal extension of the lower limbs, either in whole or in part, according as we sit on the ground, or on a more elevated seat, is another circumstance contributing very greatly to extend the basis of support towards the front, in the sitting attitude.

In considering the pelvis as the point on which the lower limbs are moved, its mechanism belongs particularly to progression. The separation of the two cotyloid cavities produces an analogous separation of the thighs, and thus increases the extent of their motions. The pubes may be regarded in the lower extremity as having the same use with the clavicle in the upper; with this difference, that the latter is moveable, and accompanies all the motions of the humerus, while the former is fixed. The interval between the acetabula is more considerable in the female, because all the transverse measurements of the pelvis are greater. Hence the progression of females has in it something peculiar, arising

from the greater portion of a circle which the pelvis has to describe at each step. In the child, where the thigh bones are nearer together, the motions are easier but less secure. At this time the thigh-bones are equally approximated in both sexes. The pelvis of the male and female hardly differ in the fœtus; the distinctive characters are produced at a subsequent age.

The pelvis may be moved on the spine, or on one or both thighs. It cannot be moved on the vertebral column without the whole body being prostrate; in that attitude it may be bent, extended, or inclined laterally. These motions do not take place entirely in the sacro-vertebral articulation, but in the whole of the joints of the lumbar vertebræ; as the more extensive motions of the head are effected by a general movement in the whole neck.

Flexion of the pelvis upon the two thighs is not so easily performed, as might at first be supposed. For, if the trunk is much inclined forwards, the centre of gravity is no longer sustained, and the body very quickly falls. The trunk has two points of support; the cotyloid cavities above, and the feet below, the first of which is on a line posterior to that of the second. Hence, when the trunk is bent, the pelvis remaining immovable, the centre of gravity must pass beyond both in succession, before a fall can occur. But, if the pelvis is moved with the trunk, the centre of gravity has a single base of support, and soon goes beyond it; consequently the pelvis in general partakes but little in these motions; yet it is sometimes concerned, and then the hip-joints are the centres of motion. In the latter case, the legs, thighs, and pelvis, are carried backwards, so that the lower limbs describe an oblique line, the upper part being thrown much farther back than the lower. This inclination visibly enlarges the basis of support, which would have been too narrow, formed by the feet alone.

Extension of the pelvis on the thighs is not more marked than flexion; indeed the ligamentous fibres on the front of the joint prevent the thigh-bone from being carried backwards on the pelvis beyond a straight line, and must equally prevent the corresponding motion of the pelvis on the thigh. In inclinations of the trunk backwards, the loins are the seat of motion, and not the hip-joints; when we extend this motion as far as possible, the pelvis and thigh are both inclined. When the trunk is carried in this direction, the knees are bent forwards, so as to give the legs an oblique direction, calculated to support the line of gravity of the trunk, because there is no basis of support behind, analogous to what the feet offer in front. If we incline the trunk backwards in any sensible degree, the lower limbs remaining straight, a fall is inevitable.

Lateral inclination on the two thighs can hardly be said to take place; in fact it cannot be depressed on one side, without being raised on the other; and as the two limbs rest at the same time on the ground, this motion cannot take place.

The motions of the pelvis on one limb are quite different from those which it performs on the two. It can be moved with facility in every direction; lateral inclination and rotation are easily executed. The latter movement is seen in the pirouettes of dancers. It is very partial, the structure of the hip being such that the pelvis can describe only a small portion of a circle on the thigh.

The particular bones of the pelvis have scarcely any motion in the natural state, excepting the coccyx, which can be moved forwards and backwards.

The ossa innominata are entirely incapable of motion at both their articulations; yet, if the symphysis pubis be cut,

there is a degree of mobility in the sacro-iliac joint. At the time of pregnancy, or after several utero-gestations, there is a relaxation of these connections, allowing a visible motion between the two ossa innominata at the pubes. This phenomenon however is not constant.

The organs contained in the cavity of the pelvis are excellently protected from all external shocks. The kind of arch formed by the ossa pubis in front, the thick muscles, the hip-joints, and the trochanter at the sides, and the muscular masses of the spine behind, constitute an effectual provision for the resistance of injury. The projection of the ossa innominata beyond the sacrum behind, protects the latter bone in cases of blows or falls on this part of the pelvis.

PELVIS of Birds. See *Anatomy of BIRDS.*

PELVUS, in *Ancient Geography*, the name of an island, situated in the vicinity of that of Chios.—Also, a mountain of Italy, in Etruria.—Also, a torrent of Sicily.

PELVUS, in *Geography*, a town of Persia, in the province of Mecran; 54 miles N.N.E. of Kich.

PELVUS Armena, in the *Materia Medica*, a name given by some of the old writers to the drug that we at present call bole armoniac. This was the original name, and the term *bolus armena* is not to be found, but in the later writers.

PELVSIUM, in *Ancient Geography*, a town of Egypt, at the eastern extremity of the lake Menzale, near one of the mouths of the Nile, and, according to Strabo, about two miles from the sea. Its name, which in Greek signifies *mud*, proves its situation to be in the midst of lakes and marshes; as does also the Hebrew term *Sin*, by which the prophet Ezekiel denominates it; and also the *Thinab* of the Arabians. The period of its foundation, as well as that of the other ancient cities of Egypt, is lost in the obscurity of time. It flourished long before Herodotus. As it commanded the entrance of the country on the side of Asia, the Pharaohs rendered it a considerable fortress: one of them raised a rampart 30 leagues in length, from the walls of this town to Heliopolis. This rampart, which covered Pelusium, did not, however, stop Cambyfes, who attacked it with a formidable army. Cambyfes, after a bloody battle, in which he slaughtered his enemies, entered Pelusium in triumph. Herodotus, who visited Pelusium some years after the conquest of Cambyfes, says that he surveyed the plain where the two armies had fought, and found it covered with human bones collected in heaps; those of the Persians on one side, and those of the Egyptians on the other. Pelusium, after passing under the dominion of Persia, was taken by Alexander. The brave Antony, general of cavalry under Gabinus, took it from his successors; and Rome restored it to Ptolemy Auletes. Pompey, after the fatal battle of Pharsalia, took refuge at Pelusium; but he had scarcely landed on the shore, when Theodore, the rhetorician of the isle of Chio, Septimius the courtier, and Achilles the eunuch, who commanded his troops, wishing for a victim to present to his conqueror, stabbed him with their swords. At the sight of the assassins, Pompey covered his face with a mantle, and died like a Roman. They cut off his head, and embalmed it, to offer it to Cæsar, and left his body naked on the shore.

Pelusium was often taken and pillaged, during the wars of the Romans, the Greeks, and the Arabs; but in spite of her disasters, she preserved, to the time of the crusades, her riches and her commerce. The Christian princes, having taken it by storm, sacked it. It never again rose from its ruins, and the inhabitants went to Damietta. Farama, founded by the Arabs, a little to the eastward of Pelusium, took place of it. See *FARAMA*.

Pelusium

Pelufium gave name to the *Pelufian* branch of the Nile, but nothing now remains of it but ruins. This canal has now no communication with lake Menzale, except that which is merely temporary, on the swelling of the Nile; but at other times it is dry.

PELUSIUM, a port of Theffaly. Steph. Byz.

PELUSO, in *Geography*, a small island in the Mediterranean, near the coast of Natolia. N. lat. $36^{\circ} 45'$. E. long. $28^{\circ} 56'$.

PELUSSIN, or PELLUSIN, a town of France, in the department of the Loire, and chief place of a canton, in the district of St. Etienne; 12 miles E. of it. The place contains 3290, and the canton 11,716 inhabitants, on a territory of 140 kilometres, in 13 communes.

PEMAQUID, a bay of America, on the sea-coast of Lincoln county, in the State of Maine. It lies east of Sheepscot river, and contains a number of islands, many of which are under cultivation. N. lat. $43^{\circ} 45'$. W. long. $69^{\circ} 30'$.

PEMAQUID Point, a cape on the west side of the above bay, two miles E. of Booth bay, and about four leagues N.W. of Menhagan island. N. lat. $44^{\circ} 5'$. W. long. 69° .

PEMAR, a town of Sweden, in the province of Finland; 12 miles E. of Abo.

PEMARO, a town of Etruria; 15 miles E.S.E. of Leghorn.

PEMBA, or PENDA, an island in the Indian sea, near the coast of Africa, about 100 miles in circuit, and governed by a king, who is tributary to the Portuguese. S. lat. $5^{\circ} 55'$. E. long. 42° .

PEMBA, a province of Congo, bounded on the north by the province of Sundi, on the east by Batta, on the south by Bamba, and on the west by Songo. It is divided into the province of St. Salvador, and the marquise of Bamba, from its chief towns. It is generally fertile, more especially towards the east.—Also, a town of Congo, and capital of a marquise; 75 miles S. of St. Salvador. S. lat. $7^{\circ} 30'$. E. long. $12^{\circ} 52'$.—Also, a bay of the Indian sea, on the coast of Africa. S. lat. 13° .

PEMBRIDGE POINT, a cape on the east coast of the Isle of Wight. N. lat. $50^{\circ} 42'$. W. long. $1^{\circ} 56'$.

PEMBROKE, or PEMBROCH, a borough and market-town in the hundred of Castle-Martyn, and county of Pembroke, South Wales, is situated on a singular neck of land, dividing the small estuary of Down-Pool, which flows from Milford haven. It is the county town, and, next to Caermarthen, is one of the largest and richest towns in the southern division of the principality. The period of its foundation is unknown, but it is certainly of great antiquity, and is supposed to have derived its name from the British word *Penfro*, signifying a cape, or promontory. It was anciently fortified, and protected by a most magnificent castle, the vast ruins of which still give it an appearance of uncommon grandeur; and was likewise defended by a strong wall, still nearly entire, on the northern side, where it is flanked by numerous bastions of great thickness and strength. Through this wall were formerly three gates, on the east, north, and west sides; besides a small postern on the south side, leading to the marsh. Of these gates, that facing the north is the only one now standing; the other two having been long since destroyed. The east gate, which remained in Leland's time, is described by him as consisting of solid iron, and as being highly ornamented and fortified.

The corporation of Pembroke is composed of a mayor and council, two bailiffs and serjeants at mace, and about 1500 burgeses. The mayor holds a court every fort-

night, for the decision of civil causes arising within his jurisdiction. Here are also held the petty sessions for the hundred of Castle-Martyn. The markets are on Wednesday and Saturday; and the fairs on the 14th of May, Trinity Monday, St. Peter's day, old style, and 25th of September. Pembroke, in conjunction with the neighbouring boroughs of Tenby and Wilton, send one member to the British parliament: the mayor is the returning officer. The voters are estimated at 500 in number, and are chiefly in the interest of the Owen family.

According to the population returns of 1811, this town contains 501 houses, and 2415 inhabitants. The houses are ranged principally in one long street, which extends from east to west along the ridge of a hill, and is terminated by the castle at the west end; bearing in general appearance, but on a smaller scale, a strong resemblance to the towns of Edinburgh and Stirling, in Scotland. The public buildings are a town-hall, a free grammar-school, and two parochial churches, dedicated to St. Mary and St. Michael. St. Mary's church stands near the centre of the town, and consists of a nave, chancel, and north aisle, with a small chapel to the south. St. Michael's bears evident marks of great antiquity. The architecture is a rude specimen of the Norman style, the arches being massive, and rounded, and entirely destitute of ornament. Both these churches are consolidated with that of Monckton in one vicarage, the impropriation and presentation of which belong to viscount Hereford, as proprietor of Monckton priory, and its estates. Attached to St. Michael's was a chapel, or hospitiun, dedicated to St. Mary Magdalen, the ruins of which are now known by the name of the Marlan's chapel. St. Mary's had likewise its chapel, called St Anne's; but this edifice is now entirely demolished.

The castle, as already mentioned, forms the western extremity of the town, occupying a rocky termination of the ridge on which it is placed. It is a noble ruin, and exhibits, in certain points of view, one of the finest subjects for the pencil which Wales can boast of. This fortress, according to Caradoc of Llancarvon, was founded in 1092, by Arnulph de Montgomery, son to the earl of Shrewsbury, on the site of a more ancient British work. It seems, however, to have received great additions in the reign of Henry I., and Giraldus even refers its foundation to that period; though he acknowledges the existence of another much more slender erection of anterior date. During the wars with the Welsh it was frequently besieged, but owing to its great artificial strength, and almost impregnable natural position, it seems to have resisted successfully all the efforts of the assailants to reduce it. Oliver Cromwell also besieged it in person, in the time of the grand rebellion, and compelled its garrison to surrender, after a long and vigorous attack.

From the period of its surrender, Pembroke castle has been much neglected, and is now so ruinous as to be uninhabitable. It is divided into two parts, called the inner and outer wards; the former of which comprises the keep and the state apartments; and the latter, the buildings formerly appropriated to the garrison; though over the principal gateway from the town, and within it, there were also some very handsome apartments. Here, according to Leland, was "the chambre where king Henri VII. was born, in knowledge whereof a chymney is new made, with the arms and badges of king Henri VII." This honour, however, is traditionally given to a room in a very splendid suite of apartments built over "the marvellous vault, entitled the Hogan," which is cut out of the solid limestone rock, and forms one of the most extensive and lofty excavations of its

kind in Great Britain. Its figure approaches that of a circle, the diameter from north and south being 76 feet 8 inches, and from east to west 57 feet 4 inches. The natural opening, which was of great width, is built up, and contracted into a small door-way, that appears to have been once strongly barricaded. Above are the marks of four loop-hole windows, and of another door-way, now stopped up. Of the uses to which this vault was applied there is no account upon record, but it was most likely a *dépôt* for stores of every kind, "the *stufura* of the garrison." At its south-east corner is an adit, traditionally said to communicate with Tenby; and under the south-east bastion of the castle is another very curious passage, in some parts spacious, and in others extremely narrow, which has been explored to a considerable distance, but its termination is not known. This last is doubtless, however, in a great measure a natural duct; apertures of a similar kind frequently appearing in most limestone rocks. It is supposed by some to penetrate under the keep that rears its proud head in the centre of this magnificent ruin, terminating, as Leland observes, "with a rofe of stone, almost *in conum*, the toppe whereof is keverid with a flat mill-stone." This building is 75 feet in height to the dome, "and in girth 163 feet 7 inches at the base, the mean thickness of the wall being about 14 feet." It is divided into four stories.

The vicinity of the town presents many objects worthy of attention. Close to its south-eastern side is the village of Monekton, so called from its having been the scite of an ancient priory, founded by William Marshall, about the year 1120, as a cell to the Benedictine abbey of St. Martin at Sayes, in Normandy. Part of the priory church is still entire, as is likewise the prior's mansion; but the other buildings are in a state of great decay. From the varied style of the church, it has evidently been erected at different periods. That portion of it which is now appropriated to public worship, is completely modernized within, and scarcely a vestige of its former ornaments remains. This structure has long been the burying-place of the Owens of Orielson, and probably also of their predecessors the Wyrriots, as some early monuments of the latter family still appear here.

The village of Castle-Martyn is situated about three miles to the westward of Pembroke. This place was formerly adorned with a magnificent castle, erected by some Norman chieftain of the name of Martyn, on the scite of an extensive British earthen-work. Few vestiges of that pile now remain, but they appear to have been pretty considerable in the time of Leland. Between this village and the county town is a furzy moor, called Dry-Burrow, which is covered with tumuli, similar to those on the downs of Wiltshire. Northwards from the moor stands Orielson, the seat of the Wyrriot and Owen families; and beyond it is the village of Pwllcrochon, memorable for a skirmish between the royal and parliamentary forces, in March 1648. In the church are several ancient monuments, in honour of the Benegers of Banjeston. In the adjoining parish of Rhôscrowther is Jestington, the residence of a branch of the royal family of Wales, previous to the conquest: it is now the property of the family of Meares. Further to the westward is the village of Nangle, which was formerly a place of very considerable consequence, and had a castle attached to it, some vestiges of which are still visible near the extreme point of the curved promontory, which forms the bay of Nangle.

Cresfely, the seat of John Allen, esq., is situated about two miles and a half to the west of Pembroke. The house occupies an elevated scite, overlooking the river Creswell. Beyond this, on the same road, stands Carew-castle, one of

the most conspicuous features of this county, and celebrated as the residence of characters of great distinction at different eras. It was a royal residence, and formed part of the dowry of Nesta, daughter of Rhys ap Tewdor, who married Gerald de Windfor, lieutenant to Henry I., after the outlawry of Arnulph de Montgomery. The descendants of this lady took the name of Carew, and continued to possess the castle till the reign of Henry VIII., when it reverted to the crown, and was granted to sir John Perrot. In the time of the great rebellion, it was garrisoned for the king, and withstood a long siege; but after the ill success of the royalists at Tenby, it surrendered upon quarter. Subsequent to that period it has been suffered to go to decay, and now constitutes a most magnificent and picturesque ruin. Its form is that of a quadrangle, with a court in the centre, and an immense bastion at each exterior angle. The architecture of this pile belongs to various ages, but a great part of it is undoubtedly coeval with the original structure. The north front is peculiarly grand and majestic, and can boast of windows "than which nothing more nobly magnificent is known in the kingdom." On the south-west side appear a number of old towers, all differing from each other in height, diameter, and form. On three sides this castle is bounded by water, but to the south was formerly a very extensive deer-park, the outer wall of which is yet apparent in many places, though it is divided into several distinct inclosures, in one of which sir Rhys ap Thomas held a tilt and tournament, which was the first show of the kind recorded to have been exhibited in Wales. Near this spot stands one of the early crosses, richly ornamented with true-love knots, &c. and having an inscription upon it, which, though often copied, and submitted to the examination of the curious, has never yet been accurately decyphered. The church here contains several ancient monuments, with effigies and inscriptions in memory of various members of the Carew family.

The other places of note situated in this part of the county are Lawrenny, the seat of Hugh Barlow, esq.; Upton, a castellated mansion, anciently the residence of the Malefants; and Lamphey, or Lansey-court, a noble ruin, once the favourite palace of the bishops of St. David's. A chapel, adjoining this palace, exhibits the remains of a very finished piece of masonry. Stackpool-court, the seat of lord Cawdor, also deserves mention. It is built on the scite of a former castellated structure, and is certainly one of the most splendid modern mansions in Wales. It has two fronts, and is surrounded by very extensive and well-wooded pleasure-grounds, which are further adorned by a beautiful lake, and most luxuriant gardens. The estuary of Stackpool being the only safe and commodious landing-place on this coast, it was much frequented by the predatory chieftains of ancient times, and particularly by earl Harold, some of whose successes are supposed to be commemorated by three large upright stones, which are fixed here at the distance of about a mile from each other. A Historical Tour through Pembrokeshire, by Richard Fenton, Esq., F.S.A., 4to., 1811. The Scenery, Antiquities, and Biography of South Wales, &c. by Benjamin Heath Ma'kin, Esq., M.A., F.S.A., 2d edit. 2 vols. 8vo, 1807. The Itinerary of Archbishop Baldwin through Wales, A.D. 1187, by Giraldus de Barri, translated, &c. by Sir Richard Colt Hoare, Bart., F.R.S., F.S.A., 2 vols. 4to., 1806.

PEMBROKE, a township of America, in Plymouth county, Massachusetts; 30 miles S. by E. from Boston; incorporated in 1752, and containing 1943 inhabitants. Some vessels have been built here.—Also, the *Suncook* of the Indians, a township of Rockingham county, New Hampshire,

on the east side of Merrimack river, opposite to Concord; incorporated in 1759, and containing 982 inhabitants.

PEMBROKESHIRE, or PEMBROCHSHIRE, one of the southern counties of Wales, is bounded on the south by the Bristol channel, on the west and north by St. George's channel, and on the north-east and east by the counties of Cardigan and Caermarthen. It is irregular in its form, and deeply intersected throughout its extensive coast by bays and havens. Its extreme length from north to south is about 35 miles, and its greatest breadth from east to west 29. According to the most accurate surveys, its superficial contents amount to 335,600 acres. According to the population report of 1811, this county is divided into the hundreds of Castle-Martyn, Dewisland, Dungleddy, Kemefs, Kilgerron, Narberth, and Roefe; and contains the city of St. David, and three towns, *i. e.* Pembroke, Haverford-west, and Tenby: it also comprises 142 parishes, and 3 hamlets. The number of houses is stated to be 13,024, inhabited by 60,615 persons, of whom 27,453 are males, and 33,162 females.

At a very remote period this county formed part of the kingdom of Demetia, or Dyvet, which subsisted as an independent monarchy till conquered by Ethelwolf, king of England. Broghmael, king of Demetia, is mentioned as one of the princes who assisted Cassibelanus in compelling Julius Cæsar to evacuate Britain. How far this ancient kingdom extended is uncertain; some supposing it to have comprised the three counties of Cardigan, Caermarthen, and Pembroke; and others, that it was confined to the last mentioned county only. In the time of the Danish incursions, this county suffered more injury than perhaps any other in the principality. Among the chieftains who commanded in these depredations were Hubba and Ivar, or Inguar, both of whom are described by the old writers as men of the "most dreadful ferocity and unheard-of courage."

The name of Pembrokeshire, or rather Pembrochshire, was first given to this county shortly after the Norman conquest, and was evidently derived from that of the town which forms the subject of a former article. This district is not unusually called by the old writers, and even vulgarly at the present day, *Little England beyond Wales*, from the circumstance of the inhabitants in the hundred of Rhos being descendants of Flemings and English, and its courts being formerly subject to the king's writs, as appears by several instances of removed pleas, as late as the reign of Henry VI. Concerning the settlement of the Anglo-Flemish colony here, considerable uncertainty prevails in the writings of historians; some asserting that the Flemings, who had previously settled in England, were driven out of that county by Henry I., and seized upon Rhos as depredators; but others, with more probability, contend, that they came hither under the sanction of the English prince. That they eventually obtained his protection is undoubted, for he placed among them a great number of his own subjects, to teach them the English language, and attach them to English interests. This object he seems to have fully succeeded in; for we find that the English inhabitants of Pembrokeshire were afterwards chief instruments in the subjugation of the remaining portions of Wales. Many attempts were made by the Welsh to extirpate them from the country, but the most determined efforts proved wholly unavailing. At Llandilovaur the decisive battle was fought between Edward I. and Llewellyn, which ensured the final conquest of Wales, and its annexation to the English crown.

In later times, Milford, a port in this county, is remark-

able as having been the landing-place of Henry, earl of Richmond, afterwards king Henry VII., when he came from Brittany to wrest the throne of England from the usurper, Richard III. During the era of the civil wars, in the reign of Charles I., several of its castles, particularly those of Pembroke and Roch, were garrisoned for the king, and withstood long and obstinate sieges in the royal cause. Some skirmishes likewise appear to have been fought within Pembrokeshire, at the same period, and with various success. Even so late as the year 1797, Fishguard is rendered memorable by the landing of a French force of 1400 men in its immediate vicinity; an event which created considerable alarm, but which was attended with trivial injury to the inhabitants. Upon the collection of a considerable body of military, the French general proposed to surrender, which he accordingly did the day subsequent to his landing.

The aspect of this county presents an almost continued succession of "swells, or easy slopes;" but there are no mountainous ridges, excepting one which runs from the coast near Fishguard, to the borders of Caermarthenshire. These hills are locally denominated "the mountains," and the inhabitants distinguish the country with reference to them; the north side being said to be above the mountains, and the south side below the mountains. The central portion of this ridge is known by the name of Percelly, and its highest summit by that of Cwmkerwyn: it commands a view over the whole county. Another high point is called Carn-Englie, as tradition says, from a giant who occupied it as his place of habitation. Vrenny-Vawr, or Vryn-Vawr, is also of considerable altitude and size, as its name imports; the words Vryn Vawr signifying in English the Great-hill. The climate of Pembrokeshire is temperate. Rains are perhaps more frequent here than in any part of England, and are particularly violent during westerly winds. Frosts are neither intense nor of long continuance; nor does snow usually lie upon the ground more than two or three days. Few counties are better watered with rivers, or are more abundantly supplied with excellent springs. The names of the chief rivers are the Cwch, which divides Pembrokeshire from Cardiganshire; the Nevern, which flows by Newport; the Gwain, which falls into the sea at Fishguard; the Taf, which forms the boundary with Caermarthenshire; and the East and West Cleddy, or Cleddaw. The two last unite near Picton-castle, and flow into Milford haven: they are influenced by the tide as high almost as the half of their whole course.

The mineralogical products of Pembrokeshire are coal, limestone, freestone, and that "species of marble called pudding-stone." No metallic ores, except iron, we believe, have yet been discovered here; at least none of any consequence in a commercial estimate. Some mineral springs, particularly one in the parish of Fishguard, however, are strongly tinged with that metal; and on the Trefin are several works of iron and tin. The soil is various, but in general tolerably fertile. The state of agriculture, however, is defective, and, though much improved within the last few years, it is still susceptible of great amelioration. The practice of grazing has been introduced, as well as a spirit of "farm monopoly." Woods are rather scarce in this county, particularly towards the western coast, where, being much exposed to the winds blowing from the sea, they are thorn in a very curious manner. Cattle are reared in considerable numbers, and a large quantity of butter is made, both for home consumption and for exportation.

Pembrokeshire cannot boast of being either a manufacturing or a trading county; though it possesses manifest advantages, for commerce at least, in its numerous natural
harbours

harbours and great extent of coast. Haverford-west is the only town within its limits which has a cotton manufactory of any consequence; and all the attempts hitherto made for the introduction of the linen business have completely failed. Milford and Fishguard alone can justly claim the appellation of trading ports, and even in these towns the exports and imports are extremely limited; but they are certainly susceptible of great augmentation, with a very little exertion and expence. Indeed we have no doubt, but that if the spirit of manufacturing and commercial enterprise was once properly excited and fostered, Pembroke-shire would, from its natural advantages of situation, soon become the trading emporium of Wales. At Milford has lately been established a South sea whale-fishery, which is in a flourishing condition; and we are happy to observe, that the same thing may be affirmed of the herring-fishery of Fishguard, though it might be improved to an almost unlimited extent.

Pembroke-shire abounds with objects of antiquarian curiosity and interest, of almost every kind and era. Druidical circles and cromlechs are frequent, of which the principal are those near Castle-Hendrev, Drewson, Trellys, Long-house, Lech-y-dribedd, Pentre-Evan, and Castle-Martyn. Single stone monuments are also numerous, particularly along the coast, where they are conjectured to have been raised as memorials of predatory battles. The great Roman road to Menapia, St. David's, enters the county near Llandewi-Velfry, and proceeds by Haverford-west and Roch-Castle, almost on the same line with the present turnpike-road from Caermarthen, which it crosses at different points. Another Roman road led from the great road to the station, called Ad-Vicissimum. But the most important antiquities are its castles, of which there are nineteen mentioned as belonging to princes and great barons. Some of the churches in this county are likewise objects worthy the attention of the antiquary. The cathedral and palace of St. David's are particularly entitled to attention. See *St. DAVID'S*; also Norris's *Archæological Antiquities of Wales*, 4to. Fenton's *Historical Tour in Pembroke-shire*, 4to, 1811. *Cambrian Register* for 1796. *Camden's Britannia*, vol. ii.

PEMIGEWASSET, a river of America, in New Hampshire; one branch of it proceeds from Mousie-hillock mountain, another from the south-west extremity of White mountains, and a third from the township of Franconia. Its course of about 50 miles is generally south, and it receives on both sides a number of streams. After the union of the Winipiscogee river, at the lower end of Sanborn town, it bears the name of Merrimack to the sea.

PEMNAGUR, a fort of Hindoostan, in Bahar; 31 miles N.W. of Durbungah. N. lat. 26° 29'. E. long. 85° 45'.

PEMPHIGUS, in *Medicine*, from $\pi\epsilon\mu\phi\iota\gamma\iota\varsigma$, *bullæ*, a *bleb* or *blain*, has been variously called the *vesicular fever*, *febris vesicularis*, *ampullosa*, and *bullosa*, by the continental physicians, who have mentioned the disease.

From the descriptions of a few of these writers, Sauvages constituted this disease a distinct genus, in his system of nosology, and gave it the appellation of pemphigus, which has been adopted by subsequent authors, with the exception of Linnæus, who designated it by the barbarous term *morta*, conceiving it to be a most mortal pestilence. "Febris diaria, malignissima, funestissima." (See his *Genera Morbor.*, class i. gen. 1.) Upon the authority of Sauvages, and the authors whom he quotes, the pemphigus has been defined an idiopathic, contagious, and malignant fever, in the course of which, phlyctænæ or vesications, of the size of a silbert, with an inflamed base, appear in succession on different parts of the surface of the body, and sometimes in

the mouth. See Sauvages, *Nofol. Method.*, class iii. gen. 3. Cullen, *Nofol. Meth.*, gen. xxxiv.

Nevertheless, it is pretty clear, from an examination of the imperfect histories of the subject, that there is no such idiopathic and contagious disease, terminating in a critical eruption of bullæ, as has been thus defined, under the appellation of pemphigus. Dr. Cullen justly expressed his doubts of the accuracy of the original writers; and, after giving his definition of the disease, he says, "From the opinion of others, rather than my own, this character is taken; because I have seldom seen such a disease, and never have observed it epidemical, or pursuing a regular course, as is here described." And in respect to the species, he observes again, "Since I have never seen a pemphigus, which I could consider as an exanthematous fever, and have found only very few observations in the writings of physicians concerning a disease of this kind, almost every thing inserted in my nosology must necessarily be taken from Sauvages; therefore, I have followed him, though I would willingly have omitted this malady, since almost all that has been said about it appears to me doubtful, obscure, and ambiguous."

Dr. Willan has examined the matter more minutely, and pointed out the fallacious foundation, upon which the notion of such an epidemic contagion has been built. Sauvages has enumerated three species of pemphigus, not from his own observation, but merely from the description of three writers. The first species, pemphigus major, which is taken from a single case, related by Scaliger, (*Ephem. Acad. Nat. Curios.* Dec. 1. ann. viii. obs. 56.) which is worthy of little attention, was perhaps, as Dr. Willan suggests, a mere erysipelas, with some incidental variation in the appearance of the bullæ. The account of the epidemic at Prague, mentioned by Thierry, (see his *Medicine Experimentale*, p. 134.) which is the prototype of the second species (pemphigus castrensis) of Sauvages, is not entitled to credit, as Dr. Cullen remarked, in several of its circumstances: the bullæ are supposed by Dr. Willan to have been symptomatic of severe typhus, or of pestilential fever, in the same manner as they appeared in the plague of 1666 in London, as described by Dr. Hodges, and as they are occasionally seen, intermixed with petechiæ and vibices, or with patches of erythema, in typhoid fevers. Again, as to the third species (pemphigus helveticus) of Sauvages, which was borrowed by him from the description of Dr. Langhans, (in the *Acta Helvetica*, vol. ii. p. 260.) Dr. Cullen was of opinion, that the disease was in fact *cyanche maligna*; and Dr. Frank viewed it in the same light; for he considered it as a variety of scarlatina, accompanied with ulceration. Dr. Willan, who points out the unsatisfactory nature of the history given by Langhans, and the contradictions which it involves, proposes a query, whether the disease was not rather *endemic*, than epidemic or contagious, and referrible to dearth, or some other local cause, like the *ergot*, *mal des ardens*, &c. See his *Treatise on Cutaneous Disorders*, part iv.; and *Bateman's Synopsis of Cutaneous Diseases*, p. 135.

In short, it is evident, that the description of an idiopathic contagious fever, terminating in a critical eruption of bullæ, after the manner of the small-pox, and other exanthematous fevers, which Sauvages and the nosologists have given us, has been founded in misconception; and that no such disease exists. Yet many cases of *bullous* disease have been recorded, under the appellation of pemphigus, by medical men of considerable discernment. Those who are curious, and disposed to investigate the matter, will find such cases described by Mr. Gaitskell and Mr. Upton, in the

the Memoirs of the Medical Society of London, vol. iv. art. 1, and vol. iii. Appendix; by Mr. Christie, in the Lond. Med. Journal, vol. x. p. 385; by Dr. Stewart, in the Edin. Med. Comment., vol. vi. p. 79; by Dr. Hall, in Duncan's Annals of Med., vol. iii. art. ix; by Mr. Ring, in the Lond. Med. Journal, vol. xi. p. 235; by Dr. Dickson, in the Trans. of the Royal Irish Acad. for 1787; and in the Lond. Med. Journ., vol. ix. p. 309; by Bang, in the Acta Reg. Soc. Med. Haerleensis, vol. i. p. 8, &c.; by Withers, in his Treatise on Asthma; and by Frank, De Curand. Hom. Morb., lib. iii. p. 263. The reader will find, however, that, in these cases, the eruption of *bullæ* has either been chronic, and altogether unconnected with fever; or it has occurred in connection with common fever, dysentery, &c. in which it was merely accidental and symptomatic, and by no means the result of any particular contagion, or indicative of a distinct and peculiar species of fever.

The more common eruptions of these water-blebs, or bullæ, is unconnected with any acute fever; and, for the sake of distinguishing them from this supposititious pemphigus, Dr. Willan arranged them under a new genus, POMPHOLYX; which see.

PEMPHINGODES, or PEMPHIGODES, from the same root with the preceding, was an epithet applied by the ancients to certain fevers, said to be distinguished by flatulencies and inflations, in which they supposed some aerial effluvia passed through the skin of the patient, and was sensible to the finger of a person applied to it. (Galen, Comment. on 6. Epidem., sect. 1. app. 17.) It is not easy to refer such a description to any known disease.

Foësius says, the febris pemphingodes was supposed to be a fynochus, in which the blood-vessels were inflated, and consequently it was called an inflated fever. Both the term and the absurd hypothesis have been long obsolete.

PEMPHIS, in Botany, so named by Forster, from $\rho\epsilon\mu\phi\iota\varsigma$, a globule, in allusion to the globular protuberance of the germen above the calyx, or of what, in Linnæan language, is the receptacle of the flower. Forst. Gen. t. 34. Juss. 331. Venten. v. 3. 299. (Lythrum; Lamarck Illustr. t. 408. f. 2.)—Class and order, *Dodecandria Monogynia*. Nat. Ord. *Calycanthemæ*, Linn. *Salicariæ*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, turbinate, permanent, striated, regular, with twelve teeth, the intermediate ones smallest. Cor. Petals six, obovate, obtuse, spreading, inserted by their claws into the throat of the calyx, at the base of each lesser segment. Stam. Filaments twelve, awl-shaped, shorter than the corolla, inserted into the middle of the calyx, the six alternate ones shortest; anthers ovate, two-lobed, incumbent. Pist. Germen globose; style short, cylindrical, erect; stigma capitate, depressed. Peric. Capsule turbinate, invested with the permanent calyx, of one cell, opening by a hemispherical deciduous lid. Seeds numerous, wedge-shaped, abrupt, compressed, with a fungous angular border. Receptacle central, short, triangular, muricated.

Ess. Ch. Calyx regular, with twelve teeth. Petals six, inserted into the calyx. Capsule of one cell, splitting horizontally. Seeds numerous, bordered.

Obs. This genus is essentially different from *Lythrum*, in having a capsule which bursts horizontally, and which consists of one cell instead of two. In an early state, we suspect, the germen has three cells. The hemispherical lid of the capsule is obscurely marked with six concentric lines, which, it seems, Forster mistook, in an unripe state perhaps, for six valves. We readily assent to the maxim of the younger Linnæus, Suppl. 25c, that a natural genus ought not to be divided on account of a single peculiarity in any

one species; but where the habit is so different, and the technical character so important, as in the present case, besides both being supported by several secondary distinctions, there can no longer be room for hesitation, though only a solitary species of *Pemphis* has hitherto been discovered.

1. *P. acidula*. Forst. Gen. 34. (Lythrum Pemphis; Linn. Suppl. 249. Forst. Prodr. 36. Mangium porcellanicum; Rumph. Amboin. v. 3. 126. t. 84.)—Rumphius mentions this as growing on the muddy shores of some parts of Amboyna, or its neighbourhood. The late Mr. Christopher Smith sent us specimens, gathered in April 1797, in flower and fruit, at Nufalout. Koenig's, in the Linnæan herbarium, were found on the sea coast of Ceylon. Forster obtained his in the island of Teautea.—The stem is shrubby, decumbent, with many hoary, rigid, leafy branches. Leaves crowded, opposite, on short stalks, obovate, entire, about an inch long, coriaceous or fleshy, silky on both sides, especially when young. Rumphius, whose figure represents them rather too much pointed, says they have an agreeable salt flavour, and are eaten raw as a sauce to some kinds of fish. The flowers are axillary, solitary, on simple stalks rather shorter than the leaves, silky, as well as the calyx, which is the size of a pea. The petals are wavy, and described by Koenig as of a pale blueish hue. Lamarck, in his t. 408. f. 2, gives a sufficiently good, and apparently original, representation, of the whole plant in flower. Rumphius exhibits it in fruit only. We have never seen a specimen from Forster, but there surely can be no doubt as to the identity of his plant.

PEMPTÆUS, a word used by medical writers, as the name of an ague, the fits of which return always on the fifth day.

PEN, according to Camden, originally signifies a high mountain, which was thus called among the ancient Britons, and even the Gauls. And hence, that tall range which parts Italy and France is called *Apennines*.

PEN is often used for a pound, or head of water, artificially kept up.

PEN is also a little instrument, usually formed of a quill, and serving to write with.

PENS, Dutch, are those made of quills which have been passed through hot ashes, to take off the grosser fat and moisture thereof.

PEN, Fountain. See FOUNTAIN-PEN.

PEN, Sea, pennatula, in Natural History, a genus of zoophyte, which, though it swims about freely in the sea, approaches near to the gorgonia. This genus hath a bone along the middle of the inside, which is its chief support; and this bone receives the supply of its osseous matter by the same polype mouths that furnish it with nourishment. Linnæus reckons seven species. See PENNATULA.

PEN Stock, a sort of sluice or flood-gate placed in the water of a mill-pond, or a canal, to retain or let it go at pleasure.

PEN Unglas, in Geography, a cape of South Wales, on the N. coast of the county of Pembroke. N. lat. $51^{\circ} 57'$. W. long. $4^{\circ} 59'$.

PEN Dinas, a cape of Wales, on the N. coast of St. Bride's bay. N. lat. $51^{\circ} 48'$. W. long. $5^{\circ} 10'$.

PENA. See PEENE.

PENA Cova. See PEGNA Cova.

PENA, JOHN, in Biography, an able French mathematician in the 16th century, was descended from a noble family at Aix in Provence, and born at Moustiers, in the diocese of Riez, about the year 1530. He distinguished himself in early life by his proficiency in the Latin and Greek languages, and philosophy; but the bent of his genius particularly

cularly directed him to the study of the mathematical sciences. About the year 1556, he was appointed professor of mathematics in the College Royal; and, according to some writers, his post was professorship-extraordinary, created out of compliment to his great merit, and suppressed after his death. He published a Latin version of the *Catoptrics* of Euclid, with a curious preface, explaining and illustrating the uses of the cylindrical mirror, the "Optics" of the same geometrician; "Euclid's *Elementa Musicae*; *Sectio Regulæ Harmonicæ*," in Greek and Latin; and a Latin version accompanying the Greek text of "The *Spherics* of Theodosius." He composed some papers on the "Mechanics of Hero," and the "Geometry of Euclid," which have not been published. This young mathematician was prematurely cut off by a violent fever in 1560, when only thirty years of age. Moreri.

PENAC, in *Geography*, a town of Naples, in Abruzzo Citra; nine miles E.S.E. of Civita Borella.

PENÆA, in *Botany*, received that appellation from Linnæus, in memory of the learned Peter Pena, a native of Jouques, near Aix, in Provence; who afforded great assistance to Lobel, in the composition of his *Adversaria*; not only by his general botanical learning, but by the communication of many rare plants of the south of France; see LOBEL. Plumier had already consecrated a plant to his honour, which Linnæus reduced to POLYGALA; see that article.—Linn. Gen. 56. Schreb. 76. Willd. Sp. Pl. v. 1. 626. Mart. Mill. Dict. v. 3. Thunb. Prodr. 30. Ait. Hort. Kew. ed. 2. v. 1. 248. Juss. 419. Lamarck Illustr. t. 78.—Class and order, *Tetrandria Monogynia*. Nat. Ord. uncertain.

Gen. Ch. Cal. Perianth inferior, of two equal, opposite, lanceolate, concave, coloured, lax, deciduous leaves, half the length of the corolla. Cor. of one petal, bell-shaped; limb in four acute spreading segments, very much shorter than the tube. Stam. Filaments four, extremely short, erect, naked, inserted into the corolla between its segments; anthers erect, flattish, notched at each end. Pist. Germen superior, ovate, quadrangular; style with four membranous, dilated, longitudinal angles; stigma cruciform, obtuse, permanent. Peric. Capsule quadrangular, crowned with the style, of four cells and four valves. Seeds in pairs, rather oblong, obtuse.

Efl. Ch. Calyx of two leaves, inferior. Corolla bell-shaped, of one petal. Style quadrangular. Capsule square, of four cells, with eight seeds.

The species of this genus are singularly confounded by Linnæus. We shall attempt, by the help of his own specimens, to reduce their characters and synonyms to order. They are all natives of the Cape of Good Hope, or the adjacent regions of southern Africa. Their habit is shrubby. Leaves crowded, opposite, nearly or quite sessile, rather fleshy, undivided, entire, in almost every instance perfectly smooth. Flowers terminal or axillary, solitary or aggregate, generally handsome, red, white, or yellow. Nobody has settled the natural order of *Penæa*, nor have we a conjecture to offer on the subject. Jussieu merely hints at its possible affinity to his *Acanthi*, which we see little to countenance. Its habit, but not its characters, bears some resemblance to *Boronia*, Sm. Tracts, one of the *Rutaceæ*.

1. *P. Sarcocolla*. Linn. Sp. Pl. 162. Berg. Cap. 35. (*P. fucata* Linn. Mant. 199. Lamarck f. 1. Willd. n. 6. P. n. 48; Linn. Mat. Med. 16, character and synonym erroneous. *P. mucronata*; Berg. Mat. Med. v. 1. 68? *Tithymali myrsinites* species, arbuscula æthiopica, subrotundis foliis, e stoechadis arabicæ squamato capitulo duro lachrymam fundens; Pluk. Mant. 183. t. 446. f. 6.)—Leaves

ovate, somewhat rhomboid, acute. Bractæas wedge-shaped, pointed, coloured. Calyx-leaves linear.—Native of hills at the Cape. A humble, much-branched, bushy shrub. Leaves about half an inch long, of a pale tawny glaucous hue in the dried plant, their mid-rib rather convex. Flowers few together, at the tops of the branches, rather longer than the leaves. Bractæas but half the size of the leaves, entire, smooth, red, as well as the calyx. Segments of the corolla rounded, obtuse, slightly spreading. There is no appearance of gum about the flowers, and whether this, or any other species of *Penæa*, really yields the gum-resin called, from its reputed healing or conglutinating virtues, *Sarcocolla*, or flesh-glue, appears to be very doubtful and very unimportant. Modern surgery disclaims such aids, and has long ceased to confide in them.—Plukenet's imperfect figure is evidently done from this species, though his definition rather points at *squamosa* hereafter mentioned.

2. *P. mucronata*. Linn. Sp. Pl. 162. Berg. Cap. 37. Willd. n. 2. Ait. n. 1. Vent. Malmaif. t. 87. (*Tithymali myrsinites* species, arbuscula æthiopica, folio parvo e lato basi in acutissimum mucronem subito desinente, capitulis origani; Pluk. Mant. 183.)—Leaves heart-shaped, pointed, horizontal. Flowers in dense terminal spikes. Bractæas somewhat lunate, pointed.—The numerous, small, horizontal leaves, crossing each other in pairs, and the copious dense spikes of yellow flowers, whose corolla is not very unlike in size and figure to *Arbutus Unedo*, characterize this species. Plukenet's comparison of the beads to *Origanum* is strikingly opposite, as to the dried plant. Linnæus, in Syft. Veg. says the flowers are red, having been misled perhaps by the dried specimen. This species was sent to Kew by Mr. Masson in 1787, but has not flowered there.

3. *P. marginata*. Linn. Mant. 199. Willd. n. 3.—Leaves heart-shaped, rather concave, thick-edged, shining. Flowers lateral, axillary.—Found near rivers at the Cape. The branches are straight and wand-like, often ternate. Leaves three quarters of an inch long; dark green and shining above; paler and yellowish beneath, resembling some kind of *Celastrus* or *Buxus*; their edges remarkably thickened. Flowers not quite so long as the leaves, sessile, reddish in the dry state, but Linnæus says they are white.

4. *P. lateriflora*. Linn. Suppl. 122. Willd. n. 4.—Leaves ovate, flattish, opaque. Flowers lateral, axillary. Very distinct from the last, notwithstanding the doubt expressed by Willdenow. The leaves are rather larger, not heart-shaped, nor thickened at the edges. Flowers also larger, extending a little beyond their corresponding leaves.

5. *P. tomentosa*. Thunb. Prodr. 30. Willd. n. 5.—"Flowers lateral. Leaves ovate, downy."—Of this we have seen no specimen, but the downy leaves are peculiar to it.

6. *P. squamosa*. Linn. Mant. 331. Willd. n. 7. Linn. Sp. Pl. 162? the observation at the end certainly misapplied. (*P. Sarcocolla*; Willd. n. 1. Lamarck f. 2. *P. tetragona*; Berg. Cap. 36.)—Leaves obovate, somewhat wedge-shaped, fleshy. Bractæas fringed, glutinous, larger than the leaves. Segments of the corolla reflexed.—Distinguished by its large terminal flowers, enveloped in dark red, glutinous, broad, densely fringed bractæas. The leaves most resemble the first species, but their mid-rib is depressed, not prominent, and their colour in a dried state very dark. Linnæus at first marked his specimen *Sarcocolla*, then *resinosa*, and finally *squamosa*, under which last appellation he described this fine plant. It may, perhaps, yield a gum, as well as the first species. The corolla seems to be white or yellowish; its tube is above an inch long; the segments of the limb

ovate,

ovate, obtuse, reflexed. Lamarck's figure is much diminished as to the parts of fructification.

7. *P. fruticulosa*. Linn. Suppl. 121. Willd. n. 8.—Leaves obovate, obtuse. Flowers capitate, terminal. Tube of the corolla ovate; segments acute, erect.—Gathered by Sparrmann at the Cape. A dwarf bushy shrub, with leaves hardly half an inch long. Flowers most like those of *P. mucronata*, but much fewer together, and their corolla has a shorter tube, with a longer limb. The bractæ are said in the specific character to be orbicular and acute, but in the description to be wanting. The former is most near the truth, but they are ovate, acute, and fringed.

8. *P. myrtilloides*. Linn. Suppl. 122. Willd. n. 9.—(*P. myrtilloides*; Thunb. Prodr. 30.)—Leaves ovato-lanceolate, acute, many-ribbed. Flowers terminal. The myrtle-like leaves, (not at all like those of *Vaccinium Myrtillus*.) form the characteristic mark of this species. They are very green in the dried specimen, numerous, crowded, erect, not quite an inch long, marked with one prominent central rib, and several lateral ones. The flowers are terminal. Our specimen will not allow us to determine much of their structure, but Linnæus says they are “nearly solitary, surrounded with green acute bractæ, under which are two small leaves; the calyx acute, green, by no means coloured.”—Such is his *Penæa myrtilloides*; but its silky inner bark, and whole aspect, indicate a very different family of plants, the *Daphne* tribe, to which we have no doubt this species belongs. Indeed it comes so near to *Guidea oppositifolia*, we are almost persuaded of its being that very plant, with rather more luxuriant foliage than usual. S.

PENAL ACTION. See ACTION.

PENAL Statutes. See STATUTES.

PENALTIES NEGATIVE. See NEGATIVE.

PENALVA, in *Geography*, a town of Portugal, in the province of Beira; nine miles N. of Coimbra.

PENAMOUSHILY, a town of Hindoostan, in the circar of Rajamundry; 42 miles E. of Rajamundry.

PENANCE, PÆNITENTIA, is properly the exercise of penitence; and may be defined a punishment, either voluntary, or imposed by legal authority, for the faults a person has committed.

The Romanists define penitence, a sacrament wherein a person, who has the requisite dispositions, receives absolution at the hand of the priest, of all sins committed since baptism.

To a legitimate penance they require three things, contrition, absolution, and satisfaction.

Their priests receive a power of administering the sacrament of penance, when they receive the priesthood; but to exercise this power, it is required they have the jurisdiction of an ordinary, *i. e.* that they have a benefice, either original or delegated; with the approbation of the bishop to hear confessions. See POKERY.

PENANCE is particularly used in the Romish church, for the penalty which a confessor imposes, for the satisfaction of the sins of which a person is absolved.

The ancient discipline, Du Pin observes, was very severe on the head of penance: for great crimes people were excluded the communion of the church, expelled the assemblies of the faithful, obliged to fast, and to mortify themselves publicly, even at the church-door, cut their hair, go always on foot, &c.

He adds, that those who had done public penance were never admitted into the clergy; and that public penance was never granted more than once. Those, who fell a second time, were never to be reconciled to the church, and were to look for pardon only at the hands of God.

VOL. XXVI.

PENANCE, in our *Common Law*, is an ecclesiastical punishment, used in the discipline of the church, and affecting the body of the penitent; by which he is obliged to give a public satisfaction to the church, for the scandal he hath given by his evil example. In the case of incest, or incontinency, the offender is usually enjoined to do a public penance in the cathedral, or parish church, or public market, barelegged and bareheaded in a white sheet, and to make an open confession of his crime in a prescribed form of words, which is augmented or moderated according to the quality of the fault, and the discretion of the judge. So in smaller faults and scandals, a public satisfaction or penance, as the judge shall decree, is to be made before the minister, churchwardens, or some of the parishioners, respect being had to the quality of the offence, and circumstances of the fact, as in the case of defamation or laying violent hands on a minister or the like. And as these censures may be moderated by the judge's discretion, according to the nature of the offence: so also they may be totally altered by a commutation of penance: and this hath been the ancient privilege of the ecclesiastical judge to admit that an oblation of a sum of money for pious uses shall be accepted in satisfaction of public penance. But penance must be first enjoined, before there can be a commutation; or otherwise it is a commutation for nothing. Linwood and other canonists mention three sorts of penance; *viz.* private, enjoined by any priest in hearing confession; public, enjoined by the priest for any notorious crime, either with or without the bishop's licence according to the custom of the country; and solemn, the particulars of which are prescribed by the constitution of archbishop Peckham. By the statute of “Circumspecte agatis” (13 Edw. I. stat. 4.) the king to his judges sendeth greeting: use yourselves circumspectly concerning the bishops and their clergy, not punishing them if they hold plea in court christian of such things as be mere spiritual, that is to acts of penance enjoined by prelates for deadly sin, as fornication, adultery, and such like; for the which sometimes corporal penance, and sometimes pecuniary is enjoined (2 Roll. Rep. 384.); in which cases the spiritual judge shall have power to take knowledge, notwithstanding the king's prohibitions. By the statute of “Articuli cleri,” (9 Edw. II. stat. 1. c. 2.), if a prelate enjoins a penance pecuniary to a man for his offence, and it be demanded; the king's prohibition shall hold place; but if prelates enjoin a penance corporal, and they which be so punished will redeem upon their own accord such penance by money; if money be demanded before a spiritual judge, the king's prohibition shall hold no place. And by the same statute (c. 3.), if any lay violent hands on a clerk, the amends for the peace broken shall be before the king, and for the excommunication before a prelate, that corporal penance may be enjoined; which if the offender will redeem of his own good will, by giving money to the prelate, or to the party grieved, it shall be required before the prelate, and the king's prohibition shall not lie.

PENAT, in *Geography*, a town of Hindoostan; 30 miles S.S.E. of Agra.

PENATES, in the *Ancient Mythology*, a term applied to all the domestic gods, whom the ancients adored in their houses: whence they are ordinarily confounded with the lares. See LARES.

Authors are not all agreed about the origin of the dii penates, who were properly the tutelary gods of the Trojans, and were only adopted by the Romans, who gave them the title of penates.

De Meziriac, in his notes on Dido's Epistle to Æneas, relates at large what he has met with in the ancient writers

on the subject: Dionysius Halicarnassus tells us, that Æneas first lodged these gods in the city Lavinium; and that his son Ascanius, afterwards, upon building the city Alba, translated them thither; but that they returned twice miraculously to Lavinium. The same author adds, that in Rome there is still seen a dark temple, shaded by the adjacent buildings, wherein are the images of the Trojan gods, with the inscription, DENAS, which signifies penates. These were the public penates of the city and empire, and their temple was near the circus Maximus. A light was continually burning before them, and libations and incense were offered upon almost all occasions. Lucan observes, that in time of peace, the Romans used to hang up their arms, in the place belonging to their household gods, as intrusting them to their custody; and that it was esteemed an abominable sacrilege to commit murder in the presence of Vesta, that is, in the entry, and before the perpetual fire of the household gods.

The images above-mentioned represent two young men sitting, each of which holds a lance. I have seen, adds Dionysius, several other statues of the same gods in ancient temples; who all appear like young men dressed in habits of war.

Varro fetches these penates from Samothrace to Phrygia, to be afterwards transported by Æneas into Italy. Macrobius, who relates this from Varro, adds also, that they were called penates, from the Latin words *per quos penitus spiramus*, which seems a mere subtilty. But the real etymology must be sought in the Phrygian, not the Latin tongue.

Cicero, in Aulus Gellius, derives the name hence, *quod penes nos nati sunt*. Yet in his book de Nat. Deor. he says, it is formed from *penus*, provision: or, perhaps, adds he, *quod penitus insident*; others say, *quia coluntur in penetralibus*.

Rosinus distinguishes among the penates: he makes an order of penates of the heavens, such as Pallas in the ethereal region, Jupiter in the middle region, and Juno in the lowest; besides penates of cities, penates of private families, &c. On which footing the *dii penates* were the guardians or tutelary gods of every thing.

Nigidius, an ancient author cited by Arnobius (Adv. Gent.) distinguishes four sorts of penates: those of the class of Jupiter, or chosen from among the celestial gods: those of Neptune, from the sea-gods: those of Pluto's class from among the infernal gods: and those taken indifferently from the class of all the deified men.

It is a popular question among the learned, who were the penates of Rome? Some say, Vesta; others Neptune and Apollo; Vives says, Castor and Pollux; with whom agrees Vossius, who adds, that the reason of their choosing Castor and Pollux in quality of penates, might be the important service they did the Romans in the war against the Latins.

Nor are authors more unanimous on the subject of the penates which Æneas brought into Italy. Some say they were Neptune and Apollo, who built the walls of Troy; others, Jupiter, Juno, and Minerva; and others Cælus and Terra.

Dionysius Halicarnassus, lib. i. speaking of the *dii penates*, tells us, that the historian Timæus has written, that the figure, statue, or effigy of the denates, or penates, was nothing but a crooked iron, or copper rod, and a Trojan vessel from potters' ware: and that this was all Æneas brought to Troy. But, for himself, he assures us, he had seen a temple at Rome, near the forum, where those gods were represented sitting, under the form of two young men, having each of them a dart in his hand: he adds, that the inscription was

DENATES, for that the ancients, before the invention of the letter P, used a D instead of it: But Dionysius might be mistaken: for the bottom of the P is frequently so very small on medals, that there is no sensible difference between a P and a D; which might be the case in the inscription that author mentions; for that the ancient inhabitants of Italy had no P, is a mistake sufficiently refuted by many proper names still remaining of the most early ages, *e. gr.* Capys, Capetus, Picus, Pallas. Nor were the Trojans without the same, witness Palinurus, Paris, Priamus, &c.

The penates seem to have originated in a vulgar opinion which prevailed very generally amongst mankind, that the manes of their ancestors took pleasure after death to dwell in their houses, where indeed they were frequently interred, and where their pictures used to be preserved in the places that were most respected. After having been accustomed to consider them under the character of illustrious persons, they by degrees paid them respect and homage, they then implored their assistance, and lastly they succeeded to the worship and religious ceremonies. The penates were therefore the manes of their ancestors, which St. Augustine (de Civ. Dei. l. ix. c. 11.) maintains, on the authority of Apuleius and Photinus; and in process of time they were associated with all the other gods without distinction.

The statues of these gods were made not only of wax, as some authors pretend, but indifferently of all sorts of materials, even of silver itself: they were consecrated in the most secret places; altars were erected to them, lamps kept burning, and symbols added, all of them expressive of vigilance. Anciently children were offered to them in sacrifice, but Brutus, who expelled the Tarquins, discontinued this barbarous practice, and from that time nothing was offered to them but wine, incense, fruits, and sometimes bloody victims, lambs, sheep, &c.: their statues were likewise crowned with festoons of garlic and poppy. In the public sacrifices offered to the penates, they sacrificed to them a fow. It was in the time of the Saturnalia, that they celebrated the festival of the lares and penates, and there was a day besides in each month set apart for the worship of these domestic gods. At the temple consecrated to these gods in Rome, there was set apart for them a holiday, which was observed with much solemnity; and this was the second of the kalends of January, or the last day of December. To this were added the games called "Compitales." Indeed, the respect paid to the penates was so great that no important enterprise was undertaken without consulting them: their figures were even sometimes carried about in journies, as we learn from Apuleius: "Wherever I go," says he, "I always carry with me in my journey the figure of some god."

The figure of the gods penates was sometimes the single representation of some god, genius, hero, or demi-god, or lastly of some famous ancestor: frequently they were pantheons, that is such as were charged with the symbols of several divinities. It is probable that some of the penates delivered oracles.

Authors have conjectured, that the idols which Jacob brought from the house of Laban his father-in-law, and which the scripture denominates "theraphim," were gods penates, whose worship was propagated afterwards into Phrygia, and transmitted from thence into Greece and Italy. This, it is confidently asserted, was their true original.

PENATOLEN, in *Geography*, a town of Chili; 20 miles E. of St. Yago de la Nueva Estamadura.

PENATOOR, a town of Hindoostan, in the Carnatic; eight miles W. of Gingee.

PENBRAY, a cape on the S. coast of Wales, in the British channel; 3 miles S. of Kidwelly.

PENBUGHTOE HEAD, a cape of South Wales, on the N. coast of the county of Pembroke. N. lat. $51^{\circ} 56'$. W. long. $5^{\circ} 5'$.

PENCARROW, a cape in the English channel, on the S. coast of Cornwall; two miles E. from the river Fowey.

PENCE, PETER-PENCE. See *PETER-pence*.

PENCE, Pitching. See *PITCHING-pence*.

PENCIL, from *peniculus, penicillus, or penicillum*, which signify the same, formed by diminution of *penis*, an instrument used by painters for the application of their colours. There are pencils of various kinds, and made of various matters: the most usual are of badgers' and squirrels' hair, those of swans' down, and those of boars' bristles; which last are bound to a stick bigger, or less, according to the uses they are defined for; and when large, are called *brushes*. The others are inclosed in the barrel of a quill. The ancients, M. Felibien observes, had pencils made of little pieces of sponge; whence, doubtless, the story of the painter, who, not able to express the foam of a horse, succeeded by throwing the sponge at the picture.

PENCIL, Black-lead. See *BLACK-LEAD*.

PENCIL-CASE. See *PORT-CRAJON*.

PENCIL, in Electricity. See *BRUSH, and ELECTRICITY*.

PENCIL of Rays, in Optics, is a double cone, or pyramid of rays, joined together at the base; one of which hath its vertex in some part of the object, and has the crystalline humour, or the glass GLS (*Plate XVII. Optics, fig. 10.*) for its base; and the other has its base in the same glass, or crystalline, but its vertex in the point of convergence; as at C.

Thus BGSC is a pencil of rays; and the line BLC is called the axis of that pencil.

PENCIL, in Ancient Armour, a small streamer fixed to the end of a lance, and adorned with the coat-armour of the esquire, by whom it was carried, and which served to point him out in the day of battle.

PENCK, in *Geography*, a town of Germany, in the principality of Culmbach; 4 miles N.E. of Bayreuth.

PENCKUM, a town of Anterior Pomerania; 13 miles S.W. of Old Stettin. N. lat. $53^{\circ} 15'$. E. long. $14^{\circ} 20'$.

PENDANT, EAR-RING, an ornament of gold, or some precious stone, worn by the ladies; hung by a hole made for that purpose through the ear; and frequently enriched with diamonds, pearls, and other precious stones.

The pendants of the European ladies are nothing in comparison of those worn by the East Indians, both men and women; among whom it is the fashion to lengthen out the ears, and to enlarge the hole, by putting in pendants of the size of saucers, set with stones.

In the West Indies, Columbus named a certain coast Oreja, because he found people with holes in their ears big enough to pass an egg through.

They make holes too in their lips and nostrils, and hang pendants at them: which is also practised by the Mexicans, and other nations.

PENDANT, in Heraldry, a term applied to the parts hanging down from the label, to the number of three, four, five, or six at most. These must be specified in blazoning, when there are more than three. They resemble the drops at the bottom of the triglyphs in the Doric frieze.

PENDANT Barometer. See *BAROMETER*.

PENDANT Capital, a mass of sculptured stone, or other material, in the form of the capital of a column, with ribs and

arches springing from it, which seems to support the general vaulting, but which, in fact, being destitute of a supporting column, is inserted into and hangs from that vaulting. This piece of mechanism belongs to the third order of pointed architecture, and may be seen to advantage in the chapel of King's college, Cambridge, Henry VIIIth's chapel, Westminster, &c. See *GOTHIC Architecture*.

PENDANT Feathers, in Falconry, are those feathers which grow behind the thighs of a hawk.

PENDANT Gardens, in Antiquity. See *PENSILES Horti*.

PENDANTS, among Florists, a kind of globules, growing on stamina, or chives. Such are those in the middle of tulips, lilies, &c. See *APICES, and STAMINA*.

PENDANTS of a Ship, are those long colours, or streamers, cut pointing towards the end, and there divided into two parts; hung out at the head of masts, or at the yard arm ends.

The pendants are chiefly used for show, though sometimes for distinction of squadrons, and for signals.

PENDANTS, (Rigging,) large, but short, ropes which go over the mast-heads with a splice, the ends hanging downwards, having an iron thimble, into which are hooked the main and fore-tackles. There are many other pendants, which are generally single or double ropes, with a block, or an iron thimble, spliced into their lower ends for tackles, all of which serve to transmit the effort of their tackles to some distant object: such are the bill-pendant, brace-pendants, preventer-brace-pendants, burton-pendants, fish-pendants, guy-pendants, main-stay-tackle-pendant, pendants of tackles, quarter-tackle-pendants, reef-tackle-pendants, rudder-pendants, stay-tackle-pendants, top-rope-pendants, truss-pendants, vang-pendants, winding-tackle-pendants, and yard tackle-pendants.

PENDARRYE, in Geography, a town of Hindoostan, in Oude; 17 miles N.W. of Kairabad.

PENDARTY, a town of Hindoostan, in the Carnatic; eight miles E. of Ongole.

PENDENNIS CASTLE, a fortress of England, in the county of Cornwall, situated at the mouth of Falmouth haven, built by Henry VIII., and fortified by queen Elizabeth. N. lat. $50^{\circ} 9'$. W. long. $5^{\circ} 1'$.

PENDENTIVE, in Architecture, the whole body of a vault, suspended out of the perpendicular of the walls, and bearing against the arc boutants.

Daviler defines it, a portion of a vault between the arches of a dome, usually enriched with sculpture: Felibien, the plane of the vault contained between the double arches, the forming arches, and the ogives.

The pendentives are usually of brick, or soft stone; and care must be taken, that the joints of the masonry be always laid level, and in right lines proceeding from the sweep whence the rise is taken.

The joints too must be made as small as possible, to save the necessity of filling them up with slips of wood, or of using much mortar.

PENDILHO, in Geography, a town of Portugal, in the province of Beira; 12 miles S.E. of Lamego.

PENDLETON, a township of Lancashire; 2 miles W. of Manchester.

PENDLETON, a county of Virginia, in America, bounded N.W. by Randolph, and S. by Rockingham, counties; watered by the S. branch of the Patowmack. It contains 3654 free inhabitants, and 124 slaves. Its chief town is Frankford.—Also, a district of South Carolina, on the Keowee and Savannah rivers; containing 20,050 inhabitants, of whom 2204 are slaves; 52 miles W. of Cambridge.—

Also, a county of Kentucky, containing 1573 people, of whom 239 are slaves.

PENDOUN, a town of Birmah; 12 miles S. of Raynangong.

PENDULOUS, *Hanging down*; a name which *Botanists* give to those heads of flowers which hang downwards; the stalk not being able to sustain them upright.

PENDULOUS *Roots*, such as are fixed to the ends of fibres, whence they seem to hang.

PENDULUM, in *Dynamics*, is a simple ponderous body, so suspended by a flexible cord from an axis of suspension, that it is at liberty to vibrate by the action of its own gravity alone, when it is once raised, by any external force, to the right or left of its quiescent position; and in demonstrating the theory of its motion, mathematicians are obliged to assume, that there is no rigidity in the cord; no friction at the axis of suspension; no resistance to motion opposed by the air; and no variation in the total length of the cord, arising from the variable temperature or moisture of the atmosphere; and if these assumptions were strictly correct, a pendulum, once put into motion, would continue to move *ad infinitum*, without the further accession of any external force; but when the pendulum is applied as the regulator of a clock, for which purpose it is admirably adapted, the assumptions we have named require an equal number of mechanical corrections, of which the theory, simply considered, takes no notice. In *Horology*, therefore, the pendulum must be considered, not simply as a self-moving pendulous body, without any tendency to come to a state of rest, or to have its dimensions altered by the circumstances in which it is placed; but as a body, whose motion is perpetuated by repeated accessions of force, in aid of its own gravity, and whose vibrations are rendered isochronal by a nice adaptation of mechanical contrivances, that prevent or remedy the prejudicial influences of all natural impediments to uniform and uninterrupted motion. It seemed necessary, in the first place, to establish the distinction that thus exists between the free or *detached* and *attached* pendulum; and having done this, which we must beg the reader to bear in mind, we propose to divide our article into three heads, namely, 1st, the history of the pendulum; 2dly, its theory in its *detached* state; and 3dly, its various constructions, when used in its *attached* state, as the regulator of an horological machine.

1. We have already given an historical account, under our article CLOCK, (see *History of the successive Improvements in Clocks*), of the first notice that was taken by Galileo of the vibrations of bodies suspended by long chains, and also of the application that was made soon after, by various persons, of the isochronal property of the detached pendulum, particularly in astronomy, as well as of its introduction, in its attached state, into horological machines as a regulator of their motions, after the balance had been applied for the same purpose: we beg leave, therefore, to refer the reader to the article already named, for the particulars that would have fallen under this head, had not this part of the subject been anticipated.

2. The second head of this article which we proposed to consider, was the theory of the simple pendulum vibrating in its detached state. When Galileo discovered that ponderous bodies, whether large or small, suspended by cords of equal length, perform their vibrations apparently in equal times, he was led into the contemplation of the laws of uniformly accelerated motion, produced by the constant force of gravity, and soon found that the theory of the detached pendulum was derivable from the same laws by

which bodies, left to descend in free space, were found to be accelerated, and that gravity was the sole cause of such acceleration. We have already treated of these laws at some length, under our articles ACCELERATION, DESCENT, and MOTION, which render unnecessary a repetition of this part of our subject, except so far as the vibration of the pendulum is concerned. It was, however, soon perceived, that a pendulum, vibrating in long arcs of a circle, requires a somewhat longer time for the performance of each of those vibrations, than when it vibrates in small arcs, all other circumstances remaining the same; it thence became a question among mathematicians what the nature of that curve might be, in which, substituted for the arc of a circle, both long and short vibrations would be performed in the same time. Though Galileo is acknowledged to have been the first who discovered and described the curve first called by him the cycloid, yet it remained for the celebrated Huygens to explain not only the isochronal property peculiar to this curve, but also that the involute of a cycloid is itself a cycloid, which latter discovery enabled him to make the attached pendulum actually vibrate in a cycloidal curve. Under our article CYCLOID we have given at considerable length both the geometrical and mechanical properties of this remarkable curve, which we recommend to the reader's notice, as preparatory to our doctrine of vibrations performed in cycloidal, and also in circular curves; for he will there see that short arcs of vibration, at each side of the lowest or quiescent point of the curve, are very nearly sinular, both as to coincidence in position, and also to the consequent isochronal property. He will see, not only that arcs of all lengths, when cycloidal, are performed in equal times, but that small circular arcs approximate so nearly to their correspondents in the cycloid, that they may be substituted in practice for each other, the former for the latter, without sensible deviation.

Prefuming, now, that our reader has made himself acquainted with the laws of uniformly accelerated motion, agreeably to our references, and that he has perused with attention also the article CYCLOID, we will proceed to lay before him the fluxional method of determining the actual times of a detached vibration both in *cycloidal* and in *circular arcs*. This part of our subject has been recently treated so ably by professor Bridge of the East India college, that we beg leave to avail ourselves of his labours, at the same time that we recommend to general notice his "Introduction to the Study of the Mathematical Principles of Natural Philosophy, 1813."

On the Times of Vibration in Cycloidal Arcs.—In *fig. 1. of Plate XXXIX. of Horology*, "let A V B be a cycloid, in which a body, P, suspended from the point S, performs its vibrations between the two *semi-cycloids* S A, S B, and let it begin its vibrations from the point E; also let P ρ be any very small arc, described in the descent from E to the lowest point V; draw E F, P N, ρn , parallel to the base, A B, of the cycloid, and join C M, C m, M V, m v. Let C V, the diameter of the generating circle, = d , F V = a , N V = x ; then F N = $a - x$, M V = $\sqrt{C V \times N V} = \sqrt{d x}$. Now the cycloidal arc P V being = twice the chord M V = $2 \sqrt{d x}$; let E P = z , then E V = $z + P V$; and since E V is a constant quantity, $z + P V = o, \therefore$

$z = -$ the fluxion of P V = $-\frac{\sqrt{d \cdot \dot{x}}}{\sqrt{x}}$. The velocity down E P (v) = the velocity down F N = $\sqrt{4 m \times F N} = \sqrt{\quad}$

PENDULUM.

$= \sqrt{4m \cdot a - x}$; if therefore $t =$ the time down EP, we shall have $i = \frac{\dot{z}}{v} = \frac{\sqrt{d \cdot \dot{x}}}{\sqrt{x}} \times \frac{1}{\sqrt{4m \cdot a - x}} = -\sqrt{\frac{d}{4m}} \times \sqrt{\frac{x}{ax - x^2}}$; and $t = -\sqrt{\frac{d}{4m}} \times$ circular arc, rad. $= 1$, ver. fin. $\frac{x}{\frac{1}{2}a} + \text{cor.}$; but when $t = 0$, $x = a$, $\therefore 0 = -\sqrt{\frac{d}{4m}} \times \text{cir. arc, rad.} = 1$, ver. fin. $= 2$, + cor. $= -\sqrt{\frac{d}{4m}} \times \text{femicircle, rad.} = 1$, + cor. $=$ (if $\pi = 3.1416$, &c.) $-\sqrt{\frac{d}{4m}} \times \pi + C$, or $C = \sqrt{\frac{d}{4m}} \times \pi$.

The fluent properly corrected therefore is $t = \sqrt{\frac{d}{4m}} \times \pi - \text{cir. arc, radius } 1$, verfed sine $\frac{x}{\frac{1}{2}a} =$ (when $x = 0$) $\sqrt{\frac{d}{4m}} \times \pi =$ the time of descent through the cycloidal arc EV; consequently the whole time of vibration $= \sqrt{\frac{d}{4m}} \times 2\pi = \sqrt{\frac{d}{m}} \times \pi$. Since the quantity a does not enter into this value of t , it is evident that the times of vibration will be the same, from whatever point of the cycloid the body P begins to vibrate. Moreover, since the time down the axis CV $= \sqrt{\frac{d}{m}}$, we have the time of a vibration : the time down the axis :: $\sqrt{\frac{d}{m}} \times \pi : \sqrt{\frac{d}{m}} :: \pi : 1$:: the circumference of a circle : its diameter; which conclusion coincides with our former determination under the article CYCLOID.

On the Times of Vibration in circular Arcs.—In fig. 2. of the same plate, “let the small body P, vibrating in the circular arc EVG, begin its vibrations from the point E; let PV = z , NV = x , FV = a , Pp = \dot{z} , SP or SV = r , then $\dot{z} = \frac{r \dot{x}}{\sqrt{2rx - x^2}}$. Let $t =$ the time through EP, $v =$ the velocity in the point P, then $v = \sqrt{4m \times FN} = \sqrt{4m \cdot a - x}$, and $t = \frac{-\dot{z}}{v} = \frac{-r \dot{x}}{\sqrt{2rx - x^2}} \times \frac{1}{\sqrt{4m \cdot a - x}} = -\frac{r}{\sqrt{4m}} \times \frac{\dot{x}}{\sqrt{ax - x^2}} \times \frac{1}{\sqrt{2r - x}}$ (for $\sqrt{2rx - x^2} = x \sqrt{2r - x}$), hence $t = -\frac{r}{\sqrt{4m}} \times \frac{\dot{x}}{\sqrt{ax - x^2}} \times \frac{1}{\sqrt{2r}} \times 1 + \frac{x}{4r} - \frac{3x}{32r^2}$ &c. by expanding $\frac{1}{\sqrt{2r - x}}$ into a series.

Again, let $\frac{\dot{x}}{\sqrt{ax - x^2}} = A$; then since $\sqrt{\frac{r}{4m}} \times$

$\frac{1}{\sqrt{2r}} = \sqrt{\frac{r}{8m}}$, we have $t = -\sqrt{\frac{r}{8m}} \times A + \frac{x}{4r} + \frac{3x^2}{32r^2} + \text{\&c.}$ Therefore, $t = -\sqrt{\frac{r}{8m}} \times A + \frac{aA - 2P}{8r} + \frac{9a^2A - 18aP - 12Q}{256r^2} + \text{\&c.}$ + cor. (where $P = \sqrt{ax - x^2}$, $Q = x \sqrt{ax - x^2}$, &c. &c.)

Now when $t = 0$, $x = a$, $\therefore P = 0$, $Q = 0$, &c.; and at the same time $A (= f' \frac{\dot{x}}{\sqrt{ax - x^2}} = \text{cir. arc, whose rad. is } 1, \text{ ver. fin. } \frac{x}{\frac{1}{2}a}) =$ a semi-circle whose radius is $1 = \pi$; hence $0 = -\sqrt{\frac{r}{8m}} \times \pi + \frac{a\pi}{8r} + \frac{9a^2\pi}{256r^2} + \text{\&c.} + \text{cor.}$ The fluent, therefore, when properly corrected, is $t = \sqrt{\frac{r}{8m}} \times \pi \times 1 + \frac{a}{8r} + \frac{9a^2}{256r^2} + \text{\&c.} - \sqrt{\frac{r}{8m}} \times A + \frac{aA - 2P}{8r} + \text{\&c.} =$

$\sqrt{\frac{r}{8m}} \times \pi \times 1 + \frac{a}{8r} + \frac{9a^2}{256r^2} + \text{\&c.}$ (when $x = 0$, and consequently, A, P, Q, &c. each = 0) for the time of descent down the arc EV; \therefore the whole time of one vibration $= \sqrt{\frac{r}{8m}} \times 2\pi \times 1 + \frac{a}{8r} + \frac{9a^2}{256r^2} + \text{\&c.}$

If the arcs be so very small, that the verfed sine, a , may be entirely rejected with respect to the radius r , then the time of a vibration $= \sqrt{\frac{r}{8m}} \times 2\pi =$ (if $r = 2d$)

$\sqrt{\frac{d}{4m}} \times 2\pi = \sqrt{\frac{d}{m}} \times \pi =$ the time of [a vibration in a cycloid whose axis is d or $\frac{1}{2}r$. The time of oscillation, therefore, in a very small circular arc, is the same as the time of oscillation in a cycloid, whose axis is equal to half the length of the cord by which the vibrating body is suspended, as was otherwise shewn to be the case under our article CYCLOID: for in these very small arcs, the time of descent

down EV $= \sqrt{\frac{r}{8m}} \times \pi$. Now the time down the chord $=$ the time down the diameter of a circle $= \sqrt{\frac{2r}{m}}$.

Hence the time down a very small circular arc : the time down the corresponding chord :: $\sqrt{8m} \times \pi : \sqrt{\frac{2r}{m}} :: \pi : \sqrt{\frac{1}{8}} : \sqrt{2} :: \pi : 4$:: the circumference of a circle : four of its diameters.

If the length of the arc through which the pendulum vibrates be such, that all the terms of the series except the

PENDULUM.

two first may be rejected, then the time of a vibration = $\sqrt{\frac{r}{8m}} \times 2\pi \times \sqrt{1 + \frac{a}{8r}}$; and, consequently, the time of a vibration in a circular arc (whose radius is r) : the time of a vibration in a cycloid (whose axis is $\frac{1}{2}r$) :: $1 + \frac{a}{8r}$: 1. For instance, let the arc of semi-vibration be 2° at each side of the lowest point, then $a = \text{versed sine of } 2^\circ = \frac{6r}{10000}$ nearly; $\therefore \frac{a}{8r} = \frac{1}{13333}$. In arcs which are less

than 2° , this difference will be still less; so that if the whole arc through which a pendulum vibrates does not exceed 4° , it may, without any material error, be considered as oscillating in a cycloid, and consequently all its oscillations will be performed in the same time, whether it vibrates in a greater or a lesser arc within this limit.

Lastly, let A = the arc, whose versed sine is a , then (supposing the arc to be very small) $a = \frac{A^2}{2r}$; and if n = the number of degrees in this arc, then $A : 2\pi r :: n : 360$, or $A = \frac{2\pi r n}{360}$. $\therefore a = \frac{A^2}{2r} = \frac{2\pi^2 r n^2}{360^2} =$ (for $\pi = 3.1416$, &c.) $\frac{r n^2}{6565}$ very nearly; hence $\frac{a}{8r} = \frac{n^2}{52520}$; consequently the variation for $N - n$ degrees is $\frac{N^2 - n^2}{52520}$; if therefore the pendulum keeps true time, when it oscillates through n degrees, the error arising from its vibrating through N degrees will be $\frac{N^2 - n^2}{52520}$ of the time of one vibration.

For instance, if a pendulum which vibrates 5^{e} seconds, keeps true time when it vibrates through an arc of 2° , on each side of the vertical line; then if it vibrates through an arc of 3° , it will lose $\frac{3^2 - 2^2}{52520} = \frac{5}{52520} = \frac{1}{10504}$ every

second, or $\frac{60 \times 60 \times 24}{10504} = 8''.2$ in a whole day. If the same pendulum be made to vibrate through an arc of $2^\circ 10'$ on each side of the vertical line, then it will lose only $\frac{2.16, \&c. - 2^2}{52520} = \frac{.665 \&c.}{52520}$ in a second, or $\frac{60 \times 60 \times 24 \times .665 \&c.}{52520}$, which is very nearly one second per day.

Nearly the same results will be the consequence of this still more simple process; viz. "Take $\frac{3}{4}$ of the difference of the squares of the arcs for the seconds, gained or lost by a decreased or increased arc;" thus $3^2 \times 3^0 - 2^0 \times 2^0 \times \frac{3}{4} = 7.5$ nearly as before.

When two pendulums of different lengths are made to vibrate in a detached state, at the same time, the times of their respective vibrations will be in the subduplicate ratio of their lengths: and the respective lengths of different pendulums, vibrating at the same time in similar arcs, will be in the duplicate ratio of the times of a vibration directly; or in the reciprocal duplicate ratio of the number of vibrations so made in any one and the same time. Let the length of a second's pendulum be taken in a given latitude at $39\frac{1}{2}$ inches = r , let g be $16\frac{1}{2}$ feet, or the space that a heavy body falls in free space

in the first second of time, and let $p = 3.1416$, &c. the diameter of a circle, whose radius is 1; then t , the time of vibration in a circular arc, being as $p \sqrt{\frac{r}{2g}}$, where p and g are constant or given, t will be as \sqrt{r} , and r as t^2 . Hence the length of a half-second's pendulum will be $\frac{1}{4}r$, or $\frac{39\frac{1}{2}}{4} = 9.781$ inches; and the length of a

quarter second's pendulum will be $\frac{39\frac{1}{2}}{16} = 2.445$ inches: and in this manner a table of square roots may be readily constructed of the various lengths of a pendulum, that are required to correspond to any number of seconds, or portions of a second, in each vibration.

The action of gravity, however, is not the same in all latitudes; nor yet at all heights above the earth's surface in the same latitude; for instance, the vibrations are slower at the equator than at the poles, and increase in quickness with the latitudes, north or south, as the centrifugal force decreases, and vice versa, the force of gravity being counteracted, in a certain degree, by the centrifugal force, which increases with the distance from the earth's axis of rotation, and the times of a vibration being reciprocally proportional to \sqrt{g} .

By an experiment made on the pendulum that vibrated seconds at Paris, Richter found that at the island Cayenna, 4° from the equator, it required to be shortened a line and a quarter, to perform a vibration in a second; and Mr. Campbell, in 1731, by an experiment made in Jamaica in 18° north latitude, determined that if a second's pendulum is 39.126 English inches long, agreeably to Graham's determination, the length at the equator would be required to be 39.00, and at the pole 39.206 inches. (Phil. Trans. N^o 432.) These experiments led Mr. Emerson to compute a table for the length of the pendulum to swing seconds for every five degrees of latitude, together with the length of a degree of latitude in each of those parallels, in English miles, which table we shall here subjoin.

Degrees of Lat.	Length of a Pendulum.	Length of a Degree.
	Inches.	Miles.
0	39.027	68.723
5	39.029	68.730
10	39.032	68.750
15	39.036	68.783
20	39.044	68.830
25	39.057	68.882

PENDULUM.

The numbers in this table of course suppose the pendulum vibrating close to the Earth's surface in each parallel of latitude.

Professor Bridge has also calculated a little table, on a supposition that the length of a seconds pendulum is 39.2 inches in latitude 52° , which is taken as his standard, and he has given the lengths corresponding not only to six different latitudes, but to four different heights, six at the Earth's surface, and at one, two, and three miles of elevation respectively. We shall take the liberty of giving this table also.

Latitude.	Length of Pendulum at the Earth's Surface.	One Mile above the Earth.	Two Miles above the Earth.	Three Miles above the Earth.
At the Equator	39.060	39.036	39.013	38.997
Lat. 30°	39.115	39.091	39.068	39.052
45	39.170	39.146	39.122	39.107
52	39.200	39.176	39.152	39.137
60	39.225	39.201	39.177	39.161
At the Pole	39.281	39.257	39.233	39.218

The greatest variation in the length of a pendulum vibrating at three miles above the equator, and on the Earth's surface at the pole, is only 0.284 of an inch, which affords but a small scale for determining either altitudes or the figure of the Earth, to both which purposes the observed variations in the lengths of the pendulum have been proposed as a measure.

When a pendulum of a given length has been observed to gain or lose a certain quantity daily, it is convenient, in making the adjustment for exact time, to have some concise theorem as a guide to bring it to the point desired, at one trial in all cases, which theorem professor Bridge has given in these words: "Multiply twice the length of the pendulum by the number of seconds gained or lost, and divide the result by the number of seconds in a day; the quotient will give the number of inches, or parts of an inch, by which the pendulum is to be lengthened or shortened." Suppose the gain of a seconds pendulum to be three minutes,

or $180''$ in a solar day, then $\frac{39.2 \times 2 \times 180''}{86400} = .163$ parts

of an inch, is the quantity, in this case, by which the pendulum must be lengthened to measure mean time; but if the three minutes had been lost with a half-seconds pendulum,

then $\frac{9.8 \times 2 \times 180}{86400} = .041$ of an inch, or the fourth

part of the former gain, will be the quantity by which the said pendulum will require to be shortened. This rule is not only short in its application, but easy to be remembered.

Under the title CYCLOID, we have shewn that if l be the length of a seconds pendulum, and π the periphery of a circle, or 3.1416, &c. the expression $\frac{\pi l}{2}$ will be the measure of the velocity of a falling body acquired in one second of time, and also that the expression $\frac{\pi^2 l}{2}$ will denote the space fallen through in a vertical line in the same time; if

we would apply these expressions to experiments in any given latitude, instead of the length of the pendulum determined in our own latitude, we must substitute the length given in one of the preceding tables, agreeably to the latitude proposed, and then the result arising from such length, as determined by the said expressions, will be corresponding; and the scale of acceleration will be accommodated to the increased or decreased force of gravity in that particular latitude; for instance, agreeably to Mr. Bridge's Table, the spaces fallen through in one second of time at the equator and at the pole will be respectively 192.663 and 193.753, the difference between which is only 1.09 inches; which is the greatest difference that exists between the spaces fallen through in one second on any two points of the Earth's surface.

If it should be required to know what the height of a mountain is, on which a seconds pendulum, that measured mean time truly at its base, lost a given quantity; let r = radius of the Earth, x = the height of the mountain, T = the number of seconds in an hour, or the number of vibrations in an hour at the base, and t = the seconds lost on the mountain; then $T - t$ will be the number of vibrations in an hour at the top of the mountain. When the length of the pendulum is given, it is known that the number of vibrations in a given time are directly as the square roots of the forces, which act upon the

pendulum; hence $T : T - t :: \sqrt{\frac{1}{r^2}} : \sqrt{\frac{1}{(r+x)^2}} ::$

$$\frac{1}{r} : \frac{1}{r+x} :: r+x : r, \therefore t : T - t :: x : r, \text{ or } x = \frac{tr}{T-t}.$$

If t be very small with respect to T , then x may be considered as equal to $\frac{tr}{T}$. Let T now be taken equal $3600''$,

and let t be taken successively at 1, 2, 3, &c. seconds, then x will be equal to $\frac{r}{3000}, \frac{2r}{3000}, \frac{3r}{3000}$, &c.; and supposing

r to be equal to 4000 miles, the heights of mountains upon which a pendulum, that vibrates seconds at their bases, loses 1, 2, 3, &c. seconds in an hour, will be $1\frac{1}{3}, 2\frac{2}{3}, 3\frac{1}{2}$, &c. miles respectively. Hence, if the pendulum should gain t seconds in an hour before it is carried up the mountain, and it should be required to find that point in the ascent, where it would keep true time, we have $T + t : T ::$

$r + x : r, \therefore t : T :: x : r, \text{ or } x = \frac{tr}{T}$; that is, if we

multiply the gain by the Earth's radius, and divide the product by the number of vibrations performed in the hour, the quotient will be the height of that part of the mountain, where the pendulum must be fixed to keep true time.

Hitherto we have considered the matter that constitutes the whole pendulum as collected into one point, and that the centres of gravity and of oscillation coincide in that point, which cannot be strictly the case with any shape of the bob, however slender the cord, wire, or rod of suspension. For instance, if a small ball of lead, or other ponderous body, were suspended by a silken thread; suppose the ball to be divided into two equal semi-balls by a horizontal line, as it is suspended by the vertical thread, then the lower semi-ball would move with a greater velocity than the upper one, though vibrating together, in consequence of its greater radius of motion, consequently the momentum of the lower semi-ball

PENDULUM.

femi-ball would exceed that of the upper one, and considering the two femi-balls as again united, it is clear that the common point of *oscillation* will be somewhere in the lower femi-ball, though the centre of gravity is in the middle of the line of division, even if the silk thread be assumed as having no sensible weight. As we have given the methods of determining the centres both of *gravity* and of *oscillation* of bodies of different figures, with much minuteness, under our article *CENTER*, it is not necessary to pursue this part of our subject here, but to beg of the reader to recollect that the centre of *gravity* of any single pendulum is always *above* the centre of its *oscillation*, and that the distance from the point of *suspension* to the centre of *oscillation* is always to be taken as the *true length* of the pendulum, however suspended, or whatever may be the shape or size of the bob or ball. This observation is indeed equally true, however complex the construction of the pendulum may be, for we have shewn, (see *CENTER*.) that whatever be the number of particles of matter composing a pendulum, the products of the particles lying at one side of the centre of oscillation, when multiplied both by their respective distances from the point of suspension, and also from the centre of oscillation, will make an amount, always equal to the amount of the products obtained from the particles so multiplied, lying at the other side of the centre of oscillation, without regard to shape or size. In a common seconds pendulum of 39.2 inches length, with a heavy lenticular bob, and a slender verge or rod of suspension, the centre of *gravity* is very nearly $\frac{1}{10}$ th of an inch above the centre of *oscillation*; and in all our preceding deductions the length of the pendulum must be considered as measured from the point of suspension at the vertex, to the centre of oscillation.

But we have seen a pendulum so applied for the regulation of a portable clock, that the point of suspension was not at the vertex, but in a point somewhere between the vertex and the centre of gravity; by which application, the centres of gravity and of oscillation were farther removed from each other, than they would have been with the point of suspension at the vertex. A pendulum of this description, of a short length, may be made to vibrate in times of different lengths, which will depend on the respective distances between the centres of gravity and of oscillation; but the scale of adjustment for time being very short, and liable to be altered by variable temperature, this construction may be considered as an object of curiosity rather than of utility. If it were required, however, to find the distance between the centre of oscillation and point of suspension in any pendulum of this sort, where the *time of vibration* is given, it may be thus determined: Let T be the time given, L = length of a simple or common pendulum that will vibrate in that time, $\pi = 3.1416$, $m = 16\frac{1}{2}$ feet, and F = the force

of gravity constantly acting; then since $T = \sqrt{\frac{\pi^2 L}{2 m F}}$,

we shall have $L = \frac{2 m F T^2}{\pi^2}$ for the distance from the point

of suspension to the centre of oscillation. Again, in *fig. 3, Plate XXXIX. of Horology*, let Aa be a solid uniform rod, and G its centre of gravity; then if A be taken as the point of suspension in the vertex, the centre of oscillation will be at O , at two-thirds of its length from A . But let S be put as the point of suspension below A , then $L = SG + \frac{AG \times GO}{SG}$. Let $SG = x$, $AG = D$, $GO = d$;

then $L = x + \frac{Dd}{x}$, or $x^2 - Lx + Dd = 0$, from which

$$x = \frac{L \pm \sqrt{L^2 - 4 D d}}{2}; \text{ substitute } \frac{2 m F T^2}{\pi^2} \text{ for } L \text{ in}$$

this equation, and it determines the distance of the point (S) of suspension to (G) the centre of gravity of the rod; through which point (S), if the axis of suspension be made to pass, the rod will vibrate in the *given time*. But as x has two values, it seems that there are two points at different distances from G , the centre of gravity; from which if the rod be suspended, it will oscillate in the given time. By similar reasoning it may be proved, that the rod will vibrate in the *least possible time*, when SG is a mean proportional between AG and GO ; likewise, that if o be the centre of oscillation to the point of suspension S , the point, G , of the centre of gravity will be in the middle between S and o ; and, lastly, that a rod so circumstanced will vibrate in the least time possible, when its point of suspension, S , is $\frac{2}{3}$ of the whole length of the rod from its vertex A .

3. We come, in the third and last place, to treat of the various constructions of the attached pendulum, when used as the regulator of an horological machine, as we at first proposed. It has been usual, when treating of the pendulum, to call what we have denominated the free or *detached* pendulum, vibrating by the action of its own gravity alone, the *simple* pendulum; and what we call the *attached* pendulum, where external force is introduced in aid of gravity, the *compound* pendulum. But as the attached pendulum is constructed sometimes with a *simple* rod or verge, and sometimes with a *compound* one, we propose to apply these two terms, *simple* and *compound*, exclusively to the different constructions of the attached pendulum, agreeably to the significations in which they are used by clock-makers.

In writing the article *ESCAPEMENT*, which is that portion of a clock that transmits the maintaining power, in a modified way, to the pendulum, we found it necessary to explain at some length, how the natural scale of forces, arising from gravity alone, is disturbed by the accession of any external force, such as is derived from the maintaining power; and by a reference to *figs. 1. and 2. of Plate XXXI. of Escapements*, we proved that this scale is most deranged, when the external force is applied at the extremity of the arc of excursion; and least, at the lowest point of the said arc. We also shewed how to estimate, in any point of the arc, both the force applied at that point, and the velocity with which the pendulum is moving there; as well as determined the total arc corresponding to the maximum of velocity, and other particulars of essential importance both in the theory and practice of clock-making. We must, therefore, request the reader to consult our introduction to the article *ESCAPEMENT*, so far as it relates to the *pendulum*, before he proceeds to peruse the remainder of our present article. Indeed, the different parts of a clock are so intimately and mutually connected, that the action of one frequently cannot be clearly explained, without at least a partial explanation of the properties of the other; which is the reason why we have anticipated several particulars relating to the motion of the pendulum, before we arrived at our present article.

Of the simple Pendulum in Horology.—When a pendulum was first applied to be the regulator of a clock, the crown-wheel escapement was used with it by Huygens, and the pendulum was necessarily made to vibrate in long arcs; but it was soon found that it had at least three defects: 1st, the maintaining power acted on the wheel, and consequently on the pendulum, by means of the fork, almost constantly, thereby producing an alternate acceleration and retardation of motion beyond what gravity alone would produce; 2dly, the times of vibration in the longest arcs were found

PENDULUM.

to be slower than in the shortest arcs, in the proportion of about 34 to 29; and, 3dly, the verge of the pendulum itself was found to have its total length increased or decreased by variations of atmospheric temperature. Hence arose the necessity of new escapements, and of different modifications of the pendulum, to make it act as an uniform regulator of mean time under all circumstances. As we have had occasion to describe different pendulums, and also the parts connected with them, such as the fork that gives it motion, the cock by which it is suspended, the spring of suspension, the verge, the bob, and screw of adjustment, &c. (see *CLOCK*, and *CLOCK-MAKING*;) a repetition of what we have before said would be superfluous. We will, therefore, take it for granted that every one, that has seen an ordinary clock with a seconds pendulum, which, with Dr. Hooke's anchor escapement, is called the *royal pendulum*, knows its parts and construction. The true length between the centre of oscillation and axis of suspension of any pendulum is best ascertained by adjustment for rate, first, from hour to hour roughly, and then from day to day, either by the going of a good clock already adjusted, or by a transit of one of the heavenly bodies. (See *CHRONOMETER*, prob. vii, viii, and ix.) But from what we have said under our article *ESCAPEMENT*, it will be seen that the length of any pendulum will require to be a trifle more or less, accordingly as the *external impulse*, derived from the maintaining power, is great or small, permanent or temporary, gradual or instantaneous; or, which is to the same effect, accordingly as the escapement has a *recoil*, is of the *dead-beat* sort, is *detached*, or has a *remontoire*. When, therefore, we speak of the acting length of a pendulum, we must always have a reference to both the quantity and quality of the auxiliary force that perpetuates its motion. In ordinary cases, an additional force applied in aid of gravity accelerates the pendulum, and requires a compensation by adjustment, as will be seen presently, for additional length. This adjustment was made by Huygens, by a small ball moving along the verge above the bob, but is generally effected by a tapped nut at the inferior end. This method is, however, inconvenient, inasmuch as that it requires the pendulum to be stopped; for which reason, in many regulators, or astronomical clocks, the adjustment for rate is made at the superior end, above the cock. For the shape and size of the bob of a given pendulum, we must refer to our term *BOB*, in its proper place, where we have entered into a minute detail of the particulars relating to its shape and size, with a given maintaining power and escapement, both which must be considered at the same time; but further experiments are perhaps wanting, in this department of horology, to determine the best possible combination of all the requisite agents in a moving pendulum, including the suspension. The metal of which the verge is usually composed is iron or steel; but their expansion by heat, and contraction in cold, render them improper substances for an accurate pendulum: for, in the extremes of temperature, the rate will alter by an iron pendulum more than 20" in the 24 hours. Straight-grained deal or sapadillo, well seasoned, is better for the verge than metal; though these, and indeed all sorts of wood, are subject to changes, from moisture, if not from heat, and therefore cannot be entirely depended on, in all seasons of the year, where great accuracy is required.

From what we have here had occasion to state respecting the motion of an attached pendulum, it will be evident to our readers, that our deductions with respect to the exact length of the *detached* one, where the *accelerative force* was considered constant and uniform, will not be strictly accurate when that force is *variable*, which it is more or less in its

attached state: we will therefore conclude our remarks on the *simple* attached pendulum, by shewing in what degree the length of such pendulum is affected by any accelerative force. Whatever this force (*F*) may be, the time of a body's falling down half the length of the pendulum, by the laws

of acceleration, will be $\left(= \sqrt{\frac{S}{m F}} \right) = \sqrt{\frac{L}{2 m F}}$,

where $m = 16\frac{1}{2}$ feet, and $L =$ the length of the pendulum,

and $\pi = 3.1416$; therefore $T \cdot \sqrt{\frac{L}{2 m F}} :: \pi : 1$, or T

$= \sqrt{\frac{\pi^2 L}{2 m F}}$, which *varies* as $\sqrt{\frac{L}{F}}$. Consequently,

the times of vibration of pendulums of *different lengths*, acted upon by *different accelerative forces*, will vary as the *square roots* of the *lengths* directly, and the *square roots* of the *forces*

inversely. If L be given, then $T \propto \frac{1}{\sqrt{F}}$; that is, the

times of vibration of pendulums of the *same length* vary inversely as the *square roots* of the *accelerative forces*; and if T be given, then $L \propto F$; namely, the lengths of pendulums vibrating in the *same time* vary as the *forces* which *accelerate* them.

The accelerative force, added to the natural force of gravity in a clock, is usually called the *maintaining power*, and may be derived either from an appended weight immediately through the escapement, or from a spring or springs wound up by a weight at short intervals; and in either case the quantity and mode of its action will be limited by the nature of the escapement adopted; and frequently the spring of suspension is so tapered upwards or downwards, as to become a modifier of the maintaining power, in conjunction with the escapement, all which circumstances must be taken into the account when the nature and quantity of the extraneous force is estimated.

Before we conclude our account of the simple pendulum, we will just mention that such pendulum vibrating in a given time, in a given situation on the Earth's surface, has been proposed as a perpetual standard of linear measure. Hatton, we understand, first proposed this subject for the consideration of the Society of Arts at the Adelphi buildings, (vol. i.) and Mr. Whitehurst took up the subject after him, and contrived a method of ascertaining the difference between the lengths of a seconds and half-seconds pendulum, by means of an apparatus, which afterwards came into the possession of Dr. George Fordyce, who improved it, by adding a compensation to the pendulum, and gave an account of it, with drawings, in the Philosophical Transactions of London, of the year 1794.

We may also mention here, that Huygens, in his "*Horologium Oscillatorium*," proposed a *circular* or *circulating pendulum*, to move in the concave side of a parabolic conoid, the circuits of which would be performed, he says, in equal times, when the mechanism is properly adjusted; but it would lead us beyond our mark in this place, to pursue this part of the subject further. See *Horol. Oscil.*

Of compound or compensating Pendulums.—If any substance, sufficiently long for a pendulum, could be found in nature, that has not its dimensions enlarged or diminished by heat or cold, such substance would be the most suitable for a simple attached pendulum; but all attempts to discover such a substance have hitherto been ineffectual. (See *EXPANSION*.) Hence different contrivances have been devised by ingenious

PENDULUM.

men, to counteract the effects of variable temperature in the pendulum, and some of them have succeeded in effecting this desirable purpose. So long ago as the year 1648, the different expansibilities of various metals was known by Wendelin to exist, and in 1715 that ingenious artist George Graham made several experiments with the pyrometer, invented by Musschenbroek, to ascertain the relative quantities of expansions of different metals, with a view of availing himself of the difference of the expansions of some two or more metals, when opposed to each other, in the construction of a compensating pendulum, but the difference which he detected, between iron and brass, for instance, was so small, that he relinquished all hope of being able to accomplish his object in this way, and therefore gave up the project. (Phil. Trans. London, 1726.) However, it occurred to the same artist, that mercury was affected by changes of heat and cold sufficiently to answer the purpose of keeping the centre of oscillation of a pendulum always equidistant from the point of suspension, provided the mercury could be made to ascend while the verge of the pendulum descended, or elongated, by any degree of heat; and *vice versa*. In 1721 the trial was made in a pendulum, which we shall presently describe, and in which the compensation, after some adjustment, was found so complete, that its error in the extremes of temperature was reduced to $\frac{1}{4}$ th of the quantity observable in an ordinary simple pendulum. In the mean time, the idea of arranging metallic bars of different expansibilities in such a manner, as to constitute a good compensating pendulum, being once suggested by Graham's paper on the subject, roused the ingenuity of different mechanics, and Harrison, a carpenter of Barton in Lincolnshire, in the year 1726, succeeded in completing the requisite arrangement. His rods of metal were placed in such parallel situations as to resemble those of a grid-iron, from which circumstance the pendulum, so constructed, has been denominated the *grid-iron pendulum*. Since Harrison's time, there have been various modifications of the compensating pendulums, both in England and France, the principal of which we shall describe in their order of time, but none of them have been found to excel the prototypes of Graham and Harrison, which are still used, one or other of them, in the principal observatories. If any improvement has been made on the original pendulums, it is in the external appearance, and in the easier modes of adjustment.

Graham's Mercurial Pendulum.—Graham's mercurial pendulum, which may be considered as the first compensating pendulum, is represented in *fig. 4, of Plate XXXIX. of Horology*; A B is the verge consisting of a rod of steel, carrying at its lower extremity a stirrup, B C, of the same metal, holding the glass cylindrical vessel, E F, on a circular plate, surrounded by a rim, to keep the vessel from falling out; this vessel was filled with pure mercury up to the letter F, near the top; and above there was space enough to receive more, in case the compensation should not prove on trial to be sufficient. The sliding piece of metal, D, was adjustable to any part of the verge, for fixing the rate of going, and the compensation could be made more or less by adding to or deducting from the mercury. It does not appear certain, whether the glass vessel was chosen by conjecture, as to its size and shape, or was calculated previously, from a consideration of the relative expansibility and absolute specific gravity of mercury; but we are disposed to think, that it must have been from calculation, because it very much resembles the vessel calculated by Mr. Lowe of Islington, for the mercurial pendulum recently made for the Royal Observatory of Greenwich, by Hardy. In this pendulum, as now made by Hardy, and others, the lower end of the verge

is tapped, and descends through the top of the stirrup where a milled and divided nut screws on, by means of which the adjustment for rate is made, without the sliding piece D, which is now rejected. One peculiarity of this pendulum is, that the mercury which is used as the means of compensation, constitutes also the weight of the bob. We are not made acquainted with the quantity of mercury used by Graham; nor yet with the particulars of Mr. Lowe's calculation; but the vessel which the latter determined, as the most suitable, was cylindrical, seven inches and a half long within, and two inches in diameter, exclusively of the thickness of the glass, which was one-eighth of an inch; the capacity proposed was for twelve pounds, but by eliminating the solid contents of such a vessel, and trying its bulk of mercury, from a table of specific gravities, we find that it will not hold more than ten pounds of this fluid, if so much. The depth to which Hardy's vessel was proposed to be filled was $6\frac{7}{8}$ inches, but on trial at the Royal Observatory, it was found necessary to add $\frac{1}{8}$ th more, and $6\frac{9}{10}$ inches are now found to compensate the steel verge so admirably, that the greatest deviation in the rate, during winter and summer, has never yet exceeded $\frac{1}{100}$ ths of a second *per day*. The escapement that acts with Hardy's pendulum is of the remontoire sort, acting almost constantly on the pendulum, and therefore requiring it to be somewhat longer than an exact standard.

Harrison's Grid-iron Pendulum.—Though we have given a general description of Harrison's grid-iron pendulum, as made by Reid of Edinburgh, under the article *CLOCK*, (see *Astronomical Clock by Mr. Thos. Reid of Edinburgh*) to which we refer our readers, as well as to *Plate XXII. of Horology*, where it is represented; yet we feel it due to that ingenious artist, to resume our observations on his contrivance in this place. When Harrison had determined the relative expansions of steel and brass to be very nearly as 3 to 5, it is probable that he reasoned on the subject in some such way as this; let a rod of steel be suspended by its upper end on a fixed point, and let it hang freely in a vertical position, then to the lower end rivet the lower end of a brass rod, so as to ascend parallel and contiguous to the iron rod, while it is supported by the rivet; if the iron rod be divided into five equal portions, and the brass rod be made just equal to three of those portions, what will be the consequence? Why the tops of the two rods will always preserve the same distance from each other, because the downward expansion of the longer iron rod will always be equal to the upward expansion of the shorter brass rod, consequently, if the vertex of the iron rod be made stationary, by being fixed to a wall or otherwise, the vertex of the brass rod will also be stationary as it respects the other. Let now the vertex of the iron rod be assumed as the point of a pendulum's suspension, and let the vertex of the brass rod be the place for the centre of oscillation, then the centre of oscillation of a single rod, or of any number of similar rods, of uniform metal, is at $\frac{2}{3}$ ds of the length from the point of suspension; but the common centre of oscillation will be still lower in a compound pendulum that has another rod, not of the same length attached to its lower end; therefore two rods so united cannot produce a proper compensation, and at the same time have the immovable point at the common centre of oscillation. But the rods may be cut into any number of lengths that the due arrangement may require; we have seen that if the long iron rod be cut in two between the second and third portion, we shall have three lengths, one of iron $\frac{2}{3}$ ths of the long rod, one of brass $\frac{2}{3}$ ths, and another of iron $\frac{1}{3}$ ths, or equal to the one of brass; in every arrangement of the various lengths to form a compound pendulum,

PENDULUM.

the rods of least expansion must necessarily expand downwards, and those of greater expansion must expand upwards, because these rods will be fewer in number, and the difference of the total expansions must compensate the lack of the combination, by which the ball is suspended; accordingly the length of the verge must be $\frac{2}{3}$ ths of the longer rod, and the other two each $\frac{1}{3}$ ths; but $\frac{1}{3}$ ths is $\frac{1}{4}$ d longer than the required pendulum; this arrangement therefore in a seconds pendulum is inconvenient, making the pendulum too long: let the iron rod then have three lengths and the brass rod two, so that there may be two pairs of equal length and one to spare for the verge, to be compensated by the surplus of expansion of the brass over the iron equal pairs of rods; this division in due proportions will make a pendulum of the requisite length, and will also preserve the centre of oscillation unchanged as it regards the axis of suspension; but there is yet an inconvenience to be surmounted; the two pairs of alternate iron and brass rods are to be united at both their extremities, each to the next contiguous rod, first below and then above, till they are all attached to each other, and the ball of the pendulum must in this case be suspended by the *extreme* rod, which will therefore make the vertical line fall diagonally across the parallel rods, and pull them to a distance from each other; but to prevent this evil the ball must hang from the *middle rod*, and also the rods must be braced to prevent their flying out; these requisites may be effected by employing two pairs more of similar iron and brass rods, at the opposite side of the fifth or spare iron rod, that carries the ball, for these additional pairs of bars will not otherwise affect the compensation, than do the same thing over again which the others did without them; and they will thus constitute a counterpoise by their weight, afford the means of a longer horizontal bracing piece, and preserve the coincidence of the vertical line with the middle rod at the quiescent position. Thus *nine* rods became necessary to constitute the grid-iron pendulum; and when they are well proportioned and nicely fitted into the holes of the connecting pieces, so as not to touch one another, nor to have friction in the holes, the pendulum completely answers its purpose in all variations of temperature, and may be brought to time, like the simple pendulum, by a screw of adjustment either at the cock of suspension under the ball, or at the point of oscillation. But the proportions of the alternate rods may not produce the exact compensation; that is, the pendulum may be either over-compensated or under-compensated; the adjustment for compensation, when that is necessary, is usually made by altering the position of one of the horizontal connecting pieces of brass, by taking out the pins and inserting them again into other holes, drilled in some of the bars to answer this purpose. This adjustment, however, is troublesome, as it cannot be made without detaching the pendulum, and putting it probably out of its rate of going; and this inconvenience constitutes one of the principal objections to this construction of the pendulum, for which there appears to be no remedy yet devised. For the construction of a grid-iron pendulum rods, drawn into wire, are preferable to square rods, both on account of their having less friction, and of their being more exposed to the air, when not quite in contact. In Harrison's pamphlet, published in 1763, it is stated that one of his clocks did not deviate from its rate, as measured by his grid-iron pendulum, more than one second in a month, for ten years together; and Berthoud has expressed his regret that all the particulars of Harrison's construction of a clock, have not been divulged, that the public may benefit from his contrivances. It should seem that notwithstanding the objections that have been

made to the cycloidal cheeks, Harrison, while unacquainted with Huygens's invention, introduced the use of them into at least one of his clocks. But their excellence did not consist of this addition. About the year 1798 the composer of this article saw, in a back lane at Lincoln, and purchased one of Harrison's clocks, which he recollects had wheels and pinions of hard wood; and that the teeth of the pinions were cylindrical rollers turning loosely on as many pins of steel: but he could not examine the escapement. The old woman, who was the possessor, was a lineal descendant from Harrison, and some of her wife neighbours persuaded her, that if she parted with Harrison's clock, his *ghost would haunt her*, which suggestion made such an impression on the good woman's spirits, that she begged she might be allowed to retain her clock; which request was accordingly granted.

Regnauld's Pendulum.—In the year 1733, Regnauld, a clock-maker of Chalons in France, contrived a metallic pendulum of brass and steel, the expansions of which were opposed to each other in such a way, that they constituted a *partial* compensation. This pendulum is represented by *fig. 5.* of the same plate that contains Graham's mercurial pendulum, and probably derived its origin from the experiments mentioned in his paper on the Philosophical Transactions of London of the year 1726. The pendulum in question was made before Harrison's account was published; it was composed of three parallel rods, two of steel and one of brass; the middle rod was of steel, and carried the horizontal cross-piece E A attached to its lower extremity; one end of this cross-piece supported the brass rod A B, to the top of which, at B, was rivetted the horizontal pin which passes through an oblong hole in the middle rod; the third rod, D E, which was of steel, was suspended by the pin B, and carried the bob L, attached to it by a tapped nut of adjustment for rate beneath: the whole pendulum must have been suspended by the top of the middle rod. The action is thus; while the middle rod elongates downward by increased heat, the brass rod of greater expansibility, A B, elongates upwards, and carries with it the pin B, by which the third rod D E is suspended; and this rod passing through the cross-piece E A, again elongates as much as its fellow, or rod A B of the same metal; therefore the compensation is effected on a supposition that one rod of brass will compensate two of steel, or that brass expands double the quantity of steel with the same degree of heat, and also contracts in the same ratio, neither of which assumptions is true. The relative expansions being in fact as 17 to 10, according to Berthoud, or, according to others, as 113 to 68, or very nearly as 5 to 3.

Deparcieux's Improvement of Regnauld's Pendulum.—In the year 1739, Deparcieux, a teacher of mathematics, and a distinguished member of the Academy of Sciences at Paris, examined the construction of Regnauld's pendulum, and proposed an improvement in its construction, which rendered it capable of adjustment for compensation as well as for time. This pendulum is given in *fig. 6.* of the same plate, and may be thus described: A R P and E F are two bars of steel passing through the perforated piece of metal S T, which forms a clamping-piece to hold them in their places; C D is a bar of brass resting with its inferior end on the toe, F, of the bar E F, so as to be supported by it. Q R is another clamping-piece, fast either at Q or R to one of the steel bars, but so adjusted, that the other two may not be restrained from passing without friction whenever they elongate. Through the clamping-piece, S T, passes a slit lever resting at the end S, as a centre of motion, in a notch, or otherwise made moveable round a fixed

PENDULUM.

pin, in the clamping-piece; this lever has a triangular point resting on the top of the brafs bar CD in such a way, that it is at liberty to ascend with the bar whenever it elongates; at the other end of the said lever the rod AR is suspended, which therefore has more or less motion upwards produced by the expansion of CD, accordingly as the triangular point on the lever is nearer to S, the centre of motion, or T, the point of the third bar's suspension: for when the rod EF elongates, the rod of brafs CD elongates more in the proportion of 17 to 10, and the surplus 7 acts on bar AR, and, by the aid of the lever, compensates it.

This pendulum was afterwards still further improved by Berthoud, who made the triangular point of bearing in the lever adjustable for distance from the centre of motion, by a screw that acted on it, and altered its situation a little. (See *Essai sur l'Horlogerie*, tome ii. p. 123.) Berthoud ascertained the relative expansions of several different metals by a pyrometer that indicated the $\frac{1}{360}$ th part of a French line, and according to his experiments, made the 17th of March 1760, when he was contriving the alteration in Deparcieux's improved pendulum, the following Table was constructed; in which the verge was taken at 3 feet 2 inches and 5 lines French, or 461 lines, in each experiment.

Berthoud's Table of Metallic Expansions.

A verge of soft steel	-	-	$\frac{40}{360}$	of a line.
— of steel hammered cold	-	-	$\frac{74}{360}$	of ditto.
— of spring-tempered steel	-	-	$\frac{77}{360}$	of ditto.
— of soft iron	-	-	$\frac{75}{360}$	of ditto.
— of hardened iron	-	-	$\frac{78}{360}$	of ditto.
— of copper	-	-	$\frac{107}{360}$	of ditto.
— of brafs	-	-	$\frac{121}{360}$	of ditto.
— of tin	-	-	$\frac{160}{360}$	of ditto.
— of lead	-	-	$\frac{193}{360}$	of ditto.
— of glafs	-	-	$\frac{62}{360}$	of ditto.
— of silver	-	-	$\frac{119}{360}$	of ditto.
— of gold softened	-	-	$\frac{92}{360}$	of ditto.
— of gold in hard wire	-	-	$\frac{94}{360}$	of ditto.
— of mercury	-	-	$\frac{1235}{3600}$	of ditto.

In this table the whole fraction of each metal gives its absolute expansion, and the numerators the relative expansions, as the denominator is common to all. These experiments were first made with simple rods, and again with 35 pounds suspended to each, without any variation in the expansions, though it appeared that the subsequent contractions were not exactly corresponding when the weight was suspended and when there was no weight; and it is to be regretted, that the author did not repeat his observations on the comparative contractions under different circumstances, as he has done the comparative expansions, in order that the results might have been ascertained as they relate to the pendulum's verge stretched by a weight; for in all the experiments we have reported under our article EXPANSION, the subsequent contractions are considered as being exactly proportional to the expansions in the same degrees of opposite temperature. In composing a pendulum of rods of any two of these metals, it is perhaps unnecessary to remark, that the rods of each metal must have their total lengths in an inverse ratio of their expansibilities, unless indeed some mechanical advantage by a lever, or otherwise, be given in aid of the difference of the absolute expansions, as is done in the instance before us.

Deparcieux's Compensation of a Simple Pendulum.—In the

same year in which Deparcieux contrived an improvement of Regnauld's pendulum, he invented a compound compensation frame to be substituted for the common cock of suspension, without altering the simple pendulum, which mechanism comes next to be described.

This contrivance is represented by *fig. 7*, of our last named plate, where ABDF is a steel bar bent into the shape of a two-pronged fork with the ends pointing upwards, and fixed to a solid wall at the points A and F. GEIH is another fork, formed smaller, of brafs, and is inverted, or made to stand with its ends resting on the horizontal part, BD, of the outer, or steel fork. The horizontal, or upper part, EI, of the brafs fork, constitutes the cock of suspension, and has a squared hole in the middle, which just admits the tapped wire K, from which the suspension-spring depends; in order that the nut of this tapped wire may give the adjustment for time. Underneath this cross-piece of the fork of brafs is a detached cock, not shewn, near C, which has a slit cut through it in the direction of the vertical line of the spring of suspension, through which the spring passes without play, and from the under side of which the length of the pendulum is reckoned. This cock of limitation is screwed to the frame of the wheel-work, and therefore remains unmoved. It is easy to see, in this disposition of the bars of steel and copper, that if the expansions of those two metals be as 10 to 17, the length of the steel verge of the pendulum added to the length, AB, of the outer fork, must be to EG, the length of the inner fork above, as 17 to 10, to make the compensation complete; and accordingly the length of the brafs fork was made $54\frac{2}{3}$ French inches, the sum of the other two being very nearly 93.

About the same time that this pendulum was made, Cassini proposed some different constructions, some with three, and some with five rods, steel and brafs alternately, in the pendulum itself, which he gave in a memoir in the *History of the Academy of Sciences at Paris* in the year 1741.

Compensating Tube and Rod of Julien le Roy, applied to the Simple Pendulum.—According to Thiout, Julien le Roy contrived a mode of compensating the simple pendulum in the same year as Deparcieux, above stated, and on the same principle, though the compensating mechanism of Le Roy was altogether above the pendulum. This contrivance, exhibited in *fig. 8*, of the same plate, consists of a vertical brafs tube, 42 French inches long, denoted by the letters *abcd*, resting at its lower end on AB, the cock of suspension, which is also the cock of limitation of the pendulum's length, by having a slit made in it just large enough to admit the spring of suspension without play, which spring hangs from the lower end of a steel rod, attached to the top part or cap, *a b*, of the brafs tube; therefore, in this construction also, the sum of the steel rods, *i. e.* of the verge of the pendulum, including its spring, and of that included in the tube, should be to the tube alone as 17 to 10. Thiout has given the length of the tube only at 42 inches, but Berthoud has remarked, that it either is, or ought to be, $54\frac{2}{3}$, like the brafs fork of Deparcieux. A pendulum of Le Roy's construction was spoken well of in Cassini's *Memoir of 1741*, and was adopted in the observatory of Cluny about 1748, after which time the clock, to which it was applied, was spoken of with great eulogium.

The principal objections that, we conceive, apply to either of these two last pendulums, are, that the spring of suspension is constantly altering its length and strength; that the slit in the cock of limitation must have the effect

PENDULUM.

of lengthening the pendulum in proportion to the play that the spring has in it, to the right and left of the vertical line, as the pendulum is vibrating; and that the pendulum rod in motion will cool sooner than the compensating parts remaining at rest.

Ellicott's Compensating Pendulum.—We have stated under our article EXPANSION, that Ellicott, of London, made very accurate experiments on the relative expansions of seven different metals, which, on a comparison, we find to differ, more or less, from Berthoud's table, as well as from the determinations of Smeaton, Ramsden, Julien le Roy, Borda, and others; so that when a compensation pendulum is constructed of any description, it seems proper, that the relative expansions of the metal used should not be taken from any table of results, but from an examination of the identical materials of which the pendulum is to be constructed, and that after tempering, hammering, filing, polishing, &c. in order to gain the due proportions in their state as prepared for use. Ellicott, we doubt not, used this precaution, and his experiments were made, most probably, with a view to the construction of the pendulum we are now going to describe. It had been objected to Harrison's grid-iron pendulum, that the adjustment of the rods for temperature was inconvenient, and accompanied by a considerable change in the rate, and that the expansion of the ball supported at its lower edge was all in an upward direction, to avoid which objections, as well as the supposed jerks during the elongation, was probably Ellicott's object, at the time of his contriving a new pendulum: whether or not he had seen the application of the lever in Deparcieux's pendulum is not certain, but his contrivance is nearly allied to that, the principal difference being that in Ellicott's pendulum two levers are adopted instead of one, and are applied at the bob instead of the superior end of the verge. In describing Ellicott's pendulum we shall avail ourselves of the inventor's own account, and then subjoin our own remarks. *Fig. 1, of Plate XL. of Horology,* represents the pendulum; in which *ab* is a bar of brass made quite fast at the upper end by pins, and held contiguous at several equal distances, by the screws 1, 2, &c. to the rod of the pendulum, which is a bar of iron; and, so far as the brass bar reaches, is filed of the same size and shape, though it does not appear so in the figure, but, a little below the end of the brass, the iron is left broader, as at *dd*, for the conveniency of fixing the work to it, and is made of a sufficient length to pass quite through the ball of the pendulum to *c*. The holes 1, 2, &c. in the brass, through which the screws pass into the iron rod of the pendulum, are filed, as in the drawing, of a sufficient length to suffer the brass to contract and dilate freely by heat and cold under the heads of the screws: *ecce* represent the ball of the pendulum; *f, f*, two strong pieces of steel, or levers, whose inner centres, or pivots, turn in two holes drilled in the broad part of the pendulum rod, and their outer ones in a strong bridge, or cock, screwed upon the same part of the rod, but omitted in the figure, to shew the mechanism: *g, g*, are two screws entering at the edges, and reaching into the cavity near the centre of the ball. The ends of the screws next the centre are turned into the form seen in the figure, which, pressing with the weight of the ball against the longer arms of the levers, cause the short ends to press against the brass bar at *b*. Things being in this situation, let us suppose that the rod of the pendulum, and the brass annexed to it grow longer by heat, and that the brass lengthens more than the iron of the same length; then the brass, by the excess of its dilation, will press the short ends of the levers downwards at *b*, and at the same time necessarily lift

up the ball, which rests on the long ends of the same lever, at *ff*, to any proportion necessary for due compensations. The calculated proportion of the short arms of the levers must be to the long ones, as the excess in the expansion of brass is to that of the whole length of iron; and if this calculation be found on trial not perfectly accurate, the slide screws *g, g*, will produce the exact compensation at a few adjustments. At *ik*, the inferior end of the iron verge, a strong double spring is fixed to bear the major part of the ball's weight, by its pressure upwards against two points of the ball, equidistant from the vertical line. This is the description of the first pendulum made in this way, and the only alteration that the inventor made afterwards was placing the slide screws in the body of the ball.

Cumming, after describing this pendulum in his *Elements of Clock and Watch-work*, proposes that the brass bar should elongate between two iron bars, in order to keep it straight, and to prevent the jerks to which he conceives Ellicott's construction is still liable, from friction impeding the free elongation of the brass bar, and from a consequent tendency to curvature before each jerk: he has also proposed to alter the structure of the short arms of the levers, by making them turn each on an axis of motion, and to change their places of pressure mutually, in order that their united action may be applied in the same point, at the centre of the brass bar, in direct opposition to the line of downward expansion; and we entertain no doubt but that the proposed alterations, once adopted, would be found to be real improvements in Ellicott's pendulum. See Cumming's *Elements*, page 106, and plate xi.

Rhomboidal Pendulum.—Mr. Hooke proposed to make a compensating pendulum of rods of steel and brass arranged into the form of a rhombus, or rhomboid, the four sides of which were of steel and the long diagonal of brass: this construction, requiring the pendulum to be broader than long, was found to be very inconvenient, and was therefore never applied to a clock. But the principle was afterwards taken up by a clock-maker at Ulverston in Lancashire, named Williamson, or Williams, who, about the time that Ellicott constructed his pendulum, made several pendulums, not however of one rhombus each, but of five united by joints at the angular points, opposed to the diagonals of brass; so that as the brass elongated more than the steel, the angles opened and kept the diagonals always at the same distance from the said angular points, and from each other. Mr. Edward Troughton also, without knowing what had been done by Williamson in this way, contrived and made a pendulum similar to his in all respects, except that seven rhombi were adopted instead of five, which narrowed the pendulum still more than Williamson's construction, and which answered its intended purpose very well. We believe this construction is very little known at the present day, and, therefore, we beg leave to give a sketch of its arrangement in *fig. 2. of Plate XL.*, which will be sufficiently understood from inspection. We have not calculated the proportions necessary for the sides and common bases of the triangles which compose these rhombi, so that the compensation may be complete; but any one competent to construct this pendulum will easily ascertain by calculation the due proportions.

Compensating Pendulum of F. Berthoud by Frames.—When Berthoud had finished his experiments on the relative expansions of metals in 1760, which was three years before Harrison had published his pamphlet relating to his pendulum, he contrived a compound pendulum, much resembling Harrison's grid-iron at the first appearance, and which is constructed to answer the same purpose. He had previously noticed

PENDULUM.

noticed that Deparcieux's improvement of Regnault's pendulum, and also his own, where the lever was introduced, were not calculated to support a heavy pendulum with steadiness; he therefore employed his mind in contriving one, by which any weight might be suspended, that might be found desirable to move in small arcs. This pendulum, or rather a sketch of it, is contained in *fig. 3. of Plate XL.*, in which the oblong frame, surrounding the other parts, and denoted by the letters *a, b, c, d*, is of steel; the upper end of which carries the knife edge suspension at *s*; *e f g h* is a second frame, open at the top, and made of brass; the horizontal portion, *e f*, rests on the interior part of the lower end of the steel frame above the ball; the upper ends do not reach the whole length of the surrounding frame, but allow another frame of steel, *i n m n*, to rest on them, by means of their chin-pieces, at their upper extremities; again, *o* and *p* are two rods of brass resting on the inferior part of the horizontal connecting piece, *i n*, of the second steel frame, and at their upper ends support a single steel rod, with a chin at each side, which rod descends in the middle of the pendulum, and holds on its lower end the ball, after it has passed through holes made in the three frames above described. In this construction, as in Harrison's, it is easy to see, that the difference of the ascending expansions of the brass frame and rods, and of the descending expansions of the steel frames and middle rod, constitutes the compensation for the effects of variable temperature; and if the sum of the lengths of steel are to the sum of the lengths of brass inversely as their expansions, the compensation will be perfect.

For the particulars relating to the suspension, and metallic thermometer of a pendulum, made agreeably to this arrangement, we beg to refer our readers to Berthoud's own account, and to the corresponding engravings. See *fig. 1. of plate 28. of Essai sur l'Horlogerie*, and *fig. 1. of plate 10. Histoire de la Mesure du Temps*.

Troughton's Mercurial Pendulum—When Graham's mercurial pendulum had been many years in use, and had performed in the most satisfactory manner, some prejudices were without reason raised against it, originating more in fancy than from experience, and Mr. Edward Troughton, about the year 1790, with a view of doing away the most material prejudice, contrived a modification of the mercurial pendulum, which may be considered as a distinct pendulum, inasmuch as that the materials are differently arranged both as to quantity, quality, and situation. An idea prevailed that the metallic rod of Graham, and the vessel of mercury, would not be affected by changes of temperature in a contemporaneous manner, but that the mercury being below the rod, and having on that account a quicker motion, would cool sooner than the metallic rod, and be moreover liable to more frequent changes from its greater susceptibility, notwithstanding the testimony of a long trial to the contrary; Mr. E. Troughton therefore substituted a strong glass tube with a bulb at the lower extremity, to be filled to a certain height with mercury, which should rise and fall precisely as in a thermometer, which instrument, in fact, his tube is; and to make it useful as such, it carries a graduated scale. The tube in question is about the size of a barometer tube, and the bulb large enough to contain 45 ounces of pure mercury, by the aid of one-half the tube. *Fig. 4. of Plate XL.* will explain Mr. Troughton's arrangement more clearly than a mere verbal description. *A B* is the mercurial rod filled with mercury to the middle point of the rod; at *A* the suspension is similar to that described in Messrs. Brockbank's astronomical clock, (see *CLOCK*,) where Troughton's tubular pendulum is described, with a reference to *Plates XXIII. and XXVII.*: *C D* is the bulb guarded by the surrounding

lenticular bob of brass and lead made in the usual way, except that it is made hollow at the centre; the metallic parts of the pendulum weigh about nine pounds exclusively of the mercury; the rim that surrounds the bulb, and by which the weight of the lenticular bob is supported, projects into two notches cut in the interior edges of the metallic lens, at each side of the cavity, and the nice fitting of the bulb to its rim, renders the glass capable of bearing the weight of metal supported by it. The compensation of this pendulum is effected entirely by the ascent and descent, alternately, of the mercury up and down the glass tube as the heat varies, and as the expansion of glass is much less than that of any of the metals, the small column of mercury contained in the tube is found sufficient to answer its purpose completely, after a trial of more than twenty years. Indeed this pendulum has proved itself equal, if not superior, to any of its predecessors, and the difficulty of the construction is perhaps the only objection why it is not more generally adopted, particularly in situations where there is no risk of carriage. We cannot dismiss our account of this pendulum, of which fort only a small number has been constructed, and of which no account has been before publicly given, without mentioning a curious property in it, known only perhaps to the contriver and to the writer of this account, which is, that if the column of mercury be made to reach either above or below the middle of the pendulum, at a mean temperature, the pendulum in either case will be *under-compensated*; but when the column reaches to the *middle exactly*, at a mean temperature, the compensation is *exact*; that is, the compensation has the greatest effect when the column reaches to the middle of the pendulum, which the inventor, we understand, foresaw would be the case, and calculated his dimensions accordingly.

Dr. G. Fordyce's Compensation of the Simple Pendulum, and others of a similar Construction.—The compensation described in the Philosophical Transactions of 1794, as the invention of Dr. G. Fordyce, is not attached to the pendulum, but to the cock of suspension, in this respect like that of Deparcieux, contrived in 1739, from which it probably was borrowed. The original pendulum of Dr. Fordyce, as altered from Whitehurst's, is now in the possession of Gen. Bentham, from which an universal standard of linear measure was attempted to be taken, and from which, as a model, some few others have been made. In *fig. 5.* of our last plate, let *A B* represent the back of the clock case, to which a tube of brass may be attached at its lower end, of such length as to compensate the verge of the pendulum, which is a long slender spring. Near the top of this tube is a bracing piece, *C*, in form of a clamping tube, through which it passes without play or friction, and by which it is kept fast to the back of the case. The upper end, *A*, carries the cock of suspension and a counterpoise to the pendulum, and under it is fixed fast to the clock frame a second cock of limitation, for the spring of suspension to be received in, and by which the effective length of the pendulum is limited. (For a minute account of this apparatus, see Nicholson's Journal, 4to. ed. vol. iii. p. 20.) The theory of this pendulum is, that as the fixed tube behind the clock case lengthens by expansion in heat, the steel pendulum, though more expanded, will be shortened in the same proportion by the upward motion of its spring and cock of suspension above the cock of limitation; and if the wood of the clock case were unalterable by heat or moisture, this theory would be a good one, but as it takes no notice of the material to which the fixed rod is attached at its lower end, the actual compensation amounts to no more than the difference between the expansion of metal and wood gives;

PENDULUM.

or in other words, it does no more so circumstanced than a wooden pendulum would do applied in the common way. But inaccurate as the compensation we have described must necessarily be, where the compensation tube is relying on another body not taken into the account; yet Mr. John Crothwaite of Dublin has described a pendulum of his invention, in the Transactions of the Royal Irish Academy, as being a superior pendulum, which differs in no respect from Dr. Fordyce's, except that the fixed rod of compensation is sold as well as the verge, and is supported by a bracket carried by a large piece of marble, and like Whitehurst's clock, has cycloidal cheeks near its spring of suspension. Likewise the Rev. J. Pine of Eastdown, near Barnstaple in Devonshire, has described in the 3d vol. of the Repository of Arts, &c. a pendulum similar in all respects to Mr. Crothwaite's, except that the cycloidal cheeks are omitted, and *spiral springs* applied to raise and lower the cock of suspension as the rod of compensation directs, which must be less steady than the original method of Dr. Fordyce.

Berthoud has described a method of compensating a simple pendulum in his "Histoire de la Mesure du Temps," tome ii. p. 84, fig. 2. plate 11, which is not liable to the same objection as the preceding ones; for he has not allowed any substance to be a part of his mechanism, if it is his own that he describes, but what is taken into the account; a frame of three bars, the middle one of steel, and the two extreme ones of brass, all fastened at the bottom to a cross piece, and the brass ones also at their tops to another cross piece, constitutes the compensation in question; the upper cross piece, or end of the frame, is fixed to the back plate of the frame that holds the wheels, and consequently the brass rods elongate downwards, while the single steel rod elongates upwards in a smaller quantity; it is not however fast to the cross piece, but passes through it, and carries a pin acting against one end of a double lever, that has its centre of motion on the cock of suspension, while the other end of the double lever bears the pendulum. The consequence is, that while the brass rods lengthen downwards, they take the steel rod with them as far as is equal to the difference of their respective expansions, and the contiguous end of the lever, which has a counterpoise for the pendulum, falls with it, and lifts the pendulum verge at the remote end of the double lever the requisite quantity for compensation of the simple rod: and this quantity is determined by an adjusting screw, altering the centre of motion between the two opposite ends of the double lever. This construction seems to possess all the requisites of a good compensation, except that the frame is not in motion.

Troughton's Tubular Pendulum of different Metals.—We have already described two pendulums of Troughton's contrivance, both of which answered their purpose of being good regulators, and hence it may be matter of surprise, why the same man should contrive a third, very different in its construction from either of the former. But pendulums which may be equally good regulators of a clock, when properly adjusted, are not equally capable of ready adjustment, particularly for variations of temperature, after they are brought to a mean time. All the pendulums which we have hitherto described required their adjustments for temperature to be made from a trial of their going in summer and winter, and eight or nine months waiting between each adjustment was an interval inconveniently long for an astronomer, who was anxious to pursue his observations; Mr. Troughton therefore, whose numerous contrivances are generally so many improvements in the mechanical arts, converted the grid-iron pendulum into a tubular one, which has all the accuracy of the old pendulum, and at the same time

all the simplicity of the external shape of the simple pendulum. This pendulum has its compensation examined, and its compensating mechanism adjusted by means of the inventor's new spirit-level pyrometer, without any trial for rate in the opposite extremes of temperature, and that as soon as it has been roughly adjusted to mean time. This saving of time, and of a repetition of adjustments, is a great improvement in the art of clock-making, and when generally known and adopted will enable the maker to send home his machine perfectly adjusted in the short space of a few days, whereas the old method of adjusting for temperature, from observations repeated at distant intervals, required as many months, and in some cases even years. Our *Plate XXVII. of Horology*, exhibits a variety of figures illustrative of the arrangement of the different parts of Troughton's tubular pendulum, and in our description of *An Astronomical Clock with Troughton's Pendulum*, under the head *CLOCK*, a minute account is given of the construction, to which our readers are desired to revert. It is asserted in the British Encyclopedia, that Finny of Liverpool, and Chandler of Seven Dials, London, both constructed tubular pendulums, very similar to Troughton's, many years before 1804, which is the date of Mr. Troughton's publication of his, in Nicholson's Journal; but as the arrangement of the two metals is not the same as in Troughton's construction, nor was known to him previously, this circumstance, if true, does not detract from his merit, as it regards the invention in question. Indeed we happen to know, that no tubular pendulum is at present, nor ever was, at the Richmond observatory, formerly superintended by M. de Mainbray, as stated in the article above referred to.

Ward's Compensation Pendulum.—In March of the year 1806, Mr. Henry Ward, of Blandford in Dorsetshire, communicated to the Society of Arts at the Adelphi, an account of a new compensation pendulum, accompanied by a model, which gained him the silver medal from the society. This pendulum consisted of three bars, two of iron and one of zinc, arranged in a manner very similar to Deparcieux's improvement of Regnault's old French pendulum, but without the lever of adjustment. The representation is given in *fig. 6.* of our last plate, where *bb* and *ii* are two flat rods of iron or steel, about half an inch wide and an eighth of an inch thick each; and *kk* is a rod of zinc, of nearly a quarter of an inch thick, interposed; the two extreme iron rods are cranked, one at the top to receive the suspension spring, and the other at the bottom to hold the ball in the same vertical line with the zinc rod. These three parallel rods are united by four screws, *l, l, l, l*, which passing through oblong holes in the bars *bb* and *kk*, screw into the rod *ii*, while the rod, *bb*, is fastened to the zinc one, *kk*, by the single screw *m*, near its lower extremity, which screw is the screw of adjustment for temperature, and requires several holes to be made in the bar *bb*, and also in *kk*, that the length of the zinc bar may be limited to its due proportion for exact compensation. The iron bar, *ii*, rests by a chin-piece on the upper end of the zinc bar, and therefore the ball supported by its lower tapped end stretches all the bars equally. If the zinc bar had rested on the crank at the bottom of the bar *bb*, instead of being held by the screw *m*, the arrangement would have been the same as in Deparcieux's, but with zinc substituted for brass, which consequently does not require the aid of a lever to increase its effect. The proportional expansions of zinc and iron were taken for this pendulum from Smeaton's table in the 48th vol. of the Phil. Trans. of London, and were made for hammered zinc as 373 : 151; but subsequent observations on the rate of the clock, to which the pendulum was applied, proved

PENDULUM.

proved that the expansion of the hammered zinc was greater than Smeaton's table gives it, though the quantity was within the reach of the adjustment.

In Nichol'son's Journal, 8vo edit. (vol. vii. page 300.) there is a notice of a similar pendulum by Benzenberg, where one rod of lead is introduced to compensate two rods of iron, but no drawing is given. For the original see Voigt's Magazine, vol. iv. page 787.

Compensation Pendulum by Adam Reid.—Another compensation pendulum, made by Mr. Adam Reid of Woolwich, was presented to the Society of Arts in April 1809, and the inventor was rewarded with fifteen guineas for his contrivance and model. This pendulum is given in *fig. 7.* of our last plate, and has its compensation of a tube of zinc acting on the ball from the lower end of the steel verge thus; A B is the steel verge, made a little thicker where it enters the ball C, and also of a lozenge shape, to prevent the ball's turning, but above and below it is cylindrical; near the centre of the ball is a shoulder in the verge, against which the upper end of the zinc tube D presses the cross piece of the ball when the nut E is turned up close to its lower extremity, but when the nut is turned back, in adjusting for rate, the tube descends a little, and the ball with it, while it rests on the upper extremity of the tube. When the compensation is too much, the tube may be shortened till it is found of the exact length, by a trial of the rate in extremes of temperature. In the figure before us the length of the zinc tube does not appear sufficiently long to compensate an entire verge of steel. The inventor observes that platina might be substituted for steel, and steel for zinc, for the formation of this kind of pendulum, but that the expense would be enhanced by the dearth of platina.

Doughty's Compensation Pendulum.—Mr. Thomas Doughty, of Charles-street, Somers-town, favoured us, in January 1811, with a sketch and short description of a compensation pendulum invented by him on the principle of flexure, by a compound bar that is applied to draw up the pendulum's ball in hot weather, after the manner of Mr. W. Nichol'son's, which we shall notice presently. *Fig. 8.* of the same plate to which we have lately referred, represents this pendulum in its reduced state; A is a compound bar of steel and brass foldered together, with the steel uppermost; the length of which is ten inches, the breadth half an inch, and thickness four-tenths; the steel portion being $\frac{1}{8}$ th of the whole; it is curved with the concave face downwards, the point E above the ball being the centre of curvature. Above this bar, and connected with it at the middle, rises the brass bar B, six inches long, to which the spring of suspension is fast, and which receives the impulse from the crutch at the point 8. C, C, are two similar sliding heads of brass, tapped to receive each a screw and saddle-piece to fix them in any given part of the compound bar: by means of two clock springs these heads are attached to the side rods D, D, of steel, each $\frac{1}{4}$ th of an inch wide, and $\frac{1}{8}$ th thick, which rods are again attached to the iron flat piece E by similar springs, while the flat piece passes through the ball and receives the nut of adjustment for rate. The compensation is effected thus; while the brass piece B, and the steel side rods D, D, elongate by heat, the curve of the compound bar, A, becomes more and more approaching towards a straight line, by the superior expansion of the brass portion, and this alteration of figure lifts up the ball of the pendulum a corresponding quantity; which quantity is regulated by the distance of the heads C, C, from the middle of the compound bar; the greater distance being always accompanied by a greater effect of the compensation,

and *vice versa*; but in making this adjustment care must be taken that the clock be not put out of beat, by moving one head more than the other; but if the clock is already out of beat, this adjustment may be used also as an adjustment for beat, at the time of adjusting for temperature. The springs are used for the purpose of preventing friction during the variations of temperature, but we suspect that there will be another consequence, not so favourable to the regular motion of the pendulum as might be wished; which is, that when the impulse is given from the maintaining power at the point 8 of the brass bar B, the springs, both near C C and E, will *yield*, or bend a little, before the heavy ball will be urged, and thereby require a greater power to keep the pendulum in motion than would be necessary without such springs; and also the ball and the rods will not begin and end their vibrations exactly in a contemporaneous manner, which circumstance, without very nice equipoise of the side rods, will produce a vacillation in the ball. Ritchie's pendulum, however, which follows, and which was intended to remedy the faults of this, is liable to the same objection, though his sliding adjustment for temperature will not interfere with the adjustment for rate, as must be the case with the pendulum before us; for bringing the upper ends C, C, of Doughty's side rods nearer together lengthens the effective length of the pendulum, thereby requiring a new adjustment for rate. The inventor heated a small room with steam till the adjustment for temperature was found complete, which turned out to require eight out of the ten inches of the compound bar to make this adjustment perfect.

Ritchie's Compensation Pendulum, and Nichol'son's.—In March of the year 1812, Mr. David Ritchie, of Clerkenwell, laid before the Adelphi Society, also, a model of a compensation pendulum, for which he received, as a reward, twenty guineas. The compensation in this pendulum was effected by means of the flexure of two compound horizontal bars interposed between the verge and the ball, which, like Doughty's, act on the same principle as the compound bars in the ordinary compensation balances of a chronometer. *Fig. 9.* represents the pendulum at present before us, in which A is the spring of suspension, B the ball, and C the steel verge as usual, with the nut of adjustment for rate at E, below the ball. The compensating bars are F and G, the upper part of F and the lower part of G being steel, and the other parts brass; so that any additional heat may bring the bars nearer together by the convexity of the brass faces of the compound bars being contiguous. These compound bars have each a sliding piece above and below *e* and *f* respectively, by the sliding of which the bars may have their effective lengths altered, in the adjustment for temperature; and are connected by the slender springs *e* and *f*, which bear a portion of the ball's weight; the remainder being borne by the springs *l* and *m* attached by screws at *b*, one to the verge piece *d* and the other to the ball piece *b*, while they themselves are united by screws at *l* and *m*. The compensation frame, so constructed, is adjusted by sliding the compound bars, before they are fixed, till the centre of the ball falls in the vertical line of the verge, where the screws at *b* fix it for trial. The impression on our mind, from a contemplation of this construction, is, that when the crutch of the clock urges the verge, the ball will not move with it till the springs *e* and *f* are bent a little, for when the ball is heavy, as is now customary in seconds pendulums, its weight will place a great stress on the slender springs that connect it with the verge, and produce, probably, a vacillation, as in Doughty's, that must be very unfavourable to isochronism,

isochronism, even allowing the compensation to be perfect. It was to avoid this evil, that Mr. Nicholson placed a similar compensation bar on the cock of suspension above the verge of his pendulum, and also above the cock of limitation, as seen in *fig.* 10. but without any spring, and in this situation the varying curvature of the horizontal compound bar, E E, altering the length of the suspension spring, produced the alternate rising and falling of the ball, as the verge carried it in an opposite direction, so that the centre of oscillation was comparatively stationary. (See *Phil. Journal*, vol. i. 4to. ed. plate 5. *fig.* 3.) The alteration in the length and strength of the spring of suspension is, however, an objection to Nicholson's construction. The same author also contrived a compensation pendulum composed of four rods of steel and one of a compound, or alloy, of zinc and silver, which is described in vol. ii. of his 4to. *Phil. Journal*. (See page 205, and plate 9.) But as there are eight figures necessary to explain the fittings of the different parts, and as the work is in every one's hands, we will satisfy ourselves by referring our readers to the author's own description.

Hardy's Compensation Pendulum.—Mr. Hardy of Clerkenwell, whose ingenuity and good workmanship have given him a high rank among chronometer makers, has lately contrived a compensation pendulum that partakes partly of the grid-iron class, and partly of Ellicott's, and that promises to be exempted from the jerks that have been imputed to the other constructions during the elongations and flexure of the bars. It was our intention to have given a drawing of this pendulum, but our plates of pendulums are full; and as the pendulum before us has not yet been applied to a clock, we will consider it as a project rather than as an approved pendulum. It is, however, completely finished. It consists of five parallel bars, the three middle ones of steel, and the two extreme ones of brass; there are two cross pieces at top, and as many at bottom, to connect the longitudinal bars, and the lowest carries a pair of small levers, on the remote ends of which the brass bars act as they elongate downwards, but the centres of their motions are springs, like those in the inventor's compensation balance, which balance performs very well; the ball is attached to the interior ends of the said levers by other springs, and a spiral spring acts near the top of the middle steel lever to carry a part of the ball's weight, in order to let the springs near the ball act without having too much stress on them. The excellence or defect of this pendulum must be proved by future trials.

Recapitulation of the principal Properties of a Pendulum.—As the various properties of, and circumstances relating to, the pendulum, have been treated of under different heads in this work, we will conclude our present account by recapitulating the principal of them in a succinct manner, thereby condensing the substance that is necessarily diffused over our work into regular order and a narrow compass.

1. The theory of a pendulum's motion is derived from the uniformly accelerative force of the gravity of its bob, considered as having all its weight concentrated into one point.

2. If such bob could be made to descend down the chord of its semi-arc of vibration, and to ascend up the chord of the other half, its long and short semi-vibrations would be performed in the same time, namely, in the time that would be taken up in falling through half the length of the pendulum, and the velocity at the lowest point would be as the length of the chord.

3. A pendulum cannot be made to move in the chords of

a circle, but will necessarily move in the arcs when suspended by a cord or rod.

4. The longer arcs of vibration require more time than the shorter ones, when those arcs are circular.

5. In that peculiar curve called a *cycloid*, or by the French a *roulette*, a semi-vibration is performed in the same time, whatever be the length of the arc, namely, in the time that would be taken up in descending down the chord of a corresponding arc of the generating circle.

6. The axis of a cycloid is equal to the diameter of the generating circle; the straight line passed over in the generation is equal to the circumference; and the whole cycloid equal to twice the circumference of the said circle.

