POETRY.

POETRY, POESY, has been defined by some writers to be the art of composing poems, or pieces in verse. But that this definition does not convey a just idea of the nature and art of poetry will sufficiently appear in the sequel of this article.

The word is formed from the Greek ποιησις, of ποιειν, *facio, I make.*

If a verse be considered as a mere series of just six feet following one after another in the same line, poetry and versification will appear two very different things; but Bossu, in his idea of verse, includes cadences, peculiar constructions, arrangements, and expressions unknown in common discourse; and, above all, a certain noble, bold, elevated, and metaphorical turn and manner of diction. These, he observes, are so essential to poetry, that without them the most exact arrangement of long and short syllables makes little else but a kind of measured prose; whereas these, in a discourse that has no poetical feet or measures, do yet give it the poetical character, and make it a kind of *unmeasured* poetry.

The rules of poetry and versifying are taught by art, and acquired by study; but this force and elevation of thought, which Horace calls *something divine*, and which alone makes the poetry of any value, must be derived from nature; or, according to Aristotle, from some happy transports, to which that author gives the name of madness: Ευφροσύνη ἢ ποικιλία ἐστὶν ἡ μακρολογία. But there must be conceived a just solid judgment, to direct and govern this fury of the poet's imagination.

Hence the critic concludes, that *the end* of poetry is to please; *its cause*, either the excellence of the poet's genius, or a poetical fury, and transport of the soul, manageable by the judgment; *its matter*, long and short syllables, and feet composed of them, with words furnished by grammar;

and *its form*, the arrangement of all these things in just and agreeable verse, expressing the thoughts and sentiments of the author, after the manner already mentioned.

But, after all, how narrow are these bounds, if we consider poetry in the light in which the works of Homer and Virgil have set it? What is here laid down pretends to no praise, which a mere translator may not rise to, and which the war of Cataline might not merit, if turned out of the prose of Sallust. It is with reason, therefore, that we distinguish the *low* and *simple* from the *greater* poetry; by giving the former the title of *versification*; and that we make *poetry* and *versification* two distinct arts: in effect, there is not more difference between grammar and rhetoric, than between the art of making verses, and that of inventing poems.

The *greater* poetry, then, consists principally in fiction, or the invention of fables; in the expressing of things by allegories, and metaphors; and in the inventing of actions, under which the truths which the poet has to teach may be agreeably disguised.

Poetry, says an ingenious writer (see Percival's Essay on the Fine Arts), comprehending under the term all numerous and rhetorical composition, derives most of its charms from allusions, similes, metaphors, or descriptions; and these are obviously imitative. In this way, its powers are so transcendent, that even a single epithet will sometimes produce a representation more picturesque, than the pencil of Poussin or Salvator Rosa ever exhibited. The first line in the following stanza of Gray's elegy, will afford an example, and a proof of what is here advanced.

“ Now fades the *glimmering* landscape on the sight,
And all the air a solemn stillness holds,
Save where the beetle wheels his droning flight,
And drowsy tinklings lull the distant folds.”

B

The

VOL. XXVIII.

The accuracy and force of the word *glimmering* must be felt by any one who has viewed, with attention, an extensive prospect, about an hour after sun-set.

In this view, scarcely any poems retain the nature and essence of the grand poetry, but the epopœia, tragedy, and comedy; the rest, be they elegies, satires, songs, or what they will, come under the name of versification.

Critics, says Dr. Blair, have differed, and disputed much, concerning the proper definition of poetry. Some have made its essence to consist in fiction, and support their opinion by the authority of Aristotle and Plato. But though fiction may have a great share in many poetical compositions, yet many subjects of poetry may not be feigned; as where the poet describes objects which actually exist, or pours forth the real sentiments of his own heart. Others have made the characteristic of poetry to lie in imitation; but in this respect it does not differ from other arts, which are imitative, as well as poetry; and besides, an imitation of human manners and characters, may be carried on in the humblest prose, no less than in the most lofty poetic strain. The most just and comprehensive definition of poetry, in this author's opinion, is, "that it is the language of passion, or of enlivened imagination, formed, most commonly, into regular numbers." The primary aim of a poet is to please, and to move; and therefore he addresses the imagination and the passions; whereas, the aim of the historian, orator, and philosopher, being to inform, to persuade, or to instruct, they address themselves, for the most part, primarily to the understanding. The poet, however, may and ought to have it in his view, to instruct and reform; but it is indirectly, and by pleasing and moving, that he accomplishes this end. To the same purpose it is observed by the eminently learned and judicious bishop Lowth, that poetry is commonly understood to have two objects in view, namely, advantage and pleasure, or rather an union of both. The learned prelate has thus adopted the sentiment expressed by Horace in the following verse, "aut prodesse volunt, aut delectare poetæ." But he wishes that utility had been proposed as the ultimate object of poetry, and pleasure as the means by which that end may be effectually accomplished. It must be allowed, however, that there are poems which merely delight; the excellence of which is founded upon the same principle with that of a beautiful picture, which is more valued for contributing to pleasure only, than many other things are for their actual utility. The philosopher and the poet, Dr. Lowth observes, seem principally to differ in the means by which they pursue the same end. Each sustains the character of a preceptor, which one supports by teaching with accuracy, with subtlety, and with perspicuity, and the other, with splendour, harmony, and elegance. The one makes his appeal to reason only, independent of the passions; the other addresses the reason in such a manner, as even to engage the passions on his side. The one proceeds to virtue and truth by the nearest and most compendious ways; the other leads to the same point through certain deflexions and deviations, by a winding, but pleasanter, path. It is the part of the former so to describe and explain these objects, that we must necessarily become acquainted with them; it is the part of the latter so to dress and adorn them, that of our own accord we must love and embrace them. Hence the prelate lays down as a fundamental maxim, that poetry is useful, chiefly because it is agreeable; and he concludes, with due respect to philosophy, that the writings of the poet are more useful than those of the philosopher, inasmuch as they are more agreeable. This assertion he vindicates and establishes by a variety of

apposite examples, and he applies it to the different species of poetry.

In heroic poetry, *e. gr.* the poet teaches not by maxims and precepts, and in the dull, sententious form; but by the harmony of verse, by the beauty of imagery, by the ingenuity of the fable, by the exactness of imitation, he allures and interests the mind of the reader, he fashions it to habits of virtue, and in a manner informs it with the spirit of integrity itself. If from the heroic we turn to the tragic muse, to which Aristotle (Poet. cap. ult.) indeed assigns the preference, because of the true and perfect imitation, the superiority of poetry over philosophy may be evinced, on the principle of its being more agreeable. It is allowed, however, that no man ever arrived at the summit of poetic fame, who did not previously lay the foundation of his art in true philosophy, properly and extensively understood.

An agreeable writer, to whose Essays we have already referred, adduces a number of instances, in which ancient and modern poets have deviated widely from nature, by adopting facts and opinions, without examination, or on insufficient authority. Who, for instance, can notice the countenance of an ox, without perceiving that it displays meekness, patience, and the most inoffensive disposition, thus described by Mr. Thomson,

" ————— And the plain ox,
That honest, harmless, guileless animal;"

and that the eyes of this animal are of no unusual dimension. Nevertheless, in many versions of Homer, that divine poet, so conversant with zoology, is made to style the artful, proud, and passionate queen of the gods, "ox-eyed Juno." This mistake of the translator has evidently arisen from the want of attention to nature. And M. Dacier has shewn, that the particle *βε* is only an augmentative signifying (*valde*) large-eyed; and that it has no direct relation to the ox. Dr. Young has also fallen into an error, more pardonable, in his paraphrase on Job; because an English poet, who has never seen the crocodile, might be ignorant that his eyes are remarkably small. If this animal be, as some have supposed, the leviathan, described in the 41st chapter of that book, the following must have a reference to the brightness, and not to the magnitude of his organs of sight, as Mr. Aikin, in his elegant and ingenious essay on the application of natural history to poetry, has judiciously remarked. "By his neefings a light doth shine; and his eyes are like the eye-lids of the morning;" (ch. xli. 18.) Dr. Young, by a misconception of the original, has rendered this strong figure still more hyperbolic.

" Large is his front; and when his burnish'd eyes
Lift their broad lids, the morning seems to rise."

The supposition that the fertilizing quality of snow arises from nitrous salts, which it is supposed to acquire in the act of freezing, is destitute of foundation. False philosophy, says the bishop of Landaff, (Dr. Watson,) in his "Chemical Essays," first gave rise to this idea, and poetry has contributed to diffuse the error. Thus, Mr. Philips:

" ————— O may'st thou often see
Thy furrows whiten'd by the woolly rain,
Nutritious; secret nitre lurks within
The porous wet; quickening the languid glebe."

Hence it may be observed, that whenever philosophy is introduced into poetry, truth, for the most part, is essential to its power of giving pleasure; and it is of great importance that the poet should be directed by just views of the system

of nature. It has been said, however, that it is sufficient, without exactly copying nature, that the productions of the poet be consistent either with general experience, or with popular opinion, or with itself, and connected with probable circumstances. But as nothing unnatural can please, poetry, the aim of which is to give pleasure, and in this way to communicate instruction, ought, as nearly as possible, to conform to nature. This constitutes its distinguishing excellence, as an imitative art. In some cases, however, the poet is allowed, by the aid of fancy, to improve (if the expression may be allowed) and to embellish nature. When gross errors in philosophy, astronomy, or natural history, are introduced into the works of the poet, sanctioned by it, and also diffused by their agreeable and captivating accompaniments, they tend to obstruct one of the principal aims of poetry, and not only to diminish its utility, but to render it instrumental in supporting and disseminating fallacious opinions. Milton, not only in his machinery on many of the various characters he has introduced, has occasionally descended from the almost peerless majesty of his work, by mixing prevalent errors with truth, and the groundless opinions of the ancients with modern discoveries. Thus, when Raphael addresses Adam, concerning the great system of nature, he says,

“ ————— Other suns, perhaps,
With their attendant moons, thou wilt descry,
Communicating *male* and *female* light.”

The idea of *male* light being communicated by the *sun*, and *female* light by the *moon*, probably originated in the mind of Milton, from his intimate acquaintance with the writings of Pliny, who mentions as a tradition (Hist. Nat. lib. ii. cap. 100.) “that the sun is a masculine star, drying all things, but that the moon is a soft and feminine star, of dissolving power; and that thus the balance of nature is preserved; some of the stars binding the elements, and others loosening them.”

The *harmony* of the spheres (see HARMONY, &c.), first taught by the Pythagoreans, is so pleasing to the imagination, that it is not surprising the poets should have adopted it. And Milton has given such a view of it, as wants nothing but philosophical truth to render it delightful.

“ Mystical dance, which yonder starry sphere
Of planets, and of fix'd, in all her wheels
Resembles most; mazes intricate,
Excentric, intervolv'd, yet regular,
Then most, when most irregular they seem;
And in their motions harmony divine,
So smooths her charming tones, that God's own ear
Listens delighted.”

Mr. Pope has not only supposed the actual existence of this heavenly harmony, but that it is possible the human ear might have been so constituted, as to have been sensible of it.

“ If Nature thunder'd in his opening ears,
And stunn'd him with the music of the spheres;
How would he wish that heav'n had left him still,
The whisp'ring zephyr, and the purling rill.”

The system of philosophy, which is now immoveably established on the basis of the discoveries and demonstrations of Copernicus, Kepler, and Newton, independently of its superiority in point of truth, infinitely exceeds in extent, elevation, and grandeur, that of the ancients. The poet should, therefore, be well versed in the science of physics, not only because he can seldom deviate from it, without in-

jury to his compositions, but because these may derive from it sublimity, embellishment, or grace. Astronomy, in particular, furnishes such magnificent ideas and boundless views, that imagination can hardly grasp, much less exalt or amplify them.

A specimen appears in the following lines, with all the charms of grace and harmony.

“ ————— Seiz'd in thought
On fancy's wild and roving wing I fail
From the green borders of the peopled earth
And the pale moon, her duteous fair attendant;
From solitary Mars; from the vast orb
Of Jupiter, whose huge gigantic bulk
Dances in ether, like the lightest leaf:
To the dim verge, the suburbs of the system,
Where cheerless Saturn 'midst his wat'ry moons,
Girt with a lucid zone, majestic sits
In gloomy grandeur, like an exil'd queen
Amongst her weeping handmaids; fearless thence
I launch into the trackless deeps of space,
Where burning round ten thousand suns appear,
Of elder beam; which ask no leave to shine
Of our terrestrial star, nor borrow light
From the proud regent of our scanty day:
Sons of the morning, first born of creation,
And only less than him who marks their track,
And guides their fiery wheels. Here must I stop?
Or is there aught beyond? What hand, unseen,
Impels me onward, through the glowing orbs
Of habitable nature; far remote,
To the dread confines of eternal night,
To solitudes of vast unpeopled space,
The deserts of creation, wide and wild;
Where embryo systems, and unkindled suns,
Sleep in the womb of Chaos! Fancy droops,
And thought, astonish'd, stops her bold career.”

Mrs. Barbauld's Evening Meditation.