7. The time of a semi-vibration in a cycloidal arc is to the time of the bob's descent down the axis of the cycloid, as a *quadrant* of a circle is to its *radius*; therefore the time of a whole cycloidal vibration is to the time of the fall down the axis as a *semi-circle* is to *radius*; or as the *circumference* of a circle is to its *diameter*.

8. The involute of a cycloid is itself a cycloid in every respect similar to the cycloid evolved.

9. Any cycloidal arc is equal to *twice* the corresponding chord of the generating circle; and therefore the axis of the generating circle is equal to half the arc of the whole semi-cycloid; hence a cord representing the length of a pendulum, evolved from contact with a semi-cycloid, till it rests at the vertex, must be *double* the length of the axis of the generating circle, and will move in a semi-cycloid.

10. Therefore the time of a pendulum's vibrating in a cycloidal curve is to the time of its bob's descent down *one-half* of its length, as the circumference of a circle is to its diameter.

11. Hence Huygens placed two portions of separate semi-cycloids, with their curves opposed to each other, and with their vertices nearly in contact at the point of suspension, that the thread of suspension might be evolved, first from one, and then from the other alternately, in each semi-vibration, in order to make all the vibrations, of whatever length, isochronal.

12. The theory of this contrivance was admirable; but it supposed the action of the pendulum's gravity to be sufficient to maintain the continuance of the vibrations, as well as all the ponderous matter collected into one point; likewise the centre of oscillation to be in the same point with all lengths of the cycloidal cord; and also the cord itself to be invariable in length, as well as perfectly free from rigidity; all which suppositions, not founded in nature, proved so many impediments to the practical adoption of the cycloidal checks for an *attached* or going pendulum, where external force is necessarily superadded to that of gravity, and where the centre of oscillation does not coincide with the centre of gravity.

13. But *small circular arcs* are so nearly coincident with cycloidal arcs near the vertical line, or line of quiescence, that they may be substituted for the latter, where they do not exceed 4° , without sensible error.

14. Hence the time of a vibration in *small circular arcs*, is to the time of the bob's falling down half the pendulum's length, *very nearly* as the circumference of a circle is to its diameter, which, in cycloidal arcs, has been shewn to be exactly so.

15. An escapement for *short arcs*, therefore, became necessary, when the cycloidal checks were laid aside, which acted with the *crown-wheel* escapement (an escapement adapted for long arcs), and Clement or Hooke contrived the *anchor-escapement*, which gave the pendulum,

vibrating in short arcs, the name of the *royal pendulum*, from the noble property it possesses as a regulator. [Query, was not the sign of the *crown* and *anchor* of horological origin?]

16. As the momentum of a pendulum is composed partly of ponderous matter, and partly of velocity, the reduction of the arc of vibration produced a necessary addition to the weight of the bob.

17. The times of vibration of pendulums of different lengths will be always directly to each other as the *square roots* of their respective lengths, where the accelerative force is constant and unaltered.

18. When pendulums of the *same length* vibrate with *different forces*, the times will vary inversely as the *square roots* of the *accelerative forces*.

19. The lengths of pendulums, vibrating in the *same times*, vary directly as the *forces* which accelerate them.

20. The times of vibration of pendulums of *different lengths*, acted upon by *different accelerative forces*, will vary as the square roots of the *lengths* directly, and the square roots of the *forces* inversely.

21. Hence the same pendulum will not vibrate in precisely the same time in all latitudes, where the force of gravity varies.

22. Nor will an attached pendulum, continuing to vibrate by the aid of some external force added to gravity, vibrate, even in the same latitude, in the same time as a detached pendulum vibrating by the force of gravity alone for a limited period.

23. Pendulums acting with different escapements, or having otherwise different maintaining powers, will therefore vary a little in their *lengths*, though they measure the same time, and even move in the same arcs.

24. External force, from the maintaining power, may be added to gravity, either instantly or gradually, for a longer or a shorter time, uniformly or variably, and commencing or ceasing to act at any given point of the vibration; or it may be applied to act in conjunction with gravity during the whole vibration; all which modes will require so many corresponding lengths of pendulum to vibrate in the same time.

25. Hence originated all the variety of escapements that act with the pendulum, and modify the maintaining power, by giving their impulses differently, as to place, quantity, quality, and duration.

26. That mode of giving the impulse is best, which either deranges the action of gravity least, or acts most in conformity with it.

27. When the same pendulum is by any cause made to vibrate in *different arcs*, the daily error, or difference, in seconds of time, will be $\frac{1}{108000}$ ths of the difference of the squares of those arcs, reckoned in degrees and parts of a degree.

28. A vibrating pendulum may have its arcs altered, not only by a variation in the additional force, or maintaining power, but may be so attracted by a contiguous heavy body, particularly if homogeneous, that its arc of vibration may be either enlarged or diminished by the position of the said body: if placed near the line of quiescence, the arc may be shortened; but if placed beyond the extremity of the arc, it may be enlarged.

29. If the point of suspension be not firmly and immovably fixed, a slight motion in it will have the same effect on the time, as lengthening the pendulum, though the maintaining power be the same; and if the points of suspension of two pendulums be contiguous, and be attached

to the same shelf or yielding substance, they will continue to vibrate *together*, though they are not exactly of the same length, nor adjusted precisely to the same time. *This curious property is observable in either the detached or attached pendulums.

30. When the pendulum is taken as an universal standard of *linear measure*, as well as of time, the experiments to ascertain the exact length of a seconds, or half-seconds pendulum, must be made always in the same latitude, on the same level, and in a detached state if possible, or otherwise the result will be affected by all or several of the variety of circumstances, which we have had occasion to consider as influencing the length of the vibrating pendulum.

31. That compensation-pendulum may be accounted the best, that changes its rate least throughout the year, provided that its adjustments can be conveniently made.

PENEDON, in *Geography*, a town of Portugal, in the province of Beira; 19 miles N.E. of Viseu.

PENELLA, a town of Portugal, in the province of Beira; 15 miles S.E. of Coimbra.

PENELOPE, in *Mythology*, the mother of *Pan* (see his article) by the god Mercury. She was the daughter of Icarus, who lived at Athens in the time of Pandion II., and had offers of marriage from several princes of Greece. Her father, to prevent quarrels that might have happened, obliged them to contend for her in the games, which he caused them to celebrate. Ulysses was the conqueror, and gained the lady for his prize. (Pausan. in Lacon.) After this marriage had been solemnized, Icarus used his utmost efforts to prevail with his son-in-law to stay with him at Sparta, where he was settled; and despairing of being able to persuade him, he conjured his daughter not to forsake him. Ulysses, tired with these importunities, referred the matter to the determination of his wife, leaving her at liberty either to accompany him to Ithaca, or to remain with her father. Penelope blushed at this speech, and answered only by covering her face with a veil. Icarus, understanding this dumb language, consented to her going with her husband; but moved by her graceful confusion, consecrated a statue to "Modesty," on the spot where Penelope had put a veil over her face. Penelope has been always considered as the most perfect model of conjugal love; but Bayle and some other authors have ridiculed the idea of her having been made a model of chastity, when it is alleged, that she suffered herself to be debauched by some of her lovers, who were always about her during the absence of her husband, and that she was expelled by him from Ithaca, whence she repaired first to Sparta, and afterwards to Mantinea, where she ended her days.

PENELOPE, in *Ornithology*, a genus of birds of the order Gallinæ. The generic character is this; bill naked at the base; head covered with feathers; clun naked; tail with twelve feathers; legs without spurs. There are four

Species.

CRISTATA, or Guan. Head with an erect crest, temples violet. It inhabits Brasil and Guiana, and is about 30 inches long. It is frequently tamed, and its flesh is reckoned very delicate. It utters a sound something like the word Jacu. The other characteristics of this species are, a black bill; irides orange; nostrils reaching from the middle of the bill to the front; orbits violet; caruncle on the chin compressed, red, covered with a few hairs; crest oblong; body black-

black-green; back brown; neck, breast, and belly, spotted with white; legs red.

CUMANENSIS; JACU or YACOU. Blackish; crell and first quill-feathers white. It is about the size of a hen turkey. It is found in Cayenne and Guiana. It erects its crest, expands its tail, and cries in a mournful tone, like a young turkey. It builds on the ground, is easily tamed, and is often domesticated.

PIPILE; Piping Curassow. Caruncle on the chin blue; belly black; back brown, spotted with black. Like the last it is found in Cayenne and other parts of South America. The voice is weak and piping.

MARAIL; Marail Turkey. Greenish-black; naked orbits and legs red; throat nakedish, speckled with white. It is the size of a common fowl, and not dissimilar in shape. Though not much known to naturalists, it is common in the woods of Guiana, at a distance from the sea. It is generally seen in small flocks, excepting at breeding time, when it is only met with in pairs, and then frequently on the ground, or on low shrubs, at other times on high trees, on which it roosts during the night. The female builds her nest on some low bushy tree, as near the trunk as possible, and lays three or four eggs. When the young have been hatched for ten or twelve days, they descend with the mother, which scratches on the ground like a hen, and broods them, till they can shift for themselves. They breed twice a year. The young birds are easily tamed, and seldom forsake the places in which they have been brought up. Their cry is not unharmonious, unless they are irritated, when it is harsh and loud. Their flesh is good for food, and highly esteemed.

PENELOPE, a species of *Anas*. See **DUCK**.

PENEO, in *Geography*, a river of Thessaly, which runs into the Ægean sea; 20 miles E. of Larissa.

PENETRABILITY. See **IMPENETRABILITY**.

PENETRALE, among the Romans, properly denoted the chapel consecrated to the *penates*, or household gods.

PENETRATION, **PENETRATIO**, the act whereby one thing enters another, or takes up the place already possessed by another.

The schoolmen define penetration the co-existence of two or more bodies, so that one is present, or has its extension in the same place as the other.

Philosophers hold the penetration of bodies absurd, *i. e.* that two bodies should be at the same time in the same place; and accordingly, impenetrability is laid down as one of the essential properties of matter. See **MATTER**.

What we popularly call penetration only amounts to the matter of one body's being admitted into the vacuity of another. Such is the penetration of water through the substance of gold.

The theory of the penetration of bodies is of great importance in military and naval affairs, the object in all cases of battery being to communicate the greatest possible momentum to the obstacle intended to be destroyed, whether it be the gates of a fortress, or the sides of a vessel; or rather we would say, that the effect to be produced should be the greatest possible, and which, it is well known, depends in a great measure upon the proper charges employed. If the charge be too small, the velocity being also proportionally small, the momentum thus communicated may fail to produce the desired effect; and again, if the charge and velocity be too great, that is, if it be such that the impinging ball passes quite through the opposing obstacle, the momentum communicated to it in this case will also be less than if the ball had lodged within it. This may be illustrated by setting up a thin deal board upon its edge, and firing a ball through it from a musket or pistol, which if the charge be at all con-

siderable, may be done without throwing down the board, whereas the same ball cast from the hand against it would infallibly produce that effect. The reason for which is, that notwithstanding the great momentum of the ball in the former case, the time of its passage is so short, that the product of the momentum into the time (which is the measure of the effect) is so small, as not to be sufficient to overcome the natural gravity of the plank. The same thing is observed in naval actions, many balls passing completely through the sides of the vessel, the shocks of which are by far less than those which lodge within them, or than those which barely pass through, and similar effects are observed in the practice of land artillery, particularly when the opposing obstacle is wood, as in the gates, &c. of fortified places. See Moore's "Treatise on Military Rockets, &c."

These circumstances have induced most authors on gunnery, to consider the penetration of bodies as part of their subject, and various experiments have been instituted in order to furnish dates for this purpose. Of these authors, Robins and Dr. Hutton have made the greatest number of experiments, and particularly the latter, an ample account of which is given in vol. iii. of his *Treatise*, from which we have selected the following small tablet, exhibiting the velocity and diameter of the ball, the penetration, &c., each case, as stated below, being a mean of a great many experiments made with the same ball, or with equal balls, and with equal charges.

Velocity.	Substance.	Diam. of Iron Ball.	Penetration in Inches.
1600	Elm	1.96	20
1200	Elm	1.96	15
1500	Elm	2.78	30
1060	Elm	2.78	16
1200	Oak	5.04	34
1300	Earth	5.50	180

In all these experiments the gun was placed within such a distance of the obstacle as not to affect the initial velocity of the ball, and the penetration was made in the direction of the fibres, the wood perfectly sound, and cut off near the root of the tree. Now in order to make this table applicable to other cases, *viz.* when the diameter and density of the ball, and the projectile velocity are different from those above stated, we may proceed as follows.

Let d represent the diameter of the ball.

f , the height of a column of water equal to the resisting force of the obstacle, considering it as uniform.

n , the specific gravity of the ball, that of water being 1.

v , the velocity of projection.

$a = .7854$, the area of a circle to diameter 1.

Then $a d^2$ will be the area of the section, $a d^2 f$ the resistance, and $\frac{2}{3} a n d^3$ the weight of the ball; so that the resistance will be to the weight of the ball as $a d^2 f$ to $\frac{2}{3} a n d^3$,

or as f to $\frac{2}{3} n d$; that is, as $\frac{3f}{2nd}$ to 1, or gravity. Now the

velocity generated or destroyed by gravity in describing any space s , is $8\sqrt{s}$, thus found, as $\sqrt{16} : \sqrt{32} :: \sqrt{s} : 8\sqrt{s}$; and when the space is the same, the velocities generated or destroyed, are as the square roots of the forces, or the forces are as the squares of the velocities, and the velocity destroyed by the force

$\frac{3f}{2nd}$, in describing the space s , being

PENETRATION.

s , being v ; therefore $t : \frac{3f}{2nd} :: 64s : v^2$; hence $\frac{3f}{2nd} = \frac{v^2}{64s}$; consequently $f = \frac{nd}{3} \times \frac{v^2}{32s}$; and $s = \frac{ndv^2}{96f}$.

Hence it appears, that the depth penetrated is as the density and diameter of the ball, and the square of the velocity, divided by the strength or resisting force of the obstacle. So that if equal balls be discharged against the same obstacle, then shall the depths of penetrations be as the squares of the velocities, which pretty nearly agree with the experiments above stated. Hence also it follows, that if unequal balls, but of the same density, be discharged with equal velocity, the depths of penetration will be as the diameters of the balls; so that a greater ball will not only make a wider aperture, but will penetrate farther into the obstacle than a smaller ball, all other circumstances being the same in both. Again, if it be known from experiment, how far a given ball will penetrate into any substance with a given velocity, the force of resistance may be determined from the above formula $f = \frac{nd}{3} \times \frac{v^2}{32s}$, and hence the depth of penetration with any other ball, and with any other velocity, may be determined while the obstacle remains the same.

This however is upon a supposition, that the resistance of the obstacle is constant, like the force of gravity, which cannot in fact be the case, as it is obvious, that the farther a ball penetrates into any obstacle, the greater will be the resistance, in consequence of the increased density arising from the parts of the obstacle driven before the ball; but it is extremely difficult to establish any law of resistance that will answer in all cases, we must therefore adopt the hypothesis of uniform resistance, till farther experiments enable us to proceed with greater certainty; the resisting force of elm on

this supposition, according to the first four results in the above tables, will be as follows.

$$\begin{aligned} 1. f &= \frac{ndv^2}{32s} = \frac{7\frac{1}{2} \times 1.96 \times 1600^2}{32 \times \frac{2}{12}} = 20000. \\ 2. f &= \frac{ndv^2}{32s} = \frac{7\frac{1}{2} \times 1.96 \times 1200^2}{32 \times \frac{1}{12}} = 15000. \\ 3. f &= \frac{ndv^2}{32s} = \frac{7\frac{1}{2} \times 2.78 \times 1500^2}{32 \times \frac{3}{12}} = 16406. \\ 4. f &= \frac{ndv^2}{32s} = \frac{7\frac{1}{2} \times 2.78 \times 1000^2}{32 \times \frac{1}{12}} = 15362. \end{aligned}$$

The mean of these four results is 16692, which expresses the resisting force of elm, on the hypothesis of an uniform resistance, the force of gravity being assumed as unity; and now this value of f being established for elm, the formula

$$s = \frac{ndv^2}{96f}$$

will obviously furnish the means of determining s , or the depth of penetration in any other case that may be proposed. Also the resistance being supposed uniform, we

have, according to the doctrine of forces, $t = \frac{2s}{v}$ for the time of penetration.

In the second of the above recited experiments, the velocity of the ball is 1200 feet, and the depth of penetration 15 inches; let it hence be required to find the time of penetration, and the time of passing through each successive inch of the 15, and the velocity lost at each of them.

Here $v = 1200$ feet $= 14400$ inches, also $s = 15$ inches,

$$\text{whence } t = \frac{2 \times 15}{14400} = \frac{1}{480} \text{ of a second the time of penetration.}$$

Again, the velocities and times being as the square roots of the spaces, we have

Velocity lost.	$\sqrt{15} : \sqrt{15} - \sqrt{14} :: v$	Time in passing.
$\frac{\sqrt{15} - \sqrt{14}}{\sqrt{15}} v = 40.7$	$:: t :$	$\frac{\sqrt{15} - \sqrt{14}}{\sqrt{15}} t = .00007$ 1st inch.
$\frac{\sqrt{14} - \sqrt{13}}{\sqrt{15}} v = 42.2$	$:: t :$	$\frac{\sqrt{14} - \sqrt{13}}{\sqrt{15}} t = .00007$ 2d
$\frac{\sqrt{13} - \sqrt{12}}{\sqrt{15}} v = 43.8$	$:: t :$	$\frac{\sqrt{13} - \sqrt{12}}{\sqrt{15}} t = .00008$ 3d
$\frac{\sqrt{12} - \sqrt{11}}{\sqrt{15}} v = 45.7$	$:: t :$	$\frac{\sqrt{12} - \sqrt{11}}{\sqrt{15}} t = .00008$ 4th
$\frac{\sqrt{11} - \sqrt{10}}{\sqrt{15}} v = 47.8$ &c.	$:: t :$	$\frac{\sqrt{11} - \sqrt{10}}{\sqrt{15}} t = .00008$ 5th

Sum $\frac{1}{480} = 00208$

Hence, as the motion lost at the beginning is very small, and consequently the motion communicated to any body, as an inch plank, in passing through it, very small also; we may conceive how such a plank may be shot through when standing upright without overfetting it. For more on this subject, see Hutton's Traacts, vol. iii. p. 288.

PENEUS, in *Ancient Geography*, and *Mythology*, a river of Theffaly, which ran from W. to E., its source being in mount Pindus, and its mouth at the entrance of the Thermaic gulf. Some doubts have been suggested concerning the course of this river. The ancients thought that the breach by which it discharged itself into the sea, was occasioned by an earthquake, that separated the mountains. Hence it has been sometimes called "Araxes," from *αραξω*, feindo, to cleave. The modern name of "Salampria" is ancient, as, according to Eustathius, this river was in his time called "Salimprias," a name, according to Hesychius, of Greek origin, *σαλαβρη* and *σαλαμβρη*, signifying the openings of gates.

Most authors are of opinion, that Deucalion's deluge was occasioned by the river Peneus. (See DEUCALION.) To this purpose, Herodotus observes, (l. i.) "It is said that Theffaly once was nothing but a lake, being environed on all sides with hills. The country which lies between those hills is what they call Theffaly, which is watered with plenty of rivers, the chief of which are the Peneus, the Apidannus, the Onfchones, the Eripeus, and the Panito. These five rivers, falling down from the neighbouring mountains, after having run through the low country, difembogue themselves into the sea by a very narrow canal, where they all unite, and make but one great river, which retains the name of Peneus. They tell us farther, that before the canal was made, these rivers flooded the whole country, and turned it into a great lake; but that Neptune having formed that great canal, all the waters retired." Peneus, on account of its beauty, was an object of worship.

PENEUS, a river of the Elide, in the northern part of the country, which flowed from its source eastward towards mount Scollis by Elis, and discharged itself into the sea to the west of Ephyra.—Also, a name given to the Araxes, a river of Armenia, on account of its resemblance to the Peneus of Theffaly, according to Strabo.

PENGEBUR, a town of Persia, in the province of Mecran; 130 miles N. of Kidge.

PENGHIOUM, a town of the Birman empire, at the confluence of a small river with the Irrawaddy; near Yay-nangheoum, or Earth-oil creek.

PENGUIN, in *Ornithology*, a name given by sailors of different nations to two different species of water-fowl, both web-footed, and both wanting the hinder toe.

The penguin of the English is the bird more commonly

known by the name of the *goirfugel*, or the *alca impennis* of Linnæus. See ALCA.

The penguin of the Dutch is the *anser Magellanicus* of Clusius. See PINGUIN.

PENGUIN, or *Wild Ananas*, *Karatas*, in *Botany*. See BROMELIA.

PENGUIN *Island*, in *Geography*, a small island near the coast of New Holland, at the entrance into Adventure bay. N. lat. 43° 21'. E. long. 147° 33'.—Also, a small island near the Cape of Good Hope, a little to the north of Table bay.—Also, an island near the S. coast of Newfoundland. N. lat. 47° 22'. W. long. 56° 45'.—Also, a small island near the coast of Patagonia; nine miles S.E. of Port Desire.

PENIA, in *Mythology*, the goddess of Poverty, and mother of Love.

PENICHE, in *Geography*, a sea-port town of Portugal, in Estramadura, situated on a peninsula, which runs into the Atlantic; fortified and defended by a citadel; containing three parishes, and about 2800 inhabitants. This town is sometimes called "New Lisbon;" 39 miles N.N.W. of Lisbon. N. lat. 39° 20'. W. long. 9° 5'.

PENICILLA, thus called from *penicillus*, a *penicil*, which it is supposed to resemble in shape, in *Pharmacy*, a lozenge; or form of medicine made round by rolling.

PENICILLI MARINI, in *Natural History*, a sort of marine tubuli, or cases of sea-worms, making a distinct genus of those shells. They are defined to be shelly tubes, very slender, and terminating in the shape of a painter's penicil; many of them in their native shape adhering to stones, &c. on the sea-shores, by means of a soft and lax substance. Some of these are white and pellucid, others yellowish or brown; and the more common sort are about a finger's length, and about the thickness of a wheaten straw; and some are of a sort of funnel-like shape, and have their mouths surrounded by a sort of hairs, or filaments. These are called by some *proboscipleetani*, others are called *cadi*, and others *entafia*.

PENICILLUS, among *Surgeons*, is used for a tent, to be put in wounds, or ulcers.

PENIDIUM, in *Pharmacy*, barley-sugar.

Dr. Quincy uses the word penidium for a kind of clarified sugar, with a mixture of starch, made up into little lumps.

PENJEKORCH, in *Geography*, a river of Asia, which runs into the Sewad, about five miles S. of the town of the same name. This river joins another S.E. of the town of Bijore, and in its course separates the province of that name on the W., from Sewad, on the E.

PENJEKORCH, a river of Candahar, in Cabulistan; eight miles W. of Mashanger.

PENIGK, or PENIG, a town of Saxony, and capital of

of a lordship, in the principality of Schonburg, on the Muldau. In this place are a manufactory of woollen stuffs, and a pottery; 38 miles W. of Dresden. N. lat. $50^{\circ} 52'$. E. long. $12^{\circ} 35'$.

PENING, a town of Bavaria, in the principality of Aichilatt; nine miles E.N.E. of Aichtatt.

PENINSULA, in *Geography*, a portion or extent of land, joining to the continent by a narrow neck or isthmus; the rest being encompassed with water.

The word is compounded of the Latin *pene* and *insula*, q. d. *almost island*, which the French pertinently enough render *presque îlle*.

Such is Peloponnesus, or the Morea; such also are Africa, Jutland, &c.

Peninsula is the same with what is otherwise called cheronessus.

PENINSULA Point, a cape on the W. coast of the island of Mindoro. N. lat. $12^{\circ} 40'$. E. long. $120^{\circ} 56'$.

PENINUS, or PENIN, in *Mythology*, a god acknowledged by the Penini, inhabitants of the Alps, from whom that chain of mountains derived its name: as we learn from Livy, Dec. 3. l. xi. n. 38. Guichenon, in his History of Savoy, has preserved the inscription that was upon the pedestal of a fine statue, that represented this god under the figure of a young man naked, in these terms, "L. Lucilius Deo Penino optimo Maximo donum dedit." Cato and Servius (in 3 Æn.) say, that this was a god, but a goddess, whom the one calls Penina, and the other Apenina; but both the figure and the inscription express the contrary. The statue of that god was afterwards carried off, and that of Jupiter put in its place. Nevertheless, the worship of Peninus was not abolished, but the mountaineers continued to pay adoration to him. Some say this god was Jupiter himself, which they infer from the epithets "Optimus Maximus;" but others say that he was the Sun; and that the carbuncle upon the statue, called Peninus's eye, was the same with that of Osiris, who, in Egypt, represented the sun.

PENIS, in *Anatomy*;

PENIS, *Arteria dorsalis et profunda*;

PENIS *erector*, a muscle of the organ;

PENIS *glans et preputium*;

PENIS *glandula odoriferæ*;

PENIS, *Vena magna*;

PENIS, *Amputation of*, in *Surgery*.

This operation is sometimes rendered indispensable by carcinomatous diseases, in which the mischief has not as yet extended itself either too far towards the pubes, or to the glands in the groin. It is also very erroneously recommended to be practised in cases of mortification; but every judicious surgeon will be of opinion, with Sabatier, that here it is entirely unnecessary, because if the disorder has ceased to spread, the dead part will be thrown off by a spontaneous process; and if the gangrene is still spreading, the operation is not likely to check its progress. The manner of operating is as follows: Sabatier advises the surgeon to take hold of the part with his left hand, and draw the integuments forwards, while with one sweep of the knife he makes the requisite division. A catheter is then to be introduced into the bladder. Were this precaution neglected, the corpora cavernosa and urethra might become retracted towards the pubes, and the orifice of the urethra be covered with the redundant skin, so as to obstruct the passage of the urine. Le Dran saw such an accident happen, and was obliged to puncture the skin, in order to enable the patient to make water.

This operation is occasionally followed by a considerable

degree of hemorrhage. The blood sometimes gushes out of the middle pudendal vein, and the arteries which ramify at the lateral and upper parts of the corpora cavernosa, while there is also a general flow of it from the spongy substance of the corpora cavernosa and urethra. This sort of bleeding is, in general, to be stopped like other hemorrhages. If the vessels appear large, they should be immediately tied. When they seem to be of more moderate size, and the blood only oozes from the corpora cavernosa, styptics and compression will answer.

After suppuration has taken place, Sabatier conceives that the catheter is no longer needed. Towards the completion of the healing, care must be taken to keep the orifice of the urethra from becoming contracted, should any tendency of this kind shew itself.

PENIS of Birds. See *Anatomy of Birds*

PENISAARI, in *Geography*, an island of the Baltic, three versts long, and distant six versts from Lavanfaari, which see. It is inhabited only by a few families, and has no water-springs.

PENISCOLA, a town of Spain, in Valencia, situated on the coast of the Mediterranean, surrounded on three sides by the sea, and difficult of access by land; 24 miles S. of Tortosa. N. lat. $40^{\circ} 24'$. E. long. $0^{\circ} 24'$.

PENISHEHR, or PENJESHEHR, a town of Candahar, and capital of a district in the Cabulistan, on the E. side of the Hindoo Koo mountains; 46 miles N. of Cabul. N. lat. $35^{\circ} 16'$. E. long. $68^{\circ} 24'$.

PENISTONE, or PENNISTON, a small market-town in the wapentake of Staincross, and liberty of the honor of Pontefract, West Riding of Yorkshire, England, is situated eight miles W.S.W. from Barnsley. The market is on Thursday, but it is little frequented. Here are four annual fairs, which are chiefly noted for the sale of moor sheep. The town is environed with dreary moors, especially to the westward, where nothing presents itself to the eye but bleak and barren mountains, covered with heath or ling. Penistone, according to the population returns of 1811, contains 115 houses, and 515 inhabitants. The church here is a large structure, and near the centre of the town is a well endowed grammar school. Beauties of England and Wales, vol. xvi. by John Bigland.

PENITENCE, PENITENTIA, is sometimes used for a state of repentance, and sometimes for the act of repenting. See REPENTANCE and IMPENITENCE.

PENITENCE is also used for a discipline, or punishment attending repentance; more usually called *penance*.

PENITENCE also gives the title to several religious orders, consisting either of converted debauchees, and reformed prostitutes; or of persons who devote themselves to the office of reclaiming them. Of this latter kind is

PENITENCE, *Order of, of St. Magdalen*, established about the year 1272, by one Bernard, a citizen of Marseilles, who devoted himself to the work of converting the courtezans of that city.

Bernard was seconded by several others; who, forming a kind of society, were at length erected into a religious order by pope Nicholas III. under the rule of St. Augustine.

F. Gesnay adds, that they also made a religious order of the penitents, or women they converted, giving them the same rules and observances which they themselves kept.

PENITENCE, *Congregation of, of St. Magdalen, at Paris*, owed its rise to the preaching of F. Tisseran, a Franciscan, who converted a great number of courtezans about the year 1492. Louis, duke of Orleans, gave them his house for a monastery; or rather, as appears by their constitutions, Charles

Charles VIII. gave them the hotel, called Bochaigue, whence they were removed to St. George's chapel, in 1572. By virtue of a brief of pope Alexander, Simon, bishop of Paris, in 1497, drew them up a body of statutes, and gave them the rule of St. Augustine.

To qualify a woman for admission, it was required, that she had committed the sin of the flesh. None were admitted who were above thirty-five years of age.

Till the beginning of the last century, none but penitents were admitted; but since its reformation by Mary Alvequin, in 1616, none have been admitted but maids, who, however, still retain the ancient name penitents.

PENITENTIAL, **PENITENTIALE**, an ecclesiastical book, retained among the Romanists; wherein is prescribed what relates to the imposition of penance, and the reconciliation of penitents.

In the Capitulars of Charlemagne, the priests are enjoined to study well their Penitential. There are various Penitentials: the Roman Penitential, that of Venerable Bede, that of pope Gregory III. &c.

PENITENTIARY, **PENITENTIARIUS**, an office, or tribunal, in the court of Rome, wherein are examined, and delivered out, the secret bulls, graces, or dispensations, relating to conscience, confession, &c.

The expeditions of the penitentiary are sealed up with red wax, and sent close; directed to the confessors.

PENITENTIARY is also an officer or dignitary, in some cathedrals, vested with power from the bishop to absolve in cases reserved to him; on which account he is also called the *bishop's ear*.

In some places there is a grand penitentiary, and a sub-penitentiary. Anastasius says, that pope Simplicius chose some among the Roman priests to preside over penances. At present the pope has his grand penitentiary, who is a cardinal, and the chief of the other penitentiary priests established in the patriarchal churches of Rome, who consult him in all difficult cases.

He presides in the penitentiary, dispatches dispensations, absolutions, &c. and has under him a regent, and twenty-four proctors, or advocates of the sacred penitentiary.

PENITENTIARY Houses, for the punishment of convicts. See **TRANSPORTATION**.

PENITENTS, in the church of Rome. See **PENITENTES**.

PENITENTS, an appellation given to certain fraternities, or societies of persons who assemble together for prayers, make processions bare-footed, their faces covered with linen, and give themselves discipline, &c.

There are White Penitents in Italy, at Avignon, and at Lyons. There are also Blue Penitents, and Black Penitents, which last assist criminals at their death, and give them burial.

PENITENTS, or *Converts of the name of Jesus*, a congregation of religious at Seville, consisting of women, who had led a licentious life, founded in 1550.

This monastery is divided into three quarters: one for professed religious; another for novices; a third for those under correction.

When these last give signs of a real repentance, they are removed into the quarter of the novices, where, if they do not behave themselves well, they are remanded to their correction. They observe the rule of St. Augustine.

PENITENTS of Orvieto, are an order of nuns, instituted by Antony Simoncelli, a gentleman of Orvieto. The monastery he built was at first destined for the reception of poor girls, abandoned by their parents, and in danger of losing their virtue.

In 1662 it was erected into a monastery, for the reception of such as, having abandoned themselves to impurity, were willing to take up, and consecrate themselves to God by solemn vows. Their rule is that of the Carmelites.

These religious have this in peculiar, that they undergo no noviciate. All required is, that they continue a few months in the monastery in a secular habit; after which they are admitted to the vows.

PENKEMAS POINT, in *Geography*, a cape or headland of South Wales, on the N. point of the county of Pembroke, at the mouth of the Tivy, four miles below Cardigan.

PENKRIDGE, a market-town in the hundred of Cuddleston, and shire of Stafford, England, is seated on the river Penk, whence its name is supposed to have been derived, at the distance of six miles to the south of Stafford. It is of very great antiquity, and, according to Camden, was the site of the Roman station, Pennocrucium, mentioned in the Itinerary of Antoninus; but Plot, Stukeley, and Horsley, place that station at the neighbouring village of Stretton; and Salmon transfers it to Oldbury, in Warwickshire. And though thus entertaining different opinions respecting the actual position of Pennocrucium, all these authors agree in considering the present town of Penkridge as the immediate offspring of the deserted station. Some Roman remains were discovered here about the middle of the last century, and among other smaller articles, a brass head of the bolt of a catapulta.

Penkridge is but a small mean looking town, containing, according to the late population returns, 204 houses, and 925 inhabitants, who are principally engaged in different departments of the iron trade. The market day is Tuesday; and there are, besides, two fairs annually, which are resorted to for saddle and draught horses. Here is an excellent charity school for the clothing and education of twelve boys and eight girls. The church is an old edifice, with a square tower at the west end. In the reign of king Stephen it was collegiate, and belonged to the united fees of Lichfield and Coventry; but it was afterwards bestowed on John, archbishop of Dublin, and his successors, who were perpetual deans of the college, and had the collation of all the prebendaries, who were thirteen in number. The revenue of this college was estimated at 106*l.* 15*s.* at the time of the dissolution. The lands in Penkridge and its vicinity descend according to the rule of "Borough English."

Lapley, a small village to the south of this town, is distinguished as the site of an alien priory for black monks, which was annexed as a cell to the abbey of St. Remigius at Rheims, on whom it was bestowed by Aylmer, earl of Chester and Mercia, in the time of Edward the Confessor. At its suppression by Henry V. its site and possessions were given to the college of Tong. The church belonging to this priory is still standing, and is now the parochial place of worship. It has a handsome tower, which rises between the chancel and the body of the church.

Near this village is Stretton, above-mentioned, as the supposed site of Pennocrucium. An elegant seat here, belonging to the family of Monckton, was anciently the property of the Congreves, ancestors to the celebrated dramatic poet of that name. The Roman road, called the Watling street, passes close to the south side of the village. Tanner's *Notitia Monastica*; Camden's *Britannia*; and *Beauties of England and Wales*, vol. xiii. by Mr. Nightingale.

PENKUM, a town of Anterior Pomerania, which has suffered greatly by war and fire; 15 miles S.W. of New Stettin. N. lat. 53° 19'. E. long. 14° 20'.

PENLAU LENGAU, a river of Austria, which flows from

from lake Alben, and runs into the Traun; four miles S.W. of Wells.

PENLEE POINT, a cape in the English channel, on the S. coast of the county of Cornwall.

PENLLYN, WILLIAM, in *Biography*, one of the successful champions on the harp, at the Eisteddfod, or session of the bards and minstrels, appointed in the ninth year of queen Elizabeth, at Caerwys in North Wales, where he was elected one of the chief bards and teachers of Instrumental Song. Pennant's Tour in North Wales, 1773, printed 1778.

PENMAEN MAUR, in *Geography*, a large and lofty mountain of Caernarvonshire, North Wales, rises with a rapid ascent from the southern shore of the Menai river. Its summit is about 1540 feet above the level of the sea. On the top is an ancient British fortress called "Braich y Dinas," also a bardic, or druidical circle of upright and prostrate stones. Near the base of the mountain, on the north side, is a turnpike road, from Aber-Conway to Bangor, &c., which has been formed with much difficulty and expence. In some parts it is constructed on arches, thrown across fissures, and in other parts it hangs over a steep and lofty precipice, about 200 feet above the sea, and presents a terrific appearance to the traveller. A wall has been built to guard against dangers. "The summit," says Mr. A. Aikin, "is a rude mass of shattered rock, covered with heath, difficult of ascent, and the descent even far greater than at any time we had before experienced." See Pennant's Tour in North Wales.

PENMAN HEAD, a cape of Scotland, on the N. coast of Aberdeenshire. N. lat. $57^{\circ} 37'$. W. long. $2^{\circ} 9'$.

PENMARCK POINT, a cape on the W. coast of France, S. of a bay which takes its name from the town of Audierne; 15 miles S.S.E. of Audierne. N. lat. $47^{\circ} 48'$. W. long. $4^{\circ} 17'$. East of this point are Penmarek rocks.

PENN, Sir WILLIAM, Knt., in *Biography*, an admiral of England, and one of the commanders at the taking of Jamaica, was born at Bristol, 1621. Being addicted from his youth to the sea, he became a captain at twenty-one, and after several intermediate promotions was made admiral in the first Dutch war, at thirty-two years of age. In 1655 he came home, and was chosen member of parliament for Weymouth, not without hereby incurring the displeasure of the republican government, by which he was committed for a while to the Tower, on a charge of quitting his command without leave to the hazard of the army. Upon the restoration of the monarchy, he was made a commissioner of the admiralty and navy, governor of the town and fort of Kinsale, vice-admiral of Munster, and one of the council of that province. After sustaining the chief command, under the duke of York, in the victory over the Dutch in 1665, he took leave of the sea, but continued in his other employments till 1669, when, growing infirm, he retired to Wanstead, in Essex, and died there the year following. He is said to have acquitted himself, in his several high offices, with honour and fidelity.

PENN, WILLIAM, an illustrious person among the Quakers, and founder of the colony of Pennsylvania, was the son of the admiral above-mentioned, by his wife Margaret, daughter of John Jasper, merchant of Rotterdam. He was born in London, in the vicinity of the Tower, 14th October, 1644. His father gave him a liberal education, induced, no doubt, to greater care in the finishing of it, by prospects of his son's advancement at court, where he himself was in high favour. But the mind of the son was formed for other pursuits, and before he had passed his

twelfth year, was already glowing with a sensibility to religion, which eventually unfitted him for the employments of a corrupt court, and gave him to others of a more honourable and beneficent nature. He was placed first at Chigwell school, in Essex, then at a private academy on Tower Hill, with the advantage besides of a tutor; and lastly, in 1660, entered a gentleman commoner of Christ-church college. He continued at Oxford two years, and was intimate with Robert Spencer, afterwards earl of Sunderland, and with John Locke. Though fond at this time of youthful sports, he had strong religious impressions; and, together with some other students, withdrew from the national way of worship to hold private meetings, at which they preached and prayed among themselves. This conduct gave great offence to the heads of his college; the parties were fined for nonconformity, and, proceeding after this to some public acts of imprudent zeal, Penn and several others were expelled the college. Returning home, he continued to affect the company of religious persons; from which his father, seeing the obstacles it would throw in his way to preferment, endeavoured both by words and blows to deter him; and finding all methods ineffectual, became at length so incensed, that he turned him out of doors. The patience of young Penn held out under this rough treatment, until (parental affection taking place of anger, and possibly suggesting the expedient) his father concluded to send him, in company with some persons of rank, on a tour to France. This took place in 1662. Here, though he spent some time in study under the celebrated Protestant preacher, Moses Amyraut, the very different conversation of other associates at length diverted his thoughts from religion. He had however acquired the language, together with the polished manners of the French, when, in 1664, he was recalled by his father from Turin, to which place he had proceeded from Saumur, the residence of Amyraut. The admiral joyfully received his son, concluding the main point (of his fitness for promotion) was now gained. He was admitted of Lincoln's Inn to study the law, where he continued till the breaking out of the pestilence, soon after which, being now twenty-two years of age, his father put under his management a considerable estate in Ireland, and he went to reside in that kingdom.

In solitude, the religious struggle in Penn's breast revived. On the one hand, natural vivacity, personal accomplishments, and the respect and favour of his friends attracted his regard to the present world: on the other, devotion, and an indelible sense of duty, fixed his contemplations on the next. He had been affected, about ten years before this time, by the preaching of Thomas Loe, a Quaker: and, being at Cork, was informed of a meeting for worship, then about to be convened, as it seems, by desire of the same person. Penn attended it, and Loe delivered a discourse, beginning with the words, "There is a faith, that overcomes the world, and there is a faith, that is overcome by the world;" on which he is said to have expatiated with much clearness and energy. His doctrine agreeing with the previous experience and present disposition of Penn, he now inclined to enter into communion with the Quakers, and from this time constantly attended their meetings. At one of these, held at Cork, November 1667, he, with many others, was apprehended by order of the mayor, who would have liberated Penn upon his giving bond for his good behaviour; but the latter, deeming the meeting no misdemeanour, refused bond, and was sent to prison with the rest. He wrote a few lines to the earl of Orrery, containing exceptions to the mayor's proceedings, an argument against persecution, and a request "for the speedy releasement of all" who had been

been committed on the occasion. The earl contented himself with ordering Penn's discharge.

His father, being informed by a nobleman of his acquaintance of the danger his son was in of being profelyted to Quakerism, remanded him home, and was readily obeyed. Penn had now again to pass through the ordeal of parental displeasure, and in this a principal object seems to have been, his continuance in the exterior of his education, or, as his biographer has it, in the customs and fashions of the age. But so fixed was he in the resolution to follow what he esteemed a manifestation of the will of God in his conscience to the contrary, that, although he behaved on these occasions with Christian meekness and filial affection, neither threats nor entreaties could move his constancy. The honour of the hat (in these times a matter of no light esteem) was especially contended for by the punctilious admiral; who, at last, would have tolerated his son in other instances of nonconformity, on condition that he should be uncovered before the king, the duke of York, and himself. Penn took time to consider of this proposal in secret, he even made it a subject of fasting and supplication to God to be directed aright, and he deliberately refused the terms. This was sacrificing much to sincerity and consistency in his profession, for his father, upon this, finding his hopes of the *courtier* at an end, could no longer endure the *son* in his presence, and he was a second time driven from the paternal mansion. His integrity was now put to a severe proof: it appears, that he found a shelter among his adopted friends the Quakers, while his mother privately supplied his wants. At length the admiral relented, so far as to wink at his return to the family; and when in consequence of being found at religious meetings (by the state then called seditious conventicles) he was at any time imprisoned, would privately use his influence to get him released.

The talents of Penn were soon devoted to the support of the doctrine he had espoused. He became a preacher among the Quakers, and published in 1668, on their behalf, a piece entitled "Truth exalted:" another occasion, however, more important in its consequences, presently occurred. A preacher, named Thomas Vincent, irritated by the going over of two of his hearers to the Quakers, accused the latter of holding erroneous doctrine concerning the Trinity. A dispute was held in consequence, in a meeting-house belonging to a Presbyterian congregation in London, chiefly between Vincent on the one part, and George Whitehead, an eminent Quaker, on the other. Vincent began by stating (in the gentle phrase of the time) that the Quakers held "damnable doctrines;" which being denied, he followed up his charge with a question, whether they owned "one Godhead subsisting in three distinct and separate persons." Whitehead, and those with him, rejecting these terms as unscriptural, Vincent framed the following syllogism; "There are three that bear record in heaven, the Father, the Word, and the Holy Ghost, and these three are one. These are either three manifestations, three operations, three substances, or three somethings else besides subsistences: but they are not three manifestations, three operations, three substances, nor three any things else besides subsistences: *ergo*, three subsistences."—Whitehead again rejected the terms, as not to be found in scripture, nor deducible from the text; and observing "that God did not use to wrap up his truths in heathenish metaphysics, but to reveal them in plain language," he desired an explanation. This was safe ground, though likely to prove barren of scholastic argument; but Penn, either not aware of its advantage, or as yet too full of Aristotle, chose to deny the *minor* of the syllogism, and went into some distinctions, using the rejected terms sub-

stance and subsistence. After much of this sort of logic, and some abuse bestowed on the Quakers, the dispute ended, for the present, to the satisfaction of neither side. In prosecution of the controversy thus raised, Penn wrote a piece with the following title: "The sandy Foundation shaken, or those so generally believed and applauded Doctrines, of one God, subsisting in three distinct and separate Persons: the Impossibility of God's pardoning Sinners: a plenary Satisfaction: the Justification of impure Persons by an imputative Righteousness; refuted from the Authority of Scripture and right Reason." The dispute with Vincent had excited much attention. This publication did more; it stirred up the vindictive spirit of intolerance. It was evil spoken of, says Sewel, the historian of the Quakers, and not long after Penn was committed to the Tower; and, as some thought, not without his father's being acquainted with it, perhaps to prevent a worse treatment. From what quarter this was apprehended, we shall see presently; for Penn being thus secured in the Tower, and denied the access of his friends, his servant one day brought him word (as it seems, from the admiral) that the *bishop of London* was resolved he should either publicly recant, or die a prisoner. His reply evinced a mind unterrified at the prospect of sufferings, which he considered as inflicted for conscience sake: and he began to occupy his solitude with religious compositions, the most considerable among which was a practical treatise on the Christian religion, entitled "No Cross No Crown." In this work, his contemporary, Dr. Henry More, says, he has treated the subject of a future life, and the immortality of the soul, with a force and spirit equal to most writers. It has passed through many editions.

After near seven months duration, Penn wrote to the secretary of state, lord Arlington, requesting to be heard in his own defence before the king, and complaining warmly of the manner in which his sentiments had been misrepresented by his enemies. In this letter several just and noble sentiments occur. He tells his lordship, "that he is at a loss to imagine how a diversity of religions opinions can affect the safety of the state, seeing that kingdoms and commonwealths have lived under the balance of divers parties. He conceives that *they only are unfit* for political society, who maintain principles *subversive of industry, fidelity, justice, and obedience*; but to say that men must form their faith of things *proper to another world*, according to the *prescriptions of other mortal men in this*, and, if they do not, that they have no right to be at liberty, or to live in this, is both ridiculous and dangerous. He maintains that the understanding can never be convinced by other arguments than what are adequate to its own nature. Force may make hypocrites, but can make no converts, &c. &c." He now likewise published a short piece, entitled "Innocency with her open Face, presented by way of Apology for the Book, entitled The sandy Foundation shaken." He here says, "that which I am credibly informed to be the greatest reason of my imprisonment, and of that noise of blasphemy which hath pierced so many ears of late, is my denying the divinity of Christ, and divesting him of his eternal Godhead; which most busily has been suggested, as well to those in authority, as maliciously insinuated among the people." In confutation of which charges, he proceeds to prove from scripture the Godhead of Christ. Both of these tracts were republished in the collection of his works, in folio, 1771; and the reader, who desires to obtain a just view of his sentiments on the several controverted points, will do well to compare them with each other, and with his doctrinal works at large. Soon after this explanatory defence, Penn was liberated from the Tower, and went to Ireland, where he seems to have been

occupied for twelve months in the care of his father's estate, and in various services to his friends, the Quakers; after which he returned to England.

In the year 1670, the Quakers being persecuted by some magistrates, under the act against conventicles, were forcibly kept out of their meeting-house in Gracechurch-street. They met as near it as they could, in the street, agreeably to their practice in such cases; and their firmness herein eventually procured them the free exercise of their right. On the occasion alluded to, Penn, preaching in the street, was apprehended by warrant from sir Samuel Starling, lord mayor, and committed to Newgate. At the next sessions at the Old Bailey he was indicted, along with William Mead, another eminent Quaker, for meeting in, and conspiring to preach to an unlawful and tumultuous assembly. He made, says his biographer, a brave defence, discovering both the free spirit of an Englishman, and the undaunted magnanimity of a Christian, inasmuch that, notwithstanding the most partial frowns and menaces of the bench, the jury acquitted them both. It ought to be added, that this jury exhibited an instance of firm, persevering justice, under most tyrannical and indecorous treatment by the court, worthy of the notice and remembrance of every Englishman. They were fined for the verdict which they had brought in, and ordered to be imprisoned till the fines were paid. But this dangerous assumption of power was afterwards adjudged illegal by the court of common pleas, on which occasion the chief justice Vaughan distinguished himself by a very able speech in vindication of the rights of juries. The trial of Penn and Mead is inserted in the collection of Penn's works, and has been also published separately.

Not long after this event admiral Penn died, perfectly reconciled to his son, to whom he left an estate of 1500*l.* *per annum.* Penn engaged about this time in a public dispute, at Wycomb, with Jeremy Ives, a celebrated Baptist, on the universality of a divine light in the minds of men; which doctrine Ives undertook to disprove, but seems to have quitted the field to his antagonist immediately after stating his argument. In the month called February 1670-1, Penn was again committed, on the pretext of preaching publicly, to Newgate, where he remained six months. It is observable that he had recently published a piece in favour of liberty of conscience, and another entitled "A seasonable Caveat against Popery;" the one probably offensive to the intolerant clergy, the other to the court. At his commitment he held a spirited dialogue on persecution with sir John Robinson, lieutenant of the Tower; at the close of which, the latter calling for an officer with a file of musketers, "No, no," said Penn, "send thy lacquey, *I know the way to Newgate.*"

Early in 1672 he married Gulielma Maria, daughter of sir William Springett, formerly of Darling in Sussex. He settled at Rickmansworth, Herts, continuing to render service, both by preaching and writing, to the religious cause in which he was now engaged for life. Nor did he neglect an attention to the interests of his country, but published, in this year, a pamphlet entitled "The proposed Comprehension soberly and not unseasonably considered;" and in 1675, a larger work, the title of which is "England's present Interest considered, with Honour to the Prince, and Safety to the People, in Answer to this one Question, What is most fit, easy, and safe, at this Juncture of Affairs, to be done, for quieting of Differences, allaying the Heat of contrary Interests, and making them subservient to the Interest of the Government, and consistent with the Prosperity of the Kingdom?" The answer to this, and the argument of the piece, is in three things: "1. An inviolable and impartial

maintenance of English rights. 2. Our superiors governing themselves upon a balance (as near as may be) towards the several religious interests. 3. A sincere promotion of general and practical religion." Becoming, about this time, interested in the property of West Jersey, he took an active part in the measures used to promote the settlement of that province.

In 1677 Penn, in company with George Fox, Robert Barclay, and others, went over to Holland, and assisted at a general meeting of the *Friends* in those parts, held for the purpose of settling their religious discipline; and those at Dantzic being under persecution, Penn wrote, in their name, an address to the king of Poland, with a confession of faith, and a request that he would interpose for them. He then proceeded with Barclay to Herwerden, the court of the princess Elizabeth of the Rhine, elder sister of Sophia, electress of Hanover, on whom the succession of the crown of England was afterwards settled. Their object was a religious visit to this princess, and the countess of Hornes, her companion, both Protestants, and the former esteemed one of the most learned of her sex in that age. Some correspondence, begun upon the report of their extraordinary piety, had opened the way for a personal interview. Penn and his companion were well received at Herwerden: a correspondence by letter was afterwards kept up between the former and the princess, and she dying in 1680, he inserted in the second edition of his "No Cross no Crown" a testimony to her highly exemplary character. In returning through Germany and Holland, he preached in many places, at meetings convened for the occasion. He was heard, this year, before a committee of parliament, in support of a petition from the Quakers, who were oppressed by prosecutions in the exchequer, under statutes enacted against the Papists, but converted by some magistrates into engines of annoyance to Protestant dissenters. In 1679, and during two years following, he published several things; as, "An Address to Protestants;" "England's great Interest in the Choice of this new Parliament," a piece dedicated to the electors; and "One Project for the Good of England," which he presented to the parliament itself. He likewise exerted himself to procure the return of Algernon Sidney as a member of the house, first at Guildford, and afterwards at Bramber. About this time he was elected a fellow of the Royal Society.

We come now to the most considerable of Penn's actions, the settlement of a colony in North America, on liberal and pacific principles. A tract of country on the west side of the Delaware, (formerly belonging to the Dutch, and called the New Netherlands,) was granted on petition, by Charles II., to William Penn, and his heirs, in consideration of admiral Penn's services, and of debts due to him from the crown at his decease. To this the duke of York added, by cession, a further contiguous portion of territory, seated lower on the Delaware. The king's patent bore date the 4th of March, 1680-1; and in this instrument he gave to the province, in honour of the patentee, its new name of Pennsylvania. Penn, being thus constituted absolute proprietor and governor, published "A brief Account of the Province of Pennsylvania," in which he proposed terms of settlement to such as might incline to remove thither, offering land at forty shillings purchase, and one shilling *per annum* quit-rent, for one hundred acres. A great number of buyers came forward, several of whom formed a company, calling themselves "The free Society of Traders in Pennsylvania." Three ships presently departed, with adventurers from England and Wales, chiefly industrious and reputable persons of Penn's own communion. Two of these arrived on the coast

in time to winter; the third was detained till spring in the West India islands. Thus was the settlement begun, the proprietor being occupied meantime in providing a government for the colony, and in concerting measures for its security. The native Americans, or Indians, having experienced, in some provinces on that continent, much injustice, had made the most terrible reprisals: found policy, therefore, conspiring with his own temper and principles, made it Penn's care to have them treated with candour, justice, and humanity; and his relation, W. Markham, sailing with the first settlers, he joined him with others in a commission to open a friendly intercourse with the natives, to whom he sent out considerable presents, and a letter couched in plain conciliatory terms. In the beginning of 1682 he published "The Frame of the Government of the Province of Pennsylvania in America, together with certain Laws agreed upon in England, by the Governor and divers Freemen of the aforesaid Province, to be further explained and confirmed there by the first provincial council that shall be held, if they seem meet. In the preface to this work we have a sketch of his sentiments on the forms and substance of civil government. "That," he observes, "which makes a good government, must keep it such: to wit, men of wisdom and virtue; qualities that, because they descend not with worldly inheritances, *must be carefully propagated by a virtuous education of youth*:" and in order to give effect where he had power, to that great principle of good government, liberty of conscience, in behalf of which he and his friends at home so deeply suffered, he recognized it in the first article of his "Constitutions," and proceeded to establish it by the following "Law." "All persons living in the province who shall confess and acknowledge the one Almighty and Eternal God, to be the creator, upholder, and ruler of the world, and that hold themselves obliged in conscience to live peaceably and justly in civil society, shall in no ways be molested or prejudiced for their religious persuasion, or practice in matters of faith and worship, nor shall they be compelled, at any time, to frequent or maintain any religious worship, place, or ministry whatsoever." Having completed his preparations, the governor, early in the autumn of 1682, sailed for Pennsylvania; his family (of whom he took leave in a pathetic and instructive letter) remaining behind. He was accompanied by about an hundred persons, mostly Quakers, from his own neighbourhood: but of these the small-pox, which had been inadvertently carried on board, swept off no less than thirty. In other respects the voyage was prosperous, and passing up the Delaware, he was met by the colonists, consisting of English, Dutch, and Swedes, with demonstrations of satisfaction. Having landed at Newcastle October 24, he convened and addressed the inhabitants, received legal possession of the country, and renewed the magistrates' commissions. After paying a visit to New York, he met the first provincial assembly at Chester, on the Delaware, then called Upland. Here, in a session of three days, the territory ceded by the duke of York was annexed to the province; an act of settlement was confirmed; resident foreigners naturalized; and the laws, which had been formed in England, after some revision, passed in form. Penn now visited lord Baltimore in his government of Maryland; whence he returned to Coquannock (the future site of Philadelphia), and began to purchase lands of the natives. He now likewise first entered personally with them into that firm alliance of peace and good offices, and formed (to use their own symbol) that chain of friendship, which was to last as long as sun and moon endure. Certain it is that his strict observance of justice in paying them for the soil (which was their inheritance), and the interest he manifested, during many successive treaties, in their

real welfare, not only operated to secure this colony, for a long series of years, from hostile attacks, but implanted in the generous, though uncultivated mind of the American, a regard for *Onas* (Penn), and his children (the Quakers), which bids fair to be transmitted to the latest remains of the race.

Philadelphia, the capital of the province, was next to be laid out, of which, at the time of Penn's arrival, not a house was completed; the colonists having, in general, no better lodgings than caves, hollowed out of the high banks of the river: the very plot fixed on for the city was claimed by some Swedes, to whom the governor allowed a greater quantity of land in exchange. This city extending two miles in length and one in breadth, and abutting at each end on a navigable river, was now planned, with admirable boldness, convenience, and regularity, and laid out under the inspection of Thomas Holmes, surveyor-general to the province. Ere twelve months had elapsed, the rudiments of the future metropolis shewed themselves in about fourscore dwellings, the seats of freedom, peace, and industry. The governor dispatched his plan to the committee of the Free Society of Traders, accompanied with a description (the best extant of these times) of the country, its natural history, and aborigines: this description is inserted in the collection of his works before-mentioned. The first jury was impanelled here early in 1683; and one Pickering was tried, with others his accessaries, before the governor and council, and convicted of counterfeiting the Spanish silver money current in the province. His sentence discovers the same spirit of mildness and equity, which, at this day, constitutes the praise and the efficacy of the criminal code of Pennsylvania. He was to pay a fine of forty pounds towards the building of a court-house, standing committed till payment; find securities for his good behaviour; and make restitution, in good silver, to the holders of his base coin, *which, being first melted down, was to be restored to him*. Various legislative, economical, and religious measures, together with a tedious dispute with lord Baltimore, on the subject of the boundary line between this province and Maryland, continued to occupy Penn till about Midsummer 1684; when he found it needful, on various considerations, to return to England. His interest at court had declined during his absence: but it was now restored, upon the death of Charles II, by the accession of his more immediate patron James II. He made use of his influence for the relief of his friends, the Quakers, who still lay under the scourge of penal statutes; and for the gratuitous service of many others. In particular he exerted himself in favour of the measure at that time so much, though so insincerely, held out by the court, of universal liberty of conscience. In 1686 (as we learn from bishop Burnet), being in Holland, in the course of a tour to Germany, &c. he had several interviews on this subject with the prince of Orange, on behalf (though not as an accredited minister) of king James: but his proposal going so far as to abolish the tests, it was rejected, probably by Burnet's advice, who was then with the prince, and in his confidence. However freely we may excuse Penn, on the fair plea of gratitude, for his attachment to James, it is to be lamented that he gave implicit credit to pretended schemes of religious liberty, the duplicity of which was so fully penetrated by others. His intimate reception at court, and the appearance of being in some way trusted or employed by the king, now subjected him to the general imputation of being a concealed Papist. Even his old acquaintance, Dr. Tillotson (afterwards archbishop of Canterbury), suspected him; but some expressions of Tillotson's on the subject coming to Penn's ears, a correspondence ensued between them, at the close of which Tillotson acknowledged

ledged himself fully satisfied that there existed no just grounds for the surmise. About this time (besides a further account of his province) Penn published several pieces on his favourite topic, liberty of conscience, one of which was entitled "Good Advice to the Church of England, Roman Catholic, and Protestant Dissenter, in which it is endeavoured to be made appear, that it is their duty, principle, and interest to abolish the penal laws and tests."

The last occasion in which we have to view Penn in connection with the court of James, is in an occasional attendance on the movements of the latter, this year, through several of the midland counties. Penn seems to have made use of several intervals in this *progrès*, to pay religious visits to his friends, and to preach to the people. On some of the latter occasions the king, too, was present to hear him. At Oxford he remonstrated with James on his arbitrary treatment of the fellows of Magdalen college, and attempted a mediation between them and the king, which he farther prosecuted afterwards at Windsor; but it proved abortive.

The revolution brought Penn again into difficulties, as a suspected Papist, or Jesuit, and a secret agent for the old government. On the 10th of December 1688, walking in Whitehall, he was sent for by the lords of the council, then sitting, who, though nothing was laid to his charge, obliged him to give sureties for his appearance on the first day of the next term: he was continued on these to the Easter term following, on the last day of which he was cleared in open court. In 1690 he was again brought before the council, on an accusation of holding correspondence with the late king James; he appealed to king William, who, after a conference of near two hours, inclined to acquit him; but to please some of the council he was held upon bail for a while, and in Trinity term, of the same year, again discharged. He was yet a third time attacked, and his name inserted in a proclamation, dated July 18th this year, wherein (among divers of the nobility, and others, to the number of eighteen) he was charged with adhering to the king's enemies, but proof failing respecting him, he was again cleared by order of the court of king's bench. He now purposed to go again to his province, and gave out proposals for a new settlement there. It appears that though his stay in England might be necessary to the security of his title as proprietary, it was highly detrimental both to his interests in America, and, through deficiency hitherto of revenue from it, to his private estate. His order for convoy had already passed the secretary of state, when the voyage was prevented by a new charge against him, backed by the oath of one Fuller, a wretch who was afterwards declared by parliament an impostor: the charge, however, being that of partaking in a plot to restore the late king, a warrant was granted for his apprehension, which he narrowly escaped at his return from George Fox's burial, the 16th of the month called January 1690. Seeing now no probability of fair treatment, he retired (or, as Burnet chuses to say, absconded) for two or three years: during which time, besides a preface to the collected works of Barclay, he wrote the following pieces: 1. "Just Measures," an epistle to the Quakers in vindication of religious discipline: 2. "A Key," or a treatise explanatory of their principles and practice: 3. "Reflections and Maxims relating to the Conduct of Human Life:" the two latter of these have gone through many editions. At the close of 1693, being admitted through the intercession of some of the nobility to appear before the king and council, he now effectually repented his innocence, and got clear of this long political persecution. About this time his wife, who was an amiable and accomplished woman, died, and he married, after two years, Hannah, daughter of Thomas Callowhill, of Bristol; and

soon after lost, by a consumption, his eldest son, a promising youth, just of age. The interval from his appearing again in public, to the year 1699, appears to have been chiefly devoted to religious labours and controversies: he also presented to parliament some arguments for exempting Quakers from oaths; and some remarks on a bill against *blasphemy*, in which he very rationally proposed that the term should be so defined as to preclude malicious interpretations: this bill was dropped.

On the prevalence of Penn's enemies at court, he had been deprived of his government of Pennsylvania, which was annexed, in October 1692, to that of New York, under colonel Fletcher. The ostensible reasons for this step were mal-administration, and danger of the loss of the province thereupon: the real one probably was a jealousy excited by the growing prosperity of the colony, and by principles and practices in its jurisprudence too liberal for the age. Penn's rights were restored to him by an instrument of William and Mary, dated in August 1694, but it was not till five years after this, that he embarked a second time for the province, accompanied by his family. The vessel, being three months at sea, did not arrive at Philadelphia "until the beginning of the tenth month, 1699, when a dangerous and contagious distemper, called the *yellow fever*, having raged in the province, and carried off great numbers of people, had ceased." Penn seems now to have intended to spend the remainder of his life in America, and he applied himself diligently to the offices of government; in which the inevitable difficulties arising from a mixed population, of various dispositions and interests, and enjoying a great share of liberty, required the exercise of both skill and patience. His administration was successful, and the colony is stated to have been at this period, when compared with others of the same standing on the continent, in an easy and flourishing condition. His old allies, the natives, were not overlooked, and religion being ever a predominant consideration with Penn, he engaged his friends at a monthly meeting for discipline, held the beginning of 1700, in a plan for the instruction of the natives and of the negroes, who had now been introduced among them, in the principles of the Christian faith. Later experience has shewn that Christianity, to obtain a cordial and general reception among these people, should be preceded by her handmaid, civilization. A public school, (free to the children of the poor,) had been already founded here. In the second month 1701, a treaty was held between the governor and about forty of the chief persons among the natives, in which, besides renewing former covenants, the parties established some regulations on the subject of trade between them: a principal care of the governor, on this occasion, seems to have been to prevent the abominable practice, already used by some unworthy colonists, of drawing the natives into a ruinous traffic, by offering them spirituous liquors.

During these transactions an attempt was making, at home, under pretence of advancing the prerogatives of the crown, and of national benefit, to invade the several proprietary governments in America, and reduce them to regal ones. A bill for this purpose was already before the lords, when the land-owners of Pennsylvania, present in England, petitioned the house, and gained time for the governor's return; who, on notice of the measure, presently embarked, and arrived at Portsmouth in December 1701. The bill which had been postponed, was now entirely dropped, and the accession of queen Anne, soon after, placed Penn once more in the sunshine at court. His estate, however, had now suffered much, by liberal disbursements, by inadequate

returns,

returns, and by the continual political impediments thrown in his way. He was moreover involved, in 1707, in a suit at law with the executors of a person who had been his steward; and his case not admitting of relief by the court of chancery, he was obliged to live within the rules of the Fleet, until the dispute could be adjusted. Advantage was now taken of his embarrassments by the ministry, to endeavour to buy what was before to have been taken by an act of power. He demanded for his province 20,000*l.*, and, after some discussion, had agreed to accept of 12,000*l.*, when he was incapacitated by illness from completing the sale. This defect was to have been supplied by an act of parliament, and by the queen's order one was prepared. It now appeared, on the petition of Henry Gouldney and others, that Pennsylvania had actually been mortgaged to them by its proprietor in 1708, for the sum of 6600*l.*! Let us turn from this prospect: it is sickening to see public spirit and liberal enterprise reduced to the necessity of pawning and setting to sale its honourable fruits. The estate, however, was not sold, but continued in the hands of Penn, and the proprietaries, after the revolution in America, received from the legislature of Pennsylvania the sum of 130,000*l.* in lieu of their quit-rents, besides retaining many valuable tracts of land. They also received, by an act of the British parliament, a remuneration of 4000*l.* per annum, in consideration of their losses, and of the "meritorious services" of their ancestor.

For ten years after his return to Europe, Penn lived mostly near London, and was still active in religious and civil society. He wrote, in 1709, "Some Account of the Life and Writings of Bullrode Whitelocke, esq." This was published along with the "Memorials of English Affairs," written by that excellent man and statesman, with whom Penn had been for many years acquainted. In 1710, his health declining, he took a handsome seat at Rushcombe, near Twyford, Bucks. Here, in 1712, he was attacked with fits, supposed to be apoplectic, by which his understanding and memory were much impaired, and he became, in consequence, unfit for public action, though not insensible, as it appears, to the sympathy of his friends and the comforts of religion in a peaceful conscience. He died, after a gradual declension of six years, the 30th of the month called July 1718, and was interred at the Quaker's burial-ground, at Jordans, near Beaconsfield.

One of the ablest and best informed of Penn's contemporaries, Burnet, in his history of his own times, has exhibited him, on several occasions, to some disadvantage, both as a man and a citizen. That he should no where report any good of a person so eminent might justly excite our surprize, were it not apparent that Penn was, on several accounts, odious to this historian: we must therefore receive the little he is pleased to say concerning him, with due allowance for the effect of party prejudice. That Penn was a perfect, or a faultless character, will not, by his warmest friends, be pretended. He appears to have wanted discernment in his estimate of affairs at home: but in his policy abroad, where he moved without shackles, there is a soundness of principle, and a dignity of feeling, that make ample amends for this defect: his integrity was evinced through many severe trials: his errors may be pronounced a fraction of no moment, when set against the great sum of good, of which, under the Author of every good gift, he was the conscious and the willing donor to mankind. Penn's Life, prefixed to his Works, in folio. Sewell's History of the Quakers. Proud's History of Pennsylvania.

PENN'S Cove, in *Geography*, a bay on the E. coast of

Whidbey's island, in the gulf of Georgia. N. lat. 48° 16'. E. long. 237° 39'.

PENN'S Creek, a river of Pennsylvania, which runs into the Susquehannah, N. lat. 40° 48'. W. long. 76° 56'.

PENN, Fort, lies at the mouth of a small creek, on the W. side of Delaware river, in Northampton county, about 21 miles N. of the line of Ealton, and near 70 miles N. of Philadelphia. N. lat. 40° 59'. W. long. 75° 13'.

PENN, Port, lies in Newcastle county, Delaware, on the W. bank of Delaware river, opposite to Reedy island.

PENN'S, a township of Pennsylvania, on the river Susquehannah, containing 2309 inhabitants.

PENN'S Neck, a town of Salem county, New Jersey, in Old Man's creek; 12 miles N.E. by N. of Salem.—Also, the name of a range of farms of excellent soil, situated about one mile and a half S.E. of Princeton, in New Jersey, on a point of land formed by Millstone river, and Stony creek; so called from the celebrated William Penn, who formerly owned this tract.

PENNA, LORENZO, in *Biography*, an ecclesiastic of Bologna, published a work entitled, "Li primi albori Musicali. per li principianti della Musica figurata;" one of the best treatises on practical music that appeared in Italy during the 17th century. The first sketch of this book was published in 1656. A second edition, enlarged, of the first book, appeared at Bologna, 1674. The second book at Venice, 1678: and the whole completed, in three books, 1684. In 1696, the work had gone through five editions. The author's rules for counterpoint, and extemporary playing on keyed instruments, are concise and clear, as far as they go; which is, however, very short of what is now wanted, since the bounds of modulation and use of discords have been so much extended.

PENNA, in *Geography*, a town of Italy, in the marquise of Ancona; 9 miles E. of Camerina.

PENNA d'Agber, *Is.*, a small island near the W. coast of Sardinia. N. lat. 43° 33'. E. long. 8° 16'.

PENNA di Billi, a town of Italy, in the duchy of Urbino, the see of a bishop; 14 miles W.N.W. of Urbino.

PENNANT, THOMAS, in *Biography*, celebrated as a naturalist and tourist, to whose various writings we have had frequent recourse in our researches in the several departments of natural history, was born at Downiag, in Flintshire, in the year 1726. He received his school education at Wrexham and Fulham, and from the latter place he was removed to the university of Oxford, where he entered upon the study of jurisprudence, though, probably, without any intention of pursuing the law as a profession. A present made to him, when he was about 12 years old, gave him a taste for the studies and pursuits in natural history, for which he afterwards became famous. In the year 1746 he made a tour into Cornwall, in the course of which he became acquainted with Dr. Borlase, and thus acquired a sort of passion for the science of mineralogy. In the year 1754 he was elected a fellow of the Society of Antiquaries, which was highly gratifying to him, as he had always been accustomed to combine antiquarian studies with his researches into nature. His first effort as an author, in the department of natural history, was a paper on certain coralloid bodies found in Coalbrookdale, which was inserted in the Philosophical Transactions for the year 1756. He had previously to this commenced a correspondence with the illustrious Linnæus, to whom he sent an account of a *concha anomia* from the Norwegian seas, and in return he was made a member of the Royal Society of Upsal. About this time Mr. Pennant married, and passed some years in domestic retirement. By way of occupation he began, in 1761, to prepare

prepare his British Zoology, in 132 coloured plates, imperial folio, with explanations. This work he afterwards published for the benefit of the Welsh charity-school in London. In 1763 he came into possession of the estate of Downing, and with it a rich mine of lead-ore, which enabled him to make great improvements. The death of his wife interrupted his domestic enjoyments, and in the Spring of 1765 he made a tour to the continent, and visited Switzerland, part of Germany, and Holland, and acquired an intimacy and friendship with several persons of great scientific knowledge, among whom were Buffon, Haller, the Gesners, Gronovius, and Pallas. His conference with the latter at the Hague gave rise to the plan of his "Synopsis of Quadrupeds." In 1767 he was elected a fellow of the Royal Society of London, and in the next year he republished his British Zoology, in two vols. 8vo., and in 1769 a third was added, including fishes and reptiles. In the same year he took a journey to the remotest point of Scotland, and the observations which he made were afterwards the basis of a very interesting publication. In 1770 he published 103 additional plates to his British Zoology, with several new descriptions, and in the following year he printed his Synopsis of Quadrupeds, in one volume 8vo. His well-earned reputation caused him to be presented, by his Alma Mater, with the compliment of the degree of Doctor of Laws. The account of his first Tour to Scotland was well received by the literary world, for previously to this little was known of Scotland by the people of England; and the valuable and well-arranged facts given by this excellent traveller, were highly prized by persons on both sides of the Tweed. In 1772 he repeated his northern tour, extending it to the Hebrides, the result of which was a rich harvest of valuable and entertaining observations. In the following year he published "Genera of Birds," in one volume, and employed himself in a journey through the northern counties of England.

Mr. Pennant was now become an habitual traveller, and he found his excursions equally conducive to the health of his body and vigour of his mind. In all his tours he laid up new stores of information, and he found even the most frequented tracts fertile of those topographical memoranda to which his attention was principally directed. In 1778 he gave the public an account of his native country, Wales, in a work entitled "A Tour in Wales," and in 1781 he added another volume, with the title of "A Journey to Snowden." These are particularly interesting, on account of the many anecdotes interspersed illustrative of the manners and history of that part of the island. He did not neglect his original object of pursuit, Natural History. He had, in the year 1777, added a volume to his British Zoology, containing the Vermes, Testaceous and Crustaceous animals. In 1781 he published his "History of Quadrupeds," and in the same year his "History and Natural History of the Turkey" was inserted in the Philosophical Transactions. His "Arctic Zoology," in two vols. 4to. appeared in 1785. To this there was a copious introduction, which is thought to be the most interesting and original of all his writings. It is a kind of survey of all the coasts of the arctic regions, beginning from the Straits of Dover, and proceeding to the remotest north, on the east and west, and filled with a great variety of geographical, historical, and physical facts, affording a series of the most animated pictures. In 1782 he published "A Journey from Chester to London;" and also an account of the antiquities of the capital itself, entitled "London." Several smaller pieces of the political and miscellaneous kind filled up the intervals of his greater works, and proved the continued activity of his mind.

These facts are chiefly taken from the history of his literary life by himself, which was printed in the year 1793. After which he published a natural history of the parishes of Holywell and Downing, within the latter of which he resided more than 50 years. Not long before his death appeared another work, in two volumes 4to., which was entitled "A View of Hindooſtan," which was executed in an able manner, and which bears a strong resemblance to the introduction to the "Arctic Zoology." He died at his seat at Downing in the year 1798, in the 72d year of his age. He inherited from nature a strong and vigorous constitution; his countenance was open and intelligent; his disposition active and cheerful; and his vivacity, both in writing and conversation, rendered him, at all times, an entertaining companion. He was exemplary in the relations of domestic life, zealously attached to the interests of his country, both local and general, and kindly attentive to the wants of his poor neighbours. As an author his style is lively, and well adapted to convey the ideas which he intended to express, but it is not always correct. In the department of natural history he is clear and judicious in his principles of arrangement, concise, energetic, and exact in his descriptions. His facts are regarded as of good authority.

PENNANT, or *Pendant*, in a *Ship*. See PENDANT.

PENNANTIA, in *Botany*, was so named by Forster, in honour of his friend and patron the late Thomas Pennant esq. of Downing, Flintshire, the great British zoologist, who in his various publications has incidentally touched on botany in many places, and who published in his various tours the first British figures of some of our rarest plants. Forst. Gen. t. 67. Schreb. 739. Mart. Mill. Dist. v. 3. Juss. 428. Lamæck Illustr. t. 854.—Class and order, *Polygamia Dioecia*, rather *Pentandria Monogynia*. Nat. Ord. uncertain; perhaps akin to the *Urtica* of Jusseu.

Gen. Ch. *Cal.* none, unless the corolla be taken for such. *Cor.* Petals five, equal, lanceolate, acute, concave, widely spreading. *Stam.* Filaments five, capillary, the length of the petals; anthers oblong, incumbent. *Pist.* Germen superior, obtusely triangular; style none; stigma flat, peltate, obscurely three-lobed. *Peric.* Capsule? triangular, of two cells. *Seeds* solitary, somewhat triangular.

Some flowers, on a separate plant, have the filaments twice as long as in the above, with ovate anthers, but no pistil.

Ess. Ch. Calyx none. Petals five, equal. Style none. Capsule? of two cells. Seeds solitary.

1. *P. corymbosa*. Forst Prodr. 75.—Native of New Zealand.—A tree or shrub, with round leafy branches, dotted, and somewhat downy, when young. *Leaves* alternate, flaked, two inches or rather more in length, obovate, either quite entire, or with two or three broad, blunt, shallow teeth or small lobes; furnished with a mid-rib, and many transverse interbranching veins; dark green above, nearly smooth, except the rib, which is on both sides minutely hairy; pale and smooth beneath. *Footstalks* not half an inch long, channelled, hairy. *Stipulas* minute, oblong, concave, membranous, very soon falling off. *Corymbs* terminal, much branched, many-flowered, hairy; the branches mostly alternate. *Flowers* about the size of *Laurus tinus*; as far as can be judged of them in a dry state, they seem to be pale green or yellowish-white. The whole specimen bears a general resemblance to some kind of *Viburnum*, but the absence of a calyx is a striking difference. Such is Forster's original specimen before us. The younger Linnaeus however obtained in England, if we mistake not, a specimen under the name of *Pennantia*, which is a very different

ferent thing. The *leaves* are ovate, four inches long, green on both sides, undivided and entire. *Branches* and *footstalks* smooth, with a solitary stalked gland at a little distance above each of the latter, and no *stipulas*. *Flowers* numerous, in a terminal, compound, smooth cluster; their *style* as long as the *corolla*, their *filaments* longer, and, what is most remarkable, each *flower* has a *calyx*, deeply divided into five ovate fringed segments, and rather elongated at its base. This plant therefore is unquestionably altogether different from Forster's *Pennantia*; it may be an *Ehretia*, but we know nothing of the fruit, nor is it to our present purpose to investigate this question. The true *Pennantia* above described has so much resemblance in some points to the order of *Urtica*, that we venture to hint its probable affinity thereto. Possibly the supposed *corolla* of five petals may be a deeply divided *calyx*. As to the true nature of the *fruit*, nothing certain is known. Forster examined the *germen* only, and though we allow that the rudiments of two cells is a circumstance much against our conjecture, we conceive there are not sufficient materials to lead us to any other safe conclusion.

PENNAR, in *Geography*, a river of Hindoostan, which rises in Mysore, traverses the circuit of Cuddapa and the Carnatic, and runs into the bay of Bengal, 12 miles E. of Nellore. N. lat. 12° 26'. E. long. 80° 13'.

PENNARE POINT, a cape in the English channel, on the S. coast of Cornwall; 6 miles W.S.W. of Dedman's point. N. lat. 50° 12'. W. long. 4° 46'.

PENNARTH BAY, a bay on the S. coast of Wales, in the Severn, at the mouth of the Taf, below Cardiff. A point of land, called Pennarth point, bounds it on the south.

PENNAS, LAS, a town of Peru, in the diocese of La Paz; 70 miles N. of Potosi.

PENNATA FOLIA, winged leaves, among *Botanists*, are such leaves of plants as grow directly one against another, on the same rib or stalk: as those of the ash, walnut-tree, &c. See **LEAF**.

PENNATULA, or **SEA-PEN**, in *Natural History*, a genus of the class and order Vermes Zoophyta. The generic character is as follows: animal not affixed, of various shapes, supported by a bony part within, naked at the base, the upper part with generally lateral ramifications, furnished with rows of tubular denticles, producing radiate polypes from each tube. There are eighteen

Species.

COCCINEA. The stem is round, radiating, with papillous polype-bearing sides, and clavate at the top. It inhabits the deeps of the White sea, and unites the two genera Alcyonium and Pennatula; it is soft, red, an inch and half high, and as thick as the little finger; it is wrinkled, with the papillæ disposed in rows.

GRISEA. Stem fleshy, with a smooth midrib and imbricate plated spinous ramifications. It is found in the Adriatic, and is about eight inches long; it shines by night; back of the midrib lanceolate, smoothish; rays imbricate, and undulate on the anterior margin, the lobules are armed with a spine, and obtusely crenate at the margin.

PHOSPHOREA. Stem fleshy, with a rough midrib and imbricate ramifications. It inhabits most seas, and emits a strong phosphoric light in the dark; it is about four inches long, and red; the stem is villous, with a lanceolate rough midrib, and nearly incumbent rays, the tubes pointing all one way.

FILOSA. The stem is a little fleshy, with a rib feathered on each side, and furnished with two filiform tentacula at the

base. It inhabits European seas, and is from four to six inches long.

RUBRA. Stem fleshy, with a broad, tuberculate midrib, the ramifications are imbricate, with each a short spine at the base. It inhabits the Mediterranean, is about six inches long; in colour it is whitish, varied with red dots and fassron lines.

MIRABILIS. Stem filiform, with lunate, distant, alternate ramifications. It inhabits the American, the Atlantic, and Norwegian seas; is about three or four inches long, and is fulvous; the tubes are round, with a spinous tip.

SAGITTA. Stem filiform, with close-set ramifications, and naked at the tip. It inhabits the ocean, and is thought not to be a distinct species.

ANTENNINA. Stem nearly quadrangular, fetaceous, with polype-suckers, on three sides. It inhabits the Mediterranean; is two feet ten inches high, and with regard to colour it is yellowish dotted with red.

STELLIFERA. Simple, equal, with solitary polypes towards the tip. It inhabits the Norway seas, and is about four inches long.

PHALLOIDES. Simple, with a cylindrical midrib every where covered with polypes. It inhabits the Indian ocean, is six inches long, and grey.

ARUNDINACEA. Stem quadrangular and very long. It inhabits the Norway seas, and is four feet long; the stem is linear, with cylindrical rays of solitary tubes, which are deciduous, erect, crowded, and seated on a thin pedicle.

SCIRPEA. This is simple, linear, tapering, with a round midrib producing polypes on one side. It inhabits the ocean, and is eighteen inches long; the stem is fleshy, thicker and longer than the midrib; the bone is somewhat flexile.

JUNCEA. Simple, linear, with a truncate rib, and transverse polype bearing wrinkles on each side. This is found in the Indian ocean, is two feet long, white, beneath horny, the rays mixed, fulvous and white.

GRANDIS. Pen-shaped, linear-lanceolate, with a smooth round stem, and jagged toothed ramifications. It inhabits the Indian ocean; is a foot long, greenish-grey, shines with a cinereous light in the dark, and sometimes stings the hand if it be touched.

ARGENTEA. Pen-shaped, lanceolate, with a smooth round stem, and very close-set imbricate, striate ramifications. This also is found in the Indian ocean, and is about a foot long; in colour it is a rich, silvery white, elegantly striate along the ramifications with lines of black; like many of the tribe it is luminous in the dark.

ENCRINUS. Stem quadrangular, taper, very long, bony, covered with a callous membrane, with an umbellate cluster of polypes from the top. It inhabits the Greenland seas, is about six feet long, and when taken fresh from the sea, appears like a nosegay of yellow flowers.

CYNOMORIUM. Cylindrical, fleshy, somewhat clavate, bearing polypes on the whole upper surface. It inhabits the Mediterranean, is reddish, and about four inches long.

RENIFORMIS. Stem round, verrucular, supporting a kidney-shaped leaf-like head, producing polypes on one surface. It is found in South Carolina. The body is expanded, kidney-shaped, flat, rising from a short stem, and covered on the upper surface with numerous tubular orifices, through which the polypes are protruded at pleasure; the upper surface is of a rich purple, the under side less brilliant, and sometimes yellowish.

PENNE, in *Geography*, a town of France, in the department of the Lot and Garonne, and chief place of a canton, in the district of Villeneuve d'Agen; 3 miles E. of it.

The

The place contains 854, and the canton 10,621 inhabitants, on a territory of 162½ kilometres, in 22 communes.

PENNEDO *de St. Pedro*, a small island in the Atlantic. N. lat. 0° 55'. W. long. 27° 10'.

PENNEVISCH, in *Ichthyology*, a name given by some to the most common species of the fish called *bagre*, caught in the East and West Indies.

PENNEWANG, in *Geography*, a town of Austria; three miles N. of Schwanauadt.

PENNI, GIOVANNI FRANCESCO, called *Il Fattore*, or the steward, from having been entrusted with the domestic concerns of Raphael, in *Biography*, soon became one of his principal assistants. He more than any other helped him in the execution of the cartoons of the Arazzi, and in the Loggii of the Vatican painted the histories of Abraham and Isaac. After the death of his master, he executed the fresco of the coronation in the Stanza of Constantine. The upper part of the Assumption of the Virgin at Monte Lupi, in Perugia, is ascribed to him, but the lower part was painted by Julio Romano. Few of his own works remain. Facility of conception, grace of execution, and a singular felicity in landscape, are mentioned as his characteristics.

Penni wished much to have united himself with his co-heir Julio, but being coldly received by him at Mantua, went to Naples, where his works and principles might have contributed much towards the renown of his name, had he not been intercepted by death, in the year 1528, at the age of 40. Fuseli's Pilkington.

PENNIGONDA, in *Geography*, a town of Hindoostan, in the circar of Rajamundry; 38 miles E. of Rajamundry.

PENNING, in *Commerce*, a money of account in Holland. The gilder, or florin, contains 20 stivers, and each of these is subdivided into 16 pennings; the six-dollar is = 800 pennings; 2 pennings are = a duyts, and 8 duyts = 2 groots Flemish = a stiver.

PENNINGTON, ISAAC, in *Biography*, a member of the society of friends, and a considerable writer among that people, was the son of an alderman of London, who repeatedly filled the office of chief magistrate, was a noted member of the Long Parliament, and nominated one of the judges of king Charles I., though he did not take his seat among them. Isaac was born about the year 1617, and having the prospect of succeeding to a large estate, he was furnished with the means of obtaining the best education. As he grew up, he had, from his father's situation in life, opportunities of mixing with some of the most considerable men of the age, and if he had been of an ambitious turn of mind, he might have occasionally indulged hopes of rising very high in the world. But from a very early age he was under strong religious impressions, and as he grew up to manhood, discovered an increasing attachment to retirement, serious contemplation, and the reading of the scriptures. While he was in this state of mind, he met with some of the writings of the Friends, "which," says he, "I cast an eye upon and disdained, as falling very short of that wisdom, light, life, and power which I was searching after." There was, however, something in them that roused his attention, and he went to one of their public meetings, at which George Fox preached, whose discourse produced on him a sudden and complete conversion to the principles of the new sect. From this time he joined the society in opposition to the influence of his connections, as well as unmoved at the prospect of reproaches and losses to which his profession would unquestionably expose him. In the years 1661 and 1662, Mr. Pennington was called forth to be a confessor for the profession which he had embraced. For the crime, as it was called, of holding

meetings of Friends for the worship of God in his own house, he was committed to Aylesbury gaol, where he was kept in close custody for seventeen weeks, great part of which was in the winter season; and to aggravate the severity of his treatment, he was confined in a cold and very inconvenient room, without a chimney, by which cruel usage he contracted so violent a disorder, that for several weeks after his release he was not able to turn himself in his bed. From this time till the year 1679, he suffered six different imprisonments. These repeated calamities, together with heavy pecuniary losses, arising, in many instances, from the confiscation of his property, to discharge the oppressive fines which were levied upon him, Mr. Pennington sustained with firmness and serenity, believing himself to be a sufferer for obeying God rather than man. With the same equanimity and fortitude he bore the attacks of a painful distemper, which terminated his life in the year 1679, in the 63d year of his age. His character procured him the respect and esteem of all good men, as it exhibited an excellent pattern of piety, virtue, and the strictest morality. He was most faithful in the discharge of all the duties of life, and was author of numerous writings, which were highly prized by the people with whom he associated. They were collected and published in a folio volume in 1681. They have since been reprinted in 4to. and 8vo., and in the year 1796, some of his "Letters" were published.

PENNINGTON, or *Pennytown*, in *Geography*, a pleasant and flourishing village in Hunterden county, New Jersey; 9 miles W. of Princeton, containing a church and about 42 houses.

PENNISETUM, in *Botany*, so called by Richard, from *penna*, a feather, and *seta*, a bristle; Richard in Perf. Syn. v. 1. 72. Brown Prodr. Nov. Holl. v. 1. 195. (See PANICUM.) The name alludes to the feathery structure of the bristles which compose the involucre.

PENNON, or PENON, a standard with a triangular tail, anciently borne before knights bachelors, who brought a certain number of followers into the field. Some instances occur of pennons being carried before esquires, but they were only such as possessed certain estates or fiefs; or who could bring a sufficient suite of vassals into the field. The pennon was in figure and size like a banner, which was small and of a square figure, with the addition of a triangular point. They were charged with armorial bearing of their owner. On the performance of any gallant action by the knight and his followers, the pennon was converted into a banner by the king, or commander-in-chief, cutting off the point, by which the knight was raised to the degree of a banneret. Both knights and bannerets were bound to appear in the field at the head of a certain number of men, whence ancient historians frequently express the strength of an army by the number of banners and pennons of which it consisted.

PENNSBOROUGH, WEST, in *Geography*, a town of America, in Cumberland county, Pennsylvania; famous for a remarkable flow of water from a ridge of lime-stone, called "The Big Spring," which, after turning six mills, discharges itself through Conidogwinnet creek into the Susquehannah.

PENNSBOROUGH, *East*, a township in the same county. PENNSBURY, a small town of Pennsylvania, in Bucks county, on a small creek of Delaware river. This was a manor which Mr. Penn reserved for himself, where he built a house, and planted orchards and gardens; which, with many additional buildings and improvements, still continue.

PENNSYLVANIA, one of the principal provinces of the United States of America, extending in length 228, and

PENNSYLVANIA.

and in breadth 156 miles, between 39° 43' and 42° N. lat. and 74° 48' and 80° 8' W. long. and comprehending 46,000 square miles. It is bounded E. by Delaware river, which divides it from New Jersey; N. by New York and lake Erie; N.W. by a part of lake Erie, where is a good port; W. by the state of Ohio and a part of Virginia; S. by Virginia, Maryland, and Delaware. The figure of this state is a parallelogram, if we except the N.W. corner of this state, containing about 202,000 acres, lately purchased of Congress by the states. In the year 1800 Pennsylvania was divided into thirty-five counties, as in the following Table :

Counties.	No. of Towns.	No. of Inhabitants.	Chief Towns.	No. of Inhabitants.
City and County } of Philadelphia }	18	81,009	Philadelphia	41,220*
Montgomery	28	24,150	Norristown	922

Erie	6	1,468	Erie	
Total 35	523	602,545		

* The suburbs contain 39,789 inhabitants.

A new census having taken place since the above table was formed, some of the statements admit of considerable alteration. The interruption of intercourse between the two countries has prevented our obtaining this census; but as soon as it is received, the necessary corrections shall be made.

The total number of acres in all the counties is reckoned at 29,634,840; and a great portion of the state is divided into townships, in each of which the freemen assemble annually to chuse overseers of the poor, assessors, a collector, supervisors of roads, and a constable. The number of inhabitants, which is 602,545, includes 1706 slaves. In this

state are six considerable rivers, viz. the Delaware, Schuylkill, Susquehannah, Youghiogeny, Monongahela, and Alleghany. The only swamps, worthy of notice, are the Great Swamp, between Northampton and Luzerne counties, and Buffalo Swamp, near the head waters of the Susquehannah. These swamps are found, upon examination, to be bodies of firm land, thickly covered with beech and sugar maple. A considerable proportion of this state may be reckoned mountainous. The principal ridges, in the great range of Alleghany mountains, comprehended in Pennsylvania, are the Kittatinny, or Blue mountains. Behind these, and nearly parallel to them, are Peters, Tuscarora, and Neshocope mountains, on the E. of the Susquehannah; and on the W. Sharemon's hills, Sideling hills, Ragged, Great Warriors, Evits and Will's mountains; then the great Alleghany ridge, which being the largest gives name to the whole range; and W. of this are the Chefnut ridges. Between the Juniata and the W. branch of the Susquehannah are Jacks, Tuffys, Nittiny, and Bald Eagle mountains. The vales between these mountains are generally of a rich, black soil, suited to the various kinds of grafs and grains. Some of the mountains admit of cultivation almost to their summits. The other parts of the state are generally level, or agreeably variegated with hills and vallies.

The soil of Pennsylvania is of various kinds; in some parts it is barren; but a great proportion of the state is good land, and no inconsiderable part of it is very good. In general, however, the soil is more fit for grain than for grafs. This state includes the greater part of the kinds of trees, shrubs, and plants, that grow within the United States. Oaks of several species form the chief bulk of the woods. Hickory and walnut are also more abundant than in the northern states. Sassafras, mulberry, and tulip or poplar trees are frequent and thriving. The Magnolia glauca grows in low grounds; and the acuminata attains to great height about the western mountains. Grapes are common; and some of them, mellowed by froit, with the addition of sugar, make good wine. The white pine and white cedar grow well in some parts; and also red cedars are not rare in high grounds. The sugar maple is plentiful in the western and northern parts of the state, and the inhabitants are supplied from them with a considerable quantity of sugar.

Iron ore is distributed in large quantities through various parts of the state; and in some places appear copper, lead, and alum. Here are also limestone quarries, and various kinds of marble. In the middle and western country is abundance of coal. In the new settlements of the country there are large flocks of wild turkies. Partridges are numerous; pheasants are dear; and grouse are found in some districts. In the cold season pigeons migrate from the north in large numbers. In spring and autumn, several kinds of ducks, and some wild geese, are found on the rivers. The singing birds migrate to Pennsylvania from the north and south in certain seasons, and are numerous. In the rivulets trouts are common; in the eastern rivers the principal fish are roch, shad, and herring, which, in the spring, come from the sea in large shoals. In the western waters are a species of catfish, weighing from 50 to 100 pounds, and also yellow perch and pike, which are large and numerous.

Among the useful quadrupeds in the new districts are deer in great number, beavers, otters, racoons, and monkeys. Buffaloes rarely cross the Ohio, and elks seldom advance from the north. Panthers, wild cats, bears, foxes, and wolves, are not rare; the fur of all which is valuable. In the north settlements rabbits and squirrels are frequent; in the marshes are minks and musk-rats: but opossums and ground hogs are rare. The best settled land is on the south

PENNSYLVANIA.

side of Pennsylvania; which is owing to the roads that have been formed in this part of the country and adjacent districts. The principal article of agricultural cultivation is wheat. The next in value is Indian corn. Buck-wheat, rye, barley, and oats, are also cultivated. As are also German spelts, chiefly as food for horses. Potatoes are plentiful; and also turnips, cabbage, parsneps, and carrots, and the small oval pea. The culture of meadows is a considerable object in this state; those on the rivers are banked, drained, tusked, ploughed, and harrowed; and sown with Timothy grass and clover. The summer is long enough to admit of two mowings, and even three in rich ground. On farms that have springs and streams, dairies are built over them so as to place the milk-vessels in the water, which is necessary to avoid the injurious effects of heat. Horses, it is said, are raised beyond the proper use, as oxen might more generally supply their place. The best for teams are bred in Lancaster county; and the elegant saddle and coach horses have more or less of the blood of stallions imported from England. The number of sheep is considerable, and increases. Hogs, supplied with food from the woods of oak and beech, exceed home consumption. Mules and asses are hitherto very rare. Poultry are abundant, and turkeys are cheap. Flax and hemp are cultivated; the growth of hops is inconsiderable: bees are objects of attention. In favourable seasons, cherries, apples, and cider abound. Some attempts have been lately made about eleven miles from Philadelphia for the plantation of vineyards. Improved farms and roomy lots in the country towns have gardens, which supply common vegetables, fruits, and flowers.

The general style of architecture in this state is neat and solid. Stone buildings are most common in the old settlements; log and frame-houses in the new. Towns have a considerable proportion of brick houses: shingles cover the roofs. Necessary tradesmen and mechanics are settled on small farms or lots throughout the improved country, and also in villages. Manufacturers dwell chiefly in towns, though many of them are scattered through the country. The product of domestic female industry is considerable. The wives and daughters of even opulent farmers knit and spin; and in the towns, some females of higher rank do the same. Woollen stockings are made in sufficient quantity for use; and hemp, which is used in several places for coarse wearing apparel, bags, lines and nets, &c. is manufactured, in large quantities, into cordage, cables, and ropes. Iron works are of long standing, and are in an improving condition. The furnaces are 16, and the forges 37. The sitting and rolling-mills are said to cut and roll 1500 tons *per annum*. The fabricated articles are numerous, and of all the common kinds. Manufactories of leather, skins, and fur, are very extensive and good. The most respectable trades employed in materials of wood are cabinet-making, house-carpentry, coach-making, and ship-building. The port of Philadelphia is said to be among the first in the world for naval architecture. Paper of most kinds form a beneficial branch of manufacture, in which are employed above 50 mills, the annual product of which is computed at 25,000 dollars. Manufactories in stone, clay, and fossils, are bricks, and various pieces of marble, common earthen ware, grind-stones, and mill-stones. Pot and pearl-ashes are gradually advancing; tin-wares are well executed for various domestic purposes. Copper, brass, lead, and pewters are also the materials of various manufactured articles. A considerable quantity of cotton is wrought in families; linens imported are now printed; sugar refineries, and distilleries of molasses, and various preparations of tobacco, furnish employment for many hands. The manufactures of

Pennsylvania are said to have greatly increased within a few years, partly by the immigration of workmen from abroad, as well as by the skill and industry of the natives. Several new machineries have been lately set up at Philadelphia, and in some other places.

The commerce of Pennsylvania with the eastern and northern states, is, in great part, an exchange of staple commodities; which are too numerous to be recited. The commerce of Pennsylvania with the west is carried on by the Ohio with the Spanish, and by the lakes with the British dominions; and both ways with the Indian tribes. At present nearly the whole foreign commerce is carried on by the port of Philadelphia. The value of the exports from this state in the year ending September 30, 1791, was 3,436,092 dollars, 58 cents; in 1792, 3,820,662 dollars; in 1793, 6,958,836 dollars; in 1794, 6,643,092 dollars; in 1795, 11,528,260 dollars; in 1799, 12,431,967 dollars; in 1801, 17,438,193 dollars; in 1804, 11,030,157 dollars. The importation is very great, both for the consumption of Pennsylvania, and of the districts supplied from Philadelphia: common and fine imported linens and woollens are used to a great amount, notwithstanding the quantity of home-made; much Swedish iron and Russian hemp is imported; and English hard-ware is in great demand. The tonnage of this state amounted, in 1796, to 98,237 tons; in 1799, to 93,824 tons.

The population of this state (for which see the Table) is, according to the census of 1800, more than 13 for every square mile. The inhabitants are principally the descendants of English, Irish, and Germans, with some Scotch, Welsh, Swedes, and a few Dutch. The Friends and Episcopalians are chiefly of English extraction, and compose about one-third of the inhabitants. The Germans compose about one-quarter of the inhabitants of Pennsylvania: they consist of Lutherans (who are the most numerous), Calvinists or the Reformed church, Moravians, Catholics, Mennonists, Dutch Baptists (corruptly called Tunkers and Dunkers, by way of reproach), and Zwingfelters, who are a species of Quakers. They are all distinguished for their temperance, industry, and economy. The Baptists (except the Mennonist and Dutch Baptists) are chiefly the descendants of emigrants from Wales, and are not numerous. The original Swedes went over in the year 1638, as a colony, under the government and protection of Sweden. Few Swedes have since settled in America: and their language is nearly extinct. These people uniformly had the character of probity, mildness and hospitality; but have been careless of their lands and interest. A privilege, almost peculiar to this state, has been granted to foreigners by the legislature; *viz.* that of buying and holding lands and houses within this commonwealth, without relinquishing their allegiance to the country in which they were born.

The character of the Pennsylvanians is naturally diversified by difference of extraction, various degrees of education, and of opulence.

The congregations of the different denominations of Christians in Pennsylvania are as follow; *viz.* Presbyterians, 86 congregations; German Calvinists, 84; German Lutherans, 84; Friends or Quakers, 54; Episcopalians, 26; Baptists, 15; Roman Catholics, 11; Scotch Presbyterians, 8; Moravians, 8; Free Quakers, 1; Universalists, 1; Covenanters, 1; Methodists, several; besides a Jewish synagogue; amounting in all to about 400 religious societies. Religious liberty was formerly on a more respectable establishment in this state than in the other parts of America. But even here it was imperfect till the late revolution; for Roman Catholics and Jews were excluded from a share in the government. The latter continued under this disadvantage,

PENNSYLVANIA.

tage, until the new constitution gave them, and all people of whatever nation or religion, unlimited liberty of conscience, with capacity for all civil rights and privileges.

The military strength of this country consisted, in 1799, of 93,221 men.

Pennsylvania abounds with literary, humane, and other useful institutions more than any other of the American States. We shall here merely enumerate them, and mention the time of their institution. They are the American Philosophical Society, formed in 1769 (see SOCIETY); the Society for promoting Political Inquiries, instituted in February 1787; the College of Physicians, instituted in the same year, and incorporated in 1789; the Pennsylvania Hospital, established in 1751; Philadelphia Dispensary, instituted in 1786; the Pennsylvania Society for the Abolition of Slavery and the Relief of free Negroes unlawfully held in bondage, begun in 1774 and enlarged in 1787; the Society for alleviating the Miseries of Prisons, which is become a regular work-house with an annexed place of confinement; the Society of United Brethren for propagating the Gospel among the Heathens, instituted in 1787; the Pennsylvania Society for the Encouragement of Manufactures and useful Arts, instituted in 1787; the Philadelphia Society for the Information and Assistance of Persons emigrating from foreign Countries, instituted in 1794. Besides these there are two insurance companies, an humane society, for the recovery of drowned persons, instituted in 1770; an agricultural society, a society for the relief of German, and another for the relief of Irish emigrants, a marine society, a charitable society for the support of widows and families of Presbyterian clergymen, and St. George's and St. Andrew's charitable societies. Most of these societies are in the city of Philadelphia.

Under the head of colleges, &c. we may enumerate the University of Pennsylvania, founded and endowed by the legislature during the late war, and lately united with the college of Philadelphia; Dickinson college, at Carlisle; Franklin college, at Lancaster; and the college at Washington (see COLLEGE); the academy of the Episcopalians, at York-town; the academies at German-town, Pittsburgh, Allen's-town, and other places; the schools of the Moravians, and other private schools in different parts of the state. The principal cities and towns of Pennsylvania are Philadelphia, the metropolis, the borough of Lancaster, Pittsburgh, Bethlehem, Nazareth, Carlisle, Harrisburg, Yorktown, Washington, Sunbury, &c. See the Table at the beginning of this article, and an account of each town under its respective name.

As to the constitution of this state, we may observe, that the supreme executive power of the commonwealth is vested in a governor; the legislative, in a general assembly, consisting of a senate and a house of representatives. The governor is chosen for three years, but cannot hold his office more than nine years in twelve. A plurality of votes makes a choice. The representatives are elected for one year; the senators for four. The latter are divided into four classes. The time of one class expires each year, whose seats are then filled by new elections. Each county chooses its representatives separately. The senators are chosen in districts formed by the legislature. There is to be an enumeration of the inhabitants once in seven years. The number of senators and representatives is, after each enumeration, to be fixed by the legislature, and apportioned among the several counties and districts, according to the number of taxable inhabitants. There can never be fewer than sixty, nor more than one hundred representatives. The number of senators cannot be less than one-fourth, nor greater than

one-third of the representatives. The elections are made on the second Tuesday of October. The general assembly meets on the first Tuesday of December, in each year, unless sooner convened by the governor. A majority of each house makes a quorum to do business, and a less number may adjourn from day to day and compel the attendance of members. Each house chooses its speaker and other officers, judges of the qualifications of its members, and establishes the rules of its proceedings. Impeachments are made by the house of representatives, and tried by the senate. All bills for raising revenue originate in the lower house, but the senate may propose amendments. The senators and representatives are free from arrests, while attending the public business, except in cases of treason, felony, and breach of the peace; and are not liable to be questioned concerning any thing said in public debate. They are compensated out of the public treasury, from which no money can be drawn but in consequence of appropriation by law. The journals of both houses are published weekly, and their doors kept open, unless the business require secrecy. All bills which have passed both houses, must be presented to the governor. If he approve he must sign them, but if he does not approve he must return them, within ten days, with his objections, to the house in which they originated. No bills so returned shall become a law, unless it be re-passed by two-thirds of both houses. The governor is commander-in-chief of the military force; may remit fines and forfeitures, and grant reprieves and pardons, except in cases of impeachment; may require information from all executive officers; may, on extraordinary occasion, convene the general assembly, and adjourn it, for any term not exceeding four months, in case the two branches cannot agree on the time themselves. He must inform the general assembly of the state of the commonwealth; recommend such measures as he shall judge expedient; and see that the laws are faithfully executed. In case of vacancy in the office of governor, the speaker of the senate exercises that office. The judicial power is vested in a supreme and inferior court, the judges of which, and justices of the peace, are appointed by the governor, and commissioned during good behaviour; but are removeable on the address of both houses. The other officers of the state are appointed, some by the governor, some by the general assembly, and some by the people. The qualifications for an elector are 21 years of age, two years' residence, and payment of taxes. They are privileged from arrests in civil actions, while attending elections. Those for a representative are 21 years of age, and three years inhabitancy. For a senator, 25 years of age, and four years inhabitancy. For a governor, 30 years of age, and seven years inhabitancy. The governor can hold no other office. The senators and representatives none, but of attorney at law, and in the militia. No person, holding an office of trust, or profit, under the United States, can hold any office in this state, to which a salary is by law annexed. All the officers of the state are liable to impeachment, and are bound by oath, or affirmation, to support the constitution, and perform the duties of their offices.

The declaration of rights asserts the natural freedom and equality of all; liberty of conscience; freedom of election, and of the press; subordination of the military to the civil powers; trial by jury; security from unreasonable searches and seizures; a right to an equal distribution of justice; to be heard in criminal prosecutions; to petition for the redress of grievances; to bear arms; and to emigrate from the state. It declares that all power is inherent in the people, and that they may, at any time, alter their form of government; that no person shall be obliged to maintain religious

worship, or support any ministry; that all persons, believing in the being of a God, and a future state of rewards and punishments, are eligible to office; that laws cannot be suspended but by the legislature; that all persons shall be bailable, unless for capital offences, when the proof is evident, or presumption strong; that every debtor shall be released from prison, on delivering his estate to his creditors, according to law, except there be strong presumption of fraud; that the privileges of the writ of *habeas corpus* shall not be suspended but in time of rebellion, or public danger; that no *ex post facto* law shall be made; that no person shall be attainted by the legislature, or forfeit his estate for a longer term than his own life; that no title of nobility, or hereditary distinction, shall ever be granted. The constitution above described was ratified in 1790.

Under the head of the history of this state it is not necessary to enlarge. Pennsylvania was granted by king Charles II. to Mr. William Penn, son of the famous admiral Penn, in consideration of his father's services to the crown (see his biographical article); and the charters received the royal signature on the 4th of March 1681. To secure his title against all claims, and prevent future altercation, Mr. Penn procured a quit-claim deed from the duke of York, of all the lands covered by his own patent, to which the duke could have the least pretensions. This deed bears date August 21, 1682. In the same month he obtained from the duke, by deed of feoffment, Newcastle, with 12 miles of the adjacent territory, and the land south to the Hoarkills. In December following, Mr. Penn effected an union of the lower counties with the province of Pennsylvania. The first frame of government for Pennsylvania is dated in 1682; another was proposed by Mr. Penn in 1683; in 1699, while Mr. Penn remained in Pennsylvania, the last charter of privilege, or frame of government, which continued till the revolution, was agreed upon and established. It was delivered to the people in October 1701. In 1700, 1701 and 1708, Mr. Penn obtained from different denominations of Indians some portion of territory. By the favourable terms which Mr. Penn offered to settlers, and an unlimited toleration of all religious denominations, the population of the province was extremely rapid. At the revolution the government was abolished; and the people, by their representatives, formed a new constitution on republican principles. The proprietaries were excluded from all share in the government, and the legislature offered them 130,000*l.* in lieu of all quit-rents, which was finally accepted. The proprietaries, however, still possess in Pennsylvania many large tracts of excellent land. After many disputes the republicans acquired the ascendancy, and the constitution underwent an alteration, that assimilated it nearly to the federal constitution. The federal constitution was ratified by Pennsylvania December 13, 1787. Morse's Geography, 1805.

PENNY, or PENY, in *Commercie*, an ancient English coin, which had formerly considerable course; but is now dwindled into an imaginary money, or money of account.

It is derived by Camden from *pecunia*; but others suppose that the word is formed from *pendo*, to weigh, and it was sometimes written, according to this origin, *penning*.

The ancient English penny, *penig*, or *pening*, was the first silver coin struck in England; nay, and the only one current among our Saxon ancestors; as is agreed by Camden, Spelman, Dr. Hickes, &c.

Of the heptarchic pennies we have given an account under the article MEDALS, &c., *Modern*; and we have there

given a brief history of the penny, as a silver coin, both before and after the Conquest.

The penny, which in Ethelred's time was the 20th part of the troy ounce, was equal in weight to our three-pence; five of them made one shilling, or scilling Saxon; and thirty a mark or mancuse, equal to our 7*s.* 6*d.* It was the largest silver coin in England, and retained this value till the reign of Edward III.

Till the time of king Edward I. the penny was struck with a cross so deeply indented in it, that it might be easily broke, and parted, on occasion, into two parts; thence called *half-pennies*; or into four, thence called *fourthings*, or *farthings*. But that prince coined it without indenture; in lieu of which he first struck round half-pence and farthings.

Stow, in his Annals, p. 200, observes, that half-pennies were first coined round, A. D. 1279, in the reign of Edward I. But historians have since discovered, that half-pennies of this kind were coined by Henry I., and that though the usual way in the reign of the two first Williams was to cut the penny into two for making of half-pennies, &c. yet it has been supposed that some few half-pennies might even then be coined round. Some few pieces of this kind are preserved in the cabinets of the curious. See Mr. Pegge's remarks on this subject in *Gent. Mag.* vol. xxviii. p. 64. &c.

Edward I. also reduced the weight of the penny to a standard; ordering that it should weigh thirty-two grains of wheat, taken out of the middle of the ear. (Stat. 13 Edw. I.) This penny was called the penny sterling. Twenty of these pence were to weigh an ounce; whence the penny became a weight, as well as a coin.

By 9 Edw. III. it was diminished to the twenty-sixth part of the troy ounce; by 2 Henry VI. it was the thirty-second part; by 5 Edw. IV. it became the fortieth, and also by 36 Hen. VIII. and afterwards the forty-fifth; but by 2 Eliz. sixty pence were coined out of the ounce, and during her reign sixty-two, which proportion is observed in our times.

The penny sterling is now disused as a coin; and scarcely subsists, but as a money of account, containing the twelfth part of a shilling, or the two hundred and fortieth part of a pound.

The course of exchange between England and France is settled on the foot of so many pence sterling, for a French crown of three livres. See EXCHANGE.

For an account of the French penny, or denier, in the old system, see DENIER. For the Dutch penny, see PENNING. For the German penny, see PFENING.

The *penny Flemish*, called "grote," or "groot," is a money of exchange in Flanders, Holland, and Hamburg. Accounts are sometimes kept in Brabant and Flanders in pounds Flemish of 20 shillings Flemish, subdivided into twelve groots or pence Flemish; but mostly in florins or gilders of 20 fluyvers or stivers, called also patacs, each of which was formerly subdivided into 16 pennings, but for a long time they have been divided into twelve parts or deniers. The pound Flemish, or pond Vlams, is reckoned at 2½ rix-dollars, 6 florins, 20 shillings, 120 stivers, 240 groots, or 1920 Brabant pennings. The rix-dollar, or patacon, is worth 2½ florins, 8 shillings Flemish, 48 stivers, or 96 pence Flemish. The Brabant penning contains three mites. See PFENING.

PENNY, in *Ancient Statutes*, &c. is used for all silver money.

And hence the *ward-penny*, *aver-penny*, *hundred penny*, *tithing-penny*, and *brothal-penny*. See PENCE, &c.

PENNY,

PENNY, in *Geography*, a town of Bengal; 18 miles S.E. of Purneah.

PENNY-Earth, in *Agriculture*, a term used by the farmers for a hard, loamy, or sandy earth, with a very large quantity of sea-shells intermixed in it, some of which being round and flat, and in some measure resembling pieces of money, have occasioned the earth's being called by this name. It is an earth not easily dug, but is usually undermined with pick-axes, and then falls in large lumps: which, with the frosts, break to pieces, and leave the shells loose. It is prepared by breaking and mixing well with water, and then makes very desirable floors. The Jersey combers' comb-pots are also made of it, and the sides and roofs of ovens are plastered with it; and being rightly managed, it combines into a floor almost as strong as plaster of Paris.

PENNY, *Bord*, *Half*. See *BORD Half-penny*.

PENNY, *Half*. See *HALF penny*.

PENNY, *Rete*. See *RETE-penny*.

PENNY, *Schar*. See *SCHAR-penny*.

PENNY, *Ward*. See *WARD-penny*.

PENNY or *Two-penny Post*. See *POST*.

PENNY-Royal, in *Botany*, &c. See *MENTHA Pulegium*.

PENNY-Royal, *Virginian*, a species of *Satureia*; which see.

PENNY-Weed, in *Agriculture*, a troublesome weed, known sometimes by the name of nettle.

PENNY-Wort, in *Botany*. See *COTYLEDON*.

PENNY-Wort, *Marj* and *Water*. See *HYDROCOTYLE*.

PENNY-Weight, a troy weight, containing twenty-four grains; each gram weighing a gram of wheat, gathered out of the middle of the ear, well dried.

The name took its rise hence, that this was actually the weight of one of our ancient silver pennies.

Twenty of these penny-weights make an ounce troy. See *WEIGHT*.

PENOBSCOT, in *Geography*, a river of America, which is the most considerable in the district of Maine, and rises by two branches in the high lands. Between the source of the W. fork, and its junction with the E., is Moosehead lake, 30 or 40 miles long, and 15 wide. The E. branch passes through several smaller lakes. From the Forks, as they are called, the Penobscot Indians pass to Canada, along either branch, principally the W., the source of which, as they say, is not more than 20 miles from the waters which empty into the St. Lawrence. At the Forks is a remarkable high mountain: and from thence down to Indian Old Town, situated on an island in this river, the distance is about 60 miles, and in the interval the river widens and embraces a great number of islands. Just below Indian town are the Great Falls, where is a carrying place of about 20 rods, and thence for 12 miles to the head of the tide there are no falls to obstruct boats. From thence for 35 miles to the head of Penobscot bay, or to the site of old fort Pownal, the river flows in a pretty straight course, and is easily navigated. Passing by Mahagaduse on the E. seven miles, and Owl's head twenty miles farther, you enter the ocean. The Indians have a communication from this river to Scoodick river, by a portage of three miles. This river was the eastern limit of Nova Scotia or Acadia, by the treaty of Utrecht. Within about twenty miles there are more than sixty islands, of various sizes, comprehending in the whole about 12,000 acres. Fifty-four of these the Indians have reserved to their own use.

PENOBSCOT, a bay on the coast of Hancock county, in the state of Maine, and called by the first discoverer "Norembege," about sixteen leagues wide from Naskeag point and Burnt-coat island on the E., to the point on which

Thomastown stands, on the W. side of the bay. The chief islands it incloses are Fox, Haut, Long and Deer islands; besides a number of small isles, rocks, and ledges. On a fine peninsula on the E. side of the bay, the British built a fort, and made a settlement, which is now the fire-town of the county of Hancock, and is a commodious place for the lumber trade. Haut island, or the isle of Holt, lies in N. lat. $44^{\circ} 23'$, and W. long. $68^{\circ} 10'$, and is the southernmost of the large isles.

PENOBSCOT, a post-town of Maine, on the E. side of the bay of its name, which is a port of entry, and carries on a small trade in fish and lumber. In 1796 it was divided into two towns; the one retaining the name of Penobscot, containing 935 inhabitants, and the other named "Castine," which see.

PENOBSCOTS, a small tribe of Indians who live in Indian Old Town, on an island in Penobscot river, and who say, that they have for five hundred years possessed the island on which their town stands. (See *INDIAN Old Town*.) In a former war, this tribe lost its lands; but at the commencement of the last war, some new restrictions were settled, and they consider that, notwithstanding these, they have a right to haul and fish as far as the mouth of the bay of Penobscot extends. This was their original right, in opposition to any other tribe, and they now enjoy it.

PENOMAZIN, a town of Siam; 60 miles S. of Tennasserim.

PENON. See *PENNON*.

PENON, *El*, in *Geography*, a town of South America, in the province of Carthagea; 36 miles S. of Mompox.

PENOWAL, a town of Hindoostan, in the circar of Oudeypour; 20 miles S.E. of Cheitor.

PENRHYN, a sea-port of North Wales, in the county of Caernarvon, on the Menai, from which great quantities of slate are exported; two miles S.W. of Bangor.

PENRHYN Dwa, a cape on the W. coast of Wales, and county of Caernarvon; 10 miles S. of Pwllhely.

PENRHYS, or *PENRICE*. See *OXWICH*.

PENRISE, a town of South Wales, in the county of Glamorgan, on the W. side of a bay in the Bristol channel, having a castle and a weekly market on Thursday; 14 miles W.N.W. of Swansea. N. lat. $51^{\circ} 46'$. W. long. $4^{\circ} 10'$. See *OXWICH*.

PENRITH, *NEW*, a market town in Leath ward, and county of Cumberland, England, is situated in a vale within the district called Inglewood Forest, 18 miles from Carlisle, and 283 from London. It is a place of considerable antiquity, and was successively in possession of the English and Scottish sovereigns; during whose contentions it suffered by the depredations of the Scots, by whom it was burned in the 18th of Edward III., and again in the following reign. About that period the plague raged in Penrith: and in the year 1597, a second visitation of this dreadful disorder nearly depopulated the parish; for 2260 persons fell victims to it within a year and a half. The fear of infection prevented the continuance of the regular markets; and places were appointed, without the town, for purchasing the provisions brought by the country people. Penrith is built in a very irregular manner: the houses are, in general, composed of red stone, and covered with blue slate. The population, in the year 1811, amounted to 4328, occupying 938 houses. The inhabitants are chiefly employed in agriculture, and in weaving checks and fancy cloths for waistcoats. A weekly market is kept on Tuesday, and here are five annual fairs. The stations for marketable commodities are disposed in a singular manner: the wheat market is in one part of the town, barley is sold

in

in another part, rye and potatoes in a third: cattle, hogs, and horses, have also distinct places of sale. The church is a neat, but plain structure: the body was rebuilt of red stone in the year 1722, at the expence of 2253*l.* and connected with the ancient tower. In the church-yard is a singular monument of antiquity, called the Giant's Grave, the origin of which has frequently exercised the sagacity and speculations of antiquarians. It consists of two stone pillars, standing at the opposite ends of a grave, about the distance of fifteen feet asunder, eleven feet six inches in height, and nearly five feet in circumference at the bottom, where they are mortised into round stones embedded in the earth. The space between them is two feet in breadth, and is inclosed by four thin semi-circular stones, two on each side, of unequal lengths, but little more than twenty inches in height. Three of these stones have an ornament of foliage, rudely sculptured, remaining round their upper edges; the fourth is plain, of a different kind, and seems to have been placed in the room of one decayed. The pillars taper upwards; their lower parts are rounded to about the height of seven feet, where they assume a square form, and appear to have terminated in a point; but the tops are broken. On the square parts are some traces of ornamental fret-work; and the interior side of one pillar has a rude delineation of some animal, resembling the wolf. Near the summit of each pillar are the vestiges of a raised cross, now almost obliterated. Bishop Lyttleton, in his remarks on this monument (published in the *Archæologia*;) inclines to the opinion of its being the sepulchre of some British prince interred here subsequent to the introduction of Christianity; and tradition ascribes it to the British king Ewain, a warrior of gigantic size, who reigned in this county in the time of Athelstan, or Ida. That this Ewain was actually buried at Penrith, appears in the highest degree probable, from the notice of his sepulchre in the "Verses of the Graves of the British Warriors," written about the close of the sixth century. At a small distance from this monument, with which, however, it does not appear to have any connection, is a single stone, called the Giant's Thumb, five feet eight inches in height, about fourteen inches broad at the lower part, but contracting upwards to ten inches: the head, which appears to have been circular, expands to the diameter of about eighteen inches. This seems to have been an ancient stone cross.

Previous to the year 1400, the inhabitants of Penrith were frequently distressed for fresh water: but about that time, Strickland, bishop of Carlisle, purchased a sufficiency of the water of the river Peteril, which he conveyed to the town at his own expence. He also founded a chantry here, and endowed it with six pounds annually for the support of a priest. The revenues of this establishment were given by queen Elizabeth to an ancient school (instituted so early as the year 1340,) which she refounded, by the title of "The Free Grammar School of Queen Elizabeth in Penrith."

Westward of this town are the ruins of a castle, which appears to have been built of an oblong form, and fortified with a very deep outward foss, and a walled rampart. This fortress was dismantled in the time of the commonwealth: the principal remains are the outside walls and arched vaults.

On the heights, to the north of Penrith, is a square stone building, called the Beacon, difficult of access, but affording a variety of delightful views of the surrounding country. *History and Antiquities of Westmoreland and Cumberland*, by Nicholson and Burn, 2 vols. 4to. 1777. *Beauties of England and Wales*, vol. iii. by Britton and Brayley.

PENRY, AR-HENRY, JOHN. in *Biography*, a victim to persecution and tyranny in the reign of queen Elizabeth, was born in some part of the county of Brecknock in the year 1559. When he was about the age of nineteen, he became a sub-sizer of Peter-House, in the university of Cambridge, where he was admitted to the degree of B.A. about the year 1583. After he had finished his college studies he took holy orders, and preached several times at Oxford, as he did afterwards at Cambridge, with much reputation, but he soon rendered himself obnoxious to the ruling party in the church, by adopting the sentiments of that body of the clergy who were distinguished by the name of *Puritans*. Having chosen his lot with this proscribed party, he travelled into Wales, and he is said to have been the first who preached the gospel publicly in Welsh, and sowed the good seed among his countrymen. In the year 1588 he published "A View of some Part of such Public Wants and Disorders as are in the Service of God, within her Majesty's Country of Wales, with an humble Petition for speedy Redress;" in which he undertook to shew, not only the necessity of reforming the state of religion among the Welsh, but also the most proper means of bringing about that work. He likewise published, about the same time, "An Exhortation to the Governors and People of her Majesty's Country of Wales, to labour earnestly to have the preaching of the Gospel planted among them." Both these pieces were written upon Puritanical principles, and were attacked by some zealous friends to the established hierarchy.

As the public printing-presses were shut against the Puritans, some of them purchased a private one, and carried it about from one part of the country to another to prevent discovery. The publications which excited the greatest attention, were supposed to be the productions of a club of writers, of whom Mr. Penry was esteemed one of the most active. Among the tracts which were printed and dispersed by them all over the kingdom, one that gave the most offence bore the title of "Martin Mar-Prelate," which contained a violent and bitter satire against the hierarchy, and all its supporters, and was soon followed by other pieces of the same description. When these pieces were known, a special warrant was issued by the privy-council in 1590, with the signatures of archbishop Whitgift and other members, for the apprehension of Mr. Penry as an enemy of the state, and calling upon all the queen's good subjects to consider him in that light. Penry withdrew into Scotland, where he drew up many observations on subjects relating to religion for his own private use; and he prepared the heads of a petition to the queen, intended to lay before her the true state of religion, and the many abuses in the church of England, especially in the management of ecclesiastical matters, of which her majesty was ignorant. One object of it was that he might be allowed to return to Wales, to preach the gospel in his native country. With the intention of finishing the petition above-mentioned, when opportunity should offer, and of delivering it afterwards to the queen with his own hands, Mr. Penry ventured back to England in the year 1593, and lived in concealment at Stepney, near London, till he was discovered, seized, and thrown into prison. Having obtained his papers, the privy-council determined to prosecute him without delay for a capital offence. No evidence could be brought against him but what his own private papers afforded; nevertheless, upon this, his enemies contrived to get a verdict against him, and it was soon resolved that he should be put to death. He protested against the sentence as totally contrary to the law of the land: he defied his persecutors to prove against him a single

a single act of disloyalty, but he had attacked the hierarchy, and could not be forgiven. Archbishop Whitgift was the first person who signed the warrant for his execution. As soon as the warrant was signed, it was sent to the sheriff, who, on the same day, gave orders to erect a gallows at St. Waterings, and while the prisoner was at dinner, sent his officers to bid him prepare to die that afternoon. He was accordingly carried, without delay, to the place of execution, and so savage was the conduct of the sheriff that he refused him the opportunity of addressing his friends, but was turned off in a hurry on the 29th of May 1593, when he was in the 34th year of his age. His learning and piety were highly extolled by his friends; and Mr. Strype says of him, "that he was well disposed to religion, but mistaken in his principles, and so very hot in his temper, and became so busy in church controversies, to his own destruction." He had connected himself with that branch of the Brownists, who maintained the discipline of the church of England to be popish and anti-christian, and all her ordinances and sacraments invalid. (See BROWNISTS.) Besides the articles already noticed, Mr. Penry was author of "An Appellation to the High Court of Parliament, from the bad and injurious Dealing of the Archbishop of Canterbury, &c.;" "A Dialogue on the injurious Dealings of the Bishops;" and "A Treatise to shew that Reformation, and those that sincerely favour the same, are unjustly charged to be Enemies to her Majesty and the State." The editor of this Cyclopædia traces his genealogy, by the maternal branch, to the family of Mr. Penry.

PENRYN, in *Geography*, a borough and market-town in the parish of St. Gluvias, hundred of Kerriar, and county of Cornwall, England, is situated three miles from Falmouth, and 266 from London, on the side of a hill, and bank of a river, called the King's road, which unites with Falmouth harbour. The town formerly possessed a college, which, according to Leland, was castellated, and had three strong towers. Parts of this were lately to be seen, but are now enveloped by modern buildings. The manor was an appendage to the see of Exeter, and the town appears to have been made a borough by one of the bishops towards the end of the reign of Edward I. The town was incorporated in the 18th year of James I. and is governed by a mayor, recorder, steward, portreeve, twelve aldermen, twelve common-council-men, a town clerk, and other officers. Two members are returned to parliament; the right of election is in the mayor, aldermen, and inhabitants paying scot and lot. Three weekly markets are held on Wednesday, Friday, and Saturday, and three fairs annually. The market-house, which is also used as a town-hall, stands near the middle of the principal street, from which others diverge at right angles. From the peculiar situation of the town, it possesses an extensive fishery. In the population returns of the year 1811, Penryn is stated to contain 362 houses, inhabited by 2713 persons. On the opposite side of the river is the village of St. Gluvias, the church and parsonage house of which are placed in very beautiful situations. Polwhele's History, &c. of Cornwall. Beauties of England and Wales, vol. ii.

PENS, a town of the island of Cuba; 22 miles S.W. of Bayamo.

PENSA LIBRA, in our *Ancient Customs*, a pound of money paid by weight, not by tale.

PENSACOLA, in *Geography*, the capital of West Florida, situated on the W. side of a bay, to which it gives name. The harbour is on the N. shore of the gulf of Mexico; 11 leagues E. of Port Lewis and Mobile, and 158 W. of the islands of Tortuga. It is spacious, and fe-

cure from all winds, and has four fathoms of water at its entrance, deepening gradually to seven or eight. The bay lies in N. lat. 30° 15', and W. long. 87° 14', and admits of vessels drawing no more than 21 feet of water. The town is of an oblong form, healthfully, as well as delightfully situated, about one mile in length, and a quarter of a mile in breadth. While the British nation possessed it, it contained several hundred habitations, and many of the houses and public buildings were spacious and elegant. But since the Spaniards took possession of it, it has been upon the decline. The exports from this town, consisting of skins, logwood, dyeing stuff, and silver dollars, amounted, while it belonged to Britain, to 63 000*l* annually; and the average value of imports from Great Britain was 97,000*l*. The town and fort of Pensacola surrendered, after a spirited defence, to the Spaniards in 1781; and with them the whole province. The entrance into the bay is defended by a small fort and the W. end of Rose's island, and a battery nearly opposite, on the main land. Escambia Coenecuh river is the largest stream which falls into the bay; it admits shallops some miles up, and boats upwards of 50 miles. N. lat. 30° 18'. W. long. 87° 17'.

PENSEN, a town of Germany, in the principality of Culmbach; six miles E. of Bayreuth.

PENSFORD *St. Thomas*, or as it is sometimes called *Publow St. Thomas*, a small market town in the hundred of Keynsham, and county of Somerset, England, is seated on the river Chew, which here flows through a fine wooded vale environed by small hills, the acclivities of which are covered with orchards. It is a town of high antiquity, and is conjectured by Dr. Stukeley to have derived its name from the British words *Pen Ifc*, signifying the head of the river, being near the source of the Chew. In the time of Leland it seems to have been a very flourishing place, for it is mentioned by that assiduous antiquary as "a praty townlet, occupied with clothinge." This business is now, however, much declined, and the town is nearly bereft of all its former trade. None of its buildings deserve notice except the church, which is a handsome, modern structure, with a tower at the west end, apparently of more ancient date than its other portions. The market day here is Tuesday, and there are two fairs annually. An old stone bridge of three arches is thrown over the river, and connects the town with the village of Publow, to the church of which that of Pensford is a chapelry, though in other respects it is parochial.

According to the late population returns, (1811,) Pensford town and parish contain 66 houses and 144 inhabitants. By the same census the parish of Publow contains 166 houses and 820 inhabitants. History of Somersetshire by the Rev. John Collinson, vol. ii. 4to. Beauties of England and Wales, vol. xiii.

PENSILES HORTI, in *Antiquity*, gardens raised on arches by Nebuchadnezzar, king of Babylon, in order to gratify his wife Amyctis, daughter of Altyages, king of Media. Q. Curtius makes them equal in height to the walls of the city, viz. fifty feet. They contained a square of four hundred feet on every side, and were carried up into the air in several terraces, laid above one another, and the ascent from terraces to terraces was by stairs ten feet wide. The arches sustaining the whole pile were raised above one another, and it was strengthened by a wall, surrounding it on every side, of twenty-two feet in thickness. The floors of each of the terraces were laid in the following manner: on the top of the arches were first laid large flat stones sixteen feet long and four broad, and over them was a layer of reed, mixed with a great quantity of bitumen, over which were two rows of bricks closely cemented together by plaster,

plaster, and over all were laid thick sheets of lead; and, lastly, upon the lead was laid the mould of the garden. The mould or earth was of such a depth, as to admit the largest trees to take root and grow; and it was covered with various kinds of trees, plants, and flowers. In the upper terraces there was an aqueduct or engine, whereby water was drawn up out of the river, for watering the whole garden. *Diod. Sic. lib. ii. Strab. lib. xvi. Q. Curtius, lib. v. c. 1. or Prid. Conn. vol. i. p. 144.*

PENSION, PENSIO, a yearly appointment, or sum of money paid any one for services or considerations already past. Of this kind are pensions from the crown, which disqualify those, on whom they are conferred, for being elected members of the house of commons. (See **PARLIAMENT**.) Those pensions exceeding the value of 100*l. per annum* are subject to a duty consisting in an annual payment of one penny in the pound, (over and above all other duties). A person, who takes a pension from any foreign prince without the consent of the king, is chargeable with the crime of contempt against the king's prerogative. See **CONTEMPT**.

For pensions of an ecclesiastical nature, see **CORODY** and the article **PENSIONS**.

PENSION, in *Military Language*, denotes the annual allowance granted by his majesty to the indigent widows of officers killed, or dying in the service, which may be considered as a kind of military reward. The fund for these pensions arises from the pay of two fictitious men, borne on the muster-roll of every troop or company in the army on the British establishment. The mode of granting this bounty is subject to certain regulations accompanying this grant in the year 1737. An augmentation has been since made to the amount of these pensions; and the new rates, commencing from the 25th of December, 1798, are as follow: for a colonel's widow, 80*l. per annum*; lieutenant colonel's, 50*l.*; major's, 40*l.*; captain and captain lieutenant's, 30*l.*; lieutenant's, 26*l.*; second lieutenant, cornet, ensign, quarter-master, and adjutant's, 20*l.*; pay-master's of the regiment or district, 26*l.*; chaplain's, 16*l.*; surgeon's of the regiment, 26*l.*; staff surgeon and apothecary's, 26*l.*; physician and purveyor's, 30*l.*; assistant and veterinary surgeon's, 20*l.*; deputy purveyor and hospital mate's, 16*l. per annum*. The pensions to widows of sea-officers, granted by the admiralty, are considerably increased, commencing from January 1814.

PENSION in the inns of court. That, which in the two Temples is called a *parliament*, and in Lincoln's Inn a *council*, is in Gray's Inn termed a *pension*; viz. an assembly of the members of the society to consult of the affairs of the house. *Pensions* also denote certain annual payments of each member to the house, for certain occasions.

When a pension writ is issued, none sued thereby in the inns of court shall be discharged, or permitted to come into commons, till all duties be paid.

Hence, a pension order, in the same inn, is a peremptory order against such of the society, as are in arrear for pensions, and other duties.

PENSIONS of Churches, are certain sums of money paid to clergymen in lieu of tithes; and some churches have settled on them annuities or pensions, payable by other churches; which pensions are due by virtue of some decree made by an ecclesiastical judge upon a controversy for tithes, by which the tithes have been decreed to be enjoyed by one, and a pension instead of them to be paid to another; or they have arisen by virtue of a deed made by the consent of the parson, patron, and ordinary; and if such pension hath been usually paid for twenty years, then it may be claimed by prescription, and be recovered in the spiritual court; or a

parson may prosecute his suit for a pension by prescription, either in that court, or at common law, by a writ of annuity; but if he takes his remedy at law, he shall never afterwards sue in the spiritual court. If the prescription be denied, that must be tried by the common law. *F.N.B. 51. Hard. 230. Ventr. 120.*

PENSIONARY, or PENSIONER, a person who has a pension, appointment, or yearly sum, payable during life, by way of acknowledgment: charged on the estate of a prince, company, particular person, or the like.

In the Romish countries it is frequent to have pensions on benefices; these were anciently granted with a great deal of ease, under pretence of infirmities, poverty, &c. But since the twelfth century, these pretences were carried so far, that the incumbents, or titularies, of benefices, were little more than farmers.

This obliged the spiritual powers to fix the causes, and the quantities, of pensions. Pensions are now only creatable by the pope, and are never to exceed one-third of the revenue; two-thirds being still to remain to the incumbent.

PENSIONARY was also the appellation of the first minister of the states of the province of Holland; under the old system.

The pensionary was chairman in assemblies of the states of that province; he proposed the matters to be consulted on, collected the votes, formed and pronounced the resolutions of the states; he also opened letters, conferred with foreign ministers, &c.

He was charged with inspecting the finances, preserving the rights of the province, maintaining the authority of the states, and seeing to the observation of the laws, &c. for the good of the state. He assisted in the college of deputy-counsellors of the province, who represented the sovereignty in the absence of the states; and he was perpetual deputy of the states-general of the United Provinces. His commission was only given for five years; after which it was deliberated whether or no it should be renewed. Indeed there was no instance of its having been revoked. Death only put a period to the functions of this important minister. Formerly he was called the *advocate of the province*: the title pensionary was only given at the time Barneveldt had the office. Grotius calls him in Latin *adversor jurisperitus*; Merula, *advocatus generalis*; and Matthæus, professor at Leyden, *filiarius pensionarius*, which is the quality the states gave him in their instruments.

PENSIONARY was also the first minister of the regency of each city, in the province of Holland.

His office was, to give his advice in matters relating to the government, either of the city in particular, or of the state in general; and in assemblies of the states of the province he was speaker in behalf of his city.

Yet the function of these pensionaries was not alike every where; in some cities they only gave their advice; and were never found in assemblies of the magistrates, except when expressly called thither; in others they attended constantly; and in others they even made the propositions on the part of the burgher-masters, drew up their conclusions, &c. They were called pensionaries, because they received an appointment or pension.

PENSIONERS, GENTLEMEN, a band of gentlemen, whose business it is to guard the king's person in his own house; and who for that end wait in the presence-chamber.

They were first set on foot by king Henry VII.; the number is forty; and each is obliged to keep three double horses, and a servant, who is to be armed; so that they properly

properly make a troop of guards, and have accordingly been mustered by their own officers; but this part of duty, to which they are sworn, the king usually dispenses with.

Their officers are a captain, whose salary is 100*l.* a-year, lieutenant, with 50*l.* a-year, standard-bearer, with 31*l.* a-year, and clerk of the cheque, whose annual appointment is 12*l.* Their ordinary arms are gilt pole-axes, with which they attend the king to and from the chapel royal; receiving him in the presence-chamber, or coming out of his private lodging; as also at all great solemnities. Their pension 100*l. per annum.*

To this band belong also a pay-master, harbinger, axe-keeper, and messenger.

PENSTOCK. See PEN.

PENTA, in *Geography*, a town of the island of Corsica; seven miles N.E. of La Porta.

PENTACEROS, in *Natural History*, a name given by Linkius, and some other authors, to a kind of *stella marina*, or sea star-fish, composed of five principal rays, with several transverse hairy or downy processes.

PENTACHONDRA, in *Botany*, from *πεντε*, *five*, and *χονδρος*, *a grain*, because of the five seeds in the berry, by which character the genus is distinguished from its allies. Brown Prodr. Nov. Holl. v. 1. 549. Class and order, *Pentandria Monogynia*. Nat. Ord. *Epacrideæ*, Brown.

Gen. Ch. *Cal.* Perianth inferior, double; the innermost of five equal, lanceolate, concave leaves; outermost of four or more, much smaller, imbricated ones. *Cor.* of one petal, funnel-shaped; limb in five spreading equal segments, longitudinally bearded on the upper side with dense hairs. Nectary of five scales, at the base of the germen. *Stam.* Filaments five, thread-shaped, equal, inserted into the tube; anthers incumbent, oblong. *Pist.* Germen superior, roundish, of five cells; style short, columnar; stigma obtuse. *Peric.* Berry with five seeds.

Ess. Ch. Outer calyx of four or more leaves. Corolla funnel-shaped; its limb spreading, longitudinally bearded. Berry with five seeds.

Obs. This genus might perhaps, without impropriety, be referred to *LEUCOPOGON*, see that article; it being very difficult in this tribe to define the limits between a drupa and a berry, at least in some cases.—The species are dwarf mountain shrubs, with scattered stalked leaves, and solitary, terminal, erect, white flowers.—They are natives of Van Diemen's land and New Zealand.

1. *P. involucrata*.—Filaments projecting beyond the tube. Calyx fringed; the outer one of eight scales. Leaves elliptic-lanceolate, flattish, many-ribbed. Young branches downy. Stem erect.—Gathered by Mr. Brown, in Van Diemen's land.

2. *P. pumila*. (*Epacris pumila*; Forst. Gen. t. 10. f. a—b. Prodr. 13.)—Stamens shorter than the tube. Outer calyx of four scales. Leaves nearly elliptical, three-ribbed, naked at the margin. Young branches smooth. Stem prostrate, much branched.—Found by Forster in New Zealand; by Mr. Brown in Van Diemen's land.

PENTACHORD, in *Ancient Music*, an instrument of five strings invented by the Scythians, played with the jaw-bone of a dog, instead of a plectrum. Laborde. The concord of the fifth is sometimes called pentachord.

PENTACROSTIC, a set or series of verses, so disposed as that there are always found five acrostics of the same name, in five divisions of each verse. See *ACROSTIC*.

PENTACTINODOS, in *Natural History*, a name given by some authors to those species of star-fish which are composed of a body divided into five rays.

PENTADACTYLON, *Five-Fingers*, in *Botany*, a name

given by some authors to the ricinus, or palma Christi, from the figure of its leaf.

PENTADACTYLOS PISCIS, the *Five-fingered Fish*, in *Ichthyology*, the name of a fish common in all the seas about the East Indies, and called by the Dutch there *wijfinger visch*.

It has this name from five black streaks which it has on each side, resembling the prints of five fingers. It grows to about a foot and half long; its head is small in proportion to its body; its snout is long, and its fins large, and reaching almost to its tail; its general colour is very bright and elegant, a yellow, with an admixture of purple, and of a silvery gloss; it has no scales, and is a dry but not ill-tasted fish.

PENTADACTYLOS-ASTER, in *Natural History*, a name given by Linkius, and some other authors, to a species of star-fish, composed of a small body, and five principal rays, which have each several processes coming from them, covered with down.

PENTAEDROSTYLA, the name of a genus of spars. The word is derived from the Greek *πεντε*, *five*, *ηδρον*, *sides*, and *στυλος*, *a column*.

The body of the genus are spars, in form of pentangular columns, terminated by pentangular pyramids at one end, and irregularly fixed at the other to some solid body.

Of this genus there are three known species.

PENTAGLOSSUM, in *Botany*, from *πεντε*, *five*, and *γλωσσα*, *the tongue*, in allusion probably to the shape of the five red petals, is a genus founded by Forskall, Fl. Ægypt. Arab. 11, upon the *Lythrum thymifolium* of Linnæus, which having but two stamens, was not recognized by its finder, as a *Lythrum*, though its whole habit, and every character besides, precisely accord with that well-known genus. See *LYTHRUM*.

PENTAGON, from *πενταγωνος*, *quinguanulus*, compounded of *πεντε*, *five*, and *γωνια*, *angle*, in *Geometry*, a figure of five sides and five angles.

If the five sides are equal, the angles are so too; and the figure is called a *regular pentagon*, as *Plate X. Geometry, fig. 17*. Most citadels are regular pentagons.

The most considerable property of a pentagon is, that one of its sides, *v. gr.* DE, is equal in power to the sides of a hexagon and a decagon inscribed in the same circle ABCDE; that is, the square of the side DE is equal to the sum of the squares of the sides Da and Db.

A pentagon, and also a decagon, may be inscribed in a circle, by drawing the two diameters AP, mn (*fig. 18.*) perpendicular to each other, and bisecting the radius on at q. With the centre q, and distance qA, describe the arc Ar, and with the centre A, and radius Ar, describe the arc rB. Then AB is one-fifth of the circumference, and AB carried five times over will form the pentagon; and the arc AB bisected in s will give As the 10th part of the circumference, or the side of the decagon. See *DECAGON*.

If tangents be drawn through the angular points, they will form the circumscribing pentagon or decagon. See *POLYGON*, and *REGULAR Figure*.

Pappus has also demonstrated, that twelve regular pentagons contain more than twenty triangles inscribed in the same circle, lib. v. probl. 45.

The dodecahedron, which is the fourth regular body, consists of twelve pentagons.

PENTAGON-ASTER, in *Natural History*, a name given by Linkius, and other authors, to a kind of *stella marina*, or star-fish, composed of five rays, with a number of transverse

transverse processes issuing from them, covered with a hairiness.

It is one of the general classes of the *stella crinitæ*, so called from this hairiness.

PENTAGONIA, in *Botany*, from *πεντε*, *five*, and *γωνια*, *an angle*, because of the figure of the corolla, a name given by some old writers to those species of *Campanula* that have a wheel-shaped corolla, with five angles, of which *C. Speculum*, or *Venus's looking-glass*, is an example. L'Heritier once intended to form a separate genus of these plants, by the name of *Prisnatocarpus*; but on due consideration of the great diversity of figure, in the corolla, of other species of the very natural genus *Campanula*, he gave up his design.

PENTAGONOTHECA, from *πεντε*, *five*, *γωνια*, *an angle*, and *κερα*, *a case or cell*, a name given by Vaillant to the *PEISONIA*, (see that article,) on account of the form of its feed-vessel.

PENTAGRAPH, an instrument whereby designs, prints, &c. of any kind, may be copied in any proportion, without a person's being skilled in drawing.

The instrument is otherwise called a *parallelogram*.

The common pentagraph (represented *Plate XXIII. Miscel. fig. 5.*) consists of four brass or wooden rulers, two of them from fifteen to eighteen inches long, the other two half that length. At the ends, and in the middle of the longer rulers, as also at the ends of the shorter, are holes, upon the exact fixing of which the perfection of the instrument chiefly depends. Those in the middle of the long rulers are to be at the same distance from those at the end of the long ones, and those of the short ones; so that, when put together, they may always make a parallelogram.

The instrument is fitted together for use by several little pieces, particularly a little pillar, N^o 1, having at one end a screw and a nut, whereby the two long rulers are joined; and at the other a little knot for the instrument to slide on. The piece, N^o 2, is a rivet with a screw and nut, with which each short ruler is fastened to the middle of each long one. The piece, N^o 3, is a pillar, one end of which, being hollowed into a screw, has a nut fitted to it. At the other end is a worm to screw into the table; when the instrument is to be used, it joins the ends of the two short rulers. The piece, N^o 4, is a pen, porcupine, or pencil, screwed into a little pillar. Lastly, the piece, N^o 5, is a brass point, moderately blunt, screwed likewise into a little pillar.

Use of the Pentagraph, or Parallelogram.—1. To copy a design in the same scale or bigness as the original; screw the worm, N^o 3, into the table: lay a paper under the pencil, N^o 4, and the design under the point, N^o 5. This done, conducting the point over the several lines and parts of the design, the pencil will draw or repeat the same on the paper.

2. If the design be to be reduced, *e. gr.* into half the pace, the worm must be placed at the end of the long ruler, N^o 3, and the paper and pencil in the middle. In this situation conduct the brass point over the several lines of the design, as before; and the pencil at the same time will draw its copy in the proportion required; the pencil here only moving half the lengths that the point moves.

Hence, on the contrary, if the design be to be enlarged by one half, the brass point, with the design, must be placed in the middle at N^o 3, the pencil and paper at the end of the long ruler, and the worm at the other.

3. To enlarge or reduce in other proportions, there are holes drilled at equal distances on each ruler: *viz.* all along the short ones, and half way of the long ones, in order for placing the brass point, pencil, and worm, in a right line therein; *i. e.* if the piece carrying the point be put in the

third hole, the two other pieces must be put in its third hole.

If, then, the point and design be placed at any hole of the great rulers, and the pencil with the paper at any hole of the short ruler, which forms the angle therewith, the copy will be less than half the original. On the contrary, if it be placed at one of the holes of that short ruler, which is parallel to the long ruler, the copy will be greater than half the original.

The construction of this instrument requires a very considerable degree of accuracy; for which reason there are very few of the instruments that succeed. Few will do any thing tolerably but straight lines; and many of them not even those. In order to prove that the figure described by a pentagraph is similar to the given figure; let C, (*fig. 6.*) be the fixed centre of motion; P the pencil for tracing the given figure PP, and p the pencil which traces the other figure pp; p, &c. must be so adjusted, that p, C, and P, may lie in one straight line; then, since Bp : Ap :: BP : AC, whatever be the situation of the pentagraph, the angles PCP and pCp, are vertical; and, therefore, PCp will in every position of the instrument be a right line; but PC : pC :: BA : Ap, in each of the two positions in the figure, and consequently the triangles PCP, pCp, are similar; and PP : pp (:: PC : C p) :: BA : Ap, or in a given ratio. Hence it appears, that by moving the pencil p, Ap may be equal to BA, or less in any proportion; and consequently pp may be equal to PP, or less in the same proportion.

PENTAGYNIA, in *Botany, from *πεντε*, and *γυνη*, *a female*, the name of an order which occurs in the 5th, 10th, 11th, 12th, and 13th classes of the Linnæan artificial system. Its character depends, as the name expresses, on the presence of five styles, or, if styles be wanting, of so many sessile stigmas. In the 12th class however, *Icofandria*, it is necessary to take this character with considerable latitude. Plants of the natural tribe of *pomaceæ*, which make an important part of that class, are very uncertain as to the number of their styles in the same genus, and even variable in the same species. Hence the writer of the present article has, in his Introduction to Botany, chap. 24, presumed to advise that the order in question should admit flowers with from two to five styles, or even a few more occasionally. In the 13th class, *Polyandria*, the order *Pentagynia* separates some genera, from others, to which they are closely allied, in the *Trigynia*, and admits *Nigella*, some species of which have ten styles. Hence it is no less eligible to adopt the same latitude here as in *Icofandria*. Perhaps the definition of the order, in both these classes, might most conveniently be "*styles from two to ten.*"*

Some genera in other classes may have five styles; but the orders of such classes being marked by other characters, the number of styles usually becomes a part of the generic definition.

PENTALOBA, so named by Loureiro, from the five lobes of the berry. Loureir. Cochinch. 154.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Meliæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of five lanceolate, erect, hairy leaves. *Cor.* Petals five, lanceolate, erect, cohering by their lower part, somewhat reflexed at their summits. Nectary tubular, erect, with five teeth. *Stam.* Filaments five, thread-shaped, flattish, inserted into the incisions of the nectary, about as long as the petals; anthers ovate, erect. *Pistl.* Germen roundish, hairy, with five furrows; style short, thick, hairy; stigma simple. *Peric.* Berry roundish, five-lobed, of one cell. *Seeds* five, ovate.

Ess. Ch. Corolla of five petals, bell-shaped. Nectary tubular,

tubular, five-cleft, bearing the stamens. Calyx of five leaves. Berry superior, with five lobes, and five seeds.

1. *P. fessilis*.—Native of hills in Cochinchina, where it is known by the name of Cáy Cuong tau, and forms a middle-sized tree, with ascending branches. Leaves alternate, lanceolate, slightly serrated, smooth. Flowers sessile, clustered together, of a pale hue.—We have seen no specimen, but we do not recognize any known plant in the above characters and description.

PENTALUPO, in *Geography*, a town of Naples, in Calabria Ultra; 6 miles E. of Reggio.

PENTAMETER, derived from πενταμετρος, *q. d.* five measures, in *Poetry*, a kind of verse, consisting of five feet or metres.

The two first feet of a pentameter may be either dactyls or spondees; the third must be always a spondee; and the two last anapaests.

It is usually joined to hexameters, in elegies, epistles, epigrams, and other little pieces. There is no work extant of pentameters alone.

PENTANDRIA, in *Botany*, the fifth class in the Linnæan artificial system, is so called from its distinctive character of having five unconnected stamens, in the same flower with the pistil or pistils. This is the largest of all the Linnæan classes. The number five prevails far beyond any other in the structure of flowers; for the great class *Syngenesia* has also five stamens in nearly every known instance, but their anthers are united into a tube, and the flowers compound. Some genera of the *Pentandria* indeed have likewise combined anthers, and such, having simple flowers, constitute the Linnæan order of *Syngenesia Monogamia*; an order now, by common consent, abolished, being found not only unnatural, but highly inconvenient, various species of other genera, as *Gentiana*, having likewise combined anthers.

The orders of the 5th class are six. 1. *Monogynia*, one of the largest and most important in the whole system, comprehending several natural tribes or orders, as the *Asperifoliae*, to which Borage and Viper's Bugloss belong, strongly evincing their claim to the last-mentioned appellation; the elegant *Precie*, of which the Primrose is an example; the *Rotaceae*, to which the beautiful *Hottonia* belongs; the *Lurida* or Nightshade tribe, the *Campanulaceae*, the *Vites*, amongst various other things, follow, and the order closes with a part of the *Contortae*. 2. *Digynia*, begins with the remainder of the *Contortae*, followed by some genera with incomplete flowers, as *Chenopodium*, *Salsola*, *Ulmus*; to which succeed *Swertia*, *Gentiana*; and others. The rest of the order is made up of the *Umbelliferae*, an extensive, peculiar, and difficult tribe, of which we shall speak in its proper place hereafter. 3. *Trigynia*, has the Sumach, Elder, and *Viburnum*, with *Passiflora*, and various other plants; but this order is much smaller than either of the preceding. 4. *Tetragynia*, consists merely of *Evolvulus* and *Parnassia*. 5. *Pentagynia* has, from the agreement between the number of styles and of stamens, a considerable proportion of plants, among which are *Statice*, *Linum*, *Drosera*, *Crassula*, all large genera, with a few smaller ones. 6. *Polygynia* consists of *Myosurus* and *Xanthorrhiza*.

Willdenow has made an order, *Pentandria Decagynia*, for the admission of Forster's *Schefflera*, which has ten styles; but he properly records an observation of the late Mr. Dryander, that this genus is an *Aralia*.

PENTANDRIA is also the appellation of some orders in the Linnæan system, as the second of the class *Monadelphia*, comprehending *Erodium*, *Hermannia*, &c.: the 1st in *Dia- delphia*, consisting of *Monneria* only; the 5th in *Gynandria*,

according to Linnæus, but we scarcely know a genuine example; and finally the 5th orders in *Monocia* and *Dioecia*.

PENTANGLE, in *Geometry*, a figure with five angles.

PENTAPETALOUS PLANTS, are such whose flowers consist of five leaves.

PENTAPETES, in *Botany*, πενταπέτης, having five leaves, an ancient name for Cimquefoil, adopted for a very different plant by Linnæus. Though he declines any explanation of it, the five leafy expansions, which, in his *Pentapetes*, accompany the stamens, seem so well to account for this appellation, that one cannot but think the idea of such an adaptation of the word had occurred to him, though he might have forgotten it when he wrote the *Philosophia Botanica*, p. 175. There seems otherwise no possibility of accounting for his choice of the name, for the particular genus in question; of which indeed what is now separated under the denomination of *PTEROSPERMUM*, see that article, was the original type, but the above character is common to that and the present genus.—Linn. Gen. 351. Schreb. 459. Willd. Sp. Pl. v. 3. 727. Mart. Mill. Dict. v. 3. Juss. 276. Lamarek Illustr. t. 576. Gærtn. t. 134.—Class and order, *Monadelphia Dodecandria*. Nat. Ord. *Columniferae*, Linn. *Malvaceae*, Juss.

Gen. Ch. Cal. Perianth inferior, double; the outer a little remote, of three lanceolate, pointed, deciduous leaves; inner of one leaf, in five deep, lanceolate, pointed, spreading segments, permanent. Cor. Petals five, roundish, spreading, oblique, affixed by their claws to the tube of the stamens. Stam. Filaments 15, thread-shaped, erect, shorter than the corolla, united below into an oblong pentagonal tube, but separate above; anthers arrow-shaped, erect. Between every parcel of three stamens stands a linear-lanceolate, obtuse, erect, petal-like leaf, originating from the tube, and much longer than the stamens, being five in all. Pist. Germen superior, ovate, with five furrows; style thread-shaped, rather longer than the five leaf-like appendages, swelling upwards, striated; stigma with five slight segments. Peric. Capsule membranous, nearly globose, pointed, of five cells and five valves, the partitions from the centre of each valve. Seeds eight in each cell, inserted in two rows into the central column, obovate, angular, abrupt, without wings.

Ess. Ch. Calyx double; the outer of three leaves, deciduous. Petals five. Stamens fifteen, with five intermediate leafy appendages. Stigma club-shaped. Capsule membranous, of five cells, with contrary partitions. Seeds numerous.

1. *P. phanicea*. Scarlet Pentapetes. Linn. Sp. Pl. 958. Ait. Hort. Kew. ed. 1. v. 2. 438. I. Mill. Illustr. t. 58. Mill. Ic. t. 200. (*Dombeya phænicea*; Cavan. Diff. 129. t. 43. f. 1. *Blattaria ceylanica*, flore amplo coccineo; Comm. Hort. v. 1. 11. t. 6. Flos impius; Rumph. Amboin. v. 5. 288. t. 100. f. 1.)—Native of various parts of the East Indies, sometimes cultivated for its beauty in our stoves, where it has been known considerably above a century. It flowers in July, and is annual. The stem is two or three feet high, round, branched, leafy, besprinkled with a few close-pressed starry bristles, indicative of its natural order. Leaves alternate, stalked, lanceolate, taper-pointed, strongly crenate, smoothish, more or less hastate at the base. Stipulas in pairs, linear. Flowers axillary, solitary, drooping, on rough stalks shorter than the footstalks; they are of a beautiful scarlet colour, and above an inch in diameter; the five leafy appendages are externally rough or hoary. The foolish name by which Rumphius has distinguished this flower, and which is said to be a translation of its Indian appellation, alludes to its "profane or impious nature, in never looking towards heaven." So may flowers, as well

as men, be sometimes calumniated! The all-wise Creator, rich in infinite resources, has caused this and many more blossoms to droop, that their stamens may be sheltered from rain; whilst the same end is accomplished in others by their courting the full blaze of day, in an erect expanded position. In the spring of our damp climate, drooping or closed flowers abound; in India perhaps a different economy is generally best suited to the nature of the country. S.

PENTAPETES, in *Gardening*, comprises a plant of the exotic kind, for the stove, of which the species cultivated is the scarlet-flowered pentapetes (*P. phœnicea*).

Method of Culture.—This plant may be increased by sowing the seeds upon a good hot-bed early in March; and when the plants are fit to remove, there should be a new hot-bed prepared to receive them, into which must be plunged some small pots filled with good kitchen garden earth; into each of which one plant should be put, giving them a little water to settle the earth to their roots, shading them from the sun till they have taken new root; when they should be treated in the same way as other tender exotic plants, admitting the free air to them every day in proportion to the warmth of the season, and covering the glasses with mats every evening. When the plants are advanced in their growth, so as to fill the pots with their roots, they should be shifted into larger pots, filled with the same sort of earth as before, and plunged into another hot-bed, where they may remain as long as they can stand under the glasses of the bed without being injured; and afterwards they must be removed either into a stove or glass-case, where they may be screened from the cold, and in warm weather have plenty of fresh air admitted to them.

These plants are sometimes turned out of the pots when they are strong, and planted in warm borders; where, if the season prove very warm, the plants will flower tolerably.

PENTAPHARMACUM, a medicine consisting of five ingredients: it has also been applied in the same sense to ailments. Adrian the emperor was, as we are informed, particularly fond of a dish of five ingredients, called by this name. The ingredients were the udder of a sow, ham, peacock, brawn, and a sort of paste.

PENTAPHYLLOIDES, in *Botany*. See POTENTILLA and PENTAPHYLLUM.

PENTAPHYLLUM, an old name, synonymous with *Quinquifolium*, and applied, like that, by some of the old writers to such species of *Potentilla* as have five, or sometimes more, radiating leaflets upon one stalk, forming a digitate leaf. Those species that are furnished with leaves otherwise constructed, make Tournefort's genus of *Pentaphylloides*.

PENTAPLEURUM, a name given by some botanical writers to the common small plantain, usually called *ribwort* and *plantago quinquerivola*, from its leaves always having just five ribs running along them.

PENTAPOGON, from *πεντε*, five, and *πωγων*, a beard, was so named by M. R. Brown, in allusion to the five beards, or awns, of the husk.—Brown *Prædr. Nov. Holl. v. 1. 173.*—Class and order, *Triandria Dignia*. Nat. Ord. *Gramina*.

Gen. Ch. *Cal.* Glume of two oblong, acute, equal, beardless valves, containing one stalked floret. *Cor.* of two valves; the outermost rather longer than the calyx, ovate, bearing five awns at the summit, of which the middle one is much the longest, and spirally twisted; inner half the size of the outer, ovate, acute, concave, membranous, beardless. *Stam.* Filaments three, capillary, shorter than the corolla; anthers oblong, pendulous. *Pist.* Germen superior, roundish; styles none; stigmas two, spreading, feathery. *Peric.* none, except the permarct corolla. *Seed* one, oblong, pointed.

Eff. Ch. Calyx of two equal, beardless valves, containing

one stalked floret. Outer valve of the corolla with five terminal awns; the middle one longest, and spiral.

1. *P. Billardieri.* (*Agrotis quadrifida*; Labill. *Nov. Holl. v. 1. 20. t. 22.*)—Native of Van Diemen's land. A small and slender grass, scarcely a span high. *Root* fibrous. *Stems* several, round, striated, with one bent joint near the bottom, and one short leaf, with a long hairy sheath. *Radical leaves* numerous, tufted, short and setaceous. *Panicle* erect, about two inches long, not much branched, of 15 or 20 upright flowers. Valves of the calyx serrated at the keel. *Floret* hairy at its base.

PENTAPOLIS, Πενταπολις, in *Ancient Geography*, &c. a country wherein are five cities.

The Pentapolis of the sacred writings comprehended Sodom, Gomorrah, Adama, Seboim, and Segor; and of these the last only escaped the flames which destroyed the others.

The most celebrated was the Pentapolis Cyrenaica, or Pentapolis of Egypt, whose five cities were Berenice, Arfinoe, Ptolemais, Cyrene, and Apollonia.

Among the ancient geographers and historians we likewise read of the Pentapolis of Lybia, now called *Mesrata*; the Pentapolis of Italy; and the Pentapolis of Asia Minor, which contained Lindus, Jalyffos, Camiros, Cos, and Cnidus. This country once bore the name of Hexapolis, when it comprehended Halicarnassus.

PENTAPTEROPHYLLUM, in *Botany*, a name by which Dillenius has called the meriophyllum of other authors, characterized under that name in the *Genera Plantarum* of Linnæus, p. 459.

PENTAPTOTON, in *Grammar*, a noun which has only five cases.

PENTASTICH, PENTASTICHON, in *Poetry*, a stanza, or division of a poem consisting of five verses.

PENTASTYLE, in *Architecture*, a work wherein are five rows of columns.

Such was the portico begun by the emperor Gallienus, and which was to have been continued from the Flaminian gate to the bridge Milvius, *i. e.* from the Porto del Popolo to the Porte Mole.

PENTATEUCH, in *Sacred Literature*, the five books of Moses at the head of the Old Testament; *viz.* Genesis, Exodus, Leviticus, Numbers, and Deuteronomy. See each of these books under its respective title.

The word is formed from *πεντατευχος*, which signifies the same; compounded of *πεντε*, five, and *τευχος*, volume.

Pere Simon, in his *Hist. Crit. du Vet. Test.* produces a great number of passages to prove, that Moses was not wholly the author of the Pentateuch, as we now have it.

Indeed, those apparent interpolations at the end are sufficient to determine that point; it being absurd to suppose Moses the author of the account of his own death and burial, and of the comparison between him and the succeeding prophets in Israel.

These interpolated passages are usually attributed to Esdras, or Ezra; who, on his return from the Babylonish captivity, is supposed to have published the Old Testament, or at least a part of it, corrected and enlarged. See BIBLE and CANON.

There are two famous Pentateuchs, or editions of the Pentateuch, which have a long time disputed the preference, both as to antiquity, and as to character; *viz.* that of the Jews, called the *Jeruiss*, or *Hebrew* Pentateuch, written in the Chaldean or Assyrian character; and that of the Samaritans, written in the Samaritan or Phœnician character. Each is maintained to be the ancient Hebrew; whereas both seem to be different copies of the same Hebrew original,

written

PENTATEUCH.

written in different characters. The Samaritan Pentateuch was well known to many of the fathers, who have quoted it; and these quotations are all older than the year 600. From that time, for 1000 years, we find no mention of this Pentateuch until about the beginning of the 17th century; when Scaliger, having had notice that it was still preserved by those of that sect, and complaining that no person had taken care to procure a copy, archbishop Usher, by means of Mr. Thomas Davis, then at Aleppo, probably chaplain to the factory there, obtained two or three copies of it out of the East. Not long after, Sancius Harley, a priest of the oratory at Paris, and afterwards bishop of St. Malo's in Brittany, brought another copy into Europe, which he deposited in the library belonging to that order in Paris; from which copy, Morinus, another priest of that order, published it in the Paris Polyglot. The Samaritans, beside the Pentateuch in the original Hebrew, have also a translation of it into the language which was vulgarly spoken among them. This is also published, together with the original, in the Paris Polyglot; and it is so exactly literal, that Morinus thought that one Latin translation might serve for both. Bishop Walton has followed the same method in his Polyglot; only when there are any variations, they are marked at the bottom of the page. This Samaritan Pentateuch has some additions, variations, and transpositions, by which it differs from the present Jewish copies. But it is less a matter of wonder, that there should be some differences, than that there should not be more; considering that those who adhered to the one, and those who adhered to the other, had not only broken off all manner of communication, but had constantly been at the bitterest variance possible for more than 2000 years: for such an interval had elapsed from the apostacy of Manasseh (see SAMARITANS) to the time when these copies were first brought into Europe. In so many ages, many differences might happen by the errors of transcribers; and most of those that occur in these two copies are of this sort. See the sequel of this article.

But the grand difference is in the letter or character; the Jewish being in the Chaldean or Assyrian character, and the Samaritan in the Phœnician, *i. e.* the Canaanitish character: this latter seems to have an advantage over the vulgar Jewish Pentateuch. Yet Prideaux is of opinion, that the latter is only a transcript from the former out of the Chaldean into the old Hebrew character.

One great reason he gives is, that there are many variations in the Samaritan, manifestly occasioned by mistaking the similar letters in the Hebrew alphabet; which letters having no similitude in the Samaritan character, it is evident the variations must have arisen in transcribing from the vulgar Hebrew into the Samaritan; and not the contrary way.

Add to this, that Sæon, Allix, and many other learned men, take the Chaldean or Assyrian character to have been the character always in use among the Jews; and the Samaritan or Canaanitish, or, as it is also called, the *old Hebrew* character, to have never been used by the Jews before the captivity, in any manner, either on books or on medals.

Hence the Pentateuch must have been transcribed into that character; and that, probably, to render it legible to the inhabitants of Samaria, who, upon their introduction of the Pentateuch, might probably be versed in no other character.

Usher takes the Samaritan Pentateuch to have been compiled by Dositheus, a Samaritan, mentioned by Origen to have adulterated the Pentateuch. Dupin supposes it the work of some modern Samaritan, whom he imagines to

have compiled it chiefly out of the different copies of the Palestinian and Babylonian Jews, and the Septuagint, because it sometimes agrees with one, and sometimes with another.

Although, as we have already said, the Hebrew and the Samaritan copies of the Pentateuch agree in the main, they nevertheless differ in many places from one another; and as some of these differences are very considerable, in respect to particular letters and single words, and besides, as several whole verses are now found in the latter, but not in the former, Dr. Kennicott has attempted to establish, as to *some* of these differences, the superior authority of the Samaritan Pentateuch. One text, in particular, (Deut. xxvii. 4.) has constantly been objected to the favourers of this Pentateuch; a text which the advocates for the Hebrew copies have insisted upon as decisive against the Samaritans, and which has been almost invariably admitted to contain so shocking a corruption made voluntarily by the Samaritans, that even the more equitable judges have joined warmly with the Jews on this occasion, and have manifested an inclination to give up the whole Samaritan Pentateuch as of no authority, on account of *this one* (as they apprehend) notorious and undeniable corruption. Among those who have exclaimed loudly on this occasion have been, not only Bootius and the younger Buxtorf, Carpzovius and Leusden, with all their brother advocates for the integrity of the printed Hebrew text, but Hottinger and Lightfoot, Patrick and Calmet, Usher and Du Pin, Prideaux and Watson, father Simon and father Houbigant. To these names we may add that of Mr. Anthony Collins, in his "Grounds and Reasons of the Christian Religion." Against this host of learned men, Dr. Kennicott has appeared as an able advocate for the cause of the Samaritans.

In order to understand the ground of this dispute, we may observe, that God, by Moses, commands the Israelites, when they shall have passed over Jordan into the land of Canaan, "to put the blessing upon Gerizim, and the curse upon Ebal;" two mountains situated in the centre of the promised land between Dan and Beerseba; two mountains near each other, and having between them (at the foot of Gerizim) a small town, anciently called Sichem or Schechem, but afterwards Neapolis, and now Naplofe. The mount, which was to be dignified with the "law" and the "altar," (Deut. xxvii. 4.) is in the Hebrew text *Ebal*, and in the Samaritan *Gerizim*. About 1000 years afterwards, the Samaritans built a temple upon mount Gerizim, which was one of the principal causes of the inveterate hatred that subsisted between the Jews and Samaritans. The text, it has been said, has been wilfully corrupted, either by the Samaritans, who have, in their copies, put Gerizim, instead of Ebal, in order to recommend their temple, or by the Jews, who have, in their copies, put Ebal, instead of Gerizim, from opposition to it. That this corruption was made by the Samaritans, Walton, with whom join expressly Hottinger and Prideaux, affirms to be undeniable, for the following reasons: "cum in omnibus codicibus Hebrais, omnibusque versionibus antiquis, legatur Ebal, non Gerizim." The learned Kennicott has examined these reasons. "Ebal," it is said, "is the word in all the Hebrew copies;" and therefore Ebal is the original word. But this is almost taking the point for granted: for it might as well be said, Gerizim is the original word, because it occurs in the present Samaritan copies. Moreover, "Ebal," it is alleged, "is the word in all the ancient versions." But as the point in dispute relates to a corruption, introduced about 400 years B.C., these versions, being all too late, can be of no use: they can only serve as evidence for the state of the Hebrew

PENTATEUCH.

Hebrew copies from which they were translated, and not for copies five, or six, or seven hundred years later. The Greek version of the Pentateuch was made about 280 years B.C.; but such a version can be no proof, that this text of the Jews had not been altered by *themselves*, 100 years before. This corruption was made, without doubt, either by the Samaritans in favour of their temple, or by the Jews in opposition to it, soon after that temple was built; and it was built, as Prideaux allows, during the reign of Darius Nothus, about 409 years B.C. Hence it is concluded, that all the ancient versions, which have been made from the Hebrew text, being made after the corruption had been introduced, are too late to be admitted as evidences, that can acquit the Jews, or convict the Samaritans. But it is by no means true, that "all the ancient versions read *Ebal* in the text under consideration." For we have an ancient version of the Samaritan Pentateuch, expressed in Samaritan letters, and written in the Samaritan dialect, where is a mixture of Chaldee and Hebrew. This ancient version is of equal, nay, superior, antiquity to the version of the LXX; and this very ancient version reads *Gerizim*, in the disputed text. In some Arabic versions from the Samaritan Pentateuch MSS. preserved in the Bodleian library, the reading is the same. The authority of versions may, therefore, be adduced to oppose the authority of versions. Dr. Kennicott urges several presumptive and positive arguments in vindication of the Samaritans. *Gerizim*, he alleges, is universally allowed to have been the mount of blessings; and it seems very improbable, that the sacrificers of peace-offerings, which implied a state of favour with God, should by divine command sacrifice upon *Ebal*, confessedly the mount of cursings. Moreover, when the Samaritans determined to erect a temple for themselves, after being forbidden to join in rebuilding the temple of Jerusalem, they would, without doubt, choose some place signally honoured by God or his prophets, the more effectually to oppose the fame of the Jewish temple, and the more easily to vindicate their separate worship. *Gerizim* and *Ebal* were two mountains, on the former of which a form of blessings was to be pronounced, and on the latter a form of cursings: and one of these was to be honoured with the "Law of God," and "an altar for divine worship." This altar must have continued there for some hundred years, and the memory and fame of it continued in the country for many hundred years longer. But as both these mountains were near one another, both in the tribe of Ephraim, and both consequently in the possession of the Samaritans, so that either might be the object of their selection for the site of the temple, it is natural to imagine, that they would prefer *that mountain*, which had been, of old and by God's command, the place of his worship. Hence it is inferred, with strong probability, that *Gerizim* was the mountain of worship formerly, and not *Ebal*, which they rejected. Again, the different nature of these mountains furnishes another strong argument for the preference of *Gerizim*. For *this* mountain standing on the south, with its surface declining towards the north, is sheltered from the heat of the sun by its own shade; whereas *Ebal*, looking southward, is more open to the sun falling directly upon it: the former was therefore clothed with a beautiful verdure, while the latter was more scorched up and unfruitful. Besides, about 240 years after one of these mountains had been thus consecrated, when *Jotham* made that beautiful and solemn oration, recorded *Judg. ix. 7*, he must at that time know, which mountain had the law and the altar. Accordingly, he spoke from mount *Gerizim*, with a view of giving greater weight to his address. It is added, that the Samaritans would have been less likely to have wilfully corrupted the law of Moses, if

it be allowed, as ample testimonies prove, that they had a great veneration for it. In the interview recorded in the 4th chapter of *St. John's* gospel between our blessed Saviour and a Samaritan woman, near this mountain, he does not charge the Samaritans with having arrogated to mount *Gerizim* honours which did not belong to it: much less does he say, that *Ebal* had been the mount really honoured by God; and not *Gerizim*, as the fathers falsely pretended. We may also observe, that several instances occur in which our blessed Lord pays a general tribute of respect, either directly or indirectly, to the character of the Samaritans: as in the story of the "Good Samaritan," and also in the fact recorded *Luke, ch. xvii.* But if the Samaritans, on account of their good disposition and general character, be excused from the charge of wilful corruption, a charge of this kind against the Jews would not be the *first* that has been brought against them. Instances of this nature have been adduced by *Dr. Kennicott*, grounded upon the most unexceptionable testimonies. If we recur to the subsisting hatred of the Samaritans with respect to the Jews, and conceive that they might be thus urged to commit any crime from opposition to them, it might be retorted that the hatred of the Jews is at least equally notorious. It is further pleaded, that *Josephus*, the Jewish historian, asserts that the altar to be erected was not to be upon *Ebal*, but between this mountain and *Gerizim*, and rather nearer to the latter; and as he was the declared enemy of the Samaritans, it is not likely that he would have expressly given up the honour of *Ebal*, if he could have supported it. As *Josephus* does not charge the Samaritans with corrupting the text in question, so neither did other ancient Jews. If then the Samaritans have not corrupted their Pentateuch, in this celebrated article, it must be admitted that the Jews have corrupted it, and corrupted not only this text in their Pentateuch, but the corresponding text in *Josua, viii. 30.* For other answers to the objections of *Mr. Collins* against the Pentateuch, we refer to *Dr. Kennicott, ubi infra.* Our author concludes a learned and elaborate dissertation on the Samaritan Pentateuch with the following observation. "It is by no means here intended to recommend the adoption of the Samaritan, in the place of the Hebrew Pentateuch: or so to establish the pretensions of the former as to exclude the latter. One ancient copy has been received from the Jews; and we are truly thankful for it. Another ancient copy is offered by the Samaritans: let us thankfully accept that likewise. Both have been often transcribed; both therefore may contain errors. They differ in many instances; therefore the errors must be many. Let the two parties be heard without prejudice; let their evidences be weighed with impartiality; and let the genuine words of Moses be ascertained by their joint assistance. Let the variations of all the MSS. on each side be carefully collected; and then critically examined by the context, and the ancient version. If the Samaritan copy shall be found, in some places, to correct the Hebrew: yet with the Hebrew copy, in other places, correct the Samaritan. Each copy therefore is invaluable. Each copy therefore demands our pious veneration and attentive study. And I am firmly persuaded, that the Pentateuch will never be underflood perfectly, till we admit the authority of both." *Kennicott's* Second Dissertation.

The Jews read the whole Pentateuch every year; and for this purpose they divide it into paragraphs or sections, which they distinguish into great and small. The great are those which they read in a week, of which there are fifty-four (see *PARASCUE*); and the small regard particular matters. Each greater section, which is denominated by the word which it begins, is divided into seven parts, because they are
read

read by so many different persons: the priest begins, afterwards a Levite; and in the choice of the other readers, respect is paid to the rank of the people. After the text of Moses, they read a paragraph of the paraphrase of Onkelos. The books of the prophets are also divided in the same manner.

PENTATHLON, *πενταθλον*, in *Antiquity*, the five exercises performed at the Grecian games, and for which prizes were proposed.

These exercises were wrestling, darting, leaping, running, and quoit-playing. He who bore away the prize in them all was called *pentathlus*; by the Latins, *quingertio*; as the five exercises themselves were by those latter people called *quingertium*.

Some have pretended that by the word pentathlon no more is to be understood than a game, or trial of skill, consisting of five, and of any five exercises; but however this be, the æstus was not of that nature. It is probable, that the pentathlon did not always consist of the five exercises above-mentioned, because Pausanias informs us (lib. v.), that the Elæans from time to time made frequent changes in the Olympic games. The race in the pentathlon was of the same length with the stadium or simple foot-race, and regulated by the same laws. (See *RACE* and *RUNNING*.) The wrestling was subject to the same regulations with the simple palé, or wrestling. (See *PALÉ*.) In the exercise of leaping, in which the competitors endeavour to leap beyond one another in length, the height of the leap not being taken into the account, the athlete carried in their hands pieces of lead, or some other metal, made in the form of a half circle, not exactly round, but inclining to an oval. In these there was a place made for the fingers to pass through, in the same manner as through the handle of a shield; and with those weights, called *Αλτηρες*, Halteres, the athlete were accustomed to poise their bodies, and swing themselves forward in the leap. Some assistance of this kind seems to have been necessary to enable them to perform any thing like what is related of Phaulus of Crotona, whose leap is said to have been 52 (or, as others say, 55) feet long. For the exercise of quoiting, see *DISCUS* and *QUOITING*. In the exercise of darting, the victory was awarded to him who threw his javelin farther than the rest of his antagonists. However, there were certain limits prescribed, beyond which it was a forfeiture of the prize for an athlete to cast his javelin; and to this custom Pindar himself has frequent allusions. The javelin was sometimes thrown with the bare hand, and sometimes with the help of a theng, wound round the middle. The exercise of leaping in the pentathlon was accompanied by flutes playing Pythian airs, as we are informed by Pausanias.

The candidates in the pentathlon, as well as those in all the other gymnastic exercises, contended naked, and were also anointed with oil. Although some doubts have been suggested with regard to the conditions upon which the victory was awarded in the pentathlon, it is certain, that he who vanquished his antagonist in every one of the five exercises was alone entitled to the crown. If all hopes of gaining the pentathletic crown were lost to him who was vanquished in any one trial, it has been queried why the vanquished should contend any longer? The reply to this question is, that the pentathletes were probably obliged by the laws of the olympic games to go through all the five exercises. Although all the competitors, except one, must have despaired of gaining the crown, even from the first trial, yet they might still be desirous of carrying on the contest through the four remaining exercises, if they had not been required to do it by the olympic laws, either with a view of signaling themselves in some of the other contests, or the hopes of ravishing the

crown from him, by whose victory they had been excluded from the prospect of obtaining it. Pindar, in his thirteenth Olympic ode, congratulates Xenophon of Corinth upon his having gained in one day two olympic crowns; one in the stadium, or simple foot-race, the other in the pentathlon, which, as he says, never happened to any man before. The reason is, that the regimen of a pentathlete, as we are informed by both Epictetus and Arrian, was very different from that of an athlete, who qualified himself for a single exercise alone, as running, wrestling, or any other, whence, as both Plato and Longinus assure us, it seldom happened that a pentathlete, though very eminent in his profession, was able to contend with an athlete in that exercise, as, e. g. running, or wrestling, to which alone he had applied himself altogether. The same observation is applicable to all the athletes in general; who differed from each other in their respective regimens and diets, as much or more than in the several exercises to which they peculiarly applied themselves. West's Pindar, vol. iii.

PENTATONON, in the *Ancient Music*, a concord, by us called the redundant sixth.

It consists of four tones, and a major and minor semi-tone; whence the name, *pentatonon*, q. d. *five tones*.

PENTAUREA, a name given by some fabulous authors to a stone said to have been first found by Apollonius Tyaneus, and to possess the virtues of all the other stones, and to attract them all to it, as the magnet does iron.

PENTECONTARCHA, among the *Ancients*, the captain or commander of a galley, called *penteconteros*.

PENTECONTEROS, *πεντηκοντερος*, a vessel with fifty oars.

PENTECOST, *Πεντηκοστος*, Whitsuntide; a solemn feast of the church, held in commemoration of the descent of the Holy Ghost on the Apostles; as described in the Acts. See *WHITSUNTIDE*.

It has its name from the Greek, *πεντηκοστος*, q. d. *quingagesimus, fiftieth*, because held on the fiftieth day after Easter.

In the ancient church, Pentecost finished the Paschal time, or Easter season; wherein, as Tertullian, St. Jerom, &c. observe, Hallelujah was sung every where, the office celebrated standing, no fasting allowed, &c.

The Jews likewise had a feast they called *Pentecost*, or *Quingagesimus*, solemnized in memory of the laws being given to Moses, fifty days after their departure out of Egypt.

This was the second of the three grand festivals in the ecclesiastical year, at which all the males were to appear before the Lord at the national altar. This feast lasted but one day, and was kept with great mirth and rejoicing. It is called by several names in the Old Testament; as the Feast of Weeks, because it was celebrated seven weeks, or a week of weeks, after the Passover, or rather, after the first day of the feast of unleavened bread; the Feast of Harvest, according to Mede and Bochart, because, as the harvest begun at the Passover, it ended at Pentecost: or, according to others, because at this feast the first fruits of their wheat harvest were brought and offered to God; and the Feast of First Fruits.

PENTECOSTALS, **PENTECOSTALIA**, anciently were pious oblations made at the feast of Pentecost, by the parishioners to their parish-priest; and sometimes by inferior churches or parishes to the principal or mother church.

These parish Pentecostals were also called *Whitsun-farthings*; and their sum was divided into four parts, of which one went to the priest, one to the poor, one towards the repair of the church, and one to the bishop of the diocese.

These are paid still in some few dioceses; being now only a charge

a charge on particular churches, where by custom they have been paid. And if they are denied where they are due, they are recoverable in the spiritual court.

PENTECOSTE, in *Geography*, a river of Canada, which runs into the river St. Lawrence, N. lat. $49^{\circ} 45'$. W. long. $66^{\circ} 45'$.

PENTECOSTE, or *Whitsunday Island*, a small island in the South Pacific ocean, and one of the archipelago of the Great Cyclades, or New Hebrides discovered by M. Bougainville in 1768.

PENTEKILIS, or **PENT EKELIS**, a town of Asiatic Turkey, on the S. coast of Natolia; 30 miles W.S.W. of Meccé.

PENTELESMIS, in the *History of Shell-fish*, the name of the conchæ anatifera of some writers.

The pentelasmis is a genus of animals, composed of a shelly body, affixed to a fleshy and soft pedicle; the body is composed of five valves, and the pedicle is sometimes short, and sometimes long. The animal itself belongs to the tritons.

PENTELEICUM, **MARMOR**, in the *Works of the Ancients*, a name given to a very beautiful and glossy species of white marble, of which many of the columns and statues of larger size of the ancients were made: the Parian marble, from certain cracks and fissures in the strata, seldom affording blocks of more than five feet in length.

PENTELEICUS, in *Geography*, a mountain of Greece; six miles N.N.E. of Athens.

PENTESYRINGUS, in *Antiquity*, a sort of pillory, with five holes; wherein were fastened the legs, arms, and heads of criminals, to prevent their stirring.

PENTEXOCHÉ, a name given by authors to a species of echinites, resembling the ripe fruit of the medlar, and thence called also *mespileus lapis*.

PENTHEMIMÉRIS, *πενθημιμερίς*, compounded of *πέντε*, five, *μισος*, half, and *μερος*, part, in the Greek and Latin *Poetry*, part of a verse, consisting of two feet and one long syllable.

PENTHIER POINT, in *Geography*, a cape on the W. coast of France; six miles S.E. of Point St. Matthew. N. lat. $48^{\circ} 15'$. W. long. $3^{\circ} 17'$.

PENTHIEVRE, a town of France, in the department of the Morbihan, situated on the peninsula of Quiberon, on the E. and W. sides washed by the sea; seven miles N. of Quiberon.

PENTHORUM, in *Botany, appears to have been so called, by Gronovius, from *πέντε*, five, and *ἄρος*, a column or post, in allusion to the figure of the fruit, which he says resembles five turrets. Gron. Virg. 71. Linn. Gen. 230. Schreb. 310. Willd. Sp. Pl. v. 2. 770. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 3. 116. Juss. 308. Lamarck Illustr. t. 390. Michaux Boreal-Amer. v. 1. 278. Gærtn. t. 65.—Class and order, *Decandria Pentagynia*. Nat. Ord. *Succulentæ*, Linn. "*Sempervivis affine*," Juss.*

Gen. Ch. Cal. Perianth inferior, of one leaf, in five or ten deep, acute, permanent segments. Cor. Petals five, rarely wanting, minute, linear, between the segments of the calyx. Stam. Filaments ten, awl-shaped, equal, twice as long as the calyx, permanent; anthers roundish, deciduous. Pist. Germen roundish, with five furrows, coloured; styles five, conical, erect, distant, the length of the stamens; stigmas obtuse. Peric. Capsule simple, five-lobed, of five cells, crowned with the divaricated, nearly horizontal, styles. Seeds numerous, minute, oblong, slightly compressed.

Eff. Ch. Calyx in five or ten segments. Petals five, minute. Capsule of five cells, with five points. Seeds numerous.

Linnæus says *Penthorum* is distinguished from *Sedum*, by wanting the nectariferous scales proper to that genus. But the fruit also differs, though indeed only as that of some species of *Nigella* differs from others. Jussieu has strangely mistaken the structure of the fruit, whose cells, he says, split horizontally; and thence he was led to doubt whether the genus could properly belong to his order of *Sempervivæ*. The seed-vessel however opens exactly like those of *Sedum*, *Sempervivum*, *Cressula*, &c., nor can there be a question of the genus before us belonging to the same natural order.

1. *P. sedoides*. Linn. Sp. Pl. 620. (*Penthorum*; Linn. Aët. Upfal. ann. 1744. 12. t. 2.—Native of moist shady situations, in North America; Michaux says from Canada to Carolina. It is a hardy perennial in our botanic gardens, flowering in July and August. Root fibrous, throwing out creeping scyons. Stems numerous, diffuse, twelve or eighteen inches long, leafy, slightly branched; their opposite angles rough with minute bristles. Leaves alternate, nearly sessile, lanceolate, acute, serrated, smooth, scarcely succulent. Spikes several, terminal, recurved, collected into a sort of corymb. Petals white, some or all of them frequently wanting, while the segments of the calyx are præternaturally multiplied. The plant has no smell, nor any thing more than an herbaceous taste.

PENTICOTTA, in *Geography*, a town of Hindooستان, in the circar of Cicacole; 32 miles S.W. of Cossimcotta.

PENTIDATELO, a town of Naples, in Calabria Ultra; 12 miles S.E. of Reggio.

PENTIMA, a town of Naples, in Abruzzo Citra; five miles N.W. of Salmona.

PENTLAND FRITH, the strait which separates the main land of Scotland from the Orkney islands. It is sometimes called Piceland Frith; and indeed the latter is considered by many writers to be its proper and original appellation. This strait is about twelve miles across, and is remarkable for the impetuosity and opposition of its currents, from the meeting tides of the Atlantic and Northern oceans. So strong are these currents at times, that no vessel can navigate against them, however favourable the wind may be. Hence the navigation of this frith is so peculiarly dangerous and difficult, that few vessels attempt to pass it without the assistance of an experienced pilot. Its dangers are also greatly augmented by several whirlpools, of which those most usually fatal are the "Wells of Swinna" and the "Swalchie of Stroma," near the northern side of that island. On its southern shore is another very hazardous spot, called the "Merry Men of Mey," from the Mey, the name of a gentleman's residence on the opposite coast of Caithness. Here, from the concussion of the opposing tides, the sea is agitated in a very awful manner, even in the finest weather. From these concurrent causes, it is impossible at any time to cast anchor in any part of this frith; which, notwithstanding, is annually entered by between three and four thousand vessels. The number, however, will no doubt rapidly decrease as soon as the Caledonian canal is opened for navigation. Many of the natives of the Caithness coast, and of the islands, are said to derive their livelihood solely from the produce of the numerous ships which are foundered, or dashed to pieces in their passage through this frith. Barry's Orkney Islands, 4to.

PENTLAND SKERRIES, three small islets, or holms, at the eastern entrance to the Pentland frith; four miles N.E. from Dungsby head. Being from their situation extremely dangerous to mariners, a lighthouse is placed upon the largest of them. It was erected in 1794.

PENTLAND HILLS, a range or ridge of eminences, which extend from a place about four miles S.W. of Edinburgh, towards

towards the confines of Peebles-shire and Lanarkshire. Some of these hills are of considerable elevation; particularly the western summits, two of which, called Capelaw and Caerketan-craig, rise to the height of nearly fifteen hundred feet above the level of the sea. Logan-house hill even exceeds seventeen hundred feet above the same level. The eastern division, near Edinburgh, however, seldom reaches much above one-half that elevation; in some places it is nearly flat on the top, and affords excellent pasturage for large flocks of sheep. Several streams, noted in song, take their rise among these hills; as the North Esk, Glencrofs, and Logan water; the two latter of which dispute the honour of being the scene of Allan Ramfay's "Gentle Shepherd." Each of these vales is accordingly distinguished by the name of "Habby's Hough;" and both are frequently visited by poetical parties from the Scottish metropolis during the summer months. The composition of the Pentland hills is principally granite, but on the north side of the Logan summit is a rock of a very singular character, which has obtained the appellation of "Petunse Pentlandica," from its resemblance to the substance employed in the manufacture of Chinese porcelain. It is the only specimen of the kind in Great Britain, and probably in Europe.

PENTODRYON, in *Botany*, a name given first by the Greek writers, and after that by the Romans, to a kind of *strychnum* or *nighshade*, which caused madness in those who eat of it. This was called by others *manichum strychnum*, and by some simply *manicum*.

PENTOPHTHALMOS, in *Ichthyology*, the name of an East Indian fish, approaching to the European *liparis*, or *butterfish*, but larger, and called by the Dutch there *vijsvogel*. It has these names from five round spots in the tail-fin, resembling five eyes; it is of a yellowish colour, and is covered with a smooth skin, having no scales; its body is thick, its head small, its beak long; it has two red fins, and its tail is blueish; it is an inhabitant of the fresh waters, and is a very well tasted fish.

PENTOROBOS, in *Botany*, a name recorded in Pliny as belonging to the Pæony. It is formed of *πέντε*, *five*, and *οροβος*, a *vetch* or *legume*, evidently alluding to the fruit of that plant, which, when perfect, consists of five seed-vessels, that have very much the appearance of legumes. See **PÆONIA**.

PENTOWEN POINT, in *Geography*, a cape on the S. coast of Wales, in the Britol channel. N. lat. $51^{\circ} 45'$. W. long. $4^{\circ} 15'$.

PENTSTEMON, in *Botany*, from *πέντε*, *five*, and *στέμα*, a *stamen*; because this genus is distinguished from its allies in the *Didymia Angiospermia*, by having a fifth stamen, more or less perfect, in addition to the four unequal ones, which make the character of the class. Mitchell Ephem. Nat. Cur. v. 8. append. 214. Ait. Hort. Kew. ed. 1. v. 3. 511. Schreb. 808. Willd. Sp. Pl. v. 3. 227. Mart. Mill. Dict. v. 3. Michaux Boreal-Amer. v. 2. 21. (Chelone; Lamarck Illustr. t. 528.)—Class and order, *Didymia Angiospermia*. Nat. Ord. *Personate*, Linn. *Bignonia*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five deep, lanceolate, nearly equal, permanent segments. *Cor.* of one petal, two-lipped; tube longer than the calyx, gibbous at the base on the upper side, dilated upwards, and there most inflated at the lower side, or front; upper lip erect, in two ovate obtuse segments; lower lip longest, in three deep, ovate, obtuse, deflexed segments, shorter than the tube. *Stam.* Filaments four, thread-shaped, diverging at the summit, inserted into the tube and not extending beyond it, the two inferior ones longest; anthers roundish,

distant, inclosed within the tube, cloven, their lobes divaricated. The rudiment of a fifth filament is inserted into the tube, between the two uppermost stamens, about equal to them in length, thread-shaped, straight, bearded at the upper part. *Pist.* Germen superior, ovate; style thread-shaped, the length of the tube, deflexed at the top; stigma abrupt. *Peric.* Capsule ovate, acute, compressed, of two cells and two divided valves, with inflexed margins. *Seeds* numerous, orbicular, bordered. *Receptacle* large, flattish, meeting the inflexed margins of the valves.

Ess. Ch. Calyx in five deep segments. Corolla inflated, two-lipped. Rudiment of a fifth filament bearded above. Capsule of two cells; the partition from the inflexed margins of the valves. Receptacle parallel to the valves.

Obs. We cannot perceive the necessity of separating this genus from **CHELONE**, nor should we here have done any thing more than refer to the labours of our learned and judicious predecessor, the late Rev. Mr. Wood, under that article, had not *Pentstemon* been now so generally adopted. We must remark however, that Jussieu, who hints at its establishment under *Chelone*, Gen. 137, errs in attributing to the latter a capsule with partitions from the centre of each valve, and a receptacle contrary to the valves. There is no difference between the fruit of these genera in that respect, nor in any other, except the trivial circumstance of the valves of *Pentstemon* being split vertically, which is not the case with *Chelone glabra* at least, if we may rely on Gærtner, t. 54; for this plant does not, under our observation, perfect its fruit. The seeds are bordered in *Pentstemon* as well as *Chelone*.

For the species of *Pentstemon*, see **CHELONE**, section 2. To these we have only the following to add.

5. *P. ferrulata*. Menz. MSS.—Stem smooth. Leaves all sharply serrated, smooth; the upper ones ovate, somewhat hastate. Panicle twice or thrice forked. Barren filament bearded half way down.—Gathered by Mr. A. Menzies, on the west coast of North America. It is most nearly related to *P. levigata*, but differs in the copious acute serratures of its leaves, which are also broader, shorter, and more ovate; particularly those on the middle and upper part of the stem. The panicle is also more compact. Barren filament linear, bearded on one side, from the summit more than half way down. *Capsule* like that of *levigata*.

PENTSTEMON, in *Gardening*, contains plants of the hardy, herbaceous, flowering kind, of which the species cultivated is, the smooth pentstemon (*P. levigata*.)

Method of Culture.—This plant may be increased by sowing the seeds either in the autumn or early spring in the places where they are to remain, or in beds, to be removed in the beginning of the summer to the borders or clumps of the pleasure-grounds.

They afford variety among other plants of similar growth in these situations.

PENTZIA, in *Botany*, so named by professor Thunberg in honour of his pupil Charles John Pentz, at whose graduation at Upsal, in 1797, the learned professor's dissertation on *Diosma* was published. Thunb. Prodr. (præf. n. 54.) 145. Willd. Sp. Pl. v. 3. 1808.—Class and order, *Syngenesia Polygamia-aqualis*. Nat. Ord. *Compositæ discoideæ*, Linn. *Corymbifera*, Juss.

Gen. Ch. *Common calyx* hemispherical, of many imbricated, oblong, obtuse, membranous-edged scales. *Cor.* compound, discoid. Florets all fertile, numerous, uniform, level-topped, tubular, funnel-shaped; the limb erect, in five slight segments. *Stam.* Filaments five, capillary; anthers united into a cylindrical tube. *Pist.* Germen oblong; style thread-shaped, the length of the stamens; stigmas two, spreading.

spreading. *Peric.* none, except the permanent calyx. *Seeds* solitary, abrupt, angular, striated, each with a membranous, cup-shaped, angular *corolla*, half its own length, in five unequal, rounded, shallow segments. *Recept.* naked.

Eff. Ch. Receptacle naked. Seeds crowned with a membranous, unequally lobed, border. Calyx imbricated, hemispherical. Florets all tubular, five-cleft.

1. *P. flabelliformis*. Willd. n. 1. (*P. crenata*; Thunb. Prodr. 145. *Tanacetum flabelliforme*; L'Herit. Sert. Angl. 21. t. 27. Ait. Hort. Kew. ed. 1. v. 3. 169. *Gnaphalium dentatum*; Linn. Sp. Pl. 1194. *Coma aurea incana*, foliis obtusis tridentatis, capitulis oblongis; Burm. Afric. 185. t. 68. f. 3.)—Native of the Cape of Good Hope. Mr. Masson sent it to Kew in 1774. This is a bushy much branched *shrub*, altogether of a hoary silvery aspect, remarkable for its little alternate, fan-shaped, long-stalked *leaves*, furnished with prominent longitudinal ribs, and strongly toothed at their abrupt termination. *Corymbs* simple, terminal, but soon surmounted by young branches. *Flowers* the size of a pea, yellow, with a downy somewhat thinning *calyx*. The plant is slightly aromatic. It might perhaps have been allowed to remain in *Tanacetum*, the very conspicuous white *seed-crown* being little more than a dilatation, of what always exists, in some degree, in that genus, and the want of a few female three-cleft *florets*, justly termed obsolete, in the *radius*, being at best an obscure, if not variable character.

PENKONDA, in *Geography* a town of Hindoestan, in Myfore; 65 miles N. of Bangalore.

PENULA. See PÆNULA.

PENULTIMA, or PENULTIMATE, formed from *pene*, and *ultimus*, almost last, in *Grammar*, denotes the syllable, or foot, immediately before the last.

Hence antepenultimate is that before the penultimate, or the last but two.

PENULTIMATE, in *Musical*. M. Broffard will have it the same with what the Greeks call *paranete*; though others will not allow the *paranete* to be the penultimate chord, but the next to it.

PENULTIMATE of the *Separate*, *paranete diazeugmenon*, is a name the ancients gave to one of the chords of their lyre or system; corresponding to the *d, la, re*, of the third octave of the modern system.

PENULTIMATE of the *Acute*, *paranete hyperboleon*, a chord of the ancient system, answering to the *g, re, sol*, of the third octave of the modern system.

PENUMBRA, in *Astronomy*, a faint or partial shade, observed between the perfect shadow and the full light in an eclipse.

The penumbra arises from the magnitude of the sun's body; were he only a luminous point, the shadow would be all perfect; but by reason of the diameter of the sun, it happens that a place which is not illuminated by the whole body of the sun, does yet receive rays from a part thereof.

Thus, suppose S the sun (*Plate XVIII. Astron. fig. 17.*) and T the moon, and the shadow of the latter to be projected on a plane, as G H. The true proper shadow of T, viz. G H, will be encompassed with an imperfect shadow, or penumbra, H L and G E, each portion whereof is illuminated by an entire hemisphere of the sun.

The degree of light or shadow of the penumbra will be different in different parts, as those parts lie open to the rays of a greater or lesser part of the sun's body; thus from L to H, and from E to G the light continually diminishes; and in the confines of G and H, the penumbra

becomes lost and confounded with the total shade; as, near E and L, it is confounded with the total light.

A penumbra must be found in all eclipses, whether of the sun, the moon, or the other planets, primary or secondary; but it is most considerable with us in eclipses of the sun; as in the case here referred to.

In eclipses of the moon, the earth is encompassed indeed with a penumbra; but it is only sensible to us on the earth near the total shadow: an observer placed on a plane, whereon the shadow falls, might observe the whole penumbra, as in eclipses of the sun. Thus an eye placed at I or F, would only see the semidiameter of the sun; the rest being hid behind the moon. Going from I towards H, more and more of the sun is hid, till it be lost in the shadow itself, &c.

Hence we have eclipses of the sun when the shadow never touches the earth, provided the penumbra do but reach it: and hence there is a difference observed in eclipses of the sun, as the shadow itself, or a greater or less degree of the penumbra, passes over a place. But eclipses of the moon appear the same in all places where they are visible.

When the shadow itself falls on the earth, the eclipse is said to be total or central; when only the penumbra falls on it, the eclipse is said to be partial.

The penumbra extends infinitely in length, inasmuch as to each point of the diameter of the sun, there answers a space infinite in length, into which no rays enter from that point, though there do from others. Two rays drawn from the two extremities of the earth's diameter, and which proceed still diverging, form the two edges of the penumbra; which, of consequence, is continually growing in width, and is infinite also in this sense. All that infinite space is the penumbra; except the triangle of the shadow included in it.

The figure of this space comprehending the shadow, is a trapezium, one of whose sides is the diameter of the earth; the opposite side parallel thereto is an infinite line, *i. e.* the width of the penumbra projected to infinity, and the two other sides are two rays drawn from the two extremities of the diameter of the sun, through those of the diameter of the earth, and which, prolonged back beyond the sun, will intersect in a certain point, making an angle equal to the apparent diameter of the sun; which angle may be called the *angle of the penumbra*.

Now the penumbra will be the greater, as this angle, or which is the same thing, as the star is greater, the planet remaining the same; and if the diameter of the planet be increased, the star remaining the same, it will be the same as if the diameter still receded from the angle of the penumbra.

In order to determine how much of the surface of the earth can be involved in the penumbra, let us suppose the apparent semidiameter of the sun to be the greatest, or about $16' 23''$, which is when the earth is in her perihelion. Let A B D (*fig. 18.*) be the earth, L the moon, and A M B half the angle of the cone, which is equal to $16' 23''$; whence we shall find its height L M = $58\frac{1}{2}$ semidiameters of the earth. (See SHADOW.) Let the moon be in her apogee, and, therefore, at her greatest distance from the earth, which is 64 semidiameters of the earth, and T M = T L + L M = $122\frac{1}{2}$ semidiameters. But T B : T M :: sine of T M B : sine of M B N or M B T; and T B : T M :: 1 : $122\frac{1}{2}$, and the angle T M B = $16' 23''$, therefore the angle M B N = $35^\circ 42' = T M B + M T B$. Consequently M B N - T M B = ($35^\circ 42' - 16' 23'' =$) M T B = $35^\circ 25\frac{1}{2}'$, which is the measure of the arc A B; whole

whose double $70^{\circ} 51'$ is equal to the arc $C A B$, or about 4900 English miles. See ECLIPSE.

M. de la Hire examines the different degrees of the penumbra, and represents them geometrically by the ordinates of a curve, which shall be among themselves, as the several parts of the sun's disc, with which a body placed in the penumbra is enlightened.

PENURIE, in *Geography*, a town of Hindoostan, in Bahar; 23 miles S. of Bahar.

PENUTURA, a town of Hindoostan, in the circar of Cicacole; 25 miles N. of Cicacole.

PENY, a town of Hindoostan, in Bahar; 24 miles S.W. of Rotafgur.

PENYCUIK, is the name of a village and parish in the county of Mid-Lothian, or Edinburghshire, Scotland. The village is situated nine miles S. from the northern metropolis, and is adorned with a very handsome church, the living of which was formerly a rectory. This edifice is placed on the site of an older structure, which was dedicated to Kentingern, popularly called St. Mungo. The parish is twelve miles in length and six in breadth. Its surface is extremely various, and exhibits almost every kind of soil, from clay and moss to the poorest gravelly loam. A great number of sheep are bred in this parish; but the greater proportion of it is under tillage. It is watered throughout its whole extent by the river North Esk, and abounds with coal and peat. It also possesses several objects entitled to the attention of the topographer and the antiquary. Near the village is the elegant seat of Sir James Clerk, bart. M. P. for the county of Edinburgh. The situation of this mansion is delightful; and its prospects are both picturesque and extensive. In the library here is an excellent collection of books and paintings; and in another room is a large assortment of Roman antiquities, principally from the wall of Antoninus, and the neighbouring encampments. Close to the river, within the "policy," is Offian's Hall, the much admired work of Runciman; and behind the house is an exact model of the celebrated Roman temple, called by Buchanan *Templum Termini*, which formerly stood on the banks of the Carron, and which was known to the vulgar by the appellation of Arthur's Oon. Here is likewise an obelisk, in honour of Ramsay the poet, who frequently resided at Penycuik, and is supposed to have laid the scene of "The Gentle Shepherd" on the confines of this parish and Gleserofs. About two miles from this seat, lower down the river, stood the ancient castle of Brunstone, the baronial mansion of the Crichtons, some ruins of which still remain. New-Hall, another residence of the same family, stands three miles N.W. from the village. It is supposed to have derived its appellation of *New* from the circumstance of its occupying the site of an *old* religious house. The name of New-House, an inn on the lands of Spittal here, boasts a similar derivation, having been erected to supply the place of an ancient hospitium, for the accommodation of travellers. Even at the present day the weary and benighted traveller is considered as entitled to shelter and protection; and accordingly one of the out-houses, at the Old Spittal, is usually appropriated to that purpose. Traces of several encampments of different forms and eras are yet visible in this parish. Raven-Nook-Castle, situated on the Esk, belonged to the Sinclairs of Roslyn. Government has lately converted the buildings of two large paper manufactories here into depots for prisoners of war.

According to the parliamentary returns of 1811, the houses in this parish amount to 309 in number, and the inhabitants to 1827. Beauties of Scotland. Carlisle's Topo-

graphical Dictionary of Scotland, and of the Islands of the British Seas, 4to. 1813.

PENZA, a town of Russia, and capital of a government, near the Sura; 644 miles S.E. of Petersburg. N. lat. $53^{\circ} 50'$. E. long. $45^{\circ} 42'$.

PENZANCE, a sea-port and market town in the west division of the hundred of Penwith, county of Cornwall, and the most westerly town in England, is situated on the N.W. side of Mount's bay, 287 miles W.S.W. from London, and 10 miles from the Land's End. It is particularly distinguished for the cheapness of its fish market, the mildness of its climate, and the fertility of the neighbouring lands: these circumstances have occasioned a considerable increase of population, by the influx of inhabitants from the adjacent villages. In the year 1595, the Spaniards dispatched four vessels from Bretagne, (of which they were then masters,) to invade the English coast. They landed near Mousehole, which they burnt, together with the church of St. Paul. Meeting with little resistance, the enemy proceeded to Penzance, and the inhabitants deserting it, they entered the town in three places, and set it on fire, after which they returned to their galleys. The returning courage and increased numbers of the Cornish, prevented the Spaniards from re-landing, and Penzance has since remained undisturbed by foreign foes. The parish church is situated nearly at Madern, two miles from the town; but there is a chapel of ease nearer home, dedicated to St. Mary. There are various religious denominations residing here; Presbyterians, Quakers, Methodists, and Jews, who have separate places of worship. The government is vested in a corporation, consisting of a mayor, recorder, twelve aldermen, and twenty-four common-councilmen. Penzance is one of the four Stannary towns of the Cornish tin mines, and the petty sessions for the west division of the hundred of Penwith are holden here. There is a charity school endowed by John Buller, esq. of Morval, in 1711. The town is very pleasant, many of the houses large and respectable, and most of the streets are paved. A new pier, which was erected by the corporation some years since, affords much convenience to the considerable trade carried on here, consisting chiefly of tin, and the pilchard fishery. The packets which form the principal mode of conveyance to the Scilly islands, sail from Penzance. Thursday is the market day, and there are three annual fairs. By the census of 1811, Penzance contained 794 houses, and a population of 4022 inhabitants.

At the distance of half a mile from Penzance, are some remains of the celebrated Wherry Mine. They are situated in a part of the bay, which is dry at low water, but covered by every returning tide to the depth of several feet. The peculiar situation of this mine rendered it an object of curiosity, although the shaft is filled up, and the frame-work nearly annihilated. When the works were in operation, the labour became extremely adventurous; the miners working at the depth of seventeen fathoms below the waves, nearly 120 fathoms from the shore, and momentarily menaced with an inundation of the sea, which roared above them. The dangerous situation of the shaft, the injurious effect of storms and tides, and a partial failure of the lode, induced the proprietors to discontinue its working in 1798. A large tract of marsh-land, adjacent to Penzance, subject to occasional inundations of the sea, has been partly rescued from sterility and waste, through the laudable exertions of Dr. Samuel Moyle of Marazion. It was effected by means of an aqueduct or pipe, communicating with the sea, which carried off all the drainage water from the marsh. Several crops of corn and potatoes have been obtained from the parts so saved, and it promises to reward the adventurer for his expence

and perseverance. In cutting one of the drains, an earthen pot was discovered, containing nearly one thousand Roman copper coins, which the impressions shew to have been issued between the years A.D. 260 and 350.

West of, and contiguous to, Penzance are several small villages and antiquarian objects deserving notice. Mousehole, on the western side of Mount's bay, is celebrated among antiquaries for having been the residence of Dolly Pentreath, one of the last persons known to speak the Cornish language. She lived to the great age of 102, and was buried in the parish church-yard of St. Paul's. St. Burien is the name of a parish, which, though at present consisting only of a few wretched cottages, was formerly distinguished by a college of Augustine canons, founded and endowed by Athelstan about the year 930. It is now in the patronage of the prince of Wales. The deanery includes the parishes of Burien, Senner, and St. Levan. At the Norman conquest there were secular canons here, and in the 20th of Edward I. a dean and three prebends. The church is built on a high spot of ground; it consists wholly of granite, and its tower forms a conspicuous object from the Land's End, the Scilly islands, and the North and South channels. The greater part of the district round St. Burien, though wild and unsheltered, is interesting to the antiquary, it being interspersed with cairns, circles, cromlechs and other Druidical remains. In the parish of St. Paul is a circular inclosure of stones, called the "Roundago," fifty-two paces from north to south, and thirty-four from east to west. Some of the stones are erect, others piled in a wall-like form, but without mortar. In the parish of Senner is a circle of similar shape and character, and at Tredineck another of the same kind. In the parish of Burien is a small circle of nineteen upright stones, called the "Dance Maine" or the Merry Maidens. The stones are about four feet above the ground, and five feet distant from each other; the diameter of the circle is about twenty-five feet, and at some distance north-west from it are two taller upright stones, called the Pipers. Another of these Druidical circles is named Boscawen-un, which also consists of 19 upright stones, and is about 25 feet in diameter, having a single leaning stone in the centre. In the parish of Gulval is Boskednan-Circle, consisting also of 19 stones, but of smaller diameter than the two former. In the parish of St. Just is a considerable structure of this kind, known by the name of the Botallach circles, composed of four circles of upright stones intersecting each other. Lanyon Quoit is a cromlech, consisting of four upright stones, three of which support the other, a broad flat stone, 28 feet long, by 14 wide. In the parish of Morval is a cromlech, similar to this last, but of smaller dimensions, called Chûn Quoit; and half a mile east of Senner church is another, the quoit of which is supported by a barrow heaped round it, 14 yards in diameter. In the parish of Madern stand three stones erect, on a triangular plane, the middle one of which is perforated with a large hole near the base, nine inches in diameter. Dr. Borlase conjectures that this perforation was appropriated to superstitious rites, in the days of Druidism.

The same antiquary described various logan or rocking-stones, as formerly extant in this part of Cornwall; the most considerable and curious of which was at Treryn-Castle, in the parish of St. Levan. The chief stone is an immense granite block, supposed to weigh nearly 90 tons, poised on the top of a vast pile of rocks which project into the sea. This enormous mass, it is stated and believed, was once liable, from a peculiarity of position, to be moved to and fro. Treryn-Castle is a large piece of rocky ground, projecting into the sea, and inclosed by two formidable ramparts and ditches,

one within the other, stretching in a semicircular form from the sides of the cliffs: the perpendicular rocks form three sides of this fortification, and the land side is guarded by these thick and high embankments. About a mile and a half west of this, the cape, called Tolpedn-penwith, is divided from the main land by a stone wall. The castles, Karnijack and Boscagell, in the parish of St. Just, are also of the same kind, as well as many others on the sea-coast.

The Land's End is the most westerly promontory in England. It is a point of huge and ragged rocks, forming a barrier to the tumultuous sea, of the most awful and wildly sublime kind. It was called Bolerium by Ptolemy; by the British bards Penringhued, or the promontory of Blood; and by their historians Penwith, or the promontory to the left. Near this craggy cliff are three caverns, in which the agitated waters occasionally roar with tremendous fury. Several masses of rock are seen above the surface of the sea, more than two miles west of the Land's End, called the "Long Ships." On the largest a light-house was erected by Mr. Smith, in 1797, who obtained a grant for that purpose, and is rewarded by a certain rate on all ships that pass the Land's End. Beauties of England and Wales, vol. ii. Borlase's Antiquities of Cornwall, folio. History and Antiquities of Cornwall, by R. Polwhele, 4to.

PENZENSKOE, a government of Russia, bounded on the north by Nizegorodskoi, on the east by Simberskoe, on the south by Saratovskoe, and on the west by Tambovskoe; about 172 miles from east to west, and from 40 to 60 from north to south. The capital is Penza. N. lat. $52^{\circ} 40'$ to $54^{\circ} 36'$. E. long. 42° to 47° .

PENZINSKAIA, a gulf of Russia, at the north part of the Penzinskoe sea. N. lat. 61° to 62° . E. long. $162^{\circ} 14'$.

PENZINSKOE SEA, a large bay of the North Pacific ocean, between Russia and Kamtschatka, north-east of the sea of Ochotsk; about 320 miles in length, and from 120 to 160 broad. N. lat. 58° to 62° . E. long. 152° to 161° .

PENZLEIN, a town of the duchy of Mecklenburg; 37 miles S.E. of Gustrow.

PEONY, or PIONY, in *Botany*. See PÆONIA.

PEORY, in *Geography*, a town of Hindoostan, in Dowlatabad; 35 miles N.N.W. of Darore.

PEP, and PEPIA. See PIP.

PEPASMUS, $\pi\epsilon\pi\alpha\sigma\mu\varsigma$, in *Medicine*, the digesting and ripening of morbid humours.

PEPASTIC, or PEPTIC, $\pi\epsilon\pi\alpha\sigma\tau\iota\kappa\omicron\varsigma$, or $\pi\epsilon\pi\tau\iota\kappa\omicron\varsigma$, formed from $\pi\epsilon\pi\alpha\sigma\mu\varsigma$, to digest, or ripen, a kind of medicament of the consistence of a plaster; proper to bring vitious and corrupt humours to a head, and dispose them for suppuration.

Butter, roots of mallows, of fleurs-de-lys, onions, and leaves of oxylapathum, are esteemed good pepastics, or maturatives.

The word is also used for such medicines as promote the digestion of food in the stomach.

PEPECHAISSINIGAN, in *Geography*, a river of Canada, which runs into the St. Lawrence, N. lat. $48^{\circ} 26'$. W. long. $68^{\circ} 55'$.

PEPERAH, a town of Hindoostan, in Gurry Mundela; 10 miles S. of Gurra.—Also, a fort of Hindoostan, in Bahar; 48 miles E. of Durbungah. N. lat. $26^{\circ} 8'$. E. long. $86^{\circ} 58'$.

PEPERALLY, a town of Hindoostan, in Bahar; 30 miles N. of Durbungah.

PEPERIA, a town of Hindoostan, in Bahar; 54 miles E.S.E. of Hajypour.

PEPIN LE GROS, in *Biography*, a celebrated person in French

French history, who was surnamed *d'Heristal* from the place of his birth, on the river Meuse, near Liege. He governed Austraia after the death of Dagobert II. in 680, and was defeated in the following year by Ebroin, the powerful mayor of the palace of Neustria. He, however, levied new troops, and, after the death of Ebroin, defeated king Thierry, gained possession of Paris, and became master of the king and kingdom, with the title of mayor of the palace of Neustria and Burgundy. He was a man of extraordinary qualities, extremely brave, prudent, and politic; and one who was able to conceal his ambition under the mask of moderation, and a very mild and affable demeanour. When he had seized the reins of government, he employed himself with vigour and industry to correct abuses, restore law and order, repair the finances, and secure the obedience of all ranks of the state. He suffered Thierry to act the pageant of a king, and in public paid him all possible respect, while he excluded him from any share in the administration. After the death of Thierry, he placed the crown successively upon the heads of his sons, Clovis and Childebert, and his grandson Dagobert, who in French history are denominated, from their insignificance, "Les Rois Faineans." In the mean time, Pepin was engaged in wars with the Frisians and Germans, over whom he was constantly victorious. His excessive power excited the envy of some lords, who, while he was labouring under a dangerous illness, took up arms and assassinated his son Grimoald. He, however, recovered, and took severe vengeance on his foes. Shortly after this he died, having had the administration of the government in his hands nearly 30 years. This was in the year 714, and he left his authority so well established, that he nominated his young grandson, Theobald, mayor of the palace, under the guardianship of his widow. Pepin was father of Charles Martel, the founder of the Carolingian line of French kings. *Univer. Hist. History of France, 1790.*

PEPIN, surnamed *Le Bref*, first king of France of the second race of kings, was the second son of Charles Martel. (See FRANCE.) His father, in his last illness, divided his dominions between his sons, Carloman and Pepin: assigning to the former Austraia, to the latter Neustria and Burgundy. They united in suppressing an insurrection, and afterwards turned their arms against Odilon, duke of Bavaria, and other German princes and nations, whom they reduced to submission. In the midst of this prosperity, Carloman, disgusted with the world, retired to a monastery in 746, and resigned his possessions to Pepin. This prince had hitherto exercised the royal authority in the name of king Childeric; but finding himself perfectly established in his power, beloved by his people, respected by the nobles, and favoured by the clergy, to whom he had restored part of the property which his father had taken from them, he resolved, in the year 751, openly to assume the title, as well as the office, of king. The elder historians unanimously affirm, that the assembly of the states sent a deputation to pope Zachary, to ask whether it were not right that he who exercised all the functions of royalty should be king, rather than he who was so only in name; and that the pope pronounced in the affirmative. From this time it is probable that king Childeric was shaved, and shut up in a monastery, where he soon died; his queen was put into a convent; and their son, Thierry, passed his life in the character of a monk: and thus ended the race of Merovingian kings of France.

Pepin, soon after being proclaimed king, was consecrated at Soissons by Boniface, bishop of Mentz, the pope's legate, and is said to have been the first French king on whom this

ceremonial was performed. The solemnity was, without doubt, intended to give an additional sanctity to his character. With the same view he undertook, on various occasions, to be the champion of the church. He severely chastised the heathen Saxons, who had taken up arms, and expelled the millionaries. He attacked the Saracens in the southern provinces of France, and, after a long siege, made himself master of the important city of Narbonne. Of such importance was Pepin now in the world, that pope Stephen III. implored his protection against the enemies that pressed upon him, and even came in person to his court. He was received with all possible respect; and in return for his kindness, the holy pontiff crowned him and his queen in the church of St. Denis, bestowed the royal unction upon his sons Charles and Carloman, and conferred upon the father and his sons the title of Roman patrician. Pepin reconducted the pope to Italy with an army, besieged the king of the Lombards in Pavia, and obliged him to make a treaty, by which he relinquished the sovereignty of Rome, and all his conquests. As soon as Pepin had recrossed the Alps, the Lombard monarch broke the treaty, and invested Rome. Pepin passed again into Italy, and constrained him to accept of peace a second time, but on much harder conditions than before. He visited Rome, where he was received with great honour as its deliverer, and caused the keys of Ravenna and the other cities of the exarchate to be offered on the throne of St. Peter. As soon as he returned, he employed himself in regulating the internal affairs of his kingdom, and receiving the homage of the duke of Bavaria, and of the king of the Slavonians. A general revolt of the Saracens again gave occasion to him to exercise his arms, and he reduced them to submission. While he was thus engaged, the Lombards, under king Desiderius, attacked the pope, who applied to Pepin for his assistance, which in this and other instances he readily afforded. Pepin died in 768, at the age of 53, after having reigned with glory and success nearly 17 years. No author of a revolution ever met with less disturbance in maintaining his power, which was owing to his great prudence, and the moderation with which he exercised his authority; consulting the general assembly of the nation on all important occasions, and passing his laws by the medium of their assent. In person Pepin was very short, but he possessed extraordinary vigour and activity, as well as intrepidity. The fame of Pepin, like that of Philip of Macedon, has been in some degree impaired by the superior renown of his son, Charlemagne; but his eminent qualities sufficiently entitle him to a place among the great men of his age and nation. *Univer. Hist. History of France, 1790.*

PEPIN *Lake*, in *Geography*, an expansion of the Mississippi, where it receives the Chippeway from the north-east, in N. lat. 44° 5', and W. long. 93° 42', below the Falls of St. Anthony.

PEPITA, in the *Materia Medica*, a name given by some authors to the *fabia sancti Ignatii*, or St. Ignatius's bean.

PEPLION, or PEPLOS, names given by the ancients to medicines which they used as brisk cathartics to purge off the bile and other humours.

PEPLIS, in *Botany*, a name borrowed from Dioscorides, whose *πεπλις*, nevertheless, is evidently the Linnæan *Euphorbia Peplis*, and essentially different in characters and qualities from the genus of which we are about to treat. *Linn. Gen. 176. Schreb. 235. Willd. Sp. Pl. v. 2. 243. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 389. Prodr. Fl. Græc. Sibth. v. 1. 244. Ait. Hort. Kew. ed. 2. v. 2. 316. Juss. 333. Lamarck Illustr. t. 262. Gærtn. t. 51. (Portula;*

(Portula; Dill. Giff. 120. append. 135. t. 7.)—Class and order, *Hexandria Monogynia*. Nat. Ord. *Calycanthema*, Linn. *Salicaria*, Juss.

Gen. Ch. *Cal.* Perianth of one leaf, bell-shaped, plaited, permanent, large; its border in twelve small segments, alternately reflexed. *Cor.* Petals six, ovate, very minute, inserted into the border of the calyx, often wanting. *Stam.* Filaments six, sometimes but four, awl-shaped, short; anthers roundish. *Pist.* Germen ovate, in the bottom of the calyx; style very short; stigma orbicular. *Peric.* Capsule nearly globose, with two longitudinal furrows, membranous, not burbling, of two cells, the partition opposite to the furrows. *Seeds* numerous, minute, obovate. *Receptacle* rather compressed, in the middle of the partition.

Eff. Ch. Calyx bell-shaped; its border in twelve segments. Petals six, inserted into the calyx. Capsule superior, of two cells, not burbling.

1. *P. Portula*. Common Water-Purflane. Linn. Sp. Pl. 474. Curt. Lond. fasc. 4. t. 27. Engl. Bot. t. 1211. Fl. Dan. t. 64.—Native of waters axillary, solitary. Leaves stalked.—Native of flowery places, in various parts of Europe; common in England, flowering in July and August. The modern Greeks call it *αδρακλίδα*, or *αδραχύν*, and eat it in salads, or in soups. The root is annual. Herb smooth, pellucid and somewhat succulent. Stems prostrate, or floating, weak, simple, leafy. Leaves opposite, stalked, obovate, obtuse, entire, a quarter or half an inch long. Flowers axillary, solitary, sessile, small, reddish. Petals fugacious, and often wanting. Capsule pellucid.

Willdenow says the *P. tetrandra* of Linnæus is a *Hedyotis*, of which indeed it has all the appearance. He adds, in its stead, the following new species, for the genus of which we must depend on him, not having seen the plant ourselves.

2. *P. indica*. Willd. n. 2.—Flowers spiked, bracteated. Leaves sessile.—Native of the East Indies. “Stem ascending, square, smooth, six inches or more in height. Leaves opposite, oblong-obovate, abrupt, entire, veiny, smooth. Spikes axillary, simple, longer than the leaves. Flowers sessile, opposite, each accompanied by a lanceolate bractea, twice its own length. Calyx with only eight teeth. Petals wanting. Stamens four.” Willd.

PEPLIUM, a name given by the ancient Greek writers to a shrub which had pinnated leaves and papilionaceous flowers. It is translated by many *jena*; but this does not appear certainly to be right: the several species of *colutea* agree as well with this description as the *jena*, and they have indeed been called *jena* by many; probably it was one of these.

PEPLOUD, in *Geography*, a town of Hindoostan, in the Candeish country; 80 miles S. of Indore. N. lat. 21° 42'. E. long. 76 45'.

PEPLUS, *πεπλος*, among the ancients, a kind of garment worn by women.

The peplus was a long robe that reached to the feet, without any sleeves, and so exceeding fine, that the shape of the body could easily be discovered through it.

The peplus of Minerva is very famous among ancient mythologists. The Athenians used a great deal of ceremony in making the peplus, and dressing the statue of the goddess with it.

The peplus was worked over with gold, on which were represented the combats and grand achievements of Minerva, Jupiter, and the Hermes. On the feast of the *Panathenæa*, (which see.) this was carried about in procession, formed of persons of all sexes, ages, and ranks; the young bringing up the rear, and the aged bearing an olive branch in their hands, the young virgins baskets, and the blooming boys

crowned with millets, and singing hymns known by the name of “*Pæans*,” while those who were called “*Rhapsodists*” recited verses of Homer. The procession advanced from the Ceramicus to the temple of Ceres Eleusina. The peplus was fastened to a barge, which was moved along by machinery.

PEPLUS, in *Botany*, *πεπλος* of Dioscorides, appears by his description to be some kind of Spurge, or *Euphorbia*. Linnæus believed it the common European weed, which he denominated, for that reason, *E. Peplus*. Dr. Sibthorp was induced to think the *E. falcata* of Linnæus was rather the plant of Dioscorides; not only “because it is frequent in vineyards and other cultivated ground, in Greece and the Greek islands; but because the procumbent mode of growth of this species, and the thick bush it forms, answer much better to the description of that ancient author, than the more upright growth of *E. Peplus*.”

PEPO, a Gourd or Pumpkin. See CUCURBITA.

PEPO, in *Vegetable Physiology*, is adopted, as a technical term, by Gærtner and Willdenow, for a particular kind of succulent fruit, exemplified in the natural order of *Cucurbitaceæ*, in which the seeds are attached to the inner surface of the rind. This sort of fruit differs, in different plants, with respect to the thickness or hardness of the rind, and the more or less pulpy nature of the internal substance, as well as the number of cells into which that substance, at an early period, is usually divided. The writer of this article, as well as Gærtner, considers the *Pepo* as no other than one of the numerous forms of a *Bacca*, the insertion of the seeds differing in no respect from those of a Gooseberry. Willdenow alone has described it as a distinct kind of fruit, ranging after the *Pomum*, or Apple, with which Linnæus has, very unaccountably, confounded it, in his generic descriptions of *Trichosanthes*, *Momordica*, *Cucurbita*, and *Cucumis*.

PEPPER, or *Lizard's Tail*, in *Botany*. See PIPER.

PEPPER, *Black*, *Piper nigrum*, is an aromatic fruit, obtained from a species of piper, which grows spontaneously in the East Indies, but does not arrive at perfection without the aid of culture. It is cultivated with such success at Malacca, Java, and especially at Sumatra, that from these islands pepper is exported to every part of the world, where a regular commerce has been established. According to Mr. Marsden, (Hist. of Sumatra,) the ground chosen by the Sumatrans for a pepper garden, is marked out into regular squares of six feet, the intended distance of the plants, of which there are usually a thousand in each garden. The next business is to plant the chinkareens, which serve as props to the pepper vines, and are cuttings of a tree of that name, which is of quick growth. When the chinkareen has been some months planted, the most promising perpendicular shoot is reserved for growth, and the others lopped off; this shoot, after it has acquired two fathoms in height, is decapitated sufficiently high, and its top is cut off. Two pepper vines are usually planted to one chinkareen, round which the vines twirl for support; and after being suffered to grow three years (by which time they acquire eight or twelve feet in height) they are cut off about three feet from the ground, and being loosened from the prop, are bent into the earth in such a manner that the upper end is returned to the root. This operation gives fresh vigour to the plants, and they bear fruit plentifully the ensuing season. The fruit, which is produced in long spikes, is four or five months in coming to maturity: the berries are at first green, turn to a bright red when ripe and in perfection, and soon fall off if not gathered in proper time. As the whole cluster does not ripen at the same time, part of the berries would be left in waiting

for

PEPPER.

for the latter ones; the Sumatrans therefore pluck the bunches as soon as any of the berries ripen, and spread them to dry upon mats, or upon the ground. By drying they become black, and more or less shrivelled, according to their degree of maturity. These are imported here under the name of *black pepper*.

Pepper is also cultivated to a considerable extent in India. Dr. Roxburgh began the cultivation of black pepper in the circars in 1787; using for prop trees the Moechy woodtree, or *Erythrina corallodendron*. One thousand plants yield from 500lbs. to 1000lbs. of pepper.

PEPPER, *White, Piper album*, is the fruit of the same plant with the black, though some have erroneously thought it to be a different species. Accordingly it has been sold at the sales of the East India company, who have the monopoly of the Sumatran pepper trade, for treble the price of the black. Whereas white pepper is the ripe and perfect berries of the same species stripped of their outer coats. For this purpose the berries are steeped for about a fortnight in water, till by swelling their outer coverings burst; after which they are easily separated, and the pepper is carefully dried by exposure to the sun. Or, the berries are freed from their outer coats by means of a preparation of lime and mustard oil, called "Chinam," applied before it is dried. Pepper which has fallen to the ground over-ripe loses its outer coat, and is sold as an inferior sort of white pepper.

Of these pungent hot spices the black sort is the hottest and strongest, and most commonly made use of for medicinal as well as culinary purposes. Its virtues are entirely extracted by ether and alcohol, and partially by water. The aqueous infusion has a brown colour, and reddens vegetable blues; and the decoction of the ground pepper forms a precipitate with infusion of galls, which dissolves again when the fluid is heated to 120°. When the alcoholic infusion is distilled, a green, resinous, oily matter is left, which appears to be the source of the odour and taste of the pepper. Its principal constituents are supposed to be starch, the above oily matter, and extractive. Ether digested on powdered pepper takes up three parts in ten; and when evaporated on water, deposits an intensely hot, biting, yellowish resin, with the odour of the pepper, and an almost insipid extractive matter. It has been said, that these spices differ from most others in this, that their pungency resides not in the volatile parts, or essential oil, but in a substance of a more fixed kind, which does not rise in the heat of boiling water; and that this fixed substance is probably the resinous part; the aromatic odorous matter seeming to depend upon the essential oil. The distilled oil has a strong smell of the pepper, with little acrimony; the remaining decoction, inspissated, yields an extract of considerable pungency. The quantity of extract from both kinds of pepper is nearly the same; that by rectified spirit amounting to about one-eighth, and the watery to nearly one-half their weight; but those of the white are weaker than the other sort. A tincture made in rectified spirit is extremely hot and fiery; a few drops of it set the mouth, as it were, in a flame.

Black pepper is stimulant and carminative: its use as a condiment is well known, and though, in general, it is not hurtful, but is useful to those whose digestion is weak, yet, even in small quantities, it proves injurious, where the inflammatory diathesis is present, and to those who are subject to piles. Some have supposed pepper to be less heating to the system than other aromatics; and Gaubius asserts that, when taken in large quantities, he never found it to warm his stomach, nor to increase the frequency of his pulse. Whereas Dr. Cullen affirms, that when he took this spice, even in a small quantity, it felt warm in his stomach, and

heated his whole body; and he supposes, that Gaubius did not feel its effects from the frequent use of it. As a medicine, pepper is sometimes found serviceable in checking nausea and vomiting, and removing hiccough. It has been also successfully employed in some cases of vertigo, and in paralytic and arthritic disorders. In large doses it has been found a remedy for intermittents; but such use of it has, in some instances, produced fatal consequences. The watery infusion forms an useful gargle in relaxation of the uvula. The dose of black pepper may be from \times gr. to \mathcal{J} j. The officinal preparations are the "Emplastrum melces vesicatorii compositum" of Edinb., and the "Unguentum piperis nigri" of Dubl. Woodville. Thomson.

Pepper that is sold ground is very apt to be sophisticated; the black with burnt crust of bread, &c., and the white with beaten rice.

PEPPER, *Long, Piper longum*, is thus denominated from its form, which is cylindrical, and about an inch and a half in length; it consists of an assemblage of grains, or seeds, joined close to one another, of a brownish colour, bordering without on red, and within on black; and grows by a long pedicle to a plant, like that of the black pepper, and of the same genus, but lower, and its leaves smaller and greener. It is a native of the East Indies, especially Java, Malabar, and Bengal. The berries, or grains, are very small, and lodged in a pulpy matter; like those of the black pepper, they are first green, and become red when ripe. This fruit is hottest to the taste in its immature state, and is therefore gathered while green, and dried by the heat of the sun, when it changes to a blackish or dark grey colour. Dr. Cullen observes, that long pepper has precisely the same qualities with those of black, but in a weaker degree; and Bergius says that black pepper is hotter than this species, whereas the contrary is the fact, and is asserted both by Lewis and Murray. Its constituent parts appear to be similar to those of black pepper. Ether digested on powdered long pepper takes up $2\frac{1}{2}$ parts in 10, and when evaporated on water deposits a resin less hot than that of black pepper, but more permanent; and a smaller proportion of extractive. Its officinal preparations are "Confectio opii" Lond., "Pulvis cinnamomia comp." L. D., "Pulvis cretæ comp." L., and "Tinctura cinnamomi composita," L. E. D. Woodville. Thomson.

Some have mentioned three kinds of this pepper, that of the East Indies, that of America, and that of Ethiopia, called also grain of Zelim; though the first alone is the proper long pepper, the rest resembling it but little.

PEPPER, *Barbary, Bell, Bird, Bonnet, and Cayenne*. See CAPSICUM.

PEPPER, *Guinea, piper Indicum*, obtained from a species of the capsicum, is a reddish pod, of a coral colour, much esteemed by the Americans, from among whom it is brought, and by them called *chile*, and by the French, *garden coral*. See CAPSICUM.

Under the article CAPSICUM we have mentioned the dietetic and medicinal use of the fruit of the capsicum, or of Cayenne pepper. We shall here add some other particulars. It has been found beneficial in lethargic affections; in dropsies, and other cachectic complaints, when chalybeates are indicated, a small portion of powdered capsicum is recommended as an excellent addition by Dr. Wright; and in the diseases cynanche maligna, and scarlatina maligna, it has been found highly useful, both given internally, and used as a gargle. Cataplasms of capsicum operate as a powerful rubefacient without blistering the skin, and are used in the West Indies to relieve the coma and delirium, which almost constantly attend tropical fevers. The diluted juice of the fruit is said

to be a sovereign remedy in ophthalmia from relaxation. Capsicum may be given in the form of pills in doses from grs. vj to grs. x; or fʒj to fʒij, in a glass of water, of a tincture made with ʒiv of capsicum and fʒviij of alcohol. The gargle usually employed is made by beating into a paste ʒj of Cayenne pepper and ʒj of common salt; then adding fʒvj of boiling water; and to the solution, strained when cold, fʒiv of vinegar. But a simple infusion in the proportion of gr. j of the pepper to fʒj of boiling water, answers equally well. Thomson.

PEPPER, *Jamaica*, called by the Dutch *amoni*, by the Spaniards *pimenta de Jamaica*, is the fruit of a tree, the *myrtus foliis alternis* of Linnæus, growing plentifully in Jamaica, and other American islands.

It is a real aromatic, and may supply the defect of cloves, nutmeg, and cinnamon; whence it is called also by the English, *all-spice*. The French call it the *round clove*, from its round shape, and its taste resembling that spice. See MYRTUS and PIMENTA.

PEPPER, *Ciapa*, *pimenta de Ciapa*, a name given by the Spaniards to a sort of spice which they discovered in Ciapa, a province of Guatemala, in New Spain, and of which they were at first very fond, both in food and medicine.

In medicine it is a very good cephalic and stomachic. It is recommended very strongly also by some of the Spanish writers, as a cure for the epilepsy and gutta serena; but those who tried it in these cases do not confirm such accounts.

The descriptions we have of it are, that it has the taste of cloves, pepper, cinnamon, and ginger, all blended together; and Redi is of opinion, that it is no other than our pimenta, or Jamaica pepper.

PEPPER, *Indian*. See GUINEA PEPPER and CAPSICUM.

PEPPER, *Poor man's*, a name sometimes given to the *ditander*, or *lepidium*; which see.

PEPPER, *Wall*, a name sometimes given to a species of sedum, or lesser house-leek. See SEDUM.

PEPPER, *Water*, a species of *polygonum*; which see. Miller and others make it a species of the *persicaria*; which see.

PEPPER *grafs*. See PILULARIA.

PEPPER *mint*, the name of a species of mint. See MENTHA.

PEPPER *wort*, a name by which some call the *lepidium*; which see.

PEPPER *bird*, in *Ornithology*, the English name of the rhamphastos with a yellow rump, otherwise called *toucan*.

PEPPER *mushroom*, in *Botany*, a name given by Dr. Lister to a new species of fungus, discovered by him in the woods of Yorkshire, whose juice is acrid and hot as pepper. This is somewhat larger than the common esculent mushroom, but of the same shape with that, having a round head and open gills underneath. The head is very fleshy, and the pedicle also is solid, not hollow, as in most other of the large funguses: any part of this mushroom being cut or broken, it bleeds very freely a white milky juice, like that of the thymals. This juice tastes like pepper, only that it is much hotter. It is not viscid or clammy to the touch, and the air does not much discolour it; nor does it render the blade of the knife, with which it is cut, black, as most other vegetable juices do. When let out of the plant it very soon concretes into a firm and dry mass, making a sort of cake; and when thus dried into a solid substance, it retains its white colour and pungent taste. It is very remarkable, that this mushroom, though so hot to our tongues as not to be endured, yet is so well suited to the palates and nature of certain insects, that they can not only feed on it, but live comfortably in the midst of it. The yellow naked snail feeds

greedily on the plant while growing, and the stalks of it at such times as the juice is sharpest of all, that is, while it is growing to the full size, are full of the maggots and worms hatched from the eggs of flies, deposited there for a nidus and food for them in that state. The juice has a great affinity with euphorbium, and may be brought into medicinal use, perhaps, to very good purpose.

John Bauhine describes a mushroom much resembling this, but smaller and less fleshy; and the Prussians and Polanders have a sort of great mushroom, which they call *groozdijbys*, which agrees with this in many particulars; but it is larger and thicker. Phil. Transf. N^o 89.

PEPPER *water*, a liquor prepared by the curious for examination by the microscope, as always affording a great number of small animals.

The method of preparing it is this: put common black pepper, grossly powdered, into an open vessel, so as to cover the bottom of it half an inch thick, and put to it rain or river water, till it covers it an inch; shake or stir the whole well together, at first mixing, but never disturb it afterwards: let the vessel be exposed to the air, uncovered; and in a few days there will be seen a pellicle or thin skin swimming on the surface of the liquor, appearing of several colours.

This is a congeries of multitudes of small animals; and being examined by the microscope, will be seen all in motion: the animals, at first sight, are so small as not to be distinguishable, unless to the greatest magnifiers; but they grow daily till they arrive at their full size. Their numbers are also continually increasing, till the whole surface of the liquor is full of them, to a considerable depth. When disturbed, they will sometimes all dart down to the bottom, but they soon after come up to the surface again. The skin appears soonest in warm weather, and the animals grow the quickest; but in the severest cold it will succeed, unless the water freezes. Baker's Microscope, p. 71.

About the quantity of a pin's head of this scum, taken upon the nib of a new pen, or the tip of a hair-pencil, is to be laid on a plate of clear glass; and if first applied to the third magnifier, then to a second, and finally to the first, will shew the different animalcules it contains, of several kinds and shapes, as well as sizes. Phil. Transf. N^o 284.

The animalcules discoverable in this liquor are principally of six kinds. 1. The largest kind of all is in length about the diameter of a hair, and scarcely a fourth part of that measure in breadth; they are very thin and transparent, but their back is darker than their belly; they turn about very frequently and nimbly in the water: their sides are fringed with a great number of minute feet, which are seen principally at the two ends; and at one end there are also some bristles longer than the feet, which make a sort of tail. They are very nimble, and walk as well as swim, and will climb up a hair, if put in among them.

2. There is a smaller sort, whose length is about the third of a hair's breadth; but their tail is five or six times as long as their body. This they either carry straight, or in a spiral form; and at the other end they thrust out a sort of bearded tongue: these make a constant current of water towards them.

3. There is a smaller sort than these, which are sometimes seen of an oval figure, and sometimes long and flat, like a flounder: these also have feet, which are plainly seen when the water is evaporating.

4. A fourth may appear like slender worms, fifty times as long as broad: their thickness is not above the hundredth part of a hair's breadth; and they move with equal ease either forward or backward.

5. There is a fifth sort extremely minute and round; and 6. A sixth kind, which are longer than these, but not larger; and probably there may be yet many kinds not discovered. These small animals are easily destroyed; a little dissolved salt or fugar, or spirit of vitriol, or even spittle, will kill them; and in the drying away of the waters many of them burst. Phil. Trans. N^o 203.

PEPPER Bay, in *Geography*, a bay on the W. coast of the island of Java; 30 miles S.S.W. of Bantam. S. lat. 6 24'. E. long. 105 40'.

PEPPERBERG, a town of the island of Java, on the S. coast; 75 miles S. of Batavia.

PEPPERELBOROUGH, a township of America, in York county, and state of Maine, on the N. side of Saco river, near the mouth, which separates it from Biddeford to the south. A bank by the name of "Saco Bank" was established here in 1803; about 12 miles S.W. of Portland. It was incorporated in 1772, and contains 1842 inhabitants.

PEPPERELL, a township of Massachusetts, on the E. branch of Nashaway river, and on the N. line of Middlesex county; 40 miles N. by W. of Boston; incorporated in 1753, and containing 1198 inhabitants.

PEPSQUIACH POINT lies on the northern side of Chaleur bay, now called "Paspibiac Point;" about three leagues W.N.W. of East Nouvelle. It is a barren plain, nearly a league long, where is carried on a very extensive fishery.

PEPTIC, in *Medicine*. See PEPASTIC.

PEPUNG, in *Geography*, two small islands of the East Indian sea, near the coast of China. N. lat. 23° 22'. E. long. 107°.

PEPUSCH, JOHN CHRISTOPHER, in *Biography*, doctor in music, Oxon., a very learned musician, who was born at Berlin in 1667, and had made so great a progress in music at the age of fourteen, that he was sent for to court, where he gave such proofs of his abilities that he was appointed to teach the prince, father of the late king of Prussia. He remained at Berlin till he was about twenty, when he went into Holland, where he first began to publish his compositions; but after continuing there about a year, he came to England soon after the Revolution. His first employment in London was playing the tenor in the band at Drury-lane play-house; but having convinced the managers that he deserved a better place, he was advanced to the harpsichord about 1700. In 1707 he had acquired English sufficient to adapt Motteaux's translation of the Italian opera of "Thomyris" to airs of Scarlatti and Bononcini, and to new-set the recitatives. In 1709 and 1710, several of his works were advertised in the first edition of the *Tatlers*, particularly a set of sonatas for a flute and base, and his first book of cantatas. In 1713 he obtained, at the same time as Crofts, the degree of doctor of music at the university of Oxford. And soon after this, upon the establishment of a choral chapel at Cannons, he was employed by the duke of Chandos as maestro di capella; in which capacity he composed anthems and morning and evening services, which are still preserved in the Academy of Ancient Music. In 1715 he composed the masque of "Venus and Adonis," written by Cibber; and in 1716 "The Death of Dido," by Booth, both for Drury-lane. These pieces, though not very successful, were more frequently performed than any of his original dramatic compositions. In 1723 he published an ode for St. Cecilia's day, which he had set for the concert in York-buildings. And about the year 1724, Dr. Berkeley, dean of Londonderry, afterwards bishop of Cloyne, having formed a plan for erecting a college in one of the Summer isles, or Bermudas, among the several persons of

VOL. XXVI.

distinguished abilities whom he had engaged to accompany him thither, fixed on Dr. Pepusch. But having embarked with his associates for the intended settlement, the ship was wrecked, and the undertaking frustrated.

Being returned to England after this accident, Dr. Pepusch married Margarita de l'Epine, who had quitted the stage, where she had acquired a fortune that was estimated at 10,000*l*. These possessions, however, did not incline the doctor to relax in his musical studies or pursuits. He had always been a diligent collector of ancient music and musical tracts, and he was now enabled to gratify this passion without imprudence. He still continued to compose for the play-house in Lincoln's-Inn-Fields, and had the "Squire of Alsatia" for his benefit there in 1726, "with singing by Mrs. Chambers, also singing in Italian and English by Mrs. Forsyth, Mrs. Davies, and Mrs. Grimaldi, being the first time of their respective appearances on the stage." Soon after he was very judiciously chosen by Gay, to help him to select the tunes for the "Beggar's Opera," for which he composed an original overture upon the subject of one of the tunes (I'm like a skiff), and furnished the wild, rude, and often vulgar melodies, with bases so simple and excellent, that no judicious contrapuntist will ever attempt to alter them for the theatrical purpose for which they were originally designed. It would be easy to multiply notes, and make the base more important than the treble, at the expence of the singer, the vocal part, and of propriety; and we will venture to say that the instrument or accompaniment that robs the singer of the attention of the audience by being too loud, or too busy (if the singer is worth hearing), is much more deserving of censure than praise.

After this period, he composed but little, applying himself chiefly to the theory of music, and explaining the mysteries of composition to young professors. He had always been extremely anxious for the prosperity of the Academy of Ancient Music, of which he was one of the first founders, and continued very active in its service to the time of his death. As a consequence of his musical erudition and zeal for the advancement of his art, he published, in 1731, a correct edition of a short "Treatise on Harmony," which the late earl of Abercorn is supposed to have assisted him in putting into English. This nobleman had so long studied composition under Dr. Pepusch, and so frequently conversed with him on the subject, that he was supposed more able to explain his principles in English than the doctor himself. The first edition of this small tract appeared without the plates or the consent of the author. This work contains many elementary rules for composition that are practical and useful; but it likewise contains many prejudices and exploded doctrines, which, to revive, would shackle genius and throw the art back into Gothic times.

In 1737 he was appointed organist of the Charter-house, which afforded him a tranquil retreat well suited to his time of life and love of study; and he was visited and consulted as an oracle, not only by young musical students, to whom he was always kind and communicative, but by every master who modestly supposed he had still something to learn. Here he greatly augmented his library, which consisted of musical curiosities, theoretical and practical, of all kinds.

In 1739 he lost a son, his only child, upon whose genius and disposition there was every reason to found the greatest expectations; and in 1740 Mrs Pepusch died; after which, his time seems to have been chiefly devoted to the study of the genera and systems of the ancient Greek music, concerning which he presented a paper to the Royal Society in

1746, N^o 481, and Martin's Abridg. vol. x. and was soon after elected a member of that learned body.

From this period till the year 1752, when he died at the age of eighty-five, he persisted in the study of Greek music; and having dispatched the "Genera," was trying to illustrate the doctrines and prejudices of Isaac Vossius concerning the "Rhythmus" of the ancients, but left no papers behind him on the subject, that were either useful or intelligible to those who had the possession of them after his decease.

This profound musician was buried in the chapel of the Charter-house, where a tablet was placed, and inscribed to his memory, by his friends and associates of the Academy of Ancient Music.

As a practical musician, though so excellent a harmonist, he was possessed of so little invention, that few of his compositions were ever in general use and favour, except one of his twelve cantatas, "Alexis," and his airs for two flutes or violins, consisting of simple easy themes or grounds with variations, each part echoing the other in common divisions for the improvement of the hand. Indeed, though only one cantata of the two books he published was ever much noticed, there is considerable harmonical merit in them all; the recitatives are in general good, and the counterpoint perfectly correct and masterly. The fifth cantata of the second book seems much superior to the rest: the first air would admit of modern taste and expression, the harmony is rich, and the parts are well arranged; and the second air, with a trumpet accompaniment, is spirited, and if sung by a powerful and cultivated voice, would have a good effect. But these cantatas are by no means in the style of Alef. Scarlatti, as has been suggested; they rather resemble the cantatas of Gasparini, whose melodies were simple and modulation timid, than the original cantilena and extraneous modulation of Scarlatti. Among all the publications of Pepusch, the most useful to musical students was, perhaps, his correct edition of Corelli's sonatas and concertos in score, published in 1732.

He treated all other music in which there was fancy or invention with sovereign contempt. Nor is it true, as has been asserted, that "he readily acquiesced in Handel's superior merit." Handel despised the pedantry of Pepusch, and Pepusch, in return, constantly refused to join in the general chorus of Handel's praise.

The sole ambition of Pepusch, during the last years of his life, seems to have been the obtaining the reputation of a profound theorist, perfectly skilled in the music of the ancients; and attaching himself to the mathematician De Moivre and Geo. Lewis Scot, who helped him to calculate ratios, and to construe the Greek writers on music, he bewildered himself and some of his scholars with the Greek genera, scales, diagrams, geometrical, arithmetical, and harmonical proportions, surd quantities, apotomes, lemmas, and every thing concerning ancient harmonics, that was dark, unintelligible, and foreign to common and useful practice. But with all his pedantry and ideal admiration of the music of the ancients, he certainly had read more books on the theory of modern music, and examined more curious compositions, than any of the musicians of his time; and though totally devoid of fancy and invention, he was able to correct the productions of his contemporaries, and to assign reasons for whatever had been done by the greatest masters who preceded him. But when he is called the most learned musician of his time, it should be said, in the music of the 16th century. Indeed, he had at last such a partiality for musical mysteries, and a spirit so truly antiquarian, that he allowed no composition to be music but what was old and

obscure. Yet, though he fettered the genius of his scholars by antiquated rules, he knew the mechanical laws of harmony so well, that in glancing his eye over a score, he could by a stroke of his pen smooth the wildest and most incoherent notes into melody, and make them submissive to harmony; instantly seeing the superfluous or deficient notes, and suggesting a base from which there was no appeal.

His admirable library, the most curious and complete in scarce musical authors, theoretical and practical, was dispersed after his death. He bequeathed a considerable part of his best books and manuscripts to Kelner, an old German friend, who played the double-bass in the theatres and concerts of the time; some to Travers, and these and the rest were at last sold, dispersed, and embezzled, in a manner difficult to describe or understand. For an analysis of Dr. Pepusch's "Treatise on Harmony," see COUNTER-POINT.

There never was a great man in any art or science who had not his opponents: and there have always been two opinions concerning the merit of Pepusch. He was respected and revered by the exclusive lovers of old music, and students in harmony; while the admirers of Handel, and of modern Italian composition, regarded him as a pedant totally devoid of genius. It seemed, therefore, but just and equitable, after the decease of his friends and his foes, to point out, with the utmost truth and candour, the real merit and deficiencies in this little valuable work.

PEPUZA, in *Ancient Geography*, a town of Asia, in Phrygia Pacatiana.

PEPUZIAN, in *Ecclesiastical History*, a sect of ancient heretics; otherwise called Phrygians, or Cataphrygians.

They had their name Pepuzians, from a pretence that Jesus Christ appeared to one of their prophetesses in the city of Pepuza in Phrygia, which was their holy city. See QUINTILIANS.

PEPLYCHNUS, in *Ancient Geography*, a river which bounded Macedonia.

PEPYS'S ISLANDS, in *Geography*. See FALKLAND ISLANDS.

PEQUANACK, a township of America, in Morris county, New Jersey, separated from Bergen county N. by Pegunock river.

PEQUANNOCK Point or River. The river is a small stream which runs S. through the towns of Huntington and Stratford in Fairfield county, Connecticut, and discharges itself into a bay in the sound, where vessels may anchor. The point forms the western extremity of the bay, near which are some rocks; 5 miles S.W. of Stratford river.

PEQUEA CREEK, a river of Pennsylvania, which runs into the Susquehanna, N. lat. 39 54'. W. long. 76 22'.

PEQUESIGHAUGEM, or BEAR Lake, the source of a river of the same name, which is the north-easterly branch of Maggakadawa river: it is of an irregular form, about three miles long, and two wide.

PEQUEST CREEK, a river of New Jersey, which runs into the Delaware, N. lat. 40 47'. W. long. 75 10'.

PER, a Latin preposition often used before the two words *Arsis* and *Thesis*. *Per thesin* means, in beating time, the first note or portion of a bar, when the hand or foot is beaten down. *Per arsin* implies the second or fourth portion of a bar, when the hand or foot is lifted up. It is also said of a melody, counterpoint, or fugue, &c. that the notes move *per thesin*, when they descend from the acute to the grave; and that their motion is *per arsin*, when, on the contrary, the notes mount from the grave to the acute.

PER is also an Italian preposition which has many acceptations in the musical compositions of Italy.

1. Before the name of authors, when it is meant to signify *by* in English; but this is bad Italian.

2. It is constantly found in tables of contents to motets, indicating the occasion, the subject, and day of festivals, on which it was intended to be sung: and then it means *for*. *Per la Beata Virgine*, or the initials B. M. Y. for, or in honour of, the blessed Virgin. *Per li*, or *gli defuncti*; for the dead, &c.

3. *Per* also often signifies *A*, or *per diritto*, straight on. *Per rovescio*, by inversion, &c.

PER *Accidens*. See **ACCIDENS**.

PERA, in *Botany*. See **PERULA**.

PERA, in *Ancient Geography*, a place near mount Hymettus in Attica; where was a temple of Venus, with a fountain, which procured a happy delivery for the females who drank of it, according to the relation of Suidas.

PERA, in *Geography*, a suburb of Constantinople, in which the ambassadors, the agents of foreign courts, and almost all foreigners reside, with the exception of the merchants who are established at Galata, another suburb, being that nearer to the harbour, and more conveniently situated for their commercial affairs. Pera is one of the most populous quarters of the city, notwithstanding its distance from the port and the centre of business; and the lodgings are extremely dear, since the rich Armenians came to settle there, in order to be less exposed to exactions and the insults of the Turks, and to enjoy a little more liberty under the protection of the Europeans. See **CONSTANTINOPLE**.

PERA, a town of Portugal, in Algarva; 8 miles E. of Villa Nova de Portimao.—Also, a sea-port and capital of a kingdom, on the W. coast of Malacca, on a river of the same name; 170 miles N.W. of Malacca. N. lat. $4^{\circ} 23'$. E. long. $101^{\circ} 15'$.

PERA, or *Pulo Pera*, a small island in the East Indian sea, at the entrance of the straits of Malacca. N. lat. $5^{\circ} 54'$. E. long. $98^{\circ} 36'$.

PERACUTUM MENSTRUUM. See **MENSTRUUM**.

PERÆA, in *Ancient Geography*, a province of Asia Minor, which commenced on the frontiers of the Doride, towards mount Phœnix, N.E. of the isle of Rhodes, and terminated at Dædala. The first writer who mentions this province is Polybius. It was for a long time subject to the Rhodians, and a town called Cryassus was situated in it.—Also, a country on the other side of Jordan, which was one of the divisions of Palestine. According to Josephus, in his "Wars of the Jews," Peræa had for its limits on the E. Rabba or Philadelphia, on the W. the Jordan, on the S. Macherontes, and on the N. Pella.—Also, a small country of Asia, on the banks of the Tigris.—Also, a canton of Greece, in the territory of Corinth, the inhabitants of which were called "Peræi."

PERÆQUATOIRES, among the Romans, assessors appointed to regulate the census according to every man's circumstances, by easing those that were overcharged, and raising the taxation if too low.

PERÆTHUS, in *Ancient Geography*, a town of the Peloponnesus, in Arcadia. Pausanias says, that among the ruins of this town, there was visible a temple of the god Pan.

PERAFTA, in *Geography*, a town of Spain, in Catalonia; 10 miles N.N.W. of Vique.

PERALADA, a town of Spain, in Catalonia; 22 miles N.N.E. of Gerona.

PERALES, a town of Portugal, on the left bank of the Tagus, opposite to Abrantes.

PERALTA, a town of Spain, in Navarre, celebrated for its wine; seven miles S.S.W. of Olite.

PERAM, a small island in the gulf of Cambay. N. lat. $21^{\circ} 30'$. E. long. $72^{\circ} 3'$.

PERAMA, in *Botany*. See **MATTUSCHIKÆA**.

PERAMBULATION of the Forest, the surveying, or walking about a forest, or the limits of it, by justices or other officers appointed for this purpose, to set down the metes and bounds thereof, and what is within the forest, and what without.

PERAMBULATION of Parishes is annually performed in order to preserve those bounds of parishes, which have been long settled by custom; and because these perambulations were performed in the rogation week, the rogation days were anciently called *gange-days*, from the Saxon *gan*, or *gangen*, to go.

In the perambulation of a parish, no refreshments can be claimed by the parishioners, as due of right from any houses or lands in virtue of custom.

These perambulations were, in the times of popery, accompanied with great abuses, *viz.* with feasting and superstition; being performed in the nature of processions, with banners, hand-bells, lights, staying at crosses, and the like: and, therefore, when processions were forbidden, in the reign of queen Elizabeth, it was required, that, for the retaining of the perambulations of the circuits of parishes, the people should, once a-year, at the usual time, with the curate and the substantial men of the parish, walk about the parishes, and at their return to church make their common prayers, &c.

PERAMBULATIONE FACIENDO, is a writ commanding the sheriff to make perambulation, and set down the bounds of two or more manors, whose limits are not so well known.

The writ de perambulatione faciendi is only issued, where the lords of both manors agree to have such perambulation. If one of them refuse, the other must seek his remedy by a writ de rationabilibus divisis.

PERAMBULATOR, in *Surveying*, an instrument for the measuring of distances; called also *pedometer*, *way-wifer*, and *surveying-wheel*.

Its advantages are its handiness and expedition: its contrivance is such, that it may be fitted to the wheel of a coach; in which state it performs its office, and measures the road without any trouble at all.

There is some difference in its make; that now most usual, and most convenient, is as follows.

PERAMBULATOR, or Way-wifer, construction of the. The perambulator (represented *Plate VI. Surveying, fig. 9.*) consists of a wheel two feet seven inches and a half in diameter; consequently half a pole, or eight feet and three inches in circumference. On one end of the axis is a nut, three quarters of an inch in diameter, divided into eight teeth, which, upon moving the wheel round, fall into the eight teeth of another nut *c*, fixed on one end of an iron rod *Q*, and thus turn the rod once round, in the time the wheel makes one revolution. This rod lying along a groove, in the side of a carriage of the instrument, has at its other end a square hole, into which fits the end *b* of the little cylinder *P*. This cylinder is disposed under the dial-plate of a movement, at the end of the carriage *B*, in such manner as to be moveable about its axis. Its end *a* is cut into a perpetual screw; which falling into the thirty-two teeth of a wheel perpendicular to it, upon driving the instrument forward, that wheel makes a revolution, each sixteen poles. On the axis of this wheel is a pinion with six teeth, which, falling into

the teeth of another wheel of sixty teeth, carries it round every hundred and sixtieth pole, or half a mile.

This last wheel then carrying a hand or index round with it, over the divisions of the dial-plate, whose outer limb is divided into one hundred and sixty parts, corresponding to the one hundred and sixty poles, points out the number of poles passed over. Again, on the axis of this last wheel is a pinion containing twenty teeth, which, falling into the teeth of a third wheel, that has forty teeth, drives it once round in three hundred and twenty poles, or a mile. On the axis of this wheel is a pinion of twelve teeth, which, falling into the teeth of a fourth wheel, that has seventy-two teeth, drives it once round in twelve miles.

This fourth wheel carrying another index over the inner limb of the dial-plate, divided into twelve, for miles, and each mile subdivided into halves, quarters, and furlongs, serves to register the revolutions of the other hand, and to keep account of the half-miles and miles passed over, as far as twelve miles.

PERAMBULATOR, or *Way-wifer, use of the*. The application of this instrument is obvious from its construction. Its proper office is in the surveying of roads, and large distances, where a great deal of expedition, and not much accuracy, is required. It is evident, that driving it along, and observing the hands, has the same effect as dragging the chain, and taking account of the chains and links. See **CHAIN**.

Long distances, says major Rennell, may be accurately measured by a perambulator; and he says, that during the Bengal survey, he measured a meridian line of three degrees with this instrument; and found it to agree minutely with the observations of latitude. An allowance, however, was made for the irregularities of the ground, whenever they occurred.

PERAMES, in *Geography*, a town of America, in Bergen county, New Jersey, lying on the point of land formed by the branches of Saddle river, a N. branch of the Passaic; about 18 miles N. of Bergen.

PERAMI, a town of the island of Cuba; 25 miles S.E. of Villa del Principe.

PERANEMA, in *Ichthyology*, the name of a Brazilian fish, of the size of the perch, being ten or eleven fingers in length, and about three fingers broad in the broadest part.

Its mouth is large and round, and has no teeth, but several very rough and sharp prominences; its eyes are large, and it has one long fin running down the back, which is supported by rigid and prickly rays; its tail is not forked; its whole body is a silvery white, with a faint blush of red; its scales are extremely small, and of a triangular figure, and its belly is very white: it is a sea-fish, and is wholesome and well-tasted.

PERANITES, the name of a stone mentioned with many idle stories of its origin, by the writers of the middle ages.

It seems originally to have been only a corruption of the word *peantides*, a name by which the ancients seem to have called our *stalactites* or *dropstone*.

PERARALO, in *Geography*, a town of Italy, in the Cadornin; two miles S. of Cadora.

PERAROR, a town of Hindoostan, in the Carnatic; 10 miles S. of Tiagar.

PER ARSIN, and **THESIN**, in *Musical*. See **PER**, &c.

PERASEMAJOKI, in *Geography*, a town of Sweden, in the province of Wasa; 50 miles E.N.E. of Chrilline-stadt.

PERASHACOTTA, a town of Hindoostan; 13 miles W.N.W. of Coimbatore.

PERASTA, a town of Albania, on the Cattaro.—Also, a town of European Turkey, in Romania, on the coast of the sea of Marmora; 12 miles N.E. of Gallipoli.

PERASTORFF, a town of Austria; five miles S.S.W. of Ips.

PERAY, ST., a town of France, in the department of the Ardèche, and chief place of a canton, in the district of Tournon. The place contains 1652, and the canton 7492 inhabitants, on a territory of 165 kilometres, in 10 communes.

PERBIGA, a town of Hindoostan, in Bahar; 45 miles S.S.W. of Patna.

PERBUTPOUR, a town of Hindoostan, in Allahabad; 40 miles N.E. of Gazypour.

PERCA, the *Perch*, in *Ichthyology*, a genus of fishes of the order Thoracici, of which the generic character is, jaws unequal; teeth sharp, incurved; gill-covers scaly, of three laminae, the upper ferrate; gill-membrane seven-rayed; lateral line arched with the back; scales hard, rough; fins spinous; vent nearer the head than the tail. The name *perca* is of Greek origin, and is derived from the word *περκαος*, which signifies variegated with black or dusky spots; a character common to most of the species of this fish. About sixty species are enumerated in Gmelin's last edition of Linnæus; these are divided into three sections according as they have one dorsal fin or two.

A. *Dorsal Fins two, distinct.*

Species.

* **FLUVIATILIS**, or Common Perch. The second dorsal fin has sixteen soft rays; the eyes are large; the iris blueish, edged within with yellow; the nostrils are double, near the eyes, with four pores before them; the mouth is large; jaws nearly equal; teeth small, in the jaws and on the roof; the tongue is smooth and short; aperture of the gills large; dorsal fins violet, the first with spinous rays and a black spot at the end; pectoral reddish, the rest are red; the tail is a little forked. This well-known fish measures from eight or ten inches to nearly two feet in length. It inhabits the clear streams of Europe and Siberia; the back, and part of the sides, are of a deep green, with five broad black bars, which are sometimes dark green or blue, and very rarely wanting; belly white tinged with red; it swims with great swiftness at a certain height in the water. It is tenacious of life, and may be carried sixty miles in straw, and yet survive the journey; eagerly takes a bait: it feeds on aquatic insects and smaller fish, spawns in May and June, and is very prolific: it has no real air-bladder. Its flesh is firm and delicate, and was held in high repute at the table of the ancient Romans. In some of the northern countries, a sort of isinglass is made from the skin. It is preyed upon by the pike, eel, &c.

AMERICANUS. Red; second dorsal fin with thirteen rays. It is found in the brackish waters of North America; the lower lip, chin, gill-membrane, and upper edge of the covers red.

LUCIOPERCA. Second dorsal fin with twenty-three rays. This species inhabits the clear waters of Europe and northern Persia. It grows to four feet long; is very voracious, feeds on other fish, even of its own tribe; spawns in May, and is extremely prolific; the flesh is tender and good.

VOLGENSIS. Green-gold; second dorsal fin with twenty-three rays. It is found chiefly in the Volga and neighbour-

PERCA.

ing rivers, and is an intermediate species between the fluvial and the lucioperca.

ASPER. Yellowish, with three or four transverse bands; second dorsal fin with thirteen rays. This species inhabits the clear waters of southern Europe, is from six to eight inches long. The body above is blackish, but it is whitish beneath; it feeds on insects and worms; the flesh is delicious.

ZINGEL. Second dorsal fin with nineteen rays; the lower jaw is by much the shorter of the two. It is found in the rivers of Germany. It resembles the last, except that it is much larger; the head more pointed; the gape large; the colour less dusky, and the tail longer, truncate, and somewhat rounded.

* **LABRAX;** the Baffe. Second dorsal fin with fourteen rays; the back is dusky, tinged with blue; the belly is white. It inhabits Europe and Egypt. It sometimes grows to the weight of twelve or fourteen pounds; is strong, active, and voracious; the body is shaped like a salmon.

ALBURNUS. Dorsal fins unarmed; the gill-membrane is three-rayed; the tail entire. It inhabits Carolina: the body is oblong, with numerous oblique brown bands.

PUSILLA. Body oval, compressed, rough. It inhabits the Mediterranean, is only an inch and a half long; the body is of a reddish-silvery hue, covered with very minute prickles. The head is armed with prickles; the lower jaw a little longer, very rough beneath; the iris is white; the ventral fins with a strong spine, and serrate on the anterior edge.

LOPHAR. Silvery; ventral fins connected. It inhabits Constantinople; it is about the size and shape of a herring; the back is greenish-brown: it is thought by some naturalists not to be of the perca tribe.

ARABICA. Body silvery, with longitudinal black lines; tail with a golden spot, and black in the middle. It inhabits Arabia, the body is oblong-lanceolate, truncate, beneath without spots or lines; the scales are lax, broad, deciduous, denticulate, disposed in ten rows; it has sixteen or seventeen black lines on each side.

NILOTICA. Dorsal fins hardly distinct; tail entire. It is found in the river Nile, and also in the Caspian sea.

B. *Dorsal Fins single; Tail undivided.*

Species.

UNDULATA. Dorsal fins sub-united; body brown, waved, a brown spot at the pectoral fins. It inhabits Carolina, and is there called the croker. The anterior gill-covers have five short teeth; the tail is entire.

OCELLATA. Dorsal fins sub-united; tail with a black ocellate spot at the base. It inhabits Carolina, and is there called the baffe. The first ray of the dorsal fin very short, the first of the ventral is shorter and unarmed; the spot on the tail is encircled with white.

ARGUS. Silvery-blueish, with numerous ocellate brown spots. It grows to about a foot in length, and is reckoned a very beautiful fish. The spots on the body have white centres; those on the head, pectoral and ventral fins, are smaller and without white centres.

* **MARINA;** Sea Pearch. This species is red, with dusky lines on the sides; gill-covers with a black spot; it has fifteen dorsal spines. It is found in many parts of Europe, is about a foot long, and the flesh is very good. The head is large and deformed; the eyes are large; the teeth are small, numerous, and on the head and gill-covers are strong spines.

SCANDENS. The dorsal fin of this species has seventeen

spinous and eight soft rays; the scales are rough, with a whitish denticulate edge. It inhabits rivulets in Tranquebar; is about four inches long; has the very singular habit of crawling up trees, whence it takes its specific name, which it effects by means of the spines on the gill-covers, and spinous rays of the other fins. It is described in the Linnæan Transactions. The body is covered with a black slimy mucus; above it is of dusky-green, lighter on the sides, and beneath it is of a pale golden colour.

NOBILIS. Body silvery, with eight brown bands. It inhabits North America. The spinous rays of the dorsal fin are silvery at the sides.

POLYMNA. Body black, with three white bands. It inhabits South America and some parts of India. The middle band passes through the hind part of the dorsal fin.

MERRA. Body white, with numerous sub-hexagonal brown spots. It inhabits Japan, and is about a foot long. The lower jaw longer; posterior gill-cover spiny, tail rounded.

COTTOIDES. All the fins of the fish of this species are marked with two dotted lines. It is found in India.

PHILADELPHIA. The dorsal fin has a black spot in the middle; the scales and gill-covers are ciliate. It inhabits South America.

PALPEBROSA. The eyelids of this species are marked with a brown spot; the lateral line is curved. It is a small fish, and inhabits America.

ATRARIA. The body of this species is black, the fins are spotted with white. It is found in Carolina.

CHRYSOPTERA. The lower fins are yellow, spotted with brown. It inhabits Carolina. The gill-covers are very finely toothed; the lateral line is straight.

MEDITERRANEA. All the fins of this species, except the dorsal, are tawny; the pectoral is marked with a pectoral black spot. It inhabits the Mediterranean. The body is green, with dusky lines parallel with a lateral line on the upper part; those on the lower part are broader, and of a fine blue; about a span long; compressed, oblong.

VITTATA. The body with five white and brown transverse lines: there is a variety of this species, in which the lines are widened into bands; the first inhabits America; the second Japan. They are about eight inches long.

GUTTATA. Body sprinkled with bloody coloured dots. This and the next are natives of America.

PUNCTATA. Body dotted with blue.

SCRIBA. Pectoral and caudal fins yellow; the head with irregular zigzag marks.

GIGAS. Body clouded; gill-covers three-spined; eleven dorsal spines. It inhabits the Mediterranean, and is about three feet long. The body is oval, compressed at the sides, whitish-yellow, with dusky-brown waves.

ROGAA. Reddish-black; tail equal; fins black; gill-membrane dusky-red. It is found in divers parts of Arabia.

LUNARIA. Rusty black; pectoral fins black, behind yellow; dorsal and caudal behind of a palish hyaline. It inhabits Arabia, and is a good deal like the last.

TAUVINA. Body oblong linear, brown, with rusty black dots; the tail is rounded. It inhabits Arabia. The scales are small and denticulate.

FASCIATA. This is red, with broad whitish transverse bands. It inhabits the Red sea: is above a yard long, and the scales are small.

MINIATA. This species is scarlet, covered with blue dots; the tail is rounded; there are two varieties: 1. Brown, with ocellate blue spots. 2. Red, with blue dots. It inhabits

bits

bits Arabia, and feeds on fish; the scales are very small, round, striate; the flesh is very good.

SUMMARI. Of this species there are three varieties.

1. Tail rounded; body ashy-brown, covered with white spots.

2. Body blueish, with brown dots.

3. Whitish-ash, with yellowish-brown dots. These are natives of Arabia.

SINENSIS. Yellowish; tail oval; lower jaw shorter. It inhabits China, and resembles the *P. fluviatilis*, but is smaller.

C. Dorsal Fin single; Tail forked.

Species.

ASCENSIONIS. Above reddish, beneath whitish. It is found in Ascension isle. The body is narrower, covered with oblong narrow scales, denticulate on the fore-part.

LOUTI. Oblong-lanceolate, carmine, with pale violet dots; hind edge of all the fins yellow. It inhabits Arabia, and is about three feet long.

VENENOSA. Pectoral fins tipped with yellow; the tail is lunate; the body is marked with blood-red dots. It is a native of America, and suspected of being poisonous.

MELANURA. Tail black, edged with white; the body is marked with yellow lines. It inhabits America, as does the next.

SECTATRIX. Tail forked, red on the hind-part; the belly is of a pale yellow, with grey lines.

STIGMA. Dorsal fin filamentous; gill-covers banded. It is a native of India.

DIAGRANMA. The body of this fish is white, with longitudinal stripes; it has eleven dorsal spines. It inhabits India, in fresh waters; grows to ten inches long, and preys on smaller fishes.

STRIATA. The body of this species is striate. It inhabits North America, and differs from the *P. melanura*, chiefly in not having the tail black.

LINEATA. Dorsal fin filamentous; the body with five alternate white and brown lines.

* CERNUA, or Ruffe. The dorsal fin of this species is twenty-seven-rayed; the spines are fifteen. It inhabits the clear streams of Europe, and is from six to eight inches long; the body is round, mucous, sides yellowish, dirty-green, spotted with black, breast white, nape and back blackish; it feeds on lesser fishes, and is the prey of larger, and also of various aquatic birds; it is a very fertile fish, and spawns in March or April; the flesh is reckoned very good.

* NIGRA; Black Fish. The body of this is narrow, with small thin scales. It is found in Cornwall, and is a very indistinct species.

ACERRINA. The dorsal fin of this species has thirty-one rays and seventeen spines. It inhabits the Euxine sea, and the rivers running into it; it resembles, in its figure, colour, and habits, the *P. cernua*, but its head is longer.

SCHRÆTTER. Body with longitudinal black lines on each side. It is found in many parts of the south of Europe; the head is aculeate.

ARGENTEA. Nostrils tubular; a black spot on the spinous part of the dorsal fin. It inhabits America.

CABRILLA. Body marked with four longitudinal blood-red stripes. A variety of this species is varied with yellow and violet blotches. It inhabits the Mediterranean.

RADULA. Body with white dots disposed in lines. It is found in India.

FORMOSA; Squirrel Fish. Tail lunate; head marked with blue lines, and blotches. It inhabits Carolina. The gill-covers

are toothed; the anterior part of the dorsal fin abbreviate towards the hind part.

SACER. Body rose-coloured; secondary of the dorsal fin very long. It inhabits the Mediterranean, and is about a foot long. The posterior gill-cover ends in a spine; the tail is lunate.

LUNULATA. Reddish; tail with a black lunule at the base. It inhabits Sumatra.

AURATA. Whitish, with a longitudinal yellow stripe. It inhabits Sumatra, as does the next.

SUMATRENSIS. Body dark-silvery; fins longitudinally striate. It inhabits in shoals the coasts of Sumatra; it is about three inches long; scales small, denticulate, and dotted with brown. It is described in the Linnæan Transactions.

TRIFURCA. The tail is trifid; and the body has several blue bands. It inhabits Carolina, and is very finely variegated.

The common perch, or perca fluviatilis of Linnæus, is much admired as a firm and delicate fish; and the Dutch are particularly fond of it when made into a dish called *water-fouchy*.

Mr. Pennant mentions a singular variety of the perch, the back of which is quite hunched, and the lower part of the back bone, next the tail, strangely distorted; in colour and other respects it resembles the common kind. It is found in a lake called *Llyn Raithlyn*, in Merionethshire, and also in the Thames near Marlow.

The common perch affords good sport for the angler. The best time for their biting is, when the spring is over, and before the heats of summer come on. At this time they are very greedy, and the angler, with good management, may take at one standing all that are in the hole, be they ever so many.

The perch will bite all day long, if the weather be cloudy; but the best time is from eight to ten in the morning, and from three to six in the afternoon. The perch is very abtemious in winter, and will seldom bite in this season of the year; if he does at all, it is in the middle of the day: at which time indeed all fish bite best at that season. See FISHING.

PERCA *Amboinensis*, the name of a fresh water fish, somewhat resembling our perch, but differing in that it is of a brown colour, and has several blue lines under its snout, and some blueness in the adjoining fins, but its back and belly fins are green. It is caught in the lakes and rivers of fresh water, at Amboyna, and is a very delicately tasted fish. See SCORPENA *Volitans*.

PERCA *Rhomboides*. See SPARUS *Rhomboides*. See also SPARUS *Mormyrus*.

PERCEE, L'ISLE, in *Geography*, a small but remarkable island on the W. side of the gulf of St. Lawrence, being a perpendicular rock, pierced with two natural arches, through which the sea flows. One of these arches is large enough to admit a large boat to pass through it; 15 miles S. of Cape Gaspee.

PERCEIANA, in *Ancient Geography*, a town of Spain, in the route from the mouth of the river Anas to Emerita, according to the Itinerary of Antonine.

PERCEPIER, in *Botany*, a name attributed by Lobel, in his *Adversaria* 324, to the *Apbanes* of Linnæus, *Alchemilla arvensis*, Engl. Bot. t. 1011; see APHANES. From the manner in which Lobel is always quoted, it would seem that he considered the above name as English; but he merely declares the plant was very commonly used about Bristol for promoting the urinary secretion. Gerard says "our herbe women in Cheapside know it by the name of Parsley brake-stone."

stone." Lobel's word seems a French corruption of the latter, which expresses the appearance of the plant, and its reputed lithontriptic virtues. Pursley-Piert, its English appellation in Ray's Synopsis, is but a little further corruption, partly typographical, in the third edition. Bauhin, in his Pinax 153, has Perchepier Anglorum, and he explains it by *Saxifraga*, or Break-stone. One would suppose, that amid all this jumble of nomenclature, there might be some foundation for the reputed qualities of this plant. Ray says "it is believed violently and suddenly to promote urine, and to break down the calculus. It is eaten raw, as a salad, or preserved with salt, and a distilled water is extracted from it for the above purposes." All this we fear is illusive, and has certainly not been confirmed by experience. The herb in question is indeed slightly astringent, and more slightly mucilaginous; qualities useful in the disease alluded to. But we cannot help suspecting it came into use, in times of ignorance, from its partial resemblance to some of those various diminutive herbs, that have obtained the name of *Saxifraga*, Saxifrage or Break-stone, from their growing on stones or walls, which their roots, by the force of vegetation, penetrate and break down. Hence such herbs were presumed likely to have an effect on the stone in the bladder; for if the old writers do not expressly declare this, the manner in which they speak of the quality of the plants, and of their places of growth, tacitly implies such an opinion. By tracing these hypothetical properties of plants to their sources, the *Materia Medica* is disencumbered from much trash, and implicit faith in the assertions of herbalists is considerably weakened. Perhaps we may be able to discuss the subject to a greater extent hereafter, in treating of the VIRTUES OF PLANTS.

PERCEPTION, PERCEPTIO, in *Logic*, the act of *perceiving*, or apprehending a thing, without making any affirmation or negation. See APPREHENSION and CONCEPTION.

Some writers have confounded idea and perception, whereas these are clearly distinguishable as the cause and effect: the one is an operation of the mind, and the other the result of that operation. See IDEA.

The faculty or power of perception constitutes what we call the understanding.

The faculty of perception seems to be that which constitutes the distinction between the animate and inanimate parts of the creation. Vegetables, some of them, have some degree of motion, and, upon different applications of other bodies, alter their figures and motions; so as hence to obtain the name of *sensitive* plants; which, however, is the result of mere mechanism, and no otherwise produced than the shortening of a rope by the effusion of water. But perception is a metaphysical principle, and is found in some degree in all animals; and in them alone.

Perception is a principle or power, the existence of which can only be known by consciousness, or the experience which every man has of what passes within himself: and it has been long ago observed (see Cic. *Tusc. Quæst. lib. i. § 28.*), that the mind is as incapable of comprehending the nature of perception, as the eye is of seeing itself. Nevertheless of all the operations of our minds, the perception of external objects is the most familiar. It is one main link of that mysterious chain which connects the material world with the intellectual. In this operation, many things are unaccountable; and these are sufficient to convince us, that we know but little of our own frame, and that a perfect comprehension of our mental powers, and of the manner of their operation, is beyond the reach of our understanding. In perception there are impressions upon the organs of sense,

the nerves, and brain, which, by the laws of our nature, are followed by certain operations of the mind. These two things, though apt to be confounded, ought to be carefully distinguished. Some philosophers have, without sound reason, concluded, that the impressions made upon the body are the proper efficient cause of perception; whilst others have, with as little reason, concluded, that impressions are made on the mind similar to those made on the body. It is universally allowed, that we perceive no external object but by means of certain bodily organs which God has given us for that purpose. This is so well known from experience, that it needs no proof; and, indeed, we can give no reason for it, but that such is the will of our maker. But, as we have reason to believe that the Supreme Being perceives every thing in a much more perfect manner than we can do, without bodily organs, and that there are other created beings endowed with powers of perception more perfect and extensive than ours, without such organs, we ought not to conclude, that such bodily organs are, in their own nature, necessary to perception; but rather that, by the will of God, our power of perceiving external objects is limited and circumscribed by our organs of sense; so that we perceive objects in a certain manner, and in certain circumstances, and in no other. We ought also to be cautioned against confounding the organs of perception with the being that perceives. Perception must be the act of some being that perceives. It is another law of our nature, that we perceive no object, unless some impression is made upon the organ of sense, either by the immediate application of the object, or by some medium which passes between the object and the organ: and in consequence of this law, well known and capable of the most familiar illustration, our powers of perceiving external objects are further limited and circumscribed. It is likewise a law of our nature, that, in order to our perception of objects, the impressions made upon the organs of sense must be communicated to the nerves, and by them to the brain. From such impressions some philosophers, both ancient and modern, have deduced conclusions, that are very doubtful, if not absolutely erroneous. Hence some have inferred, that man is nothing but a piece of matter so curiously organized, that the impressions of external objects produce in it sensation, perception, remembrance, and all the other operations of which we are conscious; or, because the Author of nature has established a constant connection between certain impressions on our senses and our perception of the objects by which the impression is made, that these impressions were the proper efficient causes of the corresponding perception. But this kind of reasoning supposes, that because two things are always conjoined, one must therefore be the cause of another (see CAUSE); and it supposes also that matter, by any motion or modification of which it is capable, may produce thought. Another conclusion, very generally deduced by philosophers from the facts above stated, is, that in perception an impression is made upon the mind, as well as upon the organ, nerves, and brain. They seem to think, that the object perceived acts upon the mind in some way similar to that in which one body acts upon another, by making an impression upon it; and this impression upon the mind is conceived to be something with regard to which the mind is altogether passive, and has some effect produced on it by the object. But this, says Dr. Reid, is an hypothesis which contradicts the common sense of mankind, and which ought not to be admitted without proof. Another conclusion drawn from the impressions made upon the brain in perception, which the author just named conceives to have no solid foundation, though it has been very generally adopted by philosophers,

PERCEPTION.

is this; that by the impressions made on the brain, images are formed of the object perceived; and that the mind, being seated in the brain as its chamber of presence, immediately perceives those images only, and has no perception of the external object but by them. (See IDEA and SOUL.) But whether the brain be the seat of the soul or not, it is alleged by our author, that there is no proof nor probability of the opinion that images of all the objects of sense are formed in the brain, with regard to any of them; and that with regard to the greater part of them, these are words without any meaning. Although it be allowed, that external objects make some impression on the organs of sense, and by them on the nerves and brain; yet it is most improbable, that these impressions resemble the objects by which they are made, so as that they may be called images of the objects: not to add, that the brain itself, being a soft, moist, medullary substance, is altogether improper for receiving and retaining such images. It is added, that the word "image," when applied to all objects of sense, except figure and colour, has absolutely no meaning. Our author further observes, with respect to another part of the hypothesis just stated, *viz.* that the mind perceives the images in the brain, and external objects only by means of them; that this is as improbable as that there are such images to be perceived. If our powers of perception, he says, be not altogether fallacious, the objects we perceive are not in our brain, but without us. Dr. Reid sums up what he has said, with regard to the organs of perception, and the impressions made upon our nerves and brain, in the following manner. "It is a law of our nature, established by the will of the Supreme Being, that we perceive no external object but by means of the organs given us for that purpose. But these organs do not perceive. The eye is the organ of sight, but it sees not. A telescope is an artificial organ of sight; the eye is a natural organ of sight, but it sees as little as the telescope. We know how the eye forms a picture of the visible object upon the retina; but how this picture makes us see the object we know not: and if experience had not informed us that such a picture is necessary to vision, we should never have known it. We can give no reason why the picture on the retina should be followed by vision, while a like picture on any other part of the body produces nothing like vision."

"It is likewise a law of our nature, that we perceive not external objects, unless certain impressions be made by the object upon the organ, and by means of the organ on the nerves and brain. But of the nature of these impressions we are perfectly ignorant; and though they are conjoined by the will of our Maker, yet it does not appear that they have any necessary connection with it in their own nature, far less that they can be the proper efficient cause of it. We perceive, because God has given us the power of perceiving, and not because we have impressions from objects. We perceive nothing without those impressions, because our Maker has limited and circumscribed our powers of perception by such laws of nature as to his wisdom seemed meet, and such as suited our rank in his creation."

Dr. Reid, having discarded the old ideal system, proceeds to the investigation of that act of the mind, of which we are all conscious, and which is denominated perception. If we attend to it, we shall find in it, he says, these three things: 1st, some conception or notion of the object perceived; 2dly, a strong and irresistible conviction and belief of its present existence; and, 3dly, that this conviction and belief are immediate, and not the effect of reasoning. After the illustration of these circumstances attending perception, and observing that thus he intended the account which he has

given of our perception of external objects as a faithful delineation of what every man come to years of understanding, and capable of giving attention to what passes in his own mind, may feel in himself, our author acknowledges that he is not able to shew, nor does he pretend to shew, in what manner the notion of external objects, and the immediate belief of their existence, are produced by means of our senses. "If the power of perceiving external objects, in certain circumstances, be a part of the original constitution of the human mind, all attempts to account for it will be vain. No other account can be given of the constitution of things but the will of him that made them: as we can give no reason why matter is extended and inert, why the mind thinks and is conscious of its thoughts, but the will of him who made both; so I suspect, we can give no other reason why, in certain circumstances, we perceive external objects, and in others do not." As to the manner in which the mind exercises its powers of perception, our author professes to give no theory of his own, though he has struck at the root of all the commonly received theories on this subject. Plato conceived that by our senses we perceived the shadows of things only, and not things themselves. He seems to have borrowed his notions on this subject from the Pythagoreans, as they probably derived theirs from Pythagoras himself. Allowing for Plato's allegorical genius, his sentiments correspond very well with those of his scholar Aristotle, and of the Peripatetics. The shadows of Plato may represent the species and phantasms of the Peripatetic school, and the ideas and impressions of modern philosophers. Two thousand years after Plato, Mr. Locke, who studied the operations of the human mind so much, and with so great success, represents our manner of perceiving external objects by a similitude very much resembling Plato's cave; and both the subterraneous cave of the ancient philosopher, and the dark closet of Mr. Locke, may be easily applied to all the systems of perception that have been invented. "For," as Dr. Reid states the matter, "they all suppose that we perceive not external objects immediately, and that the immediate objects of perception are only certain shadows of the external objects. Those shadows or images, which we immediately perceive, were by the ancients called *species, forms, phantasms*. Since the time of Des Cartes, they have commonly been called *ideas*, and by Mr. Hume *impressions*. But all philosophers, from Plato to Mr. Hume, agree in this, that we do not perceive external objects immediately, and that the immediate object of perception must be some image present to the mind. So far there appears an unanimity rarely to be found among philosophers on such abstruse points."

Philosophers, Berkeley and Hume excepted, believe the existence of external objects of sense, and call them objects of perception, though not immediate objects. But what they mean by a mediate object of perception they have not clearly explained. It seems to be their opinion, that we do not really perceive the external object, but the internal only; and that when they speak of perceiving external objects, they mean to express themselves in a popular or in a figurative sense; intimating that we perceive such objects as we perceive an absent friend when we look on his picture.

Besides what is common to philosophers in accounting for our perception of external objects, as above stated, some differences subsist among them. The ideas by which we perceive external objects are said by some to be the ideas of the Deity; but it has been more generally thought, that every man's ideas are proper to himself, and are either in his mind, or in his sensorium, where the mind is immediately present. The first is the theory of Malebranche; the second may be called the common theory. (See *CARTESIAN Philosophy*,

LEIBNITZIANISM, MALEBRANCHISM, PERIPATETICS, PLATONISTS, and PYTHAGOREANS. See also CONCEPTION, IDEA, QUALITY, REFLECTION, and SENSATION.) Dr. Reid, after giving a long account of the different theories advanced by philosophers, in order to account for our perception of external objects, closes with observing "that neither Aristotle's theory of sensible species, nor Malebranche's of our seeing things in God, nor the common theory of our perceiving ideas in our own mind, nor Leibnitz's theory of monads, and a pre-established harmony, give any satisfactory account of the power of the mind, or make it more intelligible than it is without their aid. They are conjectures, and if they were true, would solve no difficulty, but raise many new ones. It is therefore more agreeable to good sense, and to sound philosophy, to rest satisfied with what our own consciousness and attentive reflection discover to us of the nature of perception, than, by inventing hypotheses, to attempt to explain things which are above the reach of human understanding. I believe no man is able to explain how we perceive external objects, any more than how we are conscious of those that are internal. Perception, consciousness, memory, and imagination, are all original and simple powers of the mind, and parts of its constitution. For this reason, though I have endeavoured to shew that the theories of philosophers on this subject are ill grounded and insufficient, I do not attempt to substitute any other theory in their place. Every man feels that perception gives him an invincible belief of the existence of that which he perceives; and that this belief is not the effect of reasoning, but the immediate consequence of perception. When philosophers have wearied themselves and their readers with their speculations upon this subject, they can neither strengthen this belief nor weaken it; nor can they shew how it is produced. It puts the philosopher and the peasant upon a level; and neither of them can give any other reason for believing his senses, than that he finds it impossible for him to do otherwise." The objects of perception are the primary and secondary qualities of bodies (see QUALITY); and besides these, certain states and conditions of our own bodies; mechanical powers or forces; chemical powers; medical powers or virtues; and vegetable and animal powers; to one or other of which classes all the objects of perception may be referred. Reid's *Essays on the Intellectual Powers of Man*. Stewart's *Elements of the Philosophy of the Human Mind*.

PERCEVAL, SPENCER, in *Biography*, born Nov. 1, 1762, was son of John, the late earl of Egmont, by Catharine Compton, sister to Spencer, earl of Northampton, from whom he took the Christian name of Spencer. His mother was, in the year 1770, created a peeress of Ireland, in her own right, with the title of baroness Arden, and dying in 1784, she was succeeded by her eldest son Charles George, who, in July 1808, was raised to the peerage of England. Mr. Perceval's infancy was spent at Charlton, in Kent, the seat of his family, where he received the elements of his education. After this he went to Harrow school, where he was distinguished for the gentleness of his manners, the benevolence of his disposition, and the goodness of his heart. Those who knew him in early life were not surprized at the good fortune which distinguished him in his future prospects, nor at the warm attachment which his political and personal friends felt for him. At Harrow he was contemporary with sir William Jones; after having passed the usual time at this school, he was sent to Trinity college, Cambridge, where he formed some of the most valuable connections of his future life. As soon as he had completed his collegiate studies, he entered himself a member of Lincoln's Inn, and pursued the study of the law as a profession. He

VOL. XXVI.

was remarkable for close and regular application: he was aware that eminence was not to be obtained in the law without industry and perseverance, and in these he studied to excel. While employed as a barrister, he was particularly noticed for his mild and gentlemanly behaviour, which he displayed in an high degree when he became prime minister, and which in the senate called forth the well-merited encomiums of his warmest political opponents.

At an early period he was appointed counsel to the admiralty: in the year 1799 he was honoured with a silk gown, and about this time he was elected counsel for the university of Cambridge. In consequence of his uncle's death a vacancy was created in the borough of Northampton, which introduced Mr. Perceval into parliamentary life. He immediately gave his support to Mr. Pitt, and pursued the fame line of politics regularly and consistently through the remainder of his life.

Mr. Perceval had not been long in parliament before he attracted the marked attention of the minister, who it is said, being asked by his friend, Mr. Ryder, now lord Harrowby, when about to engage in a duel with Mr. Tierney, who was the fittest person to succeed him if he should fall in the contest, replied Mr. Perceval is that man. At this period he endeavoured to become thoroughly master of every branch of policy, dedicating his time and talents to the study of finance. In 1801, at the formation of the Addington administration, Mr. Perceval, then in his 39th year, was appointed solicitor-general, and in 1802 he was promoted to the situation of attorney-general, become vacant by the elevation of sir Edward Law, now lord Ellenborough, to the chief-justiceship of the court of king's bench. The only prosecution instituted by Mr. Perceval, in his character of attorney-general, worthy of notice, was that against Peltier, the editor of a French journal, printed in London, for a libel on Bonaparte.

Mr. Perceval retained his situation when Mr. Pitt resumed the reins of government, and continued to distinguish himself as a ready and staunch supporter of his measures. On the death of Mr. Pitt, Mr. Perceval, for the first time, appeared in the ranks of opposition, and it has been assumed, by those who were the witnesses of his parliamentary career at that period, that his talents were most conspicuous and marked when he rose as an opposition-speaker: in this character he was animated without asperity, earnest without ostentation, attached to his own party, without an indiscriminate contention with his adversaries.