Homer's animated picture of a moonlight and starry night transports us, in our imagination and feeling, to the scene which it exhibits. Such is the following passage in his Iliad, l. viii. line 687, translated with singular felicity by Mr. Pope.

“ As when the moon, refulgent lamp of night,
O'er heaven's clear azure spreads her sacred light:
When not a breath disturbs the deep serene,
And not a cloud o'ercasts the solemn scene;
Around her throne the vivid planets roll,
And stars unnumber'd gild the glowing pole:
O'er the dark trees a yellower verdure shed,
And tip with silver every mountain's head;
Then shine the vales, the rocks in prospect rise,
A flood of glory bursts from all the skies:
The conscious swains, rejoicing in the sight,
Eye the blue vault, and bless the useful light.”

The evening scenery is admirably portrayed by Mrs. Barbauld; *ubi supra*:

“ ————— Nature's self is hush'd,
And but a scatter'd leaf which rustles thro'
The thick-wove foliage; not a sound is heard
To break the midnight air.

“ ————— 'Tis now the hour
When contemplation, from her sunless haunts,
Moves forward; and with radiant finger points
Where, one by one, the living eyes of heaven

Awake, quick kindling o'er the face of ether
One boundless blaze; ten thousand trembling fires
And dancing lustres, where th' unsteady eye,
Restless and dazzled, wanders unconfin'd
O'er all this field of glories."

The account which Don Ulloa has given of his station on the top of Cotopaxi, a mountain in Peru, more than three geographical miles above the level of the sea, would have been felt and admirably described by the poet, who furnishes us with the following passage:

"—————When lightning fires
The arch of heaven, and thunders rock the ground;
When furious whirlwinds rend the howling air,
And Ocean, groaning from his lowest bed,
Heaves his tempestuous billows to the sky:
Amid the mighty uproar, while below
The nations tremble, Shakspeare looks abroad
From some high cliff, superior, and enjoys
The elemental war." Akenfide.

The poet, who would excel in description, should also exercise his talents in the judicious selection and picturesque display of small groups, or individual objects; and for this purpose, he should draw forth what is valuable, even from the rudest materials; nearly discriminating, in every surrounding object, those attributes, which can be rendered subservient to his art.

Thomson, it is said, was accustomed to wander whole days and nights in the country; and in such sequestered walks, he acquired, by the most minute attention, a knowledge of all the mysteries of nature. These he has wrought into his "Seasons," with the colouring of Titian, the wildness of Salvator Rosa, and the energy of Raphael. Milton appears to have been no less familiar with nature than Thomson, and equally happy in his portraits of her most pleasing forms. He catches every distinguishing feature; and gives to what he describes such glowing tints of life and reality, that we have it, as it were, in full view before our eyes. How perfect is the image in the following lines!

"———The swan, with arched neck
Between her white wings mantling, proudly rows
Her state, with oary feet."

The examples we have produced evince the importance of the poet's acquiring an extensive acquaintance with science in general, and with the various branches of natural history, that he may not, through mere ignorance, deviate from nature, as it actually exists; nevertheless it is not expected, that, on all occasions, he should be restricted within the precise boundaries of truth, nor indeed is it possible to restrain a poetic writer of lively and creative fancy.

Comparing poetry with history, Dr. Lowth gives the preference to the former. "History," with respect to instruction in morals, "is confined within too narrow limits; it is subject to laws peculiar to itself; it relates things as they really were; it traces events under the guidance of authority; it must exhibit what has happened, not what might or ought to have happened. It must not deviate in quest of reasonable instruction or plausible conjecture, but confine itself to that path, which the stubbornness of fact has prescribed. History treats of things and persons, which have been in actual existence; whereas the subjects of poetry are infinite and universal. The one investigates causes through the uncertain medium of conjecture; the other demonstrates them with clearness and certainty. The

one catches the usual glimpses of truth, whenever they break forth to the view; the other contemplates her unclouded appearance. History pursues her appointed journey by a direct path; poetry ranges uncontrolled over the wide expanse of nature. The former must make her precepts subservient to the subject, the latter forms a subject subordinate to her precepts and designs. For these reasons poetry is defined by Aristotle to be something of a more serious and philosophical nature than history. (Poet. c. 9.)" Bacon (De Augm. Scient. l. ii. 13.) coincides with Aristotle in sentiment, as appears from the following passage. "Since the sensible world is in dignity inferior to the rational soul; poetry seems to endow human nature with that which lies beyond the power of history, and to gratify the mind with at least the shadow of things, where the substance cannot be had. For if the matter be properly considered, an argument may be drawn from poetry, that a superior dignity in things, a more perfect order, and a more beautiful variety delight the soul of man, than are found in nature since the fall. As, therefore, the actions and events, which are the subject of true history, are not of sufficient amplitude to content the mind of man; poetry is at hand, and invents actions of a more heroic nature. Because true history reports the success of events not proportionably to desert, or according to the virtue or vice that has been displayed in them; poetry corrects this, and represents events and fortunes according to justice and merit: because true history, from the obvious similarity of actions, and the satiety which this circumstance must occasion, frequently creates a distaste in the mind; poetry cheers and refreshes it, exhibiting things uncommon, varied, and full of vicissitude. As poetry, therefore, contributes not only to pleasure, but to magnanimity and good morals; it is deservedly supposed to participate in some measure of divine inspiration; since it raises the mind, and fills it with sublime ideas, by proportioning the appearances of things to the desires of the mind; and not submitting the mind to things, like reason and history."

It has been a very prevalent opinion, that the cultivation of poetry has contributed to the improvement of oratory. We may here observe in general, that though the language of poetry differs very widely from that of all other kinds of composition, yet he, who has bestowed some time and attention in the perusal and imitation of the poets, will find his understanding exercised and improved, the vigour and activity of his mind increased, and even his manner of expression to have insensibly acquired a tinge from his elegant intercourse. And it has been suggested, that both Cæsar and Tully (one the most elegant, the other the most eloquent of the Romans) might have derived considerable assistance from the cultivation of this branch of polite literature, since it is well known, that both of them were addicted to the reading of poetry, and even exercised in the composition of it. Accordingly, Quintilian intimates (lib. x. 5.) that Cicero acquired that luminous and splendid diction, which he possessed, by occasionally resorting to such amusing occupations. Others, however, have doubted, whether Cicero was indebted for his excellence as an orator to the cultivation of poetry; and they have observed, that he would have been accounted but as a moderate orator, if his orations had only equalled his poetry, and if he had spoken as he sung:

"Fortune foretun'd the dying notes of Rome:
Till I thy Consul sole, consol'd thy doom."

Although we might not have expected to have found that Cicero rivalled the polish and perfection of Virgil, we might

POETRY.

might at least have hoped, that his verse would have manifested some traces of that fire and fancy, which appear in his oratory. The case is far otherwise, for he appears not deficient in art, but in nature; in that energy and enthusiasm, which is called the "poetic furor." If indeed poetry serves to form an accomplished orator, we can hardly expect to find the same person excellent in both arts. The language of poetry has something in it so different and contrary to that of oratory, that we seldom find those, who have applied much to the one, rise above mediocrity in the other. The chief excellence of an orator consists in perspicuity, and in such a degree of perspicuity as is necessary to render the composition intelligible even to the common people; but though obscurity be not a necessary adjunct of a good poem, it must be considerably superior to the language and comprehension of the vulgar to rank above mediocrity. The orator must not deviate from the common and beaten track of language; the poet must aim at a happy boldness of diction, and wander into new paths. The orator, in order to be generally understood, is necessarily more copious and prolix, not only than the poet, but than all other writers; the chief commendation of the poet is brevity. A poem is always enervated by circumlocutions, unless new lights of sentiment and language are thrown in. For these and other reasons, says Dr. Lowth, I am of opinion, that if a well-cultivated genius for poetry should apply earnestly to oratory, he might indeed prove such an orator as would please a learned audience, and not be displeasing to the populace; but such a man will never prove a very popular orator, on whom the people shall gaze with admiration and rapture, and who shall acquire a perfect ascendancy over all their passions; and he who is by nature an orator, may possibly be a poet for the multitude, or by art and study, and the imitation of the best models, may make a decent proficiency, but he never can be a great and divine poet.

The writings of Plato, it has been said, indicate his acquaintance with poetry, and hence he is thought not only to have erred in his judgment, but to have acted an ungrateful part, when he excluded from his imaginary commonwealth that art, to which he was so much indebted for the splendour and elegance of his genius, from whose fountains he had derived that soft, copious, and harmonious style, for which he is so justly admired.

The ancient eloquence, it is observed, was full of mysteries and allegories. The truth was by them usually disguised under those ingenious inventions, called *μυθῶν*, *fables*, q. d. *words*; as if there were as much difference between these fabulous discourses of the learned, and the common language, as between the speech peculiar to man and the voice of brutes.

At first fables were chiefly used in treating of the divine nature, after the manner they then conceived of it: this occasioned the first poets to be called *divines*, and poetry the *language of the gods*. The divine attributes they separated into a number of persons; because the weakness of the human mind could not conceive so much power, and so much action, in a simplicity so strict and indivisible as that of God.

Nor could they speak of the operation of this almighty cause, without speaking likewise of its effect. They therefore added physics to their theology, handling both after the same manner, without quitting their veils or allegories.

Now man being the most considerable of all the works of the Deity, and there being nothing so proper for poets, or of such general use to mankind as such a subject, they therefore added ethics to the former, and treated the doctrine

of manners in the same way as they had done divinity and physiology: and hence arose the *epopœia* or epic poem.

The epic poets have done with regard to morality, just the contrary of what the divine poets did for their theology. As the too great diversity of divine actions and perfections, so little proportioned to our understanding, occasioned the latter to divide the single idea of the simple essence of God into several persons under different names, as Jupiter, Juno, Neptune, &c. so, on the contrary, the nature of moral philosophy, which never gives any rules for particular things, occasioned the epic poets to unite in one single idea, in the same person, and even in a single action, whatever of the like kind occurs in different persons and different actions.

Thus, says Aristotle, poetry teaches moral philosophy, not by reciting historically what Alcibiades has done or suffered, but proposing what such a person, whom the poet calls by any name he pleases, would necessarily or probably have done or said on the like occasion. It is in this manner that poetry represents either the unhappy consequences of designs ill concerted, of wicked actions, &c. or the reward of good actions, and pleasure reaped from a design laid in virtue, and conducted by prudence.

Thus, according to our critic, the poetical actions and persons are all feigned, allegorical, and universal, not historical and singular. This is likewise the sentiment of Horace; who adds, that poets teach morality as well as philosophy; but the preference herein he gives to Homer. This advantage of the poets over mere philosophers arises hence, that all poetry is an imitation. Now imitation is a thing extremely natural; and hence this manner of proposing things becomes better fitted to engage the auditors. Again, imitation is an instruction given by examples; and examples are the more proper to persuade, because they prove the thing possible. In effect, imitation is so much the nature of poetry, that, Aristotle tells us, it is to this the art owes its rise.

But the poets, by becoming philosophers, did not cease to be divines; on the contrary, the morality they taught obliged them frequently to introduce the Deity in their works; and the share so august a Being had in the action, obliged the poet to make it grand, important, and conducted by the persons of kings and princes.

Add to this that it likewise obliged the poet to think and speak after a manner elevated above the common pitch of men, and to use phrases equal, in some measure, to the divine persons he introduced; and to this purpose served the poetical, figurative language, and the majesty of heroic verse.

To convey their truths to the best advantage, and adapt them to the particular purposes they were intended for, poets found out various forms. Hence the *epopœia* and drama. See *EPIC Poem*.

After all, poetry must be allowed to stand eminent among the other liberal arts; inasmuch as it refreshes the mind when it is fatigued, soothes it when it is agitated, relieves and invigorates it when it is depressed; as it elevates the thoughts to the admiration of what is beautiful, what is becoming, what is great and noble: nor is it enough to say, that it delivers the precepts of virtue in the most agreeable manner; it insinuates or instils into the soul the very principles of morality itself. Moreover, since the desire of glory, innate in man, appears to be the most powerful incentive to great and heroic actions, it is the peculiar function of poetry to improve this bias of our nature, and thus to cherish and enliven the embers of virtue: and since one of the principal employments of poetry consists in the cele-

bration

bration of great and virtuous actions, in transmitting to posterity the examples of the bravest and most excellent men, and in consecrating their names to immortality; this praise is certainly its due, that while it forms the mind to habits of rectitude by its precepts, directs it by examples, excites and animates it by its peculiar force, it has also the distinguished honour of distributing to virtue the most ample and desirable rewards of its labours.

The importance of this art is most eminently conspicuous, as employed on sacred subjects, and in subserviency to religion. This indeed appears to have been the original office and destination of poetry; and this it still so happily performs, that in all other cases it seems out of character, as if intended for this purpose alone. In other instances poetry appears to want the assistance of art, but in this to shine forth with all its natural splendour, or rather to be animated by that inspiration, which on other occasions is spoken of without being felt. These observations are remarkably exemplified in the Hebrew poetry, than which the human mind can conceive nothing more elevated, more beautiful, or more elegant; in which the almost ineffable sublimity of the subject is fully equalled by the energy of the language, and the dignity of the style. And it is worthy observation, that as some of these writings exceed in antiquity the fabulous ages of Greece, in sublimity they are superior to the most finished productions of that polished people.