When the Fox administration quitted office, towards the beginning of the year 1807, Mr. Perceval was appointed chancellor of the exchequer; but as the duke of Portland, who was first lord of the treasury, was very old and infirm, and seldom took an active or decided part in the administration of public affairs, Mr. Perceval was unquestionably, even then, the prime-minister of Great Britain, and upon the death of that nobleman he became so nominally as well as virtually. The situation of the country and of Europe at this period was very difficult: it required great talents, exercised with uncommon delicacy, as well as decision and vigour. The talents of Mr. Perceval can hardly be said to be of the first order; and it cannot be denied that the decision and vigour which he undoubtedly possessed, were not unfrequently mixed with something like precipitation and obstinacy. He seemed to have imbibed and acted upon a most dangerous idea, which a prime minister should never admit into his thoughts; *viz.* that a measure once openly avowed, ought, on no account, and under no circumstances, to be abandoned. The relative circumstances of Great Britain and of Europe most undoubtedly required political bravery:

they required that the prime minister of this country should have a mind above fear and embarrassing scruples: in short, that he should be able to take a comprehensive, profound, and cool view of the state of the world, and of the means which Britain possessed of preserving her honour and independence in Europe. When this view was once taken, then decided, firm, and prompt conduct corresponding to it was equally requisite. But it is obvious, that if decision, firmness, and promptitude are not preceded by thorough political knowledge, as well as the soundest political principles and views, they are capable of much mischief. This sort of knowledge Mr. Perceval did not possess in a degree which either the state of Europe required, or which could justify the pertinacity with which he adhered to measures that he had once adopted. The events of his administration are too near to render it necessary to refer to them seriatim. He was avowedly an enemy to those concessions to the Roman Catholics, which many statesmen, at least as wise, and possessing more powerful talents, regard as essential to the safety of the state. To his unyielding and unconciliatory temper, the American war in which we have been plunged has been imputed. His death was occasioned by the hand of an assassin, who was unquestionably mad. On Monday the 11th of May, 1812, about five o'clock in the evening, Mr. Perceval having walked from his house in Downing-street, was entering the lobby of the house of commons, where a number of persons were standing; he was shot by a person named Bellingham, formerly a merchant, but whose distresses had probably deranged his mind. Having committed the deed, he made no effort to escape. Being asked if he were the villain who had shot the minister, he replied, "I am, indeed, the unhappy man:" and at the bar of the house, during a short examination, being cautioned not to criminate himself, he said "I have admitted the fact: I do admit it: I have been denied the redress of my grievances by government: I have been ill treated. They all know who I am, and what I am; through the secretary of state and Mr. Becket, with whom I have had frequent communications. They knew of my intention six weeks ago, through the Bow-street magistrates. I have fought redress in vain. I am a most unfortunate man, and feel here," pointing to his heart, "sufficient justification for what I have done." No serious attempt was, however, made on his trial to prove insanity: indeed time was not allowed for his friends, who resided at Liverpool, to appear in his behalf. The deed was committed on Monday evening; he was tried and convicted on the following Friday, which was as soon as it could be known in Liverpool that his trial would come on at the sessions then in its course. Ample provision was made for Mr. Perceval's family by parliament.

As a public speaker, Mr. Perceval rose much in reputation and excellence, after he became minister: as the leading man in the house of commons, it was necessary that he should be able to explain and defend all his measures; and this duty, arduous under all circumstances, was particularly so in his case, as there was scarcely any other member of administration, in that house, competent to the task of relieving or supporting him. He, in a short time, proved that he stood in need of no assistance: he made himself so completely acquainted with every topic that was likely to be regularly discussed, that he was never taken unawares or at a loss. In the statement of his measures, he was remarkably methodical and perspicuous. By many persons he was deemed particularly to excel in his replies; in rebutting any severe remark that came unexpectedly upon him, and in turning the fact adduced, or the argument used, against his opponent. "His speeches," says one of his biographers, "if carefully exam-

ined, will let us completely into the nature and extent of his talents: they display no large and comprehensive views; the arguments and illustrations that they contain do not proceed on any philosophical and luminous principles: but they are distinguished by their detail, by taking up a detached argument, and grounding it on the particular circumstances of the case, rather than upon any general maxim. This species of public speaking, however, was well adapted to his audience, for in a mixed and numerous assembly, such as the house of commons, there will always be found many more persons who can comprehend particular arguments, than general reasoning, and who will deem the special pleader a man of much greater abilities, than a comprehensive and philosophical statesman." In domestic life, few men were more amiable and more respected than Mr. Perceval, and few men, even in the private walks of society, can pass a greater portion of time with their family, than did this prime minister of England. Gent. Mag. Month. Mag. New Ann. Register for the year 1812.

PERCH, POLE, or *Rod*, a long measure, much used in surveying and measuring of land.

Among the old Romans, and still among geometricians, the *pertica*, *perch*, is ten feet; and they otherwise call it the *catena*, *funis*, and *decempeda*.

In England, the statute perch contains five yards and a half, or sixteen feet and a half; and for coppice-woods, &c. eighteen feet. A square perch is thirty square yards and a quarter. Forty square perches make a rood, and one hundred and sixty an acre.

The customary perch is various in various counties: in Staffordshire it is twenty-four feet; in the forest of Sherwood twenty-one, the foot there being eighteen inches, the measure of which is marked in the chancel wall of Edwynd-flo, and in the church of St. Mary in Nottingham.

In Herefordshire, a perch of walling is sixteen feet and a half; a perch of ditching twenty-one feet, &c. In France, according to the old system, the perch is from eighteen to twenty-three, and even twenty-seven, of their feet.

The arpent, or acre, of land contains, in general, 100 square perches, but the perch varies in different parts of the country. The arpent of wood-land, however, is the same all over France, the perch being 22 feet long; this arpent, therefore, contains 48,400 French square feet = 6108 English square yards, or 1 acre, 1 rood, 1 perch. The arpent for cultivated land, in the neighbourhood of Paris, contains 900 square toises, or 4088 English yards; hence, 45 such arpents equal 38 English acres nearly. See MEASURE.

PERCH, or *Pole*, of a wheel carriage, is fastened to the middle of the hind axle-tree, and passes between the fore axle-tree and its bolster, being secured by the pole-pin, so as to move about it, and connecting the fore and hind carriages together. Thus A B (*Plate XXIII. Miscellany, fig. 7.*) represents the perch passing under the body of a coach, and fastened to the hinder axle at C. DE represents the fore axle, and W, W, the sections of the wheels. It is plain, that in turning a carriage of this construction, the larger the wheel, the sooner it will strike against the perch; and in the case represented in the figure, the wheel strikes against the perch when the axle makes the angle described by the dotted lines D, D. On this account, the fore wheels are usually made smaller than the hind ones; and notwithstanding this diminution of size, the turning of such carriages is attended with great inconvenience. In order to remedy this, many expedients have been adopted, particularly in coaches, chariots, and other light vehicles, to which the crane-necked perch could be conveniently applied.

plied. But as this could not be adapted to the heavier kinds of carriages, and is, besides, attended with a very considerable expence, Mr. Jacob has contrived a more simple and less expensive method of attaining the proposed end. For this purpose, instead of fixing the pin, passing through the perch at F, in the centre of the axle, he brings a projection backwards from it, as in *fig. 8*, and makes the axle with the wheels turn round the pin passing through that projection at P; in which case the angle, which the wheel makes with the perch, becomes considerably less, before the wheel strikes against it. So that a larger wheel, in a carriage of this construction, will not touch the perch so soon as a smaller wheel in a carriage of the ordinary construction; and whatever be the size of the wheels, the carriage will turn shorter than if it were constructed in the former method, with the centre-pin in the centre of the axle. This construction is attended with no additional expence, is applicable to all kinds of carriages, and is stronger than the usual mode of construction. Jacob's *Obs. on the Structure and Draught of Wheel Carriages*, 4to. 1773, p. 79.

PERCHANT, among *Fowlers*, a decoy-bird, which the fowler has fastened by the foot, and which flutters about the place where it is tied, to draw other birds to it, and give the fowler an occasion of catching them. See *DECOY*.

PERCHE, in *Geography*, a country of France, before the revolution, which had formerly courts of its own, and enjoyed its own laws, subject to the parliament of Paris. It at present forms the department of the Orne.

PERCIPANY, a town, or rather village, of America, in Morris county, New Jersey, on a branch of Passaic river; six miles N. of Morristown.

PERCIS, in *Ichthyology*. See *COTTUS Gobio*.

PERCIVAL THOMAS, M.D., in *Biography*, an eminent physician, was born at Warrington, in September 1740. Having lost both his parents in one day, he was placed at the age of four years under the protection of his uncle, Dr. Thomas Percival, a learned and respectable physician, resident at the same place; but of his parental guidance he was also deprived at the age of ten, after which his education was directed with the most kind and judicious attention by his eldest sister. His literary pursuits commenced at a private school in the neighbourhood of Warrington, whence he was removed, at the age of eleven, to the free grammar-school of that town, where he exhibited great promise of talent, and much industry. On the institution of the Warrington academy in 1757, under the direction of the Rev. Dr. Aikin, the Rev. John Holt, and the venerable Dr. Taylor, he was enrolled the first student of that well-known seminary. After prosecuting his studies there with diligence and reputation for the space of upwards of three years, he removed to the university of Edinburgh, at which place he employed the winters of 1761, and the two following years, in close application to the study of physic. In farther pursuit of medical improvement, he visited London in the winter of 1764; and, during his residence in the metropolis, he had the opportunity of pursuing with greater intimacy a connection, which had subsisted some time, with Hugh lord Willoughby of Parham. Having, through the medium of their common friend, the Rev. John Seddon of Warrington, been honoured with the friendship of that excellent and accomplished nobleman, he became the constant companion of his walks, and the familiar partaker of his social and literary entertainments. The warm attachment of his noble patron, the uncommon advantages he derived from his freedom of access to a mansion, which was the resort of the most celebrated literati of the day, and the occasions thereby offered of conciliating the esteem and confidence of persons of the

first consequence and rank, all conspired to suggest to him the resolution of fixing his residence in the metropolis. This project, however, was relinquished on the sudden death of his highly valued friend; an event, which, to his last moments, he never recollected, but with the tenderest expressions of regret. During the course of this winter, he was elected a fellow of the Royal Society.

The following year, 1765, he spent in visiting Paris, Hamburgh, and various other places on the continent; and having graduated at Leyden, he returned to his native town, where he resided a few months; and in March 1766 he married the only daughter of Nathaniel Bassnet, esq. a merchant in London. He now determined to make Manchester the theatre of his professional practice, and settled there in the year 1767, where he continued until his death, which happened in August 1804, in the unremitting exercise of his medical duties.

The character of Dr. Percival was in every way calculated to secure for him that eminence in his profession, and that general respect, esteem, and attachment, which he every where obtained. A quick penetration, a discriminating judgment, a patient attention, a comprehensive knowledge, and, above all, a solemn sense of responsibility, were the endowments which so conspicuously fitted him at once to discharge the duties, and to extend the boundaries, of the healing art; and his external accomplishments and manners were alike happily adapted to the offices of his profession. In social discussion, he possessed powers of a very uncommon stamp, combining the accuracy of science, and the strictest precision of method, with the graces of a copious and unstudied elocution; and to these was superadded the polish of a refined urbanity, the joint result of innate benevolence, and of early and habitual intercourse with the most improved classes of society. In few words, he was an author without vanity, a philosopher without pride, a scholar without pedantry, and a Christian without guile. Affable in his manners, courteous in his conversation, dignified in his deportment, cheerful in his temper, warm in his affections, steady in his friendships, mild in his resentments, and unshaken in his principles; the grand object of his life was usefulness, and the grand spring of all his actions was religion.

As a literary character, Dr. Percival held a distinguished rank. His earlier publications were devoted to medical, chemical, and philosophical inquiries, which he pursued extensively, combining the cautious but assiduous employment of experiment, with scientific observation, and much literary research. His papers were published collectively, under the title of "*Essays Medical and Experimental*," of which the first volume appeared in 1771, the second in 1773, and a third was subsequently added. These volumes obtained for the author a considerable reputation in the philosophical world, and have gone through many editions. The subjects which occupied his pen, in later years, were of a nature most congenial to his feelings; and in the several volumes of "*A Father's Instructions to his Children*," and of "*Moral Dissertations*," which appeared at different periods, through a space of twenty-five years, and which were originally conceived with the design of exciting in the hearts of his children a desire of knowledge and a love of virtue; there is to be found as much of pure style, genuine feeling, refined taste, apt illustration, and pious reflection, as can easily be discovered, in the same compass, in any didactic composition. His last work, which he expressly dedicated as a "parental legacy" to a much-loved son, under the title of "*Medical Ethics, or a Code of Institutes and Precepts, adapted to the professional conduct of Physicians and Surgeons*," published in 1803, is a monument of his professional integrity,

integrity, in which, while he depicted those excellencies of the medical character which he approved in theory, he unconsciously drew the portrait of himself, and described those which he every day exemplified in practice.

In addition to the works already mentioned, numerous papers on various subjects, all having the impress of the clearest understanding, and the most perspicuous style, are to be found in the publications of the Literary and Philosophical Society of Manchester, an institution to the establishment and reputation of which, he eminently contributed, and which did not cease to manifest its grateful sense of his merits, by the continued appointment of him to the presidency, from the date of its incorporation. See Monthly Magazine, September 1804. Duncan's Annals of Medicine, vol. viii., and Percival's Essays.

PERCKAM, in *Geography*, a town of Austria; 18 miles S.W. of Freystadt.

PERCOLATION. See FILTRATION.

Many have attempted the condensing of wines by percolation, or separating from them that superfluous moisture or water, which dilutes them below the true standard of vinous liquors, in order to make them richer, and fitter for keeping; but it does not appear that such attempts have as yet succeeded.

PERCOTE, in *Ancient Geography*, a town which belonged to Dardania, at a small distance S.W. of Lampfacus.

PERCUNOS, the name of an ancient Prussian idol. See POTRIMPOS.

PERCUSSION, in *Physics*, the impression a body makes in falling or striking upon another; or the shock or collision of the two moving bodies; which meeting, alter each other's motion. See MOTION.

Percussion is either *direct* or *oblique*.

In bodies either perfectly hard, or perfectly soft, and so void of all elasticity, the laws of percussion are easily determined; but since even the hardest bodies have their share of elasticity, and in elastic bodies the laws are very different, and much more intricate, having been first ascertained in the Philosophical Transactions, by sir Christopher Wren, Dr. Wallis, and Mr. Huygens, we shall lay down each apart; referring for another mode of illustrating the same subject to the article COLLISION.

PERCUSSION; *Laws of, in Bodies not Elastic*. 1. If a body in motion, as A (*Plat.* XXXIV. *Mechanics*, fig. 12.) strike directly against another at rest, B, the first will lose just as much of its motion as it communicates to the second; so that the two will proceed thence with an equal velocity, as if collected into one mass.

If A therefore be triple of B, A will lose one-fourth of its motion; so that if before it moved through a line of twenty-four feet in a minute, it will now only move eighteen.

2. If a moving body, A, strike against another already in motion, B; the first will increase the velocity of the latter, but will lose less of its own motion than if the latter had been at rest; since all here required is, that some degrees of motion be added to those the latter already had, to make them both proceed with an equal velocity.

Suppose, *e. gr.* the body A, with twelve degrees of motion, to strike against the other B, less by half, and at rest, the first will transfer four degrees of its motion to the latter, and retain eight to itself: but if it strike with twelve degrees of motion on the other already moving with three degrees, it will only communicate two degrees; for A being double of B, this needs only half the motion to make it proceed with the same velocity.

3. If a moving body, A, strike on another, B, either at

rest, or moving more slowly, and either in the same direction or in a contrary one; the sum of the momenta, if the bodies move in the same direction, or their difference, if they move in a contrary one, will be the same after the percussion as before.

4. If two equal bodies, A and B, meet each other with equal velocities; after the congress, they will both remain at rest.

5. If a body, A, strike directly on another at rest, B; its celerity after the stroke is to its celerity before it, as the weight of A is to the sum of the weights of A and B: if, therefore, the weights were equal, the celerity after the shock will be half of what it was before it.

Thus if $A = Q$, and its velocity before the stroke be denominated C , and $B = q$, then QC will express the whole quantity of motion before and after the stroke, and $\frac{QC}{Q + q}$,

or, the quantity of motion divided by the weights or quantities of matter, will be equal to V , the common velocity: hence we shall have $QC = V \times Q + q$; and, therefore: $C : V :: Q + q : Q$. If $Q = q$, it will be $C : V :: 2 : 1$.

6. If a body in motion, A, strike directly on another moving more slowly, but in the same direction; the velocity, after the shock, will be equal to the sum of the momenta, divided by the sum of the weights.

For the sum of the momenta both before and after the stroke is $QC + qc$, c being the velocity of q or B; therefore $V = \frac{QC + qc}{Q + q}$. Hence if $Q = q$, $V = \frac{Q \times C + c}{Q \times 2} = \frac{C + c}{2}$, or half the sum of the former velocities.

7. If two equal bodies, moving with different velocities, strike directly against each other; after the conflict, they will proceed with the semi-difference of the velocities with which they were moved before it.

For the quantity of motion is $QC - qc$, and, therefore, $V = \frac{QC - qc}{Q + q}$: and if $Q = q$, $V = \frac{QC - Qc}{2Q} = \frac{C - c}{2}$.

And if C also = c , $V = 0$, and, therefore, the quantity of motion is not always the same, as the Cartesians maintain.

8. If two bodies, A and B, meet directly with velocities that are reciprocally as their weights; after the conflict, they will both remain at rest: *i. e.* if $Q : q :: c : C$, $QC = qc$, and $V = \frac{QC - qc}{Q + q} = 0$.

9. If two bodies, A and B, meet directly with the same velocity; the celerity, after the impulse, will be to that before it, as the difference of the weights to their sum. For $QC - qC = V \times Q + q$; therefore, $V : C :: Q - q : Q + q$.

10. If two bodies meet directly, with any velocity whatever; the celerity after the stroke will be equal to the difference of the momenta, divided by the sum of the weights.

For $V = \frac{QC - qc}{Q + q}$.

To determine the momentum lost by the conflict: multiply the celerity which the body had before the conflict, into its mass; thus you have the momentum before the conflict. In like manner, multiply the celerity after the conflict into the mass; thus have you the momentum after the conflict. The latter momentum, therefore, being subtracted from the former,

PERCUSSION.

mer, leaves the loss. And hence may the magnitudes of the strokes be eliminated.

Thus in the three cases already recited, the momentum before the conflict is QC , $QC + qc$, and $QC - qc$; and V , or the celerity after the conflict, will be respectively

$$\frac{QC}{Q+q}, \frac{QC+qc}{Q+q}, \text{ and } \frac{QC-qc}{Q+q}, \text{ and the momenta of } Q$$

$$\text{in the several cases } \frac{Q^2C}{Q+q}, \frac{Q^2C+Qqc}{Q+q}, \text{ and } \frac{Q^2C-Qqc}{Q+q}:$$

therefore the quantities of motion lost by Q will be respectively

$$QC - \frac{Q^2C}{Q+q} = \frac{Qqc}{Q+q}, \quad QC - \frac{Q^2C+Qqc}{Q+q} = \frac{QCq-Qcq}{Q+q},$$

$$\text{and } QC - \frac{Q^2C-Qqc}{Q+q} = \frac{Qqc+Qqc}{Q+q}.$$

Hence it appears, in the first case, that the magnitude of the stroke, which is as the motion lost, will be as the celerity of the striking body; for if its celerity were C ,

the motion lost would be $\frac{QCq}{Q+q}$; but if it were c , the

motion lost would be $\frac{Qcq}{Q+q}$; and $\frac{QCq}{Q+q} : \frac{Qcq}{Q+q} :: C : c$.

In the second case, the magnitude of the stroke will be the same as if q had been at rest, and Q had struck it with the difference of their celerities; for the motion lost is

$$\frac{QCq - Qcq}{Q+q}; \text{ but in the case now supposed, the motion lost would be } \frac{Qq \times C - c}{Q+q} = \frac{QCq - Qcq}{Q+q}.$$

In the third case, the magnitude of the stroke will be the same as if either body, as q , had been at rest, and the other, as Q , had struck it with the sum of their celerities: for the motion lost is

$$\frac{QqC + Qqc}{Q+q}, \text{ and in the case now supposed it would be } \frac{Qq \times C + c}{Q+q} \text{ equal to the former.}$$

Hence it appears, that the magnitude of the stroke between two given bodies is always proportional to their relative, and not to their absolute celerities.

11. A direct or perpendicular stroke is to an oblique one as the whole sine is to the sine of the angle of incidence. For let BC (*fig. 13.*) be the body struck, A the striking body, AC the oblique stroke, aC the perpendicular stroke; and the magnitude of the perpendicular stroke aC will be to that of the oblique stroke in the direction AC as aC to AC , or as $AC : AB$. For resolving the force in AC into AB perpendicular to BC and AD parallel to it; and it is evident that the force in the direction AB is the only part of AC that strikes BC , the other part AD being parallel to it. But the magnitude of a perpendicular stroke of the same body moving with the same force is to be measured by the line $aC = AC$; and therefore it is to the magnitude of the oblique stroke as aC to AB , *i. e.* as AC to AB , or as radius to the sine of the angle of incidence.

PERCUSSION, *Laws of, in Elastic Bodies.* In bodies perfectly elastic, the force of elasticity is equal to the force with which they are compressed; that is, the collision of two such bodies on each other is equivalent to the motion which either of them would acquire, or lose, by mere simple impulse. This force exerting itself contrary ways, a

motion equivalent to it must be subtracted from the motion in the impelling body, and added to that in the body impelled by mere impulse, to find their velocities after percussion. See ELASTICITY.

12. If a body strike directly on an immoveable obstacle, either one or both of them being elastic; the body will be reflected with the same velocity with which it struck, and in the same line. For if the elasticity were away, the whole force of the striking body would be spent in overcoming the resistance of the obstacle; and consequently all the motion would cease: it follows, that the whole force is employed in compressing the elastic body; by which means it acquires an elastic force equal thereto: since then the elasticity, when the compressing force is spent, reduces the body into its former state, it repels the other with the same force with which it struck; consequently, it will rebound with the same velocity. And because an elastic body restores itself in the same direction in which it was compressed (there being no reason why it should change its direction) the body will rebound in the same right line.

13. If an elastic body strike obliquely on an immoveable obstacle, it will rebound in such manner as to make the angle of reflection equal to the angle of incidence. See this demonstrated with regard to light, by a method which applies to all impinging elastic bodies, under REFLECTION.

14. If an elastic body, A , strike directly against another at rest, B , equal to it; after percussion A will remain at rest, and B will proceed with the same velocity which A had before the shock, and in the same direction.

For if the bodies were not elastic, each would proceed, after the stroke, in the same direction, and with half the velocity; but since the elastic force acts in the same direction in which the compression is made, and is equal to the compressing force; it repels A with half its velocity, and therefore stops its motion: but it drives B farther with half its velocity, and therefore accelerates its motion. It is therefore carried after the shock, with the whole celerity with which A was carried before it, and A remains at rest. The quantity of motion before the stroke is QC , and the motion lost by percussion, being the double of that lost

between non-elastic bodies, is $\frac{2CQq}{Q+q}$; therefore the momentum after the stroke will be $QC - \frac{2CQq}{Q+q} =$

$$\frac{Q^2C - QCq}{Q+q}; \text{ and } V = \frac{QC - Cq}{Q-q}; \text{ and the velocity of } q, \text{ whose motion is equal to that lost by } Q, \text{ is equal}$$

$$\text{to } \frac{2QCq}{Q+q} \div q = \frac{2QC}{Q+q}. \text{ If } Q = q, V = \frac{QC - CQ}{Q+q} = 0; \text{ and } v = C.$$

Hence, since A (*fig. 14.*) transfers all its force to B ; B , in like manner, will transfer it to C , C again to D , and D to E . Wherefore, if there be several equal elastic bodies, mutually touching each other, and A be struck against B , all the intermediate ones remaining at rest, the last alone, E , will be moved, and that with the velocity with which A struck against B .

15. If an elastic body, A , strike directly on another at rest, B ; its velocity, after percussion, will be to its velocity before it, as the difference of weights is to their sum: but the velocity it communicates to B , is to the same, as double the weight of A to the sum of the weights.

After percussion, therefore, the velocity of A is to the velocity

velocity

PERCUSSION.

velocity of B, as the difference of weights to the double of A.

Thus, $V = \frac{QC - Cq}{Q + q} = \frac{Q - q \times C}{Q + q}$; therefore, $V \times \overline{Q + q} = \overline{Q - q} \times C$; consequently, $V : C :: Q - q : Q + q$. And because $v = \frac{2QC}{Q + q}$, $v : C :: 2Q : Q + q$. Consequently $V : v :: Q - q : 2Q$.

16. If a greater body strike a less body at rest, the velocity given to it will be less than the double of its own velocity. If $Q > q$, let $Q = mq$, then $v = \frac{2QC}{Q + q}$ will be equal to $\frac{2mqC}{mq + q} = \frac{2C}{1 + \frac{1}{m}} < 2C$.

17. The velocity which a greater body gives to a less body at rest, is to that which the less body moved with the same velocity would communicate to the greater body at rest, as the magnitude of the greater to the magnitude of the less body. If $Q > q$ is supposed to be at rest, then $v = \frac{2QC}{Q + q}$; but if Q be at rest, and q strike it with the celerity C, the velocity of Q after the stroke would be $\frac{2qC}{q + Q}$; therefore the velocity given by the greater body is

to that given by the less as $\frac{2QC}{Q + q} : \frac{2qC}{q + Q} :: Q : q$.

18. If a greater body strikes against a less, the greater body will not come to rest, but move more slowly: for since $Q > q$, $Q - q$ will be positive, and therefore, in the proportion $Q + q : Q - q :: C : V$, V will be positive but less than C, because $Q - q < Q + q$.

19. Again, if an elastic body strike a larger elastic body at rest, the smaller body will always rebound, and move in a contrary direction to what it did at first, and also give the larger body a greater quantity of motion than what was originally in the smaller body. For as $q > Q$, $Q - q$ will be a negative quantity, and, therefore, V will be negative, or Q will move backwards. And this quantity of motion communicated, may be greater than the original motion in any ratio less than that of 2 to 1: For supposing the small body and its velocity to be denoted by unity, and the larger body at rest by x, the velocity

of x after the shock will be $\frac{2}{1 + x}$, and its quantity of motion will be $\frac{2x}{1 + x}$. But though the proportion of

$2x$ to $1 + x$ increases when x increases, yet its limit will be the proportion of 2 to 1; which is the limit to which the motion of x may approach indefinitely near.

Hence it follows, that if the force of moving bodies be measured by their quantity of motion, a body may, by percussion, immediately communicate a greater force than itself has to another, and this in any proportion less than double.

But if other elastic bodies be interposed, a body may mediate communicate a greater force than its own to another larger body x, in any proportion less than that of x, x to 1. Thus, if $x = 1000000$, the body 1, with the velocity 1, may, by the means of intermediate bodies, give it the force 999000000; and the sum of the

absolute forces of all these bodies taken together, arising from the percussion, may exceed the force of the first or unity, in any ratio less than $2x, \sqrt{x}$ to 1, or 200000000 to 1, although the relative force in all cases remains as at first = 1.

These are paradoxes which cannot be urged against those who maintain the forces of bodies to be measured by their masses and the squares of their velocities.

It is also to be observed, that those who measure force by the quantity of motion, must deny that there is any force lost by the impressions, made on soft bodies, or by the bending of elastic bodies; for if any were lost from such causes, the sum of the quantities of motion of bodies moving the same way, could not remain the same before, during, and after the shock, which is an universal rule admitted by the Newtonians. But they admit that a spring bent between two bodies may, by unbending itself, generate motion in these bodies. Hence it follows that, according to this doctrine, though a spring may give motion to bodies, it cannot, by a contrary action, take it away; which seems no small paradox. See FORCE.

20. If a body, A, moves towards the body C, at rest, and an intermediate body, B, of a mean magnitude, be placed at rest between them, so that A first impels B, and then B impels C, a greater motion will be given to C than if A had struck it directly. And if B be a mean proportional between A and C, the velocity communicated to C will be the greatest that can be. Huygens, de Mot. Corp. ex Percuss. prop. 12.

In the preceding series of proportional magnitudes, $B + \frac{AC}{B} < A + C$. For $A : B :: B : C$, therefore $A - B : B :: B - C : C$, and $A - B : B - C :: B : C$; but $C < B$, therefore $B - C < A - B$; and therefore $B < A - B + C$, and $2B < A + C$; but $B = \frac{AC}{B}$; therefore

$B + \frac{AC}{B} < A + C$. The same proposition might be demonstrated, if C were the greatest body, and A the least.

Now it is plain, that the velocity of the body C, struck only by A, would be $\frac{2Aa}{A + C} = \frac{4Aa}{2A + 2C}$, a denoting the velocity of A: the velocity of B, struck immediately by

A, would be $\frac{2Aa}{A + B} = b$, b denoting the velocity of B: and, therefore, the velocity of C, struck by B, moved

with the velocity b, would be $\frac{2Bb}{B + C} = \frac{2B \times 2Aa}{B + C \times A + B}$

$= \frac{4BAa}{BA + BB + CA + CB} = \frac{4Aa}{A + B + \frac{CA}{B} + C}$.

But $\frac{4Aa}{A + B + \frac{CA}{B} + C} : \frac{4Aa}{2A + 2C} :: 2A + 2C :$

$A + B + \frac{CA}{B} + C$. And the second antecedent is evidently

greater than the second consequent; therefore the first antecedent is greater than the first consequent. But if B were a mean

PERCUSSION.

a mean proportional between A and C, $B + \frac{AC}{B}$ would be less than in any other case. For if $B = m$ the mean proportional, $B + \frac{AC}{B} = m + \frac{m^2}{m} = 2m$; but if $B = m \pm D$, then $B + \frac{AC}{B} = m \pm D + \frac{AC}{m \pm D}$; *i.e.* $m^2 \pm 2mD + D^2 + AC (= m^2) > 2m^2 \pm 2mD$.

If more bodies be interposed between A and C, the motion of C will be greater; and it will be the greatest when the bodies interposed constitute a series of mean proportionals between A and C. *Ibid.* prop. 13.

21. If there be a series of a hundred bodies in the proportion of 1, 2, 4, 8, 16, &c. and the motion begins by the greatest body, the velocity communicated to the smallest will be to that with which the greatest moved nearly as 2,338,500,000,000 to 1. And, if the motion begins by the least body, the quantity of motion will be increased on the whole nearly as 1 to 4,677,000,000,000. But it is to be observed, that there is a mistake in the impression of Huygens's book, as to the first number, which is there printed 14,760,000,000, instead of 2,338, &c. so that the velocity thus given to the smallest body is 150 times greater than what the printed copy of Huygens assigns. Bernoulli, *Disc. fur le Mouv. Oper.* tom. iii. p. 34. and s'Gravesande, *Prof. ad Huygen. Oper. Post.* tom. ii. *Amst.* 1728.

This stupendous augmentation of the quantity of motion is a remarkable instance of the falsity of the Cartesian principle, that the same quantity of motion is always preserved in the world.

Some have thought this augmentation no small difficulty against those who maintain the moving force or power of action in bodies, to be proportional to their quantities of motion. This difficulty does not press the Leibnitzians; for it is to be observed, that notwithstanding the prodigious increase of motion here assigned, yet there is no increment of the *vis viva* of this system of bodies. See FORCE and VIS *Viva*.

A learned author has urged, that if the force of bodies were in proportion to their quantities of motion, the increase in the motion here mentioned might be employed to restore the motion of the first body, and hence make a perpetual motion. But it is answered, that as the motion of the last is increased in the same direction with the first, the motion of all the rest will be in the contrary direction, and equal to that of the last diminished by unity: hence the sum of the motions in the same direction remains as it did, equal to that of the first and smallest body, which we suppose unity. See Maclaurin's *Demonstrat. de Loix du Choc des Corps*, p. 21, Paris, 1724; and s'Gravesande, *Rem. fur la Possibilité du Mouvement perpetuel*, in *Journ. Liter.*

It is to be observed, that there is a limit which the velocity communicated to the last body never amounts to, (supposing the first and last bodies, and the velocity of the first before the stroke, to be given,) but to which it approaches continually, while the number of such bodies interposed between the first and last is always increased. And this limit is to the velocity of the first body before the stroke, in the subduplicate ratio of the first body to the last.

Mr. Huygens has not mentioned this limit, but the curious may see the determination of it in Mr. Maclaurin's *Fluxions*, art. 514.

22. If two equal elastic bodies, A and B, meet directly, and with equal force; each will rebound with the

same velocity with which it struck, and also in the same direction.

For setting aside the elasticity, both would remain at rest; their whole force, therefore, is spent in the compression; but their elastic force, whereby they rebound in the former direction, is equal thereto. This force, therefore, acting equally on each body, A and B, will produce the same celerity in each; and that equal to the former. So that they will rebound with the celerity with which they struck.

23. If two equal elastic bodies, A and B, strike directly against each other with unequal velocities: after the shock, they will rebound with interchanged velocities.

For suppose the bodies to concur with the velocities $C + c$ and C : if they meet with the same velocity C , after the shock, they would both move with the same velocity C .

If B were at rest, and A should strike upon it with the celerity c ; after the shock, A would remain at rest, and B be moved with the celerity c . Therefore the excess of the celerity c , with which A is carried, is transferred wholly by the conflict to B: A, therefore, is moved with the celerity C , and B with the celerity $C + c$.

Hence, after percussion, they recede from each other with the same velocity as before they concurred.

The two propositions in these two last articles may be proved otherwise, thus: the momentum of Q before the

stroke is QC ; the motion lost by it is $\frac{2QCq + 2Qcq}{Q + q}$;

therefore, its quantity of motion after the stroke will be $QC - \frac{2QCq + 2Qcq}{Q + q} = \frac{Q^2C - QCq - 2Qcq}{Q + q}$.

Consequently $V = \frac{QC - Cq - 2qc}{Q + q}$.

The quantity of motion in q before the stroke is $-qc$, and that lost by Q and acquired by q is $\frac{2QCq + 2Qcq}{Q + q}$;

and, therefore, its momentum after the stroke will be $-qc + \frac{2QCq + 2Qcq}{Q + q} = \frac{2QCq - q^2c + Qcq}{Q + q}$; and

$v = \frac{2QC - qc + Qc}{Q + q}$. But when $Q = q$, $V =$

$\frac{QC - QC - 2Qc}{2Q} = -c$, and $v = \frac{2QC - Qc + Qc}{2Q} = C$.

24. If two elastic bodies, A and B, strike directly on each other with velocities that are reciprocally proportional to their weights: after collision, they will rebound with the same velocity with which they met.

For $Q : q :: c : C$, therefore $CQ = cq$; and $V = \frac{QC - 2QC - Cq}{Q + q} = -\frac{QC - Cq}{Q + q} = \frac{Q + q \times -C}{Q + q}$

$= -C$; and $v = \frac{2qc - qc + Qc}{Q + q} = \frac{qc + Qc}{Q + q} = +c$.

25. If an elastic body, A, strike on another equal one indented with a less degree of motion B; after percussion, both will proceed in the same, *viz.* in the former direction, and with interchanged velocities.

For suppose A to strike with the velocity $C + c$, upon B moving with the velocity C . Since by reason of the equal

PERCUSSION.

equal velocities C and C , there arises no impulse; it is the same thing as if A struck on B , with the sole celerity c , on B at rest. But in that case A would remain at rest, and B would move with the velocity c : therefore, after percussion, A will move with the sole celerity C , and B with the celerity $C + c$, both according to the former direction, there being nothing to change that direction.

For in this case, the quantity of motion in Q before the stroke is QC , the motion lost by it is $\frac{2QCq - 2Qcq}{Q + q}$, and the quantity of motion after the stroke will be $QC - \frac{2QCq - 2Qcq}{Q + q} = \frac{Q^2C + 2Qcq - QCq}{Q + q}$; and therefore $V = \frac{QC + 2cq - Cq}{Q + q}$.

The momentum of q before the stroke is qc , that lost by Q and acquired by q is $\frac{2QCq - 2Qqc}{Q + q}$; therefore the momentum of q after the stroke will be $qc + \frac{2QCq - 2Qqc}{Q + q} = \frac{q^2c + 2QCq - Qqc}{Q + q}$; and $v = \frac{2QC + qc - Qc}{Q + q}$.

In the case here supposed $Q = q$, therefore $V = \frac{QC + 2Qc - CQ}{2Q} = c$, and $v = \frac{2QC + Qc - Qc}{2Q} = C$.

26. If a moving body, A , strike on another, B ; the stroke will be the same as would be made by the body A striking on B at rest, with the difference of their velocities.

Hence, since the elastic force is equal to the percussion; it acts on the bodies A and B with the difference of the velocities they had before the congresses.

27. To determine the velocities of any two elastic bodies, A and B , after striking directly on each other with any velocities.—If the elastic body A strike on B , either at rest, or moving faster than A ; the velocity, *v. gr.* of A after percussion is found thus: as the sum of the weights is to double of either of them, suppose of B , so is the sum of the velocities before collision, to a velocity which, subtracted from the velocity of A before collision, leaves its celerity after collision.

If the two elastic bodies, A and B , meet each other; the velocity of A , after the impulse, is found thus: as the sum of the weights is to the double of either of them, suppose of B , so is the sum of the velocities before collision, to a velocity which, subtracted from the velocity of A before collision, leaves its celerity after collision.

28. In the direct collision of bodies the same respective velocity is preserved, *i. e.* in a direct concurrence, the difference of velocities is the same before and after the shock; and in a direct mutual encounter, the difference of velocities after the shock is the same with their sum before it.

Hence they retire from each other, after the impulse, with the same velocity with which they met.

Thus $v - V = C \mp c$, For $v = \frac{2QC \pm qc \mp Qc}{Q + q}$,

and $V = \frac{QC \pm 2qc - Cq}{Q + q}$; therefore $v - V = \frac{2QC \pm qc \mp Qc - QC \mp 2qc + Cq}{Q + q} = \frac{QC \mp qc \mp QC + Cq}{Q + q} = \frac{Q + q}{Q + q} \times \frac{C \mp c}{Q + q} = C \mp c$.

29. In the collision of elastic bodies there is not always preserved the same momentum, or, as the Cartesians express it, the same quantity of motion; but this is sometimes increased, and sometimes diminished.

It is a mistake, therefore, of Descartes, and his followers, that the same quantity of motion is still preserved in the world.

Thus, let q at rest be greater than the impinging body Q ; and the quantity of motion will be increased by collision: let $q = Q + x$, and C the velocity of Q : the velocity of the body q after the stroke will be $\frac{2QC}{Q + q} =$

$\frac{2QC}{2Q + x} = C - \frac{x C}{2Q + x}$; but the velocity of the body

Q will be $\frac{QC - Cq}{Q + q} = \frac{-x}{2Q + x}$; therefore the absolute momentum of q after the stroke will be $= q \times C -$

$\frac{x C}{2Q + x} = \overline{Q + x} \times C - \frac{x C}{2Q + x}$.

But the momentum of the body Q is $= Q \times -\frac{x C}{2Q + x}$;

and the quantity of motion in both bodies will be $= \frac{2Q^2C + 2QxC + QxC}{2Q + x} = \frac{2Q^2C + 3QxC}{2Q + x} = QC$

$+ x C - \frac{x^2 C}{2Q + x}$; but the quantity of motion before

the stroke was QC , which is less than the former quantity, because $\frac{x^2 C}{2Q + x} < x C$; for $\frac{x^2 C}{x} = x C$. If the bodies

return to a second stroke with the velocities acquired by the first, they will recover their first velocities, in which case the quantity of motion will be diminished.

30. If two elastic bodies, A and B , meet or overtake each other directly; the sum of the factums of the masses into the squares of the velocities remains the same, before and after the congress; hence the same quantity of force is likewise preserved in the congresses.

31. To determine the motion of two bodies, A and B , (*fig. 15.*) striking obliquely against each other, whether they be elastic or not elastic.—The motion of the body A along AC is resolvable into two others, in the directions AE and AD ; and the motion of B along BC into two others according to BF and BG : and the velocities through AD and BF are to the velocities through AC and BC as the right lines AD , BF , AC , BC : now since the right lines AE and BG are parallel, the forces acting according to these directions are not mutually opposite, and must therefore be considered in the congresses.

But since the lines AD and BF , or, which is the same, EC and GC , constitute the same right line perpendicular to DC ; it is the same as if the bodies A and B should meet directly with velocities that are as EC

and

and G C. Find, therefore, the velocity of A and B according to the rules above laid down.

Suppose, *e. gr.* the velocity of the rebounding body A to be as C H; since the motion along A E is not changed by the congress, make C K = A E, and complete the parallelogram H C K I; the diagonal C I will represent the motion of A after the congress: for, after percussion, the body will move according to the direction C I, and with a velocity as C I. In the same manner it will be found, that the rebounding body B will move along the diagonal of the parallelogram C M; in which L M = B G. The velocities, therefore, after percussion, are as C I to C M.

PERCUSSION, *Centre of.* See CENTER of Percussion.

PERCY, in *Geography*, a town of France, in the department of the Channel, and chief place of a canton, in the district of St. Lo; 12 miles S. of St. Lo. The place contains 2952, and the canton 9580 inhabitants, on a territory of 160 kilometres, in 13 communes.

PERCY, an extensive township of America, in Grafton county, New Hampshire, watered by the several branches of Upper Ammonoosuck river, bounded W. by Northumberland, on Connecticut river; incorporated in 1774, and containing 148 inhabitants.

PERDICCAS, in *Biography*, one of the captains of Alexander the Great, was a Macedonian of noble birth, and rose to high favour with his master, in whose conquests he bore a considerable part. Alexander, in his last illness, entrusted his ring to Perdicas, who, at a meeting of the great officers after the death of the conqueror, resigned the ring, together with any authority it might be supposed to convey. When Aridæus, the brother of Alexander, was appointed to the succession, Perdicas gained a considerable ascendancy over him, and procured the death of Meleager, the commander of the Macedonian phalanx, of whom he was jealous. At the division of honours and provinces among the great officers, he was nominated general of the household troops, and exercised the protectorate of the Macedonian princes, Aridæus, and the new-born son of Alexander by Roxana, though Craterus had the title of protector. In conjunction with Roxana, he removed all who could be competitors to the crown, and conducted the government with great cruelty. Ambitious of extending his power, he repudiated his wife Nicæa, the daughter of Antipater, and married Cleopatra, the daughter of Philip, and sister of Alexander, at the proposal of Olympias, her mother. A league being formed against him, between Ptolemy, Antipater, and Craterus, he resolved to march into Egypt against the first, while Eumenes, who adhered to him as guardian of the royal family, should make head against the others. Perdicas, on entering Egypt, found some symptoms of disaffection in his troops, which he was at first disposed to treat with severity, but finding that this method would not succeed, he changed his conduct, and behaved to them with great condescension, insomuch that they were induced to cross the Nile, and attack Ptolemy in his intrenchments. After a bloody action, they were repulsed, and great numbers of them were drowned in repassing the river. At length their discontents were so high, that they mutinied; and a party of horse, surrounding the tent of Perdicas, murdered him in the year B.C. 321, two years after the death of Alexander. Univ. Hist.

PERDICIUM, in *Botany*, appears to have been so called by Linnæus, on account of a considerable resemblance between his original species, *semiflosculare*, and his *Leontodon* (now *Hieracium*) *bulbosum*. The latter was thought

by some to be the *περδικιον* of Theophrastus, which received that appellation, as the Greek writer expressly mentions, because partridges frequented the plant and scratched its roots out of the ground. Various other tuberous-rooted herbs have indeed been taken for the ancient *περδικιον*, but these are not to our present purpose. The roots of the Linnæan *Perdicium semiflosculare* are copious, long, and fleshy, and we cannot doubt that hence arose the scarcely warrantable assumption of an old Greek name, for a Cape and American genus, though that name had hitherto not been, with any certainty, appropriated. Linn. Gen. 428. Schreb. 559. Willd. Sp. Pl. v. 3. 2116. Mart. Mill. Diët. v. 3. Vahl. in Coperh. Transf. v. 1. fasc. 2. 8. Ait. Hort. Kew. ed. 2. v. 5. 84. Juss. 181. Lamarck Illustr. t. 677. Gærtn. v. 2. 450. t. 170. (Trixis; Browne Jam. 312?)—Class and order, *Syngenesia Polygamia-superflua*. Nat. Ord. *Compositæ discoidea*, Linn. *Corymbifera*, Juss.

Gen. Ch. *Common Calyx* oblong, of many lanceolate imbricated leaves; the innermost scarcely longer than the corolla. *Cor.* compound, imbricated, radiated. Florets of the disk perfect, tubular, cloven half way down; their inner lip deeply divided, sharp-pointed, equal; outer three-cleft half way down, linear, equal; those of the radius female, linear, tongue-shaped, three-toothed, with two teeth at the base on the inner side. *Stam.* in the perfect florets, filaments five, short; anthers forming a cylindrical tube, with five teeth. *Pist.* in the same, germen small; style simple; stigma cloven, obtuse: in the female ones, germen small; style cloven half way down; stigmas obtuse. *Peric.* none, except the unchanged calyx. *Seeds* solitary, obovate. *Down* capillary, sessile, rough, very abundant, the length of the calyx, level-topped. *Recept.* naked.

Obs. The flower resembles a semiflosculous one, though it is truly radiated. The characters were taken from the first species, *P. semiflosculare*; the *radiale*, though agreeing in the character of the two-lipped florets, differs entirely in habit. Linn. Vahl considers the florets as all uniform, and therefore places this genus in the order *Polygamia equalis*.

Eff. Ch. Receptacle naked. Florets two lipped. Down capillary, rough.

1. *P. semiflosculare*. Linn. Sp. Pl. 1248. Amoen. Acad. v. 6. 103. Thunb. Prodr. 160. (P. Taraxici; Vahl. n. 1. t. 1. Willd. n. 1.)—Stalks radical, single-flowered. Leaves runcinate, smooth, with rounded lobes.—Native of the Cape of Good Hope, in muddy places. The root is perennial, long and tuberous, with numerous, long, cylindrical, thick, fleshy fibres, running deep into the ground, totally misrepresented in Vahl's plate. *Stem* none. *Leaves* numerous, radical, spreading, stalked, three or four inches long, runcinate, obtuse, smooth; their numerous lobes short, broad, rounded, slightly toothed. *Footstalks* linear, their permanent fibrous remains crowning the root, and surrounding the present leaves. *Flower stalks* one or two, ascending, simple, round, woolly, rather longer than the leaves, each usually bearing one linear *bractea*, towards the top. *Flower* somewhat drooping, large. *Calyx* like a *Scorzonera*. *Seed down* very copious and dense, shining, rather tawny, an inch long. This plant has indeed much of the aspect of a Dandelion, but we cannot submit to the change of a good Linnæan name, expressive of the habit of the flower, for a new one of a very faulty construction.

2. *P. tomentosum*. Thunb. Jap. 319. Vahl. n. 2. t. 2. Willd. n. 2.—Stalk radical, single-flowered, with several awl-shaped bractæ. Leaves lyrate, downy beneath.—Gathered by Thunberg in Japan, flowering in April and

PERDICUM.

May. Smaller and more downy than the former, with lyrate leaves, whose terminal lobe is heart-shaped and wavy, with slight teeth. Flowers much smaller, with a purple radius and yellow disk.

3. *P. Anandria*. Siberian *Perdicum*. Brown in Ait. Hort. Kew. ed. 2. v. 5. 84. (*Tussilago Anandria*; Linn. Sp. Pl. 1213. Willd. Sp. Pl. v. 3. 1962. T. scapo unifloro, calyce clauso; Linn. Hort. Upf. 259. t. 3. f. 1. Gmel. Sib. v. 2. 141. t. 68. f. 1. *Anandria*; Linn. Amœn. Acad. v. 1. 243. t. 11.)—Stalk radical, single-flowered, with several awl-shaped bracteas. Leaves lyrate, acute, denudated on both sides. Calyx closed, longer than the florets. —Native of Siberia, in mountainous fields. Cultivated by Miller in 1759. It flowers in March and is perennial, but has nothing to recommend it as a garden plant, except botanical singularity. The root, according to Gmelin, consists of many fleshy spreading fibres, like that of *Asphodel*. Leaves radical, stalked, lyrate, minutely toothed; when young cottony beneath, but becoming naked and smooth, on both sides, when fully grown; their terminal lobe larger, more ovate, and acute, than in the last. Flower-stalk a foot high, much taller than the leaves, cottony, with several awl-shaped bracteas. Flower nearly globose; its calyx downy, closed, rising much above the florets, which appear to have the proper characters of *Perdicum*, as was first pointed out by Mr. Brown. The whole habit of the plant, compared with the two preceding species, confirms his determination of the genus.

4. *P. populifolium*. (*Tussilago scapo imbricato, unifloro, foliis ovatis, oblongis, ex sinuato dentatis*; Gmel. Sib. v. 2. 141. t. 67. f. 1.)—Stalk radical, single-flowered, with several sheathing bracteas. Leaves ovate, wavy, toothed; densely woolly beneath. Root creeping.—Native of Siberia, in stony places. We cannot but think this must be a distinct species from the last. The root creeps among stones, and is not thicker than a crow's quill. Leaves simple, (not lyrate,) wavy or coarsely toothed; cottony beneath at all times; clothed with deciduous down on the upper side when young, but afterwards smooth and shining, of a dark purplish hue. Flower-stalk invested with three or four broad, sheathing, finally smooth bracteas. Flowers white. Calyx chiefly downy at the base, scarcely more than half the length of the spreading radius, which is white.

With respect to Gmelin's *Tussilago* n. 124. t. 67. f. 2, it differs from this last in having somewhat lyrate leaves, far less cottony beneath, and a very few linear bracteas. This appears to be what Linnæus has figured in Hort. Upf. t. 3. f. 2, under the name of *Bellidiflorum*. He speaks of it as a variety of *Anandria*, with elongated radiant florets, caused by being planted in a pot, or an open dry situation. Gmelin seems not to have been satisfied with this decision, and advised the cultivation of both plants, from seed. We are also well aware of the fallibility of cultivators, and think it not impossible, that Linnæus might have received the roots of both the plants in question, without distinguishing them, and thus have been led to consider the subsequent difference in their produce as accidental. We will not however presume to decide this question, any further than that we have no doubt of the permanent difference between our *P. populifolium* and Gmelin's t. 67. f. 2; which last, if not distinct, must be a variety of *Anandria*, with which its bracteas and habit most nearly agree. Gmelin's original specimens are all before us in the Linnæan herbarium. In the moment of writing this article, the fourth and fifth volumes of the Hortus Kewensis have reached us, and have led to the above investigation. This valuable publication being now complete, we need not in future note the edition to which

we refer, except when we may occasionally want to cite the first.

5. *P. purpureum*. Vahl. n. 3. t. 3. Willd. n. 3.—Stems mostly simple, nearly leafless, ascending. Flowers solitary. Leaves pinnatifid, cut, loosely woolly. Radius revolute. —Gathered by Commerçon in the Straits of Magellan. The root is perennial, with long slender fibres. Stems several, ascending three or four inches high, simple or rarely divided, loosely woolly, bearing usually one pinnatifid leaf near the base, and several alternate, linear, undivided ones higher up. Leaves mostly radical, stalked, clothed with fine, long, lax, deciduous wool, deeply pinnatifid; their segments ovate or wedge-shaped, deeply and irregularly cut; their margins generally entire and smooth, but now and then minutely spinous. Flowers terminal, solitary, about an inch wide. Radiant florets ovate, entire, revolute, purple. Down more feathery than in the rest. Our specimen was given by Thouin to the younger Linnæus.

6. *P. magellanicum*. Linn. Suppl. 376. Willd. n. 4. Vahl. n. 4. t. 4.—Stem simple, single-flowered, lispid, nearly leafless. Leaves pinnatifid; their segments rounded, undivided, fringed. Radius spreading.—Gathered by Forster and Commerçon in the Straits of Magellan. Root much like the last. Stem solitary, from two to five inches high, slightly leafy, reddish, rough all over with minute, prominent, glandular points. Leaves chiefly radical, numerous, spreading, about two inches long including their footstalks, deeply pinnatifid, and somewhat lyrate, with numerous, opposite, rounded, entire segments, smooth on both sides, but densely bordered with minute bristles. Flower solitary, twice the size of the last, white, with spreading oblong radiant florets, toothed at the end. Leaves of the calyx bordered with purple, roughish, partly fringed. Seed-down rough, not feathery. This is a very elegant plant, on account of the regularity of its leaves, which resemble those of a *Lepidium*, and the size as well as beauty of the flower.

7. *P. nervosum*. Thuab. Prodr. 160. Willd. n. 5.—“Leaves simple; downy and ribbed beneath.”—Native of the Cape of Good Hope. We have seen no specimen of this or the next.

8. *P. chilense*. Willd. n. 6.—“Stem leafy, single-flowered. Leaves linear-lanceolate, stalked, serrated at the extremity.”—Native of Chili.—Root perennial. Stems several, a span long, ascending, smooth, leafy, single-flowered. Leaves half an inch long, linear-lanceolate, tapering at each end, very narrow, sharply serrated at the apex. Footstalks longer than the leaves. Bracteas numerous, somewhat stalked, of the shape of the leaves, surrounding the flower, which is radiated. Willd.

9. *P. laucoides*. Vahl. n. 5. t. 5. Willd. n. 7. (After magellanicus; Lamarck Dict. v. 1. 305. n. 26. Illustr. t. 681. f. 3.)—Stem leafy, single-flowered. Radical leaves elliptic-lanceolate, on long stalks; the rest sessile, clasping the stem.—Gathered at the Straits of Magellan, by Commerçon, who having marked his specimens as an *Aster*, the plant was described as such by Lamarck. The whole herb is destitute of pubescence. Stem from one to nearly two feet high, slender, quite simple, round, leafy. Radical leaves several, an inch or two long, entire, on slender, almost capillary, footstalks, three or four times their own length; those on the stem numerous, alternate, sessile, linear-lanceolate, entire, about an inch long, embracing the stem with their ovate base. Flower solitary, rather drooping, not unlike that of *P. magellanicum*, but scarcely half so large.

10. *P. squarrosum*. Vahl. n. 6. t. 6. Willd. n. 8.—Stem many-flowered. Leaves pinnatifid, with toothed bristly segments.—Gathered by Commerçon at Monte Video.

A very

A very handsome species. The *stem* is above a foot high, leafy, corymbose, hispid in the manner of the sixth species. *Leaves* sessile, two or three inches long, linear, shining, rough with minute points, deeply pinnatifid; their segments acute, toothed, each point and tooth tipped with a pale bristle: the radical leaves most numerous, somewhat stalked, their segments rather folded or imbricated. *Flowers* solitary at the top of each branch, from four to eight in all, an inch broad. *Calyx* rough, pointed, its outer leaves fringed, *Radius* purple, revolute.

11. *P. brasiliense*. Linn. Mant. 115. Willd. n. 9. Vahl n. 7.—Stem many-flowered. Leaves rough; radical ones obovate, runcinate; the rest oblong; uppermost entire.—Gathered in Brasil, by Father Panegai an astronomer, who sent it to Arduino. Commerfon also found it at Monte Video. The *root* has many thick fleshy fibres. *Herb* rough in every part, with minute bristly hairs, a foot or more in height. Radical *leaves* stalked, near three inches long, obtuse, with many shallow, runcinate, toothed segments; those on the stem sessile, oblong, undivided, the lower ones toothed, the upper gradually smaller and entire. *Flowers* four or five at the top of the stem, corymbose, the size of the last, but yellow, or pale sulphur-coloured.

12. *P. levigatum*. Berg. in Stockh. Transf. for 1772. 229. t. 7. Willd. n. 10.—Stem rather shrubby. Leaves stalked, lanceolate, entire, fringed. Flower-stalks terminal, mostly in pairs.—Native of Porto Bello. We have seen no specimen, nor even that volume of the Stockholm Transactions, in which alone this species is described.

13. *P. radiale*. Linn. Sp. Pl. 1248. Willd. n. 11. Vahl n. 8. (Inu'a Trixis; Linn. Am. Acad. v. 5. 406. Trixis n. 1; Browne Jam. 312. t. 33. f. 1.)—Stem shrubby. Leaves stalked, ovate, toothed, flat, smooth. Flowers corymbose.—Native of meadows about Kingston in Jamaica. *Browne*. Stem four or five feet high, shrubby, round, smooth; leafy. *Leaves* alternate, on short stalks, ovate, pointed, flat, smooth on both sides, three inches long, reticulated with minute veins. *Flowers* few, yellow, corymbose, at the ends of the branches, accompanied by diminished leaves. *Calyx* smooth, somewhat fringed.

14. *P. recurvatum*. Vahl n. 9. t. 7. Willd. n. 12.—Stem somewhat shrubby. Leaves linear-lanceolate, recurved, revolute, bordered with minute spines. Flowers terminal, solitary.—Gathered by Commerfon at the straits of Magellan. This seems to be a low, tufted, much branched *shrub*, with crowded, recurved, shining, linear-lanceolate leaves, an inch long, corrugated on the upper side, reflexed at the margin, the prominent edges beset with little spines. *Footstalks* broad, fringed, imbricated. Flowering *branches* terminal, erect, roughish upwards, each bearing a few alternate, fringed, clasping leaves, and one erect purple flower, about an inch wide, whose outer calyx-leaves are fringed with small spines. A very pretty and singular species, which though different in its first aspect, displays, when examined, abundant marks of affinity to the rest.

Perhaps Vahl may be right in removing *Perdicium* to the order of *Syngenesia Polygamia-aqualis*, there being, apparently, in most of the species, no more difference between the florets, than a gradual diminution as they approach the centre, like what is seen in *Hieracium* and others. In habit some of the species agree with the ligulate, others with the capitate, genera of that order. Notwithstanding all this, as the various species have not been examined living, and as Linnæus has described a difference in structure, between the florets of the radius and of the disk, we rather prefer leaving the genus where he placed it. The thirteenth spe-

cies is so different in habit, that we cannot but suspect it to belong to some other tribe. Browne's figure of the dissected flower disagrees with his description, which says the florets are all uniform. In the plate the radiant ones are as they ought to be in *Perdicium*; while the disk is made to consist of such as are equally five-cleft.

PERDIDO, in *Geography*, a river and bay on the coast of West Florida. The mouth of the river is about ten leagues E. of Mobile point and four W. of the line of Pensacola. It has a narrow entrance, with a bar of six feet, but afterwards widens considerably. This was formerly the boundary between Florida and Louisiana, separating the French and Spanish dominions, and is now considered as the eastern boundary of Louisiana, as lately ceded to the United States. The river stretches in one place N.E. where it passes within a mile of the great lagoon W. of the entrance of Pensacola harbour.

PERDIX, in *Conchology*, a name given by authors to a genus of shells, supposed to resemble the partridge in the shades and disposition of the colours.

The partridge-shell is of the dolium, or concha globosa class, and is striated and spotted in a peculiarly elegant and regular manner. See CONCHOLOGY.

PERDIX, in *Ornithology*. See TETRAO.

PERDIX *Russica*. See SCOLOPAX *Rusticola*.

PERDIX *Major Brasiliensis*. See PSOPHIA *Crepitans*.

PERDIX *Montana*. See COLUMBA *Montana*.

PERDOLI, in *Geography*, a town of Istria; four miles N.N.W. of Pola.

PERDONATIO *ut lagarie*, in *Law*, a pardon for one who is outlawed.

PERDRIX *de Mer*, in *Ornithology*. See GLAREOLA and TETRAO.

PERDU, MONT, in *Geography*, the loftiest mountain of the Pyrenées, and the most elevated in which any marine remains have been found in Europe. M. Ramond observed that this mountain was calcareous, and contained shells and other organized bodies, in a fossil state, at an elevation of about 3000 metres. As he ascended this mountain, in August 1802, by passing the Col de Fanlo, or Nifele, he constantly found strata of compact carbonated lime in a position nearly vertical. They include strata of calcareous sandstone, and these strata sometimes cover the salient angles of the vertical strata, nearly in a horizontal direction. This calcareous stone falls off spontaneously in little irregular fragments; and on the slightest friction, or dissolved in acids, it emits a nauseous fœtid smell, probably owing to the animal matter it contains. Some of the strata of this stone contain nodules of flint; others such considerable masses of "Camerines," that the stone appears entirely composed of them. The fummit is formed of a fœtid limestone, contaminated with quartz, and containing a little iron, and $\frac{1}{8}$ th of carbon, without alumine. The elevation of this fummit is the same as that of the Col du Géant in the Alps, or 3426 metres = 3727 yards.

M. Ramond has ascertained the limits of permanent snow, and of vegetation, for this lofty part of the Pyrenean chain. The snow terminates at 2440 metres. The last trees are Scotch firs, which reach 2150 metres. Next come the shrubs, of which the juniper is the highest. At 2760 metres were found the "*Ranunculus parnassie foliis*," the "*Saxifraga Groenlandica*," &c.; then the "*Artemisia rupestris*" of Lamarck; and lastly round the very peak of Mont Perdu, on rocks too sloping to retain the snow, grow the "*cerastium*," perhaps the "*alpinum*" of Linnæus, and the rose-flowering "*Aretia alpina*."

PERDUE, a soldier placed in a dangerous, and almost desperate post. Thus we say, *enfants perdus*, for the forlorn hope of an army.

The word is French, and literally signifies *lost*.

To lie *perdue*, is to lie flat on the belly, or to lie closely in wait.

PERDUE Bay, in *Geography*, a bay on the S.W. coast of the island of St. Vincent; 71 miles N.W. of Kingston bay.

PEREA, a small island near the coast of Brazil. S. lat. 2° 22'. W. long. 45° 2'.

PEREBEA, in *Botany*, Aubl. Guian. 952. t. 361. Juss. 402, a Guiana plant, whose botanical characters are not fully known. Aublet describes it as a middling-sized tree, throwing up from the root many straight flexible trunks, about four or five inches in diameter, which bear striated leafy branches. Leaves alternate, nearly sessile, elliptic-oblong, pointed, wavy and somewhat toothed, a foot or more in length, and about five inches wide, green, smooth and shining, with one principal rib, and many transverse ones. When held against the light, these leaves appear full of transparent dots. Stipules solitary, large, membranous, deciduous. Flowers axillary, on short stalks, solitary, each consisting of a flat fleshy receptacle, toothed at the edge, two inches or more in diameter, its upper surface covered with about 30 crowded florets, and at length becoming convex. Each floret consists of a tubular calyx, with four teeth, embracing a roundish germen, a fleshy columnar style, and cloven stigma. Aublet saw nothing of the stamens, which he supposes are in separate flowers, on a distinct tree. The calyx becomes a fleshy fruit, of a coral red, containing a single seed, as in the Mulberry; but each fruit falls off separate, leaving the receptacle bare. Every part of the tree yields a milky juice. The bark serves for cordage.

This genus is justly ranged by Jussieu in his natural order of *Urticæ*, being evidently allied to *Ficus*, *Morus*, *Broussonetia*, &c. See PAPIRIUS.

PERE-EN-REIZ, St., in *Geography*, a town of France, in the department of the Lower Loire, and chief place of a canton, in the district of Paimbœuf. The place contains 1973, and the canton 5988 inhabitants, on a territory of 232½ kilometres, in four communes.

PEREFIXE, HARDOUIN DE BEAUMONT, in *Biography*, a prelate and historian, descended from an ancient family in Poitou, was the son of cardinal Richelieu's maître d'hôtel. That minister took care of his education, and being brought up to the church, he was made a doctor of the Sorbonne, and preached with applause. He was chosen preceptor to the prince, afterwards Lewis XIV., and in 1654 he was admitted into the French academy. By command of the king he composed an abridgment of French history, from which he detached the life of Henry IV. which was published separately at Amsterdam in 1661, and again with augmentations at Paris the year after. Though negligently written, it is accounted an excellent work, and one which gives a better picture of that amiable monarch than the fuller history of father Daniel. It omits many circumstances of his life, the purpose being to collect those only which might serve for lessons to a great prince. This author published likewise a small piece entitled "Institutio Principis," being a plan of royal education during the period of childhood. In 1664 he was created archbishop of Paris, and had the fortune to be deeply involved in the disputes of Janseuism. He died at an advanced age in 1676. His private character has been represented as mild and amiable. Moreri.

PEREGRINARY, PEREGRINIARIUS, in the *Ancient*

Monasteries, a monk to whom was committed the care of receiving and entertaining strangers, or visitors.

PEREGRINATORRES, in *Botany*, a name for such students in that science as have taken long journies, and visited the remotest regions, in search of plants.

PEREGRINE, PEREGRINUS, a term applied among *Astrologers*, to a planet, when found in a sign where it has none of its five essential dignities.

PEREGRINUS, surnamed *Proteus*, in *Biography*, a cynic philosopher in the second century, was a native of Parium in Pontus. If we are to credit the account which Lucian has given of him, his conduct in early life was extremely profligate. Being obliged to fly from his country, he went to Palestine, where he made profession of Christianity, and gained some credit with the Christians by his firmness in submitting to imprisonment under Trajan's persecution, sooner than renounce his avowed principles. During his confinement, he was visited by the deputies from the churches of Asia, who administered to him assistance suited to his wants and sufferings, and in the character of a persecuted believer, he contrived to amass a considerable sum of money. At length he was set at liberty by the governor of Syria, who was a lover of philosophy, and admired the contempt of death which Peregrinus displayed. Upon his return to Parium, he acquired reputation in the character of a disinterested philosopher. By the charity of the Christians, whom he continued to deceive, he was furnished with all necessary supplies, till, having been detected in the commission of some crime, he was dismissed their society, and fell into indigence. He now endeavoured to recover the possession of his estates from the city, but failing in the attempt, he went into Egypt. Here, in the character of a mendicant cynic, he practised the most extravagant exploits of fanaticism, in order to shew his contempt for the opinions of the world. From Egypt he went into Italy, where he behaved extremely ill, so that he was driven away by the government. Passing over into Greece he attracted the admiration of the crowd at Athens, by the severity of his cynical manners, and the lectures which he delivered. Finding their enthusiasm in his favour becoming less ardent, he determined to procure an immortal name by burning himself at the olympic games, in imitation of Hercules. This design he announced throughout the whole of Greece, and, at the appointed time, went to Olympia, where, in the presence of a vast concourse of spectators, he raised a funeral pile, and devoted himself to a voluntary death. Such is the account given of Peregrinus by Lucian, but Aulus Gellius speaks of him as a philosopher of reputation at Athens, who was admired for his constancy, and whose moral lectures were much frequented. According to Eusebius he committed himself to the flames in the year 168. Lucian. Esfield's Hist. Phil.

PERTIRA, BARTHOLOME, a Portuguese Jesuit, and one of the many epic poets which that extraordinary society has produced. The work which he published is entitled "Paciecidas" libri xii. Coimbra 1640; it was written in honour of a Jesuit who suffered martyrdom in Japan, and to whom the poet was related. Except the names of idols, and the bronzes, there is no allusion to any rite or custom of the country. There are, however, says Mr. Southey, some curious passages in the poem, particularly a personification of Amor Vitæ, and some of real merit.

PEREIRA de Susa, in *Geography*, a town of Portugal, in the province of Beira; 18 miles S.E. of Oporto.

PEREK, a town of Persia, in the province of Farsistan; 14 miles N. of Darebghend.

PEREKOP, a fortress of Russia, in the province of Tauris,

Tauris, on the isthmus which joins the peninsula to the continent, and which has been always reckoned the key to the whole country. Its name is Sclavonian, denoting a cut made through a place, and applicable to the ditch dug here, in remote ages, across the neck of land at the entrance of the Crimea, for the security of the place. For the same reason the Greeks called it "Taphros" or "Taphraz," and the Greeks and Tartars "Or." The houses here are mean. After often changing masters, it was finally ceded, in 1783, to the Russians, with the rest of the Crimea, by the abdication of the khan. N. lat. $46^{\circ} 4'$. E. long. $33^{\circ} 20'$.

PEREKOPSKAIA, a town of Russia, in the country of the Cossacks, on the Don; 48 miles S. of Archedinskaiia.

PERELOMOV, a town of Russia, in the government of Irkutsk, on the Amor; 56 miles N.E. of Stretinsk.

PEREMSCHAL, a town of Russia, in the government of Kaluga, on the Oka; 16 miles S.S.W. of Kaluga. N. lat. $54^{\circ} 15'$. E. long. $35^{\circ} 44'$.

PEREMPTORY, in *Law*, an epithet applied to an action, exception, &c. signifying them to be absolute, final, and determinate; and not to be altered, renewed, or restrained.

Thus in our law books we find *peremptory action*, *peremptory nonsuit*, *peremptory exemption*, &c.

PERENDORE, or PERENTORAY, in *Geography*, a town of Hindoostan, in the Mysore; 10 miles S.W. of E-road.

PERENE, a river of Peru, which rises about two leagues from Tarma, runs through that town, and receives many streams from the heights of Bombon and Pasco; the Perene joins the Maranon, on the western side, at $11^{\circ} 18'$.

PERENNIAL PLANTS, in *Gardening*, are such as are of long duration. Such plants as are perpetuated by the roots, whether the leaves and stalks decay annually in winter, or always remain, provided the roots are of many years duration, are perennial. All plants, therefore, with abiding roots, both of the herbaceous, shrub, and tree kinds, are perennials; though in the general acceptance of the word perennial, it is most commonly applied to herbaceous vegetables with durable roots, more especially those of the flowery kind, which among gardeners are commonly called simply perennials, particularly the fibrous-rooted tribe; but it is equally applicable to fibrous, tuberous, and bulbous-rooted plants, whose roots are of several years duration; likewise all shrubs and trees of every denomination, as having abiding roots, are perennial plants.

And these sorts of plants consist both of deciduous and ever-green kinds; those that cast their leaves, &c. in winter being termed deciduous perennials, and those which retain their leaves, ever-greens.

The herbaceous perennials, of the fibrous, tuberous, and bulbous rooted kinds, for the greater part, have annual stalks, rising in spring, and decaying in winter; and a great many lose their leaves entirely also in that season, such as the perennial sun-flower, asters, and numerous other sorts; and many retain their leaves all the year, but not their stalks; as is exemplified in the auricula, polyanthus, some campanulas, pinks, carnations, and many other plants.

Numbers of the herbaceous perennials multiply exceedingly by off-sets of the root, by which they are readily propagated. See OFF-SET.

All the tree and shrub perennials are durable in root, stem, and branch; but renew their leaves annually. Even the ever-green kinds, although they are in leaf the year round, put forth new leaves every year, to which the old ones gradually give place. See DECIDUOUS and EVER-GREEN TREES.

PERENNIAL Winds. See WINDS.

PERES, or *Constantine Peres*, in *Geography*, an island on the coast of Chili, opposite to Port Coral. On this island is a fort called Manfera, and on the back of the island is an entrance for boats into the harbour of Valdivia.

PERESKIA, in *Botany*, received that appellation from Plumier, in honour of Nicholas Fabricius Peiresk, a magistrate of Aix in Provence, highly celebrated for his botanical learning and great love of plants. He is said to have prepared several works on natural philosophy, mathematics, and botany, whose publication was prevented by his death. The *Pereskia* of Plumier however was reduced by Linnæus to CACTUS, see that article. There are characters perhaps in the fructification sufficient to have kept it distinct, as the habit is very dissimilar.

PERESLAVALZALSKOI, in *Geography*, a town of Russia, in the government of Vladimir; 60 miles N.W. of Vladimir. N. lat. $56^{\circ} 35'$. E. long. $38^{\circ} 54'$.

PERETERION, a name given by chirurgical writers to the perforating part of the trepan.

PEREVOLOTSKAIA, in *Geography*, a fort of Russia, in the government of Upha, on the Samara; 32 miles W.N.W. of Orenburg.

PEREVOZ, a town of Russia, in the government of Niznei Novgorod; 48 miles S.S.E. of Niznei Novgorod. N. lat. $55^{\circ} 36'$. E. long. $44^{\circ} 34'$.

PEREVOZNOI, Nos, a cape of Russia, in the straits of Vaigatskoi. N. lat. $69^{\circ} 15'$. E. long. $58^{\circ} 22'$.

PEREZ, DAVID, in *Biography*, the son of Juan Perez, a Spaniard, settled at Naples, was born in 1711, and brought up in the conservatorio of Santa Maria di Loreto, in that city, under Antonio Gallo and Francesco Mancini. His progress in composition was rapid, and discovered an uncommon genius. When he quitted the conservatorio, his first preferment was at Palermo in Sicily, where he was appointed maestro di capella of the cathedral in that city, at a considerable salary, the half of which he was permitted to enjoy, not only after he quitted Sicily, but even Italy, to the time of his death.

He composed his first operas for the theatre at Palermo, from 1741 to 1748, and then returned to Naples, where his "Clemenza di Tito" was performed with such great applause at the theatre of San Carlo, as to extend his fame to Rome, whither he was invited the next year to compose for the theatre delle Dame. Here he produced "Semiramide" and "Farnace;" and for other cities in Italy "La Didone Abbandonata," "Zenobia," and "Alessandro nell' Indie."

In 1752, he went to Portugal, where he was engaged in the service of king Joseph. His first opera at Lisbon, "Demofonte," was received with very great applause. Gizziello was the principal soprano, and the celebrated Raaf the tenor. It was besides rendered magnificent in the performance by a powerful orchestra and decorations that were extremely splendid. But the new theatre of his Portuguese majesty, which was opened on the queen's birth-day, March 31st, 1755, surpassed, in magnitude and decorations, all that modern times can boast. On this occasion Perez new set the opera of "Alessandro nell' Indie," in which opera a troop of horse appeared on the stage, with a Macedonian phalanx. One of the king's riding-masters rode Bucephalus, to a march which Perez composed in the manege, to the grand pas of a beautiful horse; the whole far exceeding all that Farinelli had attempted to introduce in a grand theatre under his direction at Madrid, for the fitting out of which he had unlimited powers. Besides these splendid decorations, his Portuguese majesty had assembled together the greatest singers then existing; so that the lyric productions

of Perez had every advantage which a most captivating and perfect execution could give them.

The operas by which he acquired the greatest fame in Portugal were "Demetrio" and "Solimano," with which, as they were to be alternately performed with the operas of "Vologeso" and "Enea in Latio" that Jomelli had been requested by his most faithful majesty to compose for his theatre, were produced with a degree of exertion and emulation, which rendered him superior to himself. Jomelli on this occasion was chiefly admired for the ingenious and learned texture of the instrumental parts; and Perez for the elegance and grace of his melodies, and expression of the words.

His music for the church, of which a specimen has been printed in England, "Matutino de i Morti," published by Bremner, in score, is grave, ingenious, and expressive.

But though Perez has composed a "Te Deum," which is greatly esteemed at Lisbon, and his "Lezione prima per il Giovedì fanto," mentioned above, has considerable merit, yet it appears, on examining his scores, that this master had not, like Jomelli, much exercised his pen in the composition of fugues or learned counterpoint for the church, to the perfection of which, genius alone can contribute but little, without the assistance of great study and experience.

There is, however, an original spirit and elegance in all his productions; in which, if any defect appears, it is the want of symmetry in the phraseology of his melodies, in which there may sometimes be found what the French call *phrases manquées*, and *contre-tems*, to which critical ears, in modern times, are much less accustomed than formerly. An ear for measure, and an ear for harmony and the accuracy of tones, seem to be totally different gifts of nature; and it frequently happens that a person who dances perfectly well in time, knows not one tune or tone from another.

Perez, like Handel, was corpulent and gourmand, a propensity which has been supposed to have somewhat shortened his days. After living much admired, beloved, and respected, twenty-seven years in Portugal, where he was maestro di cappella to his most faithful majesty, and master to the royal family, at a salary exceeding 2000*l. per annum*, he died extremely regretted at the age of sixty-seven. Like Handel, he was likewise blind during the latter years of his life; but after this calamity, when confined to his bed he frequently dictated, without an instrument, compositions, in parts, to an amanuensis. His remains were deposited in the church of the Italian Barbadindros, and a solemn dirge of his own composition was performed at his funeral, by a concurrence of the best musicians in Lisbon.

PEREZ, ANTONIO, whose father was forty years sole secretary of state to Charles V. and Philip II., in which office he was succeeded by the subject of the present article, was also made secretary of war, and demeaned himself so well, as to enjoy, at the same time, the favour of the king and of the people. While in office he was commanded by the king to obtain the assassination of Don Juan de Escovedo. He unfortunately obeyed the orders of his sovereign; and supposing that the deed would be considered as a common accident, the murder was perpetrated in the streets of Madrid. Perez appears never to have suspected that he committed a very great crime. He represented Escovedo's death as necessary, and the forms of justice he thought might readily be dispensed with on extraordinary occasions. Suspicion fell on him and the princess Eboli: it had been surmised that Philip was an unsuccessful suitor to this lady, and jealous of Perez's intimacy with her. Be this, however, as it may, he took the opportunity, occasioned by the suspicion, to throw them both into prison, and suffered the accusation to

hang over the secretary's head for many years, still continuing to employ him, and promising him his protection and favour. At length he got possession of the papers which alone could have established his own share in the murder, and then suffered Antonio to be put to the rack. It was the intention of this unfortunate man to bear the tortures inflicted on him without confessing, but the violence of the pain overcame his resolution, and he declared that he had procured Escovedo's assassination, but that it was by Philip's orders. Happily for his own character, he had still by him papers sufficient to prove this, and with these he escaped to Arragon. "That kingdom," said Mr. Southey, in writing the life of Perez only a year or two since, "was still by its constitution a free country, but constitutions are nothing in the way of power, and no country has any other security for its freedom than the spirit and strength of the people." He appealed to the tribunal del justiza de Arragon, a free tribunal, to whose decision Philip did not chuse to attend, and, therefore, removed the cause to the Enquesta, a sort of star-chamber of his own, in which any wickedness that it pleased him to direct would receive the form of legality. "But," says the writer already alluded to, "the Arragonese had now espoused the cause of their injured countryman, and it was thought that the most effectual method of destroying him would be to deliver him over to the inquisition. That accursed tribunal, which had lately been established in Saragossa, laid hands on him, on a charge of witchcraft: blinded and besotted with superstition as the Arragonese were, in common with all the Spaniards, their love of liberty was not at this time to be thus betrayed. They rescued him from the holy office. In consequence of this and other tumults an army was marched into Arragon. The justiza, as he was bound to do, called upon his countrymen to resist this invasion of their rights; but he, and the nobles with him, aware of their inability to oppose veteran troops, set the example of flight. Better had it been to have died in the field, even had the cause been utterly hopeless, as he deemed it, which possibly it might not have been. He and the other chiefs were secured and beheaded. Perez made his escape into France, and the forms of liberty in Arragon were extinguished." Antonio found the protection that he implored: he published a narrative of his sufferings, and it is certain, by the great names which appear in his correspondence, that he was highly esteemed and respected both in France and England. Several unsuccessful attempts were made to murder him. He died miserably poor in the year 1611, and endured to the last the heavy affliction of being separated from his wife and children. No interest could avail to procure their liberation, and he imputes the death of his eldest daughter to grief on his account. Gen. Biog.

PERFECT, something to which nothing is wanting; or that has all the requisites of its nature and kind.

PERFECT, *Perfecti*, in *Church History*, a designation which the followers of Valentinus assumed to themselves.

PERFECT, in *Grammar*. Preter or preterit-perfect tense, is an inflection, marking a time perfectly past; as *I have heard*: plusquam-perfect, is an inflection, expressing the time more than perfectly past; as *I had heard*, &c. See TENSE.

PERFECT, in *Music*, denotes something that fills and satisfies the mind, and the ear. In which sense we say, perfect cadence, perfect concord, &c.

The ancients had two kinds of modes, the major and minor; and each of these, again, was either *perfect* or *imperfect*.

The word *perfect*, when joined by the words *mode* and *time*, usually expresses triple time, or measure; in opposition

position to double time, which they call *imperfect*. See TIME.

PERFECT, in *Physiology*. A perfect animal is used, by some writers, for that which is born by univocal generation; in opposition to insects, which they pretend to be produced by equivocal generation.

PERFECT Flowers, in *Botany*, and *Vegetable Physiology*, are such as have the flamens and pistils both perfect in the same flower. They are the *flores hermaphroditi* of Linnæus, and are sometimes called *united flowers*.

PERFECT Mixts. See MIXTS.

PERFECT Number, in *Arithmetic*, is one that is equal to the sum of all its divisors, or aliquot parts (Euclid, book vii. def. 22): thus,

$$6 = \frac{6}{2} + \frac{6}{3} + \frac{6}{6}$$

$$28 = \frac{28}{2} + \frac{28}{4} + \frac{28}{7} + \frac{28}{14} + \frac{28}{28}$$

are both perfect numbers.

To find Perfect Numbers — Find $2^n - 1$, a prime number, then will $2^{n-1}(2^n - 1)$ be a perfect number: for $2^n - 1 = 1 + 2 + 2^1 + 2^2 + 2^3 + \&c. 2^{n-1}$; and it is demonstrated by Euclid, in the last proposition of book ix, that if the above series be continued till the sum be a prime, then that sum multiplied by the last term of the series will be a perfect number, which, therefore, is identically the same as the above formula, and the truth of the theorem under its analytical form may be demonstrated as follows. Since $2^n - 1$ is a prime, put it = b , and $2^{n-1} = 2^m = a^m$, then the above is reduced to $a^m b$.

Now the sum of the divisors of $a^m b = \frac{a^{m+1} - 1}{a - 1} \times \frac{b^{1+1} - 1}{b - 1}$. See NUMBERS.

But in this formula the number itself is considered as a divisor, which is excluded in perfect numbers; therefore the sum of the divisors, exclusive of the number itself, is

$$\frac{a^{m+1} - 1}{a - 1} \times \frac{b^{1+1} - 1}{b - 1} a^m - b;$$

and it only remains to be shewn that this is equal to $a^m b$, or that

$$\frac{a^{m+1} - 1}{a - 1} \times \frac{b^{1+1} - 1}{b - 1} = 2 a^m b :$$

and this will be obvious by re-establishing again the values of

a and b , as above: for then $\frac{2^n - 1}{2 - 1} \times \frac{(2n - 1)^2 - 1}{(2n - 1) - 1} = (2^n - 1)(2^n - 1 + 1) = 2^n(2^n - 1)$, and $2 a^m b = 2 \cdot 2^{n-1}(2^n - 1) = 2^n(2^n - 1)$, which are identical.

Consequently, every number of the form $2^{n-1}(2^n - 1)$ when the latter factor is a prime, is a perfect number, the sum of its divisors being equal to the number itself.

- If $n = 2$ then $2(2 - 1) = 6$
- $n = 3 - 2^2(2^3 - 1) = 28$
- $n = 5 - 2^4(2^5 - 1) = 496$
- $n = 7 - 2^6(2^7 - 1) = 8128$
- $n = 13 - 2^{12}(2^{13} - 1) = 33550336$
- $n = 17 - 2^{16}(2^{17} - 1) = 8589869056$
- $n = 19 - 2^{18}(2^{19} - 1) = 137438691328$
- $n = 31 - 2^{30}(2^{31} - 1) = 2305843008139952128$

which are all the perfect numbers at present known.

The difficulty, therefore, of finding perfect numbers arises out of that of finding prime numbers of the form $2^n - 1$,

which is a very laborious operation. Euler ascertained that $2^{31} - 1 = 2147483647$ is a prime number, and this is the greatest at present known to be such, and consequently the last of the above perfect numbers, which depends upon it, is the greatest perfect number at present known, and in all probability the greatest that ever will be known; for being merely matters of curiosity, it is not likely that any one will ever attempt to find one beyond it. See Barlow's Theory of Numbers.

PERFECT Plants. See PLANTS.

PERFECTION, the state or quality of a thing perfect. This is of divers kinds: *physical*, *moral*, and *metaphysical*.

PERFECTION, *Physical*, or *Natural*, is that by which a thing has all its powers or faculties, and those too in their full vigour; and all its parts both principal and secondary, and those in their due proportion, constitution, &c. In which sense a man is said to be perfect, when he has a sound mind in a sound body.

This perfection is by the schoolmen frequently called *επεξετησιον*, because a thing is thus enabled to perform all its operations.

PERFECTION, *Moral*, is an eminent degree of virtue, or moral goodness; to which men arrive by often repeated acts of piety, beneficence, &c.

This some subdivide into *absolute* or *inherent*, which is actually in him to whom we attribute it; and *imputative*, which exists in some other, and not in him to whom it is attributed.

PERFECTION, *Metaphysical*, or *Transcendental*, or *Essential*, is the possession of all the essential attributes, or of all the parts necessary to the integrity of a substance: or it is that by which a thing has, or is provided of, every thing belonging to its nature.

This is either *absolute*, where all imperfection is excluded; such is the perfection of God: or *secundum quid*, and in its kind.

PERFECTISSIMATE, PERFECTISSIMATUS, a quality, or dignity, mentioned in the Code. Perfectissimi were those to whom the emperors trusted the presidentship of any province. Alciat imagined the name had been only given to the governors of Hispânia Tarraconensis, and Noricum; but Calvin has shewn the contrary in his *Lexicon Juridicum*.

The perfectissimi were inferior to the clarissimi, though the former word imply most perfect.

PERFETTO, as in the old time-table, when *perfetto* implied triple time, *consonanza perfetta*, a perfect concord.

PERFIDE, in *Italian Music*, implies a certain tendency to repeat the same thing, as in *Rosalie*, to repeat the same passages, or pursue the same design, persist in the same movement, the same character of air or melody, the same passages in the same kind of notes. (See CHANT, DESIGN, and MOVEMENT.) Such are the ground bases, in chacones, and an infinite number of constrained accompaniments, or *perfidii*, or *perfidiatii*, which depend on the caprice of the composers.

PERFOLIATA FOLIA, in *Botany*, Perfoliate Leaves, are such as have the stem or branch running through them, as in *Bupleurum perfoliatum*, thence termed *Thorough-wax*, from the old word *wax*, to grow. See LEAF.

PERFORANS, PERFORATUS, in *Anatomy*, two muscles of the fingers, called also *flexor digitorum profundus* and *sublimis*. See FLEXOR.

PERFORANS *Gasserii*, a name given to the external cutaneous nerve of the arm, which penetrates the coraco-brachialis

chialis muscle, from an Italian anatomist who described it. See NERVE.

PERFORATA, in *Botany*, a name given by some authors to the *hypericum*, or St. John's wort, from the small holes seen all over its leaves, if held up to the light.

PERFORATIVE. See TREPANUM.

PERFORATOR, in *Midwifery*, an instrument used to open the heads of children, when from some error, or defect in the pelvis of the mother, it is impossible to bring them through without mutilating them. (See LABOUR, *Difficult*.) The perforator introduced by Smellie, and which is now generally used, is that of a pair of scissors, or an instrument formed like scissors, on a large scale, viz. about thirteen inches in length, and of proportionate thickness, with the edges rounded, that they may not cut, and with a guard, or projection on each blade, about three inches from the points, to prevent their entering farther than is necessary into the skull of the child. Having pushed the perforator through one of the parietal bones of the head of the child, or through a suture, if one can be found, (see LABOUR, *Difficult*,) until stopped by the guard, the handles must be opened, and the instrument turned round, by which means the aperture in the skull will be enlarged, in every direction, when the perforator may be withdrawn. See the figure.

PERFUME, an agreeable artificial odour, striking the sense, or organ of smelling.

Perfumes are generally made or composed of musk, ambergris, civet, rose, and cedar-woods, orange-flowers, jasmijn, jonquil's, tuberoses, and other odoriferous flowers.

Into these also enter storax, frankincense, benzoin, cloves, mace, and other like drugs, commonly called *aromatics*. Some perfumes are also composed with aromatic herbs, or leaves, as lavender, marjoram, sage, thyme, hyssop, &c.

Perfumes were anciently much in use, particularly those into which musk, ambergris, and civet enter; but they are now generally disused, since people have become sensible of the harm they do to the head. In Spain and Italy, however, they are still very common.

PERFUMES, *Suffitus*, in *Pharmacy*, &c. are topical or external medicines, composed of certain powders and gums, which, being mixed together, and thrown on the coals, produce a vapour or smoke, salutary in the several diseases. See SUFFITUS.

Burnt mercury is sometimes applied by way of suffitus, called fumes of cinnabar.

There are dry perfumes, made up in troches, pills, &c. of olibanum, mastic, aloes, &c. and moist viscous ones mixed with the juices of herbs, &c.

PERG, in *Geography*, a town of Austria; 6 miles S.S.E. of Aigen.—Also, a town of Austria; 12 miles E. of Steyregg.

PERGA, in *Ancient Geography*, a town of Asia Minor, in the interior of Pamphylia, between the rivers Cestros and Cataractes.

PERGA, or *Parga*, in *Geography*, a town of Albania, on the coast of the Adriatic; 25 miles W.N.W. of Arta.

PERGAMAR, a town of European Turkey, in Rumania; the see of a bishop; 60 miles S.W. of Adrianople.

PERGAMO, a town of Asiatic Turkey, in Natolia, situated at the foot of a mountain, on a river formerly called "Caicus," with a harbour about 15 miles from the sea; inhabited chiefly by Turks, with some Christians, who have a church, and are poor; 144 miles S.S.W. of Constantinople. N. lat. 39° 11'. E. long. 27° 0'.

PERGAMUS, in *Ancient Geography*, (now *Pergamo*.) a town of Mysia, seated on a spacious plain on the banks

of the Caicus. The territory of this town was watered by two rivers, one of which traversed the town, and the other ran S.W. of it at a little distance. This territory was pleasant and fertile; and the town was built at the foot of a rock, in the form of a cone, upon which was a fortified castle, where the ancient kings deposited their treasures. The inhabitants of this city pretended to be descendants of the Arcadians, who arrived in this part of Asia with Telephus, son of Hercules; and they say that Esculapius came to Pergamus with a learned colony of Greeks, and practised medicine in this place. The Pergamenians paid him great honours, calling him by the titles of god the saviour, and the sovereign god. They constructed for him a magnificent temple, in which they offered sacrifices, and they celebrated in honour of him public games. The temple was visited by all the people of Asia Minor, and thus Pergamus became famous: the worship of this god continued in it till the establishment of Christianity. Pergamus was at first governed by its own magistrates, who were independent of any other power. It was afterwards under the dominion of the kings of Lydia, from whom it was transferred to the kings of Persia. After the death of Alexander it was subject to Antigonus, and at his death it was transferred to Lysimachus, one of the successors of Alexander, according to Strabo. This prince deposited his treasures in the castle, and entrusted the custody of them to Phileteus of Thios, who fortified the castle and laid the foundation of the kingdom of Pergamus, which lasted 153 years. Eumenes, one of the kings of Pergamus, enlarged and embellished this city. He enriched it with a library containing 200,000 choice volumes, for the transcribing of which parchment was here first invented, and thence called by the Latins *Charta Pergamena*. In Pergamus were likewise invented those costly hangings, which we call tapestry, and which the Romans named "Aulæa," from *aula*, a hall, because the hall of Attalus, who invented them, was the first room adorned with this furniture. Galen was born in this city. At Pergamus was one of the seven churches mentioned in the Revelation. Attalus III., surnamed Philometer, having no children, bequeathed his estates to the Romans, A. U. C. 621. Arilonicus, the natural son of Eumenes II, contended the kingdom of Pergamus with the Romans, but after different events, he was made a prisoner and conducted to Rome. The kingdom of Pergamus was reduced to a Roman province, and bore the name of "Proconsular Asia." In process of time, however, it was dismembered from it. Under the Romans the government of Pergamus was democratic, conducted by a council appointed by the people, under the direction and superintendance of a magistrate, who was president and who was chosen annually. Pallas, Hercules, and Jupiter were divinities held in great respect at Pergamus; but the most celebrated was Esculapius; and Apollo, who was regarded as his father, received singular honours at Pergamus. Trajan had divine honours at Pergamus; and both the gods and the emperors had temples here, the most considerable of which was that of Esculapius. The temple of Augustus in this city was constructed at the expence of the province of Asia; the pagoda had eight columns, and is represented on many medals. This city celebrated, with a magnificence that was very expensive, the Olympic, Pythic and Actian games, and also others in honour of Esculapius and the emperors. These games were preceded by solemn sacrifices. There were many persons at Pergamus, who conducted the offices of religion, the chief of whom bore the name of pontiff or chief priest. The "Nicephorium," or wood consecrated to Jupiter, was held in high veneration. This city accumu-

lated great wealth by industry, by the commerce of parchment, and by the fabric of stuffs and tapestry.

It is now an inconsiderable place, thinly inhabited. In the neighbouring fields may still be found the ruins of the palace of the Attalic kings, an aqueduct and a theatre.

PERGKIRCHEN, in *Geography*, a town of Austria; 11 miles E. of Steyregg.

PERGOLA, a town of the duchy of Urbino; 8 miles E. of Cagli.

PERGOLESI, GIOVAN BATTISTA, in *Biography*, a gifted musician, born at Casoria, a little town about ten miles from Naples, in 1704. His friends discovering, very early in his infancy, that he had a disposition for music, placed him in the conservatorio at Naples, called Dei poveri in Gesu Cristo, which has been since suppressed. Gaetano Greco, of whom the Italians still speak with reverence as a contrapuntist, presided then over that celebrated school. This judicious master soon perceiving uncommon genius in his young pupil, took particular pleasure in facilitating his studies, and communicating to him all the mysteries of his art. The progress which the young musician made was proportioned to the uncommon advantages of nature and art with which he was favoured; and at a time when others had scarcely learned the gamut, he produced specimens of his abilities which would have done honour to the first masters in Naples. At the age of fourteen, he began to perceive that taste and melody were sacrificed to the pedantry of learned counterpoint, and after vanquishing the necessary difficulties in the study of harmony, fugue, and scientific texture of the parts, he intreated his friends to take him home, that he might indulge his own fancies, and write such music as was most agreeable to his natural perceptions and feelings.

The instant he quitted the conservatorio, he totally changed his style, and adopted that of Vinci, of whom he received lessons in vocal composition, and of Haffe, who was then in high favour. And though he so late entered the course which they were pursuing with such rapidity, he soon came up with them; and, taking the lead, attained the goal, to which their views were pointed, before them. With equal simplicity and clearness, he seems to have surpassed them both in graceful and interesting melody.

His countrymen, however, were the last to discover or allow his superiority, and his first opera, performed at the second theatre of Naples, called "Dei Fiorentini," met with but little success. The prince of Stigliano, first equerry to the king of Naples, discovering, however, great abilities in the young Pergolesi, took him under his protection; and from the year 1730 to 1734, by his influence, procured employment for him at the Teatro Nuovo. But during this period, the chief of his productions were of the comic kind, and in the Neapolitan dialect, which is unintelligible to the rest of Italy, except the "Serva Padrona," set for the theatre of San Bartolomeo.

It was not till the year 1735, that an account of his merit penetrated so far as Rome, and inclined the directors of the opera there, to engage him to compose for the Tordinona theatre in that city.

Pergolesi, ambitious of writing for a better theatre, as well as for better performers, than those for which he had hitherto been employed; and happy in having the exquisite poetry of Metastasio's *Olimpiade* to set, instead of the Neapolitan jargon, went to work with the zeal and enthusiasm of a man of genius, animated by hope, and glowing with an ardent passion for his art.

The Romans, however, by some unaccountable fatality, received his opera with coldness; and the composer being a

young man but little known, they seemed to want to be told by others that his music was excellent, and would soon, by the admiration of all Europe, make them ashamed of their injustice and want of taste.

To complete his mortification at the ill reception of this opera, "Nerone," composed by Duni, the next that was brought on the stage, and for which his was laid aside, had a very great success.

Duni, a good musician, and a man of candour, though greatly inferior in genius to Pergolesi, is said to have been ashamed of the treatment which he had received; and with an honest indignation declared, that he was out of all patience with the Roman public, "frenetico contro il pubblico Romano." He even tried during the short life of this opera, to make a party in its favour among the professors and artists who were captivated with the beauty of the music; but all their efforts were vain; the time was not yet come when judgment and feeling were to unite in its favour.

Pergolesi returned to Naples with the small crop of laurels which had been bestowed on him by professors and persons of taste, who in every country compose but a very inconsiderable part of an audience. He was, indeed, extremely mortified at the fate of his opera, and not much disposed to resume the pen, till the duke of Matalon, a Neapolitan nobleman, engaged him to compose a mass and vespers for the festival of a saint at Rome, which was to be celebrated with the utmost magnificence.

Though Pergolesi had but too much cause to be dissatisfied with Roman decrees he could not decline the duke's proposition, and it was on this occasion that he composed the "Mass, Dixit, et Laudate," which have been since so often performed for the public, and transcribed for the curious. They were heard for the first time in the church of San Lorenzo in Lucina, with general rapture; and if any thing could console a man of genius for such unworthy treatment as he had lately experienced at Rome, it must have been such hearty and unequivocal approbation as he now received in the same city.

His health, however, daily and visibly declined. His friends had perceived, by his frequent spitting of blood, for four or five years before this period, that he was likely to be cut off in his prime; and his malady was still increased by this last journey to Rome. His first patron, the prince of Stigliano, who had never ceased to love and protect him, advised him to take a small house at Torre del Greco, near Naples, on the sea-side, almost at the foot of mount Vesuvius. It is imagined by the Neapolitans, that persons afflicted with consumptions are either speedily cured, or killed, in this situation.

During his last sickness, Pergolesi composed his celebrated cantata of Orpheus and Euridice, and his "Stabat Mater," at Torre del Greco, whence he used to go to Naples from time to time to have them tried. The "Salve Regina," which is printed in England, was the last of his productions, and he died very soon after it was finished, in 1737, at the age of 33!

The instant his death was known, all Italy manifested an eager desire to hear and possess his productions, not excepting his first and most trivial farces and *intermezzi*; and not only lovers of elegant music, and curious collectors elsewhere, but even the Neapolitans themselves, who had heard them with indifference during his lifetime, were now equally solicitous to do justice to the works and memory of their deceased countryman. Rome, sensible now of its former injustice, as an *amende honorable*, had his opera of *Olimpiade* revived; an honour which had never been conferred on any

composer of the 18th century. It was now brought on the stage with the utmost magnificence, and that indifference with which it had been heard but two years before, was now converted into rapture.

Pergolesi's first and principal instrument was the violin, which was urged against him, by envious rivals, as a proof that he was unable to compose for voices. If this objection was ever in force with reasonable and candid judges, it must have been much enfeebled, not only by the success of Pergolesi in vocal compositions, but by Sacchini, whose principal study and practice, during youth, were likewise bestowed on the violin.

It was the opinion of the Hon. Horace Walpole, afterwards earl of Orford, that Mr. Gray first brought the compositions of Pergolesi into England. His opera of *Olimpiade* was first performed on our stage in 1742, when Monticelli acquired uncommon applause in the air, "Tremende oscuri atroce," and the scene where the "aria parlante: Se cerca se dice" occurs; which, though it has often been set since to more elaborate and artificial music, its effect has never been so truly dramatic; all other compositions to those words are languid on the stage, and leave the actor in too languid a state for his situation. When we mentioned this opinion to Pacchierotti, in a conversation on the subject, he very well applied our English vulgar phrase to Pergolesi, by saying, "He had hit the right nail on the head."

The words "Tremende oscuri atroce," are not Metastasio's, nor have we ever been able to discover whose they are, or how they happened to be set by Pergolesi; the air, however, "A due cori," is admirable.

From all the information which we were able to procure at Rome and Naples, concerning the premature death of Pergolesi, there does not seem the least foundation for the story concerning his having been poisoned. The disease of which he died was a consumption, that preyed upon his lungs during the last five or six years of his existence, and the most active and important of his life. As envy was said to have stimulated his concurrents to have recourse to poison in order to get rid of so formidable a rival, it has been well observed, that the success of Pergolesi's productions was never sufficiently brilliant to render him such an object of envy to his brethren as to make it necessary to dispatch him by unfair means. Mem. sur la Vie et les Ouvrages de Pergolesi, par M. Boyer, Mercure de France pour Juillet, 1772, p. 191.

The art of music, however, did not die with Pergolesi, as may be seen by the list of his successors, who, pursuing the track which Vinci, Haffé, and Pergolesi first had traced out, have advanced into new regions of invention, taste, grace, elegance, and grand effects.

We were assured at Rome, by a musician who had known Pergolesi personally, that he was a slow workman; "but the gods sell to mortals," says Epicharmus, "all that is great and beautiful at the price of immense labour;" *παντα χαλπιπα τα καλα*.

Salvini tells us that the celebrated composer Carissimi, being praised for the grace and ease of his melodies, used to cry out: "Ah! with what difficulty is this ease required!" *Ah! questo facile, quanto è difficile!*

He had perhaps more energy of genius, and a finer taste, than any of his predecessors: for though no labour appears in his productions, even for the church, where the parts are thin, and frequently in unison, yet greater and more beautiful effects are often produced in performance than are promised in the score. And, indeed, it frequently happens, that a score in which the texture of the parts is very ar-

tificial, ingenious, and amusing to the eye, affords nothing but noise and confusion to the ear. As the Italians in the sixteenth century were the masters to all Europe in elaborate composition, even to a pedantic excess, so they have been the first, in modern times, to abjure its absurdity.

The ease and simplicity of Vinci's and Pergolesi's style, were soon imitated with servility by men of no genius, who always appear more contemptible in light than laboured strains; and these, pushing facility to an insipid excess, soon rendered opera music proverbially flimsy and frivolous. Of this number were Lampugnani, Pescetti, Pelegrini, Giacomelli, Paleazzi, Schiassi, Pampani, and many others.

The church music of Pergolesi has been censured by his countryman, Padre Martini, as well as by some English musical critics, for too much levity of movement, and a dramatic cast, even in some of his slow airs; while, on the contrary, Eximeno says, that "he never heard, and perhaps never shall hear, sacred music accompanied with instruments, so learned and so divine, as the *Stabat Mater*."

As the works of this master form an era in modern music, and as general praise and censure is seldom just and satisfactory to discriminating minds, it was our intention to have inserted here some critical remarks resulting from a late careful examination of his principal productions for the church; but upon calculating the business which we have still on our hands before we arrive at the end of the gigantic labour which we have, perhaps, too rashly undertaken; we find that critical discussion must give way to matters of fact, or our volumes will be rendered too numerous or too unwieldy.

Of the sonatas ascribed to Pergolesi, for two violins and a base, if they are genuine, which is much to be doubted, they will not bear comparison with the bold, varied, and elegant compositions of Boccherini, Haydn, Mozart, and Vanhal. They are composed in a flimsy style, which was worn out when Pergolesi began to write; at which time another was forming by Tartini, Veracini, and Martini of Milan, which has been since polished, refined, and enriched with new melodies, harmonies, modulation, and effects.

No fair and accurate judgment can be formed of the merit of a composer of past times, but by comparing his works with those of his predecessors and immediate competitors. The great progress that has been made in instrumental music, since the decease of Pergolesi, will not diminish his reputation, which was not built on productions of that kind, but on vocal compositions, in which the clearness, simplicity, truth, and sweetness of expression, justly entitle him to supremacy over all his predecessors and contemporary rivals, and to a niche in the temple of Fame, among the great improvers of the art, who, if not the founder was the principal polisher of a style of composition both for the church and stage, which has been constantly cultivated by his successors, and which at the distance of 70 years from the short period in which he flourished, still reigns throughout Europe.

PERGUBA, in *Geography*, a town of Russia, in the government of Olonetz; 64 miles N. of Petrozavodsk.

PERGULARIA, in *Botany*, so called from *pergula*, a balcony, or trellis, in allusion to its twining habit and fragrant blossoms, which render this genus very desirable for bowers. Rumphius first gave the name of *Flos pergularis* to the Linnæan *Pergularia glabra*, which however does not answer to the generic character, and is established by Mr. Brown as a distinct genus, under the appellation of *Vallaris*, adopted from Burmann's Fl. Ind. 51. The true Linnæan *Pergularia* is founded on our first species, hereafter described. Linn. Mant. 8. Brown Asclep. in Tr. of Wern. Soc. v. 1.

31. Ait. Hort. Kew. v. 2. 83. Schreb. 167. Willd. Sp. Pl. v. 1. 1247. Juss. 146. Lamarck Illustr. t. 176?—Clafs and order, *Pentandria Digynia*. Nat. Ord. *Contortæ*, Linn. *Apocineæ*, Juss. *Aſclepiadeæ*, Brown.

Gen. Ch. Cal. Perianth inferior, of one leaf, in five erect, acute, permanent ſegments. Cor. of one petal, ſalver-shaped; tube inflated, various in length; limb in five oblong, horizontal, ſlightly twisted ſegments. Crown of the ſtamens of five compressed erect leaves, undivided at the ſummit, concave at the back, furniſhed with the pointed appendage at the inſide. Neſtary a row of glands round the baſe of the germen. Stam Filaments five, oblong, dilated, flat, cloven at the top and bottom; anthers ſeffile, membranous, of two cells; maſſes of pollen erect, ſtalked, ſoon depoſited in pairs on the glands of the ſtigma. Piſt. Germens two, ovate; ſtyles very ſhort; ſtigma common to the two, conical, obtuſe, downy, with five lateral glands receiving the maſſes of pollen. Peric. Follicles two, ovate, ſmooth. Seeds numerous, comole.

Eff. Ch. Corolla contorted, ſalver-shaped; its tube inflated. Crown of five compressed undivided leaves, with an internal appendage. Anthers ſurmounted by a membrane. Maſſes of pollen ten, ſmooth, erect. Stigma pointleſs. Follicles inflated.

1. *P. oſoratiffima*. Sweet Green Pergularia, or Chineſe Creeper. Sm. Ic. Piſt. t. 16. Andr. Repof. t. 185.—Leaves heart-shaped, pointed, rather downy. Panicles axillary. Calyx ſhorter than the tube of the corolla. Sir Joſeph Banks is ſaid to have ſent this to Kew about the year 1784. It is cultivated in China, as a favourite bower plant, though of what precise country a native is not known. We have been told it is wild in Sumatra. The late Lady Amelia Hume received a fine plant of this ſpecies in 1789, which covered the ſtern of the ſhip with its fragrant green bloſſoms, during a great part of the voyage, and has ſince been widely propagated in this country. It thrives either in a ſtove or warm conſervatory, flowering throughout the ſummer and autumn, and exhaling, in an evening, that peculiar, light, lemon-like, but luſcious fragrance, of which the Chineſe are ſo fond, and which belongs to various greeniſh night-ſcented flowers, as the *Chloranthus inconſpicuus*, and ſome *Orchidææ*. The root is branched, widely ſpreading. Stem ſhrubby, round, branched, twining and climbing to a great extent; downy when young; the bark ſpongy and cracked when old. Leaves oppoſite, ſtalked, deflexed, heart-shaped, rather taper-pointed, entire, opaque, veiny, downy at the veins and margin, paler beneath, each two or three inches long. *Stipulas* none, but the *footſtalks*, much ſhorter than the leaves, are glandular at their ſummit, as well as on each ſide at the baſe. *Panicles* axillary, ſolitary, drooping, forked, many-flowered, downy. *Bractææ* lanceolate, at each diviſion of the panicle. *Flowers* the ſize of a primroſe, pale yellowiſh-green, bearded within, their ſegments linear-oblong, oblique, the length of the tube, fringed.

Linnaeus had in his herbarium a Chineſe ſpecimen of this plant, marked *toncatofa*, with a note at the back ſignifying that the Catholic clergy at Macao prepare, from its milky juice, a medicine for the dyſentery. He cultivated the ſame in his ſtove, and deſcribed it in his *Mantiſſa*, 53. The name and ſpecific character however do not apply to this, but to a very different plant, Forſkall's *Aſclepias cordata*. Flos ſiamicus, Rumph. Amb. aëtuar. v. 7. 58. t. 26. f. 1, ſeems to be intended for our preſent ſpecies; though *Cynanchum odoratiſſimum*, of Loureiro, by the deſcription of the yellow flowers, probably belongs rather to the following.

2. *P. minor*. Sweet Yellow Pergularia, or Weſt-Coaſt

Creeper. Andr. Repof. t. 184. Curt. Mag. t. 755. (*Cynanchum odoratiſſimum*; Lonreir. Cochinch. 166?)—Leaves heart-shaped, obtuſe with a point. Panicles axillary. Calyx nearly as long as the tube of the corolla.—Native of the Eaſt Indies, where it is cultivated for the ſame reaſon as the foregoing. By dried ſpecimens, we could hardly diſcern any ſpecific difference between theſe two plants, but when compared alive, they appear to be diſtinct ſpecies. Beſides what is noted in the ſpecific character, the preſent is rather ſmaller in all its parts, with fewer flowers in each panicle. The *corolla* has broader and blunter ſegments, of a tawny yellow on their upper ſurface, though not ſo round and orange-coloured as Mr. Andrews exhibits them. *P. minor* was introduced into England by ſir Joſeph Banks in 1784, and blooms in a ſtove all ſummer long.

3. *P. purpurea*. Purple Pergularia. Vahl. Symb. v. 3. 44. Willd. n. 4. (*Aſclepias cordata*; Burm. Ind. 72. t. 27. f. 2.)—Leaves heart-shaped, taper-pointed, ſmooth. Panicles terminal. Calyx much ſhorter than the tube of the corolla.—Native of Java. We know it but from Burmann's work. He ſays the *ſtem* is erect, and *flowers* purple, in terminal umbels or panicles. Mr. Brown has not examined the fruſtification of this or the following, and merely ſays they “may belong to *Pergularia*.”

4. *P. japonica*. Japan Pergularia. Thunb. Jap. 111. Willd. n. 5.—Leaves heart-shaped, ſmooth. Umbels ſimple, axillary. Calyx longer than the tube of the corolla.—Gathered by Thunberg near Nagafaki in Japan, flowering in Auguſt. *Stem* twining, ſimple, ſmooth. *Leaves* acute, ribbed, an inch long. *Footſtalks* ſhorter, ſmooth. *Umbels* erect. *Stigma*, according to Thunberg, terminating in a long, erect, white, wavy, tapering thread, the length of the *corolla*, which is rather contrary to the generic character.

Another ſpecies may be found in Willdenow, *P. edulis*, Thunb. Prodr. 38, diſcovered at the Cape of Good Hope, and ſaid to have an herbaceous *ſtem*, with ovate *leaves*. Of this we know nothing. Mr. Brown excludes it.

PERHAY, POINT DE, in *Geography*, a cape on the W. coaſt of France; 6 miles S.E. of Point St. Matthew.

PERHO, a town of Sweden, in the government of Waſa; 56 miles E. of Jacobſtad.

PERI, JACOPO, in *Biography*, a native of Florence, the principal inventor of recitative, and the compoſer of “*Euridice*,” written by Rinuccini, the *fiſt opera* that was compoſed in *ſtilo rappreſentivo*. This drama, written and ſet to a new ſpecies of muſic for the royal nuptials of Mary of Medicis with Henry IV. of France in 1600, was publicly exhibited at Florence in the moſt ſplendid manner, and in which Peri, the compoſer, performed a vocal part.

Peri is ſaid by Battiſta Doni to have been not only a good compoſer in the new ſtyle, but a famous ſinger and performer on keyed inſtruments.

PERIA, in *Geography*, a town of Perſia, in the province of Irac; 90 miles W. of Iſpahan.

PERIAC, a town of France, in the department of the Aude, celebrated for its ſalt works; 6 miles S.W. of Narbonne.

PERIACULTUM, a town of Hindooſtan; 30 miles S.S.W. of Dindigul.

PERIADA, in *Ancient Geography*, a town of Greece, in the iſle of Eubœa. Strabo.

PERIAGOGE, περιγογη, in *Rhetoric*, the ſame with peribole.

PERI-AGRARUM, in *Geography*, a town of Hindooſtan, in Coimbatore; three miles W.N.W. of Erroad.

PERIAGUA, in *Sea Language*, a ſort of large canoe, uſed

uled in the Leeward islands, South America, and the gulf of Mexico.

This is composed of the trunks of two trees hollowed and united together; and thus differs from the canoe, which is formed of one tree. See *BOAT*.

PERIAMMA, a word used by some medical writers to express an amulet.

PERIAMOODY, in *Geography*, a town of Hindoostan; 30 miles W.S.W. of Dindigul.

PERJAN, a town of Grand Bucharia; 34 miles E.S.E. of Anderab.

PERIANDER, in *Biography*, a tyrant of Corinth and Corcyra, was the son of Cypselus, who before him had obtained an unjust authority over his fellow-citizens. Perian-der succeeded him about the year B.C. 628, and in order to secure his power put to death the principal persons in Corinth. In almost every other respect he well merited the title of tyrant, which has ever been attached to his name; but he was very inimical to that luxury which involved the inhabitants of the city, and he kept the country in peace by means of his fleet which gave him the controul of the sea. He is also applauded for not having imposed taxes upon his people, excepting those which resulted from the export and import of merchandize. His private life was stained with enormous crimes, with a detail of which we will not fully our pages. He banished his son Lycophon to Corcyra, for shewing an abhorrence of the cruelty inflicted on his mother, but in his old age he sent to recall him, in order to govern Corinth in his stead, while he himself intended to retire to Corcyra. The people of that island prevented the exchange by putting the prince to death. Periander took a just and ample revenge on the savage perpetrators of the deed; but not contented with this, he indulged the most cruel resentment on the innocent, by sending three hundred youths of the best families to be made eunuchs by king Alyattes of Sardis. These victims to royal madness, stopping by the way to Samos, were rescued by the people, and it has been asserted that the chagrin occasioned to Periander by the disappointment, caused his death, at the age of 80, in the year B.C. 584. He was a man of great talents, and an inscription on his tomb at Corinth, preserved by Laertius, proves that his country regarded him as a wife and able ruler. He was traditionally reckoned among the seven wise men of Greece, and some of his maxims, which are rather prudential than moral, seem to justify the title. The maxim most known is, "There is nothing which prudence cannot accomplish."

PERIANTH, *PERIANTHIUM*, in *Botany*, from *περι*, about, and *ανθος*, a flower, is the most usual sort of *CALYX*, see that article, which is immediately contiguous to, or more properly makes a part of, the flower. Such are the five green leaves, with their urn-shaped base, in the rose; and the tubular cup of a pink, including the scales at its base. In this last instance the perianth may be called double; and is avowedly so in most of the mallow tribe, while in the scabious it is triple. When the term calyx is used without any particular explanation, it means a perianth.

This part is either deciduous, as in the poppy, or permanent, as in the pink. In many instances it becomes enlarged, thickened, or hardened, crowning or enveloping the fruit. Its situation is either *inferior*, below the germen, or *superior*, above that part. The petals and stamens are sometimes inserted into it, as in the strawberry. (See *PERIGYNOUS Insertion*.) Its forms are infinitely various, on which the characteristic distinctions of many genera depend. In some instances it is divided, more or less deeply,

in others undivided; in some it is of one leaf, in others of several. Its form is either regular or irregular; its divisions equal or unequal. Compound flowers have a common perianth. The hue of the part in question is usually green; but not unfrequently otherwise, in which last case only it is technically said to be coloured. Many flowers have no perianth, as the tulip, which is destitute of any calyx at all; and the narcissus, which has another kind of calyx, the sheath, or *spatha*. Some, as the umbelliferous tribe and the genus *Euphorbia*, are esteemed by Linnæus to have an involucre as well as a perianth; but we would rather use the term bractea for any external covering, or accompaniment, of a flower furnished with a real perianth.

When Linnæus and Magnol are said to have adopted a method of classing plants by the calyx, the former took into consideration, not only all his seven kinds of calyx, for that purpose, but also what he subsequently called corolla in grasses; and in his subdivisions is obliged to have recourse to the petals and stamens. Magnol takes a still wider and unauthorized range, though founded on the ideas of ancient authors. He terms the perianth the external calyx, the pericarp the inner. (See *PERICARP*.) He insists on the presence of a calyx in every case, applying that name to whatever *incloses* or *supports* the flower; so that it may mean the mere summit of a flower-stalk. The corolla is employed by this author, as well as by Linnæus, to form subdivisions of some of his principal classes.

PERIAPAT, in *Geography*, a town of Hindoostan; 27 miles N.E. of Coimbatore.

PERIAPATAM, a town of Hindoostan, in Mysore; taken in 1791 by the British army under general Abercromby; 24 miles S.W. of Seringapatam. N. lat. 12° 15'. E. long. 76° 31'.

PERIAPATTAM, a town of Hindoostan, in the Carnatic; 20 miles N.W. of Madras.

PERIAPTON, *περιπτον*, a kind of medicine, otherwise called *periamna*, or *amulet*; which, being tied about the neck, is supposed to prevent, or cure diseases.

PERIBOACA, in *Geography*, a river of Canada, which runs into the lake of St. John, N. lat. 48° 32'. W. long. 72° 20'.

PERIBOLE, in *Medicine*, a word used very frequently by Hippocrates, and in different places, in very different senses. Sometimes it signifies a translation of the humours from one part to another; sometimes only the dress or garments of a patient. In the first of these senses, the word is frequently used to express a translation of the morbid matter from the centre to the surface, in the termination of a disease, by the breaking out of pustules all over the body.

PERIBOLE, *περιβολη*, in *Rhetoric*, is used where many things are accumulated into one period; which might have been divided into several. We have an instance in Cicero's defence of Flaccus: "Quod si esset aliquando futurum, ut aliquis de L. Flacci pernicie cogitaret; nunquam tamen existimavi, judices, Decium Lælium, optimi viri filium, optimam ipsum spe præditum, summæ dignitatis, eam suscepturum accusa ionem, quæ sceleratorum potius civium odio, & furori, quam ipsius virtuti, atque institutæ adolescentiæ, conveniret."

Now this long period might very well have been divided into the three following: "1. Quod si esset aliquando futurum, ut aliquis de L. Flacci pernicie cogitaret; nunquam tamen existimavi, judices, Decium Lælium, eam suscepturum accusationem. 2. Est enim is optimi viri filius, optimam ipse spe præditus, summæ dignitatis. 3. Accusatio vero hæc sceleratorum potius odio et furori, quam ipsius virtuti

tuti atque institutæ adolescentiæ, conveniret." See PUNCTUATION.

PERICA, in *Geography*, three small islands in the bay of Panama, which give shelter to ships, out of the command of the town of Panama.

PERICALAMITES, in the *Materia Medica of the Ancients*, a name given by some to the *adarce*.

We find the word pericalamitis in a prescription recorded in Galen, and it has generally been understood to mean *Syrax*, that being called *calamita*: but the *adarce* is the thing signified by the name, which expresses its manner of formation, it being always found concreted about the stalks of reeds that grow on the edges of waters.

PERICARDIARY, an epithet given to worms generated in the pericardium, or capula of the heart.

M. Andry makes these one of the twelve kinds of worms engendered in the human body: they sometimes occasion convulsions, the paroxysms of which last but a little while, but return incessantly.

These worms are accompanied with a frightful paleness of the face, a low pulse, and violent pains of the stomach and breast.

They sometimes occasion a palpitation of the heart. M. Andry adds, that they have been known to occasion sudden death.

PERICARDITIS, in *Medicine*, signifies an inflammation of the *pericardium*, or membranous bag which surrounds the heart.

The symptoms which accompany an inflammation of the pericardium cannot be distinguished in practice from those which attend inflammation of the substance of the heart itself. In fact, the inflammations of both parts are often combined: for whenever the inflammation of the pericardium is violent, it extends to the muscular substance of the heart, to a considerable depth. The symptoms, which have been observed, are, the general affection of the system called fever; pain in the region of the heart, which is often, but not always, attended with palpitations, and with an irregular pulse, cough, difficulty of breathing, and sometimes syncope. But all these occur in inflammation of the heart. See CARDITIS.

PERICARDIUM, in *Anatomy*, (from *περι*, *about*, and *καρδια*, *the heart*;) the membrane surrounding the heart. See HEART.

PERICARP, PERICARPIUM, in *Botany*, from *περι*, *about*, and *καρπος*, *fruit*, (or more strictly, *seed*;) the seed-vessel. This is formed of the enlarged germen, and is extremely various in different plants. It is not necessarily always present, there being many tribes of plants in which the seeds are naked, and guarded only by the integuments of the flower. The latter in such cases not only enfold the seed, but in some instances so entirely assume the nature of a pericarp, as to become juicy and coloured; witness *Commelina Zannonia*, and the mulberry with its allies. Several genera of grasses are distinguished from others by the firm union of their hardened corolla to the seed, which takes place as the latter advances to maturity.

The use of the pericarp is to protect the seeds till ripe, and then, in some way or other, to promote their dispersion. It is curious to observe how admirably the very same part is contrived, to answer these opposite intentions. This is generally accomplished on hygrometrical principles. While moist or juicy, the valves remain closed; but in drying, they split or fly asunder; thus moreover, by an elastic action, assisting in the dispersion of their contents; and that in a dry state of the atmosphere, which is most favourable to the sowing of seeds in general. An exception to

this rule has been observed, in some annual species of *Mesembryanthemum*, natives of the sandy country of Africa, where the arid soil but rarely enjoys the benefit of rain. The capsules of these expand by means of wet alone, when the elastic valves, of each separate cell, project their seeds to a distance, to take advantage of a favourable moment for vegetation, that might not soon occur if they were sent abroad during the dry season.

Juicy pericarps commonly serve for the food of animals, more especially birds, in whose dung their seeds are deposited, at a distance from the spot where they grew, and in a condition peculiarly favourable for vegetation.

The different kinds of pericarp will be found under the different articles of CAPSULE, FOLLICLE, LEGUME, BACCA, DRUPA, POMUM, SILIQUA, STROBILUS. Hence genera, and occasionally even natural orders, derive some of their most important marks of distinction.

PERICARPIA, *περικαρπια*, compounded of *περι*, *about*, and *καρπος*, *the wrist*, a name sometimes given to medicines that are applied to the wrist: otherwise called *epi-carpia*.

PERICHÆTIUM, in *Botany*, from *περι*, *about*, and *χαίτη*, *a hair or bristle*, is a scaly sheath, peculiar to mosses, which owes its name to its situation around the base of their bristle-like fruit-stalk. It belongs also to the male, or barren, flowers of these plants, and indeed constitutes their calyx in both sexes. The *perichætium* consists of several imbricated leaves, differing, in a more or less striking manner, from the genuine foliage of the plant, either in structure, dimensions, or colour. In *Hypnum* it is of great consequence, constituting, by its presence, a part of the generic character, and assisting powerfully, by its diversities of shape, proportion, or structure, in the discrimination of species. Its duration is remarkable in some instances, even to the extent of three or four years, long after the seed and its pericarp have disappeared; of which we scarcely know an example among the generality of other plants. More frequently it is deciduous, after having accomplished its original purpose of protection to the tender organs which it encloses. See PERIGONIUM.

PERICHAREIA, a word used by the ancients to express a sudden surprise of joy, such as has been frequently known to occasion death.

PERICHONDRIUM, (from *περι* and *χονδρος*, *cartilage*;) the investing membrane of cartilages. See the article MEMBRANE, under the division *fibrous membranes*; and CARTILAGE.

PERICHORESIS. See CIRCUMINCESSION.

PERICHORUS, formed from *περι*, and *χωρα*, *country*, in *Antiquity*, a name given by the Greeks to their profane games and combats, *i. e.* to such as were not consecrated to any of the gods. See GAMES.

Perichorus, in the original, signifies *near*, or *neighbouring*; apparently because none of the people of the neighbourhood attended at these obscure exercises. The champions here did not fight in honour of any god, or hero, as in the others; but only for the prize-stake.

PERICHRISIS, a word used by the ancients for a liment principally of the oleaginous or spirituous kinds, and as thin and fluid as oil.

PERICLISIS, from *περι*, and *κλαω*, *to break*, in *Surgery*, a fracture attended with a considerable wound of the soft parts, and exposure of the bone.

PERICLES, in *Biography*, one of the most illustrious statesmen of ancient Greece, was a native of Athens, and son of Xantippus, a distinguished general, who gained

PERICLES.

the battle of Mycale against the Persians. He received the liberal education that was common among the Athenians of rank. One of his masters was Damon, who, under the pretext of teaching him music, in reality gave him lessons in politics. Another of his masters was the celebrated philosopher Anaxagoras, from whose instructions he gained an acquaintance with the phenomena of nature, that freed him from the effects of the superstitions of the times. Having an insatiable thirst for knowledge, he attended the lectures of Zeno of Elea, a philosopher and formidable disputant. By means of these, and other advantages which his situation in life gave him the command of, joined to excellent natural abilities and solidity of understanding, he acquired an elevation of sentiment, and strength of character, that enabled him long to maintain an almost uncontrolled authority over a people of all the most difficult to manage. The family connections of Pericles were with the aristocracy; but being sensible of the jealousy with which this party was viewed by the body of the people, in whom real power resided, and, moreover, finding the post of head of the nobility pre-occupied by Cimon, he at first held back from public affairs, and employed his talents in endeavouring to obtain the favour and suffrages of the democracy. The manners which he affected were opposite to those of Cimon: those of the latter were splendid and social; but Pericles avoided all entertainments and public amusements: he neither received nor paid any visits of ceremony, and was never seen abroad except in his way to the prytaneum and assembly, and maintained a constant gravity in his demeanour. Not being himself a member of the court of the areopagus, he endeavoured to lessen its authority. The species of eloquence which he adopted was of the lofty and dignified kind; and such were his powers, that he was said to thunder and lighten in his harangues. He was particularly careful to say nothing that might displease the people, and, probably through caution, left none of his orations in writing, though it was known that he wrote them all down before they were delivered. In early life, when the passions are more easily roused to action, he was celebrated for great patience in bearing any insults offered him, a quality which greatly favoured his rise. As an example of this power over his feelings, it is recorded, that having been treated with great outrage at a public assembly, by a simple citizen, who even followed him, at night, to his house, with the most abusive language, Pericles calmly ordered one of his servants to take a torch and light the man home.

When the popular party had procured the impeachment of Cimon, Pericles was appointed one of the conductors; he however acquitted himself with great moderation, and spoke of this great man with the respect due to his character and talents. The exile of his rival gave full scope to his ambitious pursuits. As Cimon had fed and clothed the people, for which he had received disgrace and banishment in return, Pericles, well knowing their passion for public diversions and shows, caused the poorer citizens to be supplied with money out of the treasury to enable them to obtain admission, and he likewise caused them to be paid for their attendance on the courts of judicature. In the war between the Athenians and Lacedæmonians, which broke out in the year B.C. 458, Pericles exposed himself to great danger at the battle of Tanagra, and afterwards unsuccessfully invaded the Peloponneseus, with a fleet and small body of troops. Finding the people desirous of the return of Cimon, he proposed a decree for that purpose; and it is said, through the medium of Elpinice, Cimon's sister, he made a private agreement with that general, that the latter should have the supreme command abroad, while he himself should direct the public affairs at

home. After the death of Cimon, Pericles may undoubtedly be regarded as the master of Athens. He contrived always to occupy the attention of the people, either in sending out new colonies or engaging in expeditions; and by public works, which he set on foot, he both flattered the vanity of the Athenians by the splendour of their city, and provided employment for a number of artists and mechanics of all descriptions. To supply the expences of these grand undertakings, he ventured upon a bold expedient, which was that of removing the public treasures of Greece from Delos to Athens, which violation of national faith he excused, by saying that the money having been raised for the purpose of defence against the barbarians, and the Athenians having by their sole efforts effectually answered this purpose, the allies had no longer any right to demand an account of its expenditure. His personal integrity with respect to pecuniary matters was above suspicion, of which a remarkable instance is recorded. While engaged in an expedition against Eubœa, the Lacedæmonians made an incursion into Attica. Pericles thought it most expedient to avert this storm by money, and accordingly, by means of a large bribe to the tutor of the king of Sparta, procured the return of their troops. When he came to make up his accounts, he charged a sum of ten talents, as "laid out in a fit manner upon a proper occasion;" and the Athenians passed the article without farther explanation. Pericles in his invasion of Eubœa, he made himself completely master of that important island in the year B.C. 447, and soon after concluded a truce of thirty years with the Lacedæmonians. Upon the occasion of a large present of corn to the Athenians by the king of Egypt, a law, which Pericles had procured to be passed, disfranchising all Athenians of half-blood, was enforced with such rigour, that 5000 persons, hitherto considered as freemen, were sold as slaves. This arbitrary act displays the great power of Pericles, but probably was not disagreeable to the majority of the citizens, whose consequence was increased by the diminution of the number. A war between the Athenians and Samians took place B.C. 440, which is said, in part, to have been produced by the influence of Aspasia and Pericles. It was on his return from the war that he pronounced the funeral oration which was ascribed to Aspasia, and which was so grateful to the Athenians, that the women crowded round him, and placed garlands on his head. After Thucydides had been sentenced to banishment, in the party contests of Athens, the authority of Pericles became still more overbearing, and at length excited the jealousy of the Athenians. Some of his friends were prosecuted: Anaxagoras, his revered preceptor, underwent a charge of irreligion. Aspasia was publicly accused both of impiety and of favouring the illicit amours of Pericles. He pleaded her cause in person, and procured her acquittal, and he prevented any personal attack upon Anaxagoras, by sending him out of Attica, himself accompanying him, as well to shew him a marked personal respect, as to save him from the rude attacks of the people. When the Spartans, taking part with the small states of Greece, sent their demands of reparation of injuries to Athens, denouncing war in case of refusal, Pericles, in a speech which is preserved by Thucydides, persuaded the Athenians to reject the conditions, and was thus the cause of the Peloponnesian war. His conduct was ascribed by some persons to the purpose of finding his countrymen so much employment, that they should not be able to attend to the accusations which his enemies were preparing against him; and a story to this effect is related by Plutarch, that young Alcibiades, seeing Pericles one day very thoughtful, and asking the reason, was told by him, that he was at a loss how to account for the public-money which had passed through

through his hands: then, said Alcibiades, "study to give no account at all."

When the war began B.C. 431, it was the advice of Pericles that the Athenians should neglect the defence of their estates in the country, and turn all their attention to fortifying the city, and equipping fleets. In pursuance of this policy, when he was appointed to the command, he suffered the superior army of the Spartans and their allies to advance without opposition, unmoved by the murmurs of the Athenians; but at the same time sent a powerful fleet to the coasts of Peloponnesus, and to Locris and Ægina, which more than retaliated the ravages committed in Attica. At the conclusion of the campaign, he exercised his powerful eloquence in a funeral oration for those who had fallen in the service of their country. In the next year began the memorable plague of Athens, and it required all the fortitude of Pericles to support his own spirits, and infuse courage into the hearts of his countrymen. From this time he underwent many mortifications, but his firmness did not on that account forsake him. At length, however, domestic calamity, united with public disaster, completely overwhelmed him. His eldest son Xantippus, who had lived on ill terms with his father, died of the plague, and the dreadful disease carried off the sister of Pericles, and almost all his relations and intimate friends. In short, Paralus, his only remaining son, by his first wife, also died; and at the funeral, as he was placing a wreath of flowers on the head of the corpse, he burst into tears, and withdrew in an agony of grief. The Athenians, to soothe him, repealed his own law for disfranchising children of the half-blood, and he enrolled as a freeman his son by Aspasia. But his end was now drawing near, and his faculties were well nigh impaired. He fell into a lingering illness, which enfeebled both his body and mind, still however the lamp was not entirely extinguished. Some vigour of intellect remained to the last; for when he lay near expiring, and his friends round his bed-side were enumerating the great actions of his life, he suddenly raised himself on his bed, and addressing them, said he wondered they should dwell upon circumstances in which fortune had the chief share, and which were common to him with many others, and forget that which was his peculiar glory, *viz.* "that no Athenian had ever put on mourning on his account." He died in the year B.C. 429. His character has been thus drawn: "though by no means a man of strict virtue, Pericles had many features of greatness. His philosophical education enlightened his mind, and raised him above the prejudices of the age. Of his happy application of this superiority the following instance is mentioned. As he was going on board his galley to take the command of the fleet, an eclipse of the sun took place, which terrified his pilot so as to render him incapable of his duty. Pericles, perceiving his embarrassment, pulled off his cloak, and wrapping it round the man's head, asked him if there were any thing ominous in being thus deprived of light? the man replied in the negative: then, said he, what difference can you make between this darkness and the other, except that which shades the sun is bigger than my cloak? The pilot felt the comparison, and was cured of his fear. The administration of Pericles is particularly memorable for the magnificent decorations it conferred on the city of Athens. Vast sums were undoubtedly lavished on those subjects, but they stamped that character of refined art upon Athens, which she retained after she had lost all her political distinction. Pericles was less excusable in fostering that high ambition and spirit of aggrandisement in his countrymen, which was the cause of their greatest disasters, and he too much favoured that corruption of manners of which he himself participated. Univer. Hist. Plutarch.

PERICLESE, in *Ecclesiastical Music*, a term in canto fermo. It implies the interposition of one or more notes in the intonation of certain chants, in order to arrive at the final close, and to inform the choir that they have to pursue and finish the rest. This, in secular music, would be called a cadence.

PERICLYMENUM, in *Botany*, *περικλυμένον*, an ancient name for some climbing shrub, has generally been applied to the common British Honeyfuckle (*see* LONICERA); or to other species of that genus.

PERICNEMIA, a word used by some medical writers for the parts about the calf of the leg.

PERICO, in *Geography*, a town of South America, in the province of Tucuman; 15 miles S. of St. Salvador de Jugue.

PERICONIA, in *Botany, a genus of *Fungi*, so named by Tode, from *περι*, *about*, and *κονις*, *powder*; because it is entirely surrounded, when ripe, with its own dusty seeds. Tode Fung. Mecklenb. v. 2. 2. Perf. Syn. 686.—Class and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi*.*

Ess. Ch. Stalk rigid, simple, terminating in a dry sari, naccous head.

The species are three. 1. *P. lichenoïdes*, Tode, t. 8. f. 61. This is found in summer on the stems of plants, and proceeds from a black crust-like base, so as very nearly to approach the nature of that genus of *Lichenes* called *Calicium*; 2. *P. byssoides*; and 3. *P. steemonitis*, both found likewise on the stems and branches of plants.

PERICRANIUM, from *περι* and *κρανιον*, *the skull*, in *Anatomy*, the periosteum of the skull.

PERIDIUM, in *Botany, a term introduced by Perfoon, for the round, membranous, dry case of the seeds, in some of his first section of *Fungi*, the *Angiocarpi*, which bear their seeds internally, and not throughout the surface of an expanded membrane called **HYMENIUM**; see that article.—The various kinds of Puff-ball, *Lycoperdon* and its allies, afford good examples of a *Peridium*.*

PERIDONIUS LAPIS, in *Natural History*, a name given by some of the writers of the middle ages to the *pyrites*, which they call also *pyrithe*.

PERIDOT, in *Mineralogy*. See **CHRYSOLITE**.

PERIDOT Granuliforme of Haüy. See **OLIVIN**.

PERIDROME, **PERIDROMUS**, in the *Ancient Architecture*, the space or an isle in a periptere, between the columns and the wall.

Salmassius observes, that the peridromes served for walks among the Greeks.

PERIDROMIDES, *Περιδρομίδης*, in *Antiquity*. See **XYSTI**.

PERIDROMOS, a word used by the old Greek writers to express the extreme edge of the hairs of the head, when hanging down in their natural form.

PERIEGETES, *Περιηγέτης*, a Greek term, signifying a person who leads or conducts another about a thing, to shew it him, &c.

It is applied in antiquity to geographers; especially to those who described the sea-coasts: thus Dionysius is styled *periegetes*, for publishing a geography in hexameter verses, which Eustathius has commented on, both in Greek.

The name *periegetes* was also given to those who conducted strangers about in cities, to shew them the antiquities, monuments, curiosities, &c. thereof. These were the same with what they now call the antiquaries in Italy.

PERIERS, **BONAVENTURE DES**, in *Biography*, a French writer, was born at Arnai-le-Duc, in Burgundy. In 1536 he became valet-de-chambre to Margaret of Valois, sister of Francis I. He published several translations and other pieces,

pieces, in verse and prose; but he is chiefly noted for his work, entitled "Cymbalum Mundi," written first in Latin, and translated by himself into French, under a fictitious name, first printed at Paris in 1537 by Morin, who was imprisoned on account of it. This work consists of four dialogues in the Lucianic style, ridiculing the follies and false opinions of mankind. It has been charged with gross impiety, upon the supposition, that under the appearance of laughing at the heathen theology, it meant to mask an attack upon Christian mysteries, and religion in general. It was censured by the theologians of Paris, and ever after passed as a prohibited, or at least a scandalous work, on which account it became very rare, and much sought after by the curious. It is said the author of it made an unhappy end, by falling on his sword in a fit of despair. Moreri.

PERIERS, in *Geography*, a town of France, in the department of the Channel, and chief place of a canton, in the district of Coutances; 8 miles N. of Coutances. The place contains 2557, and the canton 10,255 inhabitants, on a territory of 140 kilometres, in 16 communes.

PERIESTECOS, in *Medicine*, an epithet for diseases, signs, and symptoms, which are salutary, and prognosticate the future better health of the patient.

PERIGÆUM, PERIGEE, formed of *περι* and *γη*, earth, in *Astronomy*, that point of the sun's or moon's orbit, wherein they are at their least distance from the earth.

In which sense perigee lands opposed to apogee.

PERIGEE, in the *Ancient Astronomy*, denotes a point in a planet's orb, wherein the centre of its epicycle is at the least distance from the earth.

PERIGNAC, in *Geography*, a town of France, in the department of the Lower Charente; 10 miles S.E. of Saintes.

PERIGONIUM, in *Botany*, a more recent term than *Perichætium*, invented by Linnæus for the same part in Mosses, the scaly leaves investing the flowers. It is derived from *περι*, about, and *γεννη*, generation, and being common to the flowers of those plants in general, whether male or female, united or separated, the author judged it more proper than a word which literally applied only to the leaves that surround the fruit-stalk. (See *PERICHÆTIUM*.) There is however no end of thus changing terms, when once generally established; and the inconveniences of such a measure, greatly counterbalance any possible advantages. This improved denomination conveys no new idea, nor additional information, but rather less; for it is, in its meaning, ambiguous, as applicable to both *calyx* and *corolla*; whereas these plants possess a distinct and peculiar *corolla* in their *calyptra*, which is equally a *perigonium*, as encompassing the flower during impregnation, but not a *perichætium*, because it is removed upwards, as soon as the fruit-stalk, or *bristle*, is formed. *Perichætium* therefore, as an appropriate appellation for the calyx, and for the calyx only, is preferable, in our opinion, to *Perigonium*.

PERIGORD, in *Geography*, a country of France, so called before the revolution; now the department of the Dordogne.

PERIGRAPHE, a word usually understood to express a careless or inaccurate delineation of any thing: but in Vesalius it is used to express the white lines or impressions that appear in the musculus rectus of the abdomen.

PERIGUEUX, in *Geography*, a town of France, and principal place of a district, in the department of the Dordogne, and the capital of Perigord before the revolution; the see of a bishop, and residence of a governor. This place has some remains of antiquities, has an amphitheatre,

a temple of Venus, &c. It is famous for its partridge-pies, which are sent all over Europe. The town contains 5733, and the canton 11,676 inhabitants, on a territory of 140 kilometres, in 10 communes. N. lat. 45° 11'. E. long. 0° 47'.

PERIGYNOUS INSERTION, in *Botany*, from *περι*, about, and *γεννη*, a female, expresses the insertion of the stamens neither above nor below the germen, but into a surrounding part, whether calyx or corolla. Such is the character of the third, sixth, ninth, and fourteenth classes in Jussieu's system. In the first of these instances the author considers such insertion to be into the calyx; as he arbitrarily so denominates the covering of the flower, in all his monocotyledonous classes, whatever its appearance or structure may be, and whether it be single, as in most, or double, as in *Narcissus*, *Tulbaghia*, &c. In the 6th class he assumes a similar principle. In the 9th he considers the insertion to be sometimes into the calyx, sometimes into the corolla. In the 14th the stamens, as well as the polypetalous corolla, are inserted into the calyx.

Mr. Salisbury, in a paper published by the Linnæan Society, in the 8th volume of its Transactions, contends that there is no such thing in nature as an insertion of stamens into the calyx, but that where they proceed from any real integument of the flower, it must be a corolla. This appears to us well made out, with respect to the liliaceous plants. But the most valuable part of Mr. Salisbury's paper is a demonstration that Jussieu has, in various instances, mistaken the origin of the stamens, and that in such they are inserted into the receptacle, which he is pleased to name *torus*, and not into either calyx or corolla. This is the case with the *Atriplices*, *Junci*, and *Polygoni*; while in the *Bicornes*, the corolla, whether it bears the stamens or not, is itself inserted into the receptacle, not as Jussieu supposes, into the calyx, and therefore the plants of that order are neither mediately nor immediately perigynous.

The chief difficulty in the subject before us, and it is one of the most arduous in theoretical botany, respects Jussieu's 14th class. In the plants which compose this class, Mr. Salisbury considers every thing below the line where the stamens are inserted, whatever its appearance, texture, or substance may be, as either a germen, or a receptacle, alias *torus*. We should feel little difficulty in acceding to this decision as far as concerns *Pyrus*, *Mespilus*, *Rosa*, &c.; but it surely would be forcing analogy too far to name the lower part of the deciduous calyx of *Amygdalus* a receptacle, and the teeth only a calyx, though both together are forced off entire, by the swelling germen, nor is there any line of distinction between them. Neither among the *Onagra* of Jussieu, can we bring ourselves to distinguish between the teeth of the calyx, though deciduous, and its tube, in *Epilobium*, or *Fuchsia*. In *Ribes*, whose affinity to *Saxifraga*, so ingeniously pointed out by Mr. Salisbury, we cannot but admit, the whole calyx, bearing the faded petals and stamens, falls off entire. Who can distinguish its lower part from the upper, so as to term one a calyx the other a receptacle? Perhaps these are among the exceptions to which all systematic laws, as applied to nature, are always found liable. We do not point them out for the sake of invalidating an ingenious hypothesis, which we consider as throwing great light upon the subject, at least; but rather as matter of caution. The curious reader may find in the Transactions of the Linnæan Society, v. 10. p. 3—5, and on the subject of calyx and corolla, in *Introductio ad Botanicam*, more than we think it necessary to introduce here, on a matter chiefly hypothetical.

PERIHELIIUM, formed from *περι*, and *ηλιος*, sun, in *Astronomy*,

Astronomy, that point of the orbit of a planet, or comet, wherein it is at its least distance from the sun.

Perihelium stands opposed to aphelium. The ancient astronomers, instead of this term, used *perigæum*; because they placed the earth in the centre.

PERIJA, in *Geography*, a town of South America, in the government of Caraccas; 80 miles S.W. of Maracaybo.

PERILEUCOS, in the *Natural History of the Ancients*, a name given to an agate; but not of a distinct species, but only a particular appearance of the lead-coloured agate, more usually known among them by the name of *phassa-chates*.

PERILLA, in *Botany*, a name of whose meaning or derivation we find no account. Linn. Gen. App. 578. Schreb. 387. Willd. Sp. Pl. v. 3. 83. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 3. 390. Juss. 113. Lamarek Dict. v. 5. 186. Illustr. t. 503.—Class and order, *Didynamia Gynnospermia*. Nat. Ord. *Verticillate*, Linn. *Labiata*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, erect, permanent, cloven half way down into five nearly equal segments, the uppermost very short. Cor. of one petal, irregular, four-cleft; the upper segment emarginate; the lateral ones spreading; the lower longer, obtuse. Stam. Filaments four, simple, distant, shorter than the corolla; anthers cloven. Pist. Germens superior, four; styles two, thread-shaped, joined together, the length of the filaments; stigmas simple. Peric. the unchanged calyx. Seeds four.

Ess. Ch. Upper segments of the calyx very short. Stamens separate. Styles two, joined together.

1. *P. oeymoides*. Balm-leaved Perilla. Linn. Syst. Veg. ed. 14. 533. Willd. n. 1. (*Melissa maxima*; Arduin. Spec. fasc. 2. 28. t. 13.)—Originally obtained by Arduino from India. It was introduced at Kew in 1770, by M. Richard, where it flowers in July and August.—Root annual, branched. Stem erect, herbaceous, three feet or more in height, quadrangular, furrowed, purple when old, rough with hairs. Branches opposite, crossing each other in pairs, short. Leaves opposite, stalked, ovate, rough, veined beneath, acute at each end. Bractæas lanceolate, erect, scarcely hairy. Flowers in spikes at the extremities of the stem and branches, all inclined one way, very hairy, of a white colour. Seeds ovate, rusty-coloured, reticulated.—The whole plant has a strong balsmy fragrance, and may be substituted for the balm of the shops.

PERIM, in *Geography*, a small island in the straits of Babel-Mandeb, about four miles from the coast of Africa, having a good port, but no fresh water. N. lat. $12^{\circ} 36'$. E. long. $43^{\circ} 50'$.

PERIMETER, formed from *περι*, and *μετρον*, *measure*, in *Geometry*, the ambit or extent that bounds a figure or body.

The perimeters of surfaces, or figures, are lines: those of bodies are surfaces.

In circular figures, &c. instead of perimeter, we say circumference or periphery.

PERINÆOCELE, from *perinæum*, and *κελη*, a rupture, in *Surgery*, a rupture, or hernia, in the perinæum.

PERINALDO, in *Geography*, a town of France, in the department of the Maritime Alps, and chief place of a canton, in the district of Monaco; 18 miles E.N.E. of Nice. The place contains 1283, and the canton 4858 inhabitants, on a territory of $57\frac{1}{2}$ kilometres, in 6 communes.

PERINDA, a town of Hindoostan, in Dowlatabad; 23 miles S.E. of Carmulla. N. lat. $18^{\circ} 33'$. E. long. $75^{\circ} 50'$.

VOL. XXVI.

PERINDARY, a town of Hindoostan, in Coimbetore; 5 miles S.W. of Errood.

PERINDE VALERE, in the *Canon Law*, a dispensation granted a clerk, who being legally incapable of a benefice, or other ecclesiastical function, is *de facto* admitted to it.

The perinde valere is a kind of writ, thus called from two words therein signifying the dispensation to be equivalent or tantamount to a legal capacity.

PERINENEUCOS, an epithet given to a peculiar sort of irregular pulse common in hectic patients, in which the artery beats more strongly in some parts than in others. See EPINENEUCOS.

PERINEUM, from *περινειον*, the penis, in *Anatomy*, that part of the body which extends from the organs of generation in either sex to the anus. The space in question is much longer in the male, than in the female; being about four or five inches in the former, one inch, or one and a half in the latter. A roughish line, called the raphe, runs along the middle of it. A few hairs are scattered over it. Some muscles are placed under the skin in this part, and are called muscles of the perineum; these are the transversus, and transversus alter perinei; see INTESTINE; erector penis, see GENERATION; and accelerator urine, see ACCELERATOR. There is also a small artery, called arteria perinei. (See ARTERY.) The perineum is more particularly described in the article GENERATION.

PERINGIANO, in *Geography*, a town of the island of Sardinia; 20 miles S. of Villa d'Iglesias.

PERINGOODY, a town of Hindoostan, in Marawar; 20 miles N.W. of Ramanadporum.

PERINGSKIOLD, JOHN, in *Biography*, a learned Swede, was born in Sudermania, in 1654. He became secretary of antiquities and counsellor to the king of Sweden, and professor at Upsal. He died in 1720. His works are "A History of the Kings of the North;" "History of the Kings of Norway," in two vols. fol.; "Historical and Chronological Tables from Adam to Jesus Christ."

PERINRAPAX, in *Geography*, one of the Laccadive islands, in the Indian sea. N. lat. $11^{\circ} 10'$. E. long. $71^{\circ} 18'$.

PERIOCHA, Περιοχη, an argument, indicating the sum of a discourse.

PERIOD, Περίοδος, in *Astronomy*, the time taken up by a star or planet in making a revolution; or the duration of its course, till it return to the same point of the heavens.

The sun's, or properly the earth's, period is three hundred and sixty-five days, five hours, forty-nine minutes. That of the moon is twenty-seven days, seven hours, forty-three minutes, &c. The periods of the comets are now many of them pretty well ascertained. See COMET.

There is a wonderful harmony between the distances of the planets from the sun, and their periods round him; the great law of which is, that the squares of the periodic times are ever proportional to the cubes of their mean distances from the sun.

For the several periods and mean distances of the several planets, see SOLAR SYSTEM, and each planet respectively.

PERIOD, in *Chronology*, denotes an epocha, or interval of time, by which the years are accounted; or a series of years, whereby, in different nations, and on different occasions, time is measured.

Such are the Calippic and Metonic periods, two different corrections of the Greek calendar; the Julian period, invented by Joseph Scaliger; the Victorian period, &c.

PERIOD, *Calippic*. See CALIPPIC PERIOD.

PERIOD, *Constantinopolitan*. See JULIAN PERIOD.

PERIOD, *Dionysian*. See VIKTORIAN PERIOD.

PERIOD, *Hipparchus's*, is a series of three hundred and four solar years, returning in a constant round, and restoring the new and full moons to the same day of the solar year; according to the sentiment of Hipparchus.

This period arises by multiplying the Calippic period by four. Hipparchus assumed the quantity of the solar year to be 365 days, 5 hours, 55' 12"; and hence concluded, that in one hundred and four years Calippus's period would err a whole day. He therefore multiplied the period by four, and from the product cast away an entire day. But even this does not restore the new and full moons to the same day throughout the whole period: but they are sometimes anticipated 1 day, 8 hours, 23' 29" 20". See **CALIPPIC Period**.

PERIOD, *Julian*, so called as being adapted to the Julian year, a series of seven thousand nine hundred and eighty Julian years; arising by the multiplication of the cycles of the moon, the sun, and indiction, *viz.* 28, 19, 15, into one another; commencing from the first day of January in the Julian year.

The Julian period is also produced by multiplying the Victorian period by fifteen. Since every year in the Julian period has its particular cycles of the moon, sun, and indiction; *e. gr.* only the first has the moon's cycle one, the sun's cycle one, and cycle of indiction one; all the years of this period are accurately distinguished from each other.

This period was invented by Scaliger, as a common receptacle of epochas, to facilitate the reduction of years of a given epocha to those of another epocha likewise given. It agrees with the Constantinopolitan epocha, or period, used by the Greeks, except in this, that the cycles of the sun, moon, and indiction, are reckoned differently; and in that the first year of the Constantinopolitan period differs from that of the Julian period.

To find the year answering to any given year of the Julian period, and *vice versa*, see **EPOCHAS**.

PERIOD, *Metonic*, or *Cycle*. See **CYCLE of the Moon**.

PERIOD, *Victorian*, an interval of five hundred and thirty-two Julian years; which elapsed, the new and full moons return on the same day of the Julian year, according to the sentiment of the inventor Victorinus, or Victorius, who lived in the time of pope Hillary.

Some ascribe this period to Dionysius Exiguus, and hence call it the Dionysian period: others call it the *great paschal cycle*, because it was invented for computing the time of Easter.

The Victorian period is produced by multiplying the lunar cycle nineteen, by the solar circle eighteen; the product of which is five hundred thirty-two. But neither does this restore the new and full moons to the same day throughout its whole duration, by 1 day, 16 hours, 58' 59" 40".

PERIOD, *Chaldaic*. See **SAROS**.

PERIOD, in *Grammar* and *Rhetoric*, denotes a little compass of discourse, containing a perfect sense; distinguished at the end by a point or full stop (.) ; and its members or divisions marked by commas, colons, &c.

De Colonia defines period, a short, but perfect sentence, consisting of certain parts or members, depending one on another, and connected together by some common vinculum.

The celebrated definition of Aristotle is, a period is a discourse which has a beginning, a middle, and an end, all visible at one view.

Rhetoricians consider period, which treats of the structure of sentences, as one of the four parts of composition.

The periods allowed in oratory are three: a period of two

members, called by the Greeks *dicolos*, and the Latins *bimembris*; a period of three members, *tricolos*, *trimembris*; and a period of four, *quadrimembris*, *tetracolos*.

A strict oratorical period does not allow of either more or fewer than these: it is possible indeed to introduce a period of one member, called by Aristotle *monocolos*, or simple period; but it will be reputed a flaw, and is a thing never practised by the masters.

The period may be likewise prolonged to five or six members; but then it changes its name, and, instead of period, commences what they call a *periodical discourse*.

A period of two members Cicero supplies us with: "Ergo & mihi mea pristinae vitae consuetudinem, C. Cæsar, interclusam aperuisti: & his omnibus ad bene de republica sperandum quasi signum aliquod sustulisti."

A period of three members the same Cicero gives us in the exordium of his Manilian oration: "Nam cum antea per ætatem hujus auctoritatem loci contingere non auderem; statueremque nihil huc nisi perfectum ingenio, elaboratum industria, afferri oportere; omne tempus amicorum temporibus transmittendum putavi."

A period of four members he gives us in that admirable description of punishment of parricides: "Ita vivunt, ut ducere animum de cælo non queant: ita moriuntur, ut eorum ossa terram non tangant: ita jactantur fluctibus, ut nunquam abluantur: ita postremo ejiciuntur, ut ne ad saxa quidem mortui conquelescant."

The laws and measures of periods are pretty strictly regarded by orators, at least they are so by the ancient ones: in ordinary discourse, and in the modern tongues, authors are much less severe. In oratory, the members of periods are to be equal, or nearly equal; that the pauses or rests of the voice at the close of each member may be nearly equal: but in writing not intended for rehearsal, this is disregarded.

Common discourse allows of periods both longer and shorter than oratory; which admits of none less than two members, nor greater than four. Short mutilated periods break the stream, and check the course of the sublime; and long ones embarrass and keep the mind too long in suspense; and even strain the voice, which is never to stop but at the ends of periods. Philareus, Hermogenes, Terence, &c. confine the just period, called by the Latins *ambitus* and *circuitus*, to four members; agreeably to the distich:

"Quatuor e membris plenum formare videbis
Rhetora circuitum, five ambitus ille vocetur."

Of which sentiment is Cicero, who in his Orator says, "Constat ille ambitus & plena comprehensio e quatuor fere partibus, quæ membra dicuntur, ut & aures impleat, & ne brevior sit quam satis sit neque longior." An instance of a periodical discourse the same author gives us in the opening of his oration for Archias the poet: "Si quid in me sit ingenii, judices, quod sentio quam sit exiguum; aut si qua exercitatio dicendi, in qua me non inficior mediocriter esse versatum; aut si hujuscæ rei ratio aliqua ab optimarum artium studis & disciplina profecta a qua ego confiteor nullum ætatis meæ tempus abhorruisse; earum rerum omnium vel in primis hæc A. Licinus fructum a me repetere prope suo jure debet."

In the formation of these periods, two things are chiefly to be regarded, their length and cadence. As the length ought to be suited to the breath of the speaker, the ancient rhetoricians scarcely admit of more than four colons. As to the cadence, what Cicero has observed is found true by experience, that the ears judge what is full, and what is deficient; and direct us to fill up our periods, that nothing be

wanting

wanting of what they expect. When the voice is raised at the beginning of a sentence, they are in suspense till it be finished; and are pleased with a full and just cadence, but are sensible of any defect, and are displeas'd with redundancy. Care must, therefore, be taken, that periods be neither deficient, and as it were maim'd, that is, that they do not drop before their time, and defraud the ears of what seem'd to be promis'd to them; nor, on the other hand, offend them by too long and immoderate excursions. This rise and cadence of the voice in pronunciation depend on the nature and situation of the members. In a period of two members, the turn of the voice begins with the latter member. If a sentence consists of three members, the inflexion is best made at the end of the second member. But a period of four members is reckon'd the most complete and perfect, where the inflexion begins at the middle, that is, with the third member. An equality of the members should likewise be attend'd to in the composition of a period, the better to adjust their rise and cadence. And for this reason in sentences of three members, where the cadence begins with the third; or in those of four members, where it begins at the fourth, it promotes the harmony to make the last member the longest. Ward's Or. vol. i. lect. 22. See SENTENCE.

Periods are said to be either *rotundi*, round, or *quadrati*, square, according to their different economy and cadences.

PERIOD, *Square*, is that consisting of three or four equal members, formally distinguished from each other: as that of Cicero on the punishment of parricides.

PERIOD, *Round*, is that whose members or parts are so connect'd, and fitted into each other, as that the junctures or commissures are scarcely seen; but the whole slides equally round, without any notable stops or inequalities. Such are the *dicolos* and *tricolos* of Cicero above mention'd.

PERIOD is also used for the character (.) with which the periods of discourse are terminated and express'd; this is popularly call'd a *full stop*, or *point*. See PUNCTUATION.

Father Buffier observes two difficulties in the use of the period, or point; *i. e.* in distinguishing it from the colon, or double point; and in determining justly the end of a period, or perfect sentence.

It is observ'd, that the supernumerary numbers of a period, separat'd from the rest by colons and semicolons, usually commence with a conjunction. Yet it is certain these same conjunctions sometimes rather begin new periods, than supernumerary members of old ones. It is the sense of things, and the author's own discretion, that must make the proper distinction which of the two in effect it is. No rules will here be of any service, unless this be admitted as one, that when what follows the conjunction is of as much extent as what precedes it, it is usually a new period: otherwise not.

The second difficulty arises hence, that the sense appears perfect in several short detached phrases, wherein it does not seem there should be periods: a thing frequent in free discourse; as, *We are all in suspense: make your proposals immediately: you will be to blame for detaining us longer.* Where it is evident, that simple phrases have perfect senses like periods, and ought to be marked accordingly; but that the shortness of the discourse making them easily comprehended, the pointing is neglected.

PERIOD, *Semi*. See SEMI-Period.

PERIOD, in *Numbers*, is a distinction made by a point or comma, after every sixth place, or figure: and is used in numeration, for the reader distinguishing and naming the several figures or places, which see under NUMERATION.

PERIOD, in *Medicine*, signifies both the paroxysm and the

interval of those diseases, which occur and cease, and again return and go through a similar course, at regular periods of time. See INTERMITTENT.

PERIOD of the *Blood*, *periodus sanguinis*, the circle of the blood, or the tour it makes round the body, for the support of life. See CIRCULATION.

PERIOD of *Perfection*, in *Greek Music*. With respect to the period of greatest perfection in the music of Greece, it is a subject which seems to merit some discussion. Plato, Aristotle, Aristoxenus, and Plutarch, were for ever complaining of the corruption and degeneracy of music. The pious Plato, indeed, regard'd it as fit only for the gods, and their celebration in religious ceremonies, or as a vehicle for religious and moral lectures in the education of youth; and with a methodical spirit censur'd all such as was used in theatres, social festivity, or domestic amusement; but modern divines might, with equal propriety, declaim against the profane use of bread as an aliment, because it is administered in the most solemn rite of our religion. A line should certainly be drawn between the music of the church and of the theatre; but totally to silence all musical sound, except upon solemn occasions, seems to border upon downright fanaticism.

With respect to perfection and depravity, there is nothing so common among musical disputants, as for the favourers of one sect to call that *degeneracy*, which those of another call *refinement*. But Plato seems to have been always too fond of ideal excellence in every thing, to be satisfied with any other.

PERIODEUTA, Περαιοδευτής, a church officer among the Greeks, established by the council of Laodicea, in towns, &c. where there were no bishops.

The *periodeutæ* were a kind of rural deans; so called according to Zonaras, because always on the road, going from one quarter to another, to keep the people in their duty.

Hence Gregory of Thessalonica calls them *ambulantes*, *walkers*. Balsamon calls them *exarchæ*; by which name they are known among the Greeks at this day.

PERIODIC, PERIODICAL, something that terminates and comprehends a period.

PERIODIC, in *Grammar*, is applied to a style, or discourse, that has numbers, or which consists of just and artful periods.

PERIODICAL DISEASES are such as occur, in regular paroxysms, at certain intervals of time. In this sense they are nearly the same as intermittents. See INTERMITTENT.

PERIODICAL *Month*. See MONTH.

PERIODICAL *Winds*. See WINDS.

PERICEI, Περικαιοί, formed from περι, *about*, and οικησ, *I inhabit*, in *Geography*, such inhabitants of the globe as have the same latitudes, but opposite longitudes; or live under the same parallel, and the same meridian, but in different semicircles of that meridian, or opposite points of the parallel.

These have the same common seasons throughout the year, and the same phenomena of the heavenly bodies; but their hours, or times of the day, are opposite to each other. When, *v. gr.* with the one it is mid-day, with the other it is midnight.

PERIOPHTHALMIUM, compounded of περι, *about*, and οφθαλμος, *eye*, in *Natural History*, a thin skin, which birds can draw over their eyes to defend them, without shutting their eye-lids; otherwise call'd the nictitating membrane.

PERJOREE, in *Geography*, a town of Bengal; 10 miles W. of Curruckdeagh.

PERIOSTEUM, from περι, and οστέον, *a bone*, in *Anatomy*, the membrane which covers the bones. See **MEMBRANE**.

The periostrum is liable to inflammation from a variety of causes, and particularly the venereal disease and the scurvy: this generally terminates in an abscess or gangrene: if not speedily removed, the bones will be injured. The cure is, in general, the same as in other inflammations; but the particular intention will be to carry the peccant matter outwards by fomentations and incisions. Cases of this kind generally terminate in amputation.

PERIPATETIC PHILOSOPHY, the system of philosophy taught and established by Aristotle, and maintained by his followers, the Peripatetics.

A specimen of the Peripatetic philosophy, see under **ARISTOTELIAN**.

PERIPATETICS, Περηπατητικοί, a sect of philosophers, the followers of Aristotle, or the maintainers of the Peripatetic philosophy: called also Aristotelians.

Cicero tells us, that Plato left two excellent disciples, Xenocrates and Aristotle, who founded two sects, which only differed in name; the former taking the appellation of Academics, who were those that continued to hold their conferences in the academy, as Plato had done before: the others, who followed Aristotle, were called Peripatetics; from περιπατεῖν, *I walk*; because they disputed walking in the Lyceum; which was a grove in the suburbs of Athens, which had previously been used for military exercises. See **LYCEUM**.

Ammonius derives the name Peripatetic from Plato himself, who only taught walking; and adds, that the disciples of Aristotle, and those of Xenocrates, were equally called Peripatetics; the one Peripatetics of the Academy, the other Peripatetics of the Lyceum; but that, at length, the former quitted the title Peripatetic, for that of Academic, on occasion of the place where they assembled; and the latter retained simply that of Peripatetic.

The greatest and best part of Aristotle's philosophy, (for an account of which, see the biographical article of **ARISTOTLE**;) he borrowed from his master Plato: Serranus affirms confidently, and says he is able to demonstrate it, that there is nothing exquisite in any part of Aristotle's philosophy, dialectics, ethics, politics, physics, or metaphysics, but is found in Plato. And of this opinion are many of the ancient authors, Clemens Alexandrinus, &c.

Gale endeavours to shew, that Aristotle borrowed a good deal of his philosophy, both physical, about the first matter, and metaphysical, about the first being, his affections, truth, unity, goodness, &c. from the sacred books; and adds, from Clearchus, one of his (Aristotle's) scholars, that he made use of a certain Jew, who assisted him therein.

Aristotle, when he withdrew to Chalcis (see his article), was succeeded in the school of the Lyceum by one of his favourite pupils, Theophrastus, whom he appointed to this office in the 2d year of the 114th olympiad, B.C. 323. (See **THEOPHRASTUS**.) Under his conduct the Peripatetic school maintained such high reputation that he had about 2000 scholars. Theophrastus was succeeded by Strato of Lampascus (see **STRATO**), who undertook the charge of it in the 3d year of the 123d olympiad, B.C. 286. After his death this school was continued, in succession, by Lycon of Troas, who enjoyed the friendship of Attalus and Eumenes, and filled the chair till the 138th olympiad; by Aristotle of the island of Cos, whom Cicero characterizes as more distinguished for the elegance of his language than the depth of his philosophy; by Critolaus, a Lydian, who, with Carneades and Diogenes, was deputed by the Athenians on an

embassy to Rome, and who is said to have held the doctrine of the eternity of the world; and by Diodorus, with whom the uninterrupted succession of the Peripatetic school terminated. Of this school *Demetrius Phalereus* was an illustrious ornament, see his article. The Peripatetic philosophy found its way into Rome, in the time of Sylla, with the writings of Aristotle and Theophrastus. However, the obscurity of Aristotle's writings greatly obstructed the progress of this philosophy; and Cicero, who seems to have had some respect for the Peripatetic philosophy, acknowledges that it was understood by very few even of the philosophers themselves. Under the Cæsars, it regained its ancient credit; and from the time of Andronicus, the preceptor of Plutarch, who, with Tyrannio, brought it to Rome, to that of Ammonius, that is, till the time of Nero, the peripatetic doctrines were taught with great purity in its schools. But after Ammonius it began to experience the influence of that spirit of confusion, which prevailed among the Eclectic philosophers; and the plan of Antiochus, who had formerly attempted a coalition between Aristotle, Plato, and Zeno, was revived. From this time the Peripatetic sect was divided into two branches; the one consisting of such as attempted to combine the doctrines of other schools with those of Aristotle; the other, including those who wished to follow more closely the steps of the Stagyræite.

Julius Cæsar and Augustus patronized the Peripatetic philosophy; the former in the person of Sosigenes, the latter in that of Nicolaus. Under the tyrannical reigns of Tiberius, Caligula, and Claudius, it experienced worse fortune; many excellent men of this sect, as well as others, being either banished from Rome, or obliged, through fear of persecution, to remain silent. In the reign of Nero, the philosophers of this sect, as well as others, enjoyed the temporary protection of the imperial court; but after a period of five years, they shared the fate of the professors of magical arts, or, as they were then called, mathematicians, and were again banished the city. During the first century of the Roman empire, we find few celebrated names among the Peripatetic philosophers. The principal are Sosigenes, Boethius, Nicolaus, and Ægeus. About this time Ammonius, the preceptor of Plutarch, attempted to extend the authority of Aristotle beyond the limits of his own sect, by blending the Platonic and Stoic doctrine with the Peripatetic. After his death many Platonists studied the writings of Aristotle, and commented upon them; and thus prepared the way for the formation of the Eclectic sect under Ammonius Saccas, who flourished about a century later than Ammonius the Peripatetic. (See **AMMONIUS** and **ECLECTICS**.) After this time we meet with several genuine followers of Aristotle, of whom the most celebrated was Alexander Aphrodisæus. (See his article.) Among the Eclectic commentators upon Aristotle, we may reckon, besides Porphyry, Jamblichus, Plutarchus, Nestorius, &c., Darippus, Themistius, Olympiodorus, and Simplicius. From this concise detail, we may learn, that under several of the Cæsars, the philosophers of this school shared, with their brethren, the common discouragements and infelicities of oppression. The concise and logical method of philosophizing, which prevailed in this school, could obtain few admirers at a period remarkable for a loose and florid kind of eloquence. Besides, the doctrine, which the Peripatetics of this period had received from their master, suffered much adulteration from the unwearied endeavours of the Alexandrian philosophers to establish an Eclectic system. Many bold, but injudicious grammarians and critics, attempted to supply chasms, and to clear up absurdities, in the writings of Aristotle, from their own ingenious conjectures, which they presumed to incorporate with

PERIPATETICS.

the author's text. Even Alexander Aphrodisæus, who professed to restore the genuine Aristotelian system, not confining himself to the doctrine of his master, contributed towards its adulteration. But nothing proved so injurious to the Peripatetic philosophy, as the rage for commenting upon the works of Aristotle, which prevailed among his followers. Notes, paraphrases, arguments, summaries, and dissertations, piled up, century after century, under the general name of commentaries upon Aristotle, created, as might be expected, endless disputes concerning the meaning of his writings; and it may perhaps be asserted with truth, that their genuine sense, after all the pains which have been taken to explore it, yet remains, in many particulars, undiscovered.

Some knowledge of the Aristotelian system was introduced among the Jews by Aristobolus, an Alexandrian Jew, who lived in the reign of Ptolemy Philometer, and was an admirer of the Greek philosophy. In order to facilitate the study of Aristotle among the Jews, his writings were, in a subsequent period, translated from the Arabic into the Hebrew tongue; and towards the close of the 13th century, the name of Aristotle was so highly respected among the Jews, that they not only called him the prince of philosophers, but maintained that his philosophy was the perfection of human science, and could only be excelled by the doctrine of divine revelation; and in order to screen themselves from censure for submitting to receive wisdom from a heathen philosopher, they pretended that Aristotle was himself a profelyte to Judaism, and was indebted to Solomon for a great part of his philosophy.

The commencement of the Aristotelian philosophy among the Arabians may be referred to the time of Al-Mamon, who, among other writings in various languages, caused the works of Galen and of Aristotle to be translated into Arabic. After his death, which happened in the year 833, philosophy continued its progress among the Saracens, to which the eminent schools that were founded in different parts of the empire in no small degree contributed. (See SARACENS.) In order to accommodate the established system, which was guarded by the sanction of penal laws, to their philosophical ideas, they blended the abstract speculations of the schools with the gross and vulgar conceptions of the Koran. They made use of the subtleties of the Aristotelian philosophy in the defective and corrupt state in which it had come into their hands, to assist them in improving upon the literal meaning of their sacred books, and thus gave a new, and for the most part a metaphysical, turn to the religion and law of Mahomet. This, it is said, by one of their own writers, was the origin of their religious sects. Many of the Arabian philosophers, among whom we may reckon Jacobus-Al-Kendi of Bassora, Al-Farabi, or Abu Nair, a native of Balch Farab, who flourished in the 10th century, Al-Rasi, called also Abubeker and Al-Mansor, a native of Rai, in Persia, Avicenna, Avenpace, a Spanish Saracen, who flourished about the middle of the 12th century, Avenzoar of Seville, Thophail of the same city, and Averroes, acquired celebrity by their commentaries upon Aristotle, and other philosophical works. In every branch of science, in which Aristotle led the way, the Arabian philosophers followed him as an infallible guide; inasmuch that their tenets, as far as they are distinct from the peculiar dogmas of the Koran, are, without variation, those of the Peripatetic school.

In the earlier ages of Christianity, the Platonic philosophy was more generally preferred to the Peripatetic: the Christian fathers pointed the severest censures against the Peripatetic and Epicurean sects. The doctrines of the Peripatetics concerning divine providence, and the eternity

of the world, chiefly excited their aversion against this sect; and besides this, they were much displeased with Aristotle, for having furnished heretics and infidels with the weapons of sophistry. Nevertheless this did not prevent the doctrine of Aristotle from forcing its way into the Christian church. Towards the close of the fifth century, it rose into considerable credit: the Platonics, interpreting, in their schools, some of the writings of Aristotle, particularly his dialectics, and recommending them to young persons. This seems to have been the first step to that universal dominion, which Aristotle afterwards obtained in the republic of letters; which was also very much promoted by the controversies which Origen had occasioned: he was zealously attached to the Platonic system: and, therefore, after his condemnation, many, to avoid the imputation of his errors, and to prevent their being counted among the number of his followers, openly adopted the philosophy of Aristotle. Nor was any philosophy so proper for furnishing those weapons of subtle distinctions and captious sophisms, which were used in the Nestorian, Arian, and Eutychian controversies. About the close of the sixth century, the Aristotelian philosophy, as well as science in general, was almost universally decried; and it was chiefly owing to Boethius, who had explained and recommended it, and who united the Platonic with the Aristotelian doctrine, that it obtained a higher degree of credit among the Latins than it had hitherto enjoyed. Towards the end of the seventh century, the Greeks, abandoning Plato to the monks, gave themselves up entirely to the direction of Aristotle, and in the succeeding century, the Peripatetic philosophy was taught every where in their public schools, and propagated in all places with considerable success. John Damascenus, who flourished at the beginning of the eighth century, very much contributed to its credit and influence, by composing a concise, plain, and comprehensive view of the doctrines of the Stagirite, for the instruction of the more ignorant, and in a manner adapted to common capacities. Under the patronage of Photius, and the protection of Barda, the study of philosophy, having for some time declined, revived again about the end of the ninth century. About the year 1050, a revolution in philosophy commenced in France; when several eminent logicians, who followed Aristotle as their guide, took nevertheless the liberty of illustrating and modelling anew his philosophy, and extending it far beyond its ancient limits. In the twelfth century, three methods of teaching philosophy were practised by different doctors; the first was the ancient and plain method, which confined its researches to the philosophical notions of Porphyry, and the dialectic system, commonly attributed to St. Augustine, and in which were laid down this general rule, that philosophical inquiries were to be limited to a small number of subjects, lest, by their becoming too extensive, religion might suffer by a profane mixture of human subtilty with its divine wisdom. The second method was called the Aristotelian, because it consisted in explications of the works of that philosopher, several of whose books, being translated into Latin, were almost every where in the hands of the learned. The third was termed the free method, employed by such as were bold enough to search after truth, in the manner the most adapted to render their inquiries successful, without rejecting the success of Aristotle and Plato.

About this time, dialectic philosophy was supposed to be the key of theology, without which it would be impossible to unlock the mysteries of sacred wisdom. On account of this supposed alliance between logic and theology, the former was made the principal object of study in all the schools, and those who excelled in the dialectic art were regarded with

PERIPATETICS.

with the highest admiration, and attended by crowds of pupils. The Aristotelian philosophy had now for several centuries been studied by the Saracens, and was at this time taught in their schools in Spain. These schools were visited by many of the western Christians, who learned Arabic, that they might be able to read translations of Aristotle, and other philosophical writers, and who afterwards translated many Arabic books into the European tongues. Another cause which served to establish a general taste for the Peripatetic philosophy, and particularly for the Aristotelian logic was, that about this period many Greek copies of the writings of Aristotle were brought from Constantinople into the west. Before this time, though they had been read in the original by a few monks, more learned than the rest, most persons had been contented with the translations of Victorinus and Boethius. But, at the beginning of the 12th century, the original writings of Aristotle were studied in Paris; whence they were introduced among the Germans, by Otho of Freisingen, in the time of Abelard. The guardians of the church were alarmed by the inundation of new opinions, which this fondness for logical disputations introduced; and after having sentenced the works of two Parisian teachers of theology to be publicly burned, a general prohibition of the use of the physical and metaphysical writings of Aristotle in the schools, was issued first by the synod of Paris, and afterwards, under pope Innocent III., by the council of Lateran. The evil that had caused the alarm was not suppressed; but the fondness for the subtleties of Aristotelian logic and metaphysics became so general, that the orthodox clergy complained, that scholars spent their whole time in disputation. It was at length found necessary, under certain restrictions, to favour the study of Aristotle. Accordingly his dialectics, physics, and metaphysics, were by express statute received into the university of Paris. It was ordered, however, in 1231, by a bull of pope Gregory IX., that only such books of Aristotle should be used in the schools, as had been examined and purged from errors. In several other countries, the Aristotelian philosophy was received with less opposition. In England, the writings of the Stagirite were read with great avidity; and in Germany and Italy the study of Aristotle was very much encouraged. The name of Aristotle, from the end of the twelfth century, obtained universal dominion; and so far were his writings, after this time, from falling under the censure of councils and popes, that the philosophy of Aristotle, and that of the Saracens, became the main pillars of ecclesiastical hierarchy. In the year 1452, Charles VII. ordered the works of Aristotle to be read and publicly explained in the university of Paris. Thus the union between the Peripatetic philosophy and the Christian religion was confirmed, and Aristotle became not only the interpreter, but even the judge of St. Paul. At the commencement of the reformation, Luther, who was early initiated in the Peripatetic philosophy, rejected both this and the scholastic, as not only irreconcilable with the Christian system, but the cause of endless controversies in the Christian church. In various parts of his writings he expresses great contempt for Aristotle and his followers. Melancthon so far espoused the doctrine of Aristotle, as to attempt the revival of the pure Peripatetic philosophy in the schools. Although at the beginning of the 16th century, the scholastic philosophy began to fall into general contempt, Aristotle still retained, in a great degree, his authority. This event was owing to many concurring circumstances. The partizans of the Platonic system, who, under the patronage of the Medicean family, had long maintained their ground against the Aristotelians, lost their influence as that of their patrons de-

clined; and the advocates of the Peripatetic philosophy proportionally increased, and, after a violent conflict, obtained a victory. This victory was facilitated and completed by those enquirers extending beyond the region of metaphysics and theology, into the subjects of natural history and philosophy, which were now prosecuted. Among the followers of the church of Rome, the Peripatetic philosophy continued to be zealously maintained, on account of the assistance which its dialectics afforded them in the defence of the established system; and because many of the doctrines of this system coincided with those of the school of Aristotle. The deference which had been long paid to the decisions of Aristotle, induced the first restorers of learning to direct their principal attention to his writings: accordingly the number of critics and common tutors became very considerable. The first persons of this description employed themselves in verbal, rather than philosophical criticism, and in correcting the text of their author. But commentators of a different class were chiefly employed, from Pomponatius to the middle of the seventeenth century, in ascertaining and restoring the true Aristotelian philosophy. It would be an endless task to enumerate all the learned men, who, in the fifteenth and sixteenth centuries, attached themselves to the Aristotelian system. Among the Roman Catholics we may mention Nicholas Leonicus Thomæus, a Venetian, born in 1457, who seems to have been one of the first that attempted to restore the genuine Aristotelian philosophy; Pomponatius of Mantua, born in 1462, who taught the doctrines of Aristotle and Averroës in the schools of Padua and Bologna, and who had many followers of great celebrity; such were Simon Porta, a Neapolitan, Julius Cæsar Scaliger, a celebrated philologist, and Lazarus Bonamicus, who rivalled Erasmus in elegant Latinity:—Majeragius of Milan:—Sepulveda of Cordova:—Peter Victor of Florence:—Zubaralla of Padua:—Strozza of Florence:—Cæsalpinus, an Italian:—and Cæsar Cremoninus of Modena. Among the Protestants, especially in Germany, we find in their public schools many learned men, who were followers of Aristotle. At the commencement of the reformation, indeed, both the *scholastic* philosophy, (which see,) and the dogmas of Aristotle, were rejected with great indignation, particularly, as we have already observed, by Martin Luther. But afterwards, when men of the soundest judgment and best erudition, perceived the value of philosophy as a guard against fanaticism, much labour was devoted to the promotion of learning, and to the encouragement of a love of science. The first place in this class of reformers is unquestionably due to Philip Melancthon (see his article.) At Leipzig, Simon Simon of Lucca was distinguished; in the academy at Tubingen flourished Jacobus Schegkuis, and in that of Altdorf, Philip Scherbius, whose contemporary, of the same school, was Nicholas Taurullus. To these we may add Ernestus Soverus, a native of Nuremberg, and Hermannus Conringius, one of the most illustrious ornaments of the Germanic schools, (see his article); and also Christianus Drierus, a native of Stettin in Pomerania, Melchior Zeidler of the same place, and Jacobus Thomafius of Leipzig, chiefly memorable as the preceptor of the illustrious Leibnitz.

The general prepossession in favour of the Aristotelian system, which from a variety of causes, some of which have been enumerated, prevailed for several centuries after the revival of letters, was attended with much inconvenience and mischief. Opinions were imbibed from the Peripatetic philosophy, wholly inconsistent with the principles of true religion; such as, for example, that God, the first mover, wholly intent upon the contemplation of his own intellect, disregards

disregards the affairs of the world; that the Intelligence, which presides over the lower sphere, is the universal soul of the world, of which all men partake; and consequently, that the soul of man has no distinct existence, and will no longer subsist as such, than whilst the body continues to live. In consequence of these and similar tenets infidelity prevailed; and the minds of the multitude, both ecclesiastics and laity, were deeply tinctured with Atheism; and this fatal relaxation of principle produced an uncommon depravity of manners. In order to restrain this evil, the fathers of the Lateran council issued a bull in 1510, against the Aristotelian corruptions; but the Peripatetics ridiculed this idle fulmination. The Stoicite having, for many centuries, possessed authority in the schools little inferior to that of Jesus Christ in the church, and his dogmas being intimately interwoven with those of religion, it was thought exceedingly hazardous to whisper any thing to the discredit of his philosophy. This reverence for Aristotle was supported, in Popish universities, by statutes which required the professors to promise upon oath, that in their public lectures on philosophy they would follow no other guide. Among Protestants, the errors and corruption of the Peripatetic philosophy met with opposition; but it was attended with little success. Several eminent men ventured to inveigh against Aristotle himself, as the author of many pernicious errors. But, still, his system, for the most part, retained its authority, and even those who forsook this master, thought it necessary to make choice of some other ancient guide; so that, after all, the question was, what Aristotle, Plato, or Pythagoras had taught rather than what was truth.

The Peripatetic system, after having prevailed with very great and very extensive dominion for many centuries, began rapidly to decline towards the close of the seventeenth century, when the disciples of Ramus attacked it on the one hand, and it had still more formidable adversaries to encounter in Des Cartes, Gassendi, and Newton. Brucker's Hist. of Philos. by Enfield. Mosheim's Eccl. Hist. See ARISTOTLE.

PERIPEŒIA, Περὶπέσια, in the *Drama*, that part of a tragedy in which the action is turned, the plot unravelled, and the whole concludes.

The word is formed from the Greek Περὶπέσια, something falling into a different state; formed of Περὶ, *about*, and Πέσσω, *cado*, *I fall*.

The peripetia is properly the change of condition, whether happy or unhappy, which the principal person or persons undergo; arising from some discovery, or incident, which gives a new turn to the action.

The peripetia, therefore, concludes with the catastrophe, or unravelling; unless we make the peripetia to depend on the catastrophe, &c. as an effect on its cause.

The peripetia is sometimes induced by remembrance, or discovery; as in the *Œdipus*, where the messenger sent from Corinth to invite *Œdipus* to the crown, informs him, that Polybus and Merope were not his father and mother; which begins a discovery, that Laius, whom he had killed, and Jocasta, whom he had then to wife, were his father and mother, and throws him into the deepest distress. This instance Aristotle calls a *double peripetia*.

The qualities of the peripetia are, that it be probable and necessary; in order to which it must be the natural result, at least the effect, of the foregoing action, or of the subject itself; and must not start out from any foreign, or collateral cause.

Sometimes the peripetia is occasioned without any discovery; as in the *Antigone* of Sophocles, where the change

in Creon's fortune is produced by the effect of his own obstinacy; and sometimes by a mere change of the will, which, though the least artful, yet, Mr. Dryden observes, may be so managed, as to become exceedingly beautiful.

These two cases Aristotle calls *simple peripetias*; in these the change only consists in a passage out of trouble and action into tranquillity and rest. See FABLE ACTION, &c.

PERIPHALLIA, Περὶφάλλια, in *Antiquity*, the same with *phallogia*. See PHALLAGOGIA and DIONYSIA.

PERIPHERES, a term in the *Ancient Greek Music*, which signifies a series of notes ascending, or descending, and which in a manner return upon themselves. The *peripher* was formed upon the *Anacamplos* and the *Eutibia*.

PERIPHERY, formed from Περὶφραζω, *I surround*, or Περὶ, *about*, and Φέρω, *I bear*, or *carry*, in *Geometry*, the circumference or bounding-line of a circle, ellipsis, parabola, or other regular curvilinear figure.

The periphery of every circle is supposed to be divided into three hundred and sixty degrees; which are again subdivided, each into sixty minutes, the minutes into seconds, &c.

The division of degrees, therefore, are fractions, whose denominators proceed in a sexagecuple ratio; as, the minute $\frac{1}{60}$, second $\frac{1}{3600}$, third $\frac{1}{21600}$. See SEXAGESIMAL.

But these denominators being troublesome, in their stead are used the indices of their logarithms; hence the degree, being the integer, or unit, is marked by $^{\circ}$, the minute by $'$, second by $''$, &c. See CIRCLE, and CIRCUMFERENCE.

PERIPHERY. *Angle at the*. See ANGLE.

PERIPHRAŒSIS, Περὶφρασις, *circumlocution*, formed of Περὶ, *about*, and Φραζω, *I speak*, in *Rhetoric*, a circuit, or tour of words, much affected by orators, to avoid common and trite manners of expression.

The periphrasis is of good use on many occasions: and we are frequently forced to have recourse to it, to make things be conceived which are not proper to name.

It is often a piece of politeness to suppress the names, and only intimate, or design them. These turns of expression are also particularly serviceable in oratory; for, the sublime admitting of no direct citations, there must be a compass taken to insinuate the authors whose authority is borrowed. A periphrasis, by turning round a proper name to make it understood, amplifies and raises the discourse; but care must be taken it be not too much swelled, nor extended *mal à propos*; in which case it becomes flat and languid. See CIRCUMLOCUTION.

PERIPHYMOSIS. See PARAPHIMOSIS.

PERIPLOCA, in *Botany*, an old name, adopted by Tournefort and Linnæus, derived from Περὶ, *about*, and Πλοκω, *a binding*, or *twining*. It alludes to the long trailing stems and branches, which twine about each other to a great extent. Linn. Gen. 119. Schreb. 166. Willd. Sp. Pl. v. 1. 1248. Mart. Mill. Dict. v. 3. Sm. Prodr. Fl. Græc. Sibth. v. 1. 165. Brown Tr. et Vern. Soc. v. 1. 57. Ait. Hort. Kew. v. 2. 74. Juss. 146. Tourn. t. 22. Lamarck Illustr. t. 177. Jacq. Misc. v. 1. t. 1. f. 2. Class and order, *Pentandria Digynia*. Nat. Ord. *Contortæ*, Linn. *Apocineæ*, Juss. *Asclepiadeæ*, Br. wn.

Gen. Ch. *Cal.* Perianth inferior, minute, in five ovate permanent segments. *Cor.* of one petal, wheel shaped, in five deep, oblong-linear, abrupt, convex, oblique, widely spreading segments, having five awned scales alternate with them. *Stam.* Filaments five, distinct, oblong, flattened, bearded at the summit; anthers of two remote cells, each cell cohering with that of the neighbouring anther; masses of pollen granulated, solitary, in four parts, applied to the stigma,

stigma. *Pist.* Germens two, ovate, approximated; styles combined above; stigma capitate, scarcely pointed, dilated, and notched at the top. *Peric.* Follicles two, cylindrical, widely spreading, smooth. *Seeds* numerous, imbricated, crowned with hair. *Receptacle* longitudinal, thread-shaped.

Ess. Ch. Corolla wheel-shaped, with five awned scales at its sinuses. Filaments distinct. Anthers coherent, bearded above. Masses of pollen five, granular. Stigma nearly pointless. Follicles cylindrical, widely spreading, smooth. Seeds crowned with hair.

Obs. From this genus are now separated, by Mr. Brown, *P. Secamone* of Linnæus, and *emetica* of Willdenow; both referred to his genus SECAMONE, hereafter to be described: as are *P. esculenta* of Linnæus, see OXYSTELMA; *P. indica*, see HEMIDESMUS; *P. capsularis* of Forster, see PARSONSIA; and *P. sylvestris* of Willdenow, see GYMNEMA. *P. tunicata* of the last-mentioned author appears to be likewise rejected by Mr. Brown; but we neither know the plant, nor where he has placed it. The Linnæan *P. africana* is made by him a *Cynanchum*. The following species only therefore remain.

1. *P. græca*. Common Periploca. Linn. Sp. Pl. 309. Sm. Fl. Græc. Sibth. t. 249, unpubl. Schmidt Arb. v. 1. t. 46. (*P. foliis oblongis*; Hort. Angl. t. 15. Duham. Arb. v. 2. 104. t. 21. *P. repens angustifolia*; Ger. Em. 902.)—Corolla hairy on the upper side. Leaves ovate, acute.—Native of hedges and thickets in the Levant. Dr. Sibthorp gathered it on mount Athos and near Prusa. Gerarde had the plant in his garden, and it has ever since been cultivated in England, as a hardy climber, flowering plentifully in July and August, and distinguished by the absurd name of Virginian silk. Lord Bute sent a description of this *Periploca*, as a new genus, without any idea of its being a described plant, to Peter Collinson, which the latter forwarded to Linnæus. The stem twines round every thing in its way to the extent of several yards, and is much branched, round, and smooth. Leaves opposite, on short stalks, ovate, sharp-pointed, entire, smooth and shining, very beautiful, two or three inches long, deciduous; the lowermost on each branch short, rounded and obtuse. Flowers corymbose, at the ends of short lateral branches, inodorous, singularly elegant though not ostentations, brown, with a velvet softness, each an inch in diameter. They convey an idea of some brown kinds of Auricula.

2. *P. levigata*. Smooth-flowered Periploca. Ait. Hort. Kew. ed. 1. v. 1. 301. Willd. n. 3. (*P. puniceifolia*; Cavan. Ic. v. 3. 9. t. 217.)—Corolla smooth. Leaves obovate.—Native of the Canary islands, whence it was sent by Mr. Masson to Kew in 1779, and where according to Cavanilles it is called *Granadillo*. The stem is stouter and more upright than in the former. Leaves smaller, mostly obovate. Flowers yellowish-green, equally terminal, but smaller and smooth. We find their segments frequently emarginate, though sometimes entire, agreeing in those respects with the following.

3. *P. angustifolia*. Narrow-leaved Periploca. Labillard. Syr. fasc. 2. 13. t. 7. Willd. n. 4.—Corolla smooth. Leaves lanceolate, obtuse.—Gathered by M. Labillardiere, from whom we have a specimen, near Laodicea ad mare, and in the island of Lampedusa. It is also found in Barbary. The stem seems still more upright and straight than in the last, and the leaves are more lanceolate, but their flowers exactly agree, notwithstanding a supposed difference in the apex of each segment, pointed out by Willdenow. This is very probably a variety of the *levigata*.

Mr. Brown mentions a fourth species, brought by Dr.

Afelius from Sierra Leone, which we have not seen, and of which no character or description is given.

PERIPLUCA, in *Gardening*, comprises plants of the woody climbing kind, of which the species cultivated are the common Virginian silk or periploca (*P. græca*); the green periploca (*P. secamone*); the Indian periploca (*P. indica*); and the African periploca (*P. africana*).

The first is sometimes called *climbing dog's-bane*.

The second species has a twining, shrubby, even stem: the leaves are opposite, petioled, even, underneath paler, veined transversely: the panicles axillary, alternate, dichotomous, shorter than the leaves: the flowers are small. It differs obviously from the first sort in its small copious flowers. It is said to be a native of Egypt; but its place of growth is uncertain; flowering in July.

The third has many slender stalks, which twine about each other, and by a shrub, or other support, will rise near three feet high, putting out several small side-branches; these are hairy, as are also the leaves; which are about three quarters of an inch long, and half an inch broad, standing by pairs upon very short footstalks; the flowers come out in small bunches from the side of the stalks; are small, of a dull purple colour, and have a sweet scent. It flowers in the summer, but does not produce seeds in this climate. It is a native of the Cape.

In the third sort there is a variety with smooth leaves and stalks, which comes from the Cape.

Method of Culture.—These plants may be easily increased by layers made from the young wood in the early spring or summer season. When they are fully rooted, they may be taken off, and planted out, the first or hardy kind, either where they are to remain, or in the nursery, to be afterwards removed; and the two last, or tender sorts, into pots, to be protected during the winter. The first sort likewise often succeeds by cuttings, and also the two last by the use of the hot-bed.

But they may all be increased also, by sowing the seeds procured from abroad in pots of light earth, plunging them in the hot-bed.

They should all be placed near support, to prevent their trailing upon the ground and fastening about other plants.

Where the two last sorts are kept constantly plunged in the tan-bed of the stove, they thrive and flower much better than in any other situation, but they should not be kept too warm in winter, and in the summer they should have a large share of free air admitted to them; for when they are kept too close their leaves will be covered with insects, and the plants become sickly in a short time.

The first sorts only require a little protection in the winter. They all afford variety among potted plants in general.

PERIPLUS, Περπλῦς, a voyage, or navigation, round a certain sea, or sea-coast.

Arrian has described all the coasts of the Black sea, after having inspected them in quality of general of the emperor Adrian; to whom he dedicates the description, under the title "Periplus of the Euxine sea."

The "Periplus Hannonis" is one of the most curious fragments transmitted to us by antiquity, and it is the only authentic monument of the Carthaginian skill in naval affairs. But some doubts have been entertained concerning its antiquity. (See AFRICA.) The periplus of the Erythrean sea was published by Dr. Vincent. See also AFRICA.

PERIPLYSIS, a name given by some authors to a diarrhœa, in which the stools are extremely thin and watery, and very frequent, and large in quantity.

PERIPNEUMONY.

PERIPNEUMONY, in *Medicine*, from *περι*, and *πνευμων*, *the lungs*, is an inflammation of the lungs and their investing membrane.

The peripneumony (*peripneumonia*) has been commonly distinguished by medical writers from the pleurisy (*pleuritis*); the former appellation being applied exclusively to inflammation seated in the substance of the lungs themselves; and the latter to inflammation affecting the *pleura*, or investing membrane of the lungs, as well as its duplicate, which lines the interior surface of the cavity of the chest. This distinction, however, is of little moment; for, as Dr. Cullen observes, "neither do our diagnostics serve to ascertain exactly the seat of the disease, nor does the difference in the seat of the disease exhibit any considerable variation in the state of the symptoms, nor lead to any difference in the method of cure." We shall, therefore, treat of pulmonary inflammation as one disease, in the symptoms of which there may be some shades of difference in different cases, but to which it is scarcely necessary to appropriate different names.

Few diseases are so distinctly characterised by their symptoms as simple inflammation of the organs of respiration. However various its seat, or its degree of violence, it is accompanied by these four symptoms; namely, *fever*, *difficult breathing*, *cough*, and *pain* in some part of the *thorax*. These symptoms may be variously modified, in different instances; but they are all invariably present, where the lungs or their investing membrane are affected with inflammation.

The disease almost always begins with a cold stage, that is, with more or less chilliness and shivering, and this is speedily followed by increased heat, frequency of pulse, depression of strength, and other symptoms of what is called *fever*. Sometimes, however, the increase of the fever is very gradual, and the symptoms at first moderate, and the peculiar pectoral symptoms do not immediately appear; but frequently these symptoms accompany the fever from the beginning. For the most part the pulse is frequent, full, strong, hard, and quick; but, in a few instances, especially in the advanced state of the disease, it is weak and soft, and at the same time irregular.

The *difficulty of breathing* is always present, and the oppression is greatest in the act of inspiration; both because the air-cells of the lungs, being compressed by the turgidity of the blood-vessels, do not easily admit of a full dilatation, and because the dilatation and distention of the inflamed membranes aggravate the pain attending the disease. The difficulty of breathing is somewhat varied by the posture of the patient: it is generally greater when he lies upon the side affected; but sometimes the contrary happens; and often he cannot lie easy upon either side, and can breathe only with ease, when lying on his back: and sometimes the oppression becomes so great, that he cannot breathe easily, except when in somewhat of an erect posture. This *orthopnea*, as it is technically called, implies a dangerous degree of violence, although to a careless observer, the circumstance of the patient sitting up (when, in fact, he is unable to lie down) might lead to an inference, that the disease was moderate. The greater facility of respiration in the erect posture, under such circumstances, is the result of the more easy descent of the diaphragm, when the abdominal viscera no longer press it upwards, and the consequent more free dilatation of the lungs.

A *cough* is also an invariable attendant on peripneumony; but, in different cases, it varies much in its violence and urgency, and in the pain which it occasions. It is sometimes dry, that is, without any expectoration, especially

in the beginning of the disease; but it soon becomes moist, from the great effusion from the turgid vessels, and more commonly it is moist even from the first. The matter expectorated is various both in consistence and colour, and frequently it is streaked with blood; sometimes, indeed, blood is brought up in considerable quantity, yet without the injurious consequences attending an ordinary hæmoptysis.

The *pain* accompanying this disease, is, in different cases, felt in different parts of the thorax, but most frequently in one side. It has been said to affect the right side more frequently than the left; but this is by no means certain. Sometimes it is felt as if it were under the sternum, or breast bone; sometimes in the back between the shoulders; and sometimes darting from the one to the other. When the pain is in the sides, its seat is very various; but the part of all others most frequently affected, is about the sixth or seventh rib, near the middle of its length, or a little more forward; in which situation it is often severe and pungent; while, in others, it is often more dull and obtuse, with a sense of weight rather than of actual pain. In general it continues fixed in one place; but sometimes it shoots from the side to the shoulder-blade, on one hand, or to the sternum and clavicle on the other.

This varying state of the symptoms has been assumed as the foundation of the different appellations given to pneumonic inflammation, and especially the different degree of acuteness or obtuseness of the pain, of hardness or softness in the pulse, and of the oppression of respiration. An *acute* pain or stitch, fixed in one point of the side, and remarkably increased by the act of inspiration, and still more by that of coughing, together with a *hard* pulse, and a *dry* cough, at first, is considered as characterising an inflammation seated in the *pleura*, surrounding the lungs, or lining the ribs; and therefore constituting the *pleurisy*: while on the other hand, an *obtuse* and *deep-seated* pain in the breast, not remarkably increased by respiration, which is constantly oppressed, and often requires an erect posture, together with a pulse often *soft*, and frequently with a tumid and livid countenance, is deemed indicative of inflammation in the substance of the lungs, and therefore called more specifically, *peripneumony*. But although an attention to these different forms of the disease is necessary, as they afford important indications in respect to the prognosis, yet there is little foundation for referring the disease to a different seat in these cases. It seems probable, as Dr. Cullen justly suggests, that every acute inflammation begins in membranous parts; and in every dissection of persons dead of peripneumony and pleurisy, both the surrounding membrane and the substance of the lungs appear to have been affected with the inflammation. In short, wherever the disease begins, it appears to be communicated speedily to the other parts of the organ.

Some writers have given a particular appellation (*parapneumonitis*) to an inflammation of the pleura, covering the upper surface of the diaphragm, and have supposed it to be attended with peculiar symptoms of delirium, risus sardonicus, and other convulsive motions: but it is certain, that an inflammation of that portion of the pleura, and affecting also even the muscular substance of the diaphragm, has often taken place without any of these symptoms: nor have any dissections, or authentic records of dissections, afforded any support to the opinion, that an inflammation of the pleura, covering the diaphragm, is attended with delirium, more commonly than other pneumonic inflammation. See PARAPNEUMONITIS.

The causes of peripneumony are very well known. Persons

PERIPNEUMONY.

of a considerable vigour of constitution are most liable to be attacked with it: whence, although it may affect any age and either sex, it seldom occurs before the age of puberty, and most commonly in the middle age of life, from thirty-five to fifty-five, more frequently in men than in women, and seldom in those who are sedentary, or delicate from any other cause. Previous diseases of the lungs, such as asthma, or the pressure of a deformed chest, and particularly the previous occurrence of peripneumony itself, occasion a predisposition to this inflammation.

Among the occasional causes, *cold* is certainly the most common, especially sudden and great vicissitudes; whence peripneumony is most frequently seen in the winter and spring, and in cold climates. Like all the other organs of the body, the lungs are liable to be inflamed by violence, or by whatever obstructs, strains, or otherwise injures their structure: whence blows on the chest, falls, &c. sometimes produce peripneumony; great exertions of the voice or breath, such as loud and long-continued speaking, singing, or playing upon wind-instruments, or even violent exercise, occasionally excite the disease; excessive intemperance was also remarked by Hippocrates as one of the causes of pneumonic, as of other inflammations. Sometimes peripneumony occurs as a symptom of other inflammatory fevers, especially of the measles and small-pox; and in many cases, it originates from common catarrh, by an extension of the inflammation from the mucous membrane of the bronchiæ to the substance of the lungs. Sometimes again it originates from *metastasis*, as it is called, of gout, rheumatism, erysipelas, &c.; or at least, it comes on suddenly at the time when the external symptoms of these diseases disappear. Cold, under certain conditions of the atmosphere, has occasionally given rise to the disease, in great numbers of people at the same time, so as to produce a sort of epidemic peripneumony, and even to excite a suspicion of its depending upon contagion.

Inflammation of the lungs may terminate either in health, in death, or in some other disease. It terminates in health, by what is called the *resolution* of the inflammation. This process, however, seldom takes place without being attended by some evident evacuation. In some rare instances, a spontaneous hæmorrhagy from the nose, occurring early in the disease, has put a period to its course; or a copious diarrhœa has had the same effect: but these are not to be looked for. The evacuation most frequently occurring, and apparently the most effectual in promoting resolution, is an expectoration of a thick white or yellowish matter, often a little streaked with blood, and which is brought up copiously, and without violent coughing. If the violence of the inflammation is not subdued, it goes on to a fatal termination, or to end in some other state of disease. One termination, by which it ends fatally, is peculiar to inflammation in this organ; namely, an effusion or extravasation of blood and coagulable lymph into the interstitial substance of the lungs, which, by compressing at once both the air-cells and the blood-vessels, interrupt both the breathing and the circulation, and produce a fatal suffocation. The most common termination of pneumonic inflammation, when it is fatal in the early part of its course, seems, however, to be in an effusion of the coagulable lymph only into the cellular substance of the lungs, producing a similar compression. In other cases, the functions of breathing are interrupted by a profuse effusion of viscid mucus into the air-cells and bronchial passages, by which the access of air is prevented.

Where peripneumony goes through its course, it is apt to terminate in other diseases, especially in suppuration and abscesses. This of itself becomes a formidable malady, and, unless the constitution of the patient be vigorous, and the

abscess opens into the branches of the trachea by a small aperture, is often fatal. These abscesses, when they take place in the substance of the lungs, are called *vomica*: they sometimes consist of small cavities containing pus; and at other times the cavities are very large, so that the greater part of the substance of the lungs has been destroyed. Where they open into the cavity of the chest, emptying their contents there, the disease called *empyema* is produced. Sometimes, however, *empyema* is formed by an inflamed state of the pleura, exterior to the lungs. In either case, the pus may be accumulated in the whole cavity of the chest, or it may be confined to a part of it by adhesions taking place between the lungs and the pleura, which inveils the ribs: but when pus is evacuated into the cavity of the chest, by the bursting of an abscess in the lungs, it is almost always confined within certain limits by adhesions. See Baillie, *Morbid Anatomy*, p. 53.

These adhesions of the lungs to the ribs, or, more properly speaking, of the *pleura* investing the lungs to the same membrane lining the chest, are among the common consequences of pneumonic inflammation. Sometimes they extend over the greater part of the chest, and, tying the lungs closely to its *parietes*, produce a permanent difficulty of breathing, with a cough. Sometimes, however, they are only partial, and loosely tied, so as not to impede the free motion of the lungs. Where the adhesions are considerable, and the inflammation has been severe, another formidable disease occasionally ensues, namely, dropsy of the chest, from the effusion of a large quantity of serum from the inflamed surface into the cavity of the former.

It may be mentioned as a singular circumstance, however, that anatomists seldom examine a body after death, in which some degree of adhesion between the lungs and the ribs is not found. "There would often seem to be slight degrees of inflammation in the pleura," says the able morbid anatomist above quoted, "where the symptoms above stated have not existed at all, or have been so obscurely marked as to be altogether overlooked. In examining the chest of adults after death, it rarely happens that adhesions are not discovered in some part of it, uniting the surface of the lungs to the pleura, which lines the parietes of the chest. The marked symptoms of pleurisy, however, are by no means so frequent. It seems, therefore, probable, that slight inflammations may attack the pleura; sufficient, however, to throw out coagulable lymph, which is afterwards changed into adhesions, and yet persons shall not be sensible of any disease in the chest." *Morbid Anat.* p. 58.

A termination of peripneumony in gangrene is mentioned by authors, but we have never seen or read of any well authenticated instance of such a termination.

The accuracy of *prognosis*, in the early stages of peripneumony, is of considerable importance; since, if the opportunity of employing active remedies be passed by, it is not easy to retrieve the injury. The danger of the disease in the early stage is chiefly to be estimated by the degree of difficulty in the respiration. When the patient can lie on one side only; when he can lie on neither side, but upon his back only; and still more, when he cannot breathe with tolerable ease, except the trunk of his body be erect, the progressive impediment to the breathing will be obvious. And if, even in the erect posture, the breathing is extremely difficult; if there is also a turgescence, and flushing, or purplish hue of the face, together with partial sweats about the head and neck, and an irregular pulse; the danger of the disease is extremely great. It will be yet more alarming, if any degree of delirium or confusion of thought occur, or if the patient speaks merely of general indisposition, without referring

PERIPNEUMONY.

referring his sufferings to any particular organ. Under such circumstances, even where there is little apprehension on the part of the patient, and when his strength is not materially sunk, death often speedily ensues.

The violence of the fever may always be considered as an indication of a violent disease, as well as an acute pain, very much interrupting inspiration; but these are not more indicative of danger, than an obtuse pain, a weak oppressed pulse, and very difficult respiration. When the pains, which at first had affected one side only, have afterwards spread into the other; or when, leaving the side first affected, they entirely pass into the other; these are always marks of an increasing, and therefore of a dangerous disease. As the inflammation is seldom resolved without some expectoration, so a continued dry cough is always an unfavourable symptom: but a sudden cessation of the expectoration, after it had already commenced, is indicative of still more danger; as it implies either a great diminution of the patient's strength, or a renewed augmentation of the inflammation. A copious yellowish expectoration, tinged with blood, is therefore to be deemed favourable.

When peripneumony terminates fatally, this event most commonly happens within the first week, some time between the third and seventh days from the attack. Nevertheless, it is not unusual for the disease to undergo a remission within the same period, which may prove fallacious, and the violence of the disorder may be renewed with greater danger than before. Hence it occasionally happens, that the disease terminates in death in the second, third, or even fourth week, after several remissions and aggravations; a circumstance which should teach us, that we should not measure the activity of our remedies according to the period of the disease, but according to the actual condition of the symptoms.

When, however, a peripneumony has continued steadily for many days, with its symptoms neither very violent nor very slight, and without any marked remissions, *suppuration* is certainly to be apprehended. This, however, is not to be determined by the number of days; for instances of resolution have occurred as late as the tenth day, and even at a much later period, where great remissions have occurred. But if, during a steady continuance of the symptoms for ten or twelve days, no signs of a resolution have appeared; and if the difficulty of breathing have increased, while the pain and other symptoms have somewhat abated; and, at the same time, the expectoration, which had begun, have again ceased, suppuration must be confidently expected. When suppuration is actually begun, the patient is affected with frequent rigors or shiverings, and with a sense of cold felt in different parts of the body; the pulse also becomes less frequent and softer, but sometimes fuller than before, and occasionally quicker; and the patient can now lie more easily upon the affected side than upon the other. As the suppuration proceeds, there is a considerable remission of the pain, which had before subsisted, while at the same time the cough, and more especially the difficulty of breathing, continue, and are rather augmented. The frequency of the pulse is now rather increased, and the feverish state suffers considerable exacerbations every evening, and by degrees a *hectic* in all its circumstances is formed. When the abscess is fully established, there is sometimes a very evident enlargement of the side where the matter is accumulated. If it assume the form of *empyema*, the abscess must ultimately break and discharge its contents, either into the cavity of the chest, forming the disease just named, or into the branches of the trachea (windpipe). In the former case, it may be sometimes dis-

charged either by a natural ulceration of the intercostal parts, or by a surgical operation. (See *EMPHYEMA*.) In the latter, and more common termination, the patient may be suffocated by the sudden bursting of the contained pus into all the bronchial passages; or a copious purulent spitting may ensue, by which the abscess may be more gradually and safely emptied. Nevertheless, this mode of termination is pregnant with danger: for, although in a few individuals, of robust habit, this course of purulent expectoration, and the hectic that accompanies it, will be sustained until the abscess heals; yet, in the majority of cases, all the symptoms of true pulmonary consumption ensue, and the patient dies, worn out with the perpetual irritation and discharge.

Of the Cure of Peripneumony.—The extreme importance of the lungs in the living body, as the seat of a function the most necessary to life, and the obvious danger, just described, of allowing inflammation to proceed to suppuration, even after the more early fatality of this disease has been avoided, equally prove the necessity of an early and vigorous employment of remedies, when the symptoms of peripneumony or pleurisy occur.

The remedy chiefly to be depended upon is *blood-letting*, freely and early employed. The quantity of blood drawn must of course be regulated by the violence of the disease, and the vigour of the patient's constitution, and ought generally to be as large as this last circumstance will allow. The remission of the pain and the relief of the respiration, during the flowing of the blood, may limit the quantity to be then drawn; but if these symptoms of relief do not appear, the bleeding should be continued until some degree of sickness and faintness, the signs of approaching syncope, come on. This direction is as old as the writings of Hippocrates. It will often happen, that one bleeding, however copious, will not prove a cure of the disease: for although the pain and difficulty of breathing may be much relieved by the first bleeding, these symptoms very frequently recur after a short interval, and often with as much violence as before. In the event of such recurrence, the bleeding must be repeated, even in the course of the same day, and perhaps to the same quantity as before. Sometimes the second bleeding may be larger than the first. There are persons who are constitutionally liable to faint even upon a small bleeding; and, in such persons, this may prevent the drawing of so much blood at first, as a pneumonic inflammation may require; but as the same persons are frequently found to bear subsequent bleedings better than the first, these may be carried to the extent which the symptoms of the disease seem to demand. For it is according to the state of the symptoms, that the bleedings must be determined to be repeated; and they will be more effectual, when employed in the course of the first three days, than afterwards; but they are not to be omitted although four or five days may have elapsed, before the physician is called in; nay, if there be a recurrence of the urgent symptoms, as described above, the bleeding should be repeated at any period of the disease, especially within the first fortnight, and even afterwards, if a tendency to suppuration be not evident, or if, after an apparent solution, the disease shall have again returned.

There is in peripneumony, as in some other acute inflammations, a state of pulse occasionally recurring, which, to an inexperienced practitioner, appears to contra-indicate the use of the lancet: it is soft, and small, or what has been called an oppressed pulse; but it rises, and becomes fuller and larger after blood-letting. Under such circumstances, the propriety of the blood-letting is to be determined, by

PERIPNEUMONY.

the urgency of the other symptoms, especially of the difficulty of breathing. In a similar manner, a pulse that is irregular, and beats with considerable intermissions, in peripneumony, will become regular after the relief of blood-letting; and such a state of pulse, therefore, when the pneumonic symptoms are urgent, is not to be considered as contra-indicating, but as more strongly demanding, the use of the lancet.

With respect to the *quantity of blood* which ought, or which with safety may be taken away, no general rules can be delivered; as it must be different according to the state of the disease and the constitution of the patient. In an adult male of tolerable strength, a pound of blood, avoirdupois, is a full bleeding: any quantity above twenty ounces is a large, and any quantity below twelve, a small bleeding. Sydenham was of opinion, that the average quantity of blood necessary to be drawn for the cure of pleurisy, was forty ounces: but this must differ widely in different cases. If the bleeding be performed on the first or second day, perhaps a single bleeding of fourteen or sixteen ounces may be sufficient to effect a cure; but if it be delayed, several repetitions of the operation may be necessary, and a strong man will bear the loss of even four or five pounds, in the course of two or three days.

When a large quantity of blood has been taken from the arm, and then, from the state of the patient, the safety of a repetition of that evacuation is doubtful, some blood may be still taken locally, by means of *leeches*, or *cupping*. From the slowness of the operation of leeches, the cupping is commonly to be preferred. This *local blood-letting* will be particularly proper, when the continuance or recurrence of pain, rather than the difficulty of breathing, becomes the urgent symptom; and then the cupping and scarifying should be performed as near to the seat of the pain as possible.

Fomentations and poultices to the part pained have been recommended, and may be useful; but the application of them is often inconvenient, and certainly much less beneficial than that of *blisters*. Very early in the disease, a *blister* should be applied as near to the pained part as possible. But, as when the irritation of a blister is present, in the height of the inflammation, it seems to render bleeding less effectual, so its application should be delayed till blood-letting shall have been employed. If the disease be moderate, the blister may be applied immediately after the first bleeding; but if the disease be violent, and it is presumed that a second bleeding may be necessary soon after the first, it will then be proper to delay the blister till after the second bleeding, when it may be supposed that any further bleeding may be postponed, till the irritation arising from the blister shall have ceased. It may be frequently necessary in this disease to repeat the blistering: and, in that case, the plasters should always be applied somewhere on the thorax; for, when applied to more distant parts, they have little effect. Experience has proved, that keeping blistered parts open, or making what is called a perpetual blister, has much less effect than the repeated counter-irritation of a fresh blister.

Blisters are always safe; they do not weaken the patient; neither do they tend to interrupt the expectoration. Expectoration does sometimes take place early in the disease: but, at that period, if the symptoms continue urgent, the solution of the disease cannot be trusted to the expectoration; neither has the bleeding been found then to diminish it; on the contrary, it is often observed to promote it. It is only in the more advanced stages of the disease, when

the patient has been already much debilitated by large evacuations, and by the continuance of the disorder, that bleeding seems to stop expectoration; but under such circumstances, the bleeding is on every account improper.

While these evacuations are resorted to, it must be obviously necessary to adopt most rigorously what has been called the *antiphlogistic regimen*; to exclude every thing stimulating, both in quantity and quality, from the food and drink; to supply the patient with light diluent and acidulate fluids; to keep him entirely at rest, and to interdict him from unnecessary talking; and particularly to prevent the irritation which might arise from any increase of heat. For this purpose, it will be proper to keep the patient out of bed, while he can bear it easily; and, when he cannot, to cover him very lightly while he lies in bed: the temperature of his chamber should be kept uniformly cool.

Some practitioners, apparently upon theoretical grounds, have objected to the use of *purgatives*, upon the supposition that the evacuation which they occasion may tend to suppress the expectoration: but in the vigour of the patient and of the disease, such an apprehension is absolutely groundless. On the contrary, the free evacuation of the bowels, by cooling purgatives, conduces, like the blood-letting, to diminish the local and general inflammatory action. In the turgid and loaded state of the lungs, the straining of vomiting is likely to be productive of mischief, and can answer no useful purpose; the practice of exhibiting *emetics*, even in nauseating doses, is therefore to be deprecated, and is exploded by all judicious practitioners.

As the occurrence of a free expectoration is generally a favourable symptom, and often appears to put a termination to the disease, so various *expectorant* medicines, and other means of promoting this excretion, have been proposed. But none of these appear to be possessed of any efficacy; and some of them, being acrid stimulant substances, cannot be administered with safety. It is more than questionable, indeed, whether there is any substance in nature, which possesses a direct expectorant power. (See EXPECTORANT.) The gums, such as ammoniacum, myrrh, &c. usually employed, are too heating to be given in an inflammatory affection; and squills, &c. though less stimulant, have no power, perhaps, independent of the nausea, which they may produce.

The *inhalation of the steam* of warm water, after the violence of the inflammation is subdued by blood-letting, has been found to afford considerable relief to the cough in many cases; but, in some, it has appeared to aggravate the distress.

One of the most pernicious pieces of practice, which is apt to be resorted to by the ignorant and inexperienced, is the administration of *opiates*, with a view to allay the cough, in the beginning of the disease. The effect of such medicines is directly the reverse; for they increase the oppression, and difficulty of breathing, and all the inflammatory symptoms. In a more advanced stage of the disease, however, when the highly febrile condition and the difficulty of breathing have been in a great measure subdued, and when the urgent symptom is an irritating cough, occasioned by the acrid mucus, and proving the chief source of the continuance of the pain and of want of sleep, a judicious employment of *opiates* often affords great relief. Although they moderate the cough, they actually promote expectoration, at this period of the disease: for, by occasioning a temporary stagnation of the thin fluid, which was diffused insensibly by frequent coughing, they produce a thickening, or what physicians have called a concocted state

PERIPNEUMONY.

state of the matter, which is more easily discharged. *Mucilaginous* and oily demulcents contribute in some measure, though in a much more trifling degree, to the same purpose, by allaying the acrimony of the mucus, which occasions too frequent coughing, and by befmeacing and defending the fauces from its irritation.

PERIPNEUMONY, *Bastard* or *Spurious*, the *Peripneumonia notha* of medical writers, was not very accurately distinguished till modern times; and the sagacity of Sydenham seems to have led him to the first diagnosis of the complaint. Nevertheless, even he left it under considerable obscurity, so that the term has been often employed without a definite acceptance. We shall first describe the symptoms, and then endeavour to point out the pathology of the disease.

The *peripneumonia notha* most commonly attacks persons that are somewhat advanced in life, and who are of a full phlegmatic habit, but most particularly those who have been frequently subject to catarrhal coughs, attended with much expectoration. It often makes its attack like the habitual catarrh, from which it cannot at first be distinguished. In other cases it comes on with languor, restlessness, and shiverings, alternating with fits of heat. The patient soon finds himself oppressed in his breathing, and complains of a sense of weight, soreness, and constriction in the chest, which is sometimes accompanied by an obtuse pain. The respiration is more frequent than natural, and is performed with a slight wheezing noise: and if the patient be desired to make a deep inspiration, and to expand the chest to its full capacity, his effort is either interrupted by a fit of coughing, or, if accomplished, his uneasiness is increased, and the pain, if any existed, is aggravated. At the same time with the difficulty of breathing, or soon after, a cough commences, which is often at first unaccompanied by expectoration; but this soon follows, and in many cases a considerable quantity of a white viscid mucus is brought up. The cough, when it becomes frequent and violent, is very generally attended with a peculiar rending head-ache, over the eye-brows, which is intolerably aggravated by every fit of coughing, giving a sensation, as Sydenham remarks, as if the head were torn in pieces.

The functions of the mind are in general but little disturbed in *peripneumonia notha*. There is often, however, a considerable degree of vertigo, accompanied with much flushing of the face, and not uncommonly a degree of drowsiness, which approaches to coma. The tongue invariably exhibits some deviations from the natural state, although it does not assume the dry coat of acute *peripneumony*. The digestive powers are at a stand; the patient is not merely indifferent to food, but he commonly loathes it as much as in idiopathic fever; he has thirst, but it does not appear to be urgent. The urine is constantly loaded, turbid, and high coloured. The pulse in this disease is not so correctly the measure of its urgency and violence, as in some others: it is always frequent, with some degree of sharpness; but it is at the same time small and feeble. The blood, when drawn, however, shews a buffy surface, as in other inflammatory affections.

There is often considerable uncertainty with respect to the prognosis of this disease. For although it often goes on like a common catarrh, of greater violence than usual, and, after the employment of some remedies, is entirely relieved by a free and copious expectoration; yet sometimes a violent exacerbation of the symptoms suddenly takes place, and terminates the life of the patient, when the previous indications of danger had not been very evident. Where the expectoration is free, although the excretion be copious, and when the breathing at the same time is little oppressed, a favourable issue may be commonly anticipated. But on the other hand, the disease often proves fatal in consequence of

a redundant secretion of the mucus, rapidly clogging up the bronchial passages, and producing suffocation. This occurs especially in those persons who are advanced in years, and whose lungs have been left in a relaxed state by previous attacks of the disease: for this complaint in a remarkable manner generates a predisposition to future attacks.

There is another termination of *peripneumonia notha*, which probably every practitioner has observed, and which has been well described by Dr. Badham. "It sometimes becomes," says this author, "the origin of a *spurious consumption*; and it is no uncommon thing to subdue the violence of the symptoms, and yet not to conquer the disease. The patient recovers, perhaps, a little strength, and leaves his bed, but his respiration is uneasy and oppressed. The cough and spitting, though mitigated in violence, continue to harass him: his pulse becomes more feeble and frequent, and a general debility takes place, attended with a decided loss of flesh. He becomes subject to irregular sweats, and in the course of a few months the emaciation often makes rapid advances. A person who sees this complaint after it is formed, and some time established, is ready to conclude, that he has to deal with *phthisis pulmonalis*; but if he be able to trace it from its origin, he will discern that it is an affection essentially different from consumption, however strong the resemblance in external character. There are also materials for diagnosis. The author has known patients in an extreme state of debility and emaciation, consequent to bronchial inflammation, distend the chest to its full capacity without feeling much uneasiness, and not any pain, because the substance of the lung is not diseased. They lie down in bed much more easily than consumptive patients, have no shooting pains in the chest, and though they sweat, there is nothing like that profuse discharge from the skin, which produces the solution of the hectic paroxysm. The appearance of the sputa might perhaps be taken into the account; but this cannot be exclusively depended upon." Badham, on the Inflammation of the Mucous Membrane of the Bronchiæ, p. 43.

The exciting causes of the *spurious peripneumony* are the same with those which produce the more common varieties of catarrh, namely, vicissitudes of the atmospheric temperature. The disease is, however, most frequent about the commencement of winter, when the cold suddenly sets in. We have had numerous opportunities of observing the effects of the sudden change of temperature, in the months of November and December, in producing this disease: and have seen the same individuals attacked, year after year, with a violent chronic catarrh, accompanied with a profuse excretion of mucus, until at last, as the lungs became more and more debilitated, the annual attack put on the character of *peripneumonia notha*, by which many such patients are carried off. The disease is most prevalent in damp and foggy seasons, and it is common during the occurrence of epidemic catarrh, or influenza.

Some difference of opinion has prevailed, as to the precise nature of the affection of the lungs, which constitutes the *spurious peripneumony*. Dissection of persons who have been destroyed by the disease, has always exhibited the bronchial cells and tubes loaded with a thick or puriform mucus, and commonly also bearing obvious marks of inflammation in the lining membrane. When this is considered, as well as the fact, that the disease is certainly often a common catarrhal affection at first, and that a catarrh is a mere inflammation of the mucous membrane of the bronchiæ, and, in old or relaxed habits, is frequently attended with a large excretion of mucus, little doubt can be entertained that the disease consists in an inflammation of the lining membrane of the

the bronchial passages and cells; in other words, that it is *bronchitis*, as Dr. Badham has correctly termed it. The disease, then, must be considered as differing from *catarrh* in the more extensive spreading of the inflammation, and in the more debilitated condition of the habit, and of the lungs in particular, of the patients in whom it commonly occurs. And it differs from *pleurisy* and *peripneumony*, inasmuch as the seat of the latter is confined to the parenchyma, or investing membrane of the lungs, the bronchial membrane being but slightly and secondarily affected. In like manner, perhaps, the inflammation of the mucous membrane, in *peripneumonia notha*, may, in its more acute degree, extend secondarily and partially to the parenchyma of the lungs, and thus produce an aggravated disease, in fact, a complication of the spurious with the true *peripneumony*.

The treatment of *peripneumonia notha* will of course be necessarily varied in different cases, in proportion to the age and vigour of the patient, and according as the symptoms approach more or less to those of the true *peripneumony*. When the inflammatory symptoms are considerable, indeed, the treatment in the two complaints differs only in degree.

In consequence of the great tendency to effusion, however, in all cases of the spurious *peripneumony*, and of the advanced age and relaxed habit of body in which it commonly appears, *blood-letting* must be employed with much caution. It is sometimes proper, indeed, to begin with a moderate *blood-letting*; but after the inflammatory symptoms have to a certain degree yielded, it is advisable to attempt the cure by an attention to diet, proper expectorants, and local evacuations alone. There are few complaints, indeed, in the treatment of which more caution and discrimination are required, the inflammatory symptoms often urging the necessity of one set of remedies, while the tendency to effusion points out another of very opposite effects. All that can be done in such cases, is to study with care the nature of the symptoms and the habit of body, and obviate that tendency which seems more immediately to threaten danger, but at the same time in such a way as shall as little as possible increase the opposite train of symptoms. The tendency to inflammation must be obviated with as little loss of strength as the nature of the case admits of; and that to debility, by means which tend as little as possible to excite irritation and increase inflammation. After all that can be said, therefore, much must depend on the discernment of the practitioner.

As general *blood-letting* can seldom be resorted to, without the risk of eventually increasing the complaint, we must endeavour to supply its place by the more assiduous use of local remedies, especially by local *blood-letting* and blisters. Where the disease approaches to the nature of *peripneumony*, *leeches* or *cupping glasses*, after scarification, may be applied to the chest. *Blisters*, however, are safe and useful in all cases, when applied to the thorax, and should not be omitted. The use of moderate *purgatives* seems to afford a safer mode of evacuation in *peripneumonia notha* than *blood-letting*. Dr. Cullen, indeed, is doubtful of their efficacy; but Sydenham assures us that, according to his experience, they are more useful than in the true *pneumonia*. The result of general experience, however, seems to be, that *mild cathartics* only, or *clysters*, are proper in this disease; for, although it is of great consequence to prevent irritating matter from lodging in the alimentary canal, yet much or frequent evacuation is found hurtful.

The beneficial effects of *emetics* in this complaint, in which the freedom of the expectoration is a matter of great importance, might be anticipated, and experience confirms the expectation. Nor is their tendency to promote perspiration, which, if general and not profuse, nor brought out by heat-

ing measures, is far the most favourable, to be overlooked. With respect to the other medicines, denominated *expectorants*, which are often recommended in these bronchial affections, we have already stated how little efficacy they possess, which merits the appellation. (See EXPECTORANTS.) The more stimulant articles of this class, such as the foetid gum-resins, ammoniac, *assa foetida*, &c. may be productive of some benefit as tonics, in the convalescent state of the complaint, but they are too heating to be admissible, where the inflammatory condition is still present in any degree. The *ipecacuanha*, or the squill, in its preparation with vinegar, are more applicable; but they are, perhaps, chiefly efficacious by the degree of nausea which they excite, and therefore rather belong to the class of emetics.

Where the mucus excreted is extremely thick and viscid, the inhalation of the steam of warm water contributes to facilitate expectoration, by diluting the sputa. Little, however, is to be expected from ground-ivy, hyssop, and some other popular pectoral medicines. If they produce any actual alleviation of the cough, it is probably merely in consequence of the mucilage which they contain, which, like the various emulsions, liquorice, sugar-candy, &c. relieve the irritation of the cough, by besmearing the fauces, and shielding the passages from the acrimony of the mucus.

Paregorics, which are in fact *opiates*, are too often resorted to injudiciously in this disease, and it is necessary to enforce much caution with respect to the employment of these medicines in spurious *peripneumony*. They act by lessening the sensibility of the diseased parts to the irritation of the accumulating excretions of the lungs, and thus interrupt for a time the efforts to expectorate, and at the same time they interpose, as it were, a veil between the actual state of disease and the observer, and deceive him as to the quantity of the excretion. But the great evil is, that, during the interruption to expectoration which opium occasions, if the fluid be still copiously poured into the bronchial passages, and the strength be much reduced, the lungs become clogged up, beyond the powers of the patient to unload them, and the danger of actual suffocation is aggravated, or absolutely brought on. It is only, therefore, after the inflammatory affection, and the febrile state of the constitution is gone, and nothing but irritability remains, that opiates may be used at the discretion of the practitioner.

Where the strength appears to be much sunk, cordials and stimulants can scarcely be ventured upon, so long as any inflammatory symptoms remain: preparations of the bark are generally hurtful, and even wine, diluted with water, though less irritating, can only be admitted in cases, when the patients, as often happens, have been long habituated to the use of stimulating liquors. The only safe mode of supporting the strength, is by the cautious but assiduous administration of light, liquid, vegetable food. For so long as any fever remains, the antiphlogistic regimen is indispensably required. See Cullen, First Lines, sect. 376. Wilson, on Febrile Diseases, vol. iv. chap. 11. Badham on Inflammations of the Bronchiz, chap. iii. Also, Boerhaave, Aph. 867, with Van Swieten's Commentary; Sydenham, Op. sect. vi. cap. 4. Morgagni, de Sed. et Causis Morbor. epist. xxi. art. 11—15.

PERIPOLIUM, in *Ancient Geography*, a town of Magna Græcia, in the part called Brutium. It belonged to the Locrian-Epizephyrians, on the banks of the small river Alex or Halex.

PERIPTERE, Περπτερε, formed of περι, *about*, and πτερον, *wing*; *q. d.* winged on every side, in *Ancient Architecture*, a building encompassed on the outside with a series of

of infulate columns, forming a kind of ille, or portico, all around.

Such were the basilica of Antonine, the septizon of Severus, the portico of Pompey, &c.

Peripteres were properly temples which had columns on all the four sides; by which they were distinguished from prostyle, and amphiprostyle, the one of which had no columns before, and the other none on the sides.

M. Perrault observes, that periptere, in its general sense, includes all the species of temples which have porticoes of columns all around, whether the columns be diptere, or pseudo-diptere, or simple periptere; which is a species that bears the name of the genus, and which has its columns distant from the wall by the breadth of an inter-columnation. For the difference between periptere and peristyle, see PERISTYLE.

PERIPYEMA, from περι, and πυσι, pus, in Surgery, a collection of matter around any part.

PERIRRHANTERION, περιρραντηριων, in Antiquity, a vessel usually of stone or brass, filled with holy water, with which all those that were admitted to the sacrifices were sprinkled, and beyond which it was unlawful for any one that was βεηηλοσ, or profane, to pass. Some say it was placed in the αδυτον, or inmost recess of the temple, into which none entered but the priest; but Casaubon will have it to be placed at the door of the temple, which opinion seems more probable, because all persons who were αβειηλοι, or unpolluted, were permitted to pass beyond it.

PERIRRHEUSA, in Ancient Geography, an island placed by Pliny on the coast of Ionia, a province of Asia Minor.

PERISABORA, a town of Asia, in an island of the Euphrates, according to Ammianus Marcellinus. Zosimus calls it Bersabora, and says that it was well fortified, and that it was not inferior in grandeur to Ctesiphon. It was situated S.E. of Sippara.

PERISBA, in Geography, a town of Persia, in the province of Irac; 50 miles S. of Hamadan.

PERISCEPASTRUM, from περι, and cepastrum, a wild onion, denotes, in Surgery, a particular bandage, which encircles the head in successive folds, like the layers of that bulbous root.

PERISCII, περισκιοι, q. d. circumumbres, of περι, about, and σκια, shadow, in Geography, those inhabitants of the earth, whose shadows do, in one and the same day, successively turn to all the points of the horizon.

Such are the inhabitants of the frozen zones, or those who live within the compass of the arctic and antarctic circles; for as the sun never goes down to them after he is once up, but moves always round about, so do their shadows; inasmuch that, in the same day, they have their shadows on all sides.

PERISCYLACISMUS, περισκυλακισμοσ, a method of purification in frequent use among the Greeks. It was done by drawing a whelp round the person to be purified.

The word comes from σκυλαξ, a whelp.

PERISCYPHISMUS, from περι, and κυφος, gibbous, in Surgery, an incision made across the forehead, or from one temple to the other, over the coronal suture, formerly practiced in considerable inflammations of the eyes. The lips of this wound were kept asunder with lint, and when the disorder abated, the denuded bone was rasped, and the wound healed. P. Ægineta. lib. vi. c. 7.

PERISSACHOREGIA, a term found in the Code, about the meaning of which authors are much divided.

Alciat, and some others, will have it to be the name of an office; viz. that of curator of the annona, or provisions,

from περισσεια, abundance, and χορηγειν, to lead, or bring. Others take it to be the office of a magistrate, who was to look to the augmentation of the annona, and the distribution of the same. Dom. Macri will have it to signify a donative, or distribution made to the soldiers, over and above their pay, See DONATIVE.

PERISSOLOGY, περισσολογια, in Rhetoric, a quality of style directly opposite to brachylogy, and is otherwise called macrology. See MACROLOGY, BRACHYLOGY, and DICTION.

PERISSON, in Botany, a name given by the ancient Greeks, and afterwards by the Romans, in the time of Pliny, to a kind of nightshade, which makes those people who took it internally run mad. It was also called pentadryon, and anhydron, and by some manicum strychnum, or simply manicum.

PERISSOSIS, a word used by Hippocrates to express a redundancy of humours.

PERISTALTIC, in Anatomy, from περισπλλω, to contract, a term applied to the motions of the alimentary canal, by which its contents are carried forwards or backwards. See INTESTINE.

PERISTAPHYLINUS, a name given by some writers to two muscles of the soft palate. The peristaphylinus externus is the circumflexus palati; the internus is the levator palati. See DEGLUTITION.

PERISTAPHYLO-PHARYNGEUS, a name given by Winslow to some fibres of the constrictor pharyngis superior. See DEGLUTITION.

PERISTERITES, the Pigeon-stone; in Natural History, a name given by some whimsical people to an odd conformation of a pebble, which they suppose to represent very exactly a pigeon without its wings. It seems to have been a mere lusuf natura, in the formation of a common pebble. The variations of figure in the common pebbles are so infinite, that a person of a fertile imagination might find resemblances to all the parts of the creation in the stones of a single gravel-pit. The giving names to such accidental things is not only unnecessary, but mischievous, as it causes great confusion in natural history.

PERISTERNA, in Anatomy, is used for the lateral parts of the thorax.

PERISTIARCHUS, περισπρχοσ, in Antiquity, a name given to the person that officiated in a lustration.

The word comes from περισπα, another name for κθαριμσπο.

PERISTOMA, in Anatomy, a word used by authors to express the villous coat of the intestines.

PERISTOMIUM, in Botany, from περι, about, and σωμα, the mouth, because it encircles the orifice of the capsule; see FRINGE of MOSSES.

PERISTYLE, περιστυλοσ, formed from περι, about, and στυλοσ, column, in Ancient Architecture, a place or building, encompassed with a row of columns on the inside; by which it is distinguished from the periptere, where the columns are disposed withoutside.

Such was the hypæthre temple of Vitruvius; and such are now some basilicas in Rome, several places in Italy, and most cloisters of religious.

PERISTYLE is also used by modern writers for a range of columns, either within or without a building.

Thus we say, the Corinthian peristyle of the portal of the Louvre, &c.

PERISTYLION, περιστυλιον, among the Athenians, a large square place, though sometimes oblong, in the middle of the gymnasium, designed for walking, and the performance

of

of those exercises which were not to be performed in the palaestra.

PERISYSTOLE, περισυστολή, in *Physiology*, the pause or interval between the two motions of the heart, or pulse; viz. that of the systole, or contraction; and that of the diastole, or dilatation.

PERITAS, in *Geography*, an island in the Spanish main; 10 miles W. of Cumana bay.

PERITHE, a name by which some of the writers of the middle ages have called the *pyrites*; they say it has great virtues against the gout; some of them also have called it the *lapis peridonius*.

PERITO, in *Geography*, a town of Naples, in Abruzzo Ultra; 16 miles W.S.W. of Celano.

PERITONÆOREXIS, from περιτόναιον, the *peritoneum*, and ῥήσσω, to break, in *Surgery*, a bursting of the peritoneum.

PERITONEUM, in *Anatomy*, (περιτόναιον, Gr. from περιτείνω, to stretch round,) the serous membrane which lines the abdomen, and covers the viscera contained in that cavity.

The abdomen or lower belly is a large cavity, containing the organs concerned in digestion, in the secretion and excretion of urine, and part of those employed in generation. It occupies the part of the trunk comprehended between the chest and the lower extremities. We have to consider, in the anatomy of this part, the containing parts, sides, walls, or *parietes*, as they are technically termed, and the contained organs, or the abdominal viscera.

The figure of the abdomen, viewed altogether, hardly admits of any general description; more particularly on account of its connections with the chest above, and the limbs below, which obscure its outline. We may distinguish, on the external aspect, an anterior and posterior, a superior and inferior, and two lateral regions.

The anterior region, called the belly in common language, is oblong and convex, particularly below. The whole of this division being formed of muscles and other soft parts, its figure is subject to all those changes, which the motions of the abdominal viscera in respiration, and in the various movements of the trunk, and the numerous alterations in the bulk of the organs, according as they are full or empty, must produce. The convexity of the belly is the least, when we lie horizontally on the back: it is increased in the erect attitude, because the pelvis altogether is bent backwards in relation to the upper part of the trunk; and it is still greater in the kneeling posture, because the spine is then more bent backwards, and the abdominal viscera thrown forwards. The abdominal muscles, particularly the recti, are thrown into an unpleasant state of tension in the latter position. When air is taken into the chest, the abdominal viscera are thrust forwards, so as to make the belly more prominent; and it falls again when air is expelled in expiration.

The middle and upper part of this region presents a superficial depression, called the *scrobiculus cordis*, or pit of the stomach: and a little below this, on the middle line of the abdomen, is a more or less depressed cicatrix, called the navel or umbilicus.

The front of the abdomen is subdivided into three regions; a superior, middle, and inferior, called the epigastric, umbilical, and hypogastric. The first begins at the end of the ensiform cartilage, and extends to the level of a line drawn from side to side, between the most prominent points of the inferior boundary of the chest. The middle of this region is properly called the epigastrium, while the lateral divisions, covered by the ribs, are named the right and left hypochondria. The umbilical region reaches from the lower boundary

of the epigastric to the level of a line drawn between the two cristae of the ossa innominata: the lateral portions of this division are called the flanks or sides. The remainder of the abdomen, below the line last mentioned, is the hypogastric region: this is sometimes divided into an upper and a lower: the middle of the former is the hypogastrium, and the sides are the ilia: the middle of the latter is the region of the pubes, and the sides are the groins or inguina. The arbitrary distinctions first indicated may be clearly shewn, by placing four ribbons on the body: two transversely, of which one crosses at the lower edge of the ribs, and the other at the cristae of the ossa innominata; and two perpendicularly, from the anterior and superior spines of the ossa innominata to the edges of the chest. Thus the front of the abdomen will be divided into the nine parts enumerated already.

The posterior region consists of two parts. The superior, called the loins, presents a middle depression, corresponding to the spinous processes of the lumbar vertebrae, and two lateral elevations, produced by the masses of the spinal muscles. The lumbar region, however, taken altogether, is concave from above downwards: this concavity is least in the recumbent posture, increases when we stand up, and is more considerable in proportion as we bend the chest backwards. The lower comprises two rounded prominences, formed by large masses of muscle, covered by a thick stratum of fat, and called the buttocks. They are separated from each other by a longitudinal depression leading to the anus; and each is bounded below by a large fold, which distinguishes it from the rest of the thigh.

The upper region is not perceived externally; it is formed by the diaphragm, and corresponds exactly to the basis of the chest. We have only to state here that it is convex, and slightly divided at the middle into two prominences; and that it is much higher in front than behind, rising as high as the ensiform cartilage, and even above it in the former aspect, and slanting from this to the last ribs and lumbar vertebrae in the latter. For a more particular account of the form and relations of this boundary of the abdomen, which separates it from the chest, see **DIAPHRAGM**.

The lateral regions are much less extensive than the anterior and posterior, with which they are continuous, and are defined by the lower edges of the ribs and the cristae of the ossa innominata. They are concave from above downwards, and convex from before backwards; and, as the sides of the abdomen are here, as in the front, formed by muscles, they are subject to changes from the same causes. The concavity is greater in the standing or upright, than in the recumbent posture. Above the lower edge of the ribs, the cavity of the chest begins; but the surface of the diaphragm lies in contact with that of the ribs, although they are both covered by the pleura, and the convexity of the upper region of the abdomen rises into the chest, and is covered behind and at the sides by the latter cavity. Hence a sharp instrument would pass in the intervals of the lower ribs, and through the diaphragm into the abdomen, without wounding the lung. See **LUNG** and **DIAPHRAGM**.

The inferior region of the abdomen presents at the two sides the attachments of the lower limbs; and in the middle, the generative organs and anus. The space between the two latter is called the perineum. (See **PERINEUM**.) The generative organs and anus are described under **GENERATION** and **INTESTINE**.

The abdominal parietes present the same regions on the inside: the anterior, covered throughout by the peritoneum, is concave and smooth, and contiguous to the abdominal viscera. The posterior affords attachments to the various viscera;

PERITONEUM.

viscera: when these are removed, it presents a middle column, formed by the lumbar vertebræ, and supporting the aorta and vena cava; and two broad and deep lateral depressions, which end below in two wider excavations, formed by the superior expansions of the ossa innominata, and called the iliac fossæ. The lateral regions are narrow, concave, and smooth, and continued uninterruptedly with the anterior and posterior. The superior, formed by the concavity of the diaphragm, is concave, and corresponds to the liver, stomach, and spleen. The inferior consists of the excavation of the pelvis; a rounded hollow, constituting a kind of appendix to the abdomen, and lodging the rectum and bladder, the vagina and uterus, with its appendages.

The boundaries of the abdomen, at the back and lower parts, consist of the vertebral column and pelvis, which may be regarded as fixed points; the motion of which they are capable not affecting the dimensions of the cavity. In the rest of the extent, the coverings are muscular, and capable of changing both the form and size of the part to a considerable degree. (See OBLIQUUS.) The bones belonging to the abdominal parietes are the lumbar vertebræ, sacrum, coccyx, ossa innominata, with their connecting ligaments and fibro-cartilages; the false ribs, and their cartilages: to these we may add the ensiform cartilage. The front and sides of the cavity are formed by the obliqui externi and interni, the transversi, recti, and pyramidales: at the back part we have, forming the immediate surface of the cavity, the iliaci interni and psoæ, the quadrati lumborum, and crura of the diaphragm: nearer to the surface, the multifidi spinæ, the sacrolumbales and longissimi dorfi, the obliqui interni and transversales, the serrati postici inferiores, and the latissimi dorfi: above, the abdomen is bounded by the diaphragm, which separates it from the chest: at the lower part are the following muscles; *viz.* the levatores ani, the coccygei, transversi perinei, acceleratores urinæ, and obturatores; to which might be added those which cover the pelvis.

The arteries in the abdominal parietes are the internal mammary, the epigastric, circumflexæ ilii, inferior intercostal, lumbar, iliolumbar, lateral sacral, obturatrices, pudendal, and gluteal. These are accompanied by corresponding veins. The absorbing vessels cannot be particularly enumerated.

The nerves are the diaphragmatic, dorsal, lumbar, and sacral.

These parts are covered externally by the skin, which is considerably thicker on the back than on the front aspect. Internally they are lined by the peritoneum, which we shall describe below.

There are several openings in the sides of the abdomen. On the front we have five, *viz.* the umbilicus, the two abdominal rings, and the crural arches. (See OBLIQUUS.) In the diaphragm there are three, for the vena cava inferior, the œsophagus and par vagum, and the aorta and thoracic duct. (See DIAPHRAGM.) Below, there are two for the obturator vessels and nerves, and as many for the sciatic nerves, and large vessels going to the buttock and hip.

The space circumscribed by the abdominal parietes described above represents an oval, of which the large end is turned upwards, and the point downwards. Its size is accommodated to that of the contained viscera, and undergoes commonly only those changes which the varying quantity of their contents can produce. The figure of its boundaries, we have already mentioned, is constantly changing from the process of respiration; in which the alterations affect only the superior and anterior, very seldom the lower boundary. But the yielding nature of its sides enables the abdomen to

increase considerably under various circumstances, as in pregnancy, in the accumulation of fat in the corpulent, in ascites, &c. The front is the part most affected in these enlargements; the abdominal muscles, particularly the recti, becoming distended to a vast amount. The sides are not much enlarged; the upper boundary also gives way in those cases, enlarging the abdomen at the expense of the thorax: hence the affection of the respiratory organs in the latter stages of pregnancy, and ascites. When the distending cause has ceased to act, the sides of the cavity have the power of recovering their former size.

The viscera contained in the abdomen may be arranged in three classes: the digestive, urinary, and generative. Those of the first class are the stomach, the small intestine, the large intestine, the liver and gall-bladder, the spleen, pancreas, and the omenta. The second are the kidneys, renal capsules, ureters, and urinary bladder. The third, in the male, the spermatic chords, vasa deferentia, and vesiculæ feminales; in the female, the vagina, and the uterus, with its ligaments, ovaria, and Fallopian tubes.

The peritoneum is a serous membrane, which, besides lining the cavity of the abdomen, covers the surfaces of most of the contained viscera, and forms, in order to arrive at these viscera, duplicatures or folds which fix them in their situation, and convey to them their vessels and nerves. In order to convey a notion of its arrangement with respect to the viscera, it has been compared to a bag without an opening, of which the superior, anterior, and lateral parts are not more extensive than is sufficient for covering the corresponding portions of the parietes; while the back, very large, not only covers the posterior part of the cavity, but is applied over the viscera, furnishing them an external investment. Hence it follows, that if it could be dissected off from all the viscera, we should have a large and entire bag, and see clearly that they are all on the outside of the bag.

We shall proceed, in the next place, to trace the course of the peritoneum, and follow it in the formation of its different folds.

It lines the concavity of the diaphragm, and passes from the posterior and inferior edge of the greater muscle over the appendices, the psoas, the lumbar vertebræ, aorta and vena cava, the spermatic vessels, the renal capsules, kidneys, and ureters. The three viscera last mentioned are behind the bag, and separated by it from those contained within the peritoneal cavity. It then lines the great hollows of the ossa innominata, covering the iliaci interni muscles and spermatic chords, and descends into the pelvis, covering the rectum entirely above, and about one-half of it below. From the sides of the rectum it is produced over the sacrum, the ossa innominata, the internal iliac vessels and great nerves, the obturatores interni, coccygei, and levatores ani. At about two inches from the anus, it is reflected from the upper surface of the rectum to the lower part of the vagina, and covers its posterior half. It ascends over the back of the uterus, and its appendages, envelopes the fundus uteri, and front of the organ, and is then reflected from the front of the cervix to the posterior and inferior part of the bladder. It mounts over the back of that organ, and descends a little from the fundus, particularly if it be full, to the back of the pubes; if it be empty, the membrane ascends from the bladder to the bone. Between the rectum and the vagina there is consequently a small process of peritoneum, forming a cul-de-sac, at the mouth of which there are two lateral folds more or less prominent: the end of this cul-de-sac is the most depending part of the peritoneal cavity. A similar but shorter pouch, terminating also in a blind end, is formed between the uterus and bladder, and there are two lateral

PERITONEUM.

folds connecting these organs. In the male, too, the peritoneum passes over the vasa deferentia. The corresponding cul-de-sac in the male subject is between the bladder and rectum. Where the rectum descends from the fundus of the bladder to the front of the abdomen, a third kind of process is formed. Further descriptions of these parts will be found in the articles GENERATION and KIDNEY. As the membrane passes from the bladder to the abdominal parietes, it forms three folds, including the umbilical arteries and uterus. See KIDNEY.

In the iliac fossæ the peritoneum is continued over the large intestine, covering the cæcum on the right, and the sigmoid flexure of the colon on the left side. To the latter it furnishes a loose fold, continuous with that which the rectum has in the pelvis; but it binds the former closely in its situation. (See INTESTINE.) The membrane is then continued on each side into the lumbar region. From the bladder and pelvis the peritoneum rises to bound the front of the abdominal cavity, and lines the back of the recti, and the internal surface of the transversi, and then reaches the edge of the diaphragm, the point from which we commenced the description.

Thus a large membranous bag is formed, simple and oval above, and ending in a single, double, or triple processes below; viz. the productions between the rectum and bladder, between the bladder and uterus, and vagina and rectum, and between the bladder and pubes, where it exits.

The folds of the peritoneum have been partly mentioned in this article: they are all particularly described, with the viscera to which they belong, in the various parts of this work. We have only to notice a few of them here shortly.

On the left side of the diaphragm the peritoneal lining extends, without producing any process, backwards to the spine: then it is prolonged over the splenic vessels and the spleen, reaches the great end of the stomach, and is continued with the anterior layer of the great omentum: with the peritoneum of the lumbar region it forms a small fold under the anterior end of the spleen. At the œsophageal opening of the diaphragm, the membrane passes over the front of the stomach.

On the right side of the diaphragm the peritoneum forms folds, connecting the liver to its surface, and called the ligaments of the liver. (See LIVER.) From the concave surface of this organ, the peritoneum extends to the small curvature of the stomach, under the name of the little omentum. (See EPIPLOON.) Under the edge of the latter process is an opening, called the foramen of Winslow, leading into another peritoneal cavity, in front of the vertebral column, behind the stomach, and above the transverse mesocolon, having no other communication with the general cavity. If we suppose the peritoneum to enter at the opening just mentioned, we may trace it forming the back of the little omentum, then over the back of the stomach. Uniting to the front layer on the stomach, it forms the anterior lamina of the great omentum. This, after covering the arch of the colon, and the small intestines, is reflected on itself to form the back layer, which is fixed to the arch of the colon, and is continuous with the transverse mesocolon. The latter fold is composed of two layers; the superior of which goes in front of the duodenum, the pancreas, the vena cava, and the appendices of the diaphragm, to the opening, from which we commenced the description. For a more particular account of all these parts, see EPIPLOON. The inferior layer of the transverse mesocolon goes over the lower part of the duodenum, and then is continued on the back of the abdomen.

In the lumbar regions the peritoneum is continued over the ascending and descending colon, without forming any thing like a mesentery: it also covers here more or less of the kidneys. Having enveloped the colon, it forms in the middle of the abdomen, extending obliquely from above downwards, and from left to right, the broad fold that covers the small intestine, called the mesentery. See INTESTINE.

The peritoneum, like all serous membranes, has two surfaces; an external adherent one, and an internal, which is free. The first is applied to the sides of the cavity, and to the different viscera; and, where folds are formed of two layers, these are applied to each other. The adhesion of the membrane to any of the parts just mentioned is not uniform. To the liver, spleen, stomach, and intestines, (excepting a part of the duodenum,) it is most closely and almost inseparably connected. The union is much less firm in the case of the pancreas, bladder, uterus, and vagina. To the tendons of the transversi, and of the diaphragm, the connection of the membrane is most intimate: it can hardly be separated entire. The adhesion is much less firm to the diaphragm, and to the muscular fibres of the transversus. But the loosest attachment of all is in the lumbar regions, in front of the vertebral column, and about the pelvis, where a copious and easily lacerable cellular tissue joins it to the neighbouring parts. This structure allows the pus of abscesses to pass from one part to another, as in the psoas abscess, &c. Above the pubes, and behind the recti, there is much loose cellular tissue, which allows the peritoneum to quit these muscles, and apply itself on the bladder, when that organ, in its dilated state, ascends into the cavity of the abdomen. At the opening for the vena cava, the peritoneum is separated from the pleura only by cellular tissue; the two membranes are also near together at the œsophageal and aortic orifices of the muscle. At the side of the ensiform cartilage, and the lower edge of the fibres of the diaphragm, arising from the last rib, the two membranes come in contact.

Wherever there is much cellular tissue on the surface of the peritoneum, it contains more or less fat. This fluid is also copiously deposited in most of the folds of the membrane.

The free surface of the membrane is distinguished by no peculiar character; as in all other serous membranes, it is perfectly smooth, and moistened by an exhalation, which merely gives a lubricity to the parts during life, but is visible in the form of actual fluid after death.

Unnatural adhesions, the consequence of inflammation, are much more rare here than in the pleura. Can we explain this phenomenon, by the more numerous and extensive motions of the abdominal contents? In the violent exertions of the body, in respiration, in the natural execution of the digestive functions, &c. the relations of the different parts to each other, and to the sides of the cavity, are incessantly changing; and they correspond to each other only in small points, on account of their rounded outlines. Where there is less motion, as in the upper part of the cavity, between the liver and spleen and the diaphragm, or in old irreducible herniæ, adhesions are much more common.

The peritoneum is thin, like all organs belonging to the serous system. It is thickest about the loins, and the sides of the abdomen; thinner in the folds attached to the viscera, and very thin on the liver, spleen, stomach, and intestines. In the omenta its tenuity is extreme. It is diaphanous, and consequently allows the colour of the subjacent organs to appear through it.

On its organization, properties, and uses, we have nothing

thing to add to the general account of these subjects in the article MEMBRANE.

In the fish kind, the peritoneum, or membrane furrounding the abdomen, is very variously coloured. In some it is of a shining silvery whiteness, as in the cyprini, perch, efoes, &c. In others it is of a fine pale flesh-colour, as in the salmon; and in some it is wholly black, or else variegated with very numerous black spots, as in the clupeæ, gadi, cotti, and spari.

PERITONITIS, in *Medicine*, an inflammation of the *peritoneum*, or membrane lining the cavity of the abdomen, and investing all its viscera, and also extending itself to form the omentum.

As the peritoneal membrane occurs in these three situations, somewhat distinct from each other, though still but a continuation of the same structure, Dr. Cullen divided the disease into three species; 1. The peritonitis *propria*, when the inflammation is seated in that part of the membrane strictly so called, which lines the parietes of the abdomen; 2. Peritonitis *omentalis*, when it is seated in the omentum; and 3. Peritonitis *mesenterica*, when it is seated in the investing membrane of the mesentery. The symptoms and method of treatment requisite for their cure are nearly the same under all these forms, and we shall treat of them under the same head.

It must be premised, however, that the peritoneum is subject to two kinds of inflammation; the one acute, and accompanied by symptoms of violent constitutional disturbance, which is the proper peritonitis of authors; the other of a more *chronic* form, which we shall describe separately.

§ 1. *The acute peritonitis* generally commences, like the other visceral inflammations, with chills and shiverings, though these are sometimes slight, and occasionally absent altogether: the pulse becomes quick and frequent; there is considerable thirst; and the general affection, called fever, ensues. These symptoms are attended from the very beginning with a sense of heat and pain in the abdomen, at first generally confined to some one part, though sometimes diffused over the whole of its surface. This pain is much increased by pressure, or, in other words, there is a great tenderness or soreness of the belly; but it is not accompanied by any inclination to go to stool. The pulse is at least one hundred in a minute, and small; yet the tongue is not much altered at first from its natural appearance.

In the course of twenty-four hours, however, the pain and tenderness on pressure increase, so that even the weight of the bed-clothes sometimes becomes intolerable, and the pulse rises to a hundred and twenty or thirty in a minute: at this time the tongue begins to be covered with a cream-coloured mucus, and, though it is moist, there is great thirst. A considerable degree of tension and swelling now takes place over the whole abdomen, and the patient finds most relief from pain by remaining motionless upon the back, with the knees in a small degree elevated. This position, while it throws the weight of the intestines to the spine, and therefore removes the pressure of them from the inflamed membrane, at the same time relaxes the abdominal muscles, and prevents any stricture over the outer surface of the inflamed part. As these muscles are called into action by any attempt to rise or even to turn, so such a motion necessarily aggravates the acute pain; whence absolute rest, as just stated, is most easy to the patient. The tension of the belly continues to increase to the sixth, seventh, or eighth day, on one of which days, unless proper measures have been taken to remove the disease, the patient most commonly expires. Previous to death, the pain often suddenly ceases, and the inexperienced may conceive that this is an indication

of amendment in the disease: but if the symptoms be minutely examined, it is found that, at the same time, the pulse is sinking in strength and increasing in rapidity, that the strength of the patient is also sensibly diminished, the countenance collapses, cold clammy sweats break out, the extremities lose their vital warmth, and at length a laborious respiration manifests the concluding struggle of life.

A favourable prognosis, however, is to be deduced from a gradual cessation of the pain, especially when it is accompanied by a diminution of tension and soreness, and when at the same time the pulse becomes fuller and less frequent, the skin less parched, soft, and moist, the respiration less laborious, and the countenance more open and expressive of ease.

Inflammation of the peritoneum may be distinguished from *colic* by the permanency of the pain, and the frequency of the pulse, as well as by the tenderness on pressure, even before any tension of the abdomen has taken place; and by the absence of any inclination to go to stool, when the pain is severe, as well as by the undiminished suffering, when an evacuation of the bowels is effected, either spontaneously or by medicine. It is not so easily distinguished from inflammation of the bowels or *enteritis*. In this latter disease, however, there is obstinate constipation, and the pain is more acute, and not so much aggravated by external pressure; the stomach is also commonly affected with vomiting. See *COLIC* and *ENTERITIS*.

The *appearances* which present themselves *on the dissection* of persons who die of peritoneal inflammation, are, a redness of that membrane, which is crowded with a number of very small vessels, carrying a florid blood, and also considerably thickened, more pulpy, and less transparent than natural. When a portion of the inflamed peritoneum is separated from the abdominal muscles, there is commonly no appearance whatever of the inflammation having spread into the muscles; but where the peritoneum covers the intestinal canal, the inflammation is sometimes found to have penetrated not only into the muscular coat of the intestines, but even into the villous membrane. The reason of this difference probably is, that the peritoneum is less connected with the abdominal muscles than with the intestinal canal, so that the inflammation passes more readily from the peritoneum to the former than the latter.

The inflammation of the peritoneum is sometimes found to have been slight and partial; at other times great and universal. When it is slight, and affects that part of the membrane which is connected with the intestinal canal, it often forms broad bands of inflammation, which run along the course of the intestines, and are bounded by the contact of the different portions of the intestines among themselves. In this case, the coats of the intestines are not thicker than usual, the inflammation being slight, and confined to the peritoneum itself. Where the inflammation is great, the intestines are much thicker and more massy. This evidently arises from the greater accumulation of blood in the small blood-vessels, as well as from the extravasation of fluids into the substance of the intestines, in consequence of the strong inflammatory action of the vessels. The *mesentery* and *mesocolon* are much thicker than in their natural state, and there is also a remarkable change in the *omentum*. It is frequently as thick as a person's hand, and lies as a circumscribed mass along the great curvature of the stomach. The principal cause of this change in these parts is the extravasation of the coagulable lymph into the cellular membrane between the laminæ of the peritoneum which form them.

Besides these appearances, there is in many places thrown out a layer of a yellowish pulpy matter, gluing different portions

PERITONITIS.

portions of the viscera together. This is sometimes a thin layer; at other times it is of considerable thickness; and appears to be the coagulable lymph of the blood. There is also a considerable quantity of a brownish fluid in the cavity of the abdomen, resembling the serum, which is mixed with small shreds of the coagulable lymph, and sometimes with pus, giving it a turbid appearance. The quantity of coagulable lymph and of the fluid is sometimes large, in proportion to the degree of inflammation: and, in some instances, instead of serum, a large quantity of pus is found. The stomach and intestines are also frequently found distended with air, which had accumulated in the progress of the disease.

The causes of peritoneal inflammation are perhaps the same with those which give rise to enteritis: but there is one cause of this inflammation, which is peculiar to women, and is some state of the uterus after parturition; whence this disease has been called, when occurring at that period, *puerperal fever*. It occurs, however, both in men, and in women who have not been pregnant.

Of the Cure of Peritonitis.—The nature of the disease being once ascertained, the method of cure will be obvious. As in all other acute inflammations, *blood-letting* from the system at large is the remedy to be principally depended upon, and should be resorted to at as early a period as possible. Sixteen ounces of blood or more should be taken from an adult, and a proportionably less quantity from a patient not arrived at that age. The chief guide in directing this operation must be the degree of pain expressed by the patient, particularly under the action of pressure: and if this should not be diminished in eight hours from the former bleeding, the same quantity of blood should be taken away again. Soon after this second bleeding the pain will generally be found to be less acute; but it may still be right to apply ten or a dozen leeches to the abdomen, and as soon as these have done their office, its whole surface should be covered with a blister. It is to be distinctly understood, however, that neither leeches nor blistering should be trusted to, until some diminution of pain have actually been produced by the general bleeding. And farther, if it should happen, that the pain is not diminished after the second bleeding, this operation must be repeated even to the fourth or fifth time, after intervals of ten or twelve hours each, if the strength of the patient is at all able to support it. If it should be unequivocally manifest at any one of these bleedings, that the strength of the patient is inadequate to the loss of sixteen ounces, a smaller quantity may be taken away, and we may resort, at the same time, to the topical application of leeches and blisters.

It seems preferable to delay the application of a blister till the constitutional effects occasioned by the local inflammation are partly removed by the general bleeding, and till the disorder is thus reduced to a state more nearly approaching to a more simple topical affection. For by proceeding thus, the double advantage will be obtained, of applying the topical remedies at a period, when their influence will be exerted with the greatest effect, and the practitioner moreover will not be deprived of the only means of ascertaining the variations of the disorder; namely, by pressure on the abdomen. The first symptom on which we may pronounce the recovery of the patient, is the ability of remaining in a sitting posture, after he had previously been confined to the back: this position of the body proves that the inflamed peritoneum is now able to bear the weight of the bowels, which perhaps never takes place where the patient does not recover.

With respect to internal medicine, it is of secondary im-

portance. Nevertheless it is necessary that the bowels should be kept open, and this should be effected with as little irritation as possible. For this purpose castor oil, or small doses of the sulphate of magnesia, may be administered with advantage; and emollient glysters may be injected, which, at the same time that they procure stools, will act as internal fomentations. Fomentations may be also applied externally to the abdomen, when the tenderness is sufficiently removed to admit of the pressure. It is scarcely necessary to add that the strictest antiphlogistic system must be adopted, both in respect to diet and medicine.

It may be right to mention an irregularity in the complaint, which is apt to mislead the practitioner, and to deter him from resorting to those vigorous measures, so essential to counteract the magnitude of the danger. There is now and then, at the very first attack, so great a degree of prostration of strength, accompanied likewise by a pulse scarcely perceptible at the wrist, as might induce us to consider the patient at the point of death, and unequal to undergo the treatment above recommended. The appearances, however, seem to arise wholly from the inflammation extending to the peritoneal coat of the stomach and intestines. Here, as in different circumstances, the pain or pressure must be the criterion to determine our practice; and if the pain should be found exquisite, no accidental symptom should lead us from trusting for relief chiefly to the lancet. Such a decision will soon be justified by a freedom in the action of the arterial system, the pulse becoming fuller and stronger, by an abatement of the languor and prostration of strength, and by a diminution of pain. See Pemberton on Diseases of the Abdom. Viscera, chap. i. Baillie's Morbid Anatomy, chap. vi.

§ 2. *The chronic peritonitis* was but cursorily noticed by medical writers, until the attention of the profession was called to it by Dr. Pemberton, in the valuable work to which we have just referred, and from which we shall select our description of the disease, which is by no means of very uncommon occurrence.

The attack of the chronic inflammation of the peritoneum is very different from that of the acute species. It advances by degrees, manifesting itself only by occasional superficial pricking pains over the abdomen, without producing any inclination to go to stool: the pulse is somewhat accelerated, and the tongue (particularly in the morning) is slightly covered with white fur. There is also considerable thirst; yet there is no exacerbation of fever in the evening, nor any hectic flushes on the cheeks: on the contrary, the countenance is full of languor, and the face is pale and doughy.

In the early stages of the disease, the patient is capable of performing his ordinary avocations, and only complains, after fatigue, of a certain degree of tightness and pricking soreness across the abdomen, from one *os ilium* to the other. This state will continue, with little variation, for many months, during which the operations of the bowels will sometimes proceed naturally, though more commonly the patient is costive. There is no tension of the skin of the abdomen, as in the acute species; on the contrary, the skin and abdominal muscles are sometimes observed to sit loosely upon the peritoneum, which gives a sensation to the touch, as of a tight bandage underneath, over which the skin and muscles may be said (as it were) to play. The patient always complains more of the *tightness* than of the *pain*; and as this tightness is much increased by any congestion in the intestines, the relief which he experiences from evacuating their contents, leads him to attribute his sensations to an habitual costiveness, for the removal of which supposed evil all his endeavours are usually directed.

In the mean time the disease gains ground, till it assumes, from some accidental circumstance, either the acute form above described, or till coagulable lymph is slowly thrown out from the inflamed surface, which, becoming in part organized, will glue together the convolutions of the intestines. In the former case the danger will be extreme, in consequence of the great debility to which the patient will have been reduced by the duration of the preceding disease; and in the latter case an equal danger will be incurred by the interruption of the peristaltic motion. Sometimes a resolution of the inflammation takes place from the effusion of a fluid, when dropsy in the belly is produced, which renders the situation of the patient still more hopeless.

The disease, indeed, is full of danger, as well from the slow insidious progress which it makes to undermine of itself the constitution, as from the accidents to which it exposes the patient during the long course of management required in its treatment. As another cause of danger, also, may be added, the want of resolution, which we have so often to regret in patients during the cure of a chronic disease, where the advantages of the plan, from its gradual operation, are not so obvious to the senses. The symptoms, which indicate recovery, are, an abatement of the pricking pains of the abdomen, and a diminution of the frequency of the pulse to eighty in a minute: but even under these appearances, however favourable, a relapse is always to be dreaded.

On dissection, all the convolutions of the intestines are sometimes found blended together into one mass, so that it is impossible to separate them from each other, or from the peritoneal coat of the parietes of the abdomen. Sometimes the mesenteric glands are also found enlarged, but without any appearance of suppuration or of scrofula, but apparently in consequence of the irritation of the inflamed membrane, by which they are surrounded.

The treatment of chronic peritonitis consists in forbidding animal food, or broths, and all fermented liquors; in enforcing the absolute necessity of rigidly adhering to a milk and vegetable diet; and, above all, in taking away blood once or twice in the week to the quantity of six ounces each time. This plan is to be pursued till all sensations of pricking pain, and all whiteness of the tongue, have disappeared. If the constitution should shew signs of considerable derangement, it would be preferable to take the blood from the arm: but if, on the contrary, the local disease has made but little disturbance in the system, then the blood may be taken by the application of six or eight leeches to the abdomen, or by cupping. The bowels are to be kept in an open state, so that one or two evacuations shall take place each day; for which purpose small doses of the sulphate of magnesia, or castor oil, may be given daily. See Pemberton, on Dis. of the Abdom. Viscera, chap. i.

PERITROCHIUM, in *Mechanics*, a wheel or circle, concentric with the bale of a cylinder, and moveable together with it, about an axis. The axis, with the wheel and levers fixed in it to move it, constitutes that mechanical power, called *AXIS in peritrochio*; which see. See also *MECHANICAL Powers*.

PERIVALE, in *Geography*, a town of Hindoostan, in Marawar; seven miles N. of Ramanadporum.

PERJURY, **PERJURIUM**, in *Law*, the crime of swearing wilfully, absolutely, and falsely, in a lawful oath, administered in some judicial proceeding, by one who has authority, in any matter relating to an issue, or cause in question; whether it be of the person's own accord, or by subornation of another.

The law takes no notice of any perjury but such as is committed in some court of justice, having power to admi-

nister an oath, or before some magistrate or proper officer, invested with a similar authority, in some proceedings relative to a civil suit or criminal prosecution; for it esteems all other oaths unnecessary at least, and therefore will not punish the breach of them. The perjury must also be corrupt, (that is, committed *malò animo*,) wilful, positive, and absolute; not upon surprise or the like: it must also be in some point material to the question in dispute; for if it be only in some trifling collateral circumstance, to which no regard is paid, it is no more penal than in voluntary extrajudicial oaths.

Subornation is the offence of procuring another to take such a false oath as constitutes perjury in the principal.

If a man calls another *perjured*, he may have an action upon the case. If he calls him *forsworn*, no action lies, because the forswearing may be extrajudicial.

At common law, the punishment of perjury, and subornation of perjury, was anciently death; afterwards banishment, or cutting out the tongue; then forfeiture of goods; and now it is fine and imprisonment; and the offender is ever afterwards incapable to be a witness. (3 Inst. 163.) By statute 5 Eliz. c. 9, persons committing wilful and corrupt perjury, in any cause depending concerning lands or goods, &c. in any of the courts of record, leet, ancient demesne court, hundred court, court baron, or court of stannary, shall forfeit 20*l.* and be imprisoned six months, and their oaths shall not be received in any court of record, so that they are disabled from being jurors or witnesses; and if the offenders have not goods or chattels to the value of 20*l.* they shall be set on the pillory in some market-place, and have both their ears nailed to it; and unlawful and corrupt procuring and suborning a witness to give false testimony in any court of record, &c. or corruptly procuring any witness to testify *in perpetuam rei memoriam*, incurs a forfeiture of 40*l.* And if the offender be not worth 40*l.* he shall suffer six months imprisonment, and stand on the pillory one whole hour in some open market near the place where the offence was committed; and he shall incur perpetual infamy. But the prosecution is usually carried on for the offence at common law; especially, as, to the penalties before inflicted, the statute 2 Geo. II. cap. 25. made perpetual by the 9 Geo. II. cap. 18, superadds a power for the court to order the offender to be sent to the house of correction for seven years, or to be transported for the same period; and makes it felony, without benefit of clergy, to return or escape within the time. Our ancient law inflicted the punishment of deliberate murder on wilful perjury, when it was the cause of the death of an innocent person; and by the laws of France it was universally capital.

But corporal and pecuniary punishments, exile and perpetual infamy, are more suited to the genius of the English laws; where the fact is openly discussed between witnesses on both sides, and the evidence for the crown may be contradicted and disproved by those of the prisoner. And with regard to the punishment of deliberate murder above-mentioned, as the mere attempt to destroy life by other means is not capital, there is no reason that an attempt by perjury should; much less that this crime should in *all* judicial cases be punished with death. For, as judge Blackstone observes, to multiply capital punishments lessens their effect, when applied to crimes of the deepest dye; and, detestable as perjury is, it is not by any means to be compared with some other offences, for which only death can be inflicted: and therefore it seems already (except perhaps in the instance of deliberate murder by perjury) very properly punished by our present law; which has adopted the opinion of Cicero (*de Leg. 2. g.*), derived from the law of the twelve tables, "*perjurii pœna diyina, exitium; humana, dedecus.*"

To convict a man of perjury, a probable evidence is not enough; but it must be a strong and clear evidence, and the witnesses must be more numerous than those on the side of the defendant, for otherwise it is only oath against oath. (10 Mod. 194. Str. 1230.) It seems that the court will not ordinarily at the prayer of the defendant grant a "certiorari" for the removal of an indictment of perjury; for such crime deserves all possible discountenance, and the "certiorari" might delay, if not wholly discourage, the prosecution. 2 Hawk. c. 17.

Quakers making solemn affirmation wilfully and corruptly shall suffer as in cases of perjury. 8 Geo. c. 6.

If perjury be committed in a spiritual cause, the spiritual judge hath authority to inflict canonical punishment, and prohibition will not go. But the judge cannot punish profalute animæ; and the party grieved by such perjury must recover his damages at the common law. In the statute of the 5 Eliz. c. 23, concerning the writ de excommunicato capiendo, perjury in the ecclesiastical court is specified as an offence, among others, for which a person may be excommunicated; and conviction of perjury, either in the temporal or ecclesiastical courts, is cause of deprivation of benefice.

PERIWINKLE, in *Botany*. See PERVINCA.

PERIWINKLE, in *Natural History*, the English name of a species of shells, being the turbo littoreus of Linnæus. It has five spires; the first ventricose; in younger subjects striated spirally; in the old, smooth and of a dusky colour. This abounds on moist rocks, far above low-water mark, and is eaten in great plenty by the poor. The Swedish peasants believe, that when these shells creep high up the rocks, they indicate a storm from the south.

PERIZONIUS, JAMES, in *Biography*, a learned critic, was born in 1651, at Dam, in the province of Groningen, where his father was master of a public school. His family name was Varbrek, which, according to the custom of the times, he changed to Perizonius, having a similar signification in Greek. He, in his youth, studied at Deventer, and afterwards at Utrecht under Grævius. The invasion of Lewis XIV. interrupted his academical studies in 1672, but he resumed them in 1674 at Leyden, where he attended the lectures of Theod. Rychius. His first public employment was that of rector of the Latin school at Delft. In 1681 he was appointed professor of history and eloquence at Franeker, and in 1693 he removed to the same professorship, with that of the Greek language, at Leyden. He died in his 64th year, in 1715. He was author of a great number of learned works, of which the following are the principal; "Animadversiones Historicæ," consisting of explanations of many passages in the Greek and Latin writers; "Dissertationes," in several volumes 4to., chiefly relative to Roman history; "Orationes;" "Origines Babylonicæ et Ægyptiacæ;" an edition of Ælian's *Various History*, with a Commentary. Perizonius had collected a numerous and well chosen library, and a cabinet of medals, which were sold after his death. He left to the university of Leyden several ancient manuscripts, and scarce editions of the classics. *Moreri*.

PERKELSKAREN, in *Geography*, a small island in the gulf of Finland. N. lat. 60° 15'. E. long. 27° 24'.

PERKERI, a town of Curdistan, on lake Van; 18 miles E. of Argish.

PERLEBERG, a town of Brandenburg, and capital of the Mark of Pregnitz, situated on the Stipenitz, and containing about 378 houses, occupied principally by tradesmen and farmers; 62 miles N.W. of Berlin. N. lat. 53° 8'. E. long. 11° 58'.

PERLICAN, NEW, a noted harbour on the E. coast of Newfoundland island, eight leagues W.S.W. of Old Perlican, and five leagues from Random head. It has a wide and safe entrance, and ships may ride in it, locked from all winds, in from 10 to 5 fathoms water.

PERLSTEIN, in *Mineralogy*. See PEARLSTONE.

PERM, in *Geography*, a town of Russia, and capital of a government, on the Kama; 808 miles E. of Petersburg. N. lat. 57° 40'. E. long. 56° 14'.

PERMACOIL, a town of Hindoostan, in the Carnatic; 17 miles N.N.W. of Pondicherry. N. lat. 12° 14'. E. long. 79° 55'.

PERMALOOR, a town of Hindoostan, in the Carnatic; 12 miles S.W. of Corjeveram.

PERMANENT *Air* and *Quantity*. See the substitutes.

PERMEABLE denotes a body considered as its pores are capable of letting somewhat pass through them. See PORE.

PERMELLY, in *Geography*, a town of Hindoostan, in the circar of Aurungabad; 30 miles N.W. of Nander.

PERMIANS, a branch of the Finns, called in the Icelandic Reports "Biarrians," and denominated by the Russians "Permiaki," situated in the governments of Perm and Viatka, and in the northern districts of the river Oby. In the middle ages the Scandinavians seem to have given the name of Biarmia to the whole country between the White sea and the Ural. The Permians on the Dwina were discovered in the ninth century by Othere of Halgoland, a province at the extremity of Norway, who afterwards entered into the service of Alfred the Great, and drew up an account of this voyage in the Anglo-Saxon language. The Icelandic reports abound with accounts of these people. According to these reports the Permians on the White sea, and the parts about the Dwina, were the most wealthy, most powerful, and most remarkable of all the northern Finns. Here the carved image of the god Yummala, who was the universal deity of the Finns, as Perune was of the Slavonians and Lettes, and Odin of the Germans, had its far-famed temple, the description of which borders on the marvellous. According to this description the temple was artfully constructed of costly wood, and so richly ornamented with gold and precious stones, that it threw a radiance round the whole circumjacent country. The image of the god wore a golden crown set with 12 precious stones, a necklace worth 300 marks in gold, and a dress which outweighed the lading of three of the richest ships that navigated the Grecian sea. The figure also bore on its knees a golden chalice of such capacity, that four men might quench their thirst from its contents, and this vessel was filled with the same valuable metal of which its mass consisted. The northern free-booters were tempted by the reports of the wealth of this country to make incursions into it, and to take away some spoil from this temple. Even several Norwegian kings made predatory excursions into Permian, and usually returned with rich booty. We find also that the Scandinavian mariners visited this country for the purposes of trade, &c. without any piratical views. It is a curious inquiry how these Permian Finns accumulated so much gold, and how their country became the mart of a great and lucrative commerce. In very remote ages the Permians were already famous for their trade with the Persians and Indians. These nations brought their commodities over the Caspian up the Volga, and the Kama, to Tscherdyn, a trading town of ancient date on the river Kolva; and the Permians transported these goods as well as their own products along the Petshora to the Frozen ocean, where they bartered them with the people of those parts against furs

furs for their oriental trade. The ruins of ancient towns bear witness to the flourishing condition and the civilization of this people. The Permians appear, by historical traces still subsisting, to have been the only race of the Finns, who were a polished and commercial people, and known to other nations, while their kindred tribes were in a state of barbarism. The reports likewise speak of kings and a sort of political constitution in Biarmeland. With the year 1217, the expeditions of the Norwegians to Permia cease; but probably at an earlier period in the 11th and 12th centuries, the republic of Novgorod made itself master of this country, leading thither Russian colonies to keep the people in subjection. About the year 1372 the Christian faith was propagated in Permia by bishop Stephen. The Novgorodians having renounced all claim to this country, the Permians for a considerable period maintained the liberty of choosing their rulers from their own body. In 1543 the czar Ivan gave them the first viceroy, to whom the chief of the inhabitants were to act in a subordinate capacity in the affairs of government, and who had his seat first at Kolmogor, and afterwards at Archangel. At present the whole of ancient Biarmia, the borders of which cannot now be accurately defined, is divided into several governments; and the descendants of the Permians, heretofore so famous, numerous, and powerful, are dwindled away into an insignificant remainder, who, amidst thorough Russians, have lost almost all their national characteristics, even to their very language. Tooke's Russia, vol. i.

PER MINIMA, in *Medicine*, denotes a perfect mixture of the smallest particles of several bodies, or ingredients.

PER MINIMA, in *Pharmacy*, denotes an intimate and perfect mixture of natural bodies: wherein their very *minima*, i. e. their atoms, or first component particles, are supposed to be accurately blended together.

If silver and lead be melted together, they will thus mingle *per minima*.

PERMISSION, PERMISSIO, in *Rhetoric*, a figure which differs in nothing from concession, except that the latter relates only to argument and pleading, but the former to action. *E. gr.* "Quoniam, omnibus rebus ereptis, solum mihi superest animus et corpus: hæc ipsa, quæ de multis relicta sunt, vobis et vestræ condono potestati. Vos me quæ pæcio vobis videtur, utamini, atque abutamini; licebit impune. In me quicquid libet statuite, &c."

PERMISSIVE WASTE. See WASTE.

PERMIT, a certificate granted by excise officers, and signed by them, expressing the quantity of liquor, the name of buyer and seller, and that the duty hath been paid, or that it hath been condemned as forfeited.

PERMITTIT—*quare non Permittit*. See QUARE.

PERMSKOE, in *Geography*, a government of Russia, including the province of Perm and Ekaterinburg; bounded on the N. by the government of Vologda and Tobolsk, on the E. by that of Tobolsk, on the S. by Uplimskoe, and on the W. by Viatsku, about 360 miles from N. to S., and from E. to W. 240—260. N. lat. 55° 15'—61° 15'. E. long. 52°—63°. The province of Perm extends from N. lat. 55° 30' to 61° 14', and from E. long. 52° to 58'.

PERMUTATION, the truck, or exchange, of one thing for another. See EXCHANGE.

PERMUTATION, in the *Canon Law*, a real and actual exchange of two benefices.

Permutation is a means of bringing benefices into commerce without simony.

The conditions required to a canonical permutation, are, 1. That there be benefices permuted on either side, though the revenues be unequal; and, in case of inequality, no com-

penfation is to be made in money, but only a pension is to be charged on the greater. 2. That each of the permuteds quit their benefices, and make a procuracy *ad resignandum*. 3. That the permutation be followed by a collation of the ordinary. 4. That the ordinary be informed of the cause of the permutation. 5. That those, to whom the presentation or election to the benefices belongs, give their consent; or, in case of their refusal, that the consent of the diocesan be had.

The chief rules of permutation are, that if one of the compermuteds cannot enjoy, he re-enters, with full right, into the benefice he has quitted; and that, if he die before he have accomplished the permutation, on his part, by the taking of possession, the compermuted, who has accomplished, retains both benefices, unless they fall into the regale.

PERMUTATIONS of quantities, in *Algebra*, the changes, alternations, or different combinations, of any number of quantities. See these several articles.

PERMUTATIONE Archidiaconatus, et ecclesie eidem annexa cum ecclesia et prebenda, is a writ issued to an ordinary, commanding him to admit a clerk to a benefice upon exchange made with another. *Reg. of Writs*.

PER MY & *per tout*—A joint-tenant is said to be seized of the land he holds jointly, *per my & per tout*, i. e. he is seized by every parcel, and by the whole, *totum tenet, et nihil tenet; seu totum conjunctim, et nihil separatim*. Braçt.

PERNABIACABA, or PARANABIACUBA, in *Geography*, a mountain of Brasil, near the city of St. Paul.

PERNALLA, a town of Hindoostan, in Guzerat; 38 miles S. of Surat. N. lat. 20° 35'. E. long. 72° 53'.

PERNAMBUCO. See FERNAMBUCO.

PERNANCY, from the French *prendre, to take*, in *Law*, the taking or receiving any thing.

Tithes, in pernancy, are tithes taken, or which may be taken in kind.

PERNES, in *Geography*, a town of France, in the department of Vaucluse, and chief place of a canton, in the district of Carpentras. The place contains 3621, and the canton 6358 inhabitants, on a territory of 100 kilometres, in six communes.

PERNETTI, JAMES, in *Biography*, historiographer of the city of Lyons, and a member of the academy of that place, was a native of Forez. He assumed the title of "Miles Ecclesie Lugdunensis;" he was a man of pleasant manners, and entirely void of pedantry. He died at Paris in 1777. His works are, 1. History of Cyrus, in three vols. 12mo.; 2. Counsels of Friendship; 3. Letters on Physiognomy, three vols.; 4. The Abuses of Education; 5. Picture of the City of Lyons. He had a relation who was librarian to the king of Prussia, and who wrote a dictionary of painting, sculpture, and engraving; and a dissertation on America against Pauw, in two vols. 8vo.

PERNETY, ANTONY JOSEPH, was born in 1716, at Roane, in Forez. He entered into the order of Benedictines, and devoted himself to study, and the composition of numerous works, in which he displayed a systematizing spirit with a singular mode of thinking. Some of the principal of these are the following; "Dictionnaire de Peinture, Sculpture, et Gravure," 1757; "Dictionnaire mytho-hermetique," 1758; "Discours sur la Physionomie;" "Journal Historique d'un Voyage faits eux îles Malouines, en 1763 et 1764," two vols. 8vo. 1769; this account of a voyage made by himself, contains many curious particulars; it was translated into English, and read with interest at the time of the dispute with Spain, relative to these islands, which are the same with the Falkland islands; "Dissertation sur l'Amérique

rique et les Américains:" in this work and in his "Examen des Recherches Philosophiques de Pauw sur les Américains," he controverts the opinions of Pauw. He was author of many other works, and communicated several memoirs to the academy of Berlin, of which he was a member, and in which capital he resided a long time. He at length returned to Valence, in the department of La Drôme, where he died about the close of the century.

PERNIA, in *Geography*, a town of Croatia; 16 miles S.E. of Carlstadt.

PERNICIOUS ISLANDS, a cluster of islands in the South Pacific ocean, about 15 miles in circuit, so called by Roggwein, on account of the wreck of one of his vessels on the coast of one of them in 1722. S. lat. 16°. W. long. 140° 45'.

PERNIO, from *πῆμα*, the heel, a chilblain, a kind of complaint frequently affecting the heel. See CHILBLAIN.

PERNO, in *Geography*, a town of Sweden, in the province of Nyland, at the mouth of a river which forms a bay on the N. coast of the gulf of Finland; 12 miles E. of Borgo. N. lat. 60° 26'. E. long. 16° 4'.

PERNOR of Profits, he who takes or receives the profits of any thing. From the French *preneur*, taker.

PERNOV, or PERNAV, in *Geography*, a town of Russia, in the government of Riga, on a river near the Baltic, fortified and defended by a castle. After several times changing masters, it was finally, with the rest of Livonia, annexed to Russia; 92 miles N. of Riga. N. lat. 58° 30'. E. long. 42° 16'.

PERNSTAIN, a town of Austria; 12 miles N.N.W. of St. Wolfgang.

PEROE, a town of Hindoostan, in Bahar; 45 miles S.W. of Patna.

PEROJOA, in *Botany*, Cavan. Ic. v. 4. 29. t. 349. f. 2, was so named by Louis Née, who gathered the plant at Port Jackson, New South Wales, in honour of Francis del Perojo, a Spanish apothecary, who had been his botanical companion in a journey over the hills of the north of Spain. Mr. R. Brown however reduces the *Perojoa* to his genus *LEUCOPOGON*; see that article, sect. 4.

PEROLA. See *MOMORDICA*.

PERONE, in *Anatomy*, (*περον*, Gr.) the fibula.

PERONEAL ARTERY, an artery of the leg, running near the fibula. See *ARTERY*.

PERONES, in *Roman Antiquity*, a kind of high shoes formed rudely of raw hides, and reaching up to the middle of the leg; though in the more ancient times of the commonwealth, the senators used them, yet in later ages they were only used by the ploughmen and labourers. Hence *Peronatus Arator*. Persius, Sat. 5. ver. 192. and Juvenal, Sat. 14. ver. 186.

PERONEUS, in *Anatomy*, a name given to three muscles which arise from the fibula.

The *peroneus longus*, (long péronier latéral, péronéo-tarsien) is a long muscle, situated on the outside of the leg, and extending from the upper end of the fibula to the posterior extremity of the first metatarsal bone; it is thick in its upper half; thin, narrow, and flattened in the lower. It arises from the upper third part of the outer surface of the fibula, from two aponeurotic septa, of which one separates it from the extensor digitorum longus communis, and the other from the soleus and the flexor longus pollicis pedis, and on the outside and upper part from the internal surface of the fascia of the leg. The upper extremity reaches as high as the outer part of the upper end of the fibula, and the back of the external tuberosity of the tibia. It is covered on the outside by the fascia of the leg. It descends

at first obliquely from before backwards, increasing a little in size; then it soon begins to decrease, and forms a tendon first visible on the external and anterior part. This tendon goes behind the external malleolus in a groove, common to it with that of the peroneus brevis, and is confined there by a fibrous sheath, lined with a synovial membrane. Below the malleolus it separates from the tendon of the peroneus brevis, and passes downwards and forwards in a groove of the os calcis, where it is again confined by a fibrous sheath. It then turns over the external side of the os cuboides, and runs obliquely inwards and forwards in the channel hollowed out on the under surface of that bone, to which it is confined by a very strong fibrous sheath. It terminates at last by an attachment to the under and external part of the posterior end of the first metatarsal bone. Where it rubs against the surface of the os cuboides, the tendon has a thick and hard knot of a cartilaginous consistence, and sometimes even bony.

It extends the ankle joint, either by drawing the heel backwards and upwards, or by carrying the leg backwards on the foot. If it acts in the former manner, when we are standing, the elevation of the foot is accompanied by that of the leg and of the rest of the body. It must draw the outer edge of the foot outwards, and thus point the great toe towards the ground. If it acts in company with the tibialis posticus, the foot will be extended in the straight direction.

The *peroneus brevis* (court péronier latéral, péronéo-sus-metatarsien) is an elongated and flattened muscle, placed at the outer part of the leg, and extending from the lower two-thirds of the fibula to the fifth metatarsal bone. Its origin commences from the beginning of the second third portion of the fibula from above, and it occupies the outer surface of the bone to the lower fourth part, below which it is connected to the bone only by cellular tissue. The front edge corresponds to the extensor communis digitorum longus and peroneus tertius, and the back to the flexor longus pollicis, to which muscles it is connected by aponeurotic septa. The upper end of the muscle is narrow and pointed, it increases in size as it descends, but diminishes again at the bottom of the leg, where it forms a tendon, passing behind the malleolus internus in the same groove with that of the former muscle. Having arrived at the bottom of the fibula, it turns forwards and a little downwards along the outer surface of the os calcis, and is inserted into the posterior extremity of the fifth metatarsal bone. Sometimes a small production is detached from it, to run along the metatarsal bone, and join the extensor tendon of the little toe.

The peroneus brevis is covered externally by the fascia of the leg. Its use is the same with that of the preceding muscle.

The *peroneus tertius* (nonus Vesalii, péronier antérieur, péronéo-sus-metatarsien) does not always exist. It lies on the anterior and inferior part of the leg, and extends from the lower third part of the fibula, to the posterior end of the fifth metatarsal bone. It is elongated, and flattened laterally. Its origin, which is confounded with that of the extensor digitorum longus, occupies the lower third part of the front of the fibula; the muscular fibres pass obliquely downwards and inwards, and end in a tendon, which goes under the transverse ligament at the ankle, in company with the tendons of the extensor digitorum longus. It then turns outwards, runs over the extensor brevis digitorum, and is expanded before its insertion into the posterior part of the fifth metatarsal bone. The outer surface of this muscle, which is inclined forwards, is covered by the fascia of the leg; the inner surface corresponds to the extensor longus pollicis.

pollicis. The outer edge is separated by a small aponeurosis from the peroneus brevis. It bends the ankle joint, either by moving the foot on the lower end of the leg, or by carrying the leg forwards on the foot. In bending the foot, it will raise the outer edge particularly; but, if it acts in conjunction with the tibialis anticus, the foot will be bent without any inclination to either side.

PERONNE, in *Geography*, a town of France, and principal place of a district, in the department of the Somme, surrounded by marshes and strongly fortified. It has been called "Pucelle," because, though often besieged, it has never been taken. It is a very ancient place, and the kings of the Merovingian race had a palace here. The place contains 3706, and the canton 14,215 inhabitants, on a territory of 162½ kilometres, in 22 communes. N. lat. 50° 22'. E. long. 3° 1'.

PEROQUETTE, in *Ornithology*, a name of a small species of the pittacus or parrot kind, with a long tail. See PSITTACUS.

There are several kinds of this bird. 1. The common, which is green, red, and yellowish, and was the first species of parrot brought into Europe, and well known among the ancients. 2. The perouette, which is green all over, without any variegation. 3. The pale, green, and red kind. 4. The red and green-crested kind. 5. The red kind, with wings variegated with black and green.

Beside these, Margrave has described seven other Brazilian kinds, called the *tuiaputjuba*, *tuitirisa*, *jendaya*, *tuiete*, *tuipara*, *anaca*, and *quijubatui*, and two others, to which no particular name has been given; one of the size of a swallow, all over green, with a black beak, and a very long tail; and the other of the size of a starling, of a deep green on the back, and paler green on the belly, and with a shorter tail. Ray.

PERORATION, PERORATIO, or *Conclusion*, in *Rhetoric*, the epilogue, or last part, of an oration; wherein, what the orator had insisted on through his whole discourse, is urged afresh, with greater vehemence and passion.

The peroration consists of two parts: 1. Recapitulation, wherein the substance of what was diffused throughout the whole speech, is collected briefly and cursorily, and summed up with new force and weight.

2. The moving of the passions; which is so peculiar to the peroration, that the masters of the art call this part *sedes affectuum*.

The passions, to be raised in the peroration, are various, according to the various kinds of orations; in a panegyric, love, admiration, emulation, joy, &c. In an invective, hatred, contempt, &c. In a deliberative, hope, confidence, or fear.

The qualities required in the peroration are, that it be vehement and passionate; and that it be short; because, as Cicero observes, tears soon dry up.

The peroration was Cicero's master-piece: here that great orator not only set his judges and auditors on fire, but even seemed to burn himself; especially when he was to raise pity and commiseration towards the accused; where, as he himself tells us, he frequently filled the forum with weeping and lamentation. He adds, that, where there were several orators to speak for the same person, the peroration was always reserved to him; and subjoins, that if he excelled herein, it was not owing to genius, but the grief himself shewed. This is abundantly evident in his Milonian peroration, where he says, "sed finis fit: neque enim præ lacrymis jam loqui possum, & hic se lacrymis defendi vetat:" and in that for Rabirius Posthumus: "Sed jam, quoniam, ut spero, fidem quam potui, tibi præstiti, Posthume, reddam etiam

lacrymas quas debeo—jam indicat tot hominum fletus, quam sis carus tuis, & me dolor debilitat, includitque vocem."