Having considered the nature and excellence, and utility of poetry, and transiently compared it with philosophy, history, and oratory, specifying also the assistance which the poet derives in his imitation of nature from an extensive and accurate acquaintance with the sciences and other arts, we shall now proceed to give a brief sketch of its rise and progression.

It has been a prevalent opinion, sanctioned by the concurring voice of antiquity, that poetry is older than prose. This, however, is a kind of paradox, which needs explanation, because there never existed any period of society, in which men conversed together in poetical numbers. But from the commencement of the social state, they occasionally met together for feasts, sacrifices, and public assemblies; and on all such occasions, their principal entertainment consisted in music, song, and dance. In the rude effusions, which the enthusiasm of fancy or passion suggested to untaught men, when roused by interesting events, and by their meeting together in public assemblies, we discover the first beginnings of poetic composition. Two particulars, says Dr. Blair, would early distinguish this language of song, from that in which they conversed on the common occurrences of life; namely, an unusual arrangement of words, and the employment of bold figures of speech. The order of words would be inverted to suit the train in which they rose in the speaker's imagination, or to accommodate them to the cadence of the passion by which he was moved, and the various emotions of the mind would also suggest those modes of expression, which are now distinguished by the learned names of hyperbole, prosopopeia, simile, &c.; and which were the native language of poetry, among the most barbarous nations. The same impulse likewise which prompted the enthusiastic poetic style, would dispose to a certain melody, or modulation of sound, suited to the different emotions of joy or grief, of admiration, love, or anger. Music and poetry, therefore, have the same origin; they were prompted by the same occasions; they were united in song; and as long as they continued united, they tended, without doubt, mutually to heighten and exalt each other's power. The first poets sung their own verses; and hence

sprung versification, or words arranged in a more artful order than prose, so as to be suited to some tune or melody.

If the actual origin of poetry be inquired after, says Dr. Lowth, it must be referred to religion; and since it appears to be an art derived from nature alone, peculiar to no age or nation, and only in an advanced state of society conformed to rule and method, it must be wholly attributed to the more violent affections of the heart, the nature of which is to express themselves in an animated and lofty tone, with a vehemence of expression far remote from vulgar usage. It is no less observable also, that these affections break and interrupt the enunciation by their impetuosity; they burst forth in sentences pointed, earnest, rapid, and tremulous; and in some degree the style, as well as the modulation, is adapted to the emotions and habits of the mind. Is it not probable, continues the same author, that the first effort of rude and unpolished verse would display itself in the praise of the Creator, and flow almost involuntarily from the enraptured mind? This at least is certain, that poetry has been nurtured in those sacred places, where she seems to have been first raised into existence; and that her original occupation was in the temple and at the altar. However ages and nations may have differed in their religious sentiments and opinions, in this at least we find them all agreed, that the mysteries of their devotion were celebrated in verse. According to Plato (*De Leg. lib. iii.*), the most ancient poetry, as well as music, was that which was addressed to the Deity, under the appellation of hymns. Although the Greeks, who are fond of attributing to their own nation the invention of all sciences and arts, have ascribed the origin of poetry to Orpheus, Linus, and Musæus, yet long before such names were heard of, and among nations where they were never known, poetry existed. Poetry, and also music, so far from being arts that belong only to polished nations, have their foundation in the nature of man, and belong to all nations and ages; though, like other arts founded in nature, they have been more cultivated, and, from a concurrence of favourable circumstances, carried to greater perfection in some countries than in others. Indeed, before any characters expressive of sounds were invented, at least before they were commonly received, and applied to general use, it seems to have afforded the only means of preserving the rude science of the early times; and, in this respect, to have rendered the want of letters more tolerable. It seems also to have acted the part of a public herald, by whose voice each memorable transaction of antiquity was proclaimed, and transmitted through different ages and nations. Such appears, by the testimony of authors, to have been the undoubted origin of poetry among heathen nations. Upon the whole it may be observed, that the first compositions, which were either recorded by writing, or transmitted by tradition, could be no other than poetical compositions. Nothing could attract the attention of savage tribes, addicted only to hunting and war, rouse the speaker to pour himself forth, or draw the crowd to listen, but the high powers of passion, of music, and of song. This vehicle, and no other, could be employed by chiefs and legislators, when they meant to instruct or to animate their tribes. Besides, before writing was invented, songs only could last and be remembered. The ear assisted the memory by the help of numbers; fathers repeated and sung them to their children; and by this oral tradition of national ballads, were conveyed all the historical knowledge, and all the instruction of the first ages. Greece, for several successive ages, possessed no records but the poetic. Priests, philosophers, and statesmen, all delivered their instructions in poetry. Apollo, Orpheus,

POETRY.

Orpheus, and Amphion, their most ancient bards, are represented as the first founders of law and civilization. Minos and Thales sung to the lyre the laws which they composed; and till the age immediately preceding that of Herodotus, history had assumed no other form but that of poetical tales.

The first person who published a prose oration was Pherecydes of the isle of Syrus, or Scyros, contemporary with king Cyrus, who lived some ages posterior to that of Homer and Hesiod; and somewhat after that time, Cadmus the Milesian began to compose history. (Strabo, lib. i. Plin. Nat. Hist. l. vii. 56. and v. 29.) "It is well known," says Isidorus (Hispal. Orig. l. i. 27.), "that among the Greeks, as well as among the Latins, metrical composition was much more ancient than prose. Every species of knowledge was at first contained in poetry; it was long before prose composition flourished. The first man among the Greeks, who composed in prose, was Pherecydes Syrius: among the Romans, Appius Cæcus first published a work in prose against Pyrrhus." The laws themselves were metrical, and adapted to certain musical notes: such were the laws of Charondas, which were sung at the banquets of the Athenians; such were those which were delivered by the Cretans (Ælian, Nat. Hist. l. ii. 39.) to the ingenuous youth to be learned by rote, with accompaniments of musical melody, in order that, by the enchantment of harmony, the sentiments might be more forcibly impressed upon their memories. Hence certain poems were denominated *νόμοι* (nomoi), which implied convivial or banqueting songs, as is remarked by Aristotle (Prob. S. 19. Q. 28.); who adds, that the same custom of chanting the laws to music existed even in his own time among the Agathyrsi. If we may credit Strabo (Geog. l. iii.), the Turdetani, a people of Spain, had laws in verse; but the Germans, as Tacitus positively asserts, had no records or annals but the traditional poems, in which they celebrated the heroic exploits of their ancestors. In the same manner, and on the same account, the Persians, the Arabs, and many of the most ancient Eastern nations, preserved in verse their history and politics, as well as the principles of religion and morals. Among the Scythian or Gothic nations, many of their kings and leaders were scalds or poets; and it is, as Dr. Blair observes, from their Runic songs, that the most early writers of their history, such as Saxo-Grammaticus, acknowledge, that they had derived their chief information. Among the Celtic tribes, in Gaul, Britain, and Ireland, we know in what admiration their bards were held, and what great influence they possessed over the people. They were both poets and musicians, as all the first poets in every country were. They were always near the persons of the chief or sovereign; they recorded all his great exploits; they were employed as the ambassadors between contending tribes, and their persons were held sacred. Whatever may be thought of the antiquity of Ossian's poems, it is certain that in the Highlands of Scotland there are many remains of the ancient historical ballads, which, though probably of a much later date than the age of Ossian is pretended to be, contain many marks of wild genius, and furnished Mr. Macpherson, as it has been said, with the bulk of his materials.

All science, human and divine, seems to have been deposited in the treasury of the muses, and thither it was necessary, on every occasion, to resort. The only mode of instruction, as bishop Lowth observes, adapted to human nature in an uncivilized state, when the knowledge of letters was very little, if at all, diffused, must be that which is calculated to captivate the ear and the passions, which assists the memory, which is not to be delivered into the hand, but

infused into the mind and the heart. Poetry, as professor Michaelis remarks, is much less liable to be corrupted than prose. So faithful a preserver of truth is metre, that what is liable to be changed, augmented, or violated, almost daily in prose, may continue for ages in verse, without variation, without even a change in the obsolete phraseology. The ancient use of poetry has been traced by the learned prelate, whose admirable "Prælections" have been often cited, not only in the writings of Moses, but in the most remote periods of the Mosaic history. The address of Lamech to his wives (Gen. iv. 23, 24.) presents an indubitable specimen of the poetry of the first ages. Michaelis, among the fragments of verse that are scattered through the writings of Moses, mentions his relation (Gen. iii. 24.) of the cherubs placed at the east of the garden of Eden, under which appellation the professor understands to be meant, not angels, but the "equi tonantes" of the Greek and Latin poets. The passage, he says, is unquestionably poetical. "He placed before the garden cherubims (*thundering horses*) and a flaming sword, to keep the way of the tree of life;" in plain terms, the dread of the frequent tempests and daily thunders deterred men from that track, in which paradise was situated, lest they should eat of the tree of life. Another example of genuine poetry is the execration of Noah upon Ham, with the magnificent predictions of prosperity to his two brothers, to Shem in particular, and the ardent breathings of his soul for their future happiness. (Gen. ix. 25, 27.) The inspired benedictions of the patriarchs Isaac and Jacob are altogether of the same kind. (Gen. xxvii. 27—29. 39, 40.) Many other examples of a similar kind might be produced, which would serve to shew, that the poetry, analogous to the specimens of Hebrew poetry, still remaining, was neither originally the production of Moses, nor peculiar to the Jewish nation; but that it may be accounted among the first fruits of human ingenuity, and was cultivated by the Hebrews and other eastern nations from the first ages, as the recorder of events, the preceptor of morals, the historian of the past, and prophet of the future. See Gen. xxi. 6, 7. xxiv. 60. xxv. 23. xxviii. 16, 17. Numb. xii. 6—8. See *HEBREW Poetry*.

Among the first poetic compositions we may reckon odes and hymns, dictated by religious feelings: plaintive or elegiac poetry would as naturally arise from lamentations over deceased friends: epic poetry derived its origin from the recital of the achievements of their heroes and ancestors; and not contented with simply reciting these, they would be led, at some of their public meetings, to represent them, by introducing different bards speaking in the character of their heroes, and answering each other, in which practice we discern the first outlines of tragedy, or dramatic writing. But, in the first ages of society, none of these kinds of poetry were properly distinguished or separated, as they are now, from each other. At first, history, eloquence, and poetry were all the same; but when the progress of society induced a separation of the different arts and professions of civil-life, it led also by degrees to a separation of the different literary provinces from each other. In process of time the art of writing was invented; and afterwards poetry became a separate art, calculated chiefly to please, and confined generally to such subjects as related to the imagination and passions. Even its earliest companion, music, was in a great measure divided from it. The first poetry of all nations was rude and artless, but at the same time it had somewhat in it that captivated and transported the mind. In after ages, when poetry became a regular art, studied for reputation and for gain, authors began to affect what they did not feel. Composing coolly in their closets, says Dr. Blair,

Blair, they endeavoured to imitate passion rather than to express it; they tried to force their imagination into raptures, or to supply the defect of native warmth, by those artificial ornaments, which might give composition a splendid appearance.

The separation of music from poetry produced consequences not favourable in some respects to poetry, and in many respects hurtful to music. (See Dr. Brown's Dissertation on the Rise, Union, and Separation of Poetry and Music.) As long as they remained united, music enlivened and animated poetry, and poetry gave force and expression to musical sound. Music was then in a simple state; and the poet's strain was always heard. In this state it produced all the great effects ascribed to it in ancient story. From simple music only, and from music, accompanied with verse or song, we are to look for strong expression, and powerful influence over the human mind. But when instrumental music came to be studied as a separate art, divested of the poet's song, and formed into the artificial and intricate combinations of harmony, it lost all its ancient power of inflaming the hearers with strong emotions; and sunk into an art of mere amusement, among polished and luxurious nations. Still, however, poetry preserves, in all countries, some remains of its first and original connection with music. By being uttered in song, it was formed into numbers, or into an artificial arrangement of words and syllables, very different in different countries; but such, as to the inhabitants of each, seemed most melodious and agreeable in sound. Hence arises that great characteristic of poetry, which we now call *verse*. See VERSE and VERSIFICATION.

The first poetry of nations acquires some diversity from difference of climate, and of manner of living; chiefly, as those nations are of a more ferocious, or a more gentle spirit, and according as they advance more rapidly or more slowly in the arts of civilization. Hence we find all the remains of the ancient Gothic poetry remarkably fierce, and breathing nothing but slaughter and blood; while the Peruvian and Chinese songs turned, from the earliest times, upon milder subjects. The Celtic poetry, in the days of Ossian, though chiefly of the martial kind, yet had attained a considerable mixture of tenderness and refinement; in consequence of the long cultivation of poetry among the Celtæ, by means of a series and succession of bards, which had been established for ages. Among the Grecian nations, their early poetry appears to have soon received a philosophical cast, from what we are informed concerning the subjects of Orpheus, Linus, and Musæus, who treated of creation and of chaos, of the generation of the world, and of the rise of things; and it is known that the Greeks advanced sooner to philosophy, and proceeded with a quicker pace in all the arts of refinement, than most other nations. The metrical compositions of the Arabians were of two sorts, one, which they compared to loose pearls, and the other to pearls strung. In the former, the sentences or verses were unconnected; and their beauty arose from the elegance of the expression, and the acuteness of the sentiment. (See ARABIC Poetry.) The moral doctrines of the Persians were generally comprehended in independent proverbial apophthegms, formed into verse; bearing, in this respect, a considerable resemblance to the Proverbs of Solomon. The book of Job is also in the same form of composition. Lowth's Lectures on the Sacred Poetry of the Hebrews translated by Gregory, vol. i. Beattie's Essays on Poetry and Music. Blair's Lectures, vol. iii.