The peroration, or conclusion of an oration or discourse, must vary according to the strain of the preceding part. Sometimes the whole pathetic part is most properly introduced in the peroration. (See PATHETIC.) Sometimes, when the discourse has been entirely argumentative, it is fit to conclude with summing up the arguments, placing them in one view, and leaving the impression of them full and strong on the mind of the audience. For the great rule of a conclusion, and what nature obviously suggests, is to place that last in which we choose that the strength of our cause should rest. Sermons commonly conclude with inferences; when this is the case, they should rise naturally, and so much agree with the strain of sentiment throughout the discourse, as not to break the unity of the sermon. Dr. Blair observes, that, in all discourses, care should be taken to conclude at the proper time, so as to bring our discourse just to a point; neither ending abruptly and unexpectedly; nor disappointing the expectations of the hearers, when they are looking for a close; and hovering round and round the conclusion, until they become heartily tired of us. We should endeavour to go off with a good grace; not to end with a languishing and drawing sentence; but to close with dignity and spirit, that we may leave the minds of the hearers warm; and dismiss them with a favourable impression of the subject, and of the speaker. Blair's Lect. vol. ii.

PEROS BANKOS, in *Geography*, a range of small islands in the East Indian sea. S. lat. 5° 30'. E. long. 72° 10'.

PEROSINA, an island in the Adriatic, about 12 miles in circumference. N. lat. 45° 17'. E. long. 14° 22'.

PEROT, an island of Canada. See OTTAWAS.

PEROTA, a town of Mexico, in the province of Tlascalala; 45 miles E. of Puebla de los Angeles.

PEROTIS, in *Botany*, so named by the late Dr. Solander, from *προς*, *deficient*, because the calyx was supposed to be wanting. *Art. Hort. Kew. ed. 1. v. 1. 85. v. 3. 506. ed. 2. v. 1. 136. Brown Prodr. Nov. Holl. v. 1. 172. Schreb. 786. Willd. Sp. Pl. v. 1. 324. Mart. Mill. Dict. v. 3.—Class and order, Triandria Digynia. Nat. Ord. Gramina.*

Gen. Ch. *Cal.* Glume of two equal, acute, awned valves, containing a single flower. *Cor.* of two minute, awnless, membranous valves, much shorter than the calyx: Nectary of two minute scales, at the base of the germen. *Stam.* Filaments three, capillary; anthers oblong. *Pist.* Germen superior, oblong; lyle capillary, deeply divided, shorter than the calyx; stigmas feathery, widely spreading. *Peric.* none, except the closed permanent calyx. *Seed* one, linear-oblong.

Ess. Ch. Calyx of two equal awned valves, single-flowered. Corolla of two minute awnless valves. Style deeply divided.

Obs. The characters of this genus of grasses were erroneously given by Dr. Solander, who mistook the calyx for a corolla. Willdenow copies this error, superadding another, that the "corolla is encompassed with woolliness," which last is, without any remark, adopted by Mr. Dryander in the second edition of Hort. Kew. The mistake arose from the quotation, in the first edition of *Saccharum spicatum*, Linn. Sp. Pl. 79, as a synonym to *Perotis latifolia*; for though Willdenow, even without seeing the plants, suspected a specific difference, it appears that he took his generic character from that *Saccharum*, which is no *Perotis* at all. Mr. Brown has not thought proper to point out these errors particularly, but he has, for the first time, given a correct definition of *Perotis*, which we have adopted.

1. *P. latifolia*. Broad-leaved Perotis. Ait. n. 1. Willd. n. 1, *α.* (*Anthoxanthum indicum*; Linn. Sp. Pl. ed. 1. 28. ed. 2. 40. A. n. 25; Linn. Zeyl. 10. *Gramen geniculatum brevifolium crispum, spicâ purpuro-sericeâ maderaspatanum*; Pluk. Phyt. t. 119. f. 1. *Alopecurus malabarica, foliis undulatis, spicâ prætenui*; Scheuchz. Agrost. 91. t. 2. f. 9, G. H. *Tsjeria-Kurenpullu*; Rheede Malab. v. 12. 117. t. 62.)—Stems ascending, much branched. Leaves ovate-lanceolate, wavy, with spinous teeth.—Native of the East Indies, from whence Dr. Solander is said to have procured it for Kew garden, in 1777. It is annual, flowering in the stove in August and September. *Root* of many long, whitish, wavy, downy fibres, apparently adapted to a sandy soil. *Stems* numerous, ascending, a foot high, much branched, copiously jointed, leafy, round, smooth. *Leaves* numerous, hardly an inch long, spreading, ovate, acute, rather pungent, glaucous, striated, smooth on both sides, rough at the edges with minute spinous teeth; sheaths close, ribbed, about the length of each leaf, except the upper ones, which are five times longer. *Spikes* solitary, terminal, purplish, three inches long, of very numerous flowers, which are imperfectly whorled, and stand on short stalks. *Calyx* minutely downy, strongly keeled, above half an inch long including the awns. Scheuchzer's excellent description, and correct figure, leave no doubt as to his synonym. That of Rheede, not having examined, we take upon Scheuchzer's authority chiefly, for every other writer who has touched upon this grass has made some mistake. Willdenow's variety *β* is the true *Saccharum spicatum* of Linn. Sp. Pl. ed. 1. 54, where Plukenet's t. 92. f. 5 is rightly cited for it, and Burmann has represented the genuine plant in Fl Ind. t. 9. f. 3. That grass seems to us really a *Saccharum*; or at least an *Imperata* of Brown. In Linn. Sp. Pl. ed. 2. 79, its synonyms are totally perverted, for every one there mentioned belongs to *Perotis latifolia*.

2. *P. rara*. Narrow-leaved Perotis. Br. n. 1.—“Stem erect, somewhat branched. Leaves linear, smooth; the lower ones flat; the upper involute.”—Gathered by Mr. Brown in the tropical part of New Holland. We have seen no specimen of this.

Willdenow's *P. polystachya*, which is *Saccharum panicum*, Lamarck Illustr. v. 1. 155. t. 40. f. 3, and perhaps *Andropogon crinitum*, Thunb. Jap. 40. t. 7, is judged by Mr. Brown to be a plant of a genus by itself, very nearly related to his *Imperata*, (*Saccharum cylindricum* of Lamarck, Willdenow, and Sm. Fl. Græc. Sibth. t. 54. *Lagurus cylindricus* of Linnæus,) but differing in having awns to the calyx, no inner valve to the hermaphrodite floret, and only one stamen, marks which perhaps are not sufficient in this case to found a genus upon. See SACCHARUM and LAGURUS.

PEROTTI, NICOLO, in *Biography*, one of the early Italian literati, was born in 1430. He was educated under Volpe at Bologna, and after finishing his studies, became himself a professor in that city, first of polite literature, and then of philosophy. He made himself known by various translations of Greek authors into the Latin language. As early as 1452, or 1453, he sent to pope Nicholas V. his version of the three first books of Polybius, to which he afterwards added two more, all that were then known of that author. He subsequently translated Epictetus's *Enchiridion*, the Commentary of Simplicius upon Aristotle's *Physics*, and Tatian's Oration to the Greeks. He was made poet laureat to the emperor Frederic III., and was employed in high official situations by several of the popes. He was particularly attached to cardinal Bessarion, whose conclavia he was after the death of Paul II. On this occa-

sion, it has been said that some cardinals coming to wait on Bessarion with the purpose of saluting him pope, were refused admission by Perotti, on the plea that he was engaged in his studies; and that after the election of cardinal Riario, Bessarion coolly said to him, “By your untimely care, you have lost me the tiara, and yourself a hat.” He was, however, appointed to honourable offices under the court of Rome, being made governor of Umbria in 1465; of Spoleto in 1471; and of Perugia in 1474. He died in 1480. His writings are numerous, but his most celebrated work was entitled “*Cornucopia*,” being a diffuse and learned Commentary on Martial's book on Spectacles, and the first book of his epigrams. It was not published till after his death; it contains a treasure of erudition respecting the Latin language. Moreri. Bayle.

PEROUR, in *Geography*, a town of Hindoostan, in the circar of Gooty; 24 miles S.S.W. of Anantpour.

PEROUSA, LA, a town of France, in the department of the Po, on the river Cluson; it gave name to one of the four valleys of Piedmont; six miles N. of Pinerolo.

PEROUSE, J. F. G. DE LA, in *Biography*, a celebrated but unfortunate navigator, was born at Toulouse in 1741. He entered into the French navy when he was only in his fifteenth year, in which he passed a life of almost constant service. By the firmness of his character, and his professional skill, he was regarded as fit for the most arduous enterprises. The triumphs of the French marine were few in his time; yet he commanded in the successful attempt to destroy the English settlement in Hudson's Bay in the year 1782. On the restoration of peace, it was resolved by the French ministry that a voyage of discovery should be undertaken to supply what had been left defective in the voyages of our illustrious navigator captain James Cook, and his associates. Lewis XVI, who may well be styled the *unfortunate*, drew up the plan of the intended expedition with great judgment and intelligence, and La Perouse was the person fixed upon to conduct it. With two frigates, la *Bouffole*, et l'*Astrolabe*, the first under his own command, the second under that of M. de Langle, but subject to his orders, they sailed from Brest in August 1785; touched at Madeira and Teneriffe, and in November anchored on the coast of Brazil. Thence they proceeded round Cape Horn into the South sea, and in February 1786 cast anchor in the bay of Conception, on the coast of Chili. At this time, so well had the means of preserving health been employed, that they had not a man sick. The ships reached Easter island in the month of April, and thence sailed, without touching at any land, to the Sandwich islands. On June 23d they anchored on the American coast, in lat. 58° 37', and landed on an island to explore the country and make observations. At this place, M. Perouse had the misfortune of having two boats wrecked, with the loss of all their crew. Thence he ran down to California, and in September anchored in the bay of Monterey, whence they took their departure across the Pacific ocean, and in January 1787 arrived in the Macao roads. In February they reached Manilla, which they quitted in April, shaping their course for the islands of Japan. Passing the coasts of Corea and Japan, they fell in with Chinese Tartary, in lat. 42½°, and ran to the northward. They anchored in a bay of the island of Sagalien, and thence proceeded up the shallow channel between that island and the continent as far as 51° 29'. Returning thence they reached the southern extremity of Sagalien in August, and passed a strait between it and Jesso, since named Perouse strait, into the North Pacific. On the 6th of September they anchored in the harbour of St. Peter and Paul in Kamt-

Kamtschatka. The ships having refitted they set sail, and arrived at the Navigators islands in December. In the bay of Maouna they met with a friendly reception from numerous natives, and began to take in refreshments. A party of sixty, under the command of M. de Langle, went ashore to procure fresh water, when a most unfortunate occurrence took place, in which they were attacked by the natives, and M. de Langle and eleven of his men lost their lives. Quitting this place without any attempts at vengeance, Perouse proceeded to New Holland, and arrived at Botany Bay in January 1788, and here terminates all that is known of the voyage of this navigator, from the journal which he transmitted to France. He had many and very important objects of research remaining, but was never more heard of. The vessels were probably wrecked, and all the crews perished, in that ocean which shall hereafter be called to give up its dead. Many efforts were made to obtain information of them, but they were fruitless. In 1798 was published, at the expence of the French nation, and for the benefit of the widow of Perouse, "Voyage autour du Monde par J. F. G. de la Perouse," in three vols. 4to. It was translated into the English. The discoveries of this navigator are chiefly in the seas between Japan and China, and China and Tartary.

PEROUSE, *Straits of La*. in *Geography*, a narrow channel of the North Pacific ocean, between the islands of Sagalien and Jesso; about 20 miles in breadth.

PERPENAGARDE, a town of Hindoostan; 20 miles S of Calicut.

PERPENDICULAR, in *Geometry*, a line falling directly on another line, so as to make equal angles on each side; called also a *normal* line.

Thus the line I G (*Plate XI. Geometry, fig. 4.*) is perpendicular to the line K H; *i. e.* makes right and equal angles with it.

From the very notion of a perpendicular, it follows, 1. That the perpendicularity is mutual; *i. e.* if a line, as I G, be perpendicular to another, K H; that other is also perpendicular to the first.

2. That only one perpendicular can be drawn from one point in the same plane.

3. That if a perpendicular be continued through the line to which it was drawn perpendicular; the continuation will also be perpendicular to the same.

4. That if there be two points of a right line, each of which is at an equal perpendicular distance from two points of another right line; that line is parallel to the other.

5. That two right lines perpendicular to one and the same line, are parallel to each other.

6. That a line, which is perpendicular to another, is also perpendicular to all the parallels of the other.

7. That perpendiculars to one of two parallel lines, terminated by those lines, are equal to each other.

8. That a perpendicular line is the shortest of all those which can be drawn from the same point to the same right line.

Hence the distance of a point from a line, is a right line drawn from the point perpendicular to the line or plane; and hence the altitude of a figure is a perpendicular let fall from the vertex to the base.

To erect a Perpendicular G I on any given point G, in a right line M L; one foot of the compasses being in G, with any interval at pleasure, cut off equal parts on each side G H and G K; from the points K and H, with an interval greater than the half of K H, strike two arcs intersecting in I; the right line G I is perpendicular to M L.

Perpendiculars are best described in practice by means of a square: one of whose legs is applied along that line, to or from which the perpendicular is to be let fall or raised.

To erect a Perpendicular on the end of a given line, suppose at P; open your compasses to any convenient distance, and, setting one foot in C, describe the arc R P S: lay a ruler from S through C, it will find the point R in the arc, whence draw P R, which is perpendicular to P S.

To let fall a Perpendicular on a given line M P, from a given point L (*fig. 5.*); set one foot of the compasses in L, and with the other cross the given line in the points M and G. Then setting the compasses in G and M, strike two arcs intersecting each other in a: then lay a ruler from L to a, and the line K L, described thereby, is the perpendicular required.

A line is said to be perpendicular to a plane, when it is perpendicular to all right lines, that can be drawn in that plane, from the point on which it infits.

A plane is said to be perpendicular to another plane, when all right lines drawn in the one, perpendicular to the common section, are perpendicular to the other.

If a right line be perpendicular to two other right lines, intersecting each other at the common section, it will be perpendicular to the plane passing by those two lines.

Two right lines perpendicular to the same plane are parallel to each other.

If, of two parallel right lines, the one is perpendicular to any plane, the other shall also be perpendicular to the same plane.

If a right line be perpendicular to a plane, any plane passing by that line will be perpendicular to the same plane.

Planes, to which one and the same right line is perpendicular, are parallel to each other: hence all right lines perpendicular to one of two parallel planes, are also perpendicular to the other.

If two planes, cutting each other, be both perpendicular to a third plane, their common section will also be perpendicular to the same plane.

PERPENDICULAR to a curve, is a right line cutting the curve in the point in which any other right line touches it, and is also itself perpendicular to that tangent.

PERPENDICULAR, in *Fortification*. See *Military CONSTRUCTION*, according to M. Vauban's method, and according to count Pagan's method.

PERPENDICULAR, in *Gunnery*, is a small instrument used for finding the centre line of a piece in the operation of pointing it to a given object. See *Pointing of a GUN*.

PERPENDICULAR Roots. See *FIBROUS Roots*.

PERPENDICULARITY of Plants, in *Vegetable Physiology*, or the tendency which the stems of plants in general have to ascend, while their roots descend, is a curious phenomenon, first particularly noticed by M. Dodart, who laboured without much success to explain it; nor was M. de la Hire more happy in his theory on the subject. Dr. Darwin has, in our opinion, given the best explanation. He supposes that the root is most stimulated by moisture, the ascending part of the plant by air, and that each extends itself in the direction in which it meets with its requisite stimulus. This theory accounts, not only for the general direction of the stem and root, but for the occasional variations observable in both.

PERPENSUM, in *Botany*, a name applied by the younger Burmann to the *Gunnera* of Linnæus; whether adopted from Pliny, whose *Perpensa* is synonymous with *Bacchar*, or *Baccharis*; or whether in allusion to the consideration

fideration and trouble it cost him, in trying to understand the structure of the very singular flowers, we are uninformed. See GUNNERA.

PERPETUA, CAPE, in *Geography*, lies on the N.W. coast of North America. N. lat. $44^{\circ} 6'$. E. long. $235^{\circ} 52'$. This is the northern extreme of the projecting land; and the southern extreme was called by Cook cape Gregory, in N. lat. $43^{\circ} 30'$. E. long. $235^{\circ} 57'$.

PERPETUAL, something that endures always, or that lasts for ever.

PERPETUAL is sometimes also used for a thing that lasts, or holds, during a person's life.

Thus offices, &c. held *durante vita*, are sometimes called perpetual offices. In this sense, M. Fontenelle was said to be perpetual secretary of the Royal Academy of Sciences. Hence the French called him absolutely, *M. le Perpetuel*.

PERPETUAL *Action*. See ACTION.

PERPETUAL *Curate*. See CURATE.

PERPETUAL *Glands*, in *Anatomy*, are those which are natural; thus distinguished from the adventitious ones. See GLANDS.

PERPETUAL *Lamp*. See LAMP.

PERPETUAL *Motion*, in *Mechanics*. See MOTION.

PERPETUAL *Occultation* and *Apparition*, *Circle of*. See CIRCLE.

PERPETUAL *Pills*, *Pilule Perpetue*, among *Physicians*, are pills made of regulus of antimony; which, being swallowed and voided fifty times, will purge every time with undiminished force. See ANTIMONY.

PERPETUAL, or *Endless Screw*. See SCREW.

PERPETUAL *Virginity*. See VIRGIN.

PERPETUATING *the Testimony of Witnesses*. See PROVING a *Will in Chancery*.

PERPETUITY, in *Annuities*, denotes the number of years' purchase which is to be given for an annuity that is to last for ever, and it is always the quotient of unity divided by the interest of *l.* for a year, or *100l.* divided by the rate of interest. Thus, the perpetuity is 33.33 , 28.57 , 25 , 20 , or 16.666 , according as interest is reckoned at 3 , $3\frac{1}{2}$, 4 , 5 , or 6 per cent. See ANNUITIES and ASSURANCES.

PERPETUITY, *Perpetuitas*, in the *Canon Law*, the quality of a benefice that is irrevocable, or whose incumbent cannot be deprived, except in certain cases determined by law. It is asserted with reason, that the perpetuity of benefices is established by the ancient canons; and that priests are inseparably attached to their churches, as by a spiritual marriage. It is true, by the corruption of the times, the secular priests being fallen into great disorder, and even contempt, the bishops anciently called the religious to their assistance, and committed to them the cure of souls, and the administration of parishes; still remanding them back again to their cloisters, when they thought fit, and again revoking them *ad nutum*.

But this vague and uncertain administration only lasted to the twelfth century, when benefices returned to their essential perpetuity.

PERPETUITY of the *King*. See KING.

PERPIGNAN, in *Geography*, a city of France, principal place of a district, and capital of the department of the Eastern Pyrenées; and, before the revolution, the capital of Roussillon, and the see of a bishop; situated on the river Tet, about a league from the sea. The walls are of brick and stone, very high and thick, with several bastions; and its citadel is upon an eminence, commanding the town. It was founded in 1068 by Guinard, earl of Roussillon, and is said to have derived its name from that of an inn-keeper, viz. Bernard Perpignan. The eastern and western divisions

contain, each of them, 5550 inhabitants: the canton of the former has 9440, on a territory of 85 kilometres, in 14 communes; and that of the latter 8824, on a territory of $202\frac{1}{2}$ kilometres, in 6 communes. It has been often contested by the French and Spaniards. N. lat. $42^{\circ} 41'$. E. long. $2^{\circ} 59'$.

PERPURA, a river of Brazil, which runs into the Atlantic, S. lat. $3^{\circ} 50'$. W. long. $38^{\circ} 16'$.

PER QUÆ SERVITIA, in *Law*, is a writ judicial, issuing on the note of a fine; and lies for the cognizee of a manor, feignory, chief rent, or other services, to compel the tenant of the land, at the time of the fine levied, to attend to him.

PERQUAIM, or PELHAM, in *Geography*, a small island on the south coast of England, in Pool harbour.

PERQUIMINS, a river of North Carolina, which runs into the Atlantic, N. lat. $36^{\circ} 5'$. W. long. $76^{\circ} 32'$.

PERQUIMINS, a county of Edenton district, in North Carolina, bounded west by Chowan county, and east by Pasquotank, from which last it is separated by the river Pasquotank, a water of Albemarle sound. It contains 5609 inhabitants, of whom 1980 are slaves.

PERQUISITE, PERQUISITUM, any thing gotten by a man's own industry, or purchased with his own money; in contradistinction to that which descends to him from his father or his ancestors.

PERQUISITES of *Courts*, are those profits which arise to a lord of a manor, by virtue of his court-haron, over and above the certain yearly profits of his lands; as fines of copyholds, heriots, amerciaments, waives, strays, &c.

PER QUOD *consortium amisit*, or *Per Quod servitium amisit*, are words necessary in declarations for trespass, &c. where a man's wife or servant is beaten or taken from him, and he loses their services, &c. 2 Lil. Abr. 595, 596.

PERRAHGUNGE, in *Geography*, a town of Bengal; 87 miles N. of Dinagepour.

PERRANGUNGE, a town of Bengal; 66 miles N. of Dacca.

PERRAULT, CLAUDE, in *Biography*, an eminent architect, was born at Paris in 1613. He was brought up to the medical profession, and took his degree as doctor of the faculty of Paris in 1641. He practised little, however, excepting among his friends and the poor; and having a decided taste for drawing, and the fine arts, he turned his attention to the science of architecture, in which he became greatly distinguished. When the Academy of Sciences was founded, under the patronage of Colbert, in the year 1666, Perrault, who was one of the first members, was appointed to select a spot for an observatory; and he also gave a plan of the building, which was to be executed. When it was resolved, under Lewis XIV., to proceed in completing the palace of the Louvre, all the eminent architects were invited to give in designs of the façade; and that of Perrault was preferred. This is accounted the master-piece of French architecture, and it would alone suffice to transmit his name with honour to posterity. It was in vain that persons, jealous of his reputation, endeavoured to make the public believe that the real designer was Le Veau: they entirely failed in their proof, and the glory of Perrault remained untarnished. When Colbert, after the king's first conquests, proposed to construct a grand triumphal arch to his honour, Perrault's design had the preference, and the edifice was commenced. It was, however, never finished. In its masonry, Perrault employed the practice of the ancients, of rubbing the surfaces of the stones together with grit and water, so as to make them cohere without mortar. Other works of this architect were the chapel at Sceaux, that of Notre Dame in the church of the Petits Pères in Paris, the

water-alley at Versailles, and most of the designs of the vases in the park of that palace. By the king's command, he undertook a translation of Vitruvius, with notes, published in 1673. All the designs for the plates of this work were drawn by himself, and have been esteemed as master-pieces of the kind. He afterwards published an abridgment of that author, for the use of students. He likewise facilitated the study of architecture by a work, entitled "Ordonnance des cinq Espèces de Colonnes, selon la Méthode des Anciens." In the preface to this work, he maintains that there is no natural foundation for the architectural proportions; but that they may be infinitely varied, according to taste and fancy; an opinion which gave much offence, though justified by the practice of the ancients themselves. A collection of the drawings of several machines, which he at different times invented, was published after his death, in 4to. This excellent artill holds a respectable place among writers in his original profession, and, besides various memoirs on this subject, communicated to the Academy of Sciences, he published "Memoires pour servir a l'Histoire naturelle des Animaux," in 2 vols. His other writings of this class are contained in his "Essais de Physique," 4 vols. One of these volumes relates entirely to the organ of hearing, under the title of "Traite de Bruit." Another relates to the mechanism of animals, in which he anticipated Stahl in some of his opinions respecting the functions of the animal soul. In other parts of these essays he treats on the peristaltic motion, on the senses, on nutrition, &c. He died in Paris in 1688, aged 75. He had three brothers, of whom the youngest, Charles, deserves a particular notice.

Perrault published a "Dissertation upon the Music of the Ancients," in 1680, which is chiefly employed in proving that counterpoint was unknown to antiquity. He has manifested himself to have been perfectly master of the subject; he had read all the ancient authors who have written expressly upon it; he had examined the passages which have been thought the most favourable to it, in some authors who have only mentioned it occasionally; and had considered the marvellous effects attributed to it in others. He reasons forcibly, and the facts he alleges in support of the side he has taken, are strong and well stated. This work was neither the cause nor consequence of the quarrel between Boileau and his brother, Charles Perrault, which did not break out till seven years after the publication of the "Essays in Natural Philosophy," in the second volume of which the "Dissertation upon the Music of the Ancients" first appeared. Our author had indeed given his opinion upon the subject very freely, in the notes to his excellent translation of Vitruvius in 1673; where, in his commentary of the chapter upon "Harmonic Music, according to the Doctrine of Aristoxenus," he declares that "there is nothing in Aristoxenus, who was the first that wrote upon concords and discords, nor in any of the Greek authors who wrote after him, that manifests the ancients to have had the least idea of the use of concords in music of many parts." *Les dix Liv. d'Architecture de Vitruve, liv. v. p. 161, 2d edit. 1684.*

PERRAULT, CHARLES, was born at Paris in 1633. He was placed at an early age in the college of Beauvais, where he soon attracted notice by his facility in making verses. A quarrel with the principal of the college obliged him to quit the college, and interrupted the ordinary course of his studies. He, however, by no means deserted literary pursuits, but associating himself with a friend of the same age, they read the best authors together, discussing their merits, as they went along; and this second education was, in his opinion, much more useful than the first. They also indulged in the burlesque, which was then much in vogue;

and they joined in a travestie of the sixth book of the *Æneid*. Perrault was brought up to the profession of the law, and was admitted an advocate. He was, however, taken from this career by the minister Colbert, who chose him secretary to a small society of men of letters, which assembled twice a week at his house. Their business was to plan devices for medals, and other memorials, at the king's requisition, and commemorative of the glories of his reign; and this was the foundation of the celebrated Academy of Inscriptions and Belles Lettres. Charles Perrault had a singular talent for inventions of this kind, and those which he proposed commonly obtained the preference. His influence with the minister was constantly employed in the service of science and literature. He procured for the French academy apartments in the Louvre; and his brother Claude shared in the establishment of the Academy of Sciences. When Colbert caused a sum to be set apart in the treasury, for pensioning, in the king's name, the most eminent men of letters, as well in foreign countries as in France, its distribution was principally confided to Perrault. For his great services in the cause of science and literature, the French academy manifested its gratitude, by admitting him a member in 1671; and his discourse at his reception gave so much satisfaction to that body, that it thenceforth became a custom to print the admission harangues. His connection with Colbert was interrupted by some mortifications to which the minister exposed him. Perrault retired, and refused to return when invited. He withdrew to a house in one of the suburbs of Paris, in the neighbourhood of the colleges, which he chose for the purpose of superintending the education of his two sons. Here he passed his time in literary leisure, and in the enjoyment of domestic happiness. He exercised himself in writing, and composed several poems: of these one was entitled "Le Siècle de Louis XIV." It laid the foundation of a controversy, which divided all the wits in France. In enumerating the glories of the reign, he had enhanced them by a depreciation of the ancients, in every point of comparison; and as this was regarded by the votaries of antiquity in the light of a profanation, he supported his opinion by an elaborate prose work, entitled "Parallele des Anciens, et des Moderns," 4 vols. 12mo. After Perrault had withdrawn himself personally from the controversy, he occupied himself in drawing up his "Eloge Historique d'une Partie des grands Hommes qui ont paru dans le xvii Siècle." Of this work he published two volumes, folio, in 1697, 1700, with the portraits of the subjects of his eulogy. This estimable writer, who invariably maintained the character of a man of worth, died in 1703, at the age of 70. Memoirs of Charles Perrault, written by himself, were published 60 years after his death, which have been highly valued for their frankness, and for the anecdotes which they contain. Moreri.

PERRE, in *Ancient Geography*, a town of Asia, in Comagene, situated at the confluence of two small rivers, which discharged themselves into the Euphrates, south of this town.

PERREL, in *Geography*, a small island in the gulf of Tonquin, near the coast. N. lat. 20° 59'. E. long. 106° 58'.

PERRENOT, ANTONY, in *Biography*, usually known by the name of cardinal Granvelle, a celebrated statesman, was the son of Nicholas Perrenot, lord of Granvelle, chancellor to the emperor Charles V. He was born in 1517 at Besançon, and, after studying in the universities of Louvain and Padua with great reputation, entered into holy orders. He was brought to court by his father, and was employed by Charles V. in various embassies, in which he acquitted himself so well, that he gained the confidence of his master.

He

He was made bishop of Arras at the age of 25, and upon the resignation of Charles, was recommended so strongly by that sovereign to his son Philip II., that he became his most confidential minister. From Arras he was translated to the archbishopric of Mechlin, and in 1561 was created cardinal by Pius IV. Granvelle was unquestionably a great man, and possessed very commanding talents; he is said to have occupied five secretaries at once, dictating to them in different languages, of which he thoroughly possessed seven. When Margaret of Austria was placed by Philip at the head of the government in the Low Countries, Granvelle was her principal counsellor, and in reality exercised the whole authority. He is represented by Grotius as a compound of industry, vigilance, luxury, and avarice; and as equally surpassing the common measure both in good and bad qualities. He was at all times anxious to extend the royal prerogative, and to crush the Protestants. His rule, at length, grew so odious to the nobles and people, that, in 1566, public complaints against him were transmitted to Philip, who thought it prudent to recall him, though he still had a great attachment to him. Having retired for some time to Benfauçon, of which city he was made archbishop, Philip again employed him in public affairs. He was sent to Rome at the election of Pius V., and was commissioned to negotiate a league against the Turks. After this, he resided some time at Naples, in quality of viceroy; and finally, he was nominated ambassador, to conclude the marriage of the infanta Catharine with the duke of Savoy. The fatigue attendant upon the journey threw him into an illness on his return, which carried him off at Madrid, in 1586, in the 70th year of his age. Moreri.

PERREUX, in *Geography*, a town of France, in the department of the Loire, and chief place of a canton, in the district of Roanne; 3 miles E. of Roanne. The place contains 2480, and the canton 6806 inhabitants, on a territory of 167½ kilometres, in 9 communes.

PERRHÆ, in *Ancient Geography*, one of the twelve principal towns of Etruria.

PERRHÆBI, a people who inhabited the eastern part of Thessaly, in the vicinity of the sea and of the mouth of the river Peneus, according to Strabo, lib. ix. In the wars between these people and the Lapithæ, Ixion and his son Pirithous took possession of their country: many of them retired into Epirus, and the rest withdrew into the interior of the country, near the river Peneus, and the environs of mount Olympus, and the river Titarese, where they were blended with the Lapithæ. Simonides calls them "Pelaf iotes." The migration of the Perrhæbi into Epirus took place about 30 years before the last war of Troy.

PERRITIO, in *Geography*, a river of Naples, which runs into the Crate, in the province of Calabria Citra.

PERRIWIG. See PERRUKE.

PERRON, in *Architecture*, a staircase lying open, or withoutside the building: properly, the steps before the front of the building, which lead into the first story when raised a little above the level of the ground.

Perrons are made of different forms and sizes, with regard to the space and height they are to lead to. Sometimes the steps are round, or oval; more usually they are square.

PERRON, JAMES DAVY DU, in *Biography*, a learned and celebrated cardinal, descended from two ancient and noble families of Lower Normandy, which, on account of their adherence to the Protestant faith, had sought an asylum in Switzerland, and settled in the canton of Berne, where the subject of this article was born in the year 1556. He was a youth of considerable talents, and taught himself the Greek language and philosophy. After this he applied

to the Hebrew, and soon became such a proficient in it, that he could read it with facility, and delivered a course, of lectures upon it before the Protestant ministers. In 1576 he was carried to the court of Henry III., which was then sitting at Blois, where the states were assembled, and was introduced to the king as a young man of extraordinary acquirements. Upon the breaking up of the states he went to Paris, where he mounted the rostrum in the great hall of the Augustines, in the habit of a cavalier, and held public conferences upon the sciences. About this time he changed his religious sentiments, and became reader to king Henry III., who appears to have been much attached to him. No sooner had he become a convert to the Catholic church, than he assiduously laboured for the conversion of others, and this even before he had embraced the ecclesiastical profession. When he entered into holy orders he was consecrated bishop of Evreux: this was in 1595, and in 1604 he was translated to the archbishopric of Sens. In the same year, in consequence of a letter written by the king to pope Clement VIII., that pontiff conferred on him the dignity of cardinal. After this he was employed by the pope in the most important councils and congregations. After the murder of Henry IV. he devoted himself entirely to the interests of the court of Rome, and by his subserviency to its policy, excited the indignation and hatred of the friends to the independence of the Gallican church. Towards the close of his life he passed his time chiefly in retirement, employing himself in putting his last hand to his works, which were printed in a press set up in his own house, that he might be satisfied of their correctness, by carefully revising every sheet before it was worked off. He died at Paris in the year 1618, in the sixty-third year of his age. He possessed a lively and penetrating genius, and a wonderful memory. He delivered his sentiments with ease and force, and wrote purely and eloquently. His works, which were printed separately in his life-time, were collected after his death, and published in three vols. folio, in the years 1622 and 1623. His secretary, Cæsar de Ligni, added to them a fourth volume, comprising his embassies and negotiations. Moreri.

PERRONET, JOHN RODOLPHUS, director of the bridges and roads of France, was born in 1708. He was brought up to the profession of architecture in the city of Paris, and made great progress in the art. In 1745 he became inspector of the school of engineers, of which he was afterwards a director. France is indebted to him for several of its finest bridges and best roads, the canal of Burgundy, and other great works. He was, for his public services, honoured with the order of St. Michael, and admitted a member of the Academy of Sciences at Paris; of the Royal Society of London; and of the Academy of Stockholm. He died at Paris in 1794. He wrote a description of the bridges which he had constructed, 2 vols. 12mo.; "Memoirs on the Method of constructing Grand Arches of Stone from 200 to 500 Feet in span."

PERROS GUERIC, in *Geography*, a town of France, in the department of the North Coasts, and chief place of a canton, in the district of Lannion; 4 miles N. of Lannion. The place contains 1477, and the canton 8440 inhabitants, on a territory of 157½ kilometres, in nine communes.

PERROT, Sir JOHN, in *Biography*, an eminent statesman, was born of an ancient family in Pembroke-shire about the year 1527. He was bred up in the house of the marquis of Winchester, that he might profit by the discourses and example of that great man. He was one of the knights of the Bath at the coronation of Edward VI., who had a great

great partiality for him. At the beginning of the reign of Mary he was sent to prison for harbouring Protestants, but, by the interference of friends, he was discharged. He assisted at the coronation of Elizabeth, who sent him, in 1572, to Ireland, as lord president of Munster, which was in a state of rebellion, but by his promptitude was quickly reduced to obedience. He was next appointed admiral of a fleet on the coast of Ireland, which was threatened to be invaded by the Spaniards. In 1583 he was made lord deputy of Ireland, where he carried things with so high a hand, as to give very great offence, and he was recalled in 1588, and sent to the Tower. In 1592 he was tried by a special commission, brought in guilty of high treason, and sentenced to die. He was, however, respited by favour of the queen, but died in confinement the same year. Biog. Brit.

PERROT D'ABLANCOURT, NICHOLAS, a distinguished French writer, was born, in 1606, at Chalons-sur-Marne. His father, who was a convert to Protestantism, sent him for education to the college at Sedan. He afterwards studied philosophy at home under a private tutor, and then went to Paris, where, at the age of 18, he was admitted an advocate. For a time he abjured the Protestant religion, but returned to it again. His acquisitions were very extraordinary: he was well versed both in the sciences and belles lettres, understood the ancient and several modern languages, and displayed quick parts and a penetrating judgment. He was keen in debate, but mild and easy in the commerce of life. He was admitted into the French academy in the year 1637. He began a translation of Tacitus, but before he had proceeded far in the undertaking he was obliged to go to his province to take care of his small property. Retiring with his sister to his estate of Ablancourt, he passed the rest of his life upon it, only occasionally spending the winter at Paris, for the purpose of printing his works. He was appointed, by Colbert, historiographer to the king, with a pension of 1000 crowns; but when his majesty was informed that he was a Protestant, the appointment was superseded. The pension was not formally taken away, but he probably received very little of it, as he is said to have died, very poor, in the year 1664. It is chiefly as a translator that d'Ablancourt has obtained a name among polite writers, and his industry in this office was remarkable. He published versions of Minutius Felix, four of Cicero's Orations, Tacitus, Lucian, Xenophon's Anabasis, Arrian's History of Alexander, Cæsar's Commentaries, Thucydides, &c. D'Ablancourt had studied Hebrew at Leyden, and the bible was one of the books on which he bestowed the closest attention. He relied wholly on revelation for his hopes of immortality, and on this subject he wrote a discourse to his friend Patru, which is published in the works of the latter. Moreri.

PERRUKE, or PERRIWIG, was anciently used for a long head of natural hair: such, particularly, as there was care taken in the adjusting and trimming of it.

Menage derives the word, by a long detour, from the Latin *pilus*, hair. The several stages of its passage, according to the critic, are, *pilus*, *pelus*, *pelutus*, *peluticus*, *pelutica*, *perutica*, *peruca*, *perruque*.

The Latins called it *coma*; whence part of Gaul took the denomination of *Gallia Comata*, from the long hair which the natives wore as a sign of freedom. An ancient author says, that Absalom's perruque weighed two hundred shekels.

PERRUKE is now used for a set of false or borrowed hair, curled, buckled, woven on strong thread, and sewed to-

gether on a frame, or cawl; and anciently called *capillamentum*, or false perruque. See HAIR.

It is doubted, whether or not the use of perruques was known among the ancients. It is true, they used false hair. Martial and Juvenal make merry with the women of their time, for making themselves look young with their borrowed hair: with the men who changed their colours according to the seasons; and with the dotards, who hoped to deceive the Destinies by their white hair.

But these seem to have scarcely had any thing in common with our perruques; and were, at best, only composed of hair painted, and glued together. Nothing can be more ridiculous than the description Lampridius gives of the emperor Commodus's perruque; it was powdered with scrapings of gold, and oiled (if we may use the expression) with glutinous perfumes for the powder to hang by. In effect, the use of perruques, at least in their present mode, is not more than two hundred years old: the year 1629 is reckoned the epocha of long perruques; at which time they began to appear in Paris; whence they spread, by degrees, throughout the rest of Europe. At first it was reputed a scandal for young people to wear them, because the loss of their hair at that age was attributed to a disease, the very name of which is a reproach: but at length the mode prevailed over the scruple, and persons of all ages and conditions have worn them; foregoing, without any necessity, the conveniencies of their natural hair.

However, it was some time before ecclesiastics came into the fashion: the first who assumed the perruque were some of the French clergy, in the year 1660; nor is the practice yet well authorized. The cardinal Grimaldi, in 1684, and the bishop of Lavour, in 1688, prohibited the use of the perruque to all priests, without a dispensation, or necessity. M. Thiers has a treatise exprest, to prove the perruque indecent in an ecclesiastic, and directly contrary to the decrees and canons of councils. A priest's head, embellished with an artificial hair curiously adjusted, he esteems a monster in the church; nor can he conceive any thing so scandalous as an abbot with a florid countenance, heightened with a well-curled perruque.

PERRY, JOHN, *Captain*, in *Biography*, an eminent English engineer, was recommended to the czar Peter during his abode in England, as a proper person to assist him in his favourite scheme of forming a navy, and promoting inland navigation within his dominions. He was taken into the czar's service with a liberal salary, and was employed three summers in making a communication between the rivers Don and Volga. The czar's ill success against the Swedes at the battle of Narva, and other circumstances of discouragement, caused an interruption of the work in 1707, and during the two following years he was engaged in refitting the ships at Voronetz, and making navigable the river of that name. He experienced many disappointments respecting the recompence of his labours, and was finally indebted to the protection of the English ambassador for the privilege of quitting the country in 1712. After his return, he published "The State of Russia," and in a few years afterwards he was employed in stopping the alarming breach of the embankment of the Thames at Dagenham, which he accomplished, and of which he published an account in 1721. He died in 1733.

PERRY, in *Rural Economy*, the name of a pleasant and wholesome liquor made from the juice of pears, by means of fermentation, somewhat in the same manner as cider is made from apples. See APPLE, CIDER, ORCHARD, PEAR, and PEAR-Tree.

The best pears for perry, or at least the sorts which have been hitherto deemed the fittest for making this liquor, are so excessively tart and harsh, that no one can think of eating them as fruit; for even hungry swine will not eat them; nay, hardly so much as smell to them. Of these the Bosbury pear, the Bareland pear, and the horse pear, are the most esteemed for perry in Worcestershire, and the squash pear, as it is called, in Gloucestershire; in both which counties, as well as in some of the adjacent parts, they are planted in the hedge rows and most common fields.

Mr. Knight states, that in the making of this sort of liquor, the pears are ground and pressed in exactly the same manner, as those of apples in the manufacturing of cider; but that it is not usual for the reduced pulp to be suffered to remain any length of time without being pressed. It has never been the practice in Herefordshire, or the counties in the vicinity of it, to blend the juices of the different varieties of the pear in order to correct the defects of one kind, by the opposite properties of the other. It is, however, he allows, more easy to find the required portion of sugar and of astringency as well as flavour, in three or four varieties than in one; hence, he supposes, a judicious mixture of fruits affords a prospect of great benefit.

In grinding, the pulp and rind of the pear, as in the apple, should be perfectly reduced, and though no benefit is said to have been derived from the reduced pulp remaining some hours unpressed, he has no doubt but that where all other circumstances are the same, that portion of liquor will for the most part be found the best, which has remained the longest under the power of the mill-stone.

The juices of the pear and the apple are constituted of the same component parts, but the proportions are different. In the juice of the pear the tanning principle is predominant, with a less portion of sugar, mucilage, and tinging matter.

And the method of managing this sort of liquor during the process of fermentation, is likewise nearly the same as that in cider; but that it does not afford the same indications by which the proper period of racking it off may be known. The thick scum that collects on the surface of cider rarely appears on the juice of the pear, and during the time of the suspension of its fermentation, the excessive brightness of the former liquor is seldom seen in the latter; but where the fruit has been regularly ripe, its produce will generally become moderately clear and quiet in a few days after it is made, and it should then be drawn off from its grosser lees. An excess of fermentation is prevented by the means used in the making of cider, and the liquor is rendered bright by isinglass. The power this substance possesses of fining liquors appears to be purely mechanical: it is composed of innumerable fibres, which being dispersed over the liquor, attach themselves to, and carry down, its impurities. For this purpose it should be reduced to small fragments by being pounded in a mortar, and afterwards steeped twelve or fourteen hours in a quantity of liquor sufficient to produce its greatest degree of expansion. In this state it must be mixed with a few gallons of the liquor, and stirred till it is diffused and suspended in it; and it is then to be poured into the cask, and incorporated with the whole by continued agitation for the space of two hours. This process must be repeated till the required degree of brightness is obtained, the liquor being each time drawn off, on the second or third day, from its precipitated lees. Not more than an ounce and a half, or two ounces of isinglass, are generally put into a cask of a hundred and ten gallons, at once; but

were its mode of action purely mechanical, there could be no objection to a larger quantity; but it has also a chemical action on the liquor. It combines with and carries down the tanning principle, and hence, during the process of fining, the liquor is deprived of a large portion of its astringency. This substance is most readily diffused in liquors by boiling; but by this it is dissolved, and converted into glue; and its organization, on which alone its powers of fining depend, is totally destroyed. The application of it is sometimes also necessary in the manufacture of cider; though colour is seldom wanting in that liquor.

But when perry or cider can be made sufficiently bright without it, the above cited writer would not by any means recommend its use. The liquor is rendered extremely agreeable to the eye by it; but has always appeared to him to become more thin and acid by its action.

In the after-management of perry the method is the same as that of cider; but it does not bear situations where it is exposed to much change of temperature so well, and its future merit cannot so well be judged of by its present state. In the bottle it almost always retains its good qualities, and in that situation he would always recommend it to be put, if it remains sound and perfect at the conclusion of the first succeeding summer. On the whole, the pear furnishes a less popular liquor than the apple, but the tree is capable of being grown on a greater variety of soil, and is more productive, furnishing in the proportion of 600 gallons of liquor to the acre, where the trees are full grown and in good bearing.

PERRYHAZAR, in *Geography*, a town of Persia, in the province of Ghilan, on the Caspian sea; 2 miles N. of Reshd.

PERSA, in *Ancient Geography*, a town of Asia, near the Euphrates, and in the vicinity of Samofata.

PERSA, in *Geography*, a town of Hindoostan, in Oude; 60 miles E. of Bahraitch.—Also, a town of European Turkey, in the province of Servia, on the Danube; 45 miles E. of Passarowitz.

PERSAC, a town of Persia, in the province of Irak; 25 miles S.S.E. of Sultania.

PERSAH, a town of Hindoostan, in the circar of Surooja; 10 miles N.N.E. of Surooja.—Also, a town of Mocaumpour; 36 miles S.S.W. of Mocaumpour.

PERSAIN, or BASSIEN, an old town of Pegu, situated on the western branch of the river Irrawady; 132 miles S.W. of Pegu. N. lat. 16° 45'. E. long. 94° 55'.—Also, a river of Pegu, which runs near the town of the same name, and discharges itself into the bay of Bengal, S.E. of cape Negrais.

PERSANTE, a river which rises in a small lake, about four miles N.W. from New Stettin, crosses Pomerania, and runs into the Baltic, a little below Colberg.

PERSAW, a town of Prussia, in Pomerelia; 7 miles N.W. of Marienburg.

PERSCHLING, a town of Austria, on a river of the same name, that runs into the Danube; three miles above Tullu. The town is eight miles S.W. of Tullu.

PERSCOVARI, a town of Walachia; 8 miles S.W. of Brancovani.

PER SE, in the *Schools*, is sometimes opposed to *per accidens*. In which sense, a thing is said to agree with another *per se*, when the agreement is not owing to any accidental event, but is found in the intrinsic principles of things themselves.

PER SE is sometimes also opposed to *per aliud*. In which sense, God alone is said to have a being *per se*, as not deriving

iving it from any other, but having it necessarily, and of himself.

PER SE, again, sometimes signifies as much as, of its own nature, or in virtue of its own entity. Thus the sun is said to give light *per se*; and thus quantity is extended *per se*.

PER SE, among *Logicians*. A thing is said to be known *per se*, or *per se notum*, when we immediately perceive it upon the first proposing of the terms. As, that the whole is greater than its parts.

Philosophers go so far as to consider the mode of a thing existing *per se*, or that which constitutes its existence such; which they call *perfectio*, *perfectitas*.

PER SE, *Object*. See OBJECT.

PER SE, in *Chemistry*. When a body is distilled singly, and without the usual addition of another matter to it, it is said to be distilled *per se*.

The genuine spirits of hartshorn are those raised *per se*, in opposition to those distilled with the addition of lime.

PERSEA, in *Botany*, an oriental fruit, mentioned by Pliny, book 15. chap. 13, and compared by him to the Red Myxa, or *Cordia* of Linnæus. The latter gives the specific name of *Persea* to a South American species of *Laurus*.

PERSECUTION, PERSECUTIO, literally imports any pain, affliction, or inconvenience, which a person designedly inflicts on another.

PERSECUTION more particularly denotes that tyranny which the sovereign power of any country exercises, or permits to be exercised, against those who adopt different opinions from its own in matters of religion. This kind of persecution is no less contrary to reason and sound policy, than to the forbearing, comprehensive spirit of Christianity, and the laws of humanity.

It is hardly necessary to observe, that the founder of Christianity never gave any directions to his disciples to propagate his religion by external force and violence. He was too well acquainted with the human heart to imagine that these were suitable means of making converts; and he well knew, what the experience of all ages has confirmed, that such methods disserve any cause in which they are employed, and that they are adapted only to make hypocrites or martyrs. Besides, persecution is altogether inconsistent with the distinguishing character of his religion, which is "peace on earth, and good will towards men." It is likewise altogether incredible, and even impossible, that the founder of a religion, who was himself crucified, and then raised from the dead and exalted to heaven, in confirmation of the truth of his doctrine, and as an example of fidelity to God, patience, resignation, and fortitude, and to raise the thoughts of his disciples and followers to things heavenly and divine:—it is impossible that such a teacher of religion should give any directions to his apostles and ministers to propagate his religion by force and violence.

What is religion but an exercise of the understanding and of the heart, the principles and affections of which are to regulate the conduct? Persecution, therefore, is altogether incompatible with its nature and design, and tends rather to obstruct than to promote its influence; to excite prejudices against it, than to gain proselytes to its interest. Should it be said that Christians have persecuted, and that "the weapons of their warfare," with a professed view of extending the spread, and maintaining the purity of religion, have been sometimes, and, indeed, in too many instances, "carnal," and not "spiritual;"—it is allowed and lamented. But to adopt the words of an excellent prelate of the last age, "let either the bitterest zealot, or the most bigotted infidel, shew, if they can, one instance in which the gospel gives the

Vol. XXVI.

least pretence for pious cruelty. Every where it breathes mildness, patience, forbearance; enjoins Christians of ever so different opinions, to receive one another in mutual charity, and even those who are no Christians it permits us not to judge hardly, much less to use them unmercifully. If, then, some who profess this faith will act in defiance to it, let them bear their condemnation: but to charge their guilt upon Christianity, would be like censuring the legal constitution of any government, because they who rebel against it behave unjustifiably. For indeed the spirit of persecution is rebellion against Christ, under a pretence of a commission from him; it is *the man of sin sitting as God in the temple of God*, 2 Thess. ii 3, 4. And where it is not designed impiety, it is the grossest ignorance both of the attributes of our Maker and the precepts of our Redeemer." We may observe farther, that all wise and understanding men, of every sect and religion, recommend moderation, and condemn force and compulsion in things of religion. This is true both of Christians and Gentiles, as Dr. Lardner in particular has shewn in a variety of instances, both of ancient and modern date. See HERESY.

PERSECUTION, as a term, is restrained to the sufferings of Christians, in behalf of their religion; particularly to those of the primitive Christians, under the heathen emperors Nero, &c. See MARTYR.

We usually reckon ten of these persecutions: Nero set on foot the first, A.D. 65; the second happened under Domitian, A.D. 90; the third began under Trajan, A.D. 100; the fourth under Adrian, A.D. 126; which was continued under Antoninus Pius, A.D. 140; the fifth under Marcus Aurelius, A.D. 162; the sixth under Severus, A.D. 203; the seventh under Maximinus, A.D. 236; the eighth under Decius, A.D. 251; the ninth under Valerian, A.D. 258; and the tenth under Dioclesian, A.D. 303.

It has long been a prevailing opinion, that Christians suffered ten persecutions under heathen emperors. But a learned and grave writer, deservedly much respected, has made some exceptions to this opinion. "If you speak," says Mosheim, "of heavy persecutions that prevailed every where, there were not so many; if of lesser troubles, there were more than ten. The number of ten general persecutions is no more than a popular error, which arose in the fifth century, destitute of good foundation in history, and founded on a fanciful interpretation of some texts of the Old Testament, where the Christian persecutions have been thought to be foretold. Lactantius, in his book "Of the Deaths of Persecutors," makes but six persecutions; Eusebius, in his "Ecclesiastical History," does not number the persecutions, though nine persecutions may be made out from it. Upon the whole, the notion of ten heathen persecutions had its rise in the fifth century." Mosheim de Reb. Christianor.

Mr. Gibbon, in the sixteenth chapter of the second volume of his "History of the Decline and Fall of the Roman Empire," seems disposed to mitigate the severities exercised against the Christians in the different parts of the Roman empire, and he says that the primitive Christians lamented, and perhaps magnified, their own sufferings. The ingenious parallels of the ten plagues of Egypt, and of the ten horns of the Apocalypse, says this author, after Orosius, Mosheim, and others, first suggested the calculation of ten persecutions to their minds: "and in their application of the faith of prophecy to the truth of history, they were careful to select those reigns which were indeed the most hostile to the Christian cause." After a reference to Mosheim (*ubi supra*) he adds that Sulpicius Severus was the first author of this computation; though he seemed desirous of reserving the tenth

PERSECUTION.

and greatest persecution for the coming of the antichrist. He also observes, that, "the indifference of some princes, and the indulgence of others, permitted the Christians to enjoy, though not perhaps a legal, yet an actual and public toleration of their religion." How far this was the case, will appear in the sequel of this article. The question with regard to the number of persecutions has been examined with judgment and candour by Dr. Lardner: and he has stated the result with his usual impartiality. From the book "Of the Deaths of Persecutors," erroneously ascribed to Lactantius (see his article), we can expect to derive no satisfaction on this head. It was the design of the author to speak of such persecutors only as came to an untimely end; and accordingly he writes concerning the persecutions of Nero, Domitian, Valerian, and Aurelian, who suffered a violent death; and he also mentions the misfortunes and calamities that befell Dioclesian, Maximian, Galerius and Maximin. But from this book no argument can be formed for determining the number of persecutions which Christians endured from heathen emperors. Eusebius, in his "Ecclesiastical History," has mentioned eleven persecutors, *viz.* Nero, Domitian, Trajan, Marcus Antoninus, Severus, Maximin the first, or the Thracian, Decius, Gallus, Valerian, Aurelian, Dioclesian, and his colleagues. But as the several persecutions of the heathen emperors did not terminate before the commencement of the fourth century, they could not be numbered till they all took place. Orosius, who compares the ten persecutions of the Christians with the ten plagues of Egypt, states their number to be ten, and expressly calls Dioclesian's the tenth and last. Augustine likewise reckons ten heathen persecutions, which he thus numbers: *viz.* the first, Nero's; the second, Domitian's; the third, Trajan's; the fourth, Marcus Antoninus's; the fifth, Severus's; the sixth, Maximin's; the seventh, Decius's; the eighth, Valerian's; the ninth, Aurelian's; the tenth, Dioclesian's. These two learned writers lived partly in the fourth and partly in the fifth century; and we may therefore conclude, that this mode of computing was in use before the end of the fourth century, and therefore did not originate, as some have said, in the fifth century. We have other positive testimony to the contrary. Jerom's book "Of Illustrious Men, or Ecclesiastical Writers," was published in the year 392, and he there sometimes numbers the persecutions. In one place he calls Domitian's the second persecution; in another he expressly mentions, though he does not number, Trajan's persecution; elsewhere, speaking of Polycarp, he says that he suffered in the time of the fourth persecution, under Marcus Antoninus: he expressly calls Decius's the seventh, and Cyprian's martyrdom he places in the eighth persecution, in the time of Valerian and Gallienus: and in his Latin edition of the Chronicle of Eusebius are ten persecutions, all expressly mentioned and numbered, as in Augustine's. Upon the whole we may say that, though some trifling affectation may have been manifested in numbering the persecutions, yet some have actually computed nine, others ten or eleven; but ten was a round number, and has generally prevailed.

It may be observed, that the primitive Christians called those troubles persecutions, which were ordered by edicts of emperors. Of such edicts or rescripts there were ten or eleven; and it is reasonable to suppose that all persecutions ordered by imperial edicts were general: they were intended for the whole Roman empire subject to their government, but possibly they did not all actually reach to every part of the empire.

It has been said, however, that all these ten persecutions will not prove, that Christians were all along in a state of persecution till the conversion of Constantine. The lives of

some of the persecuting emperors were short, and when they were dead, their edicts were little regarded, and then peace was restored to the churches. Dr. Lardner allows that there is some truth in this allegation; nevertheless he shews, by an appeal to historical facts and records, that Christians might be said, in a mild and qualified sense, to be in a state of persecution during this period.

Some writers have taken pleasure in contrasting the persecuting temper of the Christians with the mild toleration of the ancient heathens; and in extolling the humanity of the Roman magistrates, devising apologies for their conduct in doubtful or censurable instances, and exposing the enthusiasm of those deluded Christians, who were solicitous for obtaining the crown of martyrdom. Mr. de Voltaire was one of the number to which we now refer; and we should be glad if we could altogether exempt an historian, whose works we have read with pleasure and improvement, from the same charge. Mr. Gibbon says, "it is not improbable that some of those persons who were raised to the dignities of the empire might have imbibed the prejudices of the populace, and that the cruel disposition of others might occasionally be stimulated by motives of avarice or of personal resentment. But it is certain, and we may appeal to the grateful confessions of the first Christians, that the greatest part of those magistrates, who exercised in the provinces the authority of the emperor, and of the senate, and to whose hands alone the jurisdiction of life and death was intrusted, behaved like men of polished manners and liberal education, who respected the rules of justice, and who were conversant with the precepts of philosophy. They frequently declined the odious talk of persecution, dismissed the charge with contempt, or suggested to the accused Christian some legal evasion by which he might elude the severity of the laws. Whenever they were invested with a discretionary power, they used it less for the oppression, than for the relief and benefit of the afflicted church. They were far from condemning all the Christians who were accused before their tribunal, and very far from punishing with death all those who were convicted of an obstinate adherence to the new superstition." In other places our author seems disposed to vindicate the conduct of persecuting emperors, and on some occasions the historian assumes the character of an apologist. On the other hand, the conduct of the suffering Christians is so stated, as if their persecutors had conferred an obligation upon them, by condemning them to prison, torture, and death. See MARTYR.

The learned bishop of Landaff, in his excellent "Apology for Christianity," expresses a wish for the credit of human nature, that he could find reason to agree with the classical historian, to whom we have now referred, in what he has said of the "universal toleration of polytheism; of the mild indifference of antiquity; of the Roman princes beholding, without concern, a thousand forms of religion subsisting in peace under their gentle sway." But Dr. Watson is induced, by some passages in the Roman history, to hesitate at least in this point, and almost to believe, that the Romans were exceedingly jealous of all foreign religions, whether they were accompanied with immoral manners or not. The Romans, indeed, were accustomed to invite the tutelary gods of the nations which they intended to subdue, to abandon their charge, and to promise them the same, and even a more august worship in the city of Rome; and their triumphs were graced as much in the exhibition of their captive gods, as with the less humane one of their captive kings. But this custom, though it filled the city with hundreds of gods of various descriptions, cannot be alleged as a proof of Roman toleration: it may indicate the

excess of their vanity, the extent of their superstition, or the refinement of their policy; but it can never shew that the religion of individuals, when it differed from public wisdom, was either connived at as a matter of indifference, or tolerated as an unalienable right of human nature." We learn from Livy, the Roman historian, that the ruling powers at Rome were careful in preventing any sacrifices from being offered after a new or foreign manner; and that the ædiles had it in particular charge, that no gods should be worshipped except the Roman gods, and that the worship of these should only be conducted after the established manner of the country. Dion Cassius informs us, that Mæcenas recommends it to Cæsar, to worship the gods himself, according to the established form; and to force all others to do the same; and to *hate* and to *punish* all those who should attempt to introduce foreign religions. This system of Mæcenas contained no new doctrine; it was correspondent to the practice of the Roman senate, in the most illustrious times of the republic; and seems to have been generally adopted by the emperors, in their treatment of Christians, whilst they themselves were Pagans; and in their treatment of Pagans, after they themselves became Christians. In the investigation of the motives which induced the Roman emperors to persecute, and the Roman people to hate the Christians, our author conceives, that Mr. Gibbon was misled by the erroneous idea of the extreme tolerance of Pagan Rome.

PERSEES, or PARSEES, a name given to those ancient Persians and their descendants, who were worshippers of fire; for an account of whom we refer to the articles FIRE, *Everlasting*, GABRES, MAGI, MITHRA, ZEND, and ZOROASTER. See also PERSIA. These innocent idolaters have been almost extirpated in Persia by Mahometan fanaticism, that has propagated every scandal which malice could invent, representing them as devourers of children, and guilty of other atrocities. In Persia there are few or no remains of them, except perhaps a small number of visitors of the fiery eruptions of naphtha near Baku, on the western shores of the Caspian. (See *Everlasting* FIRE.) We learn from Mr. Hanway that they here worship the everlasting fire as an emblem of Ormuzd, or the supreme ineffable creator; while the evil principle believed to have sprung from matter was styled Ahriman. But the chief worshippers of the fire of Baku came from Hindoostan, to which the Persees retreated, on occasion of various persecutions which they suffered from the Mahometans, under the caliph Omar and his successors, and also by the shah Abbas. On occasion of the persecution under Omar, who compelled all his new subjects to abandon the religion of their forefathers, some of them fled to the most distant parts of the province of Caramania, or Kerman, in which, though belonging to Persia, the Mahometan sovereigns of the country suffered them to remain unmolested, with regard to their religion. Thevenot, who was in Persia in the year 1665, says, that they dwelt there, and also in other parts of Persia, exercising their religion without disturbance. Mr. Hanway says, that when he visited the country, there were some worshippers of fire at a place called Gueberabad, near Ispahan. The Persees who left their native country in consequence of persecution, settled in considerable numbers near Bombay and Surat, where they obtained permission of the Hindoos to take up their abode, and to exercise their religion without restraint; stipulating as a condition, that they should never kill an ox or a cow, which, it is said, they have uninterruptedly observed. Their number, in and round Surat, is estimated, according to Stavorinus, at about 100,000 persons, who almost all maintain themselves by agriculture and manufactures; and these, as Valentyn says, are the posterity of about 18,000 of their country-

men, who, flying from Omar, came by sea from Cape Jask, in the gulf of Persia, Gombroon, and Ormus, to Guzerat. Distinguished by their industry, they have among them no mendicants; and many of them are domestics in the service of the Europeans who arrive in the city. Their numbers daily increase, and they occupy many entire wards in the suburbs; and along the sea-coast from Baroche to Bazaim they have established several large and wealthy villages. Several of them, who reside at Surat, are rich, and may be reckoned among the principal merchants. In complexion, they are much fairer than either the Moors or Gentoos, and differ little from the Spaniards: they have, in general, large eyes, aquiline noses, and are well-proportioned. Their women are fair, tall, handsome, and lively. These people, it is said, are addicted to sensual pleasures of the grossest kind. By marrying wives of their own nation, their race has been preserved pure and unmixed to the present day. Adultery and fornication they punish among themselves, and even by death; giving cognizance of any capital punishment to the Moorish government: the execution is performed in secret, either by lapidation, drowning in the river, castigation, or beating to death, and sometimes by poison. Their females are marriageable before they are twelve years old; but though their marriages are contracted at an early age, yet it is not consummated till the above-mentioned age of puberty. It is not customary to give any portion with the bride; but every relation and friend of the bridegroom is obliged to present him with some articles of household furniture, money, or clothes, as soon as the intended nuptials are announced to them. When a Persian dies, the body is washed clean and dressed in the oldest clothes belonging to the deceased; it is then laid upon an iron bier, and carried out of the city to one of their receptacles of the dead, where it lies to be devoured by birds of prey.

The Persees live temperately; but, contrary to the custom of the Gentoos, they eat all kinds of flesh meat, except that of oxen and hares, that they may not give offence to that nation; but it must be killed and prepared by their own people. These Persees at Surat allege, that they possess a genuine copy of the institutes of Zoroaster: they likewise pretend, that the holy fire, which they brought with them at the time of the flight from Persia, has remained burning to the present day, without being extinguished, in their largest and principal temple, which stands near the Portuguese city of Daman. This holy fire is exposed to the vulgar only once a-year, on a festival in the month of October, which marks the commencement of their year: besides this festival, they have one every month, of a religious nature; in which they offer up devout supplications to their divinity. Every Persee likewise offers up a prayer every morning, turning towards the rising sun, and another every evening, presenting himself towards the moon, if she be visible. The element of water is also an object of reverence; and their reverence for fire is carried so far, that they will not extinguish it on any occasion, even by putting out a candle or lamp. When a fire takes place in the town, they do not endeavour to quench it with water, but pull down the houses and buildings liable to be consumed by the flames, that the fire may go out for want of combustibles to maintain it. These people have six or seven houses appropriated to their religion, which we may call churches, as well within as out of the town, in which a prayer, sermon, or exhortation is every day pronounced by their priests, and in which fire is kept constantly burning, and kept up by the most costly wood that can be procured. None but a Persee may enter one of these buildings. The Persees, it is said, never attempt to make profelytes. The Moors, Gentoos,

and Persees, notwithstanding the difference of their religions, exercise toward one another the greatest toleration and indulgence. They may be seen together in, or near the river, offering up their respective prayers, without mutual contempt or molestation. When the holy fire of the Persees is exhibited to the people, no Gentoo will either approach or touch fire, no more than the Persees themselves. This mutual forbearance exhibits an example worthy of imitation. Stavorinus's Voyages, vols. ii. & iii.

PERSEPOLIS, in *Ancient Geography*, a town of Persia, was formerly called "Elymas," now known only by its ruins and monuments, which have been described by many travellers, from Chardin to Niebuhr and Franklin. They are situated at the bottom of a mountain, fronting the S.W. about 40 miles to the N. of Shiraz. They command a view of the extensive plain of Merdasht, and the mountain of Rehumut encircles them, in the form of an amphitheatre. The nature of these ruins may be seen in the numerous plates that have been published; and without these plates, any description of the grand portals, halls, and columns, and numerous reliefs and devices, must be very unsatisfactory, and almost unintelligible. Here are many inscriptions in a character not yet explained; but which Niebuhr seems to have represented with great accuracy. The letters somewhat resemble nails, disposed in various directions, in which singularity they approach to what are called the Helsing runes of Scandinavia, but the form and disposition seem more complex, and perhaps a clue might arise from comparing the Uchen character of Thibet. Behind the ruin to the N. there is a curious apartment cut out in the rock, and a subterraneous passage, which seems to extend a considerable way. The front of the palace is 600 paces N. to S., and 390 E. to W.; and the mountain behind has been deeply smoothed to make way for the foundation. About three miles and a half to the N.E. of these rivers is the tomb of Rustan, the ancient Persian hero. Pinkerton's Geog.

The temple or palace at Persepolis, now called "the throne of Jemshid," is supposed to have been erected in the time of Jemshid, and to have been posterior to the reign of the Hindoo monarchs. The figures at Persepolis differ from those at Elephanta, which are manifestly Hindoo; and Sir William Jones conjectures, that they are Sabian, which conjecture is confirmed by a circumstance, which he believes to have been a fact, viz. that the "Takhti Jemshid" was erected after the time of Cayúmers, when the Brahmans had migrated from Irán, and when their intricate mythology had been superseded by the simpler adoration of the planets and of fire. Chardin, who observed the inscriptions on these ancient monuments on the spot, observes, that they bear no resemblance whatever to the letters used by the Gabres, in their copies of the Vendidad; whence Sir William Jones inferred that the Zend letters were a modern invention; and in an amicable debate with a friend, named "Bahman," that friend insisted that the letters, to which he had alluded, and which he had often seen, were monumental characters never used in books, and intended either to conceal some religious mysteries from the vulgar, or to display the art of the sculptor, like the embellished Cúfick and Nágári on several Arabian and Indian monuments. With regard to the unknown inscriptions in the palace of Jemshid, Sir W. Jones suggests, that it may be reasonably doubted, whether they contain a system of letters, which any nation ever adopted; in five of them the letters, which are separated by points, may be reduced to forty, or at least he could distinguish no more essentially different; and they all seem to be regular variations and compositions of a straight line and an angular figure like the head of a javelin or a leaf (to use the lan-

guage of botanists) "hearted and lanced." Many of the Runick letters appear to have been formed of similar elements; and it has been observed that the writing at Persepolis bears a strong resemblance to that which the Irish call "Ogham," (which see). The word "Agam" in Sanscrit means mysterious knowledge: but Sir William Jones dares not affirm, that the two words had a common origin; and he only means to suggest, that if the characters in question be really alphabetical, they were probably secret and sacerdotal, or a mere cypher, perhaps, of which the priests only had the key. In all the other inscriptions of the same sort, the characters are too complex, and the variations of them too numerous, to admit of an opinion, that they could be symbols of articulate sounds; for even the Nágári system, which has more distinct letters than any known alphabet, consists only of forty-nine simple characters, two of which are mere substitutions, and four of little use in Sanscrit or in any other language; while the more complicated figures, exhibited by Niebuhr, must be as numerous at least as the Chinese keys, which are the signs of *ideas* only, and some of which resemble the old Persian letters at Persepolis. The Danish traveller was convinced from his own observations, that they were written from the left hand, like all the characters used by Hindoo nations. Sir William Jones concludes with observing, that the square Chaldaic letters, a few of which are found in the Persian ruins, appear to have been originally the same with the Dévanágári, before the latter were enclosed, as they are now seen, in angular frames. Sir W. Jones's Sixth Discourse in vol. ii. of Asiatic Researches; or in his Works, vol. iii. 8vo. ed. See PERSIA.

Persepolis is now called *Istakhr*, or *Istakar*; which see.

PERSES, or PERSEUS, in *Biography*, the last king of Macedon, was the son of Philip V. by a concubine. He had a younger brother, Demetrius, who was the offspring of a legitimate marriage, and who on this and other accounts was regarded by Perseus with jealousy and dislike. Demetrius, having been given by his father as a hostage to the Romans, had received most of his education at Rome, and had acquired a predilection for that people. Perseus made a handle of this to deprive him of his father's affection, in which he too well succeeded: Demetrius was put under an arrest, under the pretence of a conspiracy, and was by the order of Philip poisoned. The king discovered the fraud that had been practised on him, and in a paroxysm of grief determined to exclude Perseus from the throne, and to appoint Antigonus in his stead, but death put an end to his projects. Perseus succeeded to the crown in the year 178 B.C. and his first act was to cause his competitor, Antigonus, to be put to death. He, however, attempted to extinguish the odium of this execution by a mild and prudent government. He ingratiated himself with his own subjects, by administering justice with impartiality, and he gained the good-will of the Grecian states by relinquishing certain claims made by his house upon their cities. To the Romans he sent an embassy of friendship, which they returned by the mission of ambassadors, who took upon themselves to controul him as a dependent, rather than treat him as a sovereign prince. Misunderstandings, therefore, soon arose between them; and in the prospect of a war Perseus cultivated the friendship of the Greek states, and the neighbouring princes. He also made ample provision of money and military stores, and kept on foot a numerous and well-disciplined army. With these laudable measures of policy he did not scruple to join base and treacherous attempts against his enemies. Eumenes, king of Pergamus, his great enemy, and who had made complaints against him before the Roman senate, having paid a visit to the temple at Delphi, was attacked by assassins on his

his return, and left for dead. This villainous deed was traced to Perfes, who was soon afterwards accused of a plot for poisoning the principal persons in Rome, who opposed the Macedonian interest. To the Roman ambassadors, who charged him with these crimes, he gave such an answer, that they left his kingdom, and every thing tended to immediate hostilities. Perfes still negotiated for peace, but was haughtily answered, that he might treat with the consul, who would shortly arrive in his kingdom with an army. When war was declared, he put himself at the head of a finer army than had been seen in Macedon since the expedition of Alexander the Great, and marched into Thessaly. He insulted in his camp the Roman consul, who was much inferior in force, and gained considerable advantage in a battle. Feeling, however, that he was not equal to cope with so formidable an enemy, he renewed his offers of peace upon very humiliating terms, which were not accepted. Perfes was obliged to retreat, and at Pydna he was under the necessity of putting his fate to the hazard of a general engagement, in which he was totally defeated. This took place in the year 168 B.C., and it is affirmed by Polybius and Livy, that during the battle Perfes was employed in sacrificing to Hercules in the city of Pydna; this has, it must be admitted, been contradicted by Posidonius, a Greek writer, who being present affirms, that Perfes, notwithstanding he had been disabled by a kick from a horse, insisted upon being conveyed into the field, where he encouraged his men during the combat, till a wound from a dart compelled him to withdraw. He fled, slenderly accompanied, to Pella, where, being remonstrated with by his two chamberlains, he stabbed them both with his own hand. Thence he retreated to Amphipolis, where having mounted the tribunal to address the people, his tears flowed so fast as to prevent his utterance. From Amphipolis he sailed to the isle of Samothrace, and took refuge in the temple of Castor and Pollux, which was regarded as an inviolable sanctuary. Doubting his safety there, he hired a mariner of Crete to carry him with his family and treasures to that island, but the man, having got the money on board, set sail, and left Perfes to regain admission into the temple. At length he surrendered himself to Octavius the Roman admiral, who conveyed him to the camp of Æmilius. The consul reproached him severely for his errors, but afterwards treated him with respect and kindness. He was, however, brought to Rome; thrown into prison, and reserved to decorate the triumph of the victor. To this disgraceful scene he came, clad in deep mourning, and followed by his two sons, his infant daughter, their attendants, and the principal Macedonian nobles. After this exhibition, he was thrown into a loathsome dungeon, and reduced to such wretchedness as to be obliged to beg a share of the small pittance allowed to his fellow prisoners. He died about two years after he had been led in triumph, but the manner of his death is not known, and in him ended the kingdom of Macedon, which had subsisted six hundred years from the time of Caranus the first king. His son Alexander was at first placed with a mechanic, a worker in wood, and is said to have become a very ingenious workman, after which he was promoted to be a clerk to the Roman senate. In these inferior occupations he probably enjoyed a greater share of happiness than he would have had in the superior rank of sovereign. Univer. Hist.

PERSEVERANCE, in *Theology*, a Christian virtue, by which, as some have maintained, we are enabled to persist in the way of salvation to the end: or, by means of which, all who have ever believed in Christ, so as to be in a state of salvation, are never suffered finally to perish, but either

continue in that state to the end of their lives, or if they fall from it are again recovered to it.

The final perseverance of the saints is an article much controverted between the Arminians and Calvinists, the latter of whom maintain it impossible for grace to be lost; and therefore make perseverance to the end, a necessary consequence thereof, which the former deny; esteeming the most confirmed believers never to be out of a possibility of falling.

Those who deny this doctrine allege against it the following arguments. 1. That there are various threatenings denounced against those who apostatize, both under the Old and under the New Testament; e. g. Ezek. iii. 20. xviii. 24. Heb. vi. 4—8. 29. Psalm, cxxv. 3, 4, 5. 2. That it is foretold as a future event, that some true Christians shall fall away. Matt. xxiv. 12, 13. John, xv. 6. Matt. xiii. 20, 21. 3. That many have in fact fallen away, as David and Solomon, and those mentioned 1 Tim. i. 19, 20. 2 Tim. iv. 10. Phil. iv. 3. Col. iv. 24. Philem. v. 24. 2 Pet. ii. 18. 4. That the doctrine of perseverance supercedes the use of means, and renders those exhortations and motives insignificant, which are so often to be found in scripture; e. g. Luke, xii. 5. Rom. xi. 10. 1 Cor. ix. 27. Heb. iii. 12. iv. 1. Rev. ii. 10. iii. 11. 2 Tim. ii. 12. 5. That the doctrine of final perseverance gives great encouragement to carnal security and presumptuous sin.

In favour of this doctrine it has been alleged, 1. That it is warranted by the promises of persevering grace. Jer. xxxii. 38—40. John, iv. 14. vi. 39. x. 28. xi. 26. 2. That it may be argued from the cheerful hope and persuasion which the apostles often express of their own perseverance, and that of their fellow-saints. Rom. viii. 35. 39. Phil. i. 6. 1 Pet. i. 4, 5. 1 Cor. i. 8, 9. 1 Thess. v. 23, 24. 3. Those passages are pleaded, in which this doctrine is said to be expressly asserted; Rom. viii. 28—30. Matt. xxiv. 24. 1 John, iii. 29. Matt. vii. 25. Compare Prov. iv. 18. Job, xvii. 9. Ps. xcii. 12—15. If. xl. 31. 4. There are many passages, in which it is asserted, that those who have fallen away from their profession were never sincere in it, which, it is said, plainly implies, that those who are sincere never fall away. 1 John, ii. 19, compared with Deut. xiii. 13. Matt. vii. 23. Luke, viii. 4—15. Those who wish to examine the arguments for and against this doctrine may consult Doddridge's Lectures, pt. viii. prop. 140, and the authors to whom he refers. The strongest argument, perhaps, in favour of the doctrine of perseverance, philosophically considered, is that which is deduced from the influence of habits: but to this argument it may probably be replied, that habits are not invincible.

PERSEUS, in *Astronomy*, a constellation of the northern hemisphere; whose stars, in Ptolemy's Catalogue, are 29; in Tycho's as many; in Hevelius's, 46; and in the Britanic Catalogue, 59. See **CONSTELLATION**.

PERSEUS, in *Mythology*, the son of Jupiter and Danaë. Danaë, according to the fable, was the daughter of Acrisius, who, having learned from the oracle, that at a future time his grandson would bereave him of his life and crown, shut her up in a tower of brass, and declined attention to every proposal of marriage for her. In the mean time Prætus, his brother, being desperately in love with his niece, by means of money, corrupted the fidelity of the keepers of the princess, and having gained access to her through the roof of the prison, made her the mother of Perfes. This fable has been comprised by Ovid (Met. l. 6.) in a single verse:

“Perfea quem pluvio Danaë conceperat auro.”

Those who have written the history of this adventure, wishing

ing to palliate the disgrace which this intrigue entailed upon the royal family, reported, that Jupiter, enamoured of Danaë, had transformed himself into a shower of gold; and this was the more probable, as Prætus, if we may believe Vossius (*De Orig. &c. Idol. l. i.*), assumed the surname of Jupiter. Pausanias (in *Corinth.*) mentions the tower, or rather apartment of brass, in which Danaë had been shut up, and assures us that it subsisted till the time of Perilaus, the tyrant of Argos, who demolished it; adding that even in his time some remains were still to be seen of the subterraneous palace, of which Danaë's chamber formed a part. Such is the story of Perseus's birth, which, considering all the circumstances attending it, is not improbable. When the princess was delivered of Perseus, Acrisius ordered her to be exposed upon the sea, with her child, in a mean barge, which, after long conflict with the winds and waves, stopped near the little island of Seriphus, one of the Cyclades in the Ægean sea. Polydectes, king of the island, hospitably received the mother and child, and took great care of the education of the young prince. But afterwards falling in love with Danaë, and fearing the resentment of Perseus, advancing to maturity, he sought a pretext for dismissing him. Under a pretence of wooing one of the Grecian princesses, he determined to make a magnificent feast for the celebration of the nuptials, and actually invited the princes of the neighbouring isles, each of whom was to bring with him a present of the best things which his country supplied. In order to prolong Perseus's expedition, he ordered him to fetch the head of Medusa, one of the Gorgons. Perseus, having rescued Andromeda from the monster that was ready to devour her, married her, and carried her to Seriphus, where, after he had put Polydectes to death, he went with her and his mother into Greece, and there slew Prætus, who, not content with his own inheritance, which was the city of Tyro, Mycæna, and the whole coast of Argolis, had dethroned Acrisius. Perseus re-established his grandfather in his dominions; but as he was endeavouring to shew his dexterity in playing at the quoit, he unfortunately slew him. Thus was accomplished the prediction delivered by the oracle before his birth. Perseus, having repaired to Argos, where he deeply regretted the paricide which he had thus accidentally committed, induced Megapentes, the son of Prætus, to exchange kingdoms with him, and he built Mycæna, which became the capital of his dominions. As our hero in his lifetime had been a patron of learning, and built an academy on mount Helicon; and as he was farther distinguished by his glorious exploits, he was advanced to heaven in the panegyrics made to his honour, and after his death became a demigod. Of this prince and all his wife's family, were also formed the constellations called Cassiopeia, Perseus, and Andromeda: and the very monster, which he was said to have killed, was placed in the heavens, where it formed the sign of the whale. They intermixed the recital of his actions with all the supernatural adventures they could devise; and it was fabled, that the gods had lent him their arms; Mercury, his wings and winged shoes, to denote the celerity of his voyages; Pluto, his helmet, a symbol of his prudence and policy, which made him conceal all his designs in deep secrecy; Pallas, his buckler, to signify the good fortune which always accompanied him.

Pausanias (in *Corinth. c. 18.*) says, this prince was worshipped as a hero at Argos, and still more in the isle of Seriphus and at Athens, where he had a temple, in which was an altar consecrated to Dictys and Clymene, who were reckoned his preservers. This Dictys was the brother of Polydectes; and he, together with his wife Clymene, had the care of his education by the king's order, when he was

driven by the waves into the island of Seriphus. If we may place any dependence on the history of the fabulous ages, Perseus lived about 100 or 120 years before the Trojan war. Accordingly, Perseus preceded Bellerophon several years, since the latter lived only 40 or 45 years at most before the destruction of Troy. Banier's *Mythology*, vol. iii.

PERSHORE, or PEARSHORE, in *Geography*, an ancient market town in the upper division of the hundred of Pershore, Worcestershire, is situated on the north side of the river Avon, 103 miles N.W. by W. from London. It consists of two parochial divisions; *viz.* the vicarage of St. Andrew, and the chapelry of Holy Cross. The road from London to Worcester passing through it, has occasioned a considerable increase in its size and population. Pershore is a town of great antiquity, and is said to have derived its name from the number of pear-trees which grew in its vicinity, and from its position on the shore, or bank of a river. According to bishop Tanner, Oswald, one of the nephews of Ethelred, king of Mercia, founded a monastery here in 689; but William of Malmesbury asserts that Egelward, duke of Dorset, in the reign of Edgar, was the first founder. Gough, in his additions to Camden's *Britannia*, accounts for the discrepancy, by stating that it was so considerably enlarged and increased in its endowments by Egelward, that he was considered a new founder. It consisted at first of secular clerks, then monks, who were dismissed by king Edgar in 984, from which time it became an abbey of Benedictine monks, dedicated at first to the blessed Virgin and the apostles Peter and Paul, but afterwards to St. Edburga. Belonging to the abbey was a large church, called the Holy Cross, 280 feet in length, and 120 broad. Of the abbey itself there are but few vestiges; but the church has been modernized, repaired, and used for parochial purposes. It has a lofty square tower, and contains several antique monuments. The church and convent, being originally built of wood, were several times destroyed by fire: on St. Urban's day, in the year 1223, and again in 1287, when an accidental conflagration reduced not only the abbey to ashes, but also consumed the greatest part of the town. In ancient times, the principal approach to the abbey was through Lice-street, a Saxon appellation derived from the corpses for interment being carried along that street. A small part of the gateway, on the north side, is still in existence; near it was the chapel of St. Edburga, the eighth daughter of king Edward the Elder, who reigned about the year 900. Pershore has two churches at present, that of Holy Cross, above-mentioned, and All Saints, which is small, but kept in neat order, and has a square tower. The parish is extensive, and contains several manors and chapelries. The town is principally situated in one street, about three-quarters of a mile in length, and has many respectable houses. Pershore formerly sent members to parliament, but none have been returned since the 23d year of Edward I. It has a market on Tuesday, and three annual fairs. By the census of 1811 the number of houses was 408, containing 1910 inhabitants, the greater part of whom are employed in the manufactory of stockings.

In the neighbourhood of the town are several villages of minor importance. Defford is a chapelry to Pershore, where are some salt springs; and near it is Coppin's court, which formerly had a magnificent edifice, now razed. At Wiston, near Wych, according to bishop Tanner, a priory of canons of the order of St. Augustine was founded by Peter de Corbizon, alias Studley, in the parish church of St. Peter, about the latter end of the reign of Henry I. It was afterwards removed to Studley, in Warwickshire; and, excepting the parish church, no traces of any ecclesiastical establishment remain. Wadborough, three miles N.W. of Pershore,

shire, was formerly called Abbot-wood, from the abbots of the monastery having had a park there. Near it is a considerable tract of woodland, called "Nash's plantation." Nash's History of Worcestershire, 2 vols. folio. Beauties of England, vol. xv.

PERSIA, or PERSIS, in *Ancient and Modern Geography*, a country of Asia, the limits of which have been various at different periods. Its ancient name was "Elam," or "Elymais," and its inhabitants were denominated "Elamites," as the descendants of Elam, the son of Shem, and under this appellation they formed, about the time of Abraham, in the 18th or 19th century B.C. a powerful state. The name of Persia is derived from the oriental term *Parsa*, and originating with the province "Pars" or "Fars," it at length comprehended the whole mighty empire. It has been also sometimes called Achemenia, from the name of Achenenes, one of its ancient kings; but more commonly by the natives, and also the more intelligent Mussulmans, "Iran," under which denomination were included all the wide regions to the S. and W. of the Oxus or Gihon; and the countries beyond that river subject to Persia were, in ancient times, denominated "Aniran." Persia extended, according to the geography of Ptolemy, between Media towards the N., and the Sinus Persicus or Persian gulf on the S.; it was separated from Babylonia by Susiana, and on the W. was Carmania. In settling the largest boundaries between which it lies, sir William Jones directs us to begin with the source of the Euphrates, and thence descend to its mouth in the Persian gulf, including in our line some considerable districts and towns on both sides the river; then coasting Persia, properly so named, and other Iranian provinces, we come to the delta of the Sindhu or Indus; whence ascending to the mountains of Cashgar, we discover its fountains, and those of the Iaihun, down which we are conducted to the Caspian, which formerly perhaps it entered, though it loses itself now in the sands and lakes of Khwárezm; we next are led from the sea of Khozar, by the banks of the Cur, or Cyrus, and along the Caucasian ridges, to the shore of the Euxine, and thence, by the several Grecian seas, to the point whence we took our departure, at no considerable distance from the Mediterranean. We cannot but include the lower Asia within this outline, because it was unquestionably a part of the Persian, if not of the old Assyrian, empire. Thus, says our author, we may look on Iran as the noblest island (for so the Greeks and the Arabs would have called it), or at least as the noblest peninsula on this habitable globe. The limits assigned by nature to Persia, and which naturally subsisted in the reign of Artaxerxes, the illustrious founder of the house of Sassan, are the sea of Oman or Persian gulf and Indian ocean to the S.; the Indus and Oxus to the E. and N.E.; the Caspian sea and mount Caucasus to the N.; and the rivers Tigris and Euphrates to the W.; which boundaries comprehend many extensive provinces and several kingdoms.

The extent of Persia, according to the statement of Mr. Pinkerton, is as follows. From the mountains and deserts, which, with the river Araba, constitute the eastern frontier towards Hindoostan, Persia extends more than 1200 miles in length, to the western mountains of Elwend, and other limits of Asiatic Turkey. From S. to N., from the deserts on the Indian sea, in all ages left to the Ichthyophagi, or wild tribes of Arabs who live on fish, to the other deserts near the sea of Aral, are about 1000 British miles. The dominion of the present king is restricted to the provinces of Fars and Irak, Lar, Chufistan, part of Curdistan, Adjerbijan, Ghilan, Mazanderan, the western parts of Khorasan, with the cities of Meshed, Nishapour, and Turshisá, and the

western division of Kerman, including the capital of that province.

It may seem strange that the ancient history of so distinguished an empire should be so imperfectly known; but this is principally owing to the superficial knowledge of the Greeks and Jews, and the loss of Persian archives and historical compositions. The first Persian emperor, with whose life or character the Grecian writers before Xenophon had any accurate acquaintance, was the great Cyrus, called by sir W. Jones "Caikhofrau." After various inquiries and diligent investigation the learned sir William concludes, that the Iranian monarchy must have been the oldest in the world; and he has taken considerable pains to ascertain to what race of kings, whether Hindoo, Arabian, or Tartar, or any other, those of Iran belonged. Our author was once of opinion, with other chronologers, that the first monarchy established in Iran was the Assyrian; that the Assyrian monarchs began to reign about 200 years after Solomon; and that, in all preceding ages, the government of Iran had been divided into several petty states and principalities. But upon farther research he changed his opinion, and concluded that a powerful monarchy had been established for ages in Iran before the accession of Cayúmers (said to be the great grandson of Noah) to the throne of Persia, in the 8th or 9th century B. C.; that it was called the Mahábáedian dynasty from Mahábád, supposed by the best informed Persians to be the first monarch of Iran and of the whole earth; and that many princes had raised their empire to the zenith of human glory. Mahábád, whose name is apparently Sanscrit, divided the people into four orders, *viz.* the religious, the military, the commercial, and the servile, to which he assigned names unquestionably the same in their origin with those now applied to the four primary classes of the Hindoos. Cayúmers was probably of a different race from the Mahábádians, and his accession seems to have been accompanied by a considerable revolution both in government and religion. The monarchy established in Iran long before the Assyrian government was, in our author's opinion, a Hindoo monarchy, or as some may probably chuse to call it, Cufian, Casdean, or Scythian; and he thinks, that it subsisted many centuries, and that its history has been ingrafted on that of the Hindoos. At the earliest dawn of history our author discovers the three distinct races of men, whom he has described as possessors of India, Arabia, and Tartary. Considering the central position of Iran, which is bounded by Arabia, by Tartary, and by India, whilst Arabia lies contiguous to Iran only, but is remote from Tartary, and divided even from the skirts of India by a considerable gulf; no country but Persia seems likely to have sent forth its colonies to all the kingdoms of Asia. The Brahmans could never have migrated from India to Iran, because they are expressly forbidden by their oldest existing laws to leave the region which they inhabit at this day: the Arabs have not even a tradition of an emigration into Persia before Mahomet, nor had they indeed any inducement to quit their beautiful and extensive dominions; and as to the Tartars we have no trace in history of their departure from their plains and forests, till the invasion of the Medes, who, according to etymologists, were the sons of Madai, and even they were conducted by princes of an Assyrian family. The three races already mentioned migrated from Iran, as from their common country: and thus the Saxon Chronicle, as sir W. Jones presumes, from good authority, brings the first inhabitants of Britain from Armenia, while, according to a very learned writer, who has made laborious researches, the Goths or Scythians came from Persia; and another writer contends with great force, that both the Irish and old Britons proceeded severally

PERSIA.

rally from the borders of the Caspian. We may, therefore, says sir William, hold this proposition firmly established, that Iran, or Persia in its largest sense, was the true centre of population, of knowledge, of languages, and of arts; which, instead of travelling westward only, as it has been fancifully supposed, or eastward, as might have been asserted with equal reason, were expanded in all directions to all the regions of the world, in which the Hindoo race had settled under various denominations.

Upon the whole there is reason to believe, that the original population of the mountainous country of Persia was indigenous, or at least no preceding nation can be traced; and in the opinion of the most learned and skilful inquirers from Scaliger and Lippius to sir W. Jones, this nation is Scythian or Gothic, and the very source and fountain of all the celebrated Scythian nations. While the northern Scythians of Iran gradually became a settled and civilized people, the barbarous northern tribes spread around the Caspian and Euxine seas; and besides the powerful settlements of the Getæ and Massagetæ, the Gog and Magog of oriental authors, and others on the N. and E. of the great ridge of mountains called Imaus, or Belur Tag, they detached victorious colonies into the greater part of Europe, many centuries before the Christian era.

The ancient Medes and Parthians, in the north of Persia, says Mr. Pinkerton, appear, however, to have been Sarmatic, or Slavonic origin, and to have spread from their native regions on the Volga towards the Caucasian mountains, along which ridge they passed to the S. of the Caspian, the ancient seats of Media and Parthenia. The grand chain of Caucasus forms a kind of central point of immigration and emigration from the E. and W., whence the great variety of nations and languages, that are traced even in modern times, proceeded.

In tracing the chief historical epochs of the Persian empire. Mr. Pinkerton, in his "Geography," first mentions the Scythians, as barbarous inhabitants of Persia, who, according to Justin's account, conquered a great part of Asia, and attacked Egypt about 1500 years before the reign of Ninus, the founder of the Assyrian monarchy. (See MONARCHY.) Ninus, with whom the history of the Assyrian monarchy commences, is said to have formed an alliance with the king of Arabia, and, in conjunction with him, to have subdued all Asia, except India and Bactriana; or, according to ancient knowledge, he subdued Asia Minor, and the west of Persia. Contemporary with him was Zoroaster, king of Bactriana, who is said to have invented magic. As Babylon, the capital of Assyrian power, was not far to the S. of Bagdad, it is likely that this power extended over great part of western Persia; and Nineveh, the foundation of which is ascribed to Ninus, was situated opposite to Mosul, about 300 British miles to the N. of Babylon. But the darkness and uncertainty of remote antiquity obscure this part of the history of Persia. When Cyrus founded the Persian empire, 559 years B. C., our knowledge of the state of Persia becomes more certain and satisfactory; and much less intermingled with fables than that which is derived from the native Persian histories, which carry us back to Kayumarras, (Cayúmers,) great grandson of Noah, and from ancient traditions referring to wars against Touran and India, which indicate the primitive eastern position of the people, and to the foundation of cities in the west, as Shiraz, Persepolis, &c. which could not have had their rise, considering the proximity of the Assyrian power, before Cyrus led the Persians from the N. and the E. to the S.W. The overthrow of the Persian empire, by Alexander, B. C. 331, (see MONARCHY), was followed by the Greek monarchs of Syria, and the

Grecian kingdom of Bactriana, which commenced about 248 years B. C., and contained several satrapies, among which was Sogdiana. The Persian empire was revived under the new name of the Parthian, which commenced about 248 years B. C. About the year 220 of the Christian era, Ardshur, or Artaxerxes, restored the Persian line of kings; and this dynasty was called Sassanides. The conquest of Persia by the Mahometans took place A. D. 636. The native kingdom was revived in Corasan or Khora'san, A. D. 820; and after several revolutions resumed its former situation. The accession of the house of Bouiah occurred A. D. 934; and that of the house of Sefi or Sofi, A. D. 1501, which was the origin of the title of Sofis of Persia. In this abstract we pass over the conquests of Zingis and Timur, together with the divisions and revolutions occasioned by them: and proceed to the reign of Shah Abbas, the great, A. D. 1586, (see ABBAS,) to the conquest of the Afghans in 1722, and to the consequent extinction of the house of Sofi, and to the elevation of Nadir, surnamed Thomas Kouli Khan A. D. 1736. (See KOULI KHAN.) The power of the successors of Nadir Shah was of short duration: and at length the government of western Persia was happily settled for a considerable space of time in the person of Kerim Khan, who died in 1779, as some say in the 30th year of his reign, or according to Dr. Pallas, in his 83d year, after an uncontested reign of only 16 years. He was acknowledged as sovereign of Persia by the Turkish emperor, and by the Hindoo sultan, Hyder Aly. His character was that of a mild and benevolent prince, and the people of Shiraz embalmed his memory with benedictions and tears of gratitude. After a scene of confusion and contest, Ali Murad, a kinsman of Kerim, took peaceable possession of the Persian throne: but in advancing against Agamamet, or Akau, who had, after the death of Kerim, assumed an independent sway in the Caspian province of Mazanderam, he fell from his horse, and instantly expired. At the close of Mr. Franklin's narration, Akau held possession of the province of Mazanderam, with the cities of Tebriz and Hamadan, and even that of Ispahan in the south, so that his sway might be said to extend over one-half of western Persia, while Iaafer, who had returned from an ineffectual expedition, to Shiraz in October 1787, possessed this city, or the province of Fars, with those of Beabun, and Shulter in the W., perhaps, says Pinkerton, the Kiab and Toftar of the maps, and he received tribute from Kerman and Lar or Laritan, and Abushehr or Basheer in the S., and the city of Yezd in the N. The wide province of Mekran is, probably, with Segitlan, tributary to the kings of Candahar. The armies of Iaafer and Akau did not each exceed 20,000 men; and they were considered as the sole candidates for the throne of western Persia. In 1792, as Dr. Pallas informs us, Akau collected an army and conquered the cities of Kasbin, and Tekheran or Tahiran; and being reinforced with the troops of Ali, khan of Hamfa, advanced against Iaafer, who retreating to Shiraz, was killed in an insurrection. Hidaet, khan of Ghilan, the only remaining rival of Akau, was forced to fly from Rasht, his place of residence, but was killed near the port of Simfil. By these events Akau became monarch of all western Persia; and being an eunuch, he nominated for his successor his nephew Baba Serdar.

Eastern Persia is separated in a great degree by high ridges of mountain and sandy deserts; and this separation has occasioned great obscurity in the ancient history of the country; as the eastern half remains distinct and independent, of the same general name with the western, but with limits and history totally different. The series of events after the Mahometan conquest; the kingdoms of Corasan, Samar-cand,

PERSIA.

cand, and Ghizni; and in recent times that of Candahar, may lead to safe conclusions concerning a similar division in remote periods. See CANDAHAR.

The provinces of Persia are Georgia; Erivan; Aderbijan, or Aiderbeitzan, including Mogan; Ghilan; Mazanderan, or Mazanderan, to the E. of which was the noted province of Hyrcania, now Corcam and Dahillan; Irac, or Irac-Agemi; Chofiltan, or Chufiltan; Pars, or Farfiltan; Kerman; Lariltan; Mekran, or Meeran; Segiltan; and Corafan, or Korafan; which see respectively. Besides these provinces, and exclusive of Asiatic Turkey on the W., the ancient Persian empire comprised Bactriana, or Balk, and on the other side of the Oxus, Sogdiana. See each in its proper place. Besides, the fifteenth satrapy of Herodotus comprised the Sacæ and Caspii, and some other tribes nearer the Caspian sea. The province of the Sacæ and Caspii adjoined on the W. to Corasma, which belonged to the sixteenth satrapy, and is now the desert space of Kharism, with the small territory of Khiva. Herodotus's account of the twenty satrapies, or great provinces of the Persian empire, in the reign of Darius Hystaspes, or Ghushtasp, has been well illustrated in a late work of major Rennell, to which we refer the reader.

The principal religion of Iran, if we rely on the authorities adduced by Moshani Fâni, a Mahometan traveller and native of Cashmere, who composed a tract on twelve different religions, entitled the "Dabistân," was that, which Newton calls the oldest, and it may be justly called the noblest, of all religions; viz. "a firm belief, that one Supreme God made the world by his power, and continually governed it by his providence; a pious fear, love, and adoration of him; a due reverence for parents and aged persons; a paternal affection for the whole human species, and a compassionate tenderness ever for the brute creation." So pure and sublime a system of devotion could not long remain among mortals unperverted; and we learn from the Dabistân, that the popular worship of the Iranians under Hushang, long anterior to that of Zeratusht (Zoroaster) was purely Sabian, a word which grammarians have deduced from "saba," a host, and particularly the host of heaven, or the celestial bodies, in the adoration of which the Sabian ritual is believed to have consisted. In the learned work just mentioned, we have a description of the several Persian temples dedicated to the sun and planets, of the images adored in them, and of the magnificent processions to them on prescribed festivals, one of which is probably represented by sculpture in the ruined city of Jeshmid at Persepolis; but the planetary worship in Persia seems to be only a part of a far more complicated religion, which we find in the Indian provinces. Mahábád, it is said, received from the creator, and promulgated among men, "a sacred book in a heavenly language," to which the Mussulman author gives the Arabic title of "defatir," or regulations, without ascertaining its original name; and they say, that fourteen Mahábáds had appeared or would appear in human shape for the government of this world. As we know, says sir W. Jones, that the Hindus believe in fourteen Menus, or celestial personages with similar functions, the first of whom left a book of "regulations" or "divine ordinances," which they held equal to the Vêda, and the language of which they believe to be that of the gods, we can hardly doubt, that the first corruption of the purest and oldest religion was the system of Indian theology, invented by the Brahmans, and prevalent in the territories, where the book of Máhabád, or Menu, is at this time the standard of all religious and moral duties. The accession of Cayúmers, already mentioned, produced a revolution both in government and religion; he was pro-

bably of a different race from the Mahábádians, who preceded him, and began perhaps the new system of national faith, which Hushang, whose name it bears, completed; but the reformation was partial; for while they rejected the complex polytheism of their predecessors, they retained the laws of Mahábád, with a superstitious veneration for the sun, the planets, and fire; thus resembling the Hindu sects, called "Saurás" and "Sagnicás," the second of which is very numerous at Benares, where many "agnihotrás" are continually blazing, and where the "Ságnicás," when they enter on their sacerdotal office, kindle, with two pieces of the hard wood "Semi," a fire, which they keep lighted through their lives for their nuptial ceremony, the performance of solemn sacrifices, the obsequies of departed ancestors, and their own funeral pile. This remarkable rite was continued by Zeratusht; who reformed the old religion by the addition of geni, or angels, presiding over months and days, of new ceremonies in the veneration shewn to fire, of a new work, which he pretended to have received from heaven, and, above all, by establishing the actual adoration of one Supreme Being. He was born, according to Moshan, in the district of Rai; and it was he, and not, as Ammianus asserts, his protector Gashtasb, who travelled into India, that he might receive information from the Brahmans in theology and ethics. Pythagoras might possibly have seen him in the capital of Irak; but the Grecian sage must have been then far advanced in years, and we have no certain evidence of an intercourse between the two philosophers. The reformed religion of Persia continued in force till that country was subdued by the Mussulmans; and without studying the Zend, we have ample information concerning it, in the modern Persian writings of several who professed it. Bahman, whom we have already mentioned, always named Zeratusht with reverence; but he was in truth a pure Theist, and strongly disclaimed any adoration of the fire or other elements; he denied, that the doctrine of two coeval principles, supremely good and supremely bad, formed any part of his faith; and he often repeated with emphasis, the verses of Ferdusi, on the prostration of Cyrus and his paternal grandfather before the blazing altar: "Think not, that they were adorers of fire; for that element was only an exalted object, on the lustre of which they fixed their eyes; they humbled themselves a week before God; and, if thy understanding be ever so little exerted, thou must acknowledge thy dependence on the being supremely pure." Sir William Jones closes this detail with avowing as firm a conviction, that the doctrines of the Zend were distinct from those of the Veda, as that the religion of the Brahmans, with whom (he says) we converse every day, prevailed in Persia before the accession of Cayúmers, whom the Parfis, from respect to his memory, consider as the first of men, although they believe in an universal deluge before his reign.

With the religion of the old Persians, their philosophy was intimately connected; for they were assiduous observers of the luminaries, which they adored, and established, according to Moshan, who confirms in some degree the fragments of Berofius, a number of artificial cycles with distinct names, which seem to indicate a knowledge of the period, in which the equinoxes revolve; they are said also to have known the most wonderful powers of nature, and thence to have acquired the fame of magicians and enchanters. Our author proceeds to make some remarks on that metaphysical theology, which has been professed immemorially by a numerous sect of Persians and Hindus, was carried in part into Greece, and prevails even now among the learned Mussulmans, who sometimes avow it without reserve. The modern philosophers of this persuasion are called "Sufis," either from the

Greek word for a *Sage*, or from the *woollen* mantle, which they used to wear in some provinces of Persia. Their fundamental tenets are, that nothing exists absolutely but God; that the human soul is an emanation from his essence; and though divided for a time from its heavenly source, will be finally reunited with it; that the highest possible happiness will arise from its reunion, and that the chief good of mankind, in this transitory world, consists in as perfect an union with the eternal spirit, as the incumbrance of a mortal frame will allow: with other particulars, for which we refer to sir William Jones's Sixth Discourse. See PERSEES and MAGI.

The religion of Persia at this time is the Mahometan, which, as it was introduced by the sword, has been followed by its usual effects, the destruction and depopulation of the country. Nevertheless the Persians are said to adopt a milder system of this creed, than that which is followed by the Turks and Arabs. As they reject several absurdities, they are regarded by the other Mahometans as heretics, and are denominated "Chias," or Schiites, while the pretended true believers assume the name of "Sunnis." Chardin has particularly described the Persian system of Mahometanism. The priests of this religion, or Mullas, are in Persia often styled "Akonds," signifying leaders; and they not only preach in the mosques, but are often schoolmasters. The Pachnamas are superior Mullas, or vicars of the Imams. The Fakirs or Calenders are wandering monks, or rather sturdy beggars; who, under the pretext of religion, compel the people to maintain them in idleness. See FAKIR.

The language of the first Persian empire was the mother of the Sanscrit, and consequently of the Zend and Parfi, as well as of Greek, Latin, and Gothic. When Anushiravan sat on the throne of Persia, two languages seem to have been generally prevalent in the great empire of Iran; that of the court, thence named "Deri," which was only a refined and elegant dialect of the "Parfi," so called from the province Pars or Fars, of which Shiraz is the capital, and that of the learned, in which most books were composed, and which had the name of "Pahlavi" or "Pehlavi," either from the heroes, who spoke it in former times, or from Pahlu, a tract of land, which is said to have included some considerable cities of Irak. The ruder dialects of both these languages were, and still are, spoken by the rustics in several provinces; and in many of them, as Hérat, Zábul, Sísán, and others, distinct idioms were vernacular, as it happens in every kingdom of great extent. Besides the Parfi and Pahlavi, a very ancient and abstruse tongue was known to the priests and philosophers, called "the language of the Zend," because a book on religious and moral duties, which they held sacred, and which bore that name, had been written in it; while the "Pázend," or comment on that work, was composed in Pahlavi, as a more popular idiom; but Bahman, a learned follower of Zerátusht, and Persian reader to sir W. Jones, assured him, that the letters of his prophet's book were properly called "Zend," and the language "Avesta," as the words of the Vedas are Sanscrit, and the characters "Nagari." The Zend, appropriating the name to the sacred language of Persia, and the old Pahlavi, are almost extinct in Iran; for among 6 or 7000 Gabres, who reside chiefly at Yezd, and in Kerman, there are very few who can read Pahlavi, and scarcely any who even boast of knowing the Zend; while the Parfi, which remains almost pure in the "Sháhnámah," has now become, by the intermixture of numberless Arabian words, and many imperceptible changes, a new language, exquisitely polished by a series of fine writers in prose and verse, and analogous to the different idioms gradually formed in Europe, after the subver-

sion of the Roman empire. Sir W. Jones assures us, that hundreds of Parfi nouns are pure Sanscrit, with no other change than such as may be observed in the numerous vernacular dialects of India; that very many Persian imperatives are the roots of Sanscrit verbs; and that even the moods and tenses of the Persian verb substantivè, which is the model of all the rest, are deducible from the Sanscrit by an easy and clear analogy. Hence he concludes, that the Parfi was derived, like the various Indian dialects, from the language of the Brahmans; and he adds, that in the pure Persian he finds no trace of any Arabian tongue, except what proceeded from the known intercourse between the Persians and Arabs, especially in the time of Bahram, who was educated in Arabia, and whose Arabic verses are still extant, together with his heroic line in Deri, which many suppose to be the first attempt at Persian versification in Arabian metre. But besides, "the composition of words," in which the genius of the Persian delights, and which that of the Arabic abhors, is a decisive proof that the Parfi sprung from an Indian, and not from an Arabian, stock. After full consideration, both sir William Jones and his reader Bahman were convinced, that the Zend bore a strong resemblance to Sanscrit, and the Pahlavi to Arabic. The Pahlavi our author conceives to be a dialect of the Chaldaic. By the nature of the Chaldæan tongue most words ended in the first long vowel, like "Shamià," heaven; and that very word, unaltered in a single letter, is found in the Pazend; together with a multitude of others, all Arabic or Hebrew with a Chaldæan termination. In Pahlavi the verbal terminations of the Persian are added to the Chaldaic root. All the words cited by the learned judge are integral parts of the language, not adventitious to it, like the Arabic nouns and verbs engrafted on modern Persian; and this distinction convinces him, that the dialect of the Gabres, which they pretend to be that of Zerátusht, is a late invention of their priests, or subsequent at least to the Mussulman invasion. Our author has further shewn, that the language of the *Zend* (which see) was at least a dialect of the Sanscrit, approaching perhaps as nearly to it as the Prácrit, or other popular idioms, which are known to have been spoken in India two thousand years ago. Upon the whole sir William Jones concludes, that the oldest discoverable languages of Persia were Chaldaic and Sanscrit; and that, when they had ceased to be vernacular, the Pahlavi and Zend were deduced from them respectively, and the Parfi, either from the Zend, or immediately from the dialect of the Brahmans; but all had perhaps a mixture of Tartarian; for all the best lexicographers assert, that numberless words in ancient Persian are taken from the language of the Cimærians, or the Tartars of Kipchak. See PERSIAN *Tongue*.

The more ancient monuments of Persian literature unhappily perished when the Mahomedan fanatics conquered the country in the 7th century. One of the oldest remains is the famous "Shahnamah," or history of kings, a long heroic poem of Ferdusi. Sadi, an excellent and entertaining moralist, writes in prose mingled with verse, like several of the Icelandic sages; and a translation of his works is very desirable. The Anacreon of the East is Hafiz, whose tomb is venerated in the vicinity of Shiraz, and a splendid copy of whose works is chained to his monument. But the arts and sciences in general are little cultivated by the Persians, who are said to be lost in abject superstition, and fond believers in astrology, a proud sophistry, as Pinkerton justly expresses it, which connects the little brief delliny of man with the vast rotation of innumerable suns and worlds. The education of the modern Persians is chiefly military; and their gross flatteries and obliquity of expression, evince, that they

PERSIA.

have totally forgotten the noble system of their ancestors, who, in the first place, taught their children to speak the truth. The low state of the arts and sciences in Persia is the more surprising, as education is exceedingly cheap. Children are taught at the schools, and afterwards at the "Madrassas," or colleges, to read and write their native tongue, Arabic, moral philosophy, metaphysics, and the principles of their religion. Some of these colleges are magnificent and richly endowed: they are built in a quadrangular form, with an open court in the centre, divided into a number of cells, which are appropriated to the use of the masters and their scholars. These colleges are principally indebted for their origin to kings and other great men, who look upon it as meritorious in the eyes of God and the prophet, to employ their wealth in pious and charitable foundations.

The *poetry* of the Persians abounds with the most sublime and varied images, as well as the most pathetic descriptions. There is no country, as it is said, where so considerable a knowledge of their best writers in poetry descends even to the lowest classes of the people. The most celebrated of the Persian poets are, as we have said, Sadi, Hafiz, and Ferdúsi. The writings of Sadi inculcate the doctrines of morality. Hafiz sings of love and wine; but many of his odes are received by his countrymen in a mystical sense, and are supposed to allude to the instability of the earthly happiness, and the duties which mortals owe to their creator. In the *Shahnamah*, the great production of Ferdúsi, the oriental scholar will discover passages, which would not, perhaps, disgrace the most eminent classical authors.

In *historical* composition, the Persians claim little consideration. All their works of this kind are written since the time of Mahomet, and are written, with few exceptions, in an inflated style, full of exaggeration and embellishment. Some of the Persian *romances* are very beautiful; but the most entertaining stories have never, for the most part, been committed to paper, and are only known from oral tradition. Story-tellers are common in this country, and the king always keeps one to amuse his leisure hours.

With regard to *science*, their knowledge is very limited; they possess some knowledge of algebra and geometry, and the most learned either really are, or pretend to be, acquainted with the writings of Euclid, Aristotle, and Plato, which have been translated into Arabic. Astronomy they regard as the most sublime of all studies, probably from its connection with astrology, to which they are, as we have said, much addicted. In physic and surgery they are grossly ignorant. In sculpture and painting the Persians have at no time attained to any degree of perfection. In architecture, as well as sculpture, the ancient Persians would appear to have surpassed their descendants, in proof of which we may refer to the ruins of Persepolis, Shuster, and Ctesiphon.

The general outlines of all the cities in Persia are the same. They are surrounded by a mud, and sometimes a brick wall, flanked at regular distances with round or square towers. The streets are narrow and dirty, having a gutter through the centre; and the houses, which are low, flat-roofed, and built of brick or mud, have each a small court surrounded by a high wall. They have seldom any windows to the street. The palaces of the nobility, though mean in their exterior appearance, are convenient and elegant within: they are divided into several courts, in the most retired of which is the "haram," or apartments of the women. The centre court is usually square, divided into parterres of flowers, with a jet d'eau continually playing before the window of the "dewan kana," or public hall. The walls and ceilings of this hall are ornamented with a profusion of paintings, and inlaid with looking-glasses; the floor is covered with

carpets and numuds; and one entire side of the room is occupied by large fash windows of painted glass. The apartments of the haram are often fitted up with great taste and magnificence; but the sleeping rooms allotted to strangers are generally small. The bazars, or market places, in some cities, particularly those of Lar and Shiraz, may be accounted handsome buildings; but the mosques, minarets, and colleges, are the chief ornaments of the Persian cities.

For an account of the manners and customs of the Persians in the 17th century, we refer to Chardin, Thevenot, Sanfon, and other travellers; and an idea of modern manners may be derived from the travels of Gmelin in Ghilan. The Persians still pride themselves in universal politeness and hospitality. With a conceit of their superior wisdom and sagacity, they blend a passionate temper; and their recent commotions have tainted their national character with cruelty. Their temperament is sanguine; and both rich and poor are generally gay, and indulge immoderate mirth after the most violent quarrels.

A late writer describes the Persians as "a remarkably handsome race of men; brave, hospitable, patient in adversity, affable to strangers, and highly polished in their manners. They are gentle and insinuating in their address, and, as companions, agreeable and entertaining; but, in return, they are totally devoid of many estimable qualities, and profoundly versed in all the arts of deceit and hypocrisy. They are haughty to their inferiors, obsequious to their superiors, cruel, vindictive, treacherous, and avaricious, without faith, friendship, gratitude, or honour." "Frugal in his diet, robust in his constitution, capable of enduring astonishing fatigue, and inured, from his infancy, to the extremes of heat and cold, hunger and thirst, nature seems to have formed the Persian for a soldier."

They are much attached to the fair sex, and not averse from wine. Their general complexion is fair, with a tint of olive; but those south about Shiraz, in Candahar, and in the provinces towards India, are of a dark brown. They are commonly fat, with black hair, high forehead, aquiline nose, full cheeks, and a large chin; and the form of the countenance is frequently oval. A Persian beauty is most esteemed when of middle stature, with long black hair, black eyes and eyebrows, long eye-lashes, fair complexion with very little red, small nose, mouth, and chin, white teeth, long neck, breast not full, small feet and hands, slender shape, and extremely smooth skin. In the purchase of Georgian and Circassian slaves, it is probable that these marks are as familiar as those of a beautiful horse among jockies. Those females that are Georgian slaves are extremely beautiful and highly animated, but they excel more in the grace and elegance of their persons than in the regularity of their features. They are sometimes brought from their native country, as an article of trade; but most of them are carried away by the Persian armies in their predatory incursions into Georgia. Their price varies according to the supply of the market. In 1810 a young and beautiful Georgian girl might be purchased for about 80*l.* sterling. In this country courtizans are not only common, but encouraged by the government; they are regularly licensed, and pay a duty to the state.

The men are generally strong and robust, and inclined to martial exercises; but they are particularly subject to disorders of the eyes. They commonly shave the head; but the beard is sacred, and an object of careful attention. To talk disrespectfully of his beard, is the greatest insult that can be offered to a native of this country; and an attempt to touch it would probably be followed by the instant death

PERSIA.

of the offender. The dress of the Persians consists of a long robe, reaching nearly to the feet, and a high cap, which, when covered with a shawl, has some resemblance to the ancient tiara. A sash is bound round the waist, in which a small dagger is stuck; and no person conceives himself dressed without a sword. They often wear three or four light dresses over one another, fastened with a belt or sash; and they are fond of large cloaks of thick cloth. The dress of the women is extremely simple: it is composed, in the summer season, of a silk or muslin shift, a loose pair of velvet trowsers, and an "ulkhaliq," or vest. The head is covered with a large black turban, over which a Cashmirian shawl is gracefully thrown, so as to answer the purpose of a veil. In the cold weather, a close-bodied robe, reaching to the knees, and fastened in front by large gold buttons, is worn over the vest. This is made of velvet, or "kimcob," and sometimes ornamented with jewels.

The natives of Persia do not recline on cushions, in the luxurious manner of the Turks, but sit in an erect posture on a thick felt, called a "numud." They seldom or ever have fire in their apartments in the coldest season; but in order to be warm, fold themselves in a fur pelisse, or a "kerounce," which is a handsome robe of crimson cloth, lined with shawls or velvet. They rise with the sun, and having dressed and said their prayers, take a cup of coffee, or some fruit. They then enter on the business of the day, if they have any; or else smoke and converse until about 11 o'clock, at which time they usually have their breakfast, and then retire into the haram. Here they remain until about 3 o'clock, when they return to the hall, see company, and finish their business. Between 9 and 10, the dinner, or principal meal, is served up. Boiled rice variously prepared, curries or pillaws, and mutton and fowl differently dressed, constitute their most usual dish; of which they eat moderately, but in a manner disgusting to European delicacy. Their meat is boiled to excess, and the meal is enlarged with pot-herbs, roots and fruits, cakes, hard eggs, and above all sweet-meats, of which they are very fond. Wine they never taste before company; although in private they are notorious drunkards, and invariably drink before they eat. They are passionately fond of tobacco, which they smoke almost incessantly through the whole day; and this constitutes the principal amusement of a man of fortune. Hunting and hawking, as well as various gymnastic exercises, are their favourite amusements. By these means their bodies become hardened and active; and as they are taught to ride from their youth, they manage their horses with great boldness and address. They frequently use the warm bath, but seldom change their linen. They are remarkable for cleanliness both in their persons and habitations. Circumcision is performed by a surgeon, sometimes within ten days after the birth, and at others ten years; but that of girls is unknown, and confined to the Arabs. Marriages are conducted by female mediation, and the ceremonies somewhat resemble the Russian. Polygamy is allowed, but the first married is the chief wife. Burials are conducted with little splendour, and the day of death is commonly that of sepulture. They believe that a particular angel is the sole author of death, by the special command of God: hence suicide is very rare, and duels absolutely unknown. The wives of the peasantry are employed in the management of the house; they never go abroad without covering the lower part of the face with a veil. In the higher circles, they are almost always confined to their cell in the haram, and chiefly pass their time in drinking coffee, and smoking the "calcan;" but agreeably to the practice of the Mahometans, little attention is paid to the improvement of their minds.

The government of Persia appears to have been always despotic. That of eastern Persia, or the kingdom of Candahar, is represented as mild; and it is to be hoped, that of western Persia, when firmly established, will assume the same character. The present monarch rules with an absolute sway, and he is under no restraint in the exercise of his power; and has an uncontrolled dominion over the lives and property of his subjects. Here is no senate or national assembly of any kind. The functions of government are exercised by the sovereign and his two principal ministers, the "vizier azem," or grand vizier, and the "ameen a doulah," or lord high treasurer. The former superintends every thing connected with foreign relations, and even commands the armies, in the absence of the king or the prince. The latter, who is subordinate to the other, principally attends to internal arrangements, such as the collection of the revenues, and the cultivation of the lands. Subordinate to the ministry is a regular gradation of officers, who occupy posts in the household, army, and revenue departments. The governors of the provinces assume the title of "beglerbegs;" those of the districts that of "hakim," or "zakit;" and each village is under the management of a "khet khodah." The jurisprudence of this empire is founded, as in other Mahometan states, on the doctrines of the Koran. The "schiek ool islam" is the nominal judge of civil and criminal law; but the governors of the different towns and provinces are, in reality, the persons who decide in cases of importance. In the capital the king himself daily sits in judgment, and the award is not always consonant to justice. The most common punishments to men of exalted rank are death and deprivation of sight; and to those of the lower orders, mutilation and the bastinado on the soles of the feet. Theft is a crime always punished with the most unrelenting severity. The body of the culprit is sometimes torn asunder, by being bound to the branches of trees afterwards separated. Trifling disputes are, in general, settled by the "cazi" and "daroga" of the bazars.

The standing army of the empire, as it may be called, consists of the king's body guard, amounting to about 10,000 men, and the "gholaums," or royal slaves, who are about 3000. But the military force of the Persian empire is constituted by the number and bravery of the wandering tribes. When the sovereign wishes to assemble an army the chiefs of the different tribes are commanded to send to the royal camp a number of men, proportioned to the power and strength of each tribe. The army, thus assembled, consists chiefly of cavalry; and as they seldom receive either clothing or pay, they are only kept together by the hope of plunder. The present king, by an extraordinary effort, might probably, in this way, be able to collect together a force of 150,000 or perhaps 200,000 men. The rulers of Persia have entrusted the defence of their dominions to the cavalry, which is excellent. Their arms are a scymetar, a brace of pistols, a carabin, and sometimes a lance, or a bow and arrow, all of which they use alternately, at full speed, with the utmost dexterity. The pistols are either stuck in the girdle, or in the holsters of the saddle; the carabin or the bow is slung across the shoulder; and the lance, which is light and shafted with bamboo, is wielded in the right hand. As the Persian armies receive no regular pay, but are kept together merely by the hope of plunder, it is considered as incumbent on the king to take the field once a year, against the Russians, Afghans, or Turcomans, his immediate neighbours. But they know nothing of war as a science; and they are entirely ignorant of the principles of fortification, and of the arts of attack and defence. The chief artillery is composed of "zumbarooks," or small swivels,

PERSIA.

swivels, mounted on and fired from the backs of camels. Their roads do not allow of the transportation of cannon. In the organisation of their armies they are in total want of good officers, and consequently no proper subordination prevails among them.

The state of the people seems to be deplorable, under the arbitrary power of the numerous khans or chiefs. As to the population of Persia, it cannot be justly estimated; but perhaps it little exceeds that of Asiatic Turkey, which has been computed at 10 millions. Of these perhaps six millions may belong to western Persia; while the other four contribute towards the population of the kingdom of Candahar. The population of the Persian empire was estimated by Chardin at about 40 millions of persons; but this estimate is universally allowed far to exceed the real amount. A modern writer (Mr. J. M. Kinneir) questions whether the inhabitants of all the countries between the Euphrates and the Indus would now be found to amount to more than 18 or 20 millions; including in this computation the "Illians," or wandering tribes, who probably exceed in number those who reside in towns. These tribes constitute the military force; and their chiefs, to whom they are entirely devoted, the hereditary nobility of this great empire. These are of Turkish origin, and still speak the language, and preserve the manners of their Scythian ancestors. The land granted to each tribe, on its introduction to the country at a remote period, is now, in consequence of long possession, considered as the property of the different chiefs. These tribes, for the most part, follow the pastoral life. Their tents are walled with mats, and covered with a coarse kind of black cloth, manufactured by themselves. In the fine season they are moving in search of pasturage; but in winter, several of the tribes settle in villages. In Dalufstan, Astrabad, and the northern parts of Khorasan, they live in small portable houses, instead of tents. They principally subsist on the produce of their flocks, and grow little corn. They manufacture cloth, and several other smaller articles for their own use; and the most beautiful Persian and Turkish carpets, so much admired in Europe, are the works of the Illians. Inured from their infancy to every danger and fatigue, and tenacious, at the same time, of the honour of their tribe, they are at once the prop and the glory of their country. Each tribe is divided into "teeras," or branches; and each "teera" has a particular leader, all of whom are, however, subservient to the chief. The chiefs are, from birth and influence, the first men in the empire: they are always mutually jealous and hostile; and the king, by fomenting their quarrels, and thus nicely balancing the power of the one against that of the other, insures his own safety, and the peace of his dominions.

The most numerous and powerful of the Persian tribes are the Búcktiari, who furnish the best infantry in the kingdom, and the Fielhi, both of whom pitch their tents in the fertile districts of Lauristan, between Shuster, Ispahan, and Kermanshaw; the Afshar, to which Nadir Shah belonged, dispersed all over the kingdom; the Kafar, of which the present king is the head, who are in possession of Astrabad and Mazanderam; and the Karagoozh, or black-eyed tribe, who inhabit the plains of Hamadan, and who are esteemed the finest horsemen. The Búcktiari and Fielhi live in a remote and very mountainous territory, bordering on the Turkish and Persian empires, and in a great measure independent of both, are at best but a lawless and savage banditti. They possess the country of the Cossaens and Uxiars, whose habits they also resemble.

The army of western Persia united, and somewhat inflated in prosperity, might amount to about 100,000

effective men, and this probably may be the amount of that of Candahar. The chief merchants in Persia are the Armenian Christians and the Hindoos, so that the commerce of the country has been always in the hands of strangers. The name of a warlike navy has been altogether unknown. The revenue of Persia cannot be accurately ascertained; but it is thought probable that the monarch of Candahar may clear from his various provinces about three millions sterling; while western Persia scarcely supplies two millions. The whole revenue has been by some estimated at 700,000 toman, the toman being computed at about 3*l.* 7*s.* or about 32 millions of French livres. The revenue, as stated by the writer above named, does not much exceed three millions, and is derived from two sources; the tax on land, and the duties and imposts on all kinds of merchandize. This writer suggests, that the tax on land belonging to the crown or to individuals, may probably amount to two-thirds of the whole.

The capital city of Persia is Ispahan, which see: and the second city is Shiraz, which also see. The other cities are Teffis, Derbent, Erivan, Tebriz or Tauriz, Rasht, Sari, Bistam, Khavar, Tahiran, Casbin, Sultania, Hamadan or Amadan, Kom, and Cashan, which see respectively. On the banks of the Ahwaz, or ancient Choaspes, Kiab and Ahwaz are of small account: nor is Toftar, or Shuster, though the capital of a province, of much account. In the proximity of the Persian gulf, Kazerun, Firuzabad, and Jarun or Yaran, hardly deserve mention. Lar (which see,) is the capital of a province. For the towns on the Persian gulf, see *PERSIAN Gulf*. Tiz and Gaudal are two ports on the coast of Mekran, of no great importance. The capital of Kerman is Yezd, which see. North of Yezd is Hirabad, which see. The other cities of western Persia scarcely deserve commemoration. In passing to the eastern division, or the kingdom of Candahar, we find Cabul, the metropolis, and Candahar, a city of small size, chiefly worthy of notice as the grand passage between these extensive empires. Zarang is supposed to equal any city in Segistan; and the other chief towns on the Hindend are Dargasp, Bost, and Rokhage or Arokhage. The dominion of Zeman Shah comprises a considerable portion of Korasan. Here we find Herat, Mefchid, &c. The southern province of Mekran naturally coincides in allegiance with Segistan and Sindi to the empire of Candahar: but its northern limits have not been defined, though major Rennell informs us that they include Gaur, a considerable city and province. Bamian belongs to the same portion of Bucharia. After this cursory mention of some of the principal places in eastern and western Persia, we refer for a more particular description of them to the articles that occur under their respective names.

The manufactures and commerce of Persia may be said to be annihilated; though a few carpets still reach Europe at extravagant prices. The trade with Russia and the Caspian is of small account, consisting of salt and naphtha from Baku, and some silk from Shirvan and Ghilan. The Persian merchants also bring goods to Balfrush, the largest town in Mazanderam, where they trade with those of Russia. On this subject the reader will derive satisfactory information from the *Travels* of Mr. Hanway; the second edition of which was published in 2 vols. 4to. 1754. From Chardin we learn what was the state of the manufactures and commerce of this country in the 17th century. Embroidery on silk, cloth, and leather, had attained high perfection: earthen-ware was made throughout Persia; but the best was that of Shiraz, Mefchid, Yezd, and Zarang, where it was singularly beautiful, equalling the Chinese porcelain

PERSIA.

porcelain in fineness and transparency: some sorts resisted fire, and the fabric was so hard as to produce lasting mortars for grinding various substances. (See MURRINE.) The manufactures of leather and shagreen were also excellent; and they were distinguished for their braziers, using the tin of Sumatra for lining their vessels. The bows of Persia, its finely damasked fabrics, its razors, and other works in steel, were in high estimation; and the Persians excelled in cutting precious stones, and dyeing bright and lasting colours. Their cotton and woollen cloths, and those made of goats' and camels' hair, with their silks, brocades, and velvets, were superior manufactures. The carpets, chiefly from the province of Segistan, were brought to Europe through Turkey, and in Chardin's time called Turkey carpets: they were valued by the number of threads in the inch, being sometimes 14 or 15. The stuffs made of camels' hair were supplied chiefly from Kerman, and those of goats' hair from Mazanderam; but the cotton cloths were obtained principally from Hindoostan; but the fabric of broad cloth was unknown, and supplied by a kind of felt. The standard native merchandize was silk. To Hindoostan were sent tobacco, preserved fruits, especially dates, wines, horses, porcelain, and leather of different colours: to Turkey, tobacco and kitchen utensils: and to Russia, manufactured silks. The little commerce which the country now enjoys is principally carried on by the Armenians, whose habits, migrations, and industry, bear some resemblance to those of the Jews. They are scattered over the kingdom, and are held in greater respect by the Persians than is consistent with the intolerant precepts of the Koran. They seldom intermarry with any other sect, and preserve inviolate the religion and customs of their ancestors. As they are never allowed to interfere either in political or military concerns, their cowardice is proverbial. The principal colony of Armenians was that brought from Julfa, on the banks of Araxes, and established by Shah Abbas the Great at Ispahan. This colony, in the time of Chardin, amounted to 14,000 families; but the tyranny of the Afghans, and subsequent civil wars, have reduced the extensive and beautiful suburb of Julfa to a heap of ruins, and its inhabitants to about 400 families. The Armenians, however, are not confined to Ispahan, but are to be found in all the commercial towns of the empire. The chief imports from India are sugar, indigo, spice, cloths, piece goods, chintz from Masulipatam, woollen cloths, cutlery, and other European articles. From Astrachan, cutlery, woollen cloths, watches, jewellery, arms, and fine glass are imported. The returns for these articles are bullion, raw silk, pearl, shawls, carpets, wine, and horses.

The climate of Persia is various in different parts; depending less on difference of latitude, than on the nature and elevation of the country, so that it is said to be the country of three climates. The northern provinces on the Caspian are comparatively cold and moist: in the centre of the kingdom, as Chardin observes, the winter begins in November, and continues till March, commonly severe, with ice and snow, the latter falling chiefly on the mountains, and remaining on those three days' journey W. of Ispahan for eight months in the year. From March to May high winds are frequent; but from May to September the air is serene, refreshed by breezes in the night. The heat, however, is during this period excessive in the low countries, bordering on the Indian ocean and Persian gulf, in Chulistan, the deserts of Kerman, and also in some parts of the interior, particularly at Tehraun, the capital. From September to November, the winds again prevail. In the centre and south the air is generally dry; thunder and

lightning are uncommon; and a rainbow is seldom seen: earthquakes are almost unknown; but heat is often destructive in the spring. Near the Persian gulf the hot wind, called "Samiel," sometimes suffocates the unwary traveller. The summers are, in general, very mild, after ascending the mountains. To the N. of Shiraz the winters are severe, inasmuch, that in the vicinity of Tehraun and Tabreez, all communication is cut off, for several successive weeks, between these cities and the adjoining villages. The climate, notwithstanding this sudden transition from heat to cold, is singularly healthy, with the exception of the provinces of Ghilan and Mazanderam. The air is dry; the dews not insalubrious. The atmosphere is always clear, and at night the planets shine with a degree of lustre unknown in Europe; and as it seldom rains, here are none of those damps or pestiferous exhalations so common in the woody parts of Hindoostan.

The distinguishing features of this country are a deficiency of rivers and a multitude of mountains: its plains, where they occur, are generally desert. So that Persia may be divided into two parts by deserts and mountains, and this division, it is said, has generally influenced its history and destinies in all ages. The soil may be regarded as unfertile, and, according to Chardin, not more than one-tenth part was cultivated in his time. The mountains of this country, which are for the most part rocky, without wood or plants, are interspersed with vallies, some of which are stony and sandy, and some consisting of a hard dry clay, which requires much watering; and hence the Persian farmer is much employed in irrigation. What has now been said relates to the central and southern provinces; those in the north being sufficiently rich and fertile. The most common grain of Persia is wheat, and this is excellent. Rice is a more universal aliment, and regarded by the Persians as delicious: this is generally produced in the northern provinces, those being the best watered: barley and millet are sown; but oats are little cultivated. In Armenia there is some rye. The plough is small, and drawn by lean cattle, so that it merely scratches the ground. After the plough and harrow, the spade is used for forming the ground into squares, with ledges or little banks to retain the water. The dung is chiefly human, and that of pigeons mingled with earth, and preserved for two years to diminish its heat. In the N.W. countries the vines are interred during the winter; and when insects attack the tree, they lay fresh earth to the roots. The nature of the soil in this country varies almost as much as the climate; in the southern and eastern provinces it is light and sandy: in the western and interior parts, hard and gravelly; and in the northern division, which borders on the Caspian sea, rich and loamy. The silk worm is cultivated in most parts of the country, but particularly in the province of Ghilan, and the vicinity of Kashan; cotton, indigo, and tobacco, are also raised; and no country can exceed this in the variety or flavours of its fruits. The present depressed state of agriculture is owing, in a great measure, to the unsettled nature and disposition of the government, which affords no protection to private property, and offers no encouragement to industry.

The rivers of Persia, not taking into account the Euphrates, Tigris, and Indus or Sinde, which are not properly Persian, are the Ahwaz (supposed by some to be the Gyndes of Herodotus), the Zeindeh of d'Anville, and called by the Turks Kara Sou (see KARASA), or the black river; which is reckoned one of the most considerable in Persia, and pursues a course of about 400 British miles, from the mountains of Elwend to the estuary of the Tigris and Euphrates:—the Rud, or Divrud, the principal of those
rivers

PERSIA.

rivers that flow from the range of mountains in the N.E. and fall into the Persian gulf:—the Krenk and Mekshid, rivers of Mekran, which join and form the river of Mend, so called from a town by which it passes:—the Haur and the Araba, the latter of which serves as a boundary towards Hindooftan:—the large river of Gihon, or Amu, in the N.E.:—the river Tedjen, or Tedyen, to the W., being the ancient Ochus, and flowing into the Caspian:—the Kizil Ozen, or Sefid Rud, rising, according to d'Anville, in the mountain of Elwend, not far N. of Hamadan, and by a winding course running into the Caspian; which river is the Mardus of antiquity,—and the Swidura of Gmelin, rising on the confines of Turkey, and falling into the sea below Langorod; abounding in pike, carp, and other kinds of fish, esteemed by the Persians; and, as Gmelin says, in sturgeons:—farther to the N., the large river Aras, the ancient Araxcs, which falls into the Kur or Cyrus (see KUR):—the central rivers of Persia, soon lost in sandy deserts, are the Zenderud, rising in the western chain of Elwend, passing by Ispahan, and soon after losing itself in the sand:—the Koh Asp of d'Anville, the Correng of Chardin, which passes by Shuster:—the Bundamir (which see):—the Kuren, a considerable stream from the N.E. that flows into the lake Baktegan:—and the Hinmend, or Hindmund, which see.

The lakes of Persia are the Aria Palus of antiquity (see ARIA):—the salt lake of Baktegan (which see):—the large lake of Urmia (see URMIA):—the lake Van:—and the lake of Erivan, about 120 British miles to the N. of Urmia, about 25 leagues in circumference, with a small isle in the middle: this lake abounds with carp and trout, and is the Lychnites of Ptolemy.

In presenting to our readers a brief view of the mountains of Persia, the first object that merits attention is the direction of its chief chains. To these we may refer the Caucasian ridge (see CAUCASUS):—the Hindoo-Kho, which is an extension of the Belur-Tag (see both these articles):—the Elwend, so called from a particular mountain in the vicinity of Hamadan, and reckoned the greatest chain of mountains in Persia, of very great height, extending to the south of the lake of Urmia, where it is connected with the Caucasian ridge:—a parallel ridge on the W., called by the Turks Aiagha Tag, supposed to be the Zagros of the ancients, which separated Assyria from Media, and extending to the lake of Van:—and Hetzardara, (which see). Chardin considers the noted Damavend of the Persians, as a ridge dividing Hyrcania from Parthia; that is, in other words the mountains of Mazanderam; and he adds that of the mountains between Fars and Kerman, the most remarkable is called Jaron; but the mountains of Kurdistan alone present forests. The great western range of mountains is called in some parts the mountains of Loozistan; and more to the S. the Adervan and Dinar, with Ajuduk, N. of Lar. It detaches some remarkable branches to the S.E., as that on the W. of Kom, Cathan, Nathan, &c. which from a particular mountain may be called the range of Elburz. Another branch spreads to the S. of Ispahan, which d'Anville considers as the same with what the Persians call the thousand mountains, or Hetzardara. Still more to the S. a large and extensive branch extends between the rivers Kuren and Bundamir; and presents on the western side of its further extremity the noted ruins of Persepolis. The pass of Khavar is near the southernmost extent of the Caucasian heights of the Mazanderam; and Mr. Pinkerton thinks there is no reason for believing that any ridge extends into the great Saline desert. We learn from Mr. Forster that there are no ranges from Candahar to Korafan. Herat stands on a plain; but to the N. of Dochabad and Turshiz, there is a range of moun-

tains covered with snow. About three miles E. of Khana-hoody, a chain of mountains of some height extends N. and S.

Some have represented the province of Fars as separated from Kerman by a range of mountains; but the real barrier is a desert of sand, extending from the S. of the lake Baktegan to the proximity of Zarang, and connected with the great desert which divides Persia into two parts. There are no mountains of consequence on the E. of Fars. A low range, called Meder by d'Anville, passes N.E. through the heart of Kerman; while that country is divided from Mekran by a range in the same direction, called by d'Anville Kofez. Some other nameless ranges traverse Mekran in the same direction; that nearest Hindooftan being called by Rochette the Lakhee mountains. On the N. of Mekran, a considerable range runs E. and W. which has not been named by d'Anville; but it seems, says Pinkerton, to be the Beticus of Ptolemy. Further to the N., the mountains of Wulli extend from the neighbourhood of Shatzan across to the lake of Vaihind, and may be considered as forming one range with that on the N. of Mekran, called by La Rochette Gebelabad. This range however terminates in the great desert to the S. of Zarang. In the E. of Segistan there is a ridge N. and S. called Soliman Koh, or the mountains of Soliman. It is probable also, that there are mountains of considerable height on the N. and W. of the sea of Zurra; one called Berfhek, and another Ouk, the former being noted for a fire-temple, the resort of the Guebres or Gabres.

The deserts of Persia are the following: on the E. of the Tigris, N. lat. 33°, a considerable desert commences, pervaded by the river Ahwaz, and extending to the N. of Shuster, which is about 140 British miles in length from E. to W., and about 80 in breadth, and is now inhabited by the wandering tribe of Arabs called Beni Kiab.

The great Saline desert extends from the vicinity of Kom, or Koom and Kashan, to that of the sea of Zurra, in a line from E. to W. of about 400 British miles, and from N. to S. in breadth about 250; but joining in the latter quarter with the great desert of Kerman by the Nauben Dejian, which extends about 350 miles. These two extensive deserts may thus be considered as stretching N.W. and S.E. for a space of about 700 miles, by a medial breadth of about 200 (not including in the length the other 200 miles of the desert of Mekran); thus intersecting the wide empire into two nearly equal portions. This immense extent is impregnated with nitre and other salts, which taint the neighbouring lakes and rivers. In the bay of Mekran, and towards the Indus, are other deserts of great extent.

A third great desert, that of Karakum, or the black sand, forms the northern boundary of Korafan and modern Persia. The desert of Margiana is placed by Ptolemy on the N.W. of Aria; and if, with d'Anville, we suppose Margiana to have derived its name from the river Margus, or Morgab, this desert may be in the vicinity of Badkis.

The Persian forests are restricted to a few spots in Korafan, the mountains of Mazanderam and Ghilan, and those towards Kurdistan. But timber is chiefly supplied by Mazanderam, which from this circumstance receives a name signifying the land of oxen.

The indigenous vegetables of Persia are very much unknown. The saline deserts are for the most part destitute of trees, and support hardly any plants except those that are also found on the sea-shore. On the high mountains they are much the same as those observed on the Alps of Switzerland and Italy. The plants on the hills and plains adjoining the Caspian are better known. On the mountainous ridges are
found

PERSIA.

found the cypress, the cedar, and several kinds of pines, while the lower hills and scars of rock are shaded and adorned with lime-trees, oaks, acacias and chestnuts: the fumach is also abundant, and the fraxinus ornus, or manna ash-tree, is less common. The most esteemed of the cultivated fruits of Europe are indigenous in Persia, and have probably been diffused from hence over the whole west. These are the fig, the pomegranate, the mulberry, the almond, peach and apricot. Orange-trees of an enormous size are found in the sheltered recesses of the mountains, and the deep warm sand on the shore of the Caspian is peculiarly favourable to the culture of the citron and the legumina. Apples, pears, cherries, walnuts, melons, besides the fruits already mentioned, are every where to be procured at very low prices; the quinces of Ispahan are the finest in the East; and no grape is more delicious than that of Shiraz. In the provinces bordering on the Caspian sea, and mount Caucasus, the air is perfumed with roses and other sweet-scented flowers. Among the vegetable productions we may enumerate cabbages, cucumbers, turnips, carrots, pease, and beans; and the potatoe, which has been lately introduced, thrives remarkably well. Poppies, from which an excellent opium is extracted, fenna, rhubarb, saffron, and assafœtida, are produced in many parts of the kingdom. The vine grows here luxuriantly, and further to the S. cotton and sugar are articles of common cultivation. Poplars, large and beautiful, and the weeping willow, border the course of the streams, and the marshy tracts abound with the kind of rush that serves for the fine Persian matting. Ornamental shrubs or herbaceous plants are little known; but the jasmine, the blue and scarlet anemone in the thickets, and the tulip, and ranunculus in the pastures, are abundant and beautiful, and give an air of elegance to the country.

According to Chardin, the Persian horses are the most beautiful in the East; but they yield in speed, and, as some say, in beauty also, to the Arabian. However, they are larger, more powerful, and all things considered, better calculated for cavalry than those of Arabia. There are several breeds of horses, but the most valuable is that called the Turkoman, which are so hardy, that they have been known to travel 900 miles in eleven successive days. The Arabian blood has also been introduced into this country. Their usual food is chopped straw and barley; their bed is made of dung, dried and pulverized, and every morning regularly exposed to the sun. They are clothed with the greatest attention, according to the climate and season of the year; and during the warm weather kept in the stable during the day, and taken out at night.

Mules are also here in considerable request; and the assembles the European: but a breed of this animal has been brought from Arabia, of an excellent kind, the hair being smooth, the head high, and the motion spirited and agile. Although the mules are small, they are fairly proportioned, carry a great weight, and those that are intended for the saddle are taught a fine amble, which carries the rider at the rate of five or six miles an hour. The camel is also common; and these animals are exported from Persia to Turkey, which have, as Chardin says, only one hunch, while those of India and Arabia have two. The Persian cattle in general resemble the European: swine are scarce, except in the N.W. provinces. The flocks of sheep, among which are those with large tails, are most numerous in the northern province of Erivan, or the Persian part of Armenia, and Balk. The few forests abound with deer and antelopes; and the mountains supply wild goats, and probably the ibex, or rock goat. Hares are common. The ferocious animals are chiefly concealed in the forests, such as the bear and boar, the lion in

the western parts, the leopard, and as some say, the small or common tiger. Seals occur on the rocks of the Caspian. The hyæna and chackal belong to the southern provinces. The seas abound with fish of various descriptions: the Caspian affords sturgeon, and delicious carp. The most common river-fish is the barbel. The same sorts of wild and tame fowl are common in Persia and in Europe, with the exception of the turkey, whose nature does not seem to be congenial to this climate. Pigeons are numerous, and partridges are large and excellent. The boobul, or oriental nightingale, enlivens the spring with his varied song.

The Persians have been long accustomed to tame beasts of prey, and even to hunt with lions, tigers, leopards, panthers, and ounces.

As to the mineralogy of this country, it affords neither number nor variety of treasures. Chardin assures us, that it has no mines of gold or silver. The lead mines of Kerman and Yezd produce the usual mixture of silver. In the northern provinces there are many mines of iron, but the metal is harsh and brittle. Mines of steel ore, or carbonated iron, are also wrought in the same districts, and these are so impregnated with sulphur, that the filings, when thrown in the fire, flash like gunpowder. Copper is chiefly found on the mountains of Mazanderam, and near Casbin, but it is brittle. There are two mines of the turquoise, one at Nishapour in Korasan, and another in a mountain called Feruzkoh, S. of the Caspian. The pearls of the Persian gulf have been long famous. (See PEARL.) Otter, an intelligent traveller in Persia, says, that among the articles sold in the bazars of Ispahan are diamonds of Golconda; rubies, topazes, and sapphires of Pegu; emeralds of Said or the Thebais; and balay rubies from Bedakshan, a country between the rivers Gihon and Murgab, which also produces lapis lazuli, amianthus, and rock crystal. Sulphur and nitre are found in the mountains of Demavend: whole deserts are, in some instances, covered with sulphur, and others with salt, that near Cashan being remarkably pure. Rock-salt is found near Ispahan, and in the dry climate of Kerman, if we may credit Chardin, it is even employed in building. Free-stone, marble, and slate, are chiefly obtained from Hamadan; and near Tauriz is a marble, as Chardin calls it, which is transparent, like rock-crystal, through tables an inch in thickness, of a white colour, blended with green, probably a kind of jade. Towards the Tigris are pools of bitumen, or rock-tar, and naphtha abounds near Baku. In Erivan and Fars are mines of talc, and of a pure white marl used like soap. For an account of the mumia of Korasan, see MUMMY. Although mineral waters abound in this mountainous country, they are generally disregarded both by the physicians and the people.

Barbarous princes seem to have entertained the idea, that bad roads contribute to the security of their dominions. The Turks and Persians are, without doubt, of this opinion; for the public highways, and particularly those that lie towards the frontier, are very much neglected. The only mode of travelling is by riding either a mule or an ass. For women of high rank, and for sick persons, there is, indeed, a vehicle, called a "tukte rowan," which is transported by two mules, one before and the other behind; but the women and children of the poor are carried in baskets, slung across the back of a mule or camel. The length of the stage (which sometimes exceeds forty miles), and badness of the accommodation, render travelling very unpleasant. Here are no regular establishments for the transmission of intelligence, and therefore it is necessary for the dispatch of letters from one part of the kingdom to another

another, to send a "chupper," or express horseman, or a messenger on foot, who is called "caffid." Although the distance be ever so great, the chupper seldom changes his horse; for in Persia, there are no post-houses and relays of horses as in Turkey. They travel at the rate of four or five miles an hour, and have been known to go from Tebraun to Busheer, a distance of 700 miles, in the space of ten days. The caffids will also travel for many days successively at the rate of sixty or seventy miles a day.

Among the chief natural curiosities of this country, we might mention the fountains of naphtha, in the vicinity of Baku, and in the adjoining promontory of Absheron; and the blue flame issuing from the ground, and particularly from an horizontal gap, about sixty feet long by three broad, in a neighbouring rock. The naphtha is much used by the Persians, and particularly by the poorer sort, as we use oil in lamps, or to boil their victuals, though it communicates a disagreeable taste. That which is white, and of a thinner consistency, and which is found only in small quantities, is drank by the Russians both as a cordial and a medicine; taken internally, it is said to be good for the stone, for disorders of the breast, and in venereal cases and sore heads. Externally applied, it is said (see Hanway's Travels, vol. i.) to be of great use in scorbutic pains, gouts, cramps, &c. It has also the property of spirits of wine to take out greasy spots in silks or woollens, but it leaves after the use of it an abominable odour. They say it is carried to India as a great rarity, and being prepared as a japan, is the most beautiful and lasting of any that has been yet found. Near the spot where this naphtha is procured are springs of hot water, which boil up in the same manner as the naphtha. Bathing in this warm water is found to strengthen and procure a good appetite, especially if a small quantity of it is drank. These remarkable springs have been described by Kämpfer at the end of the 17th century, by Gmelin in 1773, and more fully by Hanway *ubi supra*. In an adjoining peninsula there are many other wells; and the revenue arising from this uncommon product to the khan of Baku is computed at 40,000 rubles. See *Everlasting FIRE*.

The progressive geography of this celebrated country may be traced through Strabo, Pliny, the historians of Alexander, and other classical sources, and afterwards through the Arabian authors, Ebn Hankel, Edrisi, Abulfeda, &c. &c. to the modern labours of Chardin, Hanway, Franklin, Gmelin, Pallas, &c. &c. We have been principally indebted for the materials of this article to the compilation of Mr. Pinkerton, in the 2d volume of his Geography; to the 6th Discourse of Sir William Jones; to Hanway's Travels; and Kenner's Geographical Memoir on the Persian Empire, 1813.

PERSHAH, a town of Hindoostan, in Baglana; 18 miles E.S.E. of Basseen.

PERSIAN Empire, and Monarchy. See MONARCHY.

PERSIAN Gulf, called also the *Sea of Omar*, and the *Green Sea*, a sea or inland lake, bounded on the north by Persia, and elsewhere by Arabia, except at the eastern extremity, where it communicates with the Arabian sea; about 500 miles from E. to W., and from 120 to 250 in breadth, from N. to S. The principal river which runs into it is the Euphrates. The southern coast in particular has been celebrated for its pearl-fishery. (See PEARL.) The coasts both on the N. and S. belong chiefly to colonies of Arabians. This celebrated gulf has been always more remarkable for the factories of foreigners, than for its native establishments. Bender-Abassi was a port opposite to the isle of Ormus, or rather on the coast between Ormus and Kishmish, or Kishma, and is now more commonly known

by the name of Gombroon. The trade, once considerable, is now greatly declined; and even the Dutch left it, and settled in the isle of Karek or Garek. The French Indian commerce has failed; and the English staple is Bassora. But Busheer, and Rik, or Bundarik, are also sometimes frequented. See these several places under their appropriate denominations.

The Arabian shore of this gulf has never been surveyed; and as it has many sand-banks and shoals, the navigation is difficult and dangerous. The Persian shore is more elevated than that of Arabia; and the islands with which the gulf abounds are chiefly on that side. This is a safe coast, on which, generally speaking, there are regular soundings, and ships may almost every where procure shelter from violent gales of winds, either in bays or under the lee of the islands.

The promontory of Cape Mufledom (called by the natives Ras-ul-Gibel), at the entrance of the gulf, and on the Arabian shore, is said to be the termination of a mountainous tract, inhabited by a tribe of persons descended from a mixture of Arabs and Portuguese, who have hitherto bravely resisted the encroachments of the Wahabees. The small islands, or rather rocks, called the "Quoins," lie about ten miles to the N. of the Cape, and the channel between them is reported to be free from danger. At Rams, a piratical town, N. lat. 25° 53', the mountains retire, and the water begins to shoal. From this place, to the town of Shorga, a distance of seventeen leagues, it is hazardous for ships to approach the coast, owing to the prevalence of the N.W. winds. From Shorga to Granc, a large town in N. lat. 29° 12', the coast is denominated by the Arabs "The Coasts of Danger." It is unknown to Europeans, and supposed to abound in coral and pearl banks. The greatest part of the Arabian shore is in the possession of the Joasmi Arabs, a licentious band of pirates, who, by their depredations, obstruct the commerce of the gulf. Their principal rendezvous is Ras-ul-Khyma, a town about seven miles S.W. of Rams. At the mouth of the gulf is the celebrated island of Ormus or Hermus. (See ORMUS.) Larrek is a small island, ten miles S.S.W. of Ormus, about fifteen miles in circumference. The largest island in the gulf is Kishm, or Jezira Derauz, *i. e.* Long Island. (See KISHMA.) On the S. side is a most excellent harbour formed by the island of Angar. This is completely encompassed by the two islands, which are not above three miles distant from each other, so that a ship can anchor close to either shore at all seasons, there being a sufficient depth of water for a line of battle ship lying within half a mile, and small craft within one hundred yards of the shore. No pilot is necessary. The island of Angar is somewhat longer than Ormus, now uninhabited, though formerly well peopled. The Great Tomb is a low island, about three miles in length, and two and a half broad, distant eleven leagues from the S. point of Angar, N. lat. 26° 20'. The Little Tomb is rather less, and distant from the former four miles, a barren and rocky island. Bafman lies eleven leagues N.N.W. $\frac{3}{4}$ from Shorga, N. lat. 25° 54', about five miles long, remarkable for a high round hill in its centre, and uninhabited. Polior, the Pulora of the Greeks, is about five miles long, and four broad, uninhabited, encompassed with deep water, and having a long reef of dangerous rocks running out from its W. extremity, the northern end being in N. lat. 26° 20' 30". Surdy lies in the meridian of Polior, and the parallel of Bafman, and is much such an island as the latter. Nabfleur is a small uninhabited island, without vegetation, ten miles S.S.W. of Polior. Ken, the ancient Kataia, is flat, and better planted than most of the islands in the gulf. Formerly it had a

flourishing commerce, and now it can supply ships with refreshments. The S. end is in N. lat. $26^{\circ} 27'$, about 10 leagues N.E.N. $\frac{1}{2}$ N from Polior. Anderavia, or Inderabia, seven leagues from Ken, is a low, level, and narrow island, about three miles in length, N. lat. $26^{\circ} 40'$. Busheah, inhabited and covered with date trees, is about sixteen miles in length, and five or six in breadth. The island of Bahrein is one of the finest in the gulf. (See BAHREIN.) Tarent, close to the shore, and opposite to Kalif, although not so large, is a finer island than Bahrein, about seven miles long, and as much in breadth, well supplied with good fresh water, and embellished with many delightful gardens, which produce abundance of fruits of various kinds. The island of Karrack, the Icarus of Arrian, contains about twelve or thirteen square miles; affords a good anchorage at all seasons, mostly rocky, supplied with abundance of wax, and now peopled with about three or four hundred inhabitants, who subsist by gardening and fishing. The island of Corgo, lying about one and a half or two miles N. of Karrack, contains about two square miles, and is of a light sandy soil: it has plenty of water, though not so good as that of Karrack, uninhabited, but not incapable of cultivation. It will produce both wheat and barley during the rainy seasons. Kinneir's Geog. Mem. of the Persian Empire.

PERSIAN Language, one of the living oriental languages; spoken in the empire of Russia.

The Persian language is rich, melodious, and elegant; it has been spoken for many ages by the greatest princes in the politest courts of Asia; and a number of admirable works have been written in it by historians, philosophers, and poets, who found it capable of expressing with equal advantage the most beautiful and the most elevated sentiments. Accordingly sir William Jones very much laments the neglect of this language that has generally prevailed among the learned; and he recommends the acquisition of it by a variety of considerations; but particularly from its utility to those who transact the concerns of Europe in India. In order to facilitate the attainment of it, he has published an excellent compendious grammar, and prefixed to it some instructions relating to the best method of learning this language. We shall avail ourselves of his work in giving an abridged history of the Persian language, and then some account of the language itself. The history of the Persian tongue may be divided into four periods, like that of the empire; and under each dynasty there was an apparent change in the dialect of the kingdom, especially under the two last, viz. the "Sassanian" and "Mohammedan" dynasties; and these are the only periods, of which any certain records remain. In the infancy of the Persian empire, under Cayúmaras and his descendants, it cannot be supposed that any great pains were taken to polish the language, which, if it were sufficiently clear and intelligible, would not be thought to want elegance. Herodotus assures us, that even after the reign of Cyrus, the whole education of the Persian youth, from the age of five years to twenty, consisted in only three points, riding, throwing the javelin, and the practice of moral virtue; which account is also confirmed by Xenophon. Nevertheless it ought not to be imagined, that the ancient Persians, especially those of the second period, were entire strangers to the art of composition either in verse or prose; but what their language was, what were their rules of verification, or what was the course of their studies, no mortal can pretend to know with any shadow of exactness. The Greeks can give us no assistance, nor are we much enlightened by the writers after Alexander; it is necessary therefore to consult the Persians themselves. From the great traveller

Chardin, we learn, that the old Persian is a language entirely lost, in which no books are extant; and of which there are no rudiments remaining. (See PERSIA.) We have therefore no account of the Persian language till the time of the "Sassanian" kings, who flourished from the opening of the third century to the middle of the seventh, during which period an academy of physic was founded at Gandisapor, a city of Korasan, and as it gradually declined from its original institution, it became a school of poetry, rhetoric, dialectics, and the abstract sciences. In this excellent seminary the Persian tongue must have been much refined, and the rusticity of the old idiom was succeeded by a pure and elegant dialect, which being constantly spoken at the court of Beharam Gúr in the year 331, acquired the name of "Deri," or courtly, to distinguish it from the "Pehlavi" or "Pahlavi," or language of the country. (See PERSIA.) This polished idiom did not, however, supersede the ancient dialect; for several compositions in Pahlavi were extant even after Mahomet, which appear to have been written by order of the Sassanian princes. Anushirvan, surnamed "the just," who reigned at the close of the 6th century, when Mahomet was born, obtained from India a collection of fables, translated by his chief physician from the Sanscrit language, which he acquired for this purpose; this collection he translated into the Pehlavian dialect; about 140 years after, it was turned from Pehlavi into Arabic, by order of Almanfor, second caliph of the Abbassides; and this is the volume now found in every language of Europe, under the name of "Calila wa Demna," or "the fables of Pilpay." A fine copy of the Arabic version is deposited in the public library at Oxford; and if the work of Barzuick, the above-mentioned physician, could be found, we might thus recover a considerable part of the old Persian language; the same, perhaps, which was spoken in the "second period" by Themistocles and Xenophon. In the reign of Anashirvan, Mahomet polished the language of his country; and when the battle of Cadessia gave the last blow to the Persian monarchy, the whole empire of Iran was soon reduced under the power of the first Mahometan dynasty; and the ancient literature of Persia, which had been promoted by the family of Sassan, was immediately discouraged by the successors of Mahomet; because some Persian romances, brought into Arabia, were extolled to the disparagement of the Koran, the people to whom they were read alleging, that "the stories of griffons and giants were more amusing to them than the moral lessons of Mahomet." Accordingly a chapter of the Koran was immediately written to stop the progress of these opinions, and other measures were taken to check their diffusion. This is supposed to have been the moving cause of that enthusiasm of the Mahometans, which induced them to burn the famous library of Alexandria, and the records of the Persian empire. It was a long time before the native Persians could recover from the shock of this violent revolution; and their language seems to have been little cultivated under the caliphs, who gave greater encouragement to the literature of the Arabians; but when the power of the Abbassides began to decline, and a number of independent princes arose in the different provinces of their empire, the arts of elegance, and chiefly poetry, revived in Persia; and there was hardly a prince, or governor of a city, who had not several poets and men of letters in his train. The Persian tongue was consequently restored in the 10th century; but it was very different from the Deri or Pehlavi of the ancients; it was mixed with the words of the Koran, and with expressions from the Arabian poets, whom the Persians considered as their masters, and affected to imitate in their poetical measures, and the turn of their verses. The oldest Persian

PERSIAN LANGUAGE.

Persian poems, of which sir W. Jones obtained any knowledge, are those of Ferdúsi, and which, in his account of them, are represented to be a glorious monument of eastern genius and learning; and of which he further says, that if it should be generally understood in its original language, will contest the merit of invention with Homer himself, whatever be thought of its subject, or the arrangement of its incidents. He has furnished an extract from this poem, and adds, that it will exhibit a specimen of the Persian tongue, very little adulterated by a mixture with the Arabic, and in all probability, approaching nearly to the dialect used in Persia in the time of Mahomet, who admired it for its extreme softness, and was heard to say, "that it would be spoken on that account in the gardens of Paradise." Of these two languages was formed the modern dialect of Persia, which, being spoken in its greatest purity by the natives of Pars or Farfistan, acquired the name of "Parfi;" though it is even called "Deri" by Hafiz. Nearly in the same age, *viz.* at the close of the 10th and beginning of the 11th centuries, the great Aleul Ola, surnamed Alámi from his blindness, published his excellent odes in Arabic, in which he professedly imitated the poets before Mahomet. At this time, and soon after, the Persian language became altogether mixed with Arabic. At Shiraz, called "the Athens of Persia," flourished in the 13th century Sadi, a native of this city; who wrote several pieces, both in prose and verse; and by means of an extract from his "Gulistan," or bed of roses, sir W. Jones has shewn us how the Persian and Arabic languages were mixed together in his age. The same city had the honour of producing, in the 14th century, the most elegant lyric poet of Asia, Shemseddin, surnamed "Hafiz;" of whose productions sir W. Jones has transcribed two Gazals or anacreontic odes, with a translation. There is nothing, says our much respected author, which affords a stronger proof of the excellence of the Persian tongue than that it remained uncorrupted after the irruption of the Tartars, who, at different times, and under various leaders, made themselves masters of Persia; for the Tartarian princes, and chiefly Tamerlane, who was a patron of Hafiz, were so far from discouraging polite literature, like the Goths and Huns, that they adopted even the language and religion of the conquered country, and promoted the fine arts with a boundless munificence; and one of them, who founded the Mogul empire in Hindoostan, introduced the Persian literature into his dominions, where it flourishes to this day; and all the letters from the Indian governors are written in the language of Sadi. The Turks themselves improved their harsh dialect by mixing it with the Persian; and Mahomet II., who took Constantinople in the middle of the 15th century, was a protector of the Persian poets, among whom was Nouredin Jami, whose poem "On the Loves of Joseph and Zelikha" is very highly extolled by our author, who has given a specimen of his elegant style. In the 16th and 17th centuries, under the family of Sefi, the Persian language began to lose its ancient purity, and even to borrow some of its terms from the Turkish, which was commonly spoken at court.

The Persian characters are written from the right hand to the left, and the language consists of 32 letters, which vary in their form as they are initials and medials, or finals, both connected and unconnected. For the pronunciation both of the consonants and vowels, we refer to sir William Jones's Grammar, from which we make the following extracts.

The short vowels are seldom written in the Persian books, and the omission of them occasions a perplexity to the learner of the language.

He will soon perceive with pleasure a great resemblance

between the Persian and English languages, in the facility and simplicity of their form and construction. The former, as well as the latter, has no difference of termination to mark the gender, either in substantives or adjectives: all inanimate things are neuter, and animals of different sexes either have different names, or are distinguished by certain words, denoting male and female.

The Persian substantives, like ours, have but one variation of case, which is formed by adding a certain syllable to the nominative in both numbers; and answers often to the dative, but generally to the accusative case in other languages. When the accusative is used indefinitely, this syllable is omitted; but when the noun is definite or limited, that syllable is added to it. In Persian there is no genitive case; but when two substantives of different meanings come together, a *hesra*, or short *e*, is added in reading to the former of them, and the latter remains unaltered. The same rule must be observed before a pronoun possessive, and before an adjective. The other cases are expressed, for the most part, as in our language, by particles placed before the nominative.

Our article *a* is supplied in Persian by adding the letter *ya*, or as it is sounded *ee*, to a noun, which restrains it to the singular number.

The Persian plural is formed by adding certain characters for syllables to the singular: but these terminations are not, as in many languages, wholly arbitrary; on the contrary, they are regulated with the utmost precision. It must not be omitted, that the Arabic substantives frequently have two sorts of plurals: one formed according to the analogy of the Persian nouns, and another after the irregular manner of the Arabians; and this circumstance, besides several others, proves the impossibility of learning the Persian language accurately, without a moderate knowledge of the Arabic: and sir William Jones advises the learner to peruse with attention the Arabic grammar of Erpenius, of which there are two fine editions, one by Golius, and another by Albert Schultens, before he attempts to translate a Persian manuscript.

The Persian adjectives admit of no variation, but in the degrees of comparison. The positive is made comparative by adding to it one character for a syllable, and superlative by means of another. An adjective is sometimes used substantively, and forms its plural like a noun: if it be a compounded adjective, the syllables denoting the plural number and the oblique case are placed at the end of it.

The personal pronouns are, 1. *men*, I: thus, sing. *men*, I; plur. *ma*, we; obl. *merá*, me, *mára*, us. 2. *To*, thou: thus, sing. *to*, thou; plur. *shumá*, you or ye; obl. *tura*, thee; *shumará*, you. 3. *O*, he: thus, sing. *o*, he, she, or it; plur. *ishán*, they; obl. *óra*, him, her, or it; *ishánra*, them. The possessives are the same with the personals, and are distinguished by being added to their substantives. Our reciprocal pronouns, *own* and *self*, are expressed in Persian by certain words, which are applicable to all persons and sexes. For the demonstrative pronouns, *this*, *these*, *that*, *those*, in the several cases singular, plural, and oblique, there are appropriate characters or expressions. Certain syllables prefixed to pronouns personal change them into possessives, and are read with a short vowel. The relatives and interrogatives are supplied by the invariable pronouns *ke* and *che*; of which the former usually relates to persons, and the latter to things.

The Persians have active and neuter verbs, like other nations; but many of their verbs have both an active and neuter sense, which can be determined only by the construction. These verbs have properly but one conjugation, and but

three changes of tense, the imperative, the aorist, and the preterite; all the other tenses being formed by the help of certain particles, or of the auxiliary verbs signifying *to be*, and *to be willing*. The passive voice is formed by adding the tenses of the verb substantive to the participle preterite of the active.

Our author has exhibited the inflections of the auxiliary verbs, and an analysis of all the tenses of a Persian verb, shewing in what manner they are deduced from the infinitive, which is properly considered by the oriental grammarians as the spring and fountain of all the moods and tenses, and which, therefore, in Arabic is called the "masdar," or the source. The Persians are very fond of the participle preterite; and it is very often used by their elegant writers to connect the members of a sentence, and to suspend the sense till the close of a long period. In poetry it sometimes is used like the third person preterite of a verb. Our author has subjoined a table of the moods and tenses, as they answer to those of European languages.

In the ancient language of Persia, there were very few or no irregularities: the imperative, which is often irregular in the modern Persian, was anciently formed from the infinitive, by rejecting the termination *eden*; for originally all infinitives ended in *den*, till the Arabs introduced their harsh consonants before that syllable, which obliged the Persians, who always affected a sweetness of pronunciation, to change the old termination of some verbs into *ten*, and by degrees the original infinitives grew quite obsolete; yet they still retain the ancient imperatives, and the aorists which are formed from them. This little irregularity is the only anomalous part of the Persian language, which, nevertheless, far surpasses in simplicity all other languages, as sir William Jones says, ancient or modern, of which he has any knowledge.

One of the chief beauties of the Persian language is the frequent use of compound adjectives; in the variety and elegance of which it surpasses not only the German and English, but even the Greek. These compounds may be multiplied without end, according to the pleasure and taste of the writer: they are formed either by a noun and the contracted participle, as in the word signifying "heart-alluring;" or by prefixing an adjective to a noun, as in that for "sweet-smelling;" or by placing one substantive before another, as in the word denoting "rose-cheeked." If we consider the vast number of epithets that may be compounded after these three forms, and that these epithets are often used for substantives, without a noun being expressed, we must allow that the Persian language is the richest in the world. These compounds are thought so beautiful by the Persian poets, that they sometimes fill a distich with them.

The construction of the Persian tongue is very easy, and may be reduced to a few rules, most of which it has in common with other languages. The nominative is usually placed before the verb, with which it agrees in number and person. It is remarked, however, that many Arabic plurals are considered in Persian as nouns of the singular number, and agree as such with verbs and adjectives. Another irregularity in the Persian syntax is, that the cardinal numbers are usually joined to nouns and verbs in the singular. The adjective is placed after its substantive, and the governing noun is prefixed to that which it governs. Conjunctions which express conjecture, condition, will, motive, &c. require the conjunctive or potential mood. Prepositions and interjections are fixed to nouns in the nominative case.

The modern Persians borrowed their poetical measures from the Arabs, and they are very various and complicated. There are nineteen sorts of metre, which are used by the Persians; but the most common of them are the iambic

measure, or the trochaic measure, and a metre that consists chiefly of those compounded feet, which the ancients called *Επιπέδες*; and which are composed of iambic feet and spondees alternately, as *āmātōrēs pūllārūm*. In lyric poetry, these verses are generally of twelve or sixteen syllables; but they sometimes consist of fourteen syllables. Other lyric verses contain thirteen syllables. The Persians sometimes use a measure consisting of trochees and spondees alternately; but the most common Persian verse contains eleven syllables, in which measure are written all the great Persian poems, whether upon heroic or moral subjects, as the works of Ferdūsi, and of Jāmi, the Bostan of Sadi, and the Mesnavi of the excellent Gelāleddin. This sort of verse answers to our common heroic rhyme. The profody of the Persians is extremely easy and simple: their vowels called *clif*, *vau*, and *ya*, are long by nature; the points, which they commonly suppress, are naturally short; and every short syllable that ends with a consonant is long by position. But the Persians, like other poets, have many licences; they often add a short vowel, which does not properly belong to the word; they also shorten some long syllables at pleasure, by omitting the vowels *clif*, *vau*, and *ya*. We shall here add, the verses of eleven syllables, which are used in the great Persian poems, always rhyme together in couplets.

The Persian elegy differs only in its length from the ode, except that the "cassideh" often turns upon lofty subjects, and the "gazel" comprises for the most part the praises of love and merriment, like the lighter odes of Horace and Anacreon. The most elegant composers of these odes are Jāmi and Hafiz, each of whom has left an ample collection of his lyric poems. Sir William Jones, among other numerous translations, has given us a translation in verse of a beautiful Persian song by Hafiz. If this article had not already been so extended, we should have felt disposed to gratify our readers with a transcript of it; but we must content ourselves with referring to the close of sir William Jones's Persian Grammar, or to his Works, vol. v.

PERSIAN Lily, in *Gardening*, the common name of a plant of the flower kind. See FRITILLARIA.

PERSIAN Wheel, in *Agriculture*, is a machine for raising a quantity of water sufficient to overflow lands bordering on the banks of rivers, &c. where the stream is too low to do it alone.

Such a wheel is represented in *Plate XIV. Hydraulics and Hydrostatics, fig. 3*, with which water may be raised by means of a stream A B turning a wheel C D E, according to the order of the letters, with buckets, *a, a, a, a*, &c. hung upon the wheel by strong pins *b, b, b, b*, &c. fixed in the side of the rim: but the wheel must be made as high as the water is intended to be raised above the level of that part of the stream in which the wheel is placed. As the wheel turns, the buckets on the right hand go down into the water, and are thereby filled, and go up full on the left hand, until they come to the top at K; where they strike against the end, *n*, of the fixed trough M, and are thereby overset, and empty the water into the trough; from which it may be conveyed in pipes to the place which it is designed for: and as each bucket gets over the trough, it falls into a perpendicular position again, and goes down empty, until it comes to the water at A, where it is filled as before. On each bucket is a spring *r*, which going over the top or crown of the bar *m* (fixed to the trough M) raises the bottom of the bucket above the level of its mouth, and so causes it to empty all its water into the trough.

Sometimes this wheel is made to raise water no higher than its axis; and then instead of buckets hung upon it, its spokes C, *d, e, f, g, h*, are made of a bent form, and hollow within;

within; these hollows opening into the holes C, D, E, F, in the outside of the wheel, and also into those at O in the box N upon the axis. So that, as the holes C, D, &c. dip into the water, it runs into them; and as the wheel turns, the water rises in the hollow spokes *c, d*, &c. and runs out in a stream, P, from the holes at O, and falls into the trough O, from whence it is conveyed by pipes. And this is a very easy way of raising water, because the engine requires neither men nor horses to turn it. See *OVERFLOWING of Land*.

PERSIAN, or *Perfic*, in *Architecture*, a name common to all statues of men, serving instead of columns, to support entablatures. See *ORDER*.

They only differ from caryatides, in that those represent statues of women.

The Persian is a kind of order of columns, first practised among the Athenians, on occasion of a victory their general Pausanias obtained over the Persians. As a trophy of this victory, the figures of men dressed in the Persian mode, with their hands bound before them, and other characters of slavery, were charged with the weight of Doric entablatures, and made to do the office of Doric columns.

Persian columns, M. le Clerc observes, are not always made with the marks of slavery; but are frequently used as symbols of virtues, vices, joy, strength, valour, &c. as when made in the figures of Hercules, to represent strength; and of Mars, Mercury, fauns, satyrs, &c. on other occasions.

PERSIAN Era, and *Year*. See *EPOCHA* and *YEAR*.

PERSIAN Bibles, and *Coins*. See the substantives.

PERSICA, in *Botany*, the *Malus Persica*, or Persian Apple, of the ancients, our Peach. See *AMYGDALUS*.

PERSICA Concha, in *Natural History*, a name given to a very remarkable and beautiful sea-shell, which authors have long been at a loss to reduce to any genus.

Aldrovand has thrown it to the end of his work, and says, it would be of the turbinated kind, if it did not want the turba. It is truly of the genus of the concha globosa, or dolium.

PERSICA Terra, an earth of the ochre kind, known in the colour shops of London by the name of *Indian red*.

It is a very fine purple ochre, of a considerably compact texture, and great weight; while in the earth it is of a pure blood-colour, and is not to be cut with the spade, but is dug with iron crows, and falls in irregular masses. It is of a rough dusty surface, and full of considerably large, bright, glittering particles: these are white and of a fine lustre. It adheres firmly to the tongue, is rough and harsh to the touch, stains the hands very deeply, and is of a rough astringent taste, and makes a very violent effervescence with acid menstruums.

It is dug in the island of Ormus, in the Persian gulf, and in some parts of the East Indies.

PERSICARIA, in *Botany*, so called by the old writers, from the likeness of its leaves to those of the peach-tree. (See *POLYGONUM*.) The word is now become the popular English appellation of a very fine species, *Polygonum orientale*, whose leaves however bear no resemblance to the peach, nor to those of the original *Persicaria*.

PERSIUS, **AULUS PERSIUS FLACCUS**, in *Biography*, a celebrated Roman poet, is said to have been born at Volterra, in Tuscany, in the year 34 of the Christian era. He was educated according to his rank, being of an equestrian family. He studied at Rome, and as he grew up he lived in intimacy with several of the most eminent persons of his time, and was generally beloved for the modesty of his disposition, and the suavity of his manners. He died at the

early age of 28, and bequeathed to his preceptor his library of 700 volumes, with a considerable sum of money, but the philosopher accepted only the library, and divided the money among Persius's sisters. As a poet, Persius is only known by his six Satires, which were in high reputation among his countrymen. They are of a grave sententious kind, chiefly turning upon topics of general morals. The philosophy of his preceptor Cornutus, to whom one of them is dedicated, has given them an elevation and purity of sentiment, which in some parts places them in the first rank of moral poetry; but their extreme obscurity almost destroys the pleasure of a perusal. The satires of Persius are generally printed with those of Juvenal. The best editions are those of Isaac Casaubon, in 1605, Paris, and in 1647, London.

PERSO, in *Geography*, a town of Italy, in the country of Friuli; 10 miles N.W. of Udina.

PERSOLATA, in *Botany*, a word used by Pliny, as the name of a kind of burdock, different from the *personata*. He has, in the beginning of the chapter, spoken of the *artemium* of the Greeks, which he says the Latins sometimes called *personata*, and afterwards adds this *persolata*; which, he says, was a plant vulgarly known, and called by the Greeks *artemium*.

He seems to allow, that the Greeks called both these plants by the same name; but he distinguishes the *persolata* from *personata*, by saying that the former has leaves like those of the great gourd, but larger and more hairy. It is probable, therefore, that he distinguishes, under these two names, the two different species of the great burdock common with us, the one with simple, the other with woolly heads.

PERSON, **PERSONA**, an individual substance of a rational or intelligent nature.

The father and son are reputed in law as the same person; an ambassador represents the person of his prince.

The word person, *persona*, is said to be borrowed *personando*, from personating or counterfeiting; and is supposed to have first signified a mask: by reason, says Boethius, in *larva concava sonus volvatur*: and hence the actors who appeared masked on the stage, were sometimes called *larvati*, and sometimes *personati*.

The same author adds, that as the several actors represented each their single individual person, *viz.* Oedipus, or Chremes, or Hecuba, or Medea; for this reason, other people, who were also distinguished by something in their form, character, &c. whereby they might be known, came also to be called, by the Latins, *personæ*; and, by the Greeks, *προσωπα*.

Again, as these actors rarely represented any but great and illustrious characters, the word came, at length, to import the mind; as being a thing of the greatest regard and dignity among human matters. And thus men, angels, and even God himself, were called *persons*. Things merely corporeal, as a stone, a plant, or a horse, were called by them, *hypostasēs*, or *supposita*, but never *persons*.

Hence also the learned imagine, the same name person came to be used to signify some dignity, whereby a person is distinguished from another; as a father, husband, judge, magistrate, &c.

In which sense we are to understand that of Cicero: Cæsar never speaks of Pompey but in terms of honour and respect; but he does many hard and injurious things against his person.

As for the name person. As for the thing, we have already defined person, an individual substance of a reasonable nature; which is the same as Boethius's definition.

Now a thing may be individual two ways. 1. Logically,

as it cannot be predicated of any other; as Cicero, Plato, &c. 2. Physically; in which sense a drop of water, separated from the ocean, may be called an individual. Person is an individual nature in each of these senses: logically, says Boethius, since person is not spoken of universals, but only of singulars and individuals; we do not say the person of an animal, or a man, but of Cicero and Plato: and physically, since Socrates's hand or foot are never considered as persons.

This last kind of individual is denominated two ways; positively, as when the person is said to be the whole principle of acting; for whatever thing action is attributed to, that do the philosophers call a person: and negatively, as when we say, with the Thomists, &c. that a person consists in this, that it does not exist in another as a more perfect being.

Thus, a man, though consisting of two very different things, *viz.* body and spirit, is not two persons; since neither part alone is a whole principle of action, but one person, since the manner of his consisting of body and spirit is such as constitutes one whole principle of action; nor does he exist in any other as a more perfect being; as, *e. g.* Socrates's foot does in Socrates, or a drop of water in the ocean.

PERSON, in *Grammar*, is a term applied to verbs and pronouns, which being conjugated, are applicable to three different persons.

I love, is a verb used in the first person; *thou lovest*, designs the second person; *he loveth*, makes the third: and thus in the plural number.

I, thou, he, are pronouns of the first, second, and third persons.

Verbs agree with their nouns, in number and person.

PERSON, *Persona*, in *Dramatic Poetry*, the name and part of an actor; or of him presented by the comedian.

At the head of dramatic pieces come the *dramatis personæ*, the list of actors, and characters that are to appear on the stage.

The ancient tragedy was only a simple chorus: Theſpis was the first who introduced a person to relieve the chorus; and Æschylus added a second.

F. Bosſu observes, that, in the epic and dramatic poem, the same person must reign throughout; *i. e.* must sustain the chief part throughout the whole piece, and the characters of all the other persons must be subordinate to him.

PERSON, *Persona*, in *Law*. See PARSON.

PERSON, in *Geography*, a county of America, in Hillsborough district, North Carolina; containing 6402 inhabitants, of whom 2082 are slaves.

PERSONA *nec prebendarii*, *Quod*, &c. See QUOD.

PERSONABLE, *PERSONABILIS*, in *Law*, implies the being able to hold or maintain a plea in court.

That is, as the civilians would express it, *habere personam standi in judicio*.

Thus they say the defendant was judged personable to maintain this action. Old Nat. Brev. 142.

The tenant pleaded, that the demandant was an alien, born in Portugal, without the ligeance of the king; and judgment was asked, Whether he should be answered? The plaintiff said, he was made personable by parliament. Kitch. fol. 124.

PERSONABLE is also used to signify a capacity to take any thing granted or given.

PERSONAL, something that concerns, or is restrained to, the person.

In disputes among the learned, there is ever something personal intermixed; in ethics, it is a maxim, that all

faults are personal; *i. e.* they do not pass to our descendants.

PERSONAL *Action*, in *Law*. See ACTION.

PERSONAL *Goods*, or *Estate*, is that consisting of money, moveables, &c. which every person has in his own disposal (see CHATTELS), in opposition to lands and tenements, which are called *real estate*.

PERSONAL *chattels*, *covenant*, *distress*, *history*, *liberty*, *patronage*, *privilege*, *service*, and *tithes*. See the substantives.

PERSONAL *Pronoun*, or *verb Personal*, in *Grammar*, a verb or pronoun conjugated in all the three persons.

They are thus called, in opposition to *impersonals*, which have only the third person.

PERSONALITY, *PERSONALITAS*, in the schools, the quality of a person; or that which constitutes an individual in the quality of a person.

The philosophers being used to consider matter and form in every other thing, do the same in person. The matter of person, according to them, is a singular substance, endowed with reason: for substance may, at the pleasure of God, either be, or not be, a person; inasmuch as, they say, the human nature in Christ is not a person. The form of person, which they call *subsistency*, *suppositality*, and *personality*, is that by which the aforesaid substance becomes individual.

The school divines are divided about what it is that distinguishes the several personalities in the Trinity. Some will have it to be only the different relations: others, as Floraventius, contend for some incommunicable substance: St. Bonaventure, and St. Thomas, take it to be different origins that distinguish the personalities; which opinion is the most followed. See TRINITY.

PERSONALITY, or *Personalty*, in *Law*. An action is said to be in personality, when it is brought against the right person.

PERSONATA COROLLA, in *Botany*, is a monopetalous irregular corolla, whose mouth is closed by a kind of palate, as in *Antirrhinum*. The term is derived from *persona*, a mask, and its application in the present instance, whether intended or not by Linnæus, is peculiarly happy; the plants furnished with such a corolla being, as it were, of the regular pentandrous tribe, under a mask, which they occasionally lay aside. See PELORIA and PERSONATÆ.

PERSONATÆ, the fortieth natural order among the *fragmenta* of Linnæus, nearly analogous to the *Scrophulariæ* and the *Vitices* of Jussieu, embracing moreover some that are subjoined to his *Solanææ*. This order is characterized by a monopetalous unequal corolla; stemens usually four, two of them longest, or sometimes only two in all; style solitary; and a fruit, generally superior, of two cells, with numerous seeds. Many of the plants are fœtid and poisonous, few of them aromatic, though the flowers of some are fragrant. They are all more or less naturally allied to the first order of the Linnæan class *Pentandria*, but they arrange themselves either in the *Diandria Monogynia*, or rather, principally, in the *Didymania Angiospermia*, according to the laws of the artificial system. Some are shrubby in habit, but the greater part are herbaceous. The leaves are mostly simple; the inflorescence either axillary, corymbose, spiked or panicled. It is by an unaccountable error that Linnæus has marked *Melaleuca* as belonging to this natural order, in his *Manissa*, p. 14, that genus being evidently referrible to his nineteenth order, the *Hesperidææ*. Giseke, who points out this mistake, well observes, that there is no order in which so many genera bear the names of botanists as in this of the *Personatææ*.

PERSONIFYING, or PERSONALIZING, the feigning a person; or attributing a person to an inanimate being; or giving it the figure, sentiments, and language of a person. See PHOSOROPŒIA.

The poets have personified all the passions; and even made divinities of them, which were worshipped by the heathens; as the goddess Persuasion, the god Sleep, the Furies, Envy, and Discord, and Fame, Fortune, Victory, &c.

Personifying is essential to poetry, especially to the epœia.

PERSOONIA, in *Botany*, was so named by the writer of the present article, in honour of his highly deserving friend and correspondent, Christian Henry Perfoon, author of many valuable works on *Fungi*, in which department of Botany this author decidedly takes the lead. He has also edited a *Synopsis* of the vegetable kingdom, on the plan of the Linnæan *Sytema Vegetabilium*, but in a very small type, printed at Paris, where he now resides. Mr. Perfoon was, if we mistake not, born of Dutch parents, at the Cape of Good Hope. Two other genera have been ascribed to him, one by Willdenow in his *Sp. Pl.* v. 2. 331, which is the *Carapa* of Aublet, t. 387, and Lamarek t. 301; and another by Michaux, *Fl. Boreal-Amer.* v. 2. 104, of the class Syngenesia. These are both of a posterior date to the genus of which we are to treat, and which is now generally adopted. *Sm. Tr. of Linn. Soc.* v. 4. 215. *Mart. Mill. Dict.* v. 3. *Brown Tr. of Linn. Soc.* v. 10. 159. *Prodr. Nov. Holl.* v. 1. 371. *Ait. Hort. Kew.* v. 1. 203. *Gærtn.* v. 3. t. 220. (*Pentadactylon*; *ibid.* t. 220. *Br.* *Linkia*; *Cavan. Ic.* v. 4. 61.)—Class and order, *Tetrandria Monogynia*. *Nat. Ord. Proteaceæ*, *Juss.* *Brown.*

Gen. Ch. *Cal.* none, except a slight border. *Cor.* Petals four, equal, linear-oblong, recurved, deciduous. Nectary of four distinct glands, at the base of the germen. *Stam.* Filaments scarcely any; anthers four, inserted about the middle of each petal, linear, erect, prominent, at length reflexed. *Pist.* Germen superior, stalked, ovate; style thread-shaped, on a level with the anthers, permanent; stigma obtuse. *Peric.* Drupa ovate, pulpy. *Seed.* Nut of one or two cells.

Eff. Ch. Petals four, recurved, bearing the stamens about their middle. Nectary of four glands. Germen superior, stalked. Stigma obtuse. Drupa with a nut of one or two cells.

Obs. Mr. Brown remarks, that the stalk of the germen is jointed in some species, and that the cotyledons are, for the most part, more than two. The habit is shrubby or arboreseent; the bark sometimes flaky. Leaves scattered, entire, mostly flat. Flower-stalks axillary, solitary, without bractæas, or racemose, with a solitary bractæa. Flowers yellow. We follow Mr. Brown in the order and names of the twenty-two known species.

1. *P. teretifolia*.—"Leaves thread-shaped, without furrows. Stalks solitary, single-flowered. Anthers pointed. Style shorter than the germen."—Gathered by Mr. Brown, on stony hills, at Lewin's land, on the south coast of New Holland.

2. *P. microcarpa*.—"Leaves thread-shaped, channelled. Stalks solitary, in pairs, or ternate. Anthers pointless. Style longer than the germen. Stigma drooping."—Native of marshy heaths, in the same country.

3. *P. pinifolia*.—"Leaves thread-shaped, lax. Spike pyramidal, elongated, leafy. Floral leaves shorter than the rest. Germen single-seeded."—Found by Mr. Brown on

heaths, and about the banks of rivulets, at Port Jackson, New South Wales.

4. *P. juniperina*. *Labill. Nov. Holl.* v. 1. 33. t. 45.—Leaves awl-shaped, straight, pungent. Flowers axillary, solitary. Germen smooth, with two kernels. Found on dry heaths and about the sides of hills, in Van Diemen's land, as well as on the south coast of New Holland. The stem, according to Labillardiere, is a yard or more in height, determinately branched, round, and leafy. Leaves rigid, above an inch long, rather hairy, as are the short axillary flower-stalks. Petals clothed externally with rigid hairs, yellowish. Fruit red, eatable, its nut usually with two kernels.

5. *P. hirsuta*. *Perf. Syn.* v. 1. 118.—Leaves linear, revolute, hairy and rough. Flower-stalks axillary. Germen silky, single-seeded.—Native of moist heaths about Port Jackson, New South Wales. *Br.* The flowers are very hairy externally, and full as long as the leaves.

6. *P. mollis*.—"Leaves lanceolate, elongated, villous, very soft beneath. Corolla bearded. Germen smooth, with two kernels."—Gathered by Mr. Brown, near Port Jackson, about the sandy banks of rivers.

7. *P. linearis*. *Linear-leaved Persoonia*. *Ait. n. 1.* *Andr. Repof.* t. 77. *Curt. Mag.* t. 760. *Venten. Malmaif.* t. 32.—Leaves linear, elongated, smooth. Flower-stalks straight. Corolla downy. Stalk of the germen without a joint. Stem arboreous. Bark smooth.—On hills and in open fields about Port Jackson, from whence specimens and seeds were first sent by Dr. White in 1792. The plant was raised by the late Mr. Robinson of Stockwell, in 1794. It proved a hardy greenhouse shrub, flowering copiously in the latter part of summer. The young branches, as well as the flower-stalks, and backs of the petals, are downy. Leaves copious, spreading, two inches or more in length, and not a line wide. Fruit globose, smooth.

8. *P. lucida*.—"Leaves linear, somewhat lanceolate, elongated, smooth. Flower-stalks downy, straight. Corolla downy. Stalk of the germen without a joint. Stem arboreous. Bark flaky."—Found near Port Jackson, by the sides of mountain rivers, by Mr. Ferd. Bauer. It seems nearly related to the last.

9. *P. virgata*.—"Leaves linear, or somewhat oblong, scattered, vertical, very smooth in every part. Flower-stalks smooth, straight. Corolla smooth. Stem arboreous. Bark even."—Gathered by Mr. Brown, on the sea shore, near Sandy Cape, on the east coast of New Holland.

10. *P. flexifolia*.—"Leaves nearly linear, pointed, crowded, twisted at the base, smooth on both sides, besprinkled with shining dots; their edges rough. Corolla smooth. Stem shrubby."—Native of the stony sides of hills, on the south coast of New Holland.

11. *P. scabra*.—"Leaves linear-lanceolate, pointed, rough on both sides, besprinkled with shining as well as minute opaque dots. Corolla downy."—In the same country and situations as the last.

12. *P. spatulata*.—"Leaves lanceolate-spatulate, pointed, rather concave, very rough on both sides with crystalline points."—Gathered by Mr. Brown in the same places as the two last.

13. *P. nutans*.—"Leaves linear, smooth. Flower-stalks axillary, recurved, smooth as well as the corolla."—Found by Mr. Brown near Port Jackson, in woods on a sandy soil, at the foot of the mountains.

14. *P. falcata*.—"Leaves lanceolate, elongated, tapering at the base, somewhat stalked, falcate, revolved, coriaceous. Anthers pointed. Stem arboreous. Bark flaky."—Gathered

—Gathered by Sir Joseph Banks, near Endeavour river, on the east coast of New Holland; and by Mr. Brown, at Carpentaria, on the north coast, near the sea shore.

15. *P. lanceolata*. Lance-leaved Perfoonia. Ait. n. 2. Andr. Repof. t. 74.—Leaves elliptic-lanceolate, pointed, smooth and even. Stalks axillary, single-flowered. Corolla silky, with close-pressed hairs. Stalk of the germen without a joint.—Native of fields and heaths towards the sea coast at Port Jackson, from whence seeds were very early sent to this country. Plants are said to have been first raised in 1791, by J. Wilson, esq. at Islington. The leaves are about two inches long. Flowers yellow, as in all the rest. Fruit globose, the size of a black currant.

β. *P. latifolia*, Andr. Repof. t. 286, is proposed, not without hesitation, by Mr. Brown, as a variety of this. It differs in having larger and obovate leaves, which in our native specimens, sent from Port Jackson by Dr. White, appear somewhat glaucous. The flowers exactly agree. Still we should be inclined to consider this supposed variety as a distinct species, did we not rather confide in Mr. Brown's opinion, formed from observation of the wild plants.

16. *P. salicina*. Perf. Syn. v. 1. 118. (*Linkia lævis*; Cavan. Ic. v. 4. 61. t. 389.)—Leaves lanceolate-oblong, unequal, reversed. Stalks axillary or racemose. Corolla nearly smooth. Stem arboreous. Bark flaky.—Native of fields, hills, and woods, in the neighbourhood of Port Jackson. The leaves are three inches long, their sides more or less unequal, giving them a falcate aspect. Flower-stalks and young branches silky. Corolla nearly smooth. Fruit elliptical; its nut with two kernels.—Mr. Brown suspects that Cavanilles's plant may rather be a variety of the last; but it seems to us to agree best with the present species, though his plate does not express any inequality in the shape of the leaves. We have a specimen with obovate leaves, that seems a variety of *salicina*.

17. *P. ferruginea*. Sm. Exot. Bot. v. 2. 47. t. 83. (*P. laurina*; Perf. Syn. v. 1. 118. *Br.*)—Leaves elliptical, acute, veiny. Stalks axillary, many-flowered, clothed, as well as the backs of the petals, with rusty silky hairs.—Native of fields near Port Jackson, from whence it was originally sent dried by Dr. White. We have not heard of this beautiful species in any garden. The stem is shrubby, three or four feet high, with smooth branches. Leaves for the most part nearly opposite, two or three inches long, and about one broad, smooth, shining, veiny. Flowers in short, dense, axillary clusters, accompanied by small bractees, which, as well as stalks, and the backs as well as margins of the petals, are densely clothed with shining silky hairs of a deep rusty orange-colour. The germen is covered with similar hairs, but the style is smooth.—This shrub flowers in its native country in November.

18. *P. prostrata*—"Leaves oval, obtuse, downy at the margin. Stalks axillary, with one or more flowers. Stem procumbent."—Gathered by Mr. Brown in fruit, the flowers being all past, near Sandy Cape, on the east coast of New Holland, growing in sand near the sea shore.

19. *P. elliptica*—"Leaves elliptical, veiny. Clusters lateral. Petals smooth. Stalk of the germen jointed."—Gathered by Mr. Brown on the stony sides of hills at Lewin's Land, on the south coast of New Holland.

20. *P. articulata*—"Leaves lanceolate, elongated, equal, smooth. Stalks axillary, with one or more flowers. Corolla nearly smooth. Lower joint of the stalk of the germen as long as the glands."—Gathered by Mr. Brown in Lewin's Land, with the foregoing.

21. *P. longifolia*—"Leaves linear, elongated, falcate. Stalks axillary, with one or more flowers. Corolla downy,

with close-pressed hairs. Lower joint of the stalk of the germen longer than the glands."—From the same country.

22. *P. graminea*—"Leaves of the branches linear, very long, revolute. Clusters many-flowered, turned one way. Corolla smooth. Stem short, somewhat shrubby."—Found by Mr. Brown, about the sandy margins of standing pools, in Lewin's Land.

PERSPECTIVE is the art of representing objects on a definite surface, so as to affect the eye when seen from a certain position, in the same manner as the object itself would, when the eye is fixed in the point in view.

We shall introduce this article with a brief history of the rise and progress of perspective, and close it with an enumeration of the principal writers on the theory and practice of the art.

The art of perspective owes its birth to painting, and particularly to that branch of it which was employed in the decorations of the theatre, where landscapes were principally introduced, and which would have looked unnatural and horrid, if the size of the objects had not been pretty nearly proportioned to their distance from the eye. The ancients must, therefore, have had considerable knowledge of this art; though the only ancient author from whom we can obtain any information relative to its antiquity, is Vitruvius; who, in the preface to his seventh book, informs us, that Agatharcus, at Athens, was the first who wrote on this subject, on occasion of a play exhibited by Æschylus, for which he prepared a tragic scene; and that afterwards the principles of the art were more distinctly taught in the writings of Democritus and Anaxagoras, the disciples of Agatharcus, which are no longer extant.

The perspective of Euclid and of Heliodorus Larissens contains only some general elements of optics, that are by no means adapted to any particular practice; though they furnish some materials that might be of service even in the linear perspective of painters.

Geminus of Rhodes, who was a celebrated mathematician in the time of Cicero, hath likewise written on this subject.

We may also infer, that the Roman artists were acquainted with the rules of perspective, from the account which Pliny, (*Nat. Hist. lib. xxxv. cap. 4.*) gives of the representations on the scene of those plays given by Claudius Pulcher; by whose appearance, he says, the crowds were so deceived, that they endeavoured to settle on the fictitious roofs. However, of the theory of this art among the ancients we know nothing; as none of their writings have escaped the general wreck of ancient literature in the dark ages of Europe. Perspective must, without doubt, have been lost, when painting and sculpture no longer existed. Nevertheless, we have reason to believe, that it was practised much later in the eastern empire.

John Tzetzes, who lived in the twelfth century, speaks of it as if he was well acquainted with its importance in painting and statuary: and the Greek painters, who were employed by the Venetians and Florentines, in the thirteenth century, seem to have brought some optical knowledge with them into Italy: for the disciples of Giotto are commended for observing perspective more regularly than any of their predecessors in the art had done; and they lived in the beginning of the fourteenth century.

The Arabians were not ignorant of this art; as we may presume from the optical writings of Alhazen, who lived about the year 1100, cited by Roger Bacon, when treating on this subject.

Vitellus, a Polander, about the year 1270, wrote largely and learnedly on optics.

Our own friar Bacon, as well as John Peckham, archbishop of Canterbury, treated this subject with surprising accuracy, considering the times in which they lived.

The most ancient authors, who professedly laid down rules of perspective, were Bartolomeo Bramantino, of Milan, whose book, entitled "Regole di Perspectiva, e Misure delle Antichità di Lombardia," is dated 1440; and Pietro del Borgo, likewise an Italian, who was the most ancient author met with by Ignatius Danti, and who is supposed to have died in 1443. The last writer supposed objects to be placed beyond a transparent tablet, and endeavoured to trace the images, which rays of light, emitted from them, would make upon it. But his work is not now extant. However, Albert Durer constructed a machine upon the principles of Borgo, by which he could trace the perspective appearance of objects.

Leon Battista Alberti, in 1450, wrote his treatise "De Pictura," in which he treats principally of perspective.

Balthazar Peruzzi, of Sienna, who died in 1536, had diligently studied the writings of Borgo; and his method of perspective was published by Serlio in 1540. To him, it is said, we owe the discovery of points of distance, to which all lines that make an angle of 45° with the ground line are drawn.

Guido Ubaldi, another Italian, soon after discovered, that all the lines that are parallel to one another, if they be inclined to the ground line, converge to some point in the horizontal line; and that through this point, also, a line, drawn from the eye, parallel to them, will pass.

His perspective was printed at Pefaro in 1600, and contained the first principles of the method afterwards discovered by Dr. B. Taylor.

In 1583, there was published a book, written by Giacomo Barozzi, of Vignola, commonly called Vignola, intitled "The two Rules of Perspective, with a learned Comment," by Ignatius Danti. In 1615, the work of Marolois was printed, in Latin, at the Hague, and engraved and published by Hondius. And in 1625, Sirigatti published a treatise of perspective, which is little more than an abstract of Vignola's.

The art of perspective has been gradually improved by subsequent geometricians, particularly by professor Gravelande, and, in a much greater degree, by Dr. Brook Taylor, whose principles are in a considerable measure new, and far more general than those of any of his predecessors. He did not confine his rules, as his predecessors had done, to the horizontal plane only, but made them general, so as to affect every species of planes and lines, whether they were parallel to the horizon or not; and thus the principles were made universal. Farther, from the simplicity of his rules, the whole tedious progress of drawing out plans and elevations for any object is rendered entirely useless, and therefore avoided: for by this method, not only the fewest lines imaginable are required to produce any perspective representation, but every figure, thus drawn, will bear the nicest mathematical examination. Moreover, his system is the only one calculated for answering every end of those who are practitioners in the art of design; because from hence they may be enabled to produce the whole, or only so much of an object as is wanted, and by fixing it in its proper place, may determine its apparent magnitude in an instant. It explains also the perspective of shadows, the reflections of objects from polished planes, and the inverse practice of perspective.

His "Linear Perspective" was first published in 1715; and his "New Principles of Linear Perspective" in 1719, which he intended as an explanation of his first treatise. In 1738,

Mr. Hamilton published his *Stereography*, in 2 vols. folio, after the manner of Dr. Taylor. But the most complete system of perspective, both as to theory and practice, on the same principles, is that of Mr. Malton, the second edition of which was published in 1779, fol. We have also treatises on this subject, by the Jesuit, originally written in French, at Paris, translated by Mr. Chambers, and printed at London, in 1726, Highmore, Ware, Cowley, Kirby, Priestley, Ferguson, &c.

The instruments necessary for drawing according to the rules of perspective, are a tee square, a parallel ruler, a drawing board (which is only a smooth board made exactly square), a sector, a protractor; to which may be added a drawing-pen, and a black-lead pencil.

Proposition.—It is a well-known fact, founded on experience, that objects reflect their lights, shades, and colours in straight lines, and describe an image in the eye which produces that sensation of the object called *vision*; which see.

Corol. 1.—If a straight line be opposed to the eye, and not directed to it, the rays or straight lines which issue from all points of it to the eye, form a plane.

Corol. 2.—If any plane or solid be opposed to the eye, the straight lines or rays which issue from all points of the surface to the eye form a pyramid, provided that with respect to the plane the eye is out of its surface. The following are definitions of the terms employed.

1. The straight line reflected from any point of a line or surface, is called a visual ray.

2. A plane composed of visual rays is called an optic plane. See PLANE,

3. A pyramid composed of visual rays is called an optic pyramid.

4. An optic plane or pyramid is called a system of rays.

5. If a system of rays be intercepted by a plane, the common section is called the scenographic or perspective representation of the body.

Corol.—Hence the representation of any right line, or rectilinear figure, or solid, is also rectilinear.

6. The plane on which the section is made is called the picture.

7. The point, line, surface, or body, from which the rays proceed to the eye, is called the original object.

Corol. 1.—Hence, if the original object be a plane, and the picture parallel to it, the representation will be a figure similar to the original.

Corol. 2.—If any part of an original object touch the picture, the part which is thus in contact will be the scenographic representation of that part.

8. The vertex or point of the pyramid where the eye is placed, is called the point of sight, or point of view.

9. If the original object be situated on a plane, this plane is called the original or primitive plane.

10. If a plane be supposed to pass through the eye parallel to the picture, this plane is called the directing plane.

11. The intersection of the picture and the original plane is called the intersection or intersecting line of that plane.

12. The intersection of any original line with the picture, is called the intersecting point of that original line.

Corol.—Hence the intersecting points of all lines in any original plane, are in the intersecting line of that plane.

13. If a straight line be supposed to be drawn through the

PERSPECTIVE.

the eye parallel to any original line, the line so drawn is called the parallel of that original plane.

Corol.—Hence, if any number of original lines be parallel among themselves, one line can only pass through the eye parallel to them all.

14. If a plane be supposed to pass through the eye parallel to any original plane, or the plane of an original object, the plane thus passing through the eye is called the parallel of that original plane.

Corol.—Hence, if any number of original planes be parallel among themselves, one plane only can pass through the eye, which will be parallel to them all.

15. The intersection of the parallel of any original plane and the picture, is called the vanishing line of that plane.

Corol. 1.—Hence the intersecting and vanishing lines are parallel to each other.

Corol. 2.—Hence all original parallel lines have the same vanishing line.

Corol. 3.—Hence the parallels of every two original planes have the same inclinations as the originals.

Corol. 4.—The vanishing point of the common intersection of any two planes, is the intersection of the vanishing lines of these planes.

16. The intersection of the parallel of any original line is called the vanishing point of the original line.

Corol. 1.—The vanishing points of all lines in the same original plane, are in the vanishing line of that plane.

Corol. 2.—Hence any number of original parallel lines can have only one vanishing point.

Corol. 3.—Hence original lines which are parallel to the picture have no vanishing point, because their parallels can never cut it.

Corol. 4.—The lines which generate the vanishing points of two original lines, make the same angle with the eye as the originals do with each other.

17. The intersection of the original plane and the directing plane, is called the directing line of that plane.

18. The intersection of any original line with the directing plane is called the directing point of that original line.

Corol.—Hence the directing points of all lines in the same original plane are in the directing line of that plane.

19. A straight line drawn from the directing point of any original line to the eye is called the director of that original line.

20. The intersection of the vanishing plane and the directing plane is called the parallel director, or parallel of the eye.

Corol.—Hence the intersecting line, the vanishing line, the parallel director, and directing line, are all parallel to each other.

21. If a straight line be drawn from the point of sight perpendicular to the picture, the point where it meets the picture is called the centre of the picture; and the part of the line intercepted between the point of sight and the centre of the picture is called, the distance of the picture, or principal distance.

22. If a straight line be drawn from the point of sight perpendicular to a vanishing line, the point where it meets the vanishing line is called the centre of that vanishing line; and the part intercepted between the point of sight and the centre of the vanishing line, is called the distance of that vanishing line.

Corol. 1.—Hence a line drawn from the centre of the picture to the centre of a vanishing line, is perpendicular to that vanishing line.

Corol. 2.—The distance of a vanishing line is the hypotenuse of a right-angled triangle, the base of which is the distance of the picture, and the perpendicular the distance between the centre of the picture and the centre of its vanishing line.

23. If the distance on a vanishing line from the vanishing point to another point, be equal to the distance of that vanishing point from the eye, the other extremity of this distance, which is not the vanishing point, is called the point of distance.

24. The point where a perpendicular drawn from the centre of the vanishing line cuts the intersecting line, is called the centre of the intersecting line.

25. If the original plane be the level of the earth's surface or horizon, it is called the ground plane.

26. If the original plane be the horizon, the vanishing plane is called the horizontal plane.

27. If the picture be perpendicular to the horizon, it is called a vertical picture.

28. When the original plane is the ground plane, the intersecting line is called the ground line.

29. When the original plane is the ground plane, a plane drawn through the eye perpendicular to the ground plane and to the picture, is called the vertical plane.

30. The intersection of a vertical plane with the vertical picture, is called the vertical line.

31. The intersection of the vertical plane with the directing plane, is called the prime director, and by some the eye director.

32. The intersection of the vertical line with the ground plane, is called the foot of the vertical line.

33. The intersection of the vertical director with the ground plane, is called the station point, or prime directing point.

34. The distance between the station point and the foot of the vertical line, is called the station line, or line of station.

35. A straight line drawn between the intersecting and vanishing points, is called the indefinite representation, or projection of that line.

Axiom 1.—The common intersection of two planes is a straight line.

2. The common intersection of two straight lines is a point.

3. If two straight lines meet in a point, or are parallel to each other, a plane may be made to pass through both of them.

4. If a straight line meet two parallel straight lines, or two straight lines meeting in a point, all the three straight lines are in the same plane.

5. Every point in any straight line, is in any plane which the line is in.

6. Two planes which are parallel cannot intersect.

7. One part of a straight line cannot be in a plane while another part is out of it.

Several of these axioms are propositions in the eleventh book of Euclid's Elements, where they are demonstrated; but if the notion of a plane is understood, their evidence will be admitted upon the slightest reflection, so that it would be but of little use to attempt to prove them.

In *Plate I. fig. 1.* W X Z Y is the original plane; A B N I the picture; T S W X the directing plane parallel to the picture; and S V L T the vanishing plane, or parallel of the original plane; V L, the intersection of the parallel of the original plane and the picture, is the vanishing line; I N, the intersection of the picture and the original plane, is the intersecting line; S T, the intersection of the parallel of the

PERSPECTIVE.

original plane and the directing plane, is the parallel of the eye; and WX, the intersection of the directing plane and the original plane, is the directing line.

In all the *figs.* 1, 3, 4, 5, and 6, E is the place of the eye. In *figs.* 2 and 3, the parallel of the original plane is not represented. In each of the *figs.* 1, 4, 5, and 6, the intersecting line is denoted by IN the vanishing line by VL, if necessary in the figure, the directing line by WX, and the parallel of the eye by ST.

Theorem 1.—The indefinite projection of a straight line not parallel to the picture, passes through its intersecting and vanishing points.

This is evident, since the original line and its radial are parallel to each other. The eye, the intersecting point, and the vanishing point, are all in the same plane with the original line and its radial; and, therefore, if a line be drawn in the picture between the intersecting and vanishing points, all the three straight lines will be in the same plane; and, consequently, the indefinite representation will be in the same plane with the original straight line and the eye.

Since the whole practice of perspective depends upon this theorem, our readers will take the following illustration. In *Plate I. fig. 1*, QR is an original straight line, R its intersecting point, *v'* its vanishing point, and R *v'* a line in the picture joining the intersecting and vanishing points. Now since E *v'* and RQ are two parallel lines, let a plane be supposed to be drawn through both, it will pass through the eye at the extremity of the radial *v'E*; and because the straight line R *v'* joins the two straight lines QR and *v'E*, the lines RQ and R *v'* are in the same plane with the eye, and consequently R *v'* is the intersection of the plane of rays on the picture from the straight line QR.

Further, let EF, GH, IK, and LM be parallel original lines, they will have *v'* for their common vanishing point, therefore the several indefinite representations from the intersecting points F, H, K, and M, will all terminate in *v'*.

If an original straight line and its radial are in the same straight line, the whole indefinite representation of that line will be in its vanishing point.

Theorem 2.—The projection of a line parallel to the picture is also parallel to its original.

Let AB, (*fig. 2.*) be an original line parallel to the picture, *ab* its representation, and EAB the optic plane, E being the place of the eye. Now *ab* is the intersection of the optic plane, that is, of the triangle EAB with the picture; and because AB is parallel to the plane of the picture, and AB, *ab* in the plane of the triangle EAB, *ab* is parallel to AB; for if otherwise, AB would meet the picture in the intersection *ab*, or *ab* produced, and consequently could not be parallel.

Corol.—The projections of several lines parallel to one another and to the picture, are also parallel to one another. Thus, if AD and BC be parallel to one another, and to the picture MNIK, *ad* and *bc* will be respectively parallel to AD and BC, their originals.

Theorem 3.—The representation of a line parallel to the picture is to its original, as the distance of the picture is to the distance between the eye, and a plane passing through the original line parallel to the picture; for let the plane QRZY (*fig. 2.*) be parallel to the plane MNIK of the picture; and let EF be drawn perpendicular to the original plane and to the picture, to meet the original plane in F, and the picture in *f*; join AF and *af*, then AEF will be a plane, AF the intersection of the plane of the triangle and the original plane, and *af* the intersection of the plane of the triangle and the picture.

Now in the similar triangles Eab } $Ea : EA :: ab : AB$
and EAB, }
Also in the similar triangles Eaf } $Ea : EA :: af : AF$
and EAF, }
Therefore, by comparing these } $ab : AB :: af : AF$
equal ratios, }

Consequently, the representation of a line parallel to the picture, is to its original as the distance of the picture is to the distance of the eye, and a plane passing through the original line parallel to the picture.

Corol. 1.—The angle which the representations of any two original lines parallel to the picture make with each other, is equal to the angle made by the original lines; because each representation is parallel to its original.

Corol. 2.—The projection of any plane figure parallel to the picture is similar to its original, for let AB and AD be two contiguous original lines, and *ab* and *ad* their representations. Now in the similar

Triangles Eab and EAB, } $Ea : EA :: ab : AB$
Also in the similar triangles Ead } $Ea : EA :: ad : AD$
and EAD, }
Therefore, by comparison, } $ab : ad :: AB : AD$

Consequently, the sides about the equal angles are proportional.

Theorem 4.—The projection of a line is parallel to its director. Because EQ, ED, and *v'R*, (*fig. 1.*) are all in the same plane; and since the directing plane is parallel to the plane of the picture, the director ED is parallel to the indefinite representation *v'R*; because “if two planes be cut by another plane, their common sections with it are parallel.” B. 11. prop. 16. Euclid.

Corol. 1.—The projections of lines that have the same director are parallel to each other.

Corol. 2.—When the original line is parallel to the picture, it is also parallel to its director, and therefore in the parallel of any given plane passing through the original line, and consequently the vanishing line of that plane, and the projection of the line, are parallel to each other.

Theorem 5.—The distance between the projection of any point of a straight line, and the vanishing point of the line, is to the distance between the intersecting point and the vanishing point, as the distance of the picture is to the distance between the directing point and the original point.

That is, in *fig. 1.* $qv' : Rv' :: E'v' : DQ$. Now because of the parallel planes which form the diagram, *v'E'DR* is a parallelogram, therefore R *v'* is equal to D'E'; now the triangles *q'E'v'* and E'D'Q are similar, because their sides *v'q* and E'D' are parallel; therefore $qv' : D'E' \text{ or } Rv' :: E'v' : DQ$.

Corol.—Hence the distance between the representation of any point in a straight line, and the vanishing point of the line, is to the distance between the intersecting point and the vanishing point, as the distance of the picture is to the distance between the original point and the directing plane.

The foregoing theorems, with the following corollaries arising from the definitions, contain all the principles which we conceive necessary in the perspective representation of any rectilinear object. But if the reader is desirous of knowing the best methods for the representation of circular objects, he must be prepared with the knowledge of conic sections, and the harmonical division of lines.

Corol. 1. Proposition.—If there be a straight line opposed to the eye, and not directed to it, the straight lines which issue from all points of it to the eye form a plane.

Corol. def. 5.—Hence the representation of any straight line, rectilinear figure, or solid, is also rectilinear.

Corol. 1. def. 7.—Hence, if the original object be a plane, and

PERSPECTIVE.

and the picture parallel thereto, the representation will be a figure similar to the original.

Corol. 2.—If any part of an original object touch the picture, the part which is thus in contact will be the representation of that part.

Corol. def. 12.—Hence the intersecting points of all lines in any original plane, are in the intersecting line of that plane.

Corol. def. 13.—Hence if any number of original lines be parallel to each other, one line can only pass through the eye parallel to them all.

Corol. def. 14.—Hence if any number of original planes be parallel to each other, one plane only can pass through the eye, which will be parallel to them all.

Corol. 1. def. 15.—Hence the intersecting and vanishing lines are parallel to each other.

Corol. 2.—Hence all original parallel lines have the same vanishing point.

Corol. 3.—Hence the parallels of every two original planes have the same inclination as the originals.

Corol. 4.—The vanishing point of the common intersection of any two original planes, is the common intersection of the vanishing lines of these planes.

Corol. 1. def. 16.—The vanishing points of all original lines in the same plane, are in the vanishing line of that plane.

Corol. 2.—Hence any number of original parallel lines can have only one vanishing point.

Corol. 3.—Hence original lines which are parallel to the picture have no vanishing point.

Corol. 4.—The radials which generate the vanishing points of two originals make the same angle with the eye as the originals with each other.

Corol. def. 18.—Hence the intersecting line, the vanishing line, the parallel director, and the directing line, are all parallel to each other.

Corol. def. 19.—Hence the directing points of all lines in the same original plane, are in the directing line of that plane.

Corol. 1. def. 22.—Hence a line drawn from the centre of the picture to the centre of a vanishing line, is perpendicular to that vanishing line.

Corol. 2.—The distance of a vanishing line is the hypotenuse of a right-angled triangle, the base of which is the distance of the picture, and the perpendicular the distance between the centre of the picture and the centre of the vanishing line.

Description of the Diagrams for illustrating the Principles of Perspective.—In *fig. 1.* is shewn the method of finding the representation of a point, first by the intersecting and vanishing points. Let Q be any point in the original plane. Through Q draw any line, QR , meeting the intersection IN at R ; and through E' draw $E'v'$ parallel to QR , meeting the picture in v' ; join $v'R$, and draw the visual ray QE' cutting the indefinite representation $v'R$ at q , the representation of the point Q ; because from theorem 1, the indefinite representation of a line passes through its intersecting and vanishing point, and because the visual ray EQ is in the same plane with the parallelogram $RDEv'$, $E'Q$ will therefore cut Rv' at q .

Secondly, by the intersecting and directing points. Draw any line, QD' , through the original point, cutting the intersection IN at R , and the directing line WX at D' ; join $D'E'$, which will be the director of the original line by definition 19; draw Rv' parallel to $D'E'$, and draw the visual ray QE' , cutting Rv' at q , then q is the representation of Q , as before. For since $RDEv'$ is a plane, and

the points E' and Q , and the indefinite representation Rv' in that plane: the visual ray joining E' and Q must cut Rv' at q .

This diagram also shews, that if LM and QR be two original lines, having the same directing point D' , and if M and R be the intersecting points, the indefinite representations Mv' and Rv' will be parallel. This appears from *corol. 1. theorem 3.*

In this diagram it is also shewn, that if EF , GH , IK , LM , be several parallel lines intersecting the picture at F , H , K , M , and if the radial $E'v'$ be drawn parallel to any one of them cutting the picture in v' , their indefinite representations will terminate in v' . This appears evident, since any one of the lines EF , GH , &c. is in the same plane with $E'v'$, from the fourth axiom, and because the eye at E' is in $E'v'$, each of the indefinite representations will be cut by any visual ray from its original to the eye at E' .

Fig. 2. shews the representation of a plane figure parallel to the picture. Let the original figure be $ABCD$, in the plane $QRZY$ parallel to the picture $INMK$, and let E be the place of the eye in the directing plane GHW . Draw any director $E'D'$ through each angular point A , B , C , D , of the figure; draw AP , BS , CT , DQ , parallel to $E'D'$, cutting the original plane in P , S , T , Q ; draw $D'P$, $D'Q$, $D'S$, $D'T$, cutting the intersecting line in p , q , s , t ; draw pa , sb , tc , qd , parallel to $E'D'$: from the angular points A , B , C , D of the original figure, draw the visual rays $E'A$, $E'B$, $E'C$, $E'D$, cutting the plane of the picture $INMK$ respectively at the points a , b , c , d , in the lines pa , sb , tc , qd . Because AP , ap , and $E'D'$, are parallel to each other, they are therefore in the same plane; therefore the straight line Ae' will cut pa at a , consequently, a is the representation of A . In the same manner it may be proved that b is the representation of B , and so on of the rest.

Fig. 3. shews the representation of a plane figure by means of the directing plane in a plane inclined at any angle, or perpendicular to the picture. Let $ABCD$ be the original figure. Take any point D' in the directing line WX as a directing point; draw the director $D'E'$; from the angular points A , B , C , D , draw AD' , BD' , CD' , DD' , cutting the intersecting line at p , q , s , t ; draw pa , qb , sc , td , parallel to the director $D'E'$; draw the visual rays Ae' , Be' , Ce' , De' , cutting the lines pa , qb , sc , td , at the points a , b , c , d , and $abcd$ is the representation of the figure $ABCD$; for pa is parallel to $D'E'$, and the straight line AD' joins these parallels; therefore pa , $D'E'$, and AD' , are in the same plane; and because the angular point A , and E' the place of the eye, are in that plane, the visual ray Ae' is also in that plane, and therefore will cut pa at a . In the same manner each of the other points b , c , d , may be proved to be the representation of each of the points B , C , D .

Fig. 4. shews the representation of a plane figure in a plane inclined to the picture at any angle, or perpendicular to it, by means of a directing point and the vanishing points of the sides.

Let the quadrilateral $ABCD$ be the original figure. Take any directing point D' , and draw $D'E'$ the director; draw the radial $E'v'$ parallel to AD' and BC , cutting VL , the vanishing line, at v' ; also draw the radial $E'v''$ parallel to AB and DC , cutting VL at v'' . Then if the figure be a parallelogram, draw lines to the directing point D' from each of the nearest angular points, B , A , D , to cut the intersecting line IN at p , q , s ; draw pb , qa , and sd , parallel to $E'D'$; produce the side BA of the

PERSPECTIVE.

original figure to meet the intersection $I'N'$ at t ; join $t v'$, cutting qa at a , and pb at b , then a is the representation of the point a ; join $a v'$, cutting sd in d , and draw $b v'$ and $d v'$, cutting each other at c , then $abcd$ is the representation of $ABCD$, as required. For $t v'$ is the indefinite representation of BA by theorem 1, and qa is the representation of the line qA , theorem 3; and since the original lines BA and qA meet or cut each other at A , their indefinite representations will also meet each other at a , and because the vanishing point of a line is a point in the indefinite representation; and if two points in the indefinite representation are found the whole indefinite representation may be drawn. Now since a is the representation of the point A , and v' the representations of another point in the side AD , $a v'$ will be the indefinite representation of AB . In the same manner it may be shewn, that $a v'$ is the indefinite representation of AD : then since sd is the representation of sD , and the point D is both in sD and AD , therefore its representation d is at d , the intersection of sd , and $a v'$, the indefinite representation of these lines: for the same reason b is the representation of B , and by reasoning as above, it may be shewn that c is the representation of C . Therefore the whole figure $abcd$ is the representation of $ABCD$. It is upon this principle that most architectural drawings are put in perspective, by only using the original plane, first supposing the picture, the vanishing plane, and the directing plane, removed: they first draw the plan, $ABCD$, of the building or edifice, and fix upon D' as a station point, and then draw the intersection $I'N'$, then draw lines from the several points to cut $I'N'$; and supposing the picture to stand perpendicular to the original plane, as is generally the case, the directing plane $STXW$ will also be perpendicular to the original plane; then as D' in this case is the station point, the director $D'E'$ becomes perpendicular also to the original plane, and hence the directorial indefinite representations sd , qa , pb , will be perpendicular to the intersection $I'N'$. Then taking another separate piece of paper for the picture, draw two parallel lines $I'N'$ and $V'L'$ at a distance from each other, equal to the height of the eye, $I'N'$ being the intersecting line, and $V'L'$ the vanishing line; then transferring all the intersections to $I'N'$ on the picture, draw lines from each point perpendicular to $I'N'$, and they will give the directorial indefinite representations; then the vanishing points being found upon the original plane, the whole object may be represented with more advantage in this manner than in any other, as the indefinite representations of all lines on the original plane fall in the same straight lines with the representations of original lines perpendicular to the original plane from the same original points.

Fig. 5. shews the representation of a plane figure by means of vanishing points only; *viz.* by finding the vanishing points of the sides, and producing the sides of the original figure to their intersecting points, then the intersections of the indefinite representations will form the figure $abcd$, which is the representation of the original figure $ABCD$, depending entirely upon theorem 1.

This method is, however, not so convenient as the station point or prime directing point, as it requires much more space to produce all the original lines, than to draw them from each of the points of the object to the directing point, and more particularly when the plan of the object is very remote from the intersecting line, or when large in proportion to the distance, and on this account, though elegant in theory, it is not eligible for practice.

Fig. 6. is here given, in order to shew that it will be the same thing, whether the plan of the object is laid on the va-

nishing plane, extended beyond the picture, or upon the original plane, the point E' for the eye and the vanishing line being situated in the same manner with respect to the figure $abcd$, that the point D' and the intersection $I'N'$ are in respect to the similar and equal figure $ABCD$. For let the figures $abcd$, and $ABCD$, be placed so that the corresponding sides ab , AB , cd , CD , &c. shall be parallel; then suppose the lines aA , bB , &c. to be joined, then these lines will also be parallel to each other; and because the points D' and E' are alike situated to each of these figures, if $D'E'$ be joined, $D'E'$ will be parallel to aA , bB , &c. and parallel to the plane $I'N'L'V'$. Let $D'v$ be drawn parallel to AB , meeting $I'N'$, or $I'N'$ produced at v ; draw $D'C'$ perpendicular to $I'N'$, cutting it in C' ; also draw $E v'$ parallel to ab , meeting $V'L'$, or $V'L'$ produced at v' , and draw EC'' perpendicular to $V'L'$, meeting it in C'' , then the intersecting points G , M , N , will have the same distances in respect of each other, and with respect to v and C' , that g , m , n , have in respect to each other and to the points v' and C'' ; it will therefore be the same thing whether we use the vanishing plane, or the original plane, in order to ascertain the intersections, the centre and distance of the picture, and the vanishing points, so as to draw the object unconnected with the original plane, as explained in *fig. 4.* as each of the lines drawn in the one plane has the same extension as its correspondent line in the other, and the angle made by any two adjoining lines in the one plane, is equal to the angle formed by the corresponding lines of the other.

The foregoing diagrams, with the explanations which accompany them, shew the nature of forming the representation from the original object, supposing all the planes to exist in their real position; but this is not the case in practical perspective; the picture, the original plane, and the vanishing plane, must be reduced to one plane surface in the following manner: suppose the intersection, the vanishing line, the parallel of the eye, and the directing line, to be as hinges to the four planes, *viz.* the plane of the picture, the directing plane, the part of the original plane between the intersecting and directing lines, and the vanishing plane: now as these planes are all parallelograms, and the opposite planes being equal, they will, therefore, continue parallel in all positions when moved round the four hinges, and consequently may be all made to coincide in one plane: now let it be supposed that the picture, the directing plane, and the vanishing plane, are moveable upon the original plane, which remains stationary, and let these planes be made to coincide with the original plane, so that the picture may cover that part of the original plane between the intersecting line and the directing line, either entirely, or in part, then by this means the part of the original plane beyond the intersecting line will be wholly uncovered. Suppose all the radials to have been previously drawn on the vanishing plane, in order to produce the vanishing points, it is evident that these radials will be still parallel in the coincident state of the planes. The practice, with regard to the use of vanishing points, may therefore be as follows: upon any convenient part of the paper draw two parallel lines for the intersecting and vanishing lines, then the area or space comprehended between these lines is the picture, the space adjacent to the intersection is the original plane, and the space adjacent to the vanishing line is the vanishing plane, so that the picture lies between the vanishing and original planes: draw the original figure in the original plane in the intended position to the intersecting line, and fix upon the eye with regard to its distance from the vanishing line, and its position in regard of the station line: draw lines through the eye parallel to the sides of the original figure as radials, in order to produce the vanishing points; continue the sides of the original figure to the intersecting

PERSPECTIVE.

fecting line, and join the corresponding intersecting and vanishing points, then the space inclosed by the indefinite representation will be the representation of the original figure. For if the whole scheme were supposed to be raised into its original position, the eye would be brought into its true place, the radials would be parallel to the original sides of the object, and the indefinite representations would be in the same plane with the radials and sides of the original object. Though the space between the intersecting and vanishing is called the picture, the picture is by no means limited to this space, but extends upwards, and covers the vanishing lines plane, so that, in most cases, what is commonly called the picture is the least part of it, except in bird's-eye views, or where the horizon is taken very high in consequence of the spectator being placed upon an elevated situation.

In the practice of perspective, where the plan of the object is given, the principal directing point used in conjunction with the vanishing points of the sides is the most convenient, as has already been observed; the vanishing plane is here supposed to be removed, as all the planes in the practice of perspective delineation are supposed to coincide. The intersecting and vanishing lines may be drawn as before; then the principal directing point or station point may be fixed in the same position to the intersecting line, that the eye is in regard of the vanishing line; then the eye and the station point will be at a distance from each other, equal to the height of the picture, and in a straight line perpendicular to the intersecting line; or the distance of the eye from the vanishing line will be equal to the distance of the station point from the intersecting line; also the position and distance of the eye from the object will be the same as when all the planes are brought into their real position.

It must be here observed, that in the motion of these planes round the principal line, as before observed, the parallel of the eye and the vanishing line always keep the same parallel distance in all positions; but these lines vary in respect of the object in the original plane, because these lines are not in the same plane with the original plane; and the intersecting and directing lines, also the original figure, are in the same plane, *viz.* in the original plane. Therefore the station point, or any other directing point, may be fixed in position to the original object and intersecting line. This is the foundation of the practice of perspective with regard to the use of the directing line, and, therefore, the directing point has the same relation to the intersecting line that the eye has to the vanishing line.

In order to prevent repetition in the enunciation of the following problems, the eye, the vanishing line, and intersecting line, are always given in position; the eye is denoted by E' , the vanishing line by VL , and the intersecting line by IN ; but as the original object may be of an indefinite number of forms, it is only enunciated in each problem.

PROBLEM I. *Plate II. Figs. 1 and 2.*

Given any original straight line AB , oblique to the intersection IN , to find its indefinite representation.

Produce AB to its intersecting point B ; through E' draw the radial $E'v'$, and join Bv' ; then Bv' is the indefinite representation of the line AB . Theorem 1.

If there be any number of original parallel lines AB , $A'B$, &c. and if B , B , &c. be their intersecting point, and v' the vanishing point of any one, it will be the vanishing point of the whole system. Corol 2. def. 16.

PROB. II. *Figs. 3 and 4.*

Given any original point A , to find its representation.

Draw any two lines through the point A , find each of

their indefinite representations Cv' , Bv' , problem 1, and the intersection a of Cv' , Bv' , will be the representation of the original point A .

For since the original point, A , is in each of the original lines AB and AC , the representation, a , of the point, A , is in each of the indefinite representations, and is therefore at a , their intersection.

PROB. III. *Fig. 5.*

Given any original line AB , oblique to the intersection, to find its representation.

Find the indefinite representation Cv of AB by problem 1; draw AE and BE' , cutting Cv at a and b , then ab is the representation of AB .

For let AE' intersect IN at D , and VL at G , then D is the intersecting point, and G the vanishing point of the original line AD ; therefore GD is the indefinite representation of AD ; and since vC is the indefinite representation of the original line AB , and since each of the original lines is drawn from the point A , the intersection, a , of the two indefinite representations Cv and DG will be the representation of the point A by problem 2. In like manner it may be shewn that b is the representation of the point B , therefore ab is the representation of AB .

PROB. IV. *Fig. 6.*

To find the representation of any original line AB parallel to the picture.

Find a , the indefinite representation of the point A , problem 2; draw ab parallel to the original line AB ; join BE' , cutting ab at b , then ab is the representation of AB .

For since a is the representation of A , problem 2, and since any original line parallel to the intersection must have its representation also parallel to the intersection; and, lastly, because b is the representation of B , ab is the representation of AB . For it may easily be shewn, that if two planes cut one another, and if these be cut by a third plane, so that its intersection with one of them shall be parallel to the intersection of the two first, the other intersection will also be parallel to the two first.

PROB V. *Fig. 7.*

An original oblique line AB , being divided into several parts, to find the representation of the parts.

Find the representation, ab , of the original line AB , problem 3, and through the several divisions of the parts in AB draw lines to the eye at E' , cutting ab at e and f , then be , ef , fa , are the parts corresponding to those of the original line AB .

This is evident from problem 2.

PROB. VI. *Fig. 8.*

Given the seat, A , of an original line parallel to the picture, and perpendicular to the original plane, to find the representation of the said line.

Through A draw any line AB , cutting IN at B , and find its indefinite representation Bv , problem 1, and find the representation, a , of the point A in the indefinite representation Bv ; draw BC and ad perpendicular to IN ; make BC equal to the original line; draw Cv , cutting ad at d , then ad is the representation of the original line insisting upon the given point A .

Demonstration to Problem VI.—For, suppose the plane $INLV$ of the picture to be raised perpendicular to the original plane, and the objective line to be raised in position; also imagine a straight line drawn through the other extremity of the objective line, out of the original plane, parallel to

PERSPECTIVE.

to AB , till it cut the picture; this line, so drawn, will form the side of a parallelogram, of which AB is the opposite side, and the objective line insinuating upon A , and BC the other two opposite sides; therefore BC will be equal to the objective line, and the point C is the intersection of the side of the parallelogram opposite to AB ; and because v is the vanishing point of AB , it will also be the vanishing point of the side of the parallelogram opposite to BC ; therefore Cv will be the indefinite representation of the side of the parallelogram opposite to AB ; and because the point a , in the indefinite representation Bv of AB , is the representation of the point A , and because both ad and the original line are each parallel to BC , and ad is terminated at d by Cv ; ad is the representation required.

The following four problems are performed by means of the prime directing point and one vanishing point; where, observe that C' is the centre of the picture, found by drawing $E'C'$ perpendicular to the vanishing line VL , as in definitions 21 and 22; D' the prime directing point in $E'C'$, found by making $E'D'$ equal to the height of the picture, or making the distance between D' and the intersecting line equal to $C'E'$, the distance between the vanishing line and the eye.

PROB. VII. Fig. 9.

To find the representation of a line AB oblique to the intersection.

Find the indefinite representation Cv of AB by problem 1; draw AD' and BD' , cutting IN at D and E ; draw Ea and Db parallel to $D'E'$, cutting Cv at a and b , then ab is the representation of AB .

For since the representations of the points A and B are in Cv , the indefinite representation of AB , and because $E'D'$ is the director of the original lines AE and BD , and E and D the intersecting points of these lines, Ea and Db , drawn parallel to $E'D'$, will be the indefinite representations of AE and BD ; therefore the representations a and b , of the points A and B , are in these indefinite representations, theorem 3; but they are also in the indefinite representation Cv ; and, consequently, in a and b , the intersections of the indefinite representations, whose director is $D'E'$, and the indefinite representation Cv , whose vanishing point is v , therefore ab is the representation of AB .

PROB. VIII. Fig. 10.

To find the representation of an original line AB , parallel to the intersecting line.

Through either extremity A , draw any line Ae , meeting the intersection in e ; find the indefinite representation ev of Ae , problem 1; draw $D'A$ and $D'B$, cutting IN at c and d ; draw ca parallel to $D'E'$, cutting ev at a ; draw ab parallel to AB ; and draw db parallel to $E'D'$, cutting ab at b ; then ab is the representation of AB .

For the representation of the point A is in the indefinite representation ev of Ae , problem 1; it is also in the indefinite representation ca of Ae ; therefore the representation of A is at the point a , the intersection of these two indefinite representations; and because the original line, AB , is parallel to the intersection, ab will also be parallel to the intersection; therefore the representation of the point, B , will be in the line ab ; but the representation of B is also in the indefinite representation, db , of the line Bd ; wherefore the representation of the point, B , being both in ab and db , must be at b , their intersection; wherefore ab is the representation of the line ab .

PROB. IX. Fig. 11.

To find the representation of parts AD , DE , EB , into which an original line AB , oblique to the intersection, is divided.

Find the indefinite representation, cv , of the line AB , by problem 1; then by the directing point D , and director $D'E$, find the representations a, d, e, b , of the original points A, D, E, B , as in problem 7.

Then ad, de, eb , are the representations of AD, DE, EB .

This is evident from the demonstration, problem 7.

PROB. X. Fig. 12.

To find the representation of a line parallel to the picture perpendicular to the original plane.

Find the indefinite representations, bv and cv , of any straight line Ab , and that of another parallel to it, passing through the other extremity of the objective line out of the original plane, as in problem 6; draw AD' , cutting IN at f ; and draw fd parallel to $D'E'$, cutting bv at a , and cv at d ; then ad is the representation required.

This is evident from the demonstration of problem 6, and because the director, $D'E'$, is perpendicular to the intersecting line IN , the indefinite representation af of Af , as well as the representation, ad , of the original of the objective line, are perpendicular to IN ; and because the point, a , is common to the two straight lines af and ad , af is in the same straight line with ad , and, consequently, they make only one straight line, fd , perpendicular to IN .

The following problem shews the method of finding the representation of plane figures by means of the vanishing points.

PROB. XI. Figs. 13, 14, and 15.

To find the representation of any plane rectilinear figure in the original plane.

Find the indefinite representation of every side of the original figure by problem 1, and the intersections of all the indefinite representations will form the representation of the figure required.

If the vanishing points of any original line exceed the limits of the picture, the extremities of that line may be found by problem 3, or by problem 7.

Parallelograms will have two vanishing points.

The foregoing problems are requisite in finding the representation of an object in the original plane. The following is to obviate the necessity of drawing the original object, or having it given but to perform the operation from a knowledge of the construction of the figure.

PROB. XII. Plate III. Fig. 1.

Given the vanishing and intersecting points of a line, the distance of any point in that line from the intersecting point, as also the length of the radial, to find the representation of the point.

Let v' be the vanishing point, d the intersecting point; join dv' ; through v' draw any line, $v'f$, and through d draw db , on the contrary side of dv' , parallel to $v'f$; make db equal to the distance of the original point from the intersecting point d , and make $v'f$ equal to the distance between the vanishing point, v' , and the eye E' ; join fb , cutting dv' at m , then m is the point required.

This proposition is manifest from theorem 4. But, for the conveniency of practice, the distance of the eye from the vanishing point is transferred upon the vanishing line from the vanishing point; and, consequently, the distance of the original

PERSPECTIVE.

original point from the intersecting point, is transferred upon the intersecting line from the intersecting point, in order to save room: thus, if $V'L'$ be the vanishing line, $I'N'$ the intersecting line, E' the place of the eye, a an original point, drawing any line ad , and its radial $E'v'$, and joining the vanishing point, v' , to the intersecting point d and making $v'1$, on the vanishing line, equal to $v'E'$, the distance of the eye, and dc on the intersecting line equal to da , the point, m , will be found the same, whether aE' , bf , or $c1$, be joined, as is evident, because the indefinite representation, $d'v'$, is divided into two portions in the constant ratio of ad to $v'E$.

PROB. XIII. Fig. 2.

Given the vanishing and intersecting lines of a plane, the vanishing and intersecting points, v' and d , of an indefinite line in that plane, the distance of the eye, and the distance of a point in the original line, to find the representation of the point.

Join $v'd$, the intersecting and vanishing points; make $v'1$ equal to the distance of the eye, and dc equal to the distance of the point in the original line; join $c1$, cutting $d'v'$ at m , and m will be the representation of the original point.

This appears evident from problem 12.

PROB. XIV. Fig. 3.

The vanishing and intersecting lines of a plane, the vanishing and intersecting points, v' and d , of a finite line on that plane, the distance of the vanishing point from the eye, and the distance of the nearest extremity of the line to its intersecting point being given, to find the representation of the line.

Join $v'd$, the indefinite representation; make $v'1$ equal to the distance of the eye on the vanishing line, also da equal to the distance of the nearest extremity, and ab equal to the original line on the intersection IN ; join $a1$, cutting $v'd$ at f , and $b1$ cutting $v'd$ at g , then fg is the representation of the original line.

This appears evident from problem 12, as the points f and g are each the representation of a point in the original line.

PROB. XV. Fig. 4.

The definite representation ae , and the vanishing point, v' , of a line being given, to divide ae , representing the original line, consisting of parts of a given ratio.

Through either extremity, a , of the definite representation, draw IN at any angle with av' , and through v' draw $v'1$ parallel to aE , on the contrary side of av' ; make aB , BC , CD , DE , equal to the parts of the original line, or in the same ratio; join Ee , which produce to 1 ; also join $B1$, $C1$, $D1$, cutting ae at b , c , d ; then ae is divided as required.

For in the similar triangles,

$$\begin{aligned} baB \text{ and } bv'1, & \quad ba : aB :: bv' : v'1 \\ caC \text{ and } cv'1, & \quad ca : aC :: cv' : v'1 \\ daD \text{ and } dv'1, & \quad da : aD :: dv' : v'1 \\ eaE \text{ and } ev'1, & \quad ea : aE :: ev' : v'1 \end{aligned}$$

Therefore alternately,

$$\begin{aligned} ba : bv' :: aB : v'1 \\ ca : cv' :: aC : v'1 \\ da : dv' :: aD : v'1 \\ ea : ev' :: aE : v'1 \end{aligned}$$

And because the parts aB , aC , aD , aE , continue in the same ratio with $v'1$, the points, a , b , c , d , e , will be invari-

able, whatever angle the lines $a'E$ and $v'1$ form with $v'a'$ and whatever be the lengths of aB , aC , aD , aE ; and because the lines $a1$, $B1$, $C1$, $D1$, $E1$, represent a series of parallels, cutting the original of ae , the points a , B , C , D , E , will represent the intersections, and $v'1$ the distance of the eye.

PROB. XVI. Fig. 5.

The centre C , and distance of the picture, the vanishing and intersecting lines of a plane, the vanishing point of a finite line in that plane, the seat x , and distance of the nearest extremity of that line from its seat being given, to find the representation of the line.

Make $C'D$ on the vanishing line equal to the distance of the picture, and xy on the intersecting line equal to the distance of the seat of the nearest extremity of the given line; join $C'x$ and yD , cutting each other in g ; join gv' ; find the point 1 , such that the distance $v'1$ may be equal to the hypotenuse of a right-angled triangle, whose base is $v'C'$, and perpendicular $C'D$ the distance of the picture; draw $1ga$, cutting $I'N'$ at a ; make ab equal to the original line; join $b1$, cutting gv' in b , and gb is the representation required.

PROB. XVII. Fig. 6, N^o 1.

The centre and distance of the picture, the vanishing and intersecting line of a plane perpendicular to the picture, the seat of the nearest extremity of a line in that plane, the length of the line, and its inclination to the intersecting line being given, to find the representation of the line.

In N^o 1, let x be the seat of the nearest extremity of the line; make xy equal to its distance, and make $C'D$ equal to the distance of the picture; join $C'x$ and Dy , cutting each other at g . In N^o 2, make any angle acc , on the line ae ; make ea to eb as radius to the cosine of inclination of the given side; make ec equal to its length; find ed a fourth proportional to ea , eb , ec ; transferred to $I'N'$, N^o 1, from x to f , and draw fc cutting gv' at b , then gb is the line required.

This is evident, if we consider the points, a and b , in the original lines perpendicular to the picture; then the space intercepted upon the intersecting line by the two perpendiculars, will be in the same proportion to the original line as radius to the cosine of inclination.

PROB. XVIII. Figs. 7 and 8.

Given the indefinite representation of two lines in the same plane, intersecting each other at b ; a finite portion, ba , of the indefinite representation bv' , and the distance of the eye, $v'1$ and $v'2$, from each vanishing point, v' , v'' ; to find a portion of the indefinite representation bv'' , the original of which shall be equal to that represented by ab , or in any given ratio with the original of AB .

Through the point b , draw de parallel to the vanishing line $V'L'$; join $1a$, which produce to d , in fig. 7, but to cut ed in d , fig. 8; make be to bd in the ratio required, and join $e2$, cutting bv'' at c ; then the original of ba will be to the original bc as bd to be , as required.

This is evident by considering ba as the representation of a line inclined to, and bd the representation of another coinciding with, the picture, and 1 the vanishing point of a line forming the base of an isosceles triangle with each of these lines; therefore, abd will be the representation of an isosceles triangle, of which ad will represent the base, and ab and bd the two equal sides: in like manner, bce will represent an isosceles triangle, of which ce will represent the base, and cb , be , the two sides.

PERSPECTIVE.

In this and the following examples, where the representations of lines are required to be delineated without the use of the geometrical plane; the vanishing points are always marked v , with an index over the right-hand side of it, in order to distinguish the number of vanishing points: thus, v^1, v^2, v^3 , &c. denote the first, second, and third vanishing points. The distances of these vanishing points are simply denoted by their indexes: thus, 1 placed upon the vanishing line, denotes the distance of the vanishing point v^1 from the eye, 2 of v^2 , and so on of others.

PROB. XIX. Fig. 9.

The indefinite representations, $c v^1$ and $a v^1$, of two lines in the same plane; the distances, $v^1 1$ and $v^2 2$, of their vanishing points, v^1 and v^2 , on the vanishing line, $V L$, of their plane; also, a finite portion, $c d$, of the indefinite representation $c v^1$, being given: through a given point, a , in the indefinite representation $a v^2$, to represent the length of an original line, which shall be equal to, or in a given ratio to, the original line represented by $c d$.

Through c draw $g f$ parallel to $V L$, and through a draw $a b$ parallel also to $V L$; join 1 d , and produce it to g ; also produce the indefinite representation $v^2 a$ to meet $g f$ in e ; make $e f$ to $e g$, in the ratio of the original to be represented from the point a , on the indefinite representation $a v^2$, to the original represented by $c d$; join $f v^2$ cutting $a b$ at b , and join $b 2$ cutting $a v^2$ at b ; then $a b$ is the representation required.

For $a c b f$ represents a parallelogram, with two sides parallel to the picture; and because $e f$ and $a b$ represent opposite sides, the original of $e f$ is equal to the original of $a b$; and because $b a b$ represents an isosceles triangle, of which $b b$ is the base, the original of $a b$ is equal to the original of $a b$, therefore the original of $a b$ is equal to the original of $e f$; and because $d c g$ represents an isosceles triangle, the original of $e g$ is equal to the original of $c d$; and because $c g$ and $e f$ are in a line parallel to the vanishing line, the originals of $c g$ and $e f$ are parallel in the same indefinite line to the intersecting line of their plane, and have the same ratio as the representations $c g$ and $e f$; therefore the original of $c d$ has to the original of $a b$ the ratio of $c g$ to $e f$, as required.

PROB. XX. Fig. 10.

Given the eye, the vanishing and intersecting lines, and place of the eye in position; to find the representation of a parallelogram, whose angles and dimensions, also the seat, x , of the nearest angular point, and its distance from the intersecting line, are known.

Draw $E' C'$ perpendicular to $V' L'$, the vanishing line, cutting it in C' , the centre of the picture; make $C' D'$ equal to $C' E'$, and $x y$ equal to the distance of the nearest angular point of the parallelogram from the intersecting line; join $x C'$ and $y D'$, cutting each other in e , the representation of the nearest angle, as in problem 16. Through E' draw $M N$ parallel to $V' L'$; make the angle $M E' v^1$ equal to the angle which the side of the original parallelogram, adjoining the nearest angle, makes with the intersection, or makes with a line drawn from the nearest angle parallel to the intersection; make the angle $v^1 E' v^2$ equal to the nearest angle of the parallelogram; join $e v^1$ and $e v^2$; from the indefinite representation $e v^1$, cut off the portion $e f$, to represent a line equal to the original side, of which $e v^1$ is the indefinite representation, by problem 16; that is, make $v^1 1$ equal to $v^1 E'$; join 1 e , and produce it to meet the intersecting line in a ; make $a b$ equal to the original side; join $b 2$, cutting $e v^1$ at f ; in like manner, make $v^2 2$ equal to

$v^2 E'$, and join $2 e$, cutting the intersecting line in c ; make $c d$ equal to the other adjoining side of the nearest angle, and join $d 2$, cutting $e v^2$ at b ; join $b v^1$ and $f v^2$, and $e f g b$ is the parallelogram required.

The original figure, though here shewn, is of no other use than to assist the imagination in the construction.

PROB. XXI. Fig. 11.

Given the intersecting and vanishing lines, and the place of the eye in position, the seat x , the distance of the centre of a circle, and its radius, to find the representation of the circle.

Method 1.

Make $x y$, on the intersecting line, equal to the distance of the centre of the original circle from its seat x , and $C' D'$ on the vanishing line equal to $C' E'$, the distance of the eye; join $x C'$ and $y D'$, cutting each other in e , the representation of the centre of the circle; through e draw $c d$ parallel to $V' L'$, the intersection; make $x a$ and $x b$ each equal to the radius of the circle; join $C' a$, cutting $c d$ in c , and $C' b$, cutting $c d$ in d , and $c d$ is the representation of a diameter parallel to the picture; then to find the representation $f g$ of any diameter drawn through c at pleasure; produce $f g$ to its vanishing point v^2 ; make $v^2 2$, on the vanishing line, equal to $v^2 E'$, the distance of the eye from the vanishing point; join $2 c$, cutting $f g$ in g , also $2 d$, and produce it to f ; then $f g$ is the representation of a diameter of the original circle inclined to the intersecting line. In like manner may the representations $h i$, $k l$, $m n$, be found; viz. by transferring the distance of each of their vanishing points from the eye on the vanishing line, and drawing two lines from each point of distance to c , and d , the one cutting, and the other produced till it cut the indefinite representation belonging to the distance so transferred, then a curve being drawn through all the extremities of the representative diameters, will be the representation of the circle required.

The original circle, A , is placed in its position for the same reason as before given, prob. 21. This is an application of problem 18, from which its evidence appears.

The following are several easy methods of drawing the representation of a circle, and are exceedingly useful where accuracy is required, particularly in the representation of large circles.

The intersecting and vanishing lines, the centre and distance of the picture, the seat and distance of the centre, and the radius of the circle, are supposed to be given till it is otherwise announced; C' denotes the centre, and $C' D'$ the distance of the picture, and x the seat of the centre of the circle, and $x y$ its distance, as in prob. 20, 21.

Method 2. Fig. 12.

Draw $x A$ perpendicular to $V' N'$; make $x E$ and $x D$ each equal to $x A$; describe the arc $C x B$; join $A E$ and $A D$, cutting the arc $C x B$ at C and B ; draw $C F$ and $B G$ perpendicular to $V' N'$, cutting $V' N'$ at F and G ; join $E C'$, $F C'$, $x C'$, $G C'$, and $D C'$; also join $y D$, cutting $E C'$, $F C'$, $x C'$, $G C'$, and $D C'$, at b, m, n, k , and d ; draw $b a$ parallel to $V' N'$, cutting $x C'$ in e , and $D C'$ at a ; draw $d c$ parallel to $V' N'$, cutting $x C'$ in g , and $E C'$ at c ; through n draw $f b$ also parallel to $V' N'$, cutting $E C'$ at f , and $D C'$ at b ; join $a c$, cutting $G C'$ at b , and $F C$ at l , and $a c$ will also cut $f b$ or $y D'$ at n ; through the points e, b, k, g, l, f, m, c , draw a curve, which will be the representation of the circle required.

This will easily appear, when it is considered that the tan-

PERSPECTIVE.

gent of 45 degrees is equal to the radius, or by inspecting *fig. 14*, where the part *MFG* is equal and similar to *AED*.

Method 3. Fig. 13.

Make *xb* and *xa* each equal to the radius of the circle; join *bC'*, *xC'*, and *aC'*; make *xy* equal to the distance of the centre of the circle from its seat *x*, and join *yD'*, and complete the representation *d c f e* of the circumscribing square, as in *fig. 12*; divide the representation *bg*, of the parallel diameter, into seven equal parts, setting one-seventh from *b*, and the other seventh from *g*, each towards the centre; draw *kl*, and *mn*, tending to *C'*, cutting the diagonals in the points *k, l, m, n*, then through the points *l, h, k, p, n, g, m, q*, draw a curve, which will be the representation required.

This will readily appear by observing in *fig. 12*, that the representation of the parallel diameter *fb* is divided in the same proportion as *ED*, or as *EA*, *fig. 14*; now *EL*, *KA*, *FH*, or *IG*, *fig. 14*, is very nearly equal to one-seventh of the diameter *EA*; draw *MC* perpendicular to *EA*, cutting the semi-circumference at *C*; through *C* draw *FG* parallel to *EA*, and through *E* and *A* draw *EF* and *AG* parallel to *MC*, and join *FM* and *GM*, cutting the circle in *D* and *B*; through *D* and *B* draw *LH* and *KI* parallel to *MC*, cutting *EA* at *L* and *K*, and *FG* at *H* and *I*.

Now suppose the diameter *EA* to consist of seven equal parts, then the radius *ME* or *MA* will be 3.5, that is, *MD*, or *MB*, will be 3.5.

By Euclid, b. i. prop. 47, the square of *MD*, or *MB*, is equal to the squares of *ML* and *LD*; but *ML* is equal to *LD*, therefore the square of *MD* is double the square of *ML*; that is, the square of *ME* is double of the square of *ML*; hence *ML* will be obtained arithmetically thus:

$$LM = \left(\frac{ME^2}{2}\right)^{\frac{1}{2}}; \text{ therefore } EL = EM - LM =$$

$$EM - \left(\frac{ME^2}{2}\right)^{\frac{1}{2}} = 3.5 - \left(\frac{3.5^2}{2}\right)^{\frac{1}{2}} = 1.026, \text{ \&c.}$$

which is exceedingly near to unity, the error being in excess.

Fig. 15, is an application of method 3, *fig. 13*, to planes at different altitudes, to obtain the representation of a circle, when the seat of its centre is given on the original plane, and the seat of the centre of the circle on the original plane, given on the intersecting line, and the distance of the seat of the centre of the circle on the original plane, from its seat on the intersection also given. The ellipsis below is the representation of a circle below the eye.

To represent a circle above the level of the eye, let *x* be the seat of the centre of the circle on the original plane, given on the intersecting line; let *xy* be the distance of the two seats. Draw *yo* perpendicular to *I'N'*, and make *yo* equal to the distance of the centre of the circle from its seat on the original plane; draw *oD'*; then having found the representation of the circle below the eye on the original plane, as in method 3, *fig. 13*, let *ce* be the representation of the diameter parallel to the picture, and *a* the representation of the centre; draw *ap* parallel to *yo*, cutting *oD'* in *p*; draw *wz* parallel to *V'L'*, the vanishing line; draw *ew* parallel to *yo*; make *pz* equal to *pw*; through *w* draw *st*, tending to the centre *C'* of the picture, cutting *oD'* in *t*; and through *x* draw *qr*, tending also to *C'*, cutting *oD'* at *r*; draw *rs* and *qt* parallel to *V'L'*, and *sqr* will be the representation of the circumscribing square; then complete the circle as in method 3.

Method 4. Plate IV. Fig. 1.

Let *ABCD* be the representation of the circumscribing square, with two sides of the original parallel to the intersecting line, consequently the other two perpendicular thereto; and let *GH* be the representation of a diameter parallel to the intersecting line, and *I* that of the centre; *EF* the diameter perpendicular to the intersecting line. Divide *IH* into any number of equal parts (as three), and through the points of division (1, 2,) draw the lines *Fm, Fn*; draw *HK* parallel to *FE*, cutting *AB* at *K*; divide *KH* into the same number of equal parts as *IH*, and through the points of division draw the lines *Em, En*, then the points *m* and *n* are in the curve as well as the points *E* and *H*. In the same manner, the curve *EopG*, for the representation of the other quarter, will be found; also in describing the representation *GFH* of the remote semi-circle, proceed for the representation of each quarter in the same way, only changing the points *F* and *E* for each other, and the whole curve will be obtained.

Method 5. Fig. 2.

Let *GEH* be the representation of the remote semi-circle in the same position as before. Divide *IH* into any number of equal parts (as three), also divide the line *BH* respectively to represent the original of *BH*, divided into three equal parts; that is, since *BC'* is the indefinite representation of a line *C'*, its vanishing point, *Bk* is a line drawn through *B*, and *C'd* another drawn parallel thereto, and on the contrary side of *BC'*. On *Bk* set off the distances *B1, 12, 2k*, equal to each other; join *kH*, and produce it; meet *C'd* in *t*, and draw each of the lines *1l, 2m*, tending to the point *t*, cutting *BH* at *l* and *m*, the same as in problem 15; then having drawn the lines *Epl, Eqm*, as in method 4, draw *lpE, mqE*, and the points of intersection *p* and *q* will be in the curve. In the same manner may the part *ErsG* be obtained, and also the representation of the remote half, if necessary.

Fig. 3, is the representation of a segment less than a semi-circle, the chord of the original segment being parallel to the intersecting line: the operation is the same as in method 4. It is hardly possible to conceive any method more convenient and more easy than this, as the perspective representation is found geometrically, without any other vanishing points than the centre of the picture.

Method 6. Fig. 4.

Having completed the representation, *ABCD*, of a circumscribing square, the sides of the original being parallel and perpendicular to the picture; find the perspective centre *I*, which may be done by drawing the two diagonals; find the representation *GH* of the diameter parallel, and that of *FE* of the diameter perpendicular to the picture; produce *GH* both ways to *K* and *L*, making *GK*, and *HL*, each equal to *IH* or *IG*; join *KE* and *KF*, *LE* and *LF*; also join *ED*, *FA*, *EC*, and *FB*, cutting the lines drawn from *K* and *L* to the points *E* and *F*, at *a, b, c, d*, which are points in the representation of the circle; therefore through all the points *a, E, b, H, c, F, d, G*, draw a curve which will represent the circle required.

Fig. 5, shews the same thing for the representation of a semicircle with its diameter parallel to the picture.

The methods shewn by *figs. 1, 2, 3, 4*, and *5*, are derived from the following consideration.

Let *AB* (*fig. 6*.) be any straight line cutting another *CD* at *E*, and dividing it into two equal parts *EC* and *ED*; and if *CF* and *DG* be drawn parallel to *BA*, and if *FG* be drawn through *A* parallel to *CD*; and if *CE* and

PERSPECTIVE.

and CF be divided into any equal number of parts in the same ratio from C , and lines be drawn from the points of division in CF , to the point A , and lines through the several divisions in CE from the point B to cut the former drawn to the point a , the respective intersections of every two lines will be in the curve of an ellipsis, of which CE is an ordinate, and AE an abscissa. In the same manner the opposite part of the curve may be described, and also the other portion on the opposite side of the double ordinate CD . Now to shew the truth of this: let AB (*fig. 7.*) be a diameter, and gf an ordinate; draw fe parallel to BA , and Ae parallel to gf ; divide fe and fg in the same ratio, the former in b , and the latter in k , and draw bA and Bk , and produce Bk to meet bA at C , then C is a point in the curve.

Because the triangles } $BD : Bg :: DC : gk$
 BDC and Bgk are } similar,
 And because the triangles } $AD : Ai \text{ or } eb :: DC : ib \text{ or } gf$
 ADC and Aib are } similar,
 And by construction, $eb : efor Ag :: gk : gf$
 Therefore by multiplication, } $BD \times AD : Bg \times Ag :: DC^2 : gf^2$

A well-known property of the ellipsis.
 Now in *fig. 1.* EF is a diameter, and IG, IH , ordinates at the same point I ; and as the perspective representation of a circle is the section of an oblique cone, it is an ellipsis, and as the method is the same as that now demonstrated, it is therefore founded in truth. In *fig. 3.* the same data are given. In *fig. 4.* FA divides IG into two equal parts, which have their originals also equal; and FB divides IH into two equal parts, which have their originals also equal. Again, EK divides AG into two parts, the originals of which are equal; and EL divides BH into two parts, the originals of which are equal; and since a circle can be drawn through as many points found in the same manner, this method for finding eight points in the curve is correct. The same might have been observed of *fig. 2.*; for the parts in the double ordinates IG and IH are divided equally, and the parts in AG and BH perspectivevely into parts, the originals of which are equal.

Nothing can be more expeditious, nor more convenient for practice, than the method which this principle furnishes, when it is considered that no point can be found geometrically, but by the intersections of two straight lines. Its great advantage lies in the regularity of the operation; in not distracting the eye with irregular crossings. As many points may be found as required, without the least confusion, within the compass of the circumscribing parallelogram, which is not the case with many other methods derived entirely from the principles of perspective. It may be always well applied when the curve is the representation of a circle inscribing a square, the sides of which are parallel and perpendicular to the picture.

Method 7. Fig. 9.

Let $WXYZ$ be the representation of a square circumscribing the representation of the circle required; and let AB be the representation of a diameter of the original circle perpendicular to the picture, and DC the representation of the radius parallel thereto. Bisect AB in I ; through I draw bi parallel to DC ; draw Be perpendicular to bi , cutting it in e ; draw Da parallel to Be ; with the distance Be , from the point C , describe an arc cutting bi at f ; join Cf , which produce to a ; through a and I draw mn ; then if the straight line aC be moved, so that the point a may slide

along the line mn , and the point f along bi , the extremity C will trace the representation of the circle required.

For draw ft parallel to Da , cutting DC in t .
 Then because of the similar triangles Cft and CaD } $Cf : ft :: Ca : aD$
 But because $Cf = Be$ } it will be $Be : Du :: Ii : aD$
 and $Ca = Ii$ }

Again, by the similar triangles } $Be : Du :: BI : ID$
 IBe and IDu } $BI : ID :: Ii : aD$
 Therefore by equality, } $BI^2 : ID^2 :: Ii^2 : aD^2$
 But by duplication, } $BI^2 : BI^2 - ID^2 :: Ii^2 : Ii^2 - aD^2$
 And by division, }

But $BI^2 - ID^2 = (BI + ID) \times (BI - ID) = AD \times DB$, and $aD^2 = aC^2 - DC^2 = Ii^2 - DC^2$; therefore by substitution $BI^2 : AD \times DB :: Ii^2 : DC^2$, which is a known property of the ellipsis; and as the perspective representation of a circle is an ellipsis, being the section of an oblique cone, the curve described is the true representation of the original circle, for the rays which proceed to the eye form the surface of a cone, and being cut by the picture produce an ellipsis.

In this manner an ellipsis (*fig. 8.*) may be described by a continued motion, having any two conjugate diameters bi and AB given, or a diameter and ordinate, without previously finding the two axes.

But as it is not very easy to make an ellipso-graph move freely in every position of two conjugate diameters, from the obliquity of the intersections, it may be done upon the same principle, by finding points in the curve upon the straight edge of a thick piece of paper, marking the points af and C (*fig. 9.*) upon the edge; then suppose a is first placed upon any point in the line mn , carry the other end of the slip until the point marked f fall upon bi , then mark the extremity C upon the plane of description or paper, and the point so marked will be in the representation of the circle required. In the same manner as many points will be found as will be sufficient to complete the curve with sufficient accuracy.

But as the method of describing an ellipsis by continued motion from the two axes is by much the most accurate, we shall here shew the method of finding a conjugate diameter, to a diameter or ordinate given, before we can proceed with the next method.

Lemma.—Let $ABCD$ (*fig. 10.*) be the representation of a square circumscribing the original circle, and let EF be the representation of the diameter perpendicular to the picture, kl the representation of the radius parallel to the picture, and k the representation of the centre. Bisect EF at o ; through o draw mn parallel to AB or DC ; draw Fg perpendicular to mn , cutting mn at g ; from the point l , with the distance Fg , describe an arc cutting mn at h ; draw ki parallel to Fg , and produce lh to i ; make om and on each equal to il ; then mn is the diameter conjugate to FE . This method is evident from the construction given in method 7, *fig. 9.*

Method 8. Fig. 11.

The representation $ABCD$ of a square circumscribing a circle, having its sides parallel and perpendicular to the picture, being given, to find there presentation of the circle by means of the two axes.

Find G the representation of the centre, EF the representation of the diameter perpendicular, and GH the representation of the radius parallel to the picture. Then by the preceding lemma, find the semi-conjugate diameter rv ; draw Eh perpendicular to AB ; make Eh equal to rv ;
 5 B 2 join

PERSPECTIVE.

join $r k$, and bisect it by a perpendicular $n o$, meeting $A B$ at o ; from o as a centre, with the distance $o r$ or $o k$, describe the semi-circle $p k q$, cutting $A B$ at p and q ; join $k p$ and $k q$; from k , with the distance $k E$, describe the arc $m E l$, cutting $k p$ at m , and $k q$ at l ; join $r p$ and $r q$; produce $p r$ to t , and $q r$ to w ; draw $m s$ parallel to $k r$, cutting $p r$ at s , and draw $l u$, parallel also, parallel to $k r$, cutting $r q$ at u ; then $r s$ and $r u$ are the semi-axes, as shewn by the writers on conic sections; make $r w$ equal to $r u$, and $r t$ equal to $r s$, and $u w$ and $s t$ will be the axes by which the curve may be described by means of an instrument at one continued movement, and the curve thus described will be the representation of the circle required.

Method 9. Fig. 12.

Supposing every thing given as in the last method, $P F$ being the representation of a diameter perpendicular to the picture, E that of the centre, $A B$ and $D C$ that of the sides of the square parallel to the picture, and $A D$ and $B C$ the other two sides perpendicular to the picture; draw $F X$ perpendicular to $A B$; make $F X$ equal to $A F$ or $F B$; from X , with the radius $X F$, describe an arc; draw $X N$, $X B$, $X O$, &c. meeting $A B$ at N , B , O , &c.; join $N E$, $B E$, $O E$, $F E$; make angles on the other side of $F X$ equal $F X M$, $M X L$, &c.; produce the legs to meet $A B$; from the points in $A B$ draw lines to E , and produce these lines on the other side of E ; from the points $M L K$ draw $M e$, $L b$, $K a$, &c. meeting $A B$ at c , b , a ; draw the lines $c C'$, $b C'$, $a C'$, &c., cutting the lines drawn to the centre E at f , e , d , G , and g , b , i , on the opposite side of $E G$; then F , f , e , d , G , g , b , i , are points in the curve. In the same manner points may be found in the curve on the other side of $F G$, and thus any number of points may be obtained in the representation at pleasure. This is evident; for since E is the representation of X , the lines $E N$, $E B$, $E O$, $E F$, &c. are the representations of $X N$, $X B$, $X O$, $X F$, &c. Again, $a C'$, $b C'$, $c C'$, &c. are the representations of $a K$, $b L$, $c M$, &c.; therefore the points F , f , e , d , G , &c. the intersections of these lines with the former are in the curve, for each two lines are drawn from the same common point in the circle $K L M F$, which may be looked upon as the original; thus the point M is represented by f , L by e , K by d , the extremity of the diameter parallel to $A B$ by G .

In cases of this kind, where lines radiate from a centre, in approaching the parallel diameter they frequently run out to a distance beyond the bounds of the drawing. The following remedy is very convenient; let $X m$ be a line, which if produced would not meet $A B$ within a convenient distance; from any point S in $A B$, draw $S Q$ parallel to a straight line, supposed to join the points X and E ; make $S Q$ equal to the part of the line intercepted between the line $A B$ and the point X ; make $S R$ equal to the other part, and join $R Q$; now let $X m$ meet $S Q$ in m ; draw $m u$ parallel to $Q R$, cutting $S R$ at n ; make $S o$ equal $S n$, and draw $o E$, which will be the line corresponding or representing $m X$, and thus of any other.

Method 10. Fig. 13.

Let E be the representation of the centre, $D Q$ a diameter parallel, and $F G$ a diameter perpendicular to the picture; bisect $F G$ in m ; through m draw $q p$ parallel to $D Q$; find the extremities q and p by the preceding lemma, fig. 10; join $D m$, and produce it to n ; make $m n$ equal to $m D$; join $Q m$, and produce $Q m$ to o ; make $m o$ equal to $m Q$; draw $F t$ parallel to $A H$, cutting $D n$ at y , and make $y t$ equal to $F y$; draw $F s$ parallel to $B i$, cutting $Q o$ at v ,

and make $v s$ equal $v F$; draw $G u$ parallel to $H A$, cutting $D n$ at x , and make $x u$ equal to $x G$; draw $G r$ parallel to $I B$, cutting $o Q$ at w ; make $w r$ equal to $w G$; then will the points o , u , r , n , t , s , be in the representations of the circle. For since m is the centre of the ellipsis, and D is a point of contact, $D n$ will be a diameter, it will therefore be bisected by the centre m , wherefore the point n is in the curve. Again, because Q is a point of contact, $Q o$ is a diameter, therefore $m o$ is equal to $m Q$, and therefore the point o is in the curve. Again, because D and G are points of contact, and $D n$ is a diameter; and because that $G u$ is parallel to $H A$, a tangent at D , $G u$ is a double ordinate, it is therefore bisected by $D n$ at x , therefore the point u is in the curve. By the same method of reasoning as in the case of u , it will be proved, that the points r , t , and s , are in the curve of an ellipsis, wherefore all the points q , o , u , r , n , t , s , as well as the four points of contact D , F , Q , G , are in the curve of an ellipsis; here are six additional points besides those which the circumscribing square furnishes, from the considerations only, that the centre bisects all the diameters; that if there be two tangents, and the points of contact given, and if a line pass through one of the points of contact and the centre, it will be a diameter; and if another pass from the other point of contact parallel to the tangent, at the extremity of the diameter, it will be a double ordinate; and, lastly, that all the double ordinates are bisected by the diameter.

Method 11. Fig. 14.

Let $V' L'$ be the vanishing line, and $I' N'$ the intersecting line, and let b be the point where the original circle touches the intersecting line; let $D' R'$ be the directing line, D' the point of station, or prime directing point.

Through D' draw $E' D' C'$ perpendicular to $R' D'$, cutting $V' L'$ at C' , the centre of the picture; make $D' E'$ equal to the height of the picture; and make $D' R'$ equal to $D' E'$; draw $b c$ perpendicular to $I' N'$, and make $b c$ equal to the radius of the circle; from c , with the distance $c b$, describe an arc $d b a$; draw $a e$, $c t$, and $d f$, tending to the point D' , to cut $I' N'$ at e , t , and f ; draw $c a$ perpendicular to $a e$, and $c d$ perpendicular to $d f$; draw $f l$, $t n$, and $e m$, parallel to $D' E'$; draw $d k$, $t q$, and $a e$, tending to R , to cut $I' N'$ at k , q , and s ; transfer $f k$ to $f l$ from f to i ; $t q$ to $t u$ from t to u , and $e s$ to $e m$ from e to b , and join $i b$; make $o n$ equal to $o u$; then will o be the centre, $i b$ and $u n$ conjugate diameters of the ellipsis, which will be the representation of the circle.

For since D' is the directing point of the lines $d f$, $c t$, and $a e$, these lines will have parallel representations; join $R' E'$ and $k i$, or suppose them to be joined, then $k i$ will be parallel to $R' E'$, therefore $k i$ will be the representation of the line $d k$, and because $f l$ is the representation of $f d$, their intersection i will represent the point d ; in like manner it may be shewn that the point u represents t , and the point b represents a ; but the lines $d f$ and $a e$ are tangents to the circle at the points d and a ; therefore these representations $f l$ and $e m$ are tangents to the ellipsis at i and b , and therefore $i b$ is a diameter; and because $u n$ is parallel to $f l$ and $e m$, $u n$ is a diameter conjugate to $i b$.

Method 12. Fig. 15.

This process is almost similar to the last, except that the point D' is taken in a line perpendicular to the intersection; this causes the conjugate diameter $i k$ to be parallel to the intersection, and the other, $q n$, to tend to the centre of the picture.

This

PERSPECTIVE.

This method, by means of directors, furnishes conjugate diameters at once, whereas if vanishing points are only used, we have only a diameter and ordinate, or double ordinate, and consequently the other diameter, which would be conjugate to the one given, must be determined by a geometrical process. The use of the directing point is therefore much more convenient, and much more accurate in the representation of curves. The directing line is always at hand when the perspective delineation is raised from a geometrical plan instead of a perspective one.

Method 13. Plate V. Fig. 1.

Let LMJK be a square circumscribing the original circle BCDEFGHI; draw the diagonals JL and MK, cutting the circle at C, E, G, I; through the centre A draw FB parallel to MJ or LK; join GI and EC; produce MJ, GI, FB, EC, and LK, to their intersecting points n, n , &c.; find the vanishing point v^2 of the parallels of FB, and draw the indefinite representations nv, n^2v , &c.; also produce the diagonal MK to meet I'N' at x ; and find the vanishing point v of the diagonal MK; draw the indefinite representation xv^3 of the diagonal, which will cut the indefinite representations drawn to v^2 of the parallels; find the vanishing point v' of the sides JK and ML; draw lines to v' from the intersections in xv^3 , and produce these lines to cut the respective indefinite representations drawn to v^2 in the points which represent those of the circle; then a curve being drawn through the corresponding points b, c, d, e, f, g, h, i , will form the representation of the circle.

This evidently appears from the property of the circle, and the method of finding the perspective representation of a point in the original plane.

Method 14. Fig. 2.

Let A be the centre of the original circle, and let B, C, D, E, F, G, H, be points in the circumference; let E' be the place of the eye in respect of the vanishing line V'L'; draw E'C' perpendicular to V'L', cutting it in C'; make E'D' equal to the height of the picture; draw the two lines D'H and D'B tangents to the circle; draw AH perpendicular to D'H, and AB perpendicular to D'B; let the lines HD' and BD' cut IN in t, t ; from the points C, D, E, F, G, draw the lines Ct, Dt, Et, &c. tending to D', cutting the intersecting line in the points t, t , &c.; from all the points t, t, t , &c. draw lines parallel to the director D'E'; from the same points B, C, D, E, F, G, H, draw the parallels Bp, Cp, Dp, &c. cutting IN in p, p, p , &c.; find the vanishing point v of the lines Bp, Cp, Dp, &c. and join the intersecting points p, p , &c. to v , cutting tb, tc, td , &c. at b, c, d, e, f, g, h , which will be the corresponding points to B, C, D, E, F, G, H, of the original circle; draw bb , which will be a diameter. The points of the other half will therefore be found by continuing the parallel from t, t, t , &c. on the upper sides of the diameter bb , and repeating the ordinates upwards to the points i, k, l, m, n , then a curve being drawn through all the points will give the representation required, as is evident from the directing and vanishing points.

PROB. XXII. Fig. 3.

To draw the representation of a rectangle inclined to the picture, and having two of the edges perpendicular to the original plane, and consequently the other two parallel thereto, the original plane being perpendicular to the picture; the feat AB of the rectangle being given.

Produce AB to its intersecting point n ; find the vanish-

ing point v of AB, and thence the representation ab of AB; draw no perpendicular to I'N'; make ne equal to the height of the rectangle, and join ev ; now suppose the lower side to rest on the original plane, and ab will be the representation of the lower side of the rectangle; draw ad and bc parallel to ne , cutting ev at c and d , and $abcd$ is the representation of the rectangle required.

For ne is the intersection of the plane of the rectangle with the picture; and because the rectangle is perpendicular to the original plane, and the original plane perpendicular to the picture, the vertical sides of the rectangle will be parallel to the intersection ne , and consequently the representations bc and ad will be also parallel to ne ; therefore $abcd$ is the representation of the rectangle.

PROB. XXIII. Fig. 4.

To find the representation of a circle in a plane perpendicular to the original plane, the plane of the circle being inclined to the picture and the original plane perpendicular thereto; the feat AB of the plane of the circle being given on the original plane.

Find the representation $abcd$ of the circumscribing square by the preceding problem, making the sides of the square parallel and perpendicular to the original plane; then find the representation of the circle by any of the preceding methods, or bisect the intersection nf at l ; draw le perpendicular to fn ; make le equal to lf or ln ; join en and ef ; from e , with the radius el , describe the arc glh ; join ef and en , cutting the arc at g and h ; draw gk and hi parallel to el , cutting fn at k and i ; then v being the vanishing point of AB, join kv, lv, iv ; draw the diagonals ca and bd , cutting the former lines at u, w, q , and s . Then through all the points u, v, w, x, q, r, s , and t , draw a curve, which will be the representation of the circle required.

This is plain by inspecting the square circumscribing the representation of the original circle in the present figure, where the correspondence of the quarter of the square, as also that of the circle with the rectangled triangle nef , and the quadrant hg of the arc of a circle, are shewn.

The principle here used is the same as that employed in problem 21, method 2, figure 12, for finding the representation of a circle.

PROB. XXIV.

To find the representation of any rectangular prism, given its situation on the original plane.

Find the representation of the nearest angle of the base; from the point thus found draw a perpendicular; find the height of that perpendicular so as to represent the corresponding line formed by the two vertical planes of the object; from the bottom draw a line to each vanishing point; also from the top of the perpendicular draw a line again to each vanishing point; find the representations of the two remote angles of the base; from each of the points thus found draw a line parallel to the line representing the nearest vertical edge of the solid, cutting the upper line drawn to the vanishing point, and this construction will finish the representation of the prism, provided that both the base and the top are in planes on different sides of the vanishing line. If the base and top are both below the vanishing line, proceed as before, and complete the representation of the two adjoining vertical planes which form the nearest angle; then from the upper extremity of each perpendicular which forms the remote vertical areas of the object, draw a line to the vanishing point of the opposite side, which

which will complete the representation of the parallelogram, by which the top of the prism is formed.

Or in short thus; find the representation of each vertical plane which forms the front angle of the object according to problem 24, figure 3, and these planes will form the representation of the rectangular prism, provided that the planes of the base and top are on different sides of the vanishing plane; but if on the same side of the vanishing plane as the two lines nearest the vanishing line, and which run to the vanishing point, represent the nearest angle of the side next the vanishing plane, whether above or below the eye; draw a line from the remote extremity of each line to the vanishing point of the other adjoining line, which also represents the opposite side, and the quadrilateral formed by each pair of lines drawn to each vanishing point will form the representation of the plane parallel with and next to the vanishing plane.

In representing any solid situated in the original plane, it will only be necessary to produce one line of the base of the solid; by which means the height of the plane which represents the side insitting on the line produced will be ascertained by setting the height of the object on a line perpendicular to the intersecting line from the intersecting point of the side of the base, and drawing a line to the vanishing point of that line from the upper extremity, thence determining the representation of the plane insitting on the side produced; then drawing a line from each end of the line representing the arras of the two adjoining planes, will give the height of the figure representing the other adjoining plane.

In *fig. 5.* *ab c g f e* is the representation of a right prism standing upon the rectangle *A B C D*; the side *A B* is produced to *b*, and the height is set on the perpendicular from *b* to *i*; the lines *b v'* and *i v'* being drawn, give the height of the trapezoid *ab f e*, which is the representation of the side standing upon *A B*; a line being drawn from *b* and another from *f* to *v'*, gives the height of the trapezoid *b c g f*, which represents the adjoining side standing upon *B C*; and the two trapezoids *f b a e*, and *f b e g*, form the whole representation *ab c g f e* of the prism, which has *A B C D* for its base; the lines *A a*, *B b*, *C c*, drawn from the two remote angles to the point of sight *E'*, give the points *a*, *b*, *c*, upon the indefinite representations *b v'* and *b v''*; *b a* is first determined, which is the representation of the line produced; then draw the indefinite representation *b v''*, the point *e* is determined; drawing the perpendiculars *a e* and *b f*, the points *e* and *f* are determined; drawing the indefinite representation *f v''*, and drawing *c g* parallel to *b f* or *a e*, *f g* is also determined, which finishes the representation of the solid.

The prismatic solid *T* above, of the same description, is delineated by setting the height of the lowest side parallel to the vanishing plane upon *h l* from *b* to *k*, and the height of the solid itself from *k* to *l*; drawing the lines *k v'* and *l v'*; then the lines *a e* and *b f*, continued upwards to cut these lines, give the representation of the face of the solid in the same plane with *A B*; drawing lines from the point where *b f* cuts the lines *k v'* and *l v'* to *v'*, determines the adjoining face.

Any side of a solid may be produced in order to get the height, as appears by the representation *O*, which is that of a solid, the base of which is *N*; one of the remote sides being produced instead of one of the hither sides to the intersection. It is only finding the height of the line representing the corresponding arras, then completing the front parallelogram of which that arras is a side, and the other adjoining a front side, as above.

R and *S* represent right parallelepipeds with two faces parallel to the picture, and consequently the vanishing point of the horizontal lines is the centre of the picture; the side of the first comes in contact with the picture, and has therefore its representation equal and similar to the original; the principle is the same as those already described.

PROB. XXV.

To represent a pyramid, with its axis perpendicular to the original plane.

Find the representation of the base, or the front part of it, then the representation of the axis; join the apex to each point, representing the two remote angular points of the object; and that representing the nearest angle, and the two triangles thus formed, will constitute the representation of the pyramid.

In *fig. 6.* *h i k r* is the representation of a pyramid standing on *H I K L*. The height of the axis is found by drawing *M I* parallel to one side; setting the height of the pyramid on the perpendicular *I p*; drawing *p v'* and *I v''*; drawing a line from the centre, *M*, of the base to *E'*, cutting *I v'* at *s*, gives the base of the perpendicular, which being drawn to meet the indefinite representation *p v'*, gives the vertex.

The inverted pyramid is represented in the same manner. Let *A B C D* be the plan or seat of the base; then by drawing a line parallel to *A B* or *D C* from the centre of the base, to meet the intersecting line in *e*, and setting the height of the vertex from the original plane from *e* to *f*; drawing *f v'*; producing *A B* to *d*, and representing the sides *A B* and *B C*, as if the base were in the original plane; setting the height of the base, which is the uppermost side, on the perpendicular *d g*; drawing *g v'*, and the perpendiculars *a a'*, *b b'*, cutting *g v* at *a'* and *b'*; drawing *b v''* and *c c'* parallel to *b b'*, gives the two sides *b' a'* and *b' c'*, which represent the two nearest sides of the base. The representation of the seat of the centre of the base will be found by joining *e v'*, and by intersecting this line by another line from the centre of the seat of the base to the point of sight *E*; drawing a perpendicular from the intersection meeting *f v'*, gives the representation, *g*, of the meeting of the sides.

The following practical examples are derived from the preceding problems, founded on the theory of the directing plane, which theory, where a plan of the object is given, furnishes the most expeditious rules for practice, and the most easily to be comprehended. The prime director and station point are employed. The eye is only used for drawing the parallels of lines in the original object. The lines on the plan representing original vertical planes are produced to their intersecting points, and perpendiculars are raised from each such point on the intersecting line, and the height of each respective plane of the original object set thereon; these perpendiculars will be the intersections of the vertical planes of the object, and the two extremities of each perpendicular will be the intersections of lines parallel to the original plane in each vertical plane. Lines being drawn from the intersecting points of the intersecting lines of the vertical planes, to their vanishing points, gives the indefinite representation of the lines which have the said vanishing point. The prime directing point, *D'*, is used in cutting off portions from the indefinite representations, to represent original distances, which are the seats of lines parallel to the original plane given in the plan. This mode of cutting off finite portions to represent original lines is very expeditious; for by using the prime directing point, the indefinite representations of all the lines drawn on the original from all points of the plan, are perpendicular to the intersecting and vanishing lines, by the theory of the directing plane;

PERSPECTIVE.

plane; and as the vertical lines of the object are represented by vertical lines in the picture, the indefinite representations of the lines drawn to the prime directing point, forms one straight line with the representation of the perpendicular, which represents the vertical arrafes of the object. Another convenience of this method of employing the prime director and prime directing point is, that the plan of the object may be drawn on one piece of paper, the vanishing points of the sides, and the intersecting points of the lines which radiate to the station point found, and the whole may be transferred to another piece of paper, for the purpose of forming the delineation of the object. It must also be observed, that the basis of all the vertical planes which form the plan must be produced to their intersections; then proceed with the remaining part as directed above.

Curves are found by drawing two lines from each original point, and finding their indefinite representations, one by means of a vanishing point, and the other by the director and directing point, only using one directing point and vanishing point for the whole of the points so found.

Example 1. Plate VI.

Fig. 1. N^o 1. shews the representation of a house with wings by the preceding method; N^o 2 is the plan; N^o 3 the principal elevation. CD is the intersecting line of the vertical plane, insinuating upon the line AB on the plan; GH is the intersecting line of the plane of the receding part of the front, insinuating upon EF of the plan; LM is the intersection of a vertical plane, passing along the ridge of the roof, insinuating upon AI in the plan; CD is the height of the summit of the pediments, GH the height of the receding part of the elevation, and LM is the height of the ridge of the roof from the original plane or base; Mv' is the indefinite representation of the line which forms the ridge of the roof; Hv' is the indefinite representation of the top of the wall of the receding face; Dv' the indefinite representation of a line joining the tops of the pediments; and Qv' the indefinite representation of a line through the lower points of the pediment. The points n, n, which represent the summit, and r, s, t, u, which represent the bottom of the pediment, o and p, which give the representation, op, of the top of the receding plane of the front, and the points r and q, which give the representation, rq, of the ridge of the roof, represented by IA on the plan, are all found from the prime director D'E', and the prime directing point D'. The bottom part is found by drawing lines from the intersecting points, L, G, C, of the base lines of the vertical planes, which give the indefinite representations of the lines forming the base of the original object to the vanishing point: these indefinite representations to the vanishing point are cut by the parallels of the director, which limits the portions representing the lines that inclose the base of the object. The roof is formed by joining pr, oq, wq.

In the plan there are four systems of parallel lines, one parallel to each front, making two; the other two are the lines representing the hip lines of the roof. In finding the intersections of the vertical planes, only the series of parallels to AB are produced.

Example 2.

Fig. 2. N^o 1. is the representation of a house, with a bow in the middle of the front. Every thing with regard to the straight lines is found as in the preceding example; only one thing must be observed, that in the representation of the bow, or any of its intermediate horizontal sections, the intersection of each plane is found, and the intersecting points found on the intersecting line of the base plane transferred

to each intersecting line. Thus IN is the intersecting line of the base plane; and therefore the intersecting line for the representation *cddefg*, of the arc CDEFG of the circle, which represents the plan of the bow; *m, n, o, p*, are the intersecting points of a series of lines, drawn parallel to IB, the plan of the front plane; *m'n'o'p'* is the intersecting line of a plane of a section of the bow, parallel to the base of the object; *m''n''o''p''* the intersecting line of the plane of the top of the bow; *m'''n'''o'''p'''* is the intersecting line of a plane parallel to the base of the object above the level of the top of the bow, in order to shew more clearly how a section of the cylindric bow may be represented at different heights. The points are thus transferred to each of these intersections: through the intersecting point *m* of IB, in the intersecting line IN, draw the perpendicular *mm'm'm'''*; make *mm'* equal to the height of the section of the bow, *mm''* equal to the height of the top of the wall; draw the lines *m'n'o'p'*, and *m''n''o''p''*, parallel to the intersection IN, then transfer the distances of *mn, no, op*, upon *m'n', n'o', o'p'*, and *m''n'', n''o'', o''p''*; then from the points *m', n', o', p', m'', n'', o'', p''*, in each intersecting line, draw lines to the vanishing point *v'*, then the indefinite representations found by the director and directing point, will give the points in the curve, which being joined gives the representation of each curve of the bow.

N^o 3. shews the elevation of the front of the house, which therefore gives the length of the house and breadth of the bow; N^o 4. shews the elevation of the flank or end, which therefore gives the breadth of the house and the projection of the bow. Each of these elevations gives also the height of the object. By this means any arc of a circle may be represented: this is only the application of problem 21, method 14, which shews the representation of a whole circle.

Example 3. Plate VII.

Fig. 1. N^o 1. is the representation of a flight of steps with two kirbs, which are about a step higher than the top of the landing, and terminate in a plane parallel to the horizon; N^o 2 is the plan.

Find the intersection, CD, of the vertical plane passing through AB on the plan; set the height of the steps from C to D; from the extremities and several divisions of CD, draw lines to the vanishing point *v'*, which will give the indefinite representations of the horizontal lines, forming the top of each step in a section of the plane of the inside of the kirb. The vertical lines, forming the face of the risers, are represented by the intercepted part of the parallels of the director D'E'. The vanishing point of the arrafes, and internal quoins of the steps, is supposed to be out of the picture upon the vanishing line (*fig. 2.*) at *v'*: lines are then drawn through all the points, representing the section made by the inside of the kirb to the vanishing point *v'*, which gives the planes of the risers and treads. The height of the kirb might have been obtained upon CD, but is found by setting it on FG, which is the intersection of the plane of the face of the kirb, through BE upon the plan. The remaining parts of the representation to be finished is sufficiently plain by the bare inspection of the figure, and from what has been said in the preceding problems and examples.

Another very excellent method of finding the ends of the steps upon the inside of the kirb, is by finding the vanishing point of their inclination, when the vanishing point is accessible; make *v' 1*, on the vanishing line, equal to the distance, *v' E*, of the vanishing point, *v'*, from the eye *E'*: draw *v' 1* perpendicular to the vanishing line VL; make the angle *v' 1 v'* equal to PQR, N^o 3; then having obtained the point *b*, the representation of B on the plan, which

PERSPECTIVE.

which is the lower edge of the riser in the plane of the kirb, draw $b v^1$, which will be the indefinite representation of a line, touching the lines of concurrence of the internal angles in the plane of the inside of the kirb; then indefinite representations being drawn to v^1 , from all the points in $C D$, will cut the line $b v^1$; draw a perpendicular from each intersection between every two lines, from $C D$ to the vanishing point v^1 , and these perpendiculars will represent the riser on the inside of the kirb.

Example 4.

Fig. 2. $N^{\circ} 1$. represents a flight of returning steps, as shewn by the plan $N^{\circ} 2$. The diagonal plane passing through the nearest angle of the steps, is produced in order to obtain the intersection $A B$ for a line of heights. The representation of the section passing through the diagonal being found, draw lines from every point found in the said representation to each vanishing point of the sides, and the lines thus drawn are the indefinite representations of the arrases and internal quoins; the rest is completed as in the preceding examples.

Example 5.

Fig. 3. is the representation of a flight of steps, without a plan, with the top of the kirb parallel to a plane touching the nosings. Given the intersection of the plane of the riser at A ; supposing the vanishing points v^1, v^2 , to be found from the known inclination of the sides to the picture, and the vanishing point v^3 , as in the third example.

Make $A G$ equal to the distance of the intersecting point A from the nearest angle, $G H$ equal to the thickness of the kirb, $H I$ equal to the length of the steps, and $I C$ equal to the thickness of the farther kirb. Then the point 2 being the distance of the vanishing point v^2 from the eye, draw lines from the points G, H, I, C , tending to 2 , meeting $A v^2$ in k, l, m, n ; draw $k o, l p, m q$, and $n r$, perpendicular to $I' N'$. Set the height of the front part of the kirb upon the perpendicular $A B$; draw $B v^1$, cutting the perpendiculars in o, p, q, r ; draw $A v^1$; make $A E$ equal to the horizontal distance of the inclined part on the top, from the nearest point of concurrence of the lower edge of the riser, and the lower edge of the outside of the kirb; then the point 1 being the distance of the vanishing point v^1 from the eye, draw $E s$ tending to 1 , meeting $A v^1$ at s ; draw $k v^1$ and $s v^2$, meeting $k v^1$ at t ; make $E F$ equal to the whole height of the kirb; draw $s u$ parallel to $E F$, or perpendicular to $I' N'$; draw $F u$ tending to the point 1 ; draw $u v^1$; draw $t v$ perpendicular to $I' N'$, meeting $u v^1$ in v ; draw $v v^1$; make $A K$ equal to the horizontal breadth of the kirb; draw $K w$ tending to 1 , cutting $A v^1$ at w ; draw $w x$, tending to v^2 , cutting $k v^1$ at x ; draw $x y$ perpendicular to $I N$, cutting $v v^1$ at y ; and $k o v y x k$ will form the hither end of the nearest kirb. The section of the hither side of the remote kirb is completed as in the third example; having the tops $o p, q r$, of the vertical faces of the front of the kirb, the inclined surfaces may be formed by the vanishing point v^1 ; and terminated by drawing the perpendicular $v t$ to meet $o v$, tending to v^1 at v , then drawing $v v^1$. The horizontal parts at the top are found by drawing lines to v^1 , and another line to v^2 .

Example 6.

Fig. 4. $N^{\circ} 1$. shews the representation of a stair with circular steps. The principle of the method is in finding the representations of several vertical sections, all passing through the axis of a cone surfaçed, which would touch the nosings of the steps, then drawing a curve through all the corre-

sponding points of each respective nosing, will form the representation of the whole series. The sections may very easily be obtained without the use of the vanishing points, by representing the heights of each step upon the cone, and setting the heights upon each intersecting line of the plane of each section, then joining the lines from all the points in each intersecting line of heights to the respective point in the axis; then the line $D C$, on the section $N^{\circ} 2$, being drawn to touch the nosings; then $A E$ and $A B$ being produced to meet $D C$ in D and C ; with the radius $A C$, $N^{\circ} 2$, describe an arc of a circle $A B C D E$, $N^{\circ} 1$, so as to meet the two last planes which terminate the sides; find the representations a, b, c, d, e , then the axis $f f'$ of the cone being found, draw the lines $a f', b f', c f', d f', e f'$; these lines will represent the sides of the cone in each section, and consequently will represent the lines touching the nosings; then the points where these lines are cut by the lines drawn from the several points in each line of heights, to the corresponding points in the axis, gives the points in the nosings of each section; the points of concurrence for the internal angles will be found, by drawing a perpendicular from each point of representation of the nosings, to the next line, which represents a line in the plane of the vertical section, and in the plane of the tread; the distance between the foot of the perpendicular and the next lower point representing the nosings, represents the breadth of the step in the section. This, if the plane of the section $F A$ be produced so as to meet the picture in $G H$; set the heights of the steps on $G H$, draw lines from the points G and H , and also from the intermediate divisions to the corresponding points in $f f'$, gives the points a, i, k, l , in the line $a f$, representing the slant side of the cone in that section; then drawing the perpendiculars, $i m, k n, l o$, represent the sections of the risers, and $i n, k o$, represent the heads. The points a, b, c, d, e , of the curve representing the corresponding points A, B, C, D, E , of the intersection of lines in the curved surface of the cone with the horizontal plane, will be found by the directing point D .

Fig. 6. shews the method of representing several lines, drawn to a common point of concurrence, without finding the vanishing points of these lines. The method is as follows: find c the representation of the point of concurrence C ; continue all the lines which terminate in C to the intersecting line $A B$; join all the points in $A B$ to the point c , and these radiations will be the indefinite representations of the other original lines which radiate from C ; but if any of these lines should prove to be inaccessible, draw $F H$ parallel to $C c$, cutting $A B$ in F ; let $C c$ cut $A B$ in D ; make $F L$ equal to $D C$, $F E$ equal to $D c$; join $L E$; let the inaccessible lines meet $A F$ in G and H ; draw $G I$ and $H K$ parallel to $L E$, to meet $A B$ in I and K ; make $F g$ and $F h$ equal to $F I$ and $F K$; draw $h c$ and $g c$, then $h c$ and $g c$ will represent $H C$ and $G C$.