During the decline of the Roman empire, many causes concurred to accelerate the relapse of the Latin poetry into barbarism. Among these we may mention the growing in-

crease of Christianity which deprived it of its old fabulous embellishments, and in consequence of which it was chiefly employed in composing ecclesiastical hymns. Amidst these impediments, however, and the necessary degeneration of taste and style, a few poets supported the character of the Roman muse with tolerable dignity at this period. These were Ausonius, Paulinus, Sidonius, Sedulius, Arator, Juvenius, Prosper, and Fortunatus. With the last, who flourished at the beginning of the sixth century, and was bishop of Poitiers, the Roman poetry is supposed to have expired.

For an account of the introduction and progress of English poetry, with its distinguishing characters and writers at different periods in the more early ages, we refer to Mr. Warton's History of English Poetry, &c.

The first age of English poetry, in the reign of Elizabeth, displayed a fantastic combination of chivalrous fancy and feeling with classical pedantry; but, upon the whole, the native genius was unsubdued; and the poems of that age, with all their faults, and partly perhaps from their faults, are the most national part of our poetry, as they undoubtedly contain its highest beauties. From the accession of James I. to the civil war, the glory of Shakspeare turned the whole national genius to the drama; and, after the restoration, a new and classical school arose, under which our old and classical literature was abandoned, and almost forgotten. But all imported tastes in literature must be in some measure superficial. The poetry which grew in the bosoms of a people is always capable of being revived by a skilful hand. When the brilliant and poignant lines of Pope began to fall on the public ear, it was natural that we should revert to the cultivation of our indigenous poetry. During the greater part of the 18th century, the connection of the character of English poetry with the state of the country was very easily traced. The period which extended from the English to the French revolution was the golden age of authentic history. Governments were secure, nations tranquil, improvements rapid, and manners mild beyond the example of any former age. The English nation, which possessed the greatest of all national blessings, a wisely constructed popular government, necessarily enjoyed the largest share of every other benefit. The tranquillity of that fortunate period was not disturbed by any of those calamities, or even extraordinary events, which excite the imagination and inflame the passions. No age was more exempt from the prevalence of any species of popular enthusiasm. In this state of things, poetry partook of that calm, argumentative, moral, and directly useful character into which it naturally subsides, when no events occur to rouse the higher passions; when every talent is allured into the immediate service of a prosperous and improving society; and when wit, taste, diffused literature, and fastidious criticism, combine to deter the young writer from the more arduous enterprises of poetical genius. In such an age, every art becomes rational. Reason is the power which presides in a calm: but reason guides, rather than impels; and, though it must regulate every exertion of genius, it never can rouse it to vigorous action.

The school of Dryden and Pope, which prevailed till a very late period of the last century, is neither the most poetical nor the most national part of our literary annals. These great poets sometimes indeed ventured into the regions of pure poetry. But their general character is, that "not in fancy's maze they wandered long;" that they rather approached the elegant correctness of our continental neighbours, than supported the daring flight which, in the former age, had borne English poetry to a sublimer elevation, than that of any other modern people of the West,

Towards

Towards the middle of the eighteenth century, great, though quiet changes, began to manifest themselves in the republic of letters, in every European nation which retained any portion of mental activity. About that time, the exclusive authority of our great rhyming poets began to be weakened; new tastes and fashions began to shew themselves in the political world. A school of poetry must have prevailed long enough, to be probably on the verge of downfall, before its practice be embodied in a correspondent system of criticism. Johnson was the critic of our second poetical school. As far as his prejudices of a political or religious kind did not disqualify him for all criticism, he was admirably fitted by nature to be the critic of this species of poetry. Without more imagination, sensibility, or delicacy than it required,—not always with perhaps quite enough for its higher parts,—he possessed sagacity, shrewdness, experience, knowledge of mankind, a taste for rational and orderly compositions, and a disposition to accept, instead of poetry, that lofty and vigorous declamation in harmonious verse, of which he himself was capable, and to which his great masters sometimes descended. His spontaneous admiration scarcely soared above Dryden. “Merit of a loftier class he rather saw than felt.” Shakspeare has transcendent excellence of every sort, and for every critic, except those who are repelled by the faults which usually attend sublime virtues,—character and manners, morality and prudence, as well as imagery and passion. Johnson did indeed perform a vigorous act of reluctant justice towards Milton; but it was a proof, to use his own words, that

“At length our mighty Bard’s victorious lays
Fill the loud voice of universal praise;
And baffled Spite, with hopeless anguish dumb,
Yields to renown the centuries to come!”

The deformities of the life of Gray ought not to be ascribed to jealousy—for Johnson’s mind, though coarse, was not mean—but to the prejudices of his university, his faction, and his poetical sect: and this last bigotry is the more remarkable, because it is exerted against the most skilful and tasteful of innovators, who, in reviving more poetical subjects and a more splendid diction, has employed more care and finish, than those who aimed only at correctness.

The interval which elapsed between the death of Goldsmith and the rise of Cowper, is perhaps more barren than any other twelve years in the history of our poetry since the accession of Elizabeth. It seemed as if the fertile soil was at length exhausted. But it had in fact only ceased to exhibit its accustomed produce. The established poetry had worn out either its own resources, or the constancy of its readers. Former attempts to introduce novelty had been either too weak, or too early. Neither the beautiful fancy of Collins, nor the learned and ingenious industry of Warton, nor even the union of sublime genius with consummate art in Gray, had produced a general change in poetical composition. But the fulness of time was approaching; and a revolution has been accomplished, of which the commencement nearly coincides (not as we conceive accidentally) with that of the political revolution which has changed the character as well as the condition of Europe.

As the condition and character of the former age had produced an argumentative, didactic, sententious, prudential, and satirical poetry; so, the approaches to a new order (or rather at first disorder) in political society, were attended by correspondent movements in the poetical world.—Bolder speculations began to prevail. A combination of the science and art of the tranquil period, with the hardy

enterprizes of that which succeeded, gave rise to scientific poems, in which a bold attempt was made, by the mere force of diction, to give a poetical interest and elevation to the coldest parts of knowledge—and to those arts which have been hitherto considered as the meanest. Having been forced above their natural place by the first wonder, they have not yet recovered from the subsequent depression; nor will a similar attempt be successful, without a more temperate use of power over style,—until the diffusion of physical knowledge renders it familiar to the popular imagination,—and till the prodigies worked by the mechanical arts shall have bestowed on them a character of grandeur. For other observations of a similar kind, we refer to the critique on Rogers’s Poems, art. 2. Edinb. Rev. N^o 43, the anonymous author of which considers the present as one of the most flourishing periods of English poetry.

When classical studies revived amidst the chivalrous manners and feudal institutions of Gothic Europe, the imitation of ancient poets struggled against the power of modern sentiments, with various event, in different times and countries; but every where in such a manner as to give somewhat of an artificial and exotic character to poetry. Jupiter and the Muses appeared in the poems of Christian nations. The feelings and principles of democracies were copied by persons belonging to Teutonic monarchies or aristocracies. The sentiments of the poet in his verse were very different from those which actuated his conduct. The forms and rules of composition were borrowed from antiquity, instead of spontaneously arising from the manner of thinking of modern communities. In Italy, when letters first revived, the chivalrous principle was too near the period of its full vigour to be oppressed by the foreign learning. Ancient monuments were borrowed; but the romantic form was prevalent; and where the forms were classical, the spirit continued to be romantic. The structure of Tasso’s poem was that of the Grecian epic; but his heroes were Christian knights. French poetry, having been somewhat unaccountably late in its rise, and slow in its progress, reached its brilliant period, when all Europe had considerably lost its ancient characteristic principles, and was fully impregnated with classical ideas. Hence it acquired faultless elegance; and hence also it became less natural, more timid and more imitative; more like a feeble translation of Roman poetry. See ROMANCE, RUNIC, SCALDS, SCANDINAVIA, SAXON, &c.

POETRY, *the Laws of Epic and Dramatic*, see under EPIC, CHARACTER, INVOCATION, DRAMATIC, THEATRE, TRAGEDY, COMEDY, ACT, SCENE, and SENTIMENT. For the lower sorts of poetry, see ODE, SONG, EPIGRAM, EPITAPH, ELEGY, SATIRE, &c.

POFIG, in *Geography*, a town of Bohemia, in the circle of Boleslaw; 10 miles N.W. of Jung-Buntzel.

POGAH, a town of Hindoostan, in Bahar; 57 miles S.S.W. of Patna. N. lat. 24° 53'. E. long. 84° 45'.

POGAR, a town of Russia, in the government of Novgorod Sieverskoi; 20 miles N. of Novgorod Sieverskoi. N. lat. 52° 18'. E. long. 33° 14'.

POGATOVA, a town of Russia, in the government of Archangel; 92 miles S.E. of Oneg.

POGEN, a town of Bavaria, on a river of the same name, which soon after runs into the Danube; six miles E. of Straubing.

POGGE, in *Ichthyology*. See *Cottus Cataphractus*.

POGGIO, in *Geography*, a town of Italy, in the department of the Mincio; 20 miles S.E. of Mantua.—Also, a town of Italy, in the department of the Lower Po; seven miles E. of Cento.—Also, a town of the Ligurian Republic; seven miles W. of Genoa; and another 15 miles S.W. of Genoa.—Also, a town of Etruria, called *Villa Imperiale*, where the late grand duke had a palace; eight miles S.E. of Florence.

POGGIOBONZI, a town of Etruria; 21 miles S.E. of Florence.

POGGY or POGGU, *Pulo*, called also *Nassau Islands*, (see *NASSAU*), are two islands, forming part of the range of islands that lie before the W. coast of Sumatra, and separated from each other by a narrow channel. The inhabitants of these islands and of the island Mantawaye are universally tattooed in the shape of birds and beasts, and their skin discoloured. Neither of these two islands is the largest of the range. “Pulo Neas” has the greatest circumference; and this, if we except “Pulo Babe,” is the northernmost, and not far distant from Natal, on the coast of Sumatra, where the English have a settlement, and whence a great trade is carried on to the island of Neas, in rice and slaves, and of the latter not less than 450 annually, besides about 150 which go to the northern ports; in taking these unfortunate victims of the avarice of the chiefs, it is computed that no fewer than 200 are killed. The people of Neas are small in their persons, of a fair complexion, particularly the women, who are mostly sent to Batavia. Many of both sexes are infected with a kind of leprosy, which is an hereditary disease, though not contagious. Their ears are made to extend so as to admit of an aperture large enough for the hand to pass through, and so as almost to touch the shoulders, though the purchasers of females sometimes have them trimmed to the natural size. The islanders are remarkable for their ingenuity in handicraft works; and they practise letting blood by cupping in a manner similar to ours; their principal food is pork, and the chiefs ornament their houses with the jaws of the hogs as well as the skulls of the enemies whom they kill; in their disposition they are revengeful, and are accounted dangerous as domestic slaves. Earthquakes, which are common in Sumatra, extend to these islands; in 1763 an entire village was swallowed up in that of Neas. The island of Nassau is high, but not mountainous, and may be discerned, in clear weather, at the distance of eight or nine leagues. The S.E. point, called “Fish” point, runs out very low, and one or two leagues to the S. of it lie two small, and about four or five leagues further, one somewhat larger island. This last has by some been taken for the island “Met de Reeven,” or Reef island, (Pulo Mego); but the latter lies in S. lat. 3° 55', whereas the former is in 3° 30'. “Pulo Mego,” as well as some other of these islands, is uninhabited, except by rats and squirrels, that subsist on the cocoa-nuts which they produce, and which are occasionally carried off in vessels from Sumatra to that island. All these small islands are skirted near the sea-beach with cocoa-nut trees, which grow so thick together, that they almost choak each other, whilst the interior parts are entirely free from them; this is occasioned by the accidental floating of the nuts to the shore, where being planted, as it were, by the hand of nature, they shoot forth and bear fruit, and thus supply materials for reproduction. Mr. Marsden supposes that this chain of islands may probably have once formed a part of

the Main, and have been separated from it, either by some violent effort of nature, or by the gradual attrition of the sea. Various appearances confirm this supposition. The food of these islanders consists of yams, crabs, plantains, and cocoa-nuts. The dress of the women is only a piece of cloth wrapped round the middle, and reaching within two or three inches of the knee. Marsden's Sumatra. Stavorinus's Voyages, vol. iii.