Example 7. Plate VIII.

Fig. 1. $N^{\circ} 1$. shews the elevation of a cornice, $N^{\circ} 2$. the plan, which is a square. To find the representation of the said cornice, with the one series of its vertical plates parallel, and the other perpendicular, to the picture.

Let $Y F$ be the intersecting line of the top plane, parallel to the sides $A B$ and $D C$ of the plan, $V' L'$ the vanishing line, $S Q$ the distance, and C' the centre of the picture; therefore S will be the prime director, or station point. The vertical plane of each diagonal is produced to meet the intersection at $H a$ and F ; then drawing the intersecting lines $H I$ and $F G$ of these planes, set the height of the members downwards upon each vertical intersection; then the indefinite

indefinite representations of lines in each diagonal plane parallel to the original plane, being found, draw lines to the station point S, each to cut its respective line, will give the representation of the points in each mitre, and, joining the corresponding points, will give the representations of the lines of concurrence, or those which form the arrases and internal quoins. The representation of the points in one of the mitres on the front part being found, the other will easily be determined, by drawing parallels to the intersecting line from the points ascertained, and crossing these parallels by lines drawn to the directing point from the respective points of the mitre, to be ascertained on the plan N 2; draw indefinite representations from the points representing the middle mitre towards the centre of the picture; also draw lines from F G, the intersection of the diagonal plane, through the mitres which terminate the apparent magnitude, to the vanishing point on the vanishing line of the original plane, cutting the former lines drawn to C', and the intersections will give the points to represent the third mitre, which forms the other extreme boundary of the cornice.

The indefinite representations of the heights of the mouldings in the plane of each diagonal, are necessary in order to draw the curves correctly. The vanishing point of the lines in the plane of the diagonal, through the extreme mitre of the cornice being out of reach, the line R T perpendicular to the vanishing line is taken at half the distance of the intersecting point F, from a line drawn perpendicular from the vanishing point of the lines in the plane of this diagonal. Bisection T R at K; set half the heights of the members downwards from K to L; then join the corresponding points in K L to those of F G, will give the lines representing the heights of the mouldings in the diagonal plane.

Example 8.

Fig. 2. shews the representation of a cornice inclined to the picture. The method of finding the representation of the mitres is the same as in the last example: the vanishing point of the representations of the lines of concurrence of the mouldings which appear in one of the faces is supposed to be out of reach, therefore one-third of the distance of the point M from the vanishing point is taken, and set from M to *m*; then drawing *m n* perpendicular to the vanishing line, so as to be intercepted at *n* by the said line, make *m W* one-third of *m n*. Produce the line A B, and the other lines which are parallel thereto, to their intersecting points M, I, F, D, and describe the section of the cornice M I F D E G H K L N. The line W O, parallel to the vanishing line, being supposed to correspond to M D, draw a figure W T Q O P R S U V X, so that all its dimensions may be one-third of those of the section M I F D E G H K L N, then lines being drawn from the corresponding points of each similar figure, will give the indefinite representation of the lines of concurrence of the several mouldings. The remaining parts are completed by the directing point and the other vanishing point.

This method of describing a section of the cornice with the picture is much preferable in point of accuracy to that of finding the representation of the mitre of the angle of the object, which presents itself to the eye: because when the eye is in the plane of the diagonal, the points which form the divisions of the mouldings in the mitre cannot be ascertained; or if the eye is nearly in the plane of the diagonal, the intersections will be so very oblique, as to render the perspective heights very uncertain, though the lengths of the lines representing the arrases and internal quoins may be obtained with sufficient accuracy.

Given the centre C', and the distance of the picture, the seat F, and distance of the centre of a sphere from the picture, and the radius of the sphere, to find the representation of the sphere.

Method 1. Fig. 3.

Join F C'; draw C' E' and F D perpendicular to F C', and upon contrary sides of the same; make C' E' equal to the distance of the picture, and F D equal to the distance of the centre of the sphere from its seat. On D, with the radius of the sphere, describe the circle A B G C; draw A E' and C E', tangents to the circle at A and C, cutting F C' at *o* and *k*; also draw D E', cutting *ok* in *d*; bisect *ok* in *s*; and through *s* draw *m l* perpendicular to D E', cutting C E' and A E' at *m* and *l*, and D E' at *t*; from *t*, with the distance *t m* or *t l*, describe the semicircle *m n l*; draw *s n* perpendicular to *m l*, cutting the semicircle in *n*; through *s* draw *p q* perpendicular to *ok*; make *s p* and *s q* each equal to *s n*, then *ok* is the greater, and *p q* the smaller axis of an ellipsis, which will give the representation of the sphere.

For if C' E' and F D be turned perpendicular to the plane of the picture, but on contrary sides thereof, and the circle A B C' in the same plane with F D and F C', the point E', the line *ok*, the tangents C E' and A E', and the circle A B C, will be all in one plane perpendicular to the picture: then considering A B C as a section of the sphere, E' the eye, C E' and A E' will be visual rays cutting the picture in *o* and *k*; therefore the points *o* and *k* are the representations of A and C'. Again, considering all the tangent rays around the sphere to the eye at E' as forming a cone, and the picture a cutting plane, and because the plane C E A is perpendicular to the picture, the line *ok* will be the seat of the axis of the cone, and therefore *ok* will be the transverse axis of the ellipsis. Turning the plane of the semicircle *m n l* perpendicular to D E', *m n l* will be a section of the cone parallel to its base, and *s n* will be at right angles to *ok*, and *s n* will coincide with *s p*; and since it has been demonstrated that the section of a cone cut by a plane is an ellipsis, and the perspective representation is the section of a cone of rays made by the plane of the picture, *ok* and *p q* are the axes of an ellipsis, which will represent the sphere according to the conditions given.

Method 2. Fig. 4.

Join F C'; make F D equal to the distance of the centre of the sphere from its seat, and C G on the vanishing line equal to the distance of the eye; join D G, cutting C F at *d*; draw *d g* parallel to I N; make F X on the intersecting line equal to the radius of the sphere, and join X C', cutting *d g* in *g*; then *d* is the centre, and *d g* the radius of a sphere, from which a cone of rays will proceed to the eye under the same superficies, or under the same angle as one of a radius D A or D G, *fig. 3.* placed at the distance F D, from its seat F, beyond the picture. Therefore, with the radius *d g* describe the circumference *c n a* of a circle; draw E' a and E' c tangents to the circle at *a* and *c*; produce E' a to meet F C' at *o*, and let E' c cut F C' in *k*, then *ok* is the transverse axis; bisect *ok* in *s*, draw *l m* perpendicular to D E', cutting E' a and E' c at *l* and *m*, then proceed with the remaining part of the construction, as in *fig. 3.*

PROB. XXVII. *Fig. 5.*

To make a right-angled object appear under a given angle.

PERSPECTIVE.

drawn parallel to the side, $E v'$, of the triangle $C'E v'$, the other two sides, $C'E'$ and $C'v'$, will be cut proportionally; therefore $C'H$ will be a third part of $C'v'$.

Now in the similar triangles $AD F$ and $A C'H$,
 Also in the similar triangles $AD G$ and $A C'v'$,
 Therefore by equality of ratios,

$$\left. \begin{array}{l} AD : AC' :: DF : C'H \\ AD : AC' :: DG : C'v' \end{array} \right\} DF : C'H :: DG : C'v'$$

Therefore AG produced will meet the vanishing line VL , at the point v .

PROB. XXXI. *Fig. 2.*

Given two straight lines, AB and CD , inclining to each other: to draw any number of lines through each of the given points $E, F, G, \&c.$ to tend to the same point with AB and CD .

This problem has two cases.

Case 1, fig. 2.—When all the points are in the same straight line.

Produce the straight line EFG to cut AB in B , and CD in D ; draw AC parallel to BD , cutting AB in A , and CD in C ; draw Al , making any angle with AC , and make Ab, Ai, Ak, Al , respectively equal to BE, BF, BG, BD ; divide AC in the same proportion as Al , that is, join lC , and draw ko, in, bm , parallel to lC , cutting AC at o, n, m ; draw oG, nF, mE ; then Em, Fn, Go , would meet the point of concurrence of BA and DC , as is evident from the construction.

Case 2, fig. 3.—When the points E, F, G , are not in the same straight line.

Through each of the points E, F, G , draw the straight lines PQ, RS, BD , cutting the lines AB and CD in P, Q, R, S, D, B ; draw Ab at any angle with AC , and make Ab equal to the greatest, BD of the parallel lines, and join bC ; from Ab cut off An equal to BG ; draw ng parallel to bC , cutting AC at g ; join gG . Again, from the point A , with the radius SR , describe an arc, cutting bC at i ; join iA ; from Ai cut off Am equal to SF ; draw mF parallel to bC , cutting AC in f , and join fF ; find eE in like manner; then AB, gG, fF, eE , will have the same point of concurrence, if produced.

Method 2. Case 1. Fig. 4.

Draw bm parallel to BD , and produce BA to b ; make bm equal to BD , and on bm set bl, bk, bi , respectively equal to BG, BF, BE ; join mC , and produce it to meet AB in S ; then join lS, kS, iS , cutting CA in g, f, e ; lastly, join eE, fF, gG ; then Ee, Ff, Gg , will have the same point of concurrence with BA and DC .

Case 2. Fig. 5.

Draw Tb parallel to BD , and produce BA to T ; make Tb equal to BD ; join bC , and produce bC to meet BA in S ; draw ml, nk, oi , to meet Cb in l, k, i ; through the points l, k, i , draw $lt, ku, i\sigma$, cutting AT at t, u, v ; make vr equal to YG , uq equal to XF , and tp equal to WE ; draw pS, qS, rS , cutting CA at e, f, g ; join gG, fF, eE , then will Ee, Ff, Gg , have the same point of concurrence with BA and DC .

Method 3, for both cases. Fig. 6.

When two lines, DE and DF , meeting in D , have each an inaccessible point of concurrence with a third line, VL , draw DC , making any angle with VL , cutting VL in C . In DE take any point E , and draw EA parallel to DC , cutting VL in A ; also in DF take any point F , and draw

FB parallel to DC , cutting VL in B ; divide each of the lines DC, EA , and FB , into an equal number of equal parts; then if DE and DF represent any two lines in a vertical plane, any point being given in perspective in the same plane, a line being drawn through the given point, so as to divide the corresponding part of each adjacent scale in the same proportion, will tend to the vanishing point on the one side: thus, if through the point p , laying a straight edge upon p , we find that it does not cut the corresponding points of section in the lines DC and FB , by moving it till it divide each corresponding part, on which it falls in the same proportion at g and h , then gh will tend to the vanishing point of DF . In like manner, gi may be drawn to the corresponding point at i in EA , and by this means a number of lines may be drawn in the same way to represent lines in the same vertical planes, and each two which meet in CD to represent lines in a plane parallel to the original plane.

The credit of this practical invention, as well as the following one, is due to Edward Noble.

PROB. XXXII. *Fig. 7.*

Given the vanishing line VL with its centre, and supposing the distance of the eye to be known in extension only, admitting there is a want of room to extend it to its position, to determine the vanishing points of two or more lines inclined at given angles with the intersection.

Let VL be the vanishing line, F its centre; draw FE perpendicular to VL ; make FE equal to $\frac{1}{2}, \frac{2}{3}, \frac{3}{4}$, of the distance of the picture, as the space may admit; through E draw GH parallel to EL ; draw two lines, EA and ED , meeting VL in A and D , making an equal angle with GH to those of the original lines and the intersection; on the vanishing line make Fv' the same multiple of FA that the whole distance FE' of the eye is of FE ; in like manner, make Fv'' the same multiple of FD that FE' is of FE ; and v' and v'' will be the vanishing points. In the present instance, FE is one-third of the true distance of the eye. Figure 8 is found upon similar principles to figure 7 and shews the situation of the vanishing points, by taking one-fourth of the distance of the eye; in this the angle AED is acute, the other AED , in figure 7, being a right angle. The truth of this is very easily shewn; for produce FE to E' , and join $E'v'$; then, because the sides Fv' and FE' of the triangle $v'FE'$ is divided in the same ratio at A and E , the straight line EA is parallel to $E'v'$, but the straight line EA is parallel to the original; therefore $E'v'$ is also parallel to the original; consequently, v' is found in the same place as if the parallel of the original had been drawn through the eye at E , and is therefore the vanishing point of the original line parallel to EA ; v'' may also be proved in a similar manner to be the vanishing point of original lines parallel to ED .

PROB. XXXIII. *Fig. 9.*

To find the representation of a line parallel to the original plane, in a plane perpendicular to the said plane, given the seat of the line, and its distance from its seat, without having recourse to the vanishing point, which is here supposed to be inaccessible.

Let the seat of the line be AB ; at any convenient distance draw dE' perpendicular to IN , cutting IN at E ; draw the line $E'v'$ through the eye at E'' , to meet the vanishing line in v' ; draw Ad and Bc parallel to the intersection, cutting dE' at d and c ; draw db and cg parallel to $E'v'$, cutting the intersection in g and b ;

PERSPECTIVE.

draw gq and bm perpendicular to IN ; make gn and bi equal to the height of the original line; draw lines from n and i , tending to the point v , cutting EE' at 1 and 2; draw Ae and Bf parallel to $E'v'$, cutting the intersection in e and f ; draw the lines fr and eg , tending to the vanishing point v' ; draw GH and rv perpendicular to IN ; draw $1s$ and $2w$ parallel to VL , cutting rv at s , and GH at w ; join sw , which will tend to its proper vanishing point, as required. In the same manner, the representations rG , tx , uy , vH , &c. of any series of parallel lines to the original plane in a vertical plane insisting upon AB , may be found.

PROB. XXXIV. Fig. 10.

To find the representation of a line parallel to the original plane, and in a vertical plane, the vanishing points being inaccessible as before, given the seats of the extremities of the ichnography of the line, the distance of each extremity from its seat, and the centre and distance of the picture.

Let A and G be the seats of the extremities of the ichnography. We shall here suppose the distance of the picture to exceed the limit of the vanishing line: in such cases, take one-half, one-third, or one-fourth, &c. of the distance of the picture, and take the like part of the distance of each extremity of the ichnography. In this case, let C' be the centre of the picture, and $C'D$ one-fourth of the true distance; make AI and GK one-fourth of the distance of the respective extremity of the ichnography of the line from the seats A and G ; draw AC' and CG ; draw ID , cutting AC at E ; and KD , cutting $C'G$ at G' ; join EG' , which is the representation of the ichnography of the line; draw AB and EF , $G'H$ and GD , perpendicular to IN ; make AB and GD each equal to the height of the original line; join BC' , cutting EF at F ; and DC' , cutting GH at H ; draw HF , which will be the representation of the line required. In this manner, a series of lines in a vertical plane may be found, by applying the height upon AB and GD , and joining their upper extremities to the centre C' ; then joining the corresponding points of section will give the series of lines required.

PROB. XXXV.

To find the representation of a right prismatic object, so that the original may appear under a given angle, and the extremes equally distant from the centre of the picture, given in position the right section of the object, and the vanishing line of the original plane, in which it is situated in the vanishing plane.

Let $ABCD$ (*fig. 11.*) $N^{\circ} 2$, be a section of the object; draw AB , $N^{\circ} 1$, parallel to the vanishing line $N^{\circ} 2$; bisect AB in D ; draw CD perpendicular to AB ; make the angles BAC and ABC , $N^{\circ} 1$, each equal to half the supplement of the given angle; through A , $N^{\circ} 2$, draw AE' parallel to AC , $N^{\circ} 1$; and through C , $N^{\circ} 2$, draw CE' parallel to BC ; then it is evident that the angle $A'E'C$, $N^{\circ} 2$, is equal to the angle ACB , $N^{\circ} 1$; therefore the object, or its right section $ABCD$, will appear to an eye at E under the angle required. Now, suppose the object to be represented to be a house, and $ABCD$ the plan, or horizontal section, made by the vanishing plane; and let the dimensions of the plan, for the sake of conveniency in saving room, be half of those of the real object. Let $N^{\circ} 3$ be an elevation of the front to the full size. In $N^{\circ} 2$, draw $E'v'$ and $E'v'$, cutting VL in v' and v'' . In VL make $v'1$ equal to vE' , and $v''2$ equal $v'E'$; produce the side AB to meet VL in e ; draw Bf tending to the point E' , cutting VL at f ;

draw $E'C'$ perpendicular to VL , cutting it in C ; and this will be a preparation for drawing the representation of the object as follows.

Take any convenient line VL , $N^{\circ} 4$, for the vanishing line, and place thereon double the distances $C'v'$, $C'2$, $C'f$, $C'1$, $C'e$, and $C'v''$, $N^{\circ} 2$, as shewn by smaller characters at the corresponding points; then, in $N^{\circ} 4$, v' is the vanishing point for the horizontal lines of the one side of the object, and v'' that for those of the other side of the object; 1 is the dividing point for the lines tending to v' , and 2 for the lines tending to v'' , and f the point through which the representation of the angle of the building passes; through f draw yn perpendicular to VL , meeting IN in y ; make yA double of fe , $N^{\circ} 2$; draw $A'v'$, $N^{\circ} 4$, cutting yn at o ; draw AB parallel to yn ; make AB equal to the height of the elevation $N^{\circ} 3$; join $B'v'$, cutting yn at n ; then on is the representation of the angular line of the object. Join $1o$, and produce it to meet IN at g ; make gb equal to the length of the front, $N^{\circ} 3$; place on gb the intermediate divisions of the doors and windows; from the point b , from the intermediate divisions, draw lines tending to 1, cutting ov' ; from the points of section draw perpendiculars, which will terminate the breadths of the windows and door; from the point o draw oe , tending to the dividing point 2; make ex equal to the breadth of the building; join ov'' , and draw xq , tending to 2, cutting ov'' at q ; draw qp parallel to on ; also draw nv'' , cutting qp at p ; then $onqp$ is the representation of the flank of the building; set the heights of the apertures on AB , and draw lines to v' , which will complete the representation of the openings of the windows and door, and that of the entire object. If, by setting the measures upon the base line, they should give the intersections very oblique, produce AB to C , and draw CD parallel to VL , apply the measures to CD ; divide CE , then drop the perpendiculars.

This is the first time that a rule has been shewn for representing a right prismatic object, so that the original will appear under a given angle; and to fix the object at a given distance, with the plane of the picture at the same time. This also gives a rule for making the length of the picture, and the distance of the eye from its centre in a given ratio; for AB , $N^{\circ} 1$, being made equal to any distance or length, the perpendicular DC may be made in any proportion to AB . This method finds the position of the object, so as to give the most perfect representation possible, for the picture in the position here found will be the nearest to a spheric surface; the plane of the picture being considered as tanging the spheric surface at the middle of its length.

In the method hitherto used for finding the position of an object, the plan was first drawn; the point of view was moved on the paper until it came into what was thought an agreeable position for the view; then two lines were drawn to the eye from those two points of the object which would form the greatest angle; the angle of view was bisected, and a line was drawn through such a point of the bisecting line as would make the picture, as might be thought, of sufficient dimensions. But in taking the position of the picture in this way, the proportion of the length of the picture to its distance was only guessed at, nor could the object be viewed under a given angle.

It must also be noticed here, that the method of finding the representation, as is to be found in all previous writers on perspective, without the geometrical plane of the object, does not give its position.

PROB. XXXVI. Plate X. Fig. 1.

To find the representation of a rectangular solid, by making

PERSPECTIVE.

PROB. XXXVII. *Fig. 2.*

ing the centre of the picture the only dividing point for both sides of the object.

Let the object proposed to be represented be a house, *fig. 1*; $N^{\circ} 1$, the elevation; $N^{\circ} 2$, the ground plan: let $N^{\circ} 3$, for want of room, be a reduced plan to one-third of the dimensions of $N^{\circ} 1$ and $N^{\circ} 2$, shewing the preparation necessary for the perspective representation: besides what was shewn in the preparation of the vanishing points in the preceding problem, the following will also be necessary. From the remote angular points B and D of the plan $N^{\circ} 3$, draw BH and DI perpendicular to $V'L'$; and from the hither angular point A draw HI parallel to $V'L'$; draw any two parallel lines *ai* and *gk*, $N^{\circ} 5$; in *ai* apply AD from *a* to *d*, and in *gk* apply AI from *g* to *e*; join *ag* and *de*, and produce *ag* and *de* to meet each other in *f*; upon the line *ai* place the scale of the building; join *if*, cutting *gk* in *k*; divide *gk* into a scale in the same proportion to *ai*; in *gf* take any point *s*, and draw *su* parallel to *gk*; in *ai* make *abe* equal to AB, $N^{\circ} 3$; in *su* make *st* equal to HA, $N^{\circ} 3$; join *bt*, and produce it to *m*; join also *mi*, cutting *su* in *u*; divide *su* into a scale of the same proportion with *ai*; take the triple measures in the vanishing line $V'L'$, $N^{\circ} 3$, and transfer them to the vanishing line $V'L'$, $N^{\circ} 6$. In $N^{\circ} 6$, draw any line $I'N'$ for an intersecting line. In $N^{\circ} 3$, produce DA to meet $V'L'$ in G, and take the triple multiple of CG, and extend it in $V'L'$, $N^{\circ} 6$; from C to G, through G, draw *gF* perpendicular to VL, cutting $I'N'$ at F; set *Ga* downwards, equal to the height of the eye; place the height of the apertures from *a*, as also the height of the wall upon *ag*, upwards; from the points of section in *ag*, draw the indefinite representation of the horizontal lines of the building to the vanishing point v' ; draw *f v'*; produce $E'C'$, $N^{\circ} 3$, to meet HI in X; in $N^{\circ} 6$, draw *Cx* perpendicular to $I'N'$, meeting $I'N'$ at *x*; set the triple measures of XH, $N^{\circ} 3$, from *x* to *r*, $N^{\circ} 6$; now as the point *r* is found, which begins with the remote extremity of the end of the house, take the measures of the end of the house, and reduce them from the natural to the cofinal scale, and repeat each half from *r* to *s*, and from *s* to *b*, $N^{\circ} 6$; also take the measures of the length of the front and reduce them from the natural to the final scale, and repeat them in order from *b* to *i*, from *i* to *j*, from *j* to *k*, from *k* to *l*, from *l* to *m*, from *m* to *n*, and from *n* to *o*, $N^{\circ} 6$; draw *bI*, tending to the point C' , cutting $F v'$ at I; draw $I v'$; draw *rL*, tending to C' , cutting $I v'$ at L; draw *oK*, tending to C, cutting $F v'$ at K; then three lines, *Lw*, *Iy*, and *Kz*, being drawn from the points L, I, K, perpendicular to $V'L'$, will give the representation of the three quoins which are seen, *viz.* that of the hither angle, and those of the two remote ones; and being cut by $f v'$, gives *yz* the top of the front wall, and *y v'* being drawn, gives *yw* the level of the end; then by proceeding in the same manner with the intermediate points, will give the vertical sides of the windows, and the middle of the end, in order to ascertain the summit of the triangle which forms the apex of the roof.

The representation of the roof is thus determined; upon the intersecting line, *ag*, of the heights, make *fg* equal to the height of the roof; draw *gb*, tending to v' , cutting the perpendicular from I at *b*; draw *b v'*, cutting the vertical or perpendicular line in the middle of the end at *t*, which gives the apex of the end of the roof; draw *gq* parallel to $V'L'$; draw *tp*, tending to C' , cutting *gq* at *p*; make *pq* equal to *bo*; join $t v'$ gives the representation of the ridge of the roof; draw *qu*, tending to C, cutting $t v'$ at *u*, gives the representation of the other end of the ridge; then joining *ty*, *tw*, and *uz*, completes the representation of the roof.

To put a right rectangular prismatic object in perspective by one dividing point only, and by using the same measures for both sides of the object.

Let ABCD be the plan of the object, E' the point of sight, $V'L'$ the vanishing line, as before; draw the parallels E'E, and EG of the sides of the object; bisect the angle E'E'G by the straight line $E'd$, cutting EG in *d*, then *d* will be the dividing point in the vanishing line VL.

Let the object to be drawn be a house, as at *fig. 1*, $N^{\circ} 1$ and 2; the plan, *fig. 2*, $N^{\circ} 1$, being only one-third of the size, is used only for the purpose of ascertaining the vanishing points, the dividing point, or other particulars respecting the inaccessible vanishing point.

Draw an angle $A b B$, *fig. 2*, $N^{\circ} 2$; make *bA* to *bB* in the ratio of $G E'$ to $G d$; apply the several measures *bi*, *ij*, *jk*, *kl*, *lm*, *mn*, and *no*, *fig. 1*, $N^{\circ} 2$, to *bA*, *fig. 2*, $N^{\circ} 2$, from *b* to *i*, from *i* to *j*, from *j* to *k*, &c. Also at *fig. 2*, $N^{\circ} 3$, draw another angle $A b B$, making *bA* to *bB* in the ratio of $G E'$ to $G d$, as before, in $N^{\circ} 2$; upon the line *bA* make *bp*, *bq*, *br*, equal to *bp*, *bq*, *br*, *fig. 1*, $N^{\circ} 2$; join AB; draw rr' , qq' , pp' , parallel to AB, cutting *bB* at *r'*, *q'*, *p'*. Also in *fig. 2*, $N^{\circ} 2$, join AB, and draw ii' , jj' , kk' , &c. parallel to AB, cutting *bB* at the points *i'*, *j'*, *k'*.

Transfer the triple multiples of the several distances of VL, *fig. 2*, $N^{\circ} 1$, to VL, *fig. 2*, $N^{\circ} 4$, as shewn by the corresponding letters, except CE and CG.

Now because the surface of paper in *fig. 2*, $N^{\circ} 2$, is not sufficient to contain the vanishing points, prepare *fig. 2*, $N^{\circ} 1$, thus; draw EI and GH perpendicular to $V'L'$; make EI and GH equal to three-thirds of $C'E$, the distance of the picture; join I E' and H E'.

In $N^{\circ} 4$ *fig. 2*, draw $C'E'$ perpendicular to $V'L'$, and make $C'E$, $N^{\circ} 4$, equal to $C'E$, $N^{\circ} 1$; upon the vanishing line VL, make $C'E''$ equal to $C'E$, $N^{\circ} 1$; and $C'G$ equal to $C'G$, $N^{\circ} 1$; draw $E''I$ and GH perpendicular to $V'L'$, making $E''I$ and GH equal to EI and $G H$, $N^{\circ} 1$; join $E'I$ and $E'H$, which will tend to the vanishing points.

Let the dimensions in *fig. 1*, $N^{\circ} 1$, be applied in No. 4, *fig. 2*, to Cc , Cd , &c. in altitude upon the corner from C upwards and downwards; then draw lines tending to the vanishing points, as shewn in the preceding problems; draw any convenient line, PQ, parallel to $V'L'$; continue the corner line of the building to meet PQ in *b*; make *bi*, *bj*, *bk*, &c. also *bp*, *bq*, *br*, equal to *bi*, *bj*, *bk*, &c. *fig. 2*, $N^{\circ} 2$, and *bp'*, *bq'*, *br'*, $N^{\circ} 3$; then $C'd$ being the triple multiple of Cd , $N^{\circ} 1$, the point *d* will be the dividing point; draw *bR* and *bS* tending to the vanishing points; from the several points *ij*, *k*, &c. and *p*, *q*, *r*, draw lines tending to *d*, to cut *bR* and *bS*; from the point of section draw lines perpendicular to $V'L'$, which will give the corners of the building and the sides of the windows. Let us now suppose the walls completed with their apertures.

Now Cg being the height of the roof upon the corner of the building from the vanishing line, and the height of the left-hand corner being at *w*, draw *gv* and *wy*, tending to the vanishing point v' ; through *g* draw *ut* parallel to VL; make *gu* equal to *bo*; make *gt* and *ux* equal to the half of $b'r'$, $N^{\circ} 3$; draw *xy* and *tw*, tending to the dividing point *d*, gives the points *y* and *w* for the extremities of the ridge, the points *y* and *w* being joined to the wall heads completes the roof.

This method is entirely new, and perhaps is the easiest method of practice that has ever been devised.

PROB. XXXVIII. *Fig. 3.*

To find the representation of a hipped truncated roof, supposing

PERSPECTIVE.

posing the dimensions of the walls to be the same as in *fig. 2*, N^o 4.

Let v' and v'' be the vanishing points, of which v' is inaccessible, and let P be the dividing point, found as that of *fig. 2*, N^o 4, the positions of the other points being taken from *fig. 2*, N^o 1. Draw $I''N''$ the intersecting line of the truncated part of the roof, that is, draw $I''N''$ parallel to $V'L'$, equal to the height of the top of the roof from the level of the eye; make gk the proportional measure of the breadth of the inclined part of the roof; that is, the real measure being applied to the scale bA , *fig. 2*, N^o 2, or *fig. 2*, N^o 3, and reduced to the scale bB , gives the proportional measure. The other measures upon $I''N''$ are all supposed to be reduced in the same manner, and are consequently in the same ratio as the real measures; gh is the proportional measure of the sides of the truncated part parallel to the front, and gi the proportional measure of the end of the said part; draw kl , tending to the dividing point P, cutting gv'' at l ; draw ln , tending to the vanishing point v' ; draw gp , cutting ln at m ; draw mo , tending to the vanishing point v'' ; draw io , tending to the dividing point P, cutting mo at o ; also draw hn , tending to the dividing point P, cutting ln at n ; then the lines mn and mo represent the two visible parts of the truncated plane of the roof; join ny , mf , and or will complete the representation of the roof. This is evident, since the line ln represents the front line of the truncated part; and because that P is the vanishing point of the diagonal, the line gm is in the plane of the diagonal, and therefore the point m is properly ascertained.

Or a truncated hip roof may be thus represented: let g , *fig. 4*, be the height of the roof at the middle corner, as before; draw gq , tending to the vanishing point v' , upon the left, and gv , tending to the vanishing point, upon the right; make gh and gl equal to the breadth of the inclined part; make hi equal to the side of the truncated plane parallel, and next to the front, and make lm equal to the breadth of the truncated plane; draw lt , mu , tending to the dividing point P, cutting gv at s and u ; draw ts and ux , tending to the vanishing point on the left; draw bo and ip , tending to the dividing point P, cutting gq at o and p ; draw ox and ps , tending to the vanishing point on the right, cutting ts at s , and ox at r and x ; then rs and rx will be the two sides of the truncated flat; then joining sy , rf , and xw , will complete the whole representation of the roof.

It is somewhat strange that the base line, or intersection of the plane on which the objects are placed, is the only intersection that is to be found in treatises of perspective; but if the intersection of each plane above the eye were used, instead of describing every parallel plane upon the base, much less confusion would ensue, and much greater accuracy would be acquired. As the angles become less obtuse, that is to say, they approach the right angle by becoming more acute, all the indefinite representations would be cut more at right angles, and, therefore, the intersections would be less oblique. In order to comprehend clearly the perspective representation of polygons, it will be necessary to attend to their geometrical construction. An equilateral polygon may be constructed according to several methods; but the most eligible for the purpose of perspective is the following.

PROB. XXXIX. *Figs. 1, 2, 3, 4, 5, 6.*

The angle made by the two sides of a regular polygon being given, to construct the polygon according to a given side.

From the angular point cut off the two sides to their terminate length: then to obtain each successive side, proceed each time as in the following operation.

From the extremity of one side, which is not the angular point, draw a line parallel to the other side; from the extremity of the other side draw a line, making a given angle with that side equal to the angle of the sides of the polygon, and let the line last drawn meet the line parallel to the middle line; and three sides of the polygon will be thus determined. Proceed in the same manner with the two sides forming the last angle, and a fourth side will be obtained, and thus successively till the whole figure is inclosed.

From this geometrical description it appears, that if the vanishing points of the sides of a polygon are found, the whole may be constructed perspective.

PROB. XL.

To find the perspective representation of a polygon, given a similar figure to the polygon to be constructed, and the length of the sides.

Find the vanishing point of each of the sides, and the representation of the two sides nearest to the intersecting line.

Then repeat the following operations in finding each successive side. From the extremity of one of the representations of the two sides, which is not the angular point, draw a line to the vanishing point of the other side; then draw a line from the extremity of the other side, which is not the angular point, to the vanishing point of the next succeeding side, and the point of intersection of the two lines thus drawn will terminate the third side.

Then if the polygon be a trigon the thing is done, but if it consist of more sides the same operation must be repeated for each.

If one of the vanishing points of one of the sides be inaccessible, repeat the operations round in the same order, until one end of the inaccessible side is found; then repeat the operations in the contrary order, until the other end of the inaccessible line is found; then join the two points, which will complete the perspective representation of the polygon.

With regard to finding the vanishing points. If the polygon has an even number of sides, there will be only vanishing points for half the number of sides; but if the number of sides be odd, every side will have a vanishing point; should the number of sides be even, each radial may be marked with the digits 1, 2, 3, &c. then marked again with the same digits added to half the number of sides of the polygon. Thus, if the figure be a hexagon, as $ABCDEF A$, *fig. 2*, N^o 1; the figure, N^o 2, having all its radials parallel, has its radials numbered 1, 2, 3, and again 4, 5, 6, because the three lines continue the succeeding numbers. This is also manifested in *fig. 4*, N^o 1 and 2. In N^o 2, the radials are numbered 1, 2, 3, 4, then 5, 6, 7, 8, repeated upon the same lines, and thus every radial gives the vanishing points of two sides, as is indicated by the numbers. But if the number of sides of the polygon be odd, the numbers are repeated upon every second radial, then again upon the intermediate radials, beginning with that which lies between the first and second, as *figs. 1, 3, and 5*, plainly shew.

Fig. 6. shews the representation of a hexagon upon the foregoing principles; the sides ef and ek are first found by the vanishing points v^{1+4} and v^{3+6} , which are the first and last sides of the polygon, then drawing kg to the vanishing point v^{1+4} of the side ef , and from f drawing fg to the next vanishing point v^{2+5} in succession, gives the next side fg ; gb is found in the same manner.

Fig. 7. is another example of the principle; where the number of sides are even, the figure represented is an octagon. It will be observed in this as well as in *fig. 6*, that every vanishing point serves for two opposite sides, so that

in

PERSPECTIVE.

in every half number of sides in going round from any side, the last will have the same vanishing point again as that side; or in any number of adjoining sides which consist of one more than half the number of sides in the whole polygon, the first and last of these sides will have the same vanishing point; and thus in the hexagon the vanishing points v', v^2, v^3, v^4 , are respectively the vanishing points of the opposite sides, which in order would be v^1, v^2, v^3 , and are therefore marked $v^{1+3}, v^{2+3}, v^{1+6}$. The same is to be understood of *fig. 7*.

PROB. XLII. *Fig. 8.*

Given the centre and distance of the picture, the intersecting and vanishing lines of a plane perpendicular to the picture, and the insiting line AB of a plane perpendicular to the original plane inclined to the intersection, to find the intersecting and vanishing lines of the insiting plane.

If AB do not meet the intersection $I'N'$, produce it till it meet in B ; draw $E'C$ parallel to AB , cutting the vanishing line VL in C ; through C draw $V''L''$ perpendicular to $V'L'$, and $V''L''$ will be the vanishing line; also through B draw $I''N''$, and $I''N''$ will be the intersecting line of the plane.

For the angle $C'CE$ is equal to the angle IBA ; then when these angles are raised perpendicular to the plane of the picture, and on contrary sides of it, the planes whose intersections are $I''N''$ and $V''L''$ will be parallel to each other, and therefore their intersections $I''N''$ and $V''L''$ are also parallel to each other.

PROB. XLIII. *Fig. 9.*

Given the intersecting and vanishing lines of an original plane, the seat of a line at a given angle with the intersection, the inclination of the incumbent line and the position of the eye in respect of the vanishing line, to find the vanishing point of the line whose seat is given.

Let AB be the seat of the line given; through E' , the place of the eye, draw ED parallel to AB , cutting $V''L''$ in D' ; through D draw $V''L''$ perpendicular to $V'L'$; make DE equal to DE' ; and make the angle DEF equal to the inclination of the line to the original plane, the leg EF cutting $V''L''$ at F ; then F is the vanishing point required.

Or take any point H in $E'D$, and draw HK parallel to $V''L''$; make $E'H$ to HK as radius to the tangent of inclination of the line to the original plane; join $E'K$, and produce it to meet $V''L''$ in F . For draw DG and HI perpendicular to AB , and make HI equal to HK ; join $E'I$, and produce it to G ; then $E'H : E'D :: HI : DG$, also $EH : ED :: HK$ or $HI : DF$; therefore DF is equal to DG , consequently F is the point required.

PROB. XLIII. *Fig. 10.*

Given the vanishing line, its centre and distance, and the intersecting line of an original plane perpendicular to the picture; and the insiting line of a plane inclined to the original plane, and to the intersection at a given angle, to find the vanishing line of the incumbent plane, its centre, and distance, and also its intersecting line.

Let AC be the insiting line of the incumbent plane; produce AC to meet the intersection $I'N'$ in e ; through E' , the point of sight, draw $E'v'$, cutting the vanishing line $V'L'$ at v' ; also, through E' draw $E'v^2$ perpendicular to $E'v'$, cutting the vanishing line $V'L'$ at v^2 ; through v^2 draw $V''L''$ perpendicular to $I'N'$. In $E'v'$

take any point g , and draw gh parallel to $V''L''$; make $E'g$ to gh as radius to the tangents of the plane's inclination to the original line; that is, suppose ABC , N^2 , to be the inclination of the plane, take BA equal to Eg , N^2 ; draw AC perpendicular to BA , cutting BC in C ; then make gh , N^2 , equal AC , N^2 ; then in N^2 , join Eh , which produce to meet $V''L''$ at v^3 ; join v^3 and v' , and $v'v^3$ will be the vanishing line of the plane; through the point E in $I'N'$, draw $I''N''$, and $I''N''$ is the intersecting line; from C' , the centre of the picture, draw $C'k$ perpendicular to $v'v^3$, cutting it in i ; draw $C'f$ parallel to $v'v^3$; make $C'f$ equal to $C'E'$, and join if ; and lastly, make ik equal to if ; then i is the centre, and ik the distance, of the vanishing line required.

PROB. XLIV. *Fig. 11.*

Given the centre and distance of the picture, and the seats and distances of two points of an original line on the picture, to find the indefinite representation of the line.

Let C' be the centre of the picture, C and D the seats of the two points; join CD ; draw CA and DB perpendicular to CD ; make CA equal to the distance of the point, whose seat is C , and DB equal to the distance of the point, whose seat is D ; join AB ; produce AB and CD to meet each other in F ; draw $C'v$ parallel to CF ; and $C'E'$ perpendicular to $C'v$; make $C'E'$ equal to the distance of the picture; draw $E'v$ parallel to AF , and join vF , and vF is the indefinite representation required.

PROB. XLV. *Fig. 12.*

Given the intersecting and vanishing lines of an original plane perpendicular to the picture, the position of the eye in respect of the vanishing line, and the seats of two points of a line, and their distances, to find the indefinite representation of the line.

Let A and B be the seats of the two points, $V'L'$ the vanishing line, and $I'N'$ the intersecting line of the original plane, and E' the place of the eye; join AB , and produce it to meet the intersection $I'N'$ at e ; draw BD and AC perpendicular to Ae ; make BD equal to the height of the point, whose seat is B , and AC equal to the height of the point, whose seat is A ; draw ef perpendicular to Ae ; join CD , and produce it to f ; draw eg perpendicular to $I'N'$; make eg equal to ef ; through E draw $E'v'$ parallel to AB , cutting $V'L'$ at v' ; from $V'L'$ cut off $v'v^1$ equal to $v'E'$; make the angle $v'v^1v^2$ equal to the angle which the line AB makes with CD ; and through v^1 draw $V''L''$ perpendicular to $I'N'$, cutting $v'v^2$ at v^2 ; join v^2g , and v^2g is the indefinite representation required.

PROB. XLVI. *Fig. 13.*

Given the centre and distance of the picture, the intersecting line of an original plane, and its inclination to the picture, to find the vanishing line, its centre, and distance of the original plane.

Let AB be the intersecting line of the original plane, C the centre of the picture. Through C draw ef perpendicular to AB ; draw CD perpendicular to ef ; make CD equal to the distance of the picture; and make the angle CDE equal to the complement of the inclination of the original plane to the picture; through e draw $V'L'$ parallel to AB ; then $V'L'$ will be the vanishing line, e its centre, and De its distance, as required.

PROB. XLVII. *Fig. 14.*

Given the centre and distance of the picture, and the vanishing

PERSPECTIVE.

vanishing line of a plane, to find the vanishing point of lines perpendicular to that plane.

Let C' be the centre of the picture, $V'L'$ the vanishing line of the plane. Through C' draw $C''L''$ perpendicular to $V'L'$, cutting $V'L'$ at C'' ; draw $C'E$ perpendicular to $C''L''$, and make $C'E$ equal to the distance of the picture; join $C''E$, and make the angle $C''E\psi^2$ a right angle, and let $E\psi^2$ meet $C''L''$ in ψ^2 ; then ψ^2 is the vanishing point required.

PROB. XLVIII. *Fig. 14.*

Given the centre and distance of the picture, the vanishing line of a plane, and the vanishing point of the common intersection of the plane, whose vanishing line is given, and another plane at right angles, to find the vanishing point of the other planes. Let ψ^1 be the vanishing point of the common intersection.

Find ψ^1 , the vanishing point of lines, perpendicular to the plane, whose vanishing line is $V'L'$, and join $\psi^2\psi^1$, which is the vanishing line required.

This is easily conceived, by supposing the triangle $C''E\psi^2$ perpendicular to the plane of the picture upon the line $C''\psi^2$.

PROB. XLIX. *Fig. 14.*

Given the centre and distance of the picture, and the vanishing point of parallel lines, to find the vanishing line of planes perpendicular to the lines, whose vanishing point is given.

Let C' be the centre of the picture, ψ^2 the vanishing point of the parallel lines; join ψ^2C' , and produce ψ^2C' to C' ; draw $C'E$ perpendicular to ψ^2C' ; make $C'E$ equal to the distance of the picture; join ψ^2E ; draw $E\psi^1$ perpendicular to $E\psi^2$; through C draw $V'L$ perpendicular to ψ^2C' , and $V'L$ is the vanishing line required.

PROB. L. *Fig. 15.*

Given the centre and distance of the picture, the vanishing line of one of the planes of a rectangular prism, and the vanishing point of the common intersection of that plane and the plane of the adjoining side, to find the vanishing lines of the other two sides, their centres, and distance.

Let C be the centre of the picture, $V'L'$ the vanishing line of the plane of one side, ψ the vanishing point of the common intersection of that side with the next adjoining side.

Find the vanishing line $V''L''$, of parallel planes perpendicular to parallel lines, whose vanishing point is ψ^1 by the last problem. Produce ψ^1C to E'' , cutting $V''L''$ at C'' ; make $C''E''$ equal to $C''E$; draw CE' perpendicular to $V'L'$; let ψ^1 be the intersection of the vanishing lines $V'L'$ and $V''L''$, and consequently the vanishing point of the intersection of two adjoining sides; from ψ^1 , with the radius ψ^1E'' , describe an arc, cutting CE' at E ; join $E'\psi^1$, $E'\psi^2$, $E''\psi^2$; make the angle $\psi^1E''\psi^2$ a right angle, and let ψ^1 cut $V''L''$ at ψ'' ; join $\psi^1\psi''$ for the vanishing line $L''V''$; draw CE''' perpendicular to $V''L''$, cutting $V''L''$ at C''' ; from ψ^1 , with the radius ψ^1E' , describe an arc, cutting CE''' at E''' ; join $E'''E''$ and $E'''E''$; then $V'L'$, $V''L''$, $V'''L'''$, are the vanishing lines, C , C'' , C''' , their respective centres, and $C'E'$, $C'E''$, and $C'''E'''$, their respective distances; which might have been otherwise found by drawing right-angled triangles, making the distances of the centre of the picture, and the centre of the vanishing line, the bases, and the perpendicular at the centre of the picture equal to the distance, as shewn by the dotted triangles.

PROB. LI. *Figs. 16 and 17.*

Given the common intersection of two planes, the seat of a line in one of them, and the inclination of the line to the same plane, to find the seat of the line in the other plane, and its inclination to the same.

Let $I'N'$ be the common intersection of the two planes, AB the seat of the line; let ΛB meet the intersection $I'N'$ at A ; make the angle BAC equal to the inclination of the line; draw BC perpendicular to AB , cutting AC in C . This problem may be divided into two cases; one when the two planes are at right angles to each other, and the other when they stand oblique. In the former case, (see *fig. 16.*), draw Be perpendicular to $I'N'$, cutting it in d ; make de equal to BC , and join Ae ; draw ef perpendicular to Ae ; make ef equal to dB , and join fA ; then Ae is the seat of the line, and eAf its angle of elevation on the other plane. In the latter case, draw Bf perpendicular to Bd ; make Bf equal to BC ; make the angle Bde equal to the inclination of the planes; draw fe perpendicular to de ; make dg equal to de , and join gA ; draw gb perpendicular to gA ; make gb equal to ef , and join Ab ; then gA is the seat of the line on the other plane, and gAb the corresponding angle of elevation.

By means of this problem, whatever lines are given in position to the original plane, the position of the same lines may be found to the picture, and the representation may be found as in problem 16.

PROB. LII. *Fig. 1.*

Given the centre and distance of the picture, the vanishing line of a plane, and the vanishing point of the intersection of that plane, and another plane, and the inclination of the planes, to find the vanishing line of the other plane, and its centre and distance.

Let C' be the centre of the picture, V^2L^2 the vanishing line of a plane, ψ^1 the vanishing point of the intersection of that plane with another plane; join $C'\psi^1$; draw $C'E$ perpendicular to $C'\psi^1$; make $C'E$ equal to the distance of the picture, and join $E'\psi^1$; draw $C'D$ perpendicular to ψ^1E' , cutting ψ^1E' at D ; from $C'\psi^1$ take $C'B$ equal to $C'D$, and let $C'E'$ cut V^2L^2 at A ; produce AC to F ; make the angle ABF equal to the inclination of the planes; join ψ^1F , which gives the vanishing line V^3L^3 , as required; draw $C'E^2$ perpendicular to V^2L^2 , cutting it at C^2 ; make ψ^1E^2 equal to ψ^1E' , and join ψ^1E^2 ; also draw $C'E^3$ perpendicular to V^3L^3 , cutting V^3L^3 at C^3 ; make ψ^1E^3 equal to ψ^1E' , and join ψ^1E^3 .

PROB. LIII. *Figs. 2 and 3.*

Given the centre and distance of the picture, the representation of a line, with its vanishing point, and the indefinite representation of another, from a given point in the latter, to cut off a portion, so that the originals of the two representations shall have a given ratio.

Let C' be the centre of the picture, ψ^1 the vanishing point of one of the lines, and ψ^2 the vanishing point of the other; join ψ^1 and ψ^2 by the straight line V^2L^2 , which will be the vanishing line of their plane; draw $C'E^2$ perpendicular to V^2L^2 , cutting V^2L^2 at C^2 ; draw $C'E^1$ perpendicular to $C'E^2$; make $C'E^1$ equal to the distance of the picture, and join C^2E^1 ; make C^2E^2 equal to C^2E^1 ; join ψ^1E^1 and ψ^1E^2 ; from $\psi^1\psi^2$ take ψ^1I , equal to ψ^1E^2 ; also ψ^2I , equal to ψ^1E^1 .

This problem may be resolved into two cases; first, when the two lines meet in a point, figure 2.

Let $a\epsilon$ be the given representation, and $a\psi^2$ the indefinite representation, having respectively the vanishing points ψ^1

PERSPECTIVE.

v' and v'' ; through a draw cd parallel to $V^2 L^2$; join ie , which produce to c ; make ac to ad in the original ratio required; draw d' , cutting av'' at b , and c 1, cutting av' at e ; then ae and ad are the representations of two original lines in the ratio of ac to ab . But if the two lines do not meet at the same point as in figure 3; let ed be the representation given, v' its vanishing point, and av'' the indefinite representation of the other; through the extremity a , draw $I^2 N^2$; join $1c$ and $1d$, which produce to meet $I^2 N^2$ at f and g ; from a take ae to gf , in the ratio required; join $e2$, cutting av' at v ; then the original of ab will have to the original of cd the ratio required.

PROB. LIV. Fig. 4.

Given the centre and distance of the picture, the seat and distance of any point from the picture, and the vanishing points of several lines diverging from that point, to draw the indefinite representations, and to cut a portion from each; so that the original of the representations may be in a given ratio to each other, and to the distance of the point whose seat is given.

Let C' be the centre of the picture, v', v'', v''' , the vanishing points, and s the seat of the point of concurrence; now as any two vanishing points may be the vanishing points of two lines in the same plane, therefore join $C'v'$, and $C'v''$ will be the vanishing line of a plane, in which are the original lines, whose vanishing points are C' and v' ; draw $C'E'$ perpendicular to $C'v'$; make $C'E'$ equal to the distance of the picture, and join $E'v'$; from $C'v'$ take $C'd$ equal to $C'E'$; draw sD parallel to $C'v'$; make sD equal to the distance of the point of concurrence from the picture; join Dd and sC' , cutting each other at a , the representation of the point of concurrence from the picture; join Dd and sC' , cutting each other at a , the representation of the point of concurrence; join $a v', a v'', a v'''$, also join $v'v'', v''v'''$, then $v'v''$ will be the vanishing line of a plane, in which are the original lines, whose vanishing points are v' and v'' , and $v''v'''$ will be the vanishing line of a plane, in which are the original lines, whose vanishing points are v'' and v''' ; draw $C'E''$ perpendicular to $v'v''$, cutting $v'v''$ at C'' ; from v' , with the radius $v'E'$, describe an arc, cutting $C'E''$ at E'' ; join $v'E''$ and $v'E'$; draw aJ parallel to sD , and join $D C'$, cutting aJ at J ; draw aK parallel to $v'v''$; find aK , so that aJ may be to aK as the distance of the point of concurrence is to the original length to be taken from $a v'$; from $v'v''$ take $v'1$ equal to $v'E''$; draw $K1$, cutting av' at l . In like manner draw $C'E'''$ perpendicular to $v''v'''$, cutting $v''v'''$ at C''' ; from v'' , with the radius $v''E''$, describe an arc, cutting $C'E'''$ at E''' ; from v'' , with the distance $v'E''$, describe an arc, cutting $C'E'''$ at E''' ; join $v'E'''$; from v'' , with the distance $v''E''$, describe an arc, cutting $V^3 L^3$ at 2 ; draw aM parallel to $V^3 L^3$; make aM such that aK may be to aM as the original of aL is to the original of the distance to be taken from $a v''$; draw $M2$, cutting av'' at n ; find the point 3 in the vanishing line $V^3 L^3$, by making $v'3$ equal to $v'E''$; produce Ma to O ; find the distance aO , by making aM to aO , as the original of an to the original to be taken from $a v''$; draw $O3$, cutting av'' at p ; then will the originals of as, al, an, ap , have the ratio to each other, as aJ, aK, aM, aO , as was required.

By this means the representation of a solid angle may be found, or the sides of a pyramid may be determined; and, consequently, if one of the solid angles of a parallelepipedon is found, and the lengths of the lines that form the said angle, the whole solid may be completed, by drawing lines to the vanishing point of the side at right angles. When two or more indefinite representations have the

same vanishing line, they are in course found as usual. A distance may be cut off from any indefinite representation, which has its vanishing point that of the intersection of two original planes by the point of distance laid upon either vanishing line.

PROB. LV. Fig. 5.

Given the centre and distance of the picture, the intersecting and vanishing lines of a plane perpendicular to the picture, the side of a rectangle in the original plane, and the inclination of the plane of the rectangle to the original plane, and the distance of the nearest point to the intersecting line, to find the representation of the rectangle.

Let $V^2 L^2$ be the vanishing line, $I^2 N^2$ the intersecting line of a plane perpendicular to the picture, C' the centre, and $C'E'$ the distance put in position as usual; and let AD be the side of the rectangle on the original plane, e the seat of the nearest point A , and Ae its distance; find the representation a of the point A , and then of the straight line AD ; and let $E'v'$ be the parallel of AD ; draw $E'v'$ perpendicular to $E'v''$, and let $E'v'$ meet the vanishing line $V^2 L^2$ in v' ; through v' draw $V^2 L^2$ perpendicular to $V^2 L^2$; find the point 1 in $v'v''$, by making $v'1$ equal to $v'E'$; make the angle $v'1v''$ equal to the inclination of the plane to the original plane; join $v'v''$, that is, $V^2 L^2$, which will be the vanishing line of the plane incumbent on the original plane; draw $C'E^2 V^2 L^2$ perpendicular to $V^2 L^2$, cutting $v'v''$ at C^2 ; from v'' , with the radius $v''E'$, describe an arc, cutting $C'E^2$ at E^2 ; or upon $V^2 L^2$, as a diameter, describe a semicircle, cutting $C'E^2$ at E^2 ; then C' is the centre, and $C'E^2$ the distance of the vanishing line $V^2 L^2$, and v'', v''' the vanishing points of the sides; make the rectangle $E^2 M N O$ similar to the original figure, and alike situated; draw the diagonal $E^2 v'$, and produce it to meet the vanishing line $v'v''$ at v' ; join v' and a , which give the indefinite diagonal; draw $d v''$, cutting av at c ; draw $c v''$; produce $v''c$ to b , and join $a v'$, cutting $v''c$ at b , then $abcd$ is the representation required.

PROB. LVI. Fig. 6.

Given the centre and distance of the picture, to find the representation of a rectangle in a secondary plane, with an angle resting on the primitive or original plane; given also the intersection of the secondary and original planes, and their inclination, together with the seat and distance of the resting point.

Find m , the representation of the resting point, by means of its seat and distance, and the centre C' and distance $C'E'$ of the picture; draw $E'v'$ the parallel of the intersection, cutting $V^2 L^2$ at v' ; draw $E'v''$ perpendicular to $v'v''$, cutting $V^2 L^2$ in C'' ; on $V^2 L^2$ make $C''1$ equal to $C'E'$; through C'' draw $V^2 L^2$ perpendicular to $V^2 L^2$; make the angle $C''1v''$ equal to the inclination of the secondary plane to the primitive or original plane; let $1v''$ meet $V^2 L^2$ in v'' ; through v' and v'' draw $V^3 L^3$, which is the vanishing line of the inclined plane required to be represented; find its centre C^3 and distance $C^3 E^3$; join $v'E^3$; make the angle $v'E^3 v''$ equal to the angle which one of the sides of the object makes with the intersection of its plane and the primitive; let $E^3 v''$ meet the vanishing line $V^3 L^3$ in v'' ; also make the angle $v''E^3 v'$ equal to the angle of the original figure next to the intersection of its plane with the original plane; and let $E^3 v'$ meet $V^3 L^3$ at v' ; then the representation $mno p$ may be completed as in the last problem, fig. 5. Or proceed thus; bring the distance of the eye upon the vanishing line $V^2 L^2$ from each of the vanishing points; then 2 and 4 are the dividing points;

PERSPECTIVE.

join v' , and the representation m of the nearest corner; produce $v'm$ to i ; through i draw $I^3 N^3$ parallel to $V^3 L^3$, and $I^3 N^3$ will be the intersection of the inclined plane and the picture; through the points z and m draw $m d$, cutting the intersection in d ; make $d e$ equal to the original of the side $m p$; draw $e z$, cutting $m v^3$ at p ; also draw $q m$, and produce it to meet $I^3 N^3$ at b ; make $b c$ equal to the original of the side $m n$; draw $c q$, cutting $m v^3$ at n ; draw $n v^3$ and $p v^3$, cutting each other at o ; then $m n o p$ is the representation, as before.

PROB. LVII. *Fig. 7.*

To find the representation of the portion of a rectangular prism, cut by a plane so that two of the parallel faces will be equal trapezoids, the other two parallel faces being equal rectangles, the solid being formed like a pent-house; given the centre and distance of the picture as usual, the base of the prism on the original plane, the picture and the arrases of the object being perpendicular to the original plane.

Let $A B C D$ be the base of the solid; find its representation $m n o$ as usual, as also the vertical planes of the solids $n o b a$ and $m n a d$; on the vanishing line $V^1 L^1$ make $v^1 z$ equal $v^1 E^1$; through v^1 draw $V^2 L^2$ perpendicular to $V^1 L^1$; make the angle $v^2 z v^2$ equal to the inclination of the terminating plane, and let $z v^2$ meet $V^2 L^2$ in v^2 , which will be the vanishing point of the two inclined sides, and v^2 will be the vanishing point of the two level sides; the plane $a b c d$, being drawn according to the respective vanishing points, will complete the representation of the solid. The representation of the top might have been obtained without raising the vertical sides from the base; thus, draw $A S$ perpendicular to $V^1 L^1$, cutting $I^1 N^1$ in E ; make $E S$ equal to the height of the arras or quoin upon A ; draw $S A$ parallel to $V^1 L^1$; make $S A$ equal $E A$; then S is the seat of the top of the arras on the picture, and $S A$ its distance from the picture; find a the representation of the apex of the solid angle, having the centre and distance of the picture, and the seat S and distance $S A$ of the original of the point A ; then the vanishing line $V^3 L^3$ being found as before, produce $B A$ to meet $I^1 N^1$ at F ; draw $F G$ perpendicular to $I^1 N^1$; make $F G$ equal to the height of the front plane, and the point G will be a point in the intersection of the inclined plane with the picture; therefore draw the line $I^3 N^3$ parallel to $V^3 L^3$, and $I^3 N^3$ will be the intersection of the inclined plane; find the centre C^3 , and distance $C^3 E^3$ of the vanishing line $V^3 L^3$; join $E^3 v^3$ and $E^3 v^3$; on the vanishing line $V^3 L^3$ make $v^3 5$ equal to $v^3 E^3$, and $v^3 4$ equal to $v^3 E^3$; then $D Q$ being perpendicular to $A D$, and the angle $D A Q$ equal to the inclination of the plane, $A B$ will be the length of the side parallel to the base, and $A Q$ that of the side inclined thereto; through 5 , and the point a , draw $5 a$, which produce to meet $I^3 N^3$ at e ; in $I^3 N^3$ take $e f$ equal to $A Q$; join $f 5$, cutting $a v^3$ at d . In like manner join $4 a$, which produce to meet $I^3 N^3$ at g ; make $g b$ equal to $A B$, and join $b 4$, cutting $a v^3$ at b ; draw $b v^3$ and $d v^3$, cutting each other at c , and $a b c d$ is the representation of the upper surface, as before.

Or, instead of applying the full dimensions upon the intersecting line, draw $S Q'$ and $a G'$ parallel to $V^1 L^1$; in $V^1 L^1$ produced, take any point D' ; make $A' B'$ equal to $A B$, $A' Q'$ equal to $A Q$; draw a line through a parallel to $V^3 L^3$; join $A' D'$, $B' D'$, and $Q' D'$, cutting $a G'$ at E', F', G' ; then apply $E' F'$ and $E' G'$ from a , upon the line passing

through a , parallel to $V^1 L^1$; then cut off $a b$ and $a d$ by means of the points 4 and 5 , as before.

PROB. LVIII. *fig. 8.*

To find the representation of a rectangular prism, situated with its faces inclined to the original plane, and to the picture laying upon one of its arrases on the original plane; given the seat and distance of the nearest point of concurrence of a solid angle, the inclination of the arras of the solid in the original plane to the picture, and the inclination of one of the sides to the horizon, and the centre and distance of the picture.

Draw the horizontal line $V^1 C^1$ and $C^1 E^1$ perpendicular thereto; draw $E^1 A$ parallel to $V^1 C^1$; make the angle $A E^1 C^1$ equal to the inclination of the arras to the picture.

Find the point a , the representation of the nearest angle, by means of the centre and distance of the picture, and the seat and distance of the nearest point of concurrence of the sides.

Through C^2 draw $V^2 L^2$ perpendicular to $V^1 E^1$; now as the solid lays upon one of its arrases, two of its planes will be perpendicular to the horizon, and consequently will have their vanishing line perpendicular to the vanishing line of the horizon; therefore $V^2 L^2$ will be the vanishing line of the arrases in these perpendicular planes.

Draw $C^2 E^2$ perpendicular to $V^2 L^2$, and make $C^2 E^2$ equal to $C^2 E^1$. Through E^2 draw $G H$ parallel to $V^2 L^2$; make the angles $G E^2 v^2$ and $H E^2 v^2$ equal to the inclination of the planes to the horizon, then v^2 and v^1 will be the vanishing point of the arrases, which terminate the ends that are perpendicular to the horizon.

Find v^2 the vanishing point of original lines, perpendicular to original planes, whose vanishing line is $V^2 L^2$.

Cut off $a b$, $a d$, and $a f$, as in problem 54, *fig. 4*; then lines being drawn to the respective vanishing points will complete the solid.

N^1 shews the method of reducing the proportions according to what was shewn in the last problem, by applying the measures at once to the nearest angle.

PROB. LIX. *Fig. 9.*

To find the representation of a rectangular solid; given the centre and distance of the picture, the inclination of one of the faces of the solid to the picture; which have the nearest point of concurrence, and the seat and distance of the nearest point of concurrence.

Find $V^2 L^2$ the vanishing line of the plane of the two planes of the solid, whose inclination is given; also the centre C^2 , and the distance $C^2 E^2$ of the vanishing line.

Draw $G H$ parallel to $V^2 L^2$; make the angles $G E^2 v^1$ and $H E^2 v^1$ equal to the angles which the arrases make, with a line parallel to the picture at their point of concurrence in the same plane, and $v^1 v^1$ in $V^2 L^2$ will be the vanishing points of the arrases of the two sides, whose inclinations are given.

Find the vanishing point v^1 of original lines perpendicular to planes which have $V^2 L^2$ for their vanishing line.

Find f the representation of the nearest point of concurrence of three arrases.

From each of the indefinite representations cut off the different sides, and the solid will be completed, as in the last example.

PROB. LX. *Fig. 10.*

The centre and distance of the picture, and the intersection of an original plane, making a given angle with the picture, being given, to find the representation of a wedge,

with

with the point of concurrence of three of the arrafes in the picture, the base of the object being in the plane whose intersection is given, three of the sides of the solid perpendicular to the original plane.

Let $I^1 N^1$ be the intersection of the original plane, a the point of concurrence of the nearest angle in the intersection $I^1 N^1$.

Find the vanishing line, $V^1 L^1$, of the original plane, whose intersection is $I^1 N^1$, as also its centre C^1 , and distance $C^1 E^1$.

Find the vanishing point, v^1 , of the intersection of the inclined side of the wedge, with the original plane, and draw the indefinite representation av^1 .

Find the vanishing point, v^2 , of the other side; the vanishing points, v^1, v^2 , being in the vanishing line $V^1 L^1$.

Find the vanishing point, v^3 , of original lines, perpendicular to original planes, which have $V^2 L^2$ for their vanishing line.

Join the vanishing points v^1 and v^2 , and produce $v^1 v^2$ to v^3 .

Find the centre C^1 , and distance $C^1 E^1$, of the vanishing line $v^1 v^2$, that is of $V^1 L^1$; join $v^1 E^1$.

On the radials $E^1 v^1$ and $E^1 v^2$, make $E^1 G$ and $E^1 F$ in the ratio of the sides, which have $V^1 L^1$ for their vanishing line; join GF ; draw $E^1 v^3$ parallel to GF , and v^1 will be the vanishing point of the two inclined arrafes.

Find the representations, ab and ac , of the hither sides of the base. Join av^1 and bv^1 ; join $v^1 c$, which produce to meet the indefinite representation av^1 in d ; join $d v^1$, cutting bv^1 at e , which completes the entire solid.

By joining $v^1 v^2$, $V^3 L^3$ will be the vanishing line of the inclined plane $abcd$; and by finding the centre C^1 , and distance $C^1 E^1$, and joining $E^1 v^1$ and $E^1 v^2$, the original proportion of the inclined plane may be found, by drawing the diagonal ac , and producing it to meet the vanishing line $V^3 L^3$ at v^3 , and joining $v^3 E^1$; then the rectangle $KLME^1$, whose other sides meet the radial $v^3 E^1$ in L , is the original of the inclined plane: and thus any figure may be drawn in the original plane, whose vanishing line is $V^3 L^3$.

The principles of light and shade will be treated under the article SHADOWS.

The writers on perspective are very numerous. The following, (some of whom have been already mentioned in the brief history of the science at the commencement of this article,) are the principal, with the dates of their performances, as near as can be ascertained.

Guido Ubalduis, 1600, Latin, folio; Bernard Lamy, 1701, 8vo.; s'Gravefande, 1711, 8vo., translated into English by Stone, 1724; Marolois, Vredeman Frieze, the Jesuit, 4to.; Pozzo, folio. The Jesuit was translated into English by E. Chambers, 1726. Ozanam's Mathematics contain also a treatise on Perspective. These are all foreign works. The following list contains all, or nearly all, the English authors, or their works, that have written on perspective.

Humphry Ditton, 1712, 8vo.; Moxon, folio; Brook Taylor, two treatises, one in 1715, and the other in 1719, both 8vo.; Langley, 1730, 4to.; Oakley's Magazine of Architecture, Perspective, and Sculpture, 1730, folio; Halfpenny, 1731; Hamilton, 1738, folio; Dr. Brook Taylor's Method of Perspective, by Kirby, 1754, letter-press, 4to., and plates, folio; Sirigatti by Ware, 1754, folio; Kirby's Parallel suppressed; Kirby's Perspective of Architecture, 1760, large folio; Highmore, 1763, 4to.; Fournier, 1764, 4to.; Cowley's Moveable Schemes for illustrating the Principles of Perspective, 1765, 4to.; Ferguson, 1765, 8vo.; Ware's Complete Body of Architecture contains a treatise on Perspective, 1768, folio; Priestley, 1770, 8vo.; Edward Noble, 1771, 8vo.; Thomas Malton, 1775, folio; Bradberry; Shiraton in his Cabinet

and Upholsterer's Drawing-Book, 4to.; Wood of Edinburgh, 1797, 8vo.; the Painter's Maulllick by James Malton, 1800, 4to.; Douglas, 1805, letter-press, 8vo., and plates, folio; Edwards, 1806, 4to.; Thomas Noble, second edition, 1809, 4to.; Wood's Lectures, London, second edition, 1809, 4to.; W. Daniel, 1810, final 8vo. for children; a thin quarto without the name of the author, the title being "A new Treatise on Perspective, founded on the simplest Principles, containing universal Rules for drawing the Representation of any Object on a vertical Plane," 1810, thin 4to.; D. Cresswell, A.M., 1811, 8vo.; Milne in his Elements of Architecture, 1812, 4to.; and Mr. Hayter, 1813, 8vo. Besides the above authors and treatises are Muller, Martin, and Emerson, who have written octavo treatises in their mathematical courses. A thin quarto was written by Bardwell, a painter. The Artists' Repository, published by C. Taylor, Hatton Garden, contains also an article on perspective.

But of all the above works, or authors' works, Dr. Brook Taylor's is the most celebrated, on account of the universality of his principles in their application to planes and objects. For though vanishing points in every position were known to Guido Ubalduis, and s'Gravefande not only understood the use of vanishing points, but the use of directors also in the representation of a point, anterior to the appearance of any thing published by Brook Taylor; but Brook Taylor has extended his theory not only to vanishing points, but to the vanishing lines of planes in every situation, which, when once ascertained, the representation of an object is found by the same means in each plane, and consequently with the same facility. Hamilton seems to be the first writer who introduced the practice of setting the radial, or parallel of the original line from the vanishing point, upon the vanishing line, and the original line from the intersecting point upon the intersecting line, in order to ascertain the representation of any point, or any part or parts of the original line, and to find the originals from the representations given. (See problems 8 and 9, book ii. sect. 2, of his Stereography, and the following corollaries from problem 8.) This author is the first who has applied the harmonical division of lines to perspective. Noble's Perspective contains several inventions: his methods of drawing indefinite representations to inaccessible vanishing points, both by scales and other means, are new. Thomas Malton's treatise on this subject is an able performance. His theory is well arranged, and demonstrated with true geometrical spirit. The choice of his examples in the component parts of architecture, before uniting the whole into a complete edifice, are excellent.

The works on perspective of the following gentlemen, among the authors already enumerated, are performed strictly upon the principles of Dr. Brook Taylor: Hamilton, Kirby, Highmore, Fournier, Priestley, Noble, Thomas Malton, J. Wood, Edwards, J. G. Wood, Cresswell, A.M.

Though Mr. James Malton pretends to unite the principles of Dr. Brook Taylor with those of Vignola and Sirigatti, he might have referred them with more propriety to s'Gravefande's invention of directors, as the use of the station point, which is only a directing point, can be more easily explained upon the principles of the directing line, director, and directing point, than by any mechanical notion; so that the methods which he uses may be referred entirely to the principles of Dr. Brook Taylor. In the method used in James Malton's Perspective, every point of an object in the original plane is found in the picture, by a line drawn between the intersecting and vanishing point, or drawn from some point already found, and the vanishing point, and an-

other line drawn by the directing point and the director: for when the director of an original line coincides with the intersection of the vertical plane, the representations directed will be perpendicular to the intersection, or to the vanishing line; therefore, lines thus drawn in the picture will fall in the same straight lines with original lines parallel to the picture, and to the vertical plane, insisting upon the remote extremities of the lines drawn to the directing point. This, therefore, admits of the plan of the object either being connected with the picture, or separated from it, as convenience may require. This circumstance has even been overlooked in the more excellent treatise of the father of the gentleman, upon whose work the remarks are now made.

It is something remarkable, that in Brook Taylor's Perspective, he no where directs the radial to be placed upon the vanishing line, except in problem 10, in verse perspective, notwithstanding the very near affinity shewn in problems 3, and 4, which one would have thought might have led to that application; particularly, considering the great use which Kirby, Highmore, Fournier, Priestley, E. Noble, Thomas Malton, J. Wood, Edwards, and others of inferior note, have made of it, in representing original measures without the use of the plan. It is to be observed, that in Brook Taylor's Perspective, when he finds the representation of an original figure without the plan, he first finds the representation of a side of the figure; then the representation of a line, whose original will make an angle of the figure with the original side of the projection given; then determines the proportion of the last line, found by supposing the two sides to be joined by a third line, making a triangle; then finds the vanishing point of the third side. He then proceeds with another side; if more than three, in the same manner; so that he supposes the original figure divided into triangles, by drawing diagonals, and constructs angles at the eye, equal to those which he supposes the originals to have; then finds the vanishing points of the sides, and of the diagonals; and, by drawing the successive lines to the respective vanishing points, completes the whole representation. Or, he finds the projection of each triangle, if more than one, in the succession which they adjoin each other, until the whole representation is completed. Now, by placing the length of the radials upon the vanishing line, the originals may be represented, without supposing the figure to be resolved into triangles. But what is still more to be wondered at, in respect to Brook Taylor, in problem 10, of the edition 1719, the intersection of a plane, its vanishing line, with the centre and distance of the vanishing line, are given, to find only the length of the original of a projection given, which is a problem in inverse perspective; he absolutely sets the length of the radial on the vanishing line: and had he done so, in finding the representations of original figures, he would have been the sole inventor of the practice, without the use of the ground plan, or the figure to be represented being placed in its true situation.

PERSPECTIVE is also used for a kind of picture or painting, frequently seen in gardens: and at the ends of galleries; designed expressly to deceive the sight by representing the continuation of an alley, a building, landscape, or the like.

PERSPECTIVE, *Aerial*, is sometimes used as a general denomination for that which more restrictedly is called aerial perspective, or the art of giving a due diminution or degradation to the strength of light, shade, and colours of objects; according to their different distances, the quantity of light which falls upon them, and the medium through which they are seen; the *chiaro-scuro*, or *clair-obscur*, which consists in expressing the different degrees of light,

shade, and colour of bodies, arising from their own shape, and the position of their parts with respect to the eye and neighbouring objects, whereby their light or colours are affected; and *keeping*, which is the observance of a due proportion in the general light and colouring of the whole picture; so that no light or colour in one part may be too bright or strong for another. A painter who would succeed in aerial perspective, ought carefully to study the effects which distance, or different degrees or colours of light have on each particular original colour, to know how its hue or strength is changed in the several circumstances that occur, and to represent it accordingly. As all objects in a picture take their measures in proportion to those placed in the front, so in aerial perspective, the strength of light, and the brightness of the colours of objects close to the picture, must serve as a measure, with respect to which all the same colours at several distances must have a proportional degradation in like circumstances.

PERSPECTIVE, *Alley in*. See ALLEY.

PERSPECTIVE, *Architecture in*. See ARCHITECTURE.

PERSPECTIVE, *Bird's eye view in*, is that which supposes the eye to be placed above any building, &c. as in the air, at a considerable distance from it: this is applied in drawing the representations of fortification, when it is necessary not only to exhibit one view as seen from the ground, but so much of the several buildings as the eye can possibly take in at one time from any situation. In order to this, we must suppose the eye to be removed a considerable height above the ground, and to be placed as it were in the air, so as to look down into the building like a bird that is flying. In representations of this kind, the higher the horizontal line is placed, the more of the fortification will be seen, and *vice versa*.

PERSPECTIVE, *Diagonal*. See OPERA GLASS.

PERSPECTIVE, *Graphical*. See GRAPHICAL.

PERSPECTIVE *Machine*, is a machine by which any person may delineate the true perspective figure of objects, without the help of the rules of this art. Mr. Ferguson has described a machine of this kind, the invention of which he ascribes to Dr. Bevis. The plane of this instrument, *Plate XXIV. Miscellany*, exhibited in *fig. 1*, and *fig. 2*, is a representation of it when made use of in drawing distant objects in perspective. *abef* (*fig. 1*) is an oblong square board, represented by *A B E F* in *fig. 2*; *x* and *y* (*X* and *Y*) are two hinges on which the part *cld* (*C L D*) is moveable. This part consists of two arches or portions of circles *clm* (*C L M*) and *dnl* (*D N L*), joined together at the top *l* (*L*), and at bottom to the cross bar *dc* (*D C*), to which one part of each hinge is fixed, and the other part to a flat board, half the length of the board *abef* (*A B E F*), and glued to its uppermost side. The centre of the arch *cml* is at *d*, and the centre of the arch *dnl* is at *c*.

On the outer side of the arch *dnl* is a sliding-piece *n*, (much like the nut of the quadrant of altitude belonging to a common globe,) which may be moved to any part of the arch between *d* and *l*: and there is such another slider, *o*, on the arch *cml*, which may be set to any part between *c* and *l*. A thread *cpn* (*C P N*) is stretched tight from the centre *c* (*C*) to the slider *n* (*N*), and such another thread is stretched from the centre *d* (*D*) to the slider *o* (*O*); the ends of the threads being fastened to these centres and sliders.

Now it is plain, that by moving these sliders on their respective arches, the intersection *p* (*P*) of the threads may be brought to any point of the open space within the arches. In the groove *k* (*K*) is a straight sliding bar *i* (*I*),

which may be drawn farther out, or pushed farther in, at pleasure.

To the outer end of this bar I (*fig. 2.*) is fixed the upright piece H Z, in which is a groove for receiving the sliding-piece Q. In this slider is a small hole *r* for the eye to look through in using the machine: and there is a long slit in H Z, to let the hole *r* be seen through when the eye is placed behind it at any height of the hole above the level of the bar I.

In delineating a perspective representation, *e. gr.* of the house, *qsrp*, a great way off, place the machine on a steady table, with the end E F of the horizontal board, A B E F, toward the house, so that when the Gothic-like arch D L C is set upright, the middle part of the open space (about P) within it may be even with the house when you place your eye on Z, and look at the house through the small hole *r*. Then fix the corners of a square piece of paper with four wafers on the surface of that half of the horizontal board which is nearest the house; and all is ready for drawing.

Set the arch upright, as in the figure; which it will be when it comes to the perpendicular side *t* of the upright piece *st*, fixed to the horizontal board behind D. Then place your eye at Z, and look through the hole *r* at any point of the house, as *q*, and move the sliders N and O till you bring the intersection of the threads at P directly between your eye and the point *q*; then put down the arch flat upon the paper on the board, as at S T, and the intersection of the threads will be at W. Mark the point W on the paper with the dot of a black lead pencil, and set the arch upright again, as before: then look through the hole *r*, and move the sliders N and O till the intersection of the threads comes between your eye and any other point of the house, as *p*: then put down the arch again to the paper, and make a pencil mark thereon at the intersection of the threads, and draw a line from that mark to the former one at W; which line will be a true perspective representation of the corner *p'q* of the house.

Proceed in the same manner, by bringing the intersection of the threads successively between your eye and the other points of the outlines of the house, as *r*, *s*, &c. and put down the arch to mark the like points on the paper at the intersection of the threads: then connect these points by straight lines, which will be the perspective outlines of the house. In like manner find the points of the corners of the door and windows, top of the house, chimnies, &c. and draw the finishing lines from point to point: then shade the whole, making the lights and shades as you see them on the house itself, and you will have a true perspective figure of it. Great care must be taken, during the whole time, that the position of the machine be not shifted on the table; and to prevent such an inconvenience, the table should be very strong and steady, and the machine fixed to it, either by screws or clamps.

In the same way, a landscape, or any number of objects within the field of a view through the arch, may be delineated, by finding a sufficient number of perspective points on the paper, and connecting them by straight or curved lines as they appear to the eye.

The arch ought to be at least a foot wide at bottom, that the eye at Z may have a large field of view through it; and the eye should then be, at least, $10\frac{1}{2}$ inches from the intersection of the threads at P when the arch is set upright. For if it be nearer, the boundaries of view at the sides near the foot of the arch will subtend an angle at Z of more than sixty degrees, which will not only strain the

eye, but will also cause the outermost parts of the drawing to have a disagreeable appearance. To avoid this, it will be proper to draw back the sliding bar I, till Z be $14\frac{1}{2}$ inches distant from P; and then the whole field of view, through the foot-wide arch, will not subtend an angle to the eye at Z of more than forty-five degrees; which will give a more easy and pleasant view, not only of all the objects themselves, but also of their representations on the paper whereon they are delineated. So that, whatever the width of the arch be, the distance of the eye from it should be in this proportion: as 12 is to the width of the arch, so is $14\frac{1}{2}$ to the distance of the eye (at Z) from it.

If a pane of glass, laid over with gum water, be fixed into the arch, and set upright when dry, a person who looks through the hole *r* may delineate the objects upon the glass which he sees at a distance through and beyond it, and then transfer the delineation to a paper put upon the glass. Ferguson's Perspective, chap. iii.

Mr. Kirby has also contrived and described an instrument that will be useful in taking extensive views, &c. The ruler A B (*fig. 3.*) is 19 inches long, and is graduated into 19 equal parts; it has a dove-tail groove on its upper edge to receive the perpendicular ruler G, which has one end fitted to it, so as to slide very easily; this ruler is 14 inches long, and is divided into 14 equal parts, and upon the back side of it F is a line drawn exactly in the middle, to which is fixed a silken line with a small plummet at the end. The ruler A B is fixed by two screws *a, c*, to two pieces of thin brass; and these pieces of brass are fixed at the other ends by two screws *d, e*, to a stronger piece of brass *bf*, which goes close to the ruler A B, and has a joint at X turning upon a screw: below this joint is a piece of round brass about six inches long, which goes into a hole made in the top of the staff, and may be raised higher or lower, by means of a screw *S*: C D E represents part of this staff, the whole length of which is about three feet, and at the bottom is a rank screw made of iron and fixed to the staff. H I is a wire 22 inches long, with a screw at *b* to go into the hole *b*; the piece of brass wire bent into the form *ik*, is fixed to the wire H I by the screw *k*; and the part *i* goes into the hole *f* in the brass-piece *bf*. The small wire K L is about 12 inches long, and flattened at K, at which place is a little hole above one-eighth of an inch in diameter; this wire K L is fitted to the holes *l, m, n, o*, which are made in the larger wire H I, and it may be placed higher or lower by means of a small screw. This instrument is used in the following manner: fix a paper upon a drawing board, as in *fig. 4.* and divide the paper lengthways into 19 equal parts, and perpendicularly into 14 equal parts; making these divisions greater or smaller according to your design. Then take the staff, and fix it strongly in the ground by means of a screw at bottom, and at a convenient distance from the prospect which you intend to take. After this, put the instrument together as in *fig. 5.* and fix the ruler A B exactly horizontal by means of the plummet on the perpendicular ruler and the brass joint X; then fix the wire K L, so as to have the eye-hole exactly level with the horizon or equal to the height of the eye, and take care to have the greatest distance of the eye-hole from the ruler equal to the whole length of the longest ruler A B, and never less than the distance *bl*. Having thus fixed the instrument, proceed to make the drawing; look through the eye-hole, and then move the perpendicular ruler in the groove, till you get one edge exactly against some principal object; then will the parts upon the ruler shew how high the object is from the bottom of the ruler, *i. e.* from the bottom of the picture, and you will

will also know its apparent height; therefore transfer this to the paper in those squares which correspond with the divisions upon the rulers. For the breadth of objects, move the perpendicular ruler so as to be even with the sides of an object, and the divisions upon the lower ruler will shew their apparent breadths. After the same manner, get the places and apparent sizes of as many principal objects as are necessary for assisting you, in completing the whole drawing, which may be done by this method with great exactness. When the drawing is finished, the instrument may be taken to pieces and put into a box, which may serve as a drawing board; the top M may be screwed into the staff, which will serve as a walking-stick, and the stool to sit on may be made very portable: so that every part of this apparatus may be carried by one person without any inconvenience. Kirby, *ubi supra*, b. ii. p. 65, &c.

PERSPECTIVE, *Military*, is that wherein the eye is supposed to be very remote from the table or plane. See *Bird's Eye View*, in PERSPECTIVE.

PERSPECTIVE, *Scenographic*. See SCENOGRAPHY.

PERSPECTIVE of *Shadows*. See SHADOW.

PERSPECTIVE, *Specular*, is that which represents the objects, in conical, spherical, or other mirrors, erect and clear, whereas on other planes they appear confused and irregular. See MIRROR and ANAMORPHOSIS.

PERSPICUITY, PERSPICUITAS, in *Rhetoric*, is a principal excellence of style, to which all the ornaments and beauties of speech ought to give way: as it is necessary to render a discourse intelligible, and forms one of the constituent parts of elegance. "Prima est eloquentiæ virtus perspicuitas," says Quintilian, lib. viii. cap. 2. There are three different ways in which perspicuity in a composition may be violated; *viz.* by obscurity, ambiguity, and unintelligible expression. The common sources of obscurity are some defect in the expression, arising from ellipses in language, the affectation of conciseness, or rapidity of thought in writers, or a bad choice of words; a bad arrangement of the words, so that the construction is not sufficiently clear; the use of the same word in different senses in the same sentence, an uncertain reference in pronouns and relatives: too complicated or artificial a structure of the sentence, so that the sense is too long suspended by parenthesis; the injudicious introduction of technical words and phrases; and, lastly, very long sentences. Ambiguity may be occasioned either by using some expression which is equivocal, or by ranging the words in such an order that the construction is rendered equivocal. The last fault proceeds either from great confusion of thought, which is commonly accompanied with intricacy of expression, or from affectation of excellence in the diction, evidenced by the injudicious use of figures, or from a total want of meaning. In these several ways, a speaker may express himself obscurely, and so convey his meaning imperfectly to the mind of the hearer; or express himself ambiguously, and so, along with his own, convey a meaning entirely different; or express himself unintelligibly, and so convey no meaning at all. Dr. Campbell in his "Philosophy of Rhetoric," vol. ii. book 2, chap. 6. has well exemplified and exposed these offences against perspicuity. It is justly observed by Quintilian, *ubi supra*, that by perspicuity, care is taken, not that the hearer may understand, if he will; but that he *must* understand, whether he will or not. See STYLE.

PERSPIRATION, in *Physiology*, the office of the skin, by which it forms and discharges various matters, principally fluids, from the blood; or the matters themselves so discharged. It is distinguished into *sensible* and *insensible*, ac-

ording as it consists of fluids recognizable by the senses, or of such as escape our observation. See INTEGUMENTS.

PERSPIRATION of *Plants*, in *Vegetable Physiology*, takes place chiefly from the surface of their leaves. In order to collect the liquor perspired, it is only necessary to introduce a branch of the plant into any sufficiently capacious glass vessel; when the fluid which exudes will trickle down the sides of the glass, in great abundance, especially if the experiment be made in sun-shine. The liquor thus obtained is of a clear watery nature, scarcely distinguishable to our senses, or to our chemical enquiries, from the sap of the same plant, whatever it may be, procured by wounding its branches before the foliage expands. This, which may be termed the insensible perspiration of plants, becomes in some cases sensible; as when it runs down, like a slight shower, from Willow or Poplar trees, in hot sunny weather; or when it collects in drops on the leaves of Plantain trees in a stove. Hales and others have made experiments to ascertain the quantity of insensible perspiration in various plants. The great annual Sun-flower was found to perspire about seventeen times as much as the ordinary insensible perspiration of the human skin. The Cornelian Cherry, *Cornus mascula*, is said to discharge, in twenty-four hours, as much fluid as is equal to twice the weight of the whole shrub. Succulent leaves perspire much slower than others, though they absorb in a far more rapid proportion.

This watery perspiration is the only excrementitious discharge of the vegetable body. The sap being carried up into the leaves, where it is acted upon by air and light, for the most important purposes, yields those various and highly curious secretions, which, being carried down into the bark, afford matter for the increase of the tree, as well as for the manifestation of its various qualities. The great bulk of the sap which remains, as it does not return to the root, like the blood of animals to their heart, can be disposed of no otherwise than by a copious evaporation. Dr. Darwin was of opinion that this watery perspiration rendered a further service to the plant, by being acted upon by light, so as to give out oxygen, which was immediately absorbed by the air-vessels. But this hypothesis is inadmissible on many accounts, nor need we here repeat that which is adopted under the article LEAF.

The sensible perspiration of many plants is of a far different nature from the above watery evaporation, and is to be considered as an actual secretion. Such are the mucilaginous exudation found on the leaves of the Lime-tree, *Tilia europæa*; the saccharine matter perceptible on Orange trees, hops, beech, and other plants, which is one kind of honey-dew, and either owing to some injury to their roots, or to the sudden influence of a cold, or otherwise noxious, atmosphere. The *Cistus* genus, and many other shrubs of warm countries, afford a resinous exudation from their leaves and young twigs. The Fraxinella, *Diosmanus albus*, is very remarkable for a highly inflammable vapour, which in hot still weather issues from, and hovers around, the plant, exploding on the approach of a lighted taper. Manna is said to have been scraped from the leaves of *Fraxinus Ornus*, though usually procured only from the sap of that tree. A kind of wax may in like manner be obtained, as some report, from the leaves of Rosemary. A copious glutinous perspiration is observable on young leaves of many kinds, as the Cherry, Plum, various Poplars, and abundance of aromatic herbs. *Pelargonium inquinans* is singular for its exudation of a soft oily matter, that stains the fingers with a red or vermilion-like tinge.

PERSTAIN, in *Geography*, a town of Bohemia, in the circle of Boleslaw; 14 miles N.W. of Jung-Buntzel.

PERSUR, a town of Hindoostan, in Allahabad; 10 miles E.N.E. of Gazypour.

PERSWAR, a town of Hindoostan, in the circar of Gurrak; 15 miles S. of Mahur.

PERTABGUR, a fort of Hindoostan; 30 miles N.E. of Allahabad. N. lat. $25^{\circ} 58'$. E. long. $82^{\circ} 23'$.

PERTABPOUR, a town of Hindoostan, in Oude; 52 miles N.E. of Manickpour.—Also, a town of Hindoostan, in Bengal; 15 miles N.W. of Midnapour. N. lat. $22^{\circ} 35'$. E. long. $87^{\circ} 10'$.

PERTELS, a town of Austria; six miles N. of Bohmish Waidhofen.

PERTH, a royal borough, and the county town of Perthshire, Scotland, is situated in the middle of a verdant plain, on the western bank of the river Tay, at the distance of forty miles and a half N. by W. from Edinburgh. This plain is divided by the town into two parts, called the north and South inches, or islands, each of which measures about a mile and a half in circumference, and both are appropriated for the benefit and amusement of the inhabitants of the place.

Perth is a town of very high antiquity, and is generally allowed to have owed its origin to the celebrated Roman general Agricola, who penetrated into this part of the country about the year 70. He is said to have fixed on this spot as the site, originally of a winter camp, and afterwards of a colonial town, from the resemblance its scenery bears to that in the vicinity of ancient Rome. So striking is the similitude, indeed, that the Roman soldiers when they first saw the river Tay, and the adjacent plain, are recorded to have exclaimed with one consent, "Ecce Tiber! Ecce Campus Martius! Behold the Tiber! Behold the field of Mars." Hence the Tay was called New Tiber, by the Italians for many centuries; and Fordun, a Scottish historian gives the name of Tyber-Mere, to an extensive moor which lies west from the town. An aqueduct, said to have been constructed here by Agricola, is still in existence, and supplies the mills and wells with water. In ancient times when the town was fortified, it also supplied the ditches, by which the latter was surrounded.

Of the history of Perth during its Roman occupation, and for several centuries after the retreat of that people from Britain, nothing certain is known. Neither is it recorded at what period it became a chartered town. Alexander Necham, an English writer, who read lectures on history at Paris in 1180, described Perth as a place of great opulence. In 1210, according to the Scottish historians, it was strongly fortified by king William, who also renewed its former charters, and granted it many additional privileges. At that time Perth was reckoned the capital city of Scotland, and even at the present day it ranks inferior only to Edinburgh and Glasgow. Between the years 1201 and 1459, no fewer than fourteen great national councils were held here. During the same period, Perth was also the usual residence of the Scottish monarch, and consequently of the nobility, many of whose ancient mansions still adorn its streets. It was then likewise, as it is still, an extensive commercial town. Fordun informs us, that the merchants of Perth visited, in their own ships, the Hanse towns; and it is a part of the eulogium conferred on Alexander III., who died in 1286, that he devised successful measures for securing the trading ships of that nation against pirates, and against being detained on slight pretences in any foreign port. "In consequence of the care which he exercised about the trade of the kingdom, which, for some years during his minority had been on the decline, multitudes of ships soon came from

divers regions loaded with goods of various kinds to be exchanged for the commodities of this country."

The German merchants, or Flemings, also early frequented the port of Perth with mercantile views; and many individuals of that nation conversant in the linen and woollen manufactures, and in staining of cloth, appear to have fixed their abode in the town, and to have been received as burghesses. King William, however, following the example of his grandfather king David, put the foreign merchants of Perth under great restrictions; and to prevent the settlement of foreign manufacturers there, granted in his charter already mentioned, that the burghesses might have a merchant guild of their own, "fullers and weavers excepted."

Edward I., of England, added greatly to the importance of Perth, by increasing the strength of its fortifications, and making it the residence of his deputies. King Robert Bruce conceiving its occupation to be of signal importance to his cause, attacked this town in 1306, but was repulsed by the earl of Pembroke, who sallied out, and defeated the king at Methven. In 1311, however, Bruce renewed the attack, and after an obstinate siege of six weeks, succeeded in storming the fortifications, which he levelled with the ground. After the battle of Duplin, these were re-edified by Edward Baliol, but were soon again razed by the patriotic Scots. In 1335 king Edward III. took possession of Perth, and resided in it for a considerable period. According to the English historians, John, earl of Cornwall, brother to that monarch, died here in Oct. 1336; but they omit a singular circumstance mentioned by Fordun, which is, that he received his mortal wound from the king's own hand. In 1339 Perth stood a long siege against the regent Robert, but was taken by draining the ditch. In 1437 king James I. of Scotland was murdered at the Black Friars monastery, by Robert Graham, who wounded him in twenty-eight different places, and the queen twice, during the scuffle between them. At this period the town walls seem to have been in a state of demolition; as we find them repaired, at a very considerable expence, by king James II., from whose reign nothing of a political nature worthy of notice occurs on record, till the year 1600, when the earl of Gowrie's house here was the scene of one of the most problematical events in Scottish history. We allude to the execution of what is commonly designated the "Gowrie conspiracy," by John Ruthven, the then earl, and his brother Alexander. These two young men, according to the story published by the court, having prevailed upon king James I. to visit Perth, (on the pretence of shewing him a suspicious person whom they had apprehended,) attempted to murder him, but were foiled in the attempt, and both slain by his majesty's attendants. Upon this, the inhabitants of the town assembled round the house, threatening revenge upon the royal party, and it was with considerable difficulty they were prevailed on to disperse.

After the battle of Tibbermoor, in 1644, Perth was seized by the marquis of Montrose; and in 1651 it was taken by Cromwell, and fortified with a citadel on the South inch, capable of containing a garrison of five hundred men. In 1715 the earl of Marr, at the head of a detachment of the rebels, obtained possession of it, and occupied it as a place of arms, till after the battle of Dunblane, on Sheriffmuir, when they were dislodged by the duke of Argyle, and compelled to retreat further to the north, with the Pretender. The same party likewise held this town in 1745, when prince Charles was proclaimed king, and new magistrates were appointed. The modern prosperity of Perth may be dated from this period; for being the centre of the rebellion,

PERTH.

rebellion, it was the resort of all the disaffected from the north, during a considerable length of time. Thus its ancient activity was in some degree revived. The march and residence of the contending armies produced a market here for all sorts of goods; capital was gained by industrious persons; and advantage taken of its favourable situation to render it a place of trade. Hence it has been remarked that Perth is a singular instance of a town that owes its prosperity in a great measure to the calamities attendant on rebellion and civil war. Since that turbulent period it has increased nearly one half in extent and population.

Perth, in its municipal capacity, is a royal borough, and joins with Dundee, Forfar, Cupar of Fife, and St. Andrew's, in sending one member to parliament. It is governed by a provost, three bailies, a dean of guild, a treasurer, and nineteen counsellors, most of whom are elected from the incorporated trades. The funds of the corporation are very considerable, and of late years have been expended with great judgment in various improvements. Perth being the county town, the sheriff's-court meets here; and the lords of judicary hold a court here every six months, when they go on their circuits. The provosts have been sheriffs within the town since the time of king Robert III. They bear also the office of coroner, which office however is never exercised in Scotland.

This town, considered in reference to its buildings, is one of the handsomest in Scotland. It occupies a site which might, indeed without impropriety, be selected as the seat of government, and the emporium of commerce. The Tay, which is navigable up to the quays at common tides for sloops and small craft, and in spring tides for vessels of large burden, admits of great extension of trade. This river flows here in a direction nearly north and south; but at a short distance below Perth it turns to the westward, and is lost behind the hill of Kinnoul. Over it is a handsome bridge of ten arches, which cost about 25,000*l.* It is 906 feet 9 inches in length, and 22 in breadth, with the parapets. The piers are founded ten feet beneath the bed of the river, upon oaken and beechen piles. The architect of this magnificent structure was Mr. Smeaton. It connects Perth with Kinnoul, which is a borough of barony under the superiority of the nobleman who holds that title.

The two chief streets in Perth are called the High street and South street, both of which run from east to west, and are nearly parallel to each other. Along the side of the river runs another considerable street. The new town, which was begun in 1798, contains a circus and a terrace of very handsome appearance. This portion of Perth is situated on a plot of ground, where formerly stood the monastery of Black friars, in which James I. of Scotland was murdered, as has been already mentioned.

Among the public buildings are several worthy of attention. The town-house, which forms the eastern termination of High street, is a large well built structure, as is likewise the guildhall, which stands about the middle of the same street. Several of the incorporated trades have halls, of which that of the glovers is the most elegant. The parish church, which was formerly the property of the abbey of Dumfermline, and is a large and ancient edifice, is now separated into three divisions, called the east, middle, and west kirks; besides there is another parish church, dedicated to St. Paul, a chapel of ease, and a variety of chapels and meeting-houses appropriated to the public worship of dissenters. St. John's church is remarkable from the circumstance of the reformation in Scotland having first publicly broke out here, on the 11th of May 1550, when John Knox preached a sermon against idolatry, after which the priest

being imprudent enough to display his images and relics, he was attacked by the audience, who broke the images in pieces, tore the pictures, overthrew the altars, and entirely defaced every implement of Catholic superstition in the church. This done, they proceeded to the different monasteries in the town and its neighbourhood, and pillaged or demolished the whole of them.

The chief institutions in Perth of a public nature are a grammar-school, an academy, and a literary and antiquarian society. The grammar-school has long been regarded as one of the best in Scotland. Many celebrated statesmen and scholars have received the early part of their education here; and, among others, the admirable Crichton, and the late celebrated and excellent William, earl of Mansfield. The academy is of much more recent establishment than the school, having been commenced about the year 1761. It is, however, in a very flourishing condition, and is usually attended by from eighty to a hundred students, who are instructed in various branches of learning. The literary and antiquarian society was founded 16th December, 1784. Belonging to this institution is a general library, besides a large collection of rare books, original essays, ancient manuscripts, coins, medals, and other subjects of antiquity, suitable to the design of the establishment.

Perth at present is a place of very considerable trade. There is a constant intercourse by water between Perth and London. Every four days, during the fishing season, a smack sails, and usually makes the passage within a week. A number of merchant vessels likewise frequent this port; and those of heavier burden are loaded or discharged in the river, by means of hoys. The staple manufacture of the town is linen; but the cotton trade is rapidly on the increase. The number of looms employed in the town and suburbs is estimated at about two thousand. Cotton-mills, bleach-fields, and print-fields, have been established in different situations. Leather is also one of the manufactured products of Perth; and great quantities of that article are made into boots, shoes, and gloves, for foreign consumption. From the vicinity of the Highlands, the manufacture of doe-skins and buck-skins has long been established in this town. Here is a respectable banking establishment, under the firm of the Perth Bank; besides a branch of the bank of Scotland.

Perth, according to the parliamentary returns of 1811, is divided into four parishes, and contains in the aggregate 4715 houses, and 16,948 inhabitants. The markets are well supplied with all kinds of provisions and luxuries. The annual fairs are eight in number, and are usually well attended.

Of the ancient importance of Perth, while it was a royal residence, few traces remain; with the exception of the parliament-house, and some modernized mansions of the old nobility; such as the houses of the bishop of Dunkeld, earl of Errol, and earl of Athol. The original fortrefs belonging to the town is now a ruin, and not even the scites of its monastic institutions are discoverable to the eye. Gowrie-castle, already mentioned as the residence of the earls of Gowrie, is situated on the south-east side of the town. It was built, or, perhaps more properly speaking, rebuilt, in 1520, by the countess of Huntly. After the forfeiture of the Gowrie estates, it became the property of the corporation, and was presented in 1746, by the magistrates, together with the freedom of the burgh, to William, duke of Cumberland, who afterwards sold it to the board of ordnance for the sum of 5000*l.*; and it has ever since been appropriated as barracks for a company of the royal artillery. In the pleasure-grounds attached to this house is a curious structure, called the Monk's-Tower, the origin and former

uses of which are not correctly ascertained. This structure is of an oval figure, and measures internally 24 feet by 13. The roof is very lofty, and vaulted; and on the ceiling are coarsely painted the twelve signs of the zodiac, the heathen gods and goddesses, and the arms, crest, and cyphers of the Hay family. From its style, this painting does not appear to be more ancient than the reign of Charles I; and some even think it has been executed by the same artist who painted the ceilings of the palace of Scoon: hence it is conjectured, that the tower has been erected for a banqueting-house, at that period. But others refer its origin to the 14th century, and assert that it obtained its appellation of Monk's-Tower from having been built at the expence of the monasteries of Lindores, Balmerinoch, Aberbrothick, and Coupar-in-Angus; which expence, Fordun says, "in a manner ruined these monasteries." This view of the subject is in some measure corroborated by Cant's Notes to the History of Perth, in the following lines and note:

" — The great and strong Spey Towre,
And Monk's-Towre builded round a wall of power."

"The Spey Tower is gone: it was a stately fortress, and had a strong prison. The Rosses of Craigie were governors of the fortresses. At the reformation, Robert Ross of Craigie delivered up the keys under a protestation. There remains nothing of it but a pitiful ruin, where the toll-house is. Monk's-Tower yet stands, as described in the poem, in the south-east corner of the garden, on the wall. It serves as a magazine of gunpowder for the train of artillery. The wall between this and the Spey Tower is the wall of the garden, and the fosse without still remains."

In digging the foundation of the house here, belonging to colonel Mercer of Aldie, the remains of an ancient British temple were discovered. This edifice is mentioned by Holinshed, and by Jeffrey of Monmouth; the latter of whom says, it was erected by a British king, son to Regan, the second daughter of king Lear. It was dedicated to Mars, and, as we presume, must have been of later date than the Roman invasion, as the architecture of its ruins exhibited considerable advancement in the building art.

The parish of Perth, without the town, extends about four miles in length, and three miles in breadth. The soil varies, but is extremely fertile, and well cultivated. The adjacent scenery is highly beautiful, but, owing to most of the estates here being entailed, gentlemen's seats are less numerous than otherwise might have been expected. The most remarkable houses are the Castle of Balhousie, an ancient seat of the earls of Kinnoul; the Castle of Pit-theveles, an ancient seat of the lords Oliphant; and Few-house, a seat belonging to Mr. Marshall of Hill-Cairney. The barracks, in the immediate vicinity of the town, likewise deserve to be mentioned among its ornaments. See Beauties of Scotland, Svo. vol. iv. 1801; also, A Topographical Dictionary of Scotland, by N. Carlisle, F.S.A., 2 vols. 4to. 1813.

The "five articles of Perth," so called because they were carried by the influence of the court and bishops at a convention or assembly summoned to meet at Perth Aug. 25th, 1618, are as follow: 1. That the holy sacrament should be received kneeling. 2. That ministers should be obliged to administer the sacrament in private houses to the sick, if they desired it. 3. That ministers might baptize children privately at home, in cases of necessity, only certifying it to the congregation the next Lord's day. 4. That ministers should bring such children of their parish as could say their catechism, and repeat the Lord's prayer, creed, and ten commandments, to the bishops, that they might confirm them and give them their blessing. 5. That the festivals of

Christmas, Easter, Whitsuntide, and the Ascension of our Saviour, should for the future be commemorated in the church of Scotland. The king ordered these articles to be published at the market-crosses of the several boroughs, and the ministers refused, as they were sanctioned by no penalty except the king's displeasure. The king, however, determining to obtain the ratification of parliament, issued a proclamation, commanding all ministers who opposed them, and who were preparing a supplication against them, to leave the city of Edinburgh within 20 hours. The ministers obeyed, leaving behind them a protestation against the articles, and an admonition to the members of parliament not to ratify them, as they would answer it in the day of judgment. The court interest prevailed, and the articles were ratified, contrary to the sense of the kirk and nation. This measure occasioned a persecution through the kingdom, and many of the Presbyterian ministers were fined, imprisoned, and banished by the high commission. Thus far king James proceeded towards the restitution of episcopacy in Scotland; but there was still wanting for the completion of the work a public liturgy, or book of common prayer. An insurrection through the whole kingdom being apprehended, he desisted from enforcing this unwise measure, and left it to be finished by his son, whose imposition of it upon the kirk, without consent of parliament or general assembly, set fire to the discontents of the people, which had been gathering for so many years.

PERTH-AMBOY, a city of America, in New Jersey, pleasantly situated in Middlesex county, at the head of Rariton bay, on a neck of land included between Rariton river and Arthur Kull Sound. Its site is elevated and salubrious. It lies open to Sandy-hook, and has one of the best harbours on the continent, into which vessels may enter in one side, in almost any weather. It is a port of entry and port-town; but although it is admirably situated for trade, and the legislature has given every encouragement to induce merchants to settle here, it is far from being in a flourishing state. It contains about 60 houses, and carries on a small trade to the West Indies; 35 miles S.W. of New York. N. lat. 40° 35'. W. long. 74° 50'.

PERTHSHIRE, one of the most extensive and important counties in the northern division of Scotland, is bounded on the S. by the Frith of Forth, and the counties of Stirling and Clackmannan; on the S.W. by the county of Dunbarton; on the W. and N. by Argyleshire and Invernessshire; on the N. by the latter county and Aberdeenshire; on the E. by Forfarshire; and on the S.E. by the counties of Kinross and Fife. Its greatest length from E. to W., that is, from Blairgowrie to Benloi, measures 77 miles; and its greatest breadth from the Forth at Culross on the S., to the northern extremity of Athol, is not less than 68 miles. According to the best surveys, its superficial contents are estimated at 5000 square miles; that is, 3,200,000 Scottish acres, or 4,068,640 English acres. The whole of this tract was anciently divided into the districts of Athol, Breadalbane, Rannoch, Strathearn, Balquidder, Monteith, Gowrie, Perth and Stormont, which were called stewardries, and were placed under the hereditary jurisdiction of the great proprietors of lands. These distinctions, however, are now abolished in effect, but are nevertheless still recognized in the common language of the inhabitants.

General Character of the County.—The surface of this county presents, as might be expected from its great extent, much diversity of appearance. It is naturally divided into two portions, called the Highland and the Lowland districts. The former is of bold, mountainous character, and exhibits

PERTHSHIRE.

scenes of the most rugged and romantic magnificence, while the other is finely interspersed with hill and vale, and displays all the beauties which the highest cultivation is capable of bestowing. At the foot of the Grampian hills is the fertile valley of Strathmore, which is succeeded by the no less luxuriant and extensive vale of Strathearn. The Carle of Gowrie has long been considered as the pride of Scotland in point of natural productiveness, and is certainly inferior to no portion of Great Britain in the excellence of its agricultural system. The territory along the Forth is likewise in many parts fertile and beautiful, and even the glens and declivities of the towering Grampians, and their rival Ochils, offer features of superior exuberance and of partial cultivation.

Mountains.—Perthshire is intersected by three very lofty chains of mountains; called the Grampian, the Ochil, and the Sidley or Sidlaw hills. The first are celebrated, and generally well known. They extend in a north-eastern direction, almost across the whole of Scotland, and constitute what may be termed the Highland district of this county. (See *GRAMPIAN HILLS*.) The Ochils bound the vale of Strathearn on the S., and stretch themselves through the county of Clackmannan into that of Fife. (See *OCHIL HILLS*.) The Sidley hills lie more to the N.E., and extend from the vicinity of Perth in a direction parallel to the Grampians. In all these ranges of hills, but particularly in the Grampian chain, are many summits of very great elevation. The following are among the most conspicuous for size, and perpendicular altitude above the level of the ocean.

Elevation.	Feet.
Dunfinnan hill	1040
Kinfeat hill	1179
Demyet	1345
Tortum	1400
Birnam hill	1580
Ben Clach (Ochil)	2420
Farragon	2584
Ben Chenzie (Strathearn)	2922
Ben Vorlich	3300
Ben Doig	3550
Ben Ledi	3009
Schichallion	3564
Ben Gload	3724
Ben More	3903
Ben Lawers	4015.

Mineralogy, and Mineral Products.—Considering the great extent of Perthshire, and the character of its surface, we might readily suppose it to afford abundant materials of interest to the mineralogist. This is accordingly the fact, in so far as regards scientific investigation; but in a political, or economical point of view, the minerals of this county are not of very high importance. The rock of which the Grampians chiefly consists is granite. On the southern ridges, or skirts of these mountains, however, both slate and free-stone are found in abundance; but here the great sandstone stratum of Scotland terminates, in like manner as the coal field does to the southward of the Ochils. Hence it may be remarked, that Perthshire contains within itself the boundary between the sandstone and the granite, for the former is only discovered in small patches to the north, and the latter seldom shews itself to the south, except in the mountains of Galloway. What is curious, the secondary minerals on the ridges of the Grampians, such as slate, limestone, and even sandstone, are affected in their properties by the proximity,

or intermixture of the primary rocks. Thus in the parish of Little Dunkeld, below Murphy, is an inexhaustible body of a very fine grained free-stone, which is of a light livid ash colour, and so hard as to resist the action of the atmosphere for many centuries. The cathedral of Dunkeld was built of stones from this district, and fully corroborates the above assertion. In the hills of Birnam the slate is of a very deep blue colour, bordering on violet; and the same is nearly the character of the limestone found at Rannoch, Glenlyon, Breadalbane, and the head of Strathearn. In Monteath is also a quarry of the same mineral, resembling marble, of a blue ground, with streaks of white.

Iron-stone appears in some parts of this county, but no mines of that metal have ever been opened, except on the southern side of the Ochils, about Culrofs, which, we may here observe, is the only coal district in Perthshire. A lead mine was wrought for many years near Tyndrum, in Breadalbane, as was likewise one in Glenlyon, but these are now both abandoned. Some lead ore was also discovered about twenty years back in the mountain of Ben-Ledi. One vein on the north-east side of the mountain was found to be extremely rich in silver, but its dimensions were too small to admit of its being wrought to advantage. In the hill of Birnam also, several pieces of lead ore have been dug up. This ore was encrusted with a white sparry, or rather quartzose substance. One piece, about six pounds in weight, consisted of unmixed compact ore, of a very small grain, which produced a considerable portion of pure lead, by mere roasting in a blacksmith's forge. It was found at the base of the hill, but the fissures on its summit are frequently filled with similar masses.

Slates are abundant in different portions of the county. The principal stratum commences on the borders of loch Lomond, in Dunbartonshire, and seems to terminate in the vicinity of Dunkeld. These slates are of two kinds, and called, from their colour, the blue, and the grey slates. The former, which are by far the most valuable, are plentiful in Monteath, and along the north side of the Ochils. Grey slates also are found in vast quantities in the same districts, as well as in Strathallan and Strathearn. They consist of sandstone, which may be split into thin layers, frequently six feet square, and are, since the introduction of blue slates in roofing, chiefly used for malt-kilns, floors, and pavement. In the parish of Wester Foulis is a blue slate quarry of great value, but it is not wrought to any very considerable extent, on account of its distance from water carriage.

The best quarries for free-stone in Perthshire, are those in the parish of Tulliallan on the Forth, and on the estate of Milnfield, in the south-eastern corner of the county. The former have long been held in high estimation; and were for many years wrought by a Dutch company. The latter, however, are still superior to them, and indeed may be justly reckoned the best in Scotland, if not in Great Britain. The stone from these quarries, on account of its fine quality, is commonly called Kingoody stone. It is of a greyish colour, difficult to work, and uncommonly hard and durable; so much so, indeed, that in several structures built of it four or five centuries ago, scarcely a single stone has yielded to the influence of the weather. The Milnfield quarries produce stones of all sizes, and for every purpose of building. Many of the blocks raised exceed fifty feet in height, and sixteen in breadth, and some are so thin as to be adapted for pavement, or for covering flat roofs.

In the vicinity of Drummond castle, and more especially close to Callender, that peculiar species of rock called breccia, or plum-pudding stone, is very common. It is composed of a vast variety of small rounded stones, cemented together

PERTSHIRE.

gether by a sort of brown lava. The rounded stones are of different colours, and are so firmly united, as to form one solid mass of rock, capable, when used as a building material, of withstanding the action of the atmosphere for ages. It is not, however, susceptible of being smoothed by the chisel, but admits of being dressed with the hammer. The vein of it above Callender runs in the direction of south-west and north-east, for a distance of many miles through lakes and rivers, mountains and vallies, in a line parallel with the slates and lime-stone strata, and at the distance of about a mile from each. The hill of Kinnoul, the most westerly of the Sidlaw chain of mountains, is indeed a perfect mineralogical curiosity, on account both of its peculiar structure and composition. The southern side presents a stupendous precipice of the most ragged rock, consisting of lava, in which different layers or currents are very evident. Some parts of this rock are perfectly compact; but the greater proportion of it is full of small cells, resembling those in the slag of an iron foundery. Its colour is generally of a greyish tinge, approaching to lilac. When melted, it forms a vitreous substance of a dark purple hue, so tenacious that it could easily be blown into bottles. Among the stones at the base of this hill, are frequently found very fine agates, which have fallen from the precipices above, where, by the assistance of a pocket telescope, great numbers may be seen sticking. Sulphate of barytes, rock crystal, and calcedony, also enter into the composition of this rock. Rhomboidal calcareous spar is likewise occasionally discovered here, together with a greenish coloured steatite, or soap-stone. A ridge of the last mentioned rock, about four miles in length, is found in the district of Monteth; and in the neighbourhood of Culrofs are extensive beds of fire clay.

From the intimate connection between the mineral springs of any county, and the solid mineral substances contained in its bowels, we may here mention that the most remarkable impregnated springs in Perthshire, are those of Pitkethly, which are famed for their efficacy in curing or alleviating the scrofula, scurvy, and gravel; while at the same time they give tone and vigour to the constitution. When these springs were discovered is unknown, as even tradition is silent upon the subject. They have, however, been much frequented for many years by patients from all parts of the country. See PITKETHLY.

Rivers.—Perthshire is most abundantly supplied with rivers, as various in their extent as they are diversified in scenery, and interesting from association with the events of history, or the strains of poetry. The principal among them are the Forth and the Tay, the former of which receives the Teath, the Allan, and the Devan, and the latter, the Earn, the Almond, the Lyon, and the Tummel, (which last is joined by the Garry, the Bruar, and the Tilt); also the Bran, and the united streams of the Isla, the Ericht, the Shee, the Eardle, and the Dean, all of which are justly deserving of separate notice, even in article so limited as the present. See FORTH.

The *Teath* has its source at Benharrow, near Glenfalloch. Shortly after its rise, it falls into loch Katharine, but issuing from it again at its eastern extremity, it forms loch Achray and loch Venachar. At Callender it is joined by the Balvay water, and meandering along by Lanrick and Downe castles, Blair Drummond and Ochertyre, enters the Forth near Drip. On this river is a valuable pearl fishery. See TEATH.

The *Allan* rises at Gleneagles, on the northern side of the Ochils. Its course is at once circuitous and winding, and its banks, especially from Dumblane to Lecropt, where it leaves Perthshire, exhibits some of the most beautiful scenery

of which Scotland can boast. Burns has made this river the theme of one of his finest songs.

The *Devon*, or *Dovan*, has its spring in the parish of Alva, whence it flows eastwards to the Crook of Devon, where it turns suddenly to the westward, and passing by Dollar, Tillincoutry, and Alva, pours its waters into the Forth, nearly opposite to its source, and only six miles from it, though it runs a course of about forty miles. This river is remarkable for several natural curiosities, called the Devil's mill, the Rumbling bridge, and the Cauldron Linn. The Devil's mill is formed by the water falling by a rapid descent into a basin excavated in the rock, and thence into a cavity under ground, in passing through which it is so strongly agitated by the peculiar construction of the enclosing rocks, that it emits a sound resembling that made by the movement of a large mill. The Rumbling bridge is situated about 350 yards below the mill. Here the precipitous banks of the river approach so close to each other, that an arch twenty feet span is sufficient to form the communication between them; yet the depth from the bridge to the water is upwards of eighty-six feet. It is called the Rumbling bridge, from the rumbling noise occasioned by the water falling from rock to rock in its passage through this almost hidden dingle. The Cauldron Linn is situated about a mile lower, and consists of two falls, not more than twenty-eight feet asunder. The first is thirty-four feet in height, and not more than twelve feet broad. The second fall is still higher, and between them are three round cavities, having the appearance of immense cauldrons, in the highest of which the water is in constant agitation, as if boiling, while the second is always covered with foam, and the third is uniformly calm and placid. These cauldrons are of different dimensions, the smallest being about sixteen feet, and the largest twenty-two feet in diameter. When the river is low, they are seen to communicate by apertures formed by the force of the water, through the rocks which separate them at perhaps the middle depth of the cauldron. Hence the great cauldron which communicates with the lower fall is perforated with a large opening, resembling a window, out of which the entire body of water precipitates itself over the rocks with much violence, and with a very striking and picturesque effect, particularly if viewed from below, when the sun shines on the rising vapour, and tinges it with the varied colours of the rainbow.

The *Tay*, the largest river in Scotland, has its source in the western extremity of Perthshire, in the district of Breadalbane. In its current to the German ocean, it forms two large lakes, loch Dochart and loch Tay, and terminates in an estuary equally important as the Forth. (See TAY River.) The Earn, which joins the Tay, takes its rise from a lake which bears its name near the mountain of Benvoirlich. It flows through a luxuriant tract of country, which is designated by the general appellation of Strathearn, and is bounded on one side by the Grampian, and on the others by the Ochil hills. The Almond springs from a glen in the Grampians, called the Narrow glen, and proceeding by Logie-Almond, Methven, and Rodgerton, discharges its waters into the Tay above Perth. The Lyon descends from glen Lyon, and runs a course almost as long as the Tay itself, before it loses its name by its junction with that river. The Tummel, which enters it at Logiereat, eight miles above Dunkeld, is still a longer stream, and is distinguished by a lake named loch Rannoch, and by some of the finest falls to be met with in Great Britain. In its course it is joined by the Garry, which unites the streams of the Bruar and the Tilt. All these rivers run with the usual rapidity of mountain torrents, and display, at different parts of their currents, several fine cascades, and much picturesque scenery. One

PERTHSHIRE.

of the falls of the Bruar is upwards of two hundred feet in perpendicular height, but is broken by projecting rocks into three divisions, which rather heighten, however, than diminish the grandeur of the scene. On the Garry, below its junction with the rivers above-mentioned, is the celebrated pass of Killiecrankie, near which viscount Dundee, one of the most intrepid generals of James VII. defeated the forces of king William, under general Mackay, with the loss of two thousand men, but fell himself in the action.

The next river to the north-east, that falls into the Tay, is the *Bran*, on the banks of which, at the distance of about a mile from the village of Inver, is one of the most enchanting scenes in nature. The path leading from the village is finely ornamented, and terminates in a building resembling a small temple. This structure is called Ossian's hall, or the Hermitage, but the ideas connected with either of these names are by no means applicable to it. In front is a vestibule, adorned with a picture of the aged Ossian, which being removed by sliding into the wainscot, the visitor enters an interior apartment, from the windows of which the most sublime and enchanting view imagination can conceive bursts upon the sight. The two rocky sides of the river almost uniting, compress the stream into a narrow compass, and the channel being oblique in its descent, the water is forced with unusual violence over a mass of rocks, undermined, disjointed, and fractured into a thousand different forms. At the bottom of the fall is a deep abyss, in which the wheeling waters suffer an agitation, of another kind, but scarcely less violent. The whole scene is finely shaded with trees; and to those who admire the efforts of art more than the simplicity of nature, is greatly heightened by the reflection of embossed mirrors, which almost completely cover the sides and ceiling of the hall. A natural cave higher up this river, is called Ossian's cave, from a tradition that it was the occasional retreat of the Celtic bard.

The other rivers which remain to be noticed, *viz.* the Isla, the Erich, the Shee, the Eardle, and the Dean, with the exception of the last, also present scenes of the most picturesque description, and scarcely inferior to those we have already mentioned. On the Erich, indeed, about two miles north from the village of Blairgowrie, is a scene of a peculiarly romantic character. Here, for an extent of 700 feet, both banks are 220 feet in perpendicular height, and are formed of rock, as smooth as if it had been chiselled by the hand of art, but shaded with a profusion of trees, and a great variety of curious plants.

Lakes.—Perthshire is no less fruitful in lakes than in rivers. These are spread throughout every district of the county, but are most numerous in its western division. Some of them are formed by the expanded waters of the rivers, in their course through glens, hemmed in on all sides by lofty hills; and others are formed simply by the occasional currents which pour down the mountain declivities. The principal among them, for extent and beauty of scenery, are loch Rannoch, loch Tummel, loch Dochart, loch Tay, loch Earn, loch Lubnaig, loch Doine, loch Voil, loch Conar, loch Ard, loch Monteath, loch Van-a-choir, loch Achray, and loch Katharine.

Loch Rannoch is formed by the streams of the Gawer and the Erich, and is about twelve miles long, and from one to two in breadth.

Loch Tummel is situated below loch Rannoch, on the river which bears its name.

Loch Dochart is formed by the river Fillan, the principal branch of the Tay. It is upwards of three miles in length, and is distinguished by very fine and romantic scenery, its banks being precipitous, and covered with a profusion of

trees. In this lake is one of those natural curiosities, called a floating island, also a stationary island, overhung by a huge promontory, and adorned with the ruins of an ancient castle. The stream which flows out from the lower extremity of this loch is called the Dochart. It discharges its waters into loch Tay, one of the finest lakes in Scotland, extending about fifteen miles in length, and from one to two in breadth. Its banks are beautifully winding, and diversified with wood and lawn, bold and sloping mountains. This lake has at different times, like loch Lomond, suffered violent and unaccountable agitations.

Loch Earn is the source of the river of that name, which falls into the Tay. It is eight miles and a half in length, and one and a half in breadth. For about five miles on each side its banks display a great profusion of natural oak-wood, and as great a variety of beautiful scenery as any district of similar extent in North Britain. Near each end is a small island, evidently artificial, on one of which are still seen the ruins of a castle. The mountain of Benvoirlich, at the head of this lake, is distinctly visible from the castle of Edinburgh, and from the vicinity of Loudon castle, in Airshire.

Loch Lubnaig is the lowest lake on the river Balvaig. It is above four miles in length; but is extremely narrow, "presenting the same picture with most of our Highland lakes, of a sheet of water arrested in a deep ravine, and thrown back by obstacles from the lower extremity." Such is likewise the character of *loch Doine* and *loch Voil*, which are placed higher up the same river. In the middle of loch Lubnaig is a tremendous rock, called Craig-na-Coleilg, the "Rock of the Joint Hunting," from having been the boundary between the estates of two ancient chieftains, who were wont to meet here on sporting days, and to hunt round the rock in common, after which they separated, each turning towards his own property, to denote that he was at the utmost boundary of his possessions.

Loch Conar, or *Chon*, is situated near the confines of this county with Stirlingshire, and between the stupendous summits of Ben Lomond and Ben Venue. It is nearly three miles in length, and one in breadth. In its bosom are several islets, which as well as the banks are clothed with trees and herbage.

Loch Ard lies to the east of loch Conar, and partakes of the same character of scenery, but is larger, and more irregular in its figure.

Loch Monteath, or *Monteith*, situated in the district of that name, is admired as one of the finest lakes in Scotland. It is nearly of a circular form, and measures about five miles in circumference. Its banks, which are only gently elevated, are well furnished with trees. On the north side, close to the water, stand the manse and church of Monteath, together with an elegant mausoleum, lately erected for the Garthmore family. But the most distinguished ornaments of this lake are its two islands, both of which are decorated with the ruins of ancient buildings. On the larger one are the remains of a priory, founded and endowed by king David I., which displays some fine specimens of "Gothic" sculpture. The ruins on the smaller island are those of the ancient residence of the Grahams, earls of Monteath.

Loch Van-a-choir, *loch Achray*, and *loch Katharine*, are all expansions of the river Teath. The first is about four miles in length, and the second somewhat more than one; they abound with salmon, trout, and pike, and exhibit at different points some fine and delightful views. The last, however, far excels the others in every respect, and is indeed at

PERTHSHIRE.

once among the most intertelling lakes any country can boast of; whether we consider the alternate beauty and grandeur of its scenery, or the classic charm it has derived from the creative imagination, and descriptive talents of the author of "The Lady of the Lake."

Soil, Climate, and Agriculture.—Perthshire, with respect to these subjects, is naturally divided into three districts, which differ from each other very materially. These divisions are termed the Highland district, the Lowland district, and the district of the Carse of Gowrie.

The Highland district, which comprehends by far the larger portion of the county, is included within, or rather formed by, the Grampian mountains. In relation to the whole extent of the Scottish Highlands, it constitutes what are usually denominated the Central or Southern Highlands, in contradistinction to those of Argyleshire, or the Western Highlands, and those of Invernesshire, or the Northern Highlands. It may also be regarded as the central district of the whole kingdom of Scotland, and is subdivided into small portions, marked by glens or valleys, called Rannoch, Glenlyon, Glenloch, Glendochart, Glenqueich, Glenshee, the environs of loch Tay, and Strath-Tay. Throughout this vast tract of country, contrary to what might be supposed from its northern latitude, the elevation of its valleys, and the altitude and naked aspect of its towering mountains, the climate is not less mild than in the moor-lands of Yorkshire. Indeed, the mountains of Perthshire may even claim an equality in temperature with those of Cornwall and Devonshire, and certainly surpass them in dryness of climature, excepting on the western margin of the district, where the quantity of rain which falls is immense. The soil in the valleys here consists in general of a brown loam, of uncommon fertility, lying on a sound, dry gravelly, or sandy bottom. A similar soil prevails on the sides of the hills to a considerable height, and is not unfrequently found under the black moory earth of the heaths. What is remarkable, the slopes of the mountains facing the north are much more productive than those which possess a southern exposure. This phenomenon is accounted for, by the supposition that the soil suffers more exhaustion on the south than on the north, because of the greater alternation of rain and snow, and of heat and cold, to which the surface of the former is liable, from the action of the sun-beams, and the greater frequency of southern rains. In this district few of the valleys contain large areas of free cultivable land, like those found in the south; and even the scanty areas that do exist have required in general the aid of human industry to clear them of the rocks which have been torn from the impending mountains. Yet as the glens are numerous, it happens here, as in most parts of the Highlands where modern sheep or cattle-farming is not prevalent, that each farm possesses its pittance of hill and dale, and its share of every description of land, as arable, meadow, green pasture, and moor. The arable lands have a two-fold distinction, the infield and outfield lands; the first of which, lying near the farm-yard, is kept constantly in tillage, and receives all the manure the possessor can collect; while the latter, consisting of such plots at the lower parts of the valleys, are level enough to be ploughed, are kept in corn and natural ley, or weedy wastes alternately, without the smallest assistance of manure. The wet plots in the vales are termed meadow, and kept uniformly under the scythe, for a scanty supply of hay. The faces of the "braes," the roots of the hills, the wood or rough stony wastes of the bottoms, and a small plot near the house, are generally appropriated to cattle in summer, and sheep in winter; the sheep and horses being kept in summer "above the head dyke," upon the hill or

minor lands. These are laid out, or distributed in different ways, as chance may have determined; lying sometimes contiguous to, or immediately above the pasture lands, and sometimes detached from the rest of the farm entirely. Sometimes they are appropriated to a particular farm, but are more frequently in a state of commonage.

Such is the general description of the Highland farms of Perthshire; whence it may reasonably be concluded, that the husbandry of this district is not in a very advanced state. This, however, does not arise from a want of knowledge, or even of industry, among the farmers, but from the peculiar constitution of society in the more northern portions of our island. Before it can be remedied, the farms, now in general small, would require to be increased greatly in extent, and the farmer assisted with capital, should he be deficient in means of his own. The pride of clanship among the proprietors ought to be laid aside, and the eventual interests of the country studied, instead of the misapplied philanthropy, which constitutes the ruling motive for continuing the small farm system. That useless and idle race of occupiers or sub-tenants, called acre-men or crofters, must likewise be extirpated, to facilitate the agricultural improvement of this district. For some further observation on this subject, see SCOTLAND.

The only crops raised here are oats, bear or bigg, flax, and potatoes, and on some spots pease. Wheat is never sown. The business of the flax-harvest, in particular, is well conducted. Indeed, in the management of that article, the Highlanders may be said to excel.

The Lowland district includes all that portion of Perthshire which lies to the south of the Grampians, with the exception of the Carse of Gowrie, to be afterwards noticed; viz. part of Strathmore (see STRATHMORE); and those districts of the county, the streams of which flow into the Forth, or the Earn. Along the Forth, for an extent of eighteen miles from Garthmore to the bridge of Allan, the soil of the level lands is a deep, rich clay, of various degrees of fertility. This soil, however, is still covered, for about four miles, by a tract of moss from six to fifteen feet deep, called the *Moss of Kincardine*, because situated chiefly in the parish of that name. This moss is supposed to have once covered the whole valley, and was well worthy the investigation of the naturalist. By the exertions of the late lord Kaimes, however, and by the judicious liberality of its proprietors, it now rapidly diminishes in size, and will doubtless be entirely cleared in a few years. It is wholly let out on leases of thirty-eight years, in proportions of eight acres, to different tenants, who pay no rent for the first seven years, and only one or two marks Scots for the succeeding thirteen years, and twelve shillings for each cleared acre during the last nineteen years. The number of men settled on this moss, in 1801, was 115, of women 113, boys 119, and girls 193.

In the low grounds of Strathearn, wheat is the great object of husbandry, generally after summer fallow, but frequently also after clover ley. In the upper parts of the district, barley and oats are the principal crops. The culture of flax is universal over the whole district, but is not carried to a great extent in any one place. Potatoes are raised in vast quantities on the light soils, as are likewise turnips, especially within the last ten years. Farms here vary in size, from 30 to 400 acres, and are for the most part managed upon the most approved system. The greater part of this district, however, is yet uninclosed. The manures chiefly in use here are lime and marle, of which last article there is great abundance found in the small lakes, and in the land-locked bogs and mosses.

PERTHSHIRE.

The third agricultural district of Perthshire, or the Carse of Gowrie, is situated along the northern shore of the frith of Tay. It is a long, narrow plain, and extends sixteen miles in length: it contains about 18,000 acres of extremely rich and fertile soil. This district, indeed, may be justly styled the boast of Great Britain for natural productiveness, and yields to no portion of the globe in the intelligence and skill of its farmers. Like the Delta land of Egypt, and those fertile tracts adjacent to the mouths of the Ganges, the Indus, and the Mississippi, the Carse of Gowrie has been formed in a long course of ages, and has grown rich by the spoils of the Highlands. The heavy rains which fall near the sources of the Earn, the Tay, the Tummel, the Garry, the Isla, and their tributary streams, have washed down great portions of soil, and have laid bare the rocks of the highest mountains to give exuberance to the banks of the Tay. The Carse, in fact, is evidently nothing more than what is called in other quarters sea-mud, or sleet, consolidated by time and gradual deposition. The substrata here are various, and might form a subject of curious and interesting investigation. The soils also differ. On the banks or braes of the Carse, which slope gently with a southern aspect, the soil is a hazle-coloured loam, except in the higher part of the ascent, where it is a sharp gravelly kind. In the "Low Carse," clay is the prevailing soil. Here the farms are classed into six divisions, as nearly equal as the nature of the ground will admit, and the following rotation is that most generally approved of: 1st year, summer fallow,—the land dunged; 2d, wheat; 3d, pease, or pease and beans; 4th, barley, with clover and rye-grass; 5th, clover; 6th, oats. Sometimes, however, fallow is excluded, and some green crop substituted. This happens almost universally on the banks or braes of the Carse; and on the higher grounds, the raising of wheat is only very partial, and the third, fourth, fifth, and sixth years are generally appropriated to hay or pasturage, the seventh to oats, and the eighth to barley. The climate of this district is mild, and favourable to vegetation, beyond perhaps any other in Scotland, as it is completely sheltered, on all sides, by lofty mountains, and by plantations of various kinds of trees. Farms are generally from 100 to 300 acres in extent, and are let on leases of nineteen years, at as high a rent as any field-land in Great Britain. The only artificial manure used is lime; for which nearly 2000*l.* is paid annually to the lime-works in Fife, or in England.

The *live stock* of this county consists of horses, cattle, sheep, fowls, bees, and swine, except in the Highland district, where the fow, till lately, was still a more rare phenomenon than a well-cultivated farm. The horses of this district, on the other hand, are too numerous, and almost wholly of the common Highland breed, as well as the cattle. The sheep, however, have of late undergone a considerable change, by intermixture, and are certainly improved. In the Lowland district, and in the Carse, the horses are an active, middling-sized breed; and in the latter district are many of a heavier kind, for the use of the plough in the lower grounds, where the soil is deep and heavy. Few black cattle are reared in either district, but a certain number of cows are kept by every farmer. On the Ochil hills, and in almost all the mountainous districts, sheep are reared in great abundance. They are mostly of the black-faced breed.

Woods and Plantations.—In ancient times a great proportion of this county was covered with thick forests of oak. In the mosses are found vast collections of trees, some of them of immense size, which have evidently been cut from their trunks by the hand of art, and as tradition reports, by the Romans, when they first crossed the Forth under Agrico-

la. The forest of Blackironside, on the banks of the Earn, is particularly noted in history, as the scene of many of the exploits of the celebrated sir William Wallace and his gallant followers. In the Highland district was the forest of Manlorn, now converted into sheep farms, besides other large forest tracts, which it is unnecessary to particularize, as the whole of them have been in a great measure destroyed. Perthshire, however, still contains many extensive woods, formed within the last fifty years, of which those of the duke of Athol, in the Highlands, are by far the largest and most valuable, and abound with deer and a variety of other game. Most of the gentlemen's seats in the county are also shaded by plantations. Indeed the spirit of planting has gone abroad here, with a degree of energy seldom paralleled in any country in Europe; and will, no doubt, eventually produce the happiest effects.

Civil and Ecclesiastical Divisions and Government.—Perthshire, like every other county in Scotland, is placed under the jurisdiction of a lord lieutenant or high sheriff, and a sheriff depute, who has the privilege of appointing a substitute to hold courts in his absence. The whole is ecclesiastically divided into sixty-seven parishes, of which nineteen belong to the Highlands, and forty-eight to the Lowlands. Of these, nineteen are included in the presbytery of Dunkeld, twenty-one in the presbytery of Perth, fifteen in that of Auchterarder, and eleven in that of Dunblane, all in the synod of Perth and Stirling. In this county are two royal boroughs, Perth and Culrofs, and a number of considerable towns and villages, of which the principal are, Downe, Callender, Scone, Dunblane, Comrie, Crieff, Auchterarder, Dunning, Abernethy, Dunkeld, Alyth, Cupar, Angus, Blairgowrie, and Longforgan.

Manufactures.—The grand object of manufacturing industry in Perthshire is the linen trade. Great quantities of linen yarn are annually spun by the women, and in every village are a number of weavers, who convert the produce of their labour into cloth, a great part of which is sold to the merchants of Perth, Dundee, and Glasgow, in its unbleached state. A large portion of it, however, is likewise bleached within the limits of the county, both for private use and for exportation. In the vicinity of Perth, and in other districts, are not less than eight or ten different bleach fields on a large scale.

Antiquities and Historical Events.—Perthshire displays a field of great interest to the antiquary, as well as to the historian. Lying north of the Roman wall it was the scene of many conflicts, fought in support of the last gleam of Caledonian independence in the Lowlands. From a passage in Claudian, we learn, that the Earn was frequently dyed with blood.

"Scotorum cumulos flevit glacialis Jerne."

And Tacitus informs us, that at the foot of mount Grampius, Agricola encountered and overthrew the heroic Galgacus. The precise spot on which this battle took place is not certain, but a variety of conjectures have been hazarded upon the subject, of which the most probable is that which fixes it in Stormont, where a large Roman encampment is still visible, together with a numerous collection of cairns, the indubitable memorials of Caledonian strife. At Ardoch is another encampment, probably the most perfect example of ancient castrametation in Great Britain, and near it are two smaller ones, less perfect in their construction. There is likewise a Roman encampment at Ochil, which communicates with Ardoch by a raised road, or causeway. Vestiges of a strong military earthen work are also to be traced about two miles from Monzie; and on the hill of Dummore is another

another fortification, said to have been Fingal's place of residence, after the destruction of his house in the vale by Gara. This fort is defended by a deep ditch and rampart; and is doubled walled, each wall measuring twenty feet in thickness, and consisting of immense stones piled up without cement of any kind. A similar fort, of still larger dimensions, is situated two miles eastward from Fienteach; and on the moor adjacent to it are numerous cairns and tumuli, one of which is assigned to Comhal, the father of Fingal. Near Culloquhey is a small fort, called in Gaelic, Comhal Kuils, *i. e.* Comhal's battle. At this place, tradition reports that Ossian was buried, and a stone vault, or coffin, is still visited as his. Druidical monuments are frequent in this county; such as circles, rocking stones, and single upright stones, denominated "Stones of Worship," to which the common people yet pay no inconsiderable degree of superstitious regard. Indeed some remnants of the Druidical worship may be said to linger here, as many of the Highland customs have an unquestioned reference to that religion. The first day of May, held sacred by the worshippers of the sun, continues to be distinguished by the appellation Beltan, or Baal-tein, "The Fire of Baa," and in some parts of the country is still celebrated by festivals of milk and eggs. See SCOTLAND.

In the church yard of Meigle are the remains of the grand sepulchral monument of Vanora, also called Vanera, Wanor, and Guineva, the British Helena, according to Prideaux. This princess was the wife of Arthur, but being taken prisoner by the Scots and Picts, she lived for some time, in miserable captivity, on Barry-hill. Some assert that she was one of the most abandoned debauchees of her sex; and that having been torn to pieces by wild beasts, this tomb was raised to perpetuate her infamy, and the manner of her death. The truth of his story, however, is extremely doubtful, and has perhaps arisen from the symbolic characters on the monument, most of which are of the monstrous kind, and represent various acts of violence on the person of a woman. This tomb is described in Pennant's Tour, and the description is accompanied by several plates. See VANORA.

Religious houses were frequent in this county, some of which still exhibit some fine specimens of ancient architecture. At Culross are the ruins of a Cistercian abbey, founded in 1217 by Malcolm earl of Fife. (See CULROSS.) And at Scone was a celebrated Augustine monastery. (See SCONE.) The cathedral of Dunblane stands on an eminence above the town; and part of it is kept in repair as the parochial church. (See DUNBLANE.) That of Duakeld is one of the finest piles of ancient buildings in Scotland, and is now undergoing a thorough repair. It is of mixed architecture, having been erected at different periods. (See DUNKELD.) The other religious houses in the county were the following.

Abernethy priory, founded A.D. 1273, for monks of the Augustine order.

Elcho nunnery, the Cistercian order, date of foundation uncertain.

Inchaffray abbey for Augustine canons, founded A.D. 1200.

Inch-Mahome abbey, also Augustine, date uncertain.

Perth. Cistercian nunnery, dedicated to St. Leonard, 1296.

Perth. Methven llege church, 1433.

———. Monastery vallis virtutis, for Carthusian monks,

1429.

Perth. Dominican convent, founded 1231.

———. Convent ervan, founded 1460.

Strathfillan priory in Breadalbane, founded by king Robert Bruce for reclus of the Augustine order.

Loch Tay priory, likewise Augustine, founded by Alexander I., A.D. 1222.

Suggeden hospital on Tay, founded ante 1296.

Tullibardine college church, founded 1446. See TULLIBARDINE.

Tullilum Carmelite convent, founded A.D. 1262.

Castles, Palaces, &c.—Perth, Scone, and Abernethy, having been early royal residences, were each adorned with stately palaces, which are now entirely demolished. Those of the two first mentioned towns fell a prey to the fanatical fury of the reformists. Many castellated mansions, however, yet exist in different districts of the county, and would be well worthy of description, would our limits allow. The most remarkable among them are castle Campbell, Finlanrig castle, castle Comrie, Doune castle, Ballumbri castle, Garth castle, Elcho castle, Kinnaird castle, Gowrie house, Murthly house, Kinfaun's castle, Macbeth's castle of Dunfinnan, Hunting tower, or Ruthven castle, Balloch castle, the residence of lord Breadalbane, Blair castle or Athol house, and Drummond castle. Some of these are in ruins, and some have been so much modernised as to alter in a great measure their original appearance. Beauties of Scotland, vol. iv. Sketches of Perthshire by the Rev. P. Graham, D.D. Edin. 1812, 2d edit. 8vo.

PERTI, GIO. ANTONIO, in *Biography*, a solid, grave composer of church music, *alla Palestrina*, was born in 1656. With his theatrical style we are unacquainted; but as he long continued to be employed, not only for the operas of Bologna, but Venice and other cities of Italy, we may reasonably imagine that it was excellent. Paolucci has printed a good duet by this master, in the church style; and Padre Martini has given several admirable specimens of his science in his "Saggio di Contrappunto." This great harmonist, however, does him still more honour, by calling himself his disciple. Perti, before his decease, must nearly have attained the age of 100; for his name appears as the composer of *Atide* in 1679, and, according to Quadrio, he was living in 1744.

PERTICA, in *Astronomy*, a sort of comet, being the same with *veru*.

PERTICA, among the Romans, a long rod for beating the fruit from trees. It was likewise used for a long measure. See PERCH.

PERTICATA, or PARTICATA *Terre*, in our *Old Law Books*, is the fourth part of an acre, or a piece of ground containing one perch in breadth, and forty in length. See ROD, and PERCH.

"Continet in integra superficie 40 perticas."

PERTICI, in *Biography*, a comic singer and admirable actor, came hither in 1748 with Larchi, another excellent comic singer and actor, and Guadagni for the first time, when he was very young, as serious man in a troop of burletta singers, brought over upon speculation by sig. Croza, whose calculations were so erroneous, that he became a bankrupt and a fugitive in a year's time.

PERTICULAS, poor scholars of the isle of Man. The king granted to "L. Mauguin de insula de Man, scholari, quandam eleemosynam vocatam Peticulas, ad sustentationem cujusdam pauperis scholaris, de insula predicta ad exercend. scholas, per progenitores nostros quondam reges Angliæ datam et concessam." Pat. Hen. IV.

PERTIGI, in *Geography*, a town of the island of Sardinia; 19 miles S.E. of Castello Aragonese.

PERTINAX, PUBLIUS HELVIUS, in *Biography*, a Roman emperor, was born in the reign of Adrian, A.D. 126.

His

His father was a freedman, by occupation a maker of charcoal; but notwithstanding his humble condition, he took care to give his son a literary education. The young man first employed himself in teaching at a grammar-school, but dissatisfied with a sphere that gave no hope of advancement, he entered into the army, and served as a common soldier in Syria. He soon obtained considerable rank, and at length the government of the two Mærias was committed to him, and afterwards that of Syria, which he held till the accession of Commodus, in the year 180. Upon this event he returned to Rome, where he passed three years in retirement. During this period he employed himself in embellishing his native place with several elegant buildings; but he permitted his father's house and shop to remain unaltered, as a memorial of his humble origin. He was now sent by the emperor into Britain, where the legions were in a state of great disaffection and indiscipline. The soldiers would very willingly have transferred their allegiance to Pertinax, but he preserved his fidelity inviolate, and incurred much personal danger in quelling the mutinous spirit of the troops. At length he was recalled, and appointed to the important trust of superintending the supply of Rome with provisions. After this he was made proconsul of Rome, twice a consul and governor of Rome. Pertinax was in possession of this last office, when the tyranny of Commodus brought his detestable reign to an end; and he succeeded to the imperial purple, by an apparently free election. All the measures of his short reign were directed to the public good. He found the treasury empty, which he replenished by a public sale of all the articles of prodigal luxury which he found in the palace. He himself adopted a frugal and simple mode of living, and by it, which has been condemned as the meanest parsimony, he was enabled to abolish many oppressive taxes, and he shewed a great disinterestedness and disregard to the accumulation of wealth, by declaring that he would accept of no legacies from persons who left children or other lawful heirs. He discouraged all informations for treason, and administered justice with equal mildness and impartiality. Such a course of conduct was not likely to please those who had profited from the vices of Commodus; and plots were soon formed to subvert the new government. While Pertinax was absent at Ostia, an attempt was made to raise to the throne the consul Falco. He hastened back and com-

plained of the fact before the senate, but when that body proposed to condemn Falco as a traitor, he declared that no senator should suffer death in his reign, and dismissed him in safety. A spirit of mutiny was by false representations excited among the guards, and three hundred of them proceeded with drawn swords to the palace. The emperor's officers and friends sought for safety by flight, but Pertinax disdained even to conceal himself. He appeared before them with a firm and intrepid air, and expostulated with them upon their conduct, which made such an impression on the minds of the conspirators, that they began to sheath their swords. At this critical moment a Tungrian soldier threw his javelin at the emperor's breast, and the feeling of respect being thus dissolved, the rest rushed in, and dispatched him with many wounds. When he saw that his fate was inevitable, he wrapt his head in his toga, and fell without a struggle. This event took place on the 28th of March 193, after a reign of only three months. Electus, and some other of his attendants, who attempted to defend him, were also slain; his son and daughter only escaped, who happened at the time to be out of the palace. From the number of his adventures, he was called the tennis-ball of fortune, and no man experienced so many changes in his life, with so blameless a character. His character is highly spoken of by contemporary historians, and his memory was highly revered by the Roman people.

PERTISTEGNO, in *Geography*, a town of Italy, in Friuli; seven miles N.N.W. of Friuli.

PERTUIS, a town of France, in the department of the Vaucluse, and chief place of a canton, in the district of Apt; 12 miles S.S.E. of Apt. The place contains 4000, and the canton 12,601 inhabitants, on a territory of 337½ kilometres, in 14 communes.

PERTUIS *d'Antioch*, a strait, or narrow part of the sea, between the isle of Oleron and the isle of é.

PERTUIS *Breton*, a narrow strait of the sea, between the isle of Ré and the coast of France.

PERTUIS *de Maumussou*, a strait between the isle of Oleron, and the coast of France, S. of the island, about one mile wide.

PERTURBATION *of the Planets, &c.*, in *Astronomy*. See PLANETS, MOON, SATELLITE, and SOLAR SYSTEM.