POGINSK, a town of Russia, in the government of Pskov, on the Louvat; 16 miles N.N.W. of Veliki Luki.

POGLIZA, a district of Dalmatia, between the river Cetina and the Adriatic.

POGNY, a town of France, in the department of the Marne, on the Marne; nine miles S.S.E. of Châlons sur Marne.

POGO, in *Ornithology*, a name by which the inhabitants of the Philippine islands call their quail: it is very like our common quail, but smaller.

POGOIANA, in *Geography*, a town of European Turkey, in Macedonia; nine miles N. of Saloniki.

POGONIA, in *Botany*, from *πρωγων*, a beard, a genus founded by Jussieu, to which he refers various plants of the natural order of *Orchideæ*, that have a fringed or bearded lip to their nectary, without a spur. Mr. Brown limits it to such as have a terminal permanent anther; a sessile hooded lip, crested on the inside; five separate petals destitute of glands and farinaceous pollen.—Juss. 65. Brown in Ait. Hort. Kew. v. 5. 203. Class and order, *Gynandria Monandria*. Nat. Ord. *Orchideæ*.

The only species mentioned as cultivated in our garden is

P. divaricata. Lily-leaved Pogonia. (*Arethusa divaricata*; Linn. Sp. Pl. 1346. Willd. Sp. Pl. v. 4. 81. Pursh v. 2. 590. Lamarck Illustr. t. 729. f. 3. Helleborine lili folio caulem ambiente, &c.; Catesb. Carol. v. 1. t. 58.)—Root somewhat palmate. Stem-leaf and bractea linear-oblong. Calyx-leaves linear-lanceolate.—Found in swamps near the sea-coast, from Virginia to Florida, blossoming in July. Mr. Frazer brought living plants to England in 1787. The root is perennial. Stem two feet high, simple, single-flowered, smooth, bearing a short sheath near the bottom, a linear-oblong smooth leaf about the middle, and a bractea, of smaller size, at the top, under the large handsome flower, which has a dull-purple calyx, with broader rose-coloured petals and nectary.

POGONIA is used by Mr. Andrews, in his Repository t. 212 and 283, as a name for the genus previously called *MYOPORUM*; see that article, as well as Ait. Hort. Kew. v. 4. 60.

POGONIA, according to Ambrosinus, is a name for the chestnut, alluding to its bristly or bearded covering.

POGOR, in *Geography*, a river on the W. coast of the island of Borneo, which runs into the sea, S. lat. 0° 5'.

POGORE, a town of Germany, in the county of Goritz; four miles W. of Goritz.

POHAN, a town of Persia, in the province of Laristan; 15 miles N.E. of Tarem.

POHERBICZE, a town of Russian Poland; 35 miles E.N.E. of Winnicze.

POHLEN, a town of Saxony, in the Vogtland; four miles N.N.E. of Plauen.

POHLIA, in *Botany*, so named by Hedwig, after his friend John Ehrenfreid Pohl, physician to the Elector of Saxony, and professor of Botany at Leipzig, who was born in 1746, and published, in 1771, a dissertation on the structure and figure of the leaves of plants, which may

be found in Usteri's *Delectus Opusc. Bot.* v. 1. 145. This genus consists of only one species, belonging to the natural order of *Musci*; *P. elongata*; Hedw. Crypt. v. 1. 96. t. 36. Sp. Musc. 171. (*Bryum elongatum*; Dickf. Crypt. fasc. 2. 8. Sm. Fl. Brit. 1349. Engl. Bot. t. 1603.) It is, like the *Webera* of Hedwig, a *Bryum*, in which both organs of impregnation are in the same flower; *Poblia* and *Webera* differing from each other in a most trifling character only, founded on the divisions of the inner fringe. See BRYUM.

There is no question that Dr. Pohl deserves botanical commemoration, but the system is overloaded with names too nearly alike; see POLIA and POLLIA; the latter only will probably remain.

POHOFT, in *Geography*, a town of Lithuania; 16 miles S. of Pinsk.

POJAUHTECATL, a mountain of Mexico, which discharged smoke from the year 1545 to 1565, and then the smoke ceased: its form is conical, and it is so lofty that navigators perceive it from the gulf of Mexico, at the distance of 150 miles; 40 miles W.S.W. of Vera Cruz.

POIG, a river which runs into the gulf of Trieste, about one mile N. of Trieste.

POILE, LA, a bay on the S. of Newfoundland; 32 miles E. of Cape Ray.

POINCIANA, in *Botany*, was so named by Tournefort, in compliment to M. de Poinci, governor of the Antilles in the middle of the 17th century, who is said to have paid considerable attention to the natural history of those islands. His remarks have not reached us. The genus in question was adopted by Linnæus, and the generality of botanists; till Dr. Solander first judged it to be not clearly distinct from CÆSALPINIA, in which it is now sunk; see that article.

POINCIANA, in *Gardening*, comprehends plants of the shrubby, flowering, exotic kind, of which the species chiefly cultivated are, the fair poinciana or double-spined Barbadoes flower fence (*P. pulcherrima*); the bijugated single-spined poinciana (*P. bijuga*); and the loftier spineless poinciana (*P. elata*).

Method of Culture.—These plants are commonly increased by means of the seeds, which are annually received from the West Indies and sown in small pots of light earth, plunging them into some hot-bed or into the bark-bed of the stove, where they soon come up in a plentiful manner. When about three or four inches in height, the young plants should be pricked out into small separate pots, plunging them again into the bark-bed of the stove until they become of a good size, giving them occasional waterings, when they mostly make a rapid growth. Afterwards, as they advance in size, they should be shifted, with balls of earth about their roots, into larger pots, being plentifully supplied with water in the summer season, but sparingly in the winter time. In this way they commonly grow well, advancing fast in height, and in a short time begin to display their elegant flowers. They must be kept constantly in the stoves or hot-houses in this country, where they generally begin to flower in the autumn or winter, imparting a very agreeable fragrance, and are highly ornamental.

POINSON, in the *Manege*, is a little point or piece of sharp pointed iron, fixed in a wooden handle, which the cavalier holds in his right-hand when he means to prick a leaping horse in the croupe, or beyond the end of the saddle, in order to make him jerk out behind.

POINT, derived from *punctum*, which is formed from *pungere*, to prick, is a term in various arts.

POINTS, in *English Antiquity*, were a necessary article in the dress at least of men; and mention of them frequently occurs in the ancient comedies and other old books.

They were pieces of string about eight inches in length, consisting of three strands of cotton yarn, of various colours twisted together, and tagged at both ends with bits of tin-plate: their use was to tie together the garments worn on different parts of the body; particularly the breeches, or hose as they were called: hence the phrase, to untruss a point. With the leathern doublet or jerkin, buttons were introduced, which in time rendered points useless. These points continued to be given on Ascension-day to boys that perambulated the parishes, together with willow wands, as a kind of honorary rewards, though distinguished only by the name of tags, and become useless.

POINT, in *Architecture*. *Arches of the third point*, and *arches of the fourth point*. See ARCHES.

POINT, *Gauge*. See GAUGE.

POINT, in *Astronomy*, is a term applied to certain parts or places marked in the heavens, and distinguished by proper epithets.

The four grand points or divisions of the horizon, *viz.* the east, west, north, and south, are called the *cardinal* points. (See CARDINAL: see also EAST, WEST, &c.) The zenith and nadir are the *vertical* points.

The points, in which the orbits of the planets cut the plane of the ecliptic, are called the *nodes*.

The points, in which the equator and ecliptic intersect, are called the *equinoctial* points. Particularly that, whence the sun ascends towards the north pole, is called the *vernal* point. And that, by which he descends to the south pole, the *autumnal* point.

The points of the ecliptic, where the sun's ascent above the equator, and descent below it, terminate, are called the *solstitial* points. Particularly the former of them the *estival* or *summer* point, the latter, the *brumal* or *winter* point.

POINTS, in *Electricity*, are those acute terminations of bodies which facilitate the passage of the electrical fluid *from* or *to* such bodies.

Mr. Jallabert was, probably, the first person who observed that a body, pointed at one end and round at the other, produced different appearances upon the same body, according as the pointed or round end was presented to it. But Dr. Franklin first observed and evinced the entire effect of pointed bodies, both in drawing and throwing off electricity at greater distances than other bodies could do it; though he candidly acknowledges, that the power of points to throw off the electric fire was communicated to him by his friend Mr. Thomas Hopkinson. Dr. Franklin electrified an iron shot three or four inches in diameter, and observed, that it would not attract a thread, when the point of a needle, communicating with the earth, was presented to it; but he found it impossible to electrify an iron shot, when a sharp needle lay upon it. He also observed, that a piece of leaf gold, suspended between two plates (see *Experiments in ELECTRICITY*), always removed farther from that plate to which its sharpened point was presented; and that if one of the points was very blunt and the other very sharp, it would be suspended in the air by its blunt end, though no electrified plate was held below it.

This remarkable property, possessed by pointed bodies, of gradually and silently receiving or throwing off the electric fluid, has been evinced by a variety of familiar experiments. Thus, if one hand be applied to the outside coating of a large jar fully charged, and the point of a needle, held in the other, be directed towards the knob of the jar,

and moved gradually near it, till the point of the needle touches the knob or ball, the jar will be entirely discharged, so as to give no shock at all, or a shock scarcely sensible. In this case the point of the needle has gradually and silently drawn away the super-abundant electricity from the electrified jar.

Farther, if the knob of a brass rod be held at such a distance from the prime conductor, that sparks may easily escape from the latter to the former whilst the machine is in motion; and when this is the case, if the point of a needle be presented, though at twice the distance of the rod from the conductor, no more sparks will be seen passing to the rod: when the needle is removed, the sparks will be seen, but upon presenting it again they will disappear, so that the point of the needle draws off silently almost all the fluid, which is thrown by the cylinder or globe of the machine upon the prime conductor. This experiment may be varied by fixing the needle upon the prime conductor with the point upwards; and then, though the knob of a discharging rod or the knuckle of the finger be brought very near the prime conductor, and the excitation be very strong, no spark will be perceived, or if there be any, it will be exceedingly small.

The influence of points is also evinced in the amusing experiment, commonly called the electrical horse-race. See *Experiments in ELECTRICITY*.

Again, if a small lock of cotton be suspended from the prime conductor by a thread, and electrified, its filaments will repel one another, and extend themselves towards the nearest conductor; but if the finger or the knob of a rod be presented to it, it will move toward the finger or knob, and endeavour to touch it: at the same time let a pointed needle be presented with the other hand to the cotton a little above the end of the finger, and it will shrink upwards and move towards the prime conductor; but upon removing the needle, the cotton will return towards the finger; on presenting the needle again, it will shrink; and hence it is inferred, that the point of the needle draws off the electric fluid from the cotton, so that it is capable of being attracted by the prime conductor, an effect which the finger or blunt end of the wire could not produce. See *THUNDER-House*.

The late Mr. Henly exhibited the efficacy of pointed bodies by suspending a large bladder well blown and covered with gold, silver, or brass leaf, by means of gum water, at the end of a silken thread six or seven feet long, hanging from the ceiling of a room, and electrifying the bladder by giving it a strong spark with the knob of a charged bottle: he then presented to it the knob of a wire, which caused the bladder to move towards the knob, and when nearly in contact to give it a spark, and thus to discharge its electricity. By giving the bladder another spark, and presenting to it the point of a needle, the bladder was not attracted by the point, but rather receded from it, especially if the needle was suddenly presented towards it. But experiments evincing the efficacy of pointed bodies for silently receiving or throwing off the electric fluid, may be infinitely diversified according to the fancy or convenience of the electrician; and in a work of this kind it is needless to enumerate them.

In connection with this subject it may be proper to remember, that, in case of points throwing off or receiving electricity, a current of air is sensible at an electrified point, which is always in the direction of a point, whether the electricity be positive or negative. This fact has been sufficiently ascertained by many electricians, and particularly by Dr. Priestley and Sig. Beccaria: the explication of it will be subjoined in the sequel of this article.

Dr. Priestley contrived to exhibit the influence of this current on the flame of a candle, presented to a pointed wire, electrified negatively as well as positively. The blast was so strong (and in both cases alike) as to lay bare the greatest part of the wick, the flame being driven from the point; and the effect was the same, whether the electric fluid issued out of the point or entered into it. He diversified this experiment in a variety of ways, by placing the flame between two points, variously circumstanced in their connection with the prime conductor, electrified positively, and the floor; with the rubber and the floor; with the rubber and the conductor, &c. He also tried the force of this current upon paper vanes, stuck into the sides of a cork, which by means of a needle was suspended on a magnet: these vanes he held two or three inches from the point of a wire, communicating with the outside coating of a jar placed upon an electrical stand, and he observed, that whenever he took a spark from the wire communicating with the inside, the vanes were strongly blown up and made to turn, as if the current of air had flowed from the point; in which case, according to Dr. Franklin's theory, the electric fluid was entering it. If they were made to turn the contrary way, the current soon stopped them, and never failed to bring them back and make them move as before. This experiment was varied, and vanes were prepared of thin pieces of brass, which are conductors, and the effect was similar to that of the former. Dr. Priestley also found, as Mr. Wilson had before observed, that the vanes would not turn in vacuo, nor in a close unexhausted receiver where the air had no free circulation. In much the same manner Beccaria exhibited to sense the influence of the wind or current of air driven from points. See *Experiments in ELECTRICITY*.

POINTS, Theory of. Dr. Franklin endeavoured to account for the efficacy of points, by supposing that the base on which the electric fluid at the point of an electrified body rested being small, the attraction by which the fluid was held to the body was slight; and that, for the same reason, the resistance to the entrance of the fluid was proportionably weaker in that place than where the surface was flat: but he was not satisfied with this hypothesis. The facility with which pointed bodies receive or discharge the electric fluid may, perhaps, be more satisfactorily explained by considering, that the electric fluid, superinduced upon an insulated body, is confined upon that body by the surrounding air, and that electricity, by being continually communicated to the air, which is never a perfect electric, is gradually dissipated; whence it follows, that as a greater or less quantity of air is contiguous to a given quantity of electrified surface, that surface will lose its electricity more suddenly or more slowly. Thus, as the point of a needle, supposed to be connected with an electrified prime conductor, is surrounded by the air, the electricity will be dissipated more easily from that than from any other part of the prime conductor of the same dimensions, but exposed to a less quantity of air. Besides, the air about the point may be more easily moved in consequence of the electrical repulsion than at any other part of the surface of the prime conductor; and new air, *i. e.* unelectrified air, passes more frequently by it, which taking always part of the electricity of that body, farther promotes its dissipation. When the pointed body is negatively electrified, it acquires the electric fluid through the point more easily than through any other part of its surface; because the point presenting the least surface to the greatest quantity of air receives a proportionable greater quantity of the electric fluid.

Lord Mahon, (now earl Stanhope,) in his *Principles of Electricity*, in 1779, explains the influence of points in a different

different manner: he first premises, that electric atmospheres are constituted of the particles of air surrounding the electrified body: if, *e. gr.* the body be positively electrified, he maintains that it will deposit, upon all the particles of air that surround it, and come successively in contact with it, a proportional part of its superabundant electricity; so that they will become likewise positively electrified, and form a positively electrified atmosphere. The same reasoning is applied, *mutatis mutandis*, to negatively electrified bodies, and their negative atmospheres.

From this principle, and the observation that the density of an electrical atmosphere diminishes, in a certain ratio, as the distance from the electrified body increases, as well as from other considerations, his lordship undertakes to assign the cause why an electrified body, to which a projecting point is fixed, parts with or receives electricity more readily than a smooth cylinder or globular body: because the superabundant electricity of the body, supposing it to be positively electrified, which, in all cases, tends to quit it, will, when a point is fixed to it, meet with less resistance to its escape; as the point projects beyond the dense part of the electrical atmosphere of the body into the rarer, and, consequently, more unresisting part of that atmosphere. But the escape of the electric matter from any part of a smooth cylindrical body, positively electrified, is prevented or impeded; because every part of its surface is in contact with the densest part of its own strongly resisting electric atmosphere. The surface, too, of the point being extremely small, the less will be the resistance opposed to the escape of the superabundant electricity of the body into that rare part of its electrical atmosphere into which the point projects. Besides other illustrations of this principle, he produces the instance of a pointed wire, placed between two round or prominent metallic bodies, with its point on a level with their surface. In this situation, when presented to an electrified body, it acts no longer as a point, or only in a very small degree; because the dense parts of the electrical atmosphere of the two round bodies flows or is extended over it.

As for the current of air issuing from the points of bodies electrified *plus* or *minus*, Dr. Priestley observes, that it is not more difficult to be accounted for on Dr. Franklin's hypothesis of positive and negative electricity, than any other case of electrical repulsion. The particles of the atmosphere, near the points of electrified bodies, having by their means become possessed of more or less than their natural share of the electric fluid, must retire to places where they can discharge or replenish themselves as occasion may require. If it be asked why the particles of the atmosphere do not, in the same manner, recede from all the parts of the electrified body, as well as from the points; it is answered, that as the pressure of the atmosphere will prevent a vacuum, and as electrical attraction and repulsion are most powerful at the points of bodies, on account of the easier entrance or exit of the fluid at the points (upon whatever principle that effect depends), the electrified atmosphere, whether negative or positive, must fly off at the points preferable to any other places, and the weight of the atmosphere will force the air of the neighbouring places upon the flatter parts of the electrified conductor, notwithstanding the real endeavour it may have to recede from it. *Hist. of Elect.* vol. ii. p. 191. 8vo. edit. 1775.

Beccaria accounts for this phenomenon by observing, that points annexed to electrified bodies, or presented to them, throw into the contiguous air, or draw from it the electrified fire with such a force, that in both cases they repel from themselves the air, either loaded with part of the fire with which they superabound, or deprived of its own

fire, if these bodies were themselves in a state of negative electricity: and these points, while they drive away the air next to them, throw into or draw from the air, which laterally succeeds the electrical fire; and they do this in such a divided manner, that little light or noise is produced, but with such rapidity, that a great quantity of fire is really discharged in a small space of time. He accordingly distinguishes between that tickling sensation, which the electrical fire excites in us, when the face or hand is immersed into the atmosphere of an electrified body, and the current of air above mentioned. The excessive fire, he says, which actuates this atmosphere, drives the natural fire from the contiguous air to the face, &c. and this fire, in passing into the skin, produces the sensation of tickling: but if the body near which we stand be negatively electrified, the fire within the skin flows to the external surface of it, and thus the same kind of feeling is produced, whether the fire issues out of the body, or passes into it. But the electric wind is a real current of air, driven from a point either annexed or presented to a body strongly electrified, and with such rapidity, that the direction of it cannot be discerned either with the naked eye, or with the assistance of any glass. *Artificial Electricity*, 1776, p. 331, &c.

POINTS, *Application of the Doctrine of.*—There is not a more important fact in the history of electricity, than the use to which the discovery of the efficacy of pointed bodies was applied.

Dr. Franklin, having ascertained the sameness of electricity and lightning, was immediately led to propose a cheap and easy method of securing buildings from the damage of lightning, by fixing a pointed metalline rod higher than any part of the building, and communicating with the ground or with the nearest water. See CONDUCTORS.

This contrivance was actually executed in a variety of cases, and has proved an excellent preservative: some few instances, however, having occurred, in which buildings provided with such conductors have been struck and damaged, a controversy arose with regard to their expediency and utility. In this controversy Mr. Wilson has taken the lead, and with him Dr. Musgrave and some few other electricians have concurred in their opposition to elevated and pointed conductors. They allege, that every point, as such, solicits the lightning, and thus contributes not only to increase the quantity of every actual discharge, but also frequently to occasion a discharge where it might not otherwise have happened: whereas, they say, if, instead of pointed conductors, those with blunted terminations were used, they would as effectually answer the purpose of conveying away the lightning safely, without the same tendency to increase or invite it. Accordingly, Mr. Wilson, in a letter to the marquis of Rockingham (*Phil. Trans.* vol. liv. art. 44.), expresses his opinion, that, in order to prevent lightning from doing mischief to high buildings, large magazines, &c. the several buildings should remain as they are at the top, that is, without having any metal above them, either pointed or not, by way of a conductor; but that on the inside of the highest part of such a building, and within a foot or two of the top, it may be proper to fix a rounded bar of metal, and to continue it down along the side of the wall to any kind of moisture in the ground.

On the other hand, it is urged by the advocates for pointed conductors, that points, instead of increasing an actual discharge, prevent a discharge where it would otherwise happen, and that blunted conductors tend to invite the clouds charged with lightning. And it seems to be a certain fact, that though a sharp point will draw off a charge of electricity silently at a much greater distance than

than a knob, yet a knob will be struck with a full explosion or shock, the charge being the same in both cases, at a greater distance than a sharp point.

The efficacy of pointed bodies for preventing a stroke of lightning is ingeniously explained by Dr. Franklin in the following manner: an eye, he says, so situated as to view horizontally the underside of a thunder-cloud, will see it very ragged, with a number of separate fragments or small clouds one under another; the lowest sometimes not far from the earth. These, as so many stepping-stones, assist in conducting a stroke between a cloud and a building. To represent these by an experiment, he directs to take two or three locks of fine loose cotton, and connect one of them with the prime conductor by a fine thread of two inches, another to that, and a third to the second, by like threads, which may be spun out of the same cotton. He then bids us to turn the globe, and says we shall see these locks extending themselves towards the table, as the lower small clouds do towards the earth, but that, on presenting a sharp point, erect under the lowest, it will shrink up to the second, the second up to the first, and all together to the prime conductor, where they will continue as long as the point continues under them. May not, he adds, in like manner, the small electrified clouds, whose equilibrium with the earth is soon restored by the point, rise up to the main body, and by that means occasion so large a vacancy, as that the grand cloud cannot strike in that place. (Letters, p. 121, &c.) Mr. Henly, with a view of determining the question, whether points or knobs are to be preferred for the terminations of conductors, made several experiments, two or three of which it may not be improper to recite. Having placed two of Mr. Canton's electrometers, A and B, insulated, upon stands of sealing-wax about seven inches asunder, and as far from the end of a prime conductor, eighteen inches long, and $1\frac{1}{2}$ inch in diameter, with a ball at each end, $2\frac{1}{2}$ inches in diameter, the diameter of the electrical globe being nine inches; on the top of the box A he placed a wire, projecting three inches from the end of it, and terminated by a ball $\frac{3}{4}$ ths of an inch in diameter: on the top of the box B he placed a sharp-pointed wire, projecting also three inches from its end. After giving the winch five or six turns, the balls hanging from the box A were repelled to the distance of an inch from each other, but those hanging from the box B separated full two inches. Then touching the prime conductor with a finger, the balls at A closed, while those at B remained a full inch asunder: hence he infers, that a sharp point is much better adapted to draw off lightning than a knob of $\frac{3}{4}$ ths of an inch in diameter.

In another experiment he insulated three of his largest jars, containing together about sixteen square feet of coated surface; from the bottom of these jars projected a wire terminated in a ball $\frac{3}{4}$ ths of an inch in diameter; and at the distance of $1\frac{1}{2}$ inch from it, he placed the insulated ball C, on which he brought down the charge of the three jars by his discharging rod, which leaped from thence to the ball in contact with the jars, and discharged them by a loud and full explosion: but the same thing did not happen when he removed the insulated ball only $\frac{1}{4}$ th of an inch farther from the other. He then removed the wire which was terminated by the ball, and placed in its stead another of the same length and diameter, but very nicely tapered to a point: then placing the insulated ball C one inch from the point, he brought down the charge of the three jars as before, which flew upon the point, and melted it a little: the jars were discharged with a loud and full explosion. But having removed the ball C to the distance of $1\frac{1}{4}$ inch

from the point, the charge did not strike it, though much of it was presently drawn off silently by the point, as appeared by the falling of the index of the electrometer. Whence it seems probable, that a conductor terminated by a ball of $\frac{3}{4}$ ths of an inch in diameter, would be in danger of a stroke from a highly electrified cloud at a much greater distance than another with a sharp termination. He also varied this experiment by placing the large copper ball, C, at such a distance from that in contact with the jar, that on bringing down the charge by his discharging rod, it seemed to remain almost undiminished, though the rod was kept in contact with the prime conductor a full minute. Then repeating the experiment with a point instead of a knob, the charge was in a great measure presently drawn off silently.

In another experiment, he suspended a large bullock's bladder gilded with leaf copper by a silken string, at one end of an arm of wood, placed horizontally, and turning freely upon the point of a needle; the bladder was balanced by a leaden weight. In this situation he gave the bladder a strong spark from the knob of a charged bottle, when presenting towards it a brass rod, terminated by a ball, two inches in diameter, he observed that the bladder would come towards it at the distance of three inches; and when it had got within one inch of it, it would throw off its electricity in a full and strong spark, nearly, if not quite as large as that which it had received. But giving it another strong spark, and presenting towards it a pointed wire, he could never perceive that it attended to that, and when it was brought nearly into contact with the bladder, there was no spark at all, scarcely any quantity of electricity remaining in it. This experiment was frequently repeated with the same result. Phil. Trans. vol. lxiv. part ii. art. 18. See *THUNDER-House*.

It has been universally allowed, that in cases where the quantity of electricity with which thunder-clouds are charged is small, or when they move slowly in their passage to and over a building, pointed conductors, which draw off the electrical fluid silently, within the distance at which rounded ends will explode, will gradually exhaust them, and thus contribute to prevent a stroke, and preserve the buildings to which they are annexed.

But it has been said by those that are averse to the use of such conductors, that if clouds of great extent and highly electrified, should be driven with great velocity directly over them, or if a cloud hanging directly over buildings to which they are annexed, suddenly receives a charge by explosion from another cloud at a distance, so as to enable it instantly to strike into the earth, these pointed conductors must take the explosion; on account of their superior readiness to admit electricity at a much greater distance than those that are blunted, and in proportion to the difference of that striking distance, do mischief instead of good: and, therefore, they add, that conductors terminated by sharp points are sometimes advantageous, and at other times prejudicial: and that, as the purpose for which conductors are fixed upon buildings is not to protect them from one particular sort of clouds only, but, if possible, from all, it cannot be adviseable to use that kind of conductors, which, if they diminish danger on the one hand, will increase it on the other. Besides, it is pleaded, that if sharp-pointed conductors are attended with any the slightest degree of danger, that danger must be considerably augmented by carrying them high up into the air, by fixing them upon every angle of a building, and making them project in every direction. Such is the reasoning of Dr. Musgrave, for which we must refer to his paper in the Phil. Trans. vol. lxxviii. part ii. art. 36.

POINTS.

Mr. Wilfon, dissenting from the report of a committee of the Royal Society, appointed to inspect the damage done by lightning to the house of the board of ordnance, at Purfleet, in 1777, was led to justify his dissent, and to disparage the use of pointed and elevated conductors, by constructing a magnificent apparatus, with which he might produce effects similar to those that had happened in the case referred to the consideration and decision of the committee.

With this view he prepared a model of the board-house at Purfleet, resembling it as nearly as possible in every essential appendage, and furnished with conductors of different lengths and terminations. As no apparatus sufficiently large for representing a thunder-cloud, could conveniently be put in motion, he contrived to accomplish the same end by moving the model of the building, with a velocity answering to that of the cloud, which he states, at a moderate computation, to be about four or five miles an hour. In order to construct a proper substitute for the cloud, he joined together the broad rims of one hundred and twenty drums, making the surfaces formed by the several junctures even with cloth pasted down, and covering them with tin-foil. These drums formed a cylinder above one hundred and fifty-five feet in length, and above sixteen inches in diameter. The whole cylinder was made in four separate parts, three of which could easily be made to communicate or not with each other; the fourth, consisting of eight brass drums, was reserved for a different purpose. The great cylinder, consisting of the three parts, and containing five hundred and ninety-two square feet, was suspended about five or six feet from the floor by silk lines, one end of it hanging over the middle of the long frame on which the model was proposed to move, and the other being joined occasionally to the end of a wire four thousand eight hundred feet long, that was suspended through the whole space of the room; the remote end of this wire hooked on occasionally at the end of the brass drums, which made a separate cylinder about ten feet in length, and which was suspended by silk lines about six feet from the floor, in such a manner that the farthest end thereof from the wire was within nine or ten feet from the great cylinder. The long wire with the great cylinder and brass drums made the whole of the substitute for a thunder-cloud, when they were properly charged. This apparatus was charged by a machine with one glass cylinder, about ten or eleven feet from its nearest end. The whole of the apparatus was disposed in the great room of the Pantheon, and was applied to use in no less than fifty different experiments.

It is impossible within the limits of this article to do justice to Mr. Wilfon's experiments, or to the inferences which he deduces from them. It will be sufficient to observe in general, that most of his experiments, in which the model of the house, with pointed or blunted conductors annexed to it at the same or different heights, and made to move swiftly under his large artificial cloud, were intended to shew, that conductors with points are struck at a greater distance, and with a higher elevation than those with blunt or rounded terminations; and from all his experiments made with pointed and rounded conductors (provided the circumstances be the same in both) he infers that the rounded ones are much the safer of the two; whether the lightning proceeds from one or more clouds; that those are still more safe which (instead of being, as Dr. Franklin recommends, ten feet high) are very little, if at all, above the highest part of the building itself; and that this safety arises from the greater resistance exerted at the larger surface. For a farther account of the apparatus, experiments, and reasoning of Mr.

Wilfon, the reader, desirous of more particular information, is referred to the Phil. Transf. vol. lxxviii. part i. art. 15.

The committee of the Royal Society, composed of nine of the most distinguished electricians in this kingdom, to whom the consideration of the most effectual method of securing the powder-magazines at Purfleet, against the effects of lightning, was referred, express their united opinion, that elevated rods, constructed and disposed in the manner which they direct, are preferable to low conductors terminated in rounded ends, knobs, or balls of metal, and that the experiments and reasons, made and alleged to the contrary by Mr. Wilfon, are inconclusive.

Mr. Nairne, in order to obviate the objections of Mr. Wilfon and others, and to vindicate the preference generally given to elevated and pointed conductors, constructed a much more simple apparatus than that of Mr. Wilfon, with which he made twenty-seven well-designed and well-conducted experiments, which seem to prove the point as far as it is capable of being proved by our artificial electrical apparatus. Of these, as the subject is of importance, it will be proper to give some account. His apparatus and machine were as follow, and will be sufficiently understood from the description of them. A is a glass cylinder eighteen inches in diameter, B a conductor of wood, covered with tin-foil, six feet long, and one foot in diameter, and intended to represent a cloud, and D a brass rod on a stand communicating with the earth, to the end of which other rods, terminated with balls of a different size, or a point, might be screwed, and designed to represent a conductor to a house. A brass ball, four inches in diameter, being screwed on to the end of the rod D, was struck by the ball C, at the end of the charged conductor to the distance of seventeen inches and four-tenths, and sometimes to nineteen, and even to twenty inches; a ball, one inch in diameter, received strokes to the distance of about two inches, which were succeeded by a hissing noise, and a continued light on the ball, till the distance was about ten inches; after which the strokes were renewed and continued to the distance of $14\frac{8}{10}$ inches, and occasionally to $16\frac{3}{10}$ inches; a ball of $\frac{2}{10}$ ths of an inch diameter, in the same circumstances, was struck to the distance of half an inch, and continued luminous till it was removed beyond the striking distance as far as thirty-three inches. Instead of a ball, a wire about $3\frac{1}{2}$ inches long, terminating in a point, was substituted in its stead, but no strokes happened, though the point was almost in contact with the ball C; at the distance of half a tenth of an inch, the point received a stream of fire; beyond that distance, it was luminous, and so continued whilst it was gradually removed to the distance of six feet.

In another experiment, the ball of four inches in diameter, with a hole through it, was used; through the hole a wire projected $\frac{1}{10}$ th of an inch beyond the surface of the ball, and directly pointing to the ball C; but neither the ball nor point were struck at any distance; the point was luminous at the distance of thirty inches; when the point of the wire was made even with the surface of the ball, it was struck to the distance of $17\frac{1}{4}$ inches. Having screwed a hollow brass ball $3\frac{1}{2}$ inches in diameter, with a hole through it, to a brass hollow stem, and passed a wire through it with its pointed end projecting one inch beyond the surface of the ball; this apparatus was placed on a stand communicating by metal with the earth, at the distance of five feet from the conductor or artificial cloud, and directly opposite to its sides; in this case the striking distance from the ball C to the ball of four inches diameter on the rod D, was $16\frac{1}{10}$ inches; when the point of the wire, passing through the ball and stem, was made to project nine inches beyond it,

the

the striking distance only $6\frac{3}{10}$ inches. In order to discover how far a point or differently sized balls, with small separations in the metallic communication with the earth, would act to carry off the electric fire of the artificial cloud, Mr. Nairne fixed a screw to each end of a stick of sealing-wax, and, having pasted a slip of tin-foil over its surface, and made a separation of the tin-foil of about $\frac{1}{10}$ th of an inch, screwed the pointed wire into one end, and the other end of the wax to the brass rod, where the ball with the point projecting from it was placed in the last experiment. The stand, being placed directly opposite to the side of the artificial cloud, was removed to the distance at which the light between the separation of the tin-foil no longer became visible, which was above seven feet. When a ball of $\frac{3}{10}$ ths of an inch was put in the place of the point, the light was visible at the distance of four feet six inches, but with a ball of three inches diameter, only at two feet. He took another stick of wax, $1\frac{3}{10}$ inch in diameter, and about ten inches long, and, having pasted on it round pieces of tin-foil half an inch in diameter, at about half an inch distance from each other, screwed one end of it to the receiving rod, the pointed wire being screwed into the other end. All the separations of the tin-foil, except two, were connected by a piece of brass laid on the wax, and the point of the wire was placed nearly in contact with the ball; in these circumstances the fire of the charged conductor struck into the point, and continued to strike till it was gradually removed to the distance of $1\frac{1}{10}$ inch; beyond which distance it would not strike, but the point continued luminous to the distance of three feet. When the connecting brass piece was removed, the point was not struck till it was removed to the distance of $4\frac{1}{2}$ inches; it continued to be struck to the distance of ten inches; after which it was not luminous, except when the artificial cloud discharged its electric fire into the air, by a diverging pencil from the ball C.

From the experiments above recited, we may infer, that the artificial cloud strikes at distances greater, as the termination of the conductor is more blunted; that the striking distance is less as the end of the conductor tends more to a point; and that when the end of a conductor is pointed, the point is not struck at any distance, but continues luminous to a certain distance, carrying off silently the electricity of the artificial cloud. We may also infer the utility of a pointed rod, even if it projects but a small distance above the highest part of a building; that a point within the surface of a ball does not prevent the ball being struck; that the more elevated our pointed conductors are, the greater is the chance of preserving buildings from the effects of lightning; that a conductor terminating in a point acts at a much greater distance than one terminating with a ball, in carrying off the electric fire; that the reason why the artificial cloud strikes to the point, is the separation or discontinuance of the metallic part of the conductor; that it strikes farther to the point, as the number of separations is increased; and that, if the metallic communication with the moist earth be completed, the charged cloud will not strike to the point.

Another part of Mr. Nairne's apparatus is a moveable artificial cloud, consisting of a hollow tube of wood, with a ball at each end, about six feet in length; from the ends are suspended hollow wooden cylinders E, E, which, together with the balls and tube, are covered with tin-foil; the axis of the tube rests on two semicircular hollows, in a piece of brass fixed on the glass pillar; round which axis it easily moves, and is brought to a horizontal position by means of two moveable pieces F, F. Having put this moveable cloud into an horizontal position, and the brass on which the

axis rested into contact with the end of the artificial cloud B, under each of the hollow cylinders E, E, Mr. Nairne placed stands, G, G, having a good metallic communication with the earth, one of which was furnished with a pointed wire, and the other with a brass ball, three inches in diameter. Each of these was placed twelve inches from the bottom of its corresponding cylinder; and when the clouds were charged the point became luminous, and the moveable cloud remained in a horizontal position; but when the operation of charging the two clouds was discontinued, it was immediately found, that the point had drawn off almost all the electric fire. When the clouds were again charged, and the stand with the ball removed, the point was luminous, and the moveable cloud remained horizontal, not being attracted to the point which carried off the electric fire. But when the clouds were charged, the stand with the ball restored, and that with the pointed wire removed, the end over the ball was attracted down till it came to its striking distance, where it discharged its electricity on the ball in a strong spark. It then receded a little, and being charged, approached the ball as before, and discharged its electricity at once, and thus continued striking and receding as long as the two clouds were charged. When the pointed wire was replaced, it became luminous, the striking ceased, and the moveable cloud returned to its horizontal position. The effect was the same, when the pointed wire was placed on the same side with the ball. The conclusions from these experiments are obvious. From these experiments, in which the moveable artificial cloud was made to represent a cloud in its natural state receiving electric fire from a charged cloud, it was found, that the point deprived it of its electric fire which it received from the charged one so fast, that the artificial cloud could keep constantly striking to the other end, without repelling it from it: but that, when the ball was placed in the room of the point, instead of the artificial cloud continuing to strike to the other end, without repelling that end, it now first attracted and charged it with electricity, then immediately repelled it; and being attracted by the ball under the other end, it moved down with an increasing velocity, till it came within its striking distance, when it discharged its electricity on the ball with a loud and strong spark, and so continued alternately receiving and discharging its electric fire on the ball, according to the known laws of electricity. In another experiment it was found, that, though the moveable artificial cloud was in great motion, receiving and discharging its electric fire on the ball, on taking away the ball, and putting the point in its place, the artificial storm immediately ceased. When the cloud is fixed at a certain distance between the artificial cloud and the point, the fixed cloud, at the instant it receives the electric spark, directly discharges it again on the point; but without any other alteration, besides making the cloud moveable on its axis, the distances being the same, the end of the cloud then recedes from the point, and will not strike to it; and this case is much more agreeable to nature than the other, because clouds are not fixed but floating bodies.

In order to observe the effects of rods terminating with balls of different sizes, or terminating with a point moving swiftly under the artificial cloud, Mr. Nairne made use of an apparatus, in which H is a hollow tube of wood, covered with tin-foil, with a heavy weight fastened to one end of the tube, suspended by an axis, about three inches above the weight, between two wooden pillars: in this wooden tube there was a moveable brass rod, by means of which a ball, or point, fixed on it, might be raised to any required height. To the under part of the artificial cloud, at K, was fixed a ball $1\frac{3}{10}$ ths of an inch in diameter; and then the apparatus

ratus was placed under it with a point, the swinging rod being held down to the floor, and the point covered; the artificial cloud was then charged, and the swinging rod with the point being let go, passed swiftly and very near to the ball under the artificial cloud at K. This was repeated several times, till the greatest striking distance to the point was found, which was generally $\frac{1}{10}$ of an inch. Instead of the point, a ball $\frac{3}{16}$ ths of an inch in diameter was applied in the same manner, and the striking distance was generally found to be $2\frac{1}{16}$ inches. When a ball of $\frac{1}{16}$ ths of an inch was used, the striking distance was generally fifteen inches. Here we may observe, that the singular disappearance and re-appearance of the sparks, on gradually removing the small conductor from the prime conductor, already mentioned, occurred likewise in the two first of the cases just recited; but when the large ball was used, it was struck uninterruptedly till it was removed to the distance of sixteen inches. From these last experiments it appears, that the point is struck by means of a swift motion, but that the ball of $\frac{1}{16}$ ths of an inch was struck farther than the point, and the larger ball at a much greater distance than either, even with the swiftest motion. Upon the whole, Mr. Nairne seems to be justified in preferring elevated pointed conductors; next to them those that are pointed, though they project but a little distance above the highest part of a building; and after them those terminating in a ball, and placed even with the highest part of a building. For a farther account of these curious and useful experiments, and the author's remarks on those of Mr. Wilson, the reader is referred to Phil. Trans. vol. lxviii. part. ii. art. 37.

POINT, in *Geometry*, according to Euclid, is a quantity which has no parts, or which is indivisible.

Wolfius defines it, that which terminates itself on every side; or which has no terms or boundaries distinct from itself.

This is what we otherwise call the *mathematical* point, and is only conceived by the imagination; yet it is in this that all magnitude begins and ends, the flux or motion of the point generating a line, that of a line a surface, &c.

Hence some define a point to be the inceptive of magnitude.

Hobbes defines a point to be a body whose magnitude is not considered. But his false notions of a point, line, and surface, have led him into many errors. Monsieur de Crouzas also has supposed a line to be composed of points, in his geometry and comment on the *Analyse des Infiniment petits*. This supposition only tends to confound learners. See Jo. Bernouilli *Oper.* vol. iv. p. 161, seq.

A line can only cut another line in a point. Any three points being given out of a right line, a circle, or part of a circle may be drawn, that shall pass through them all.

To draw a parallel line, a perpendicular, a tangent, &c. to a given point, are popular problems in geometry. See PERPENDICULAR, PARALLEL, TANGENT, &c.

POINT, *Conjugate*, is used for that point into which the conjugate oval, belonging to some kinds of curves, vanishes. Maclaur. *Algebr.* p. 308.

POINTS, *Proportion of Mathematical*. It is a current maxim that all infinites, whether infinitely great, or infinitely small, are equal; yet is the maxim false in both cases. Dr. Halley shews several infinite quantities, which are in a finite proportion to each other; and some infinitely greater than others. See INFINITE *Quantities*.

The like the Hon. Mr. Roberts shews of infinitely small quantities, viz. mathematical points.

He demonstrates, for instance, that the points of contact between circles and their tangents, are in a subduplicate proportion.

portion to the diameters of the circles; that the point of contact between a sphere and a plane is infinitely greater than that between a circle and a tangent; and that the point of contact in spheres of different magnitudes are to each other as the diameters of the spheres.

POINT of *contrary Flexure*, in the *Higher Geometry*. See POINT of INFLECTION, and RETROGRADATION of Curves.

POINT of *Reflection*, in *Geometry*, is commonly used instead of point of retrogradation, or retrogression.

POINT, in *Grammar*, is a character used to mark the divisions of a discourse.

The point *proper* is what we otherwise call a *full stop*, or period, and serves to denote the sense complete, and the period ended. See PAUSE.

Two points usually mark the middle of a period, and shew a construction complete, and the sense to be perfect; yet intimating something to come after it; this we call a colon.

A point with a comma, called a semicolon, marks a sense less complete than the colon: though authors seem to use them indifferently; nor are grammarians agreed about their precise difference.

The comma, or virgula, marks a subdivision of a member of a period. To these points Dr. Ward adds the semi-period.

Besides these primary points, which distinguish sentences, there are others, which Dr. Ward calls *notæ affectuum*, and which, Dr. Lowth says, denote a different modulation of the voice in correspondence with the sense: such are a point of interrogation (?), which marks something to be pronounced in a higher tone, as intimating a question asked; a point of admiration, or exclamation, (!), which marks a sudden surprize and wondering; and a parenthesis.

The interrogation and exclamation points are indeterminate as to their quantity or time, and may be equivalent in that respect to a semicolon, a colon, or a period, as the sense requires; they mark an elevation of the voice.

The parenthesis, which incloses in the body of a sentence a member inserted into it, which is neither necessary to the sense, nor at all affects the construction, marks a moderate depression of the voice with a pause greater than a comma.

Our points and accents were entirely unknown to the ancients. In the ancient Greek manuscripts, the whole discourse seems written with the same stroke of the pen; the words and letters being joined throughout.

In after-times, points were invented, and added at the top of the letters, to shew when the sense was finished. Hence the grammarians, coming to retouch the old manuscripts, thought fit to add the points and accents. Salmasius affirms, that he has even observed plainly where they have been added, by the difference of hands. See PUNCTUATION.

POINTS, or *vowel Points*, in the *Hebrew Learning*, are certain characters, which, in the writings of that language, serve to mark the vowels.

The antiquity of the points in the Hebrew tongue makes the subject of a celebrated controversy among the learned; some maintaining their origin to be the same with that of the Hebrew language; and others asserting them to have been first introduced by Ezra, after the Babylonish captivity, when he compiled the canon, transcribed the books into the present Chaldee character, and restored the purity of the Hebrew text.

Others will have them invented by the doctors of the school of Tiberias, usually called the Masorites, about 500 years after Christ. The rabbin Elias Levita was the first who started this question, in the beginning of the 16th century; and maintained them to have been an invention of the

Maforites, for the ease of those who were to learn the Hebrew tongue. See MASORA.

This sentiment was espoused by Capellus, to whom also adhered Luther, Calvin, Casaubon, Scaliger, Masclef, Erpenius, Mercer, Morinus, Drufius, Le Clerc, Walton, Hare, Bently, Newton, Sharp, &c. who are all opposers of the antiquity of vowel points. To these we might add several of the Jews, particularly Aben Ezra, who lived in the twelfth century: and almost all the learned men of the Romish persuasion. Buxtorf attacked Capellus violently on this article, and gained a great number of divines on his side, who took the alarm, imagining it a grievous wound to the holy text, to allow the vowel points to have been added by the Maforites, and not to have been found in the ancient text; because, without these, it is very difficult to fix the certain reading thereof. Yet, in the Samaritan text, there is no point or vowel, nor in many of the most ancient Hebrew manuscripts.

Those who maintain that the Hebrew points were not invented by the Maforites, allege, that there is no mention in any Jewish writer of such an alteration; as the introduction of the points, being made in the Hebrew Bible; that all the annotations or notes of the Maforites upon the vowels, relate to the irregularity of them, which could not have been occasioned by themselves, but must have existed in the copies that were before them; that express mention of the points or vowels occurs in books more ancient than the Talmud, *viz.* Babir and Zoar, the first said to be written a little before our Saviour's time, and the second about a century later. However, these books are justly rejected by others as spurious. Prideaux says, that many particulars occur in these books, which prove that they must have been written above a thousand years after the pretended time of their composition; and farther it is pleaded, that the points were in use in our Saviour's time, from Mat. v. 18, whence it appears, that the titles or points at that time belonged to the law. But Capel understands by the *קטנות*, not the points, but the corollæ or flourishes made about the Hebrew consonants.

Those who are of opinion that the points are coeval with the consonants, argue, that it is impossible to pronounce the language without vowels, and also to teach it, unless the vowels were expressed; that if the vowels are of human and late invention, the authority of the holy scriptures will be weakened, and the sacred text left to an arbitrary and uncertain reading and interpretation. But to this objection it is replied, that א, ה, ו, י, and יו, originally served for vowels. Nevertheless, this answer seems insufficient; because there are many words in which these letters do not occur; and it is argued, from the nature and structure of the Hebrew language, and its dialects, in which the radicals or primitive words are formed by triads, composed by the conjunction of different consonants or letters, that some other letters must necessarily belong to the language. However, it is certain, that the *matres lectionis*, as the above letters are called, have been sometimes omitted; for they are more frequent in some of the older manuscripts than in the later, or in the printed text.

The arguments against the antiquity of the Hebrew points, tending to prove that they were added by the Maforites, are deduced from grammar, testimony, and history. The grammatical arguments are principally founded in the Keri and Chetibh. The Keri, it is agreed, began to be collected a little before the completion of the Talmud, probably by the Maforites; and it is observed, that they are various lections merely of the consonants, and not of the vowel points; and that there are certain irregularities in the

punctuation, both with respect to whole words, and the parts of words, which shew that the points were not in the copies, from whence the Keri and Chetibh were made.

The testimony which furnishes the second class of arguments is either express or tacit. Of the first sort is the testimony of Aben Ezra, R. David Kimchi, R. Jehuda Levita, and R. Elias Levita, who deny the antiquity of the vowel points. The tacit testimony is derived from the copies of the law, which are kept and read in the synagogues, or from the cabbalistic interpretation, or from passages of the Talmud. Those copies of the law called *Sepher-torah*, read every Sabbath, and reckoned the most sacred, are constantly written without points; to which we may add, that in many manuscripts, examined by Dr. Kennicott, and those some of the oldest and best, either there are no points at all, or they are evidently a late addition. The cabbalistic interpretations relate to the consonants, and none of them to the vowels. When the Talmud was composed, the points were not affixed to the text, because there are several disputes concerning the sense of the passages of the law, which could not have been disputed, if there had been points; besides, the vowels are never mentioned, where the fairest opportunity occurred for mentioning them, if they had been in being.

The arguments from history are drawn from the Chaldee paraphrases of Jonathan and Onkelos, the Greek versions of Aquila, Symmachus, and Theodotion, and especially that of the Septuagint; whence it is argued, that the copy from which these were translated was without points; as several words are translated in a different sense from that which the points would determine them to mean. Those who wish to see a compendious abstract of the arguments for and against the antiquity of points, and of the state of this controversy, may consult Jennings's *Jewish Antiq.*, vol. ii. p. 344, &c.

Dr. Prideaux has an hypothesis peculiar to himself: he apprehends that the points were added by more ancient Maforites than those of the school of Tiberias, soon after Ezra, when the Hebrew ceased to be a living language; but that they were not in common use, nor taught in the theological schools, till after the compilation of the Talmud. *Conn. part i. book v. vol. i. p. 5—520. ed. 10.*

POINTS, in *Heraldry*, are divisions of the escutcheon into several squares, sometimes to the number of 9, sometimes to 15; some of which are of one colour or metal, the others of another; called also *equipollent* points.

There is also another, and that more frequent division of the escutcheon into points, which have several names and values, according to their several places.

There are nine principal points in an escutcheon, described under ESCUTCHEON.

Columbiere makes the points, and their situations, symbolical. As the several bearings in an escutcheon are so many types representing the commendable actions of the person they are given to; so the escutcheon itself represents the body of the man that performed them; and the points or parts signified by these letters, the principal parts of his body. Thus, A, B, C, represent the head, in which the three great faculties reside; D, the neck, where ornaments are chiefly borne; E, the heart, &c.

POINT is also the name of an ordinary, something like the pile, rising frequently from the bottom of the escutcheon to the top, very narrow, and only taking up two-thirds of the point of the escutcheon.

When the point arises from the base, it is peculiarly called *point-in-point*.

POINT *inverted*, is when it descends from the chief downwards;

wards; possessing two-thirds of the chief, but diminishing as it approaches the point of the escutcheon, though without touching it.

POINT in Bend, or Point in Bar, is when the point is placed transverse in the situation of a bend or bar.

When it comes from the sides of the escutcheon, it is also called a point *dexter* or *sinister*, according to its situation.

The *point dexter* is commonly reputed an abatement due to a braggadocio. *Point champion ten* due for killing a prisoner after quarter demanded. *Point-in-point*, a diminution belonging to a coward. *Point-plane*, an abatement belonging to a liar, &c. See DIMINUTION.

POINT is also used in heraldry for the lowest part of the escutcheon, which usually terminates in a point.

POINT Champain. See CHAMPAIN.

In the French arms, the fleur-de-lis are two in chief, and one in point.

POINT, in the Manege. A horse is said to make a point, when in working upon volts, he does not observe the round regularly, but pulling a little out of his ordinary ground, makes a sort of angle or point by his circular tread. This fault is prevented by hastening the hand. See HASTE.

POINT is also used to denote the toes of a bow of a fiddle.

POINT, in the Manufactories, is a general term used for all kinds of laces wrought with the needle.

Such are *point de Venice*, *point de France*, *point de Genoa*, &c., which are distinguished by the particular economy and arrangement of their points.

POINT is sometimes also used for lace woven with bobbins, as *English point*, *point de Molines*, *point de Havre*, &c.

POINT is also an iron or steel instrument, used, with some variety, in several arts.

Engravers, etchers, cutters in wood, stone-cutters, &c., use points to trace their designs on the copper, wood, stone, &c.

Statuaries, &c. have likewise points in manner of little chisels, used in the first forming or sketching out their work.

Turners work or fashion their common works between two points fastened to the puppets. Lapidaries have also iron points, to the ends of which are fastened pieces of diamonds, serving to pierce the precious stones.

POINT, in Music, is a mark or note anciently used to distinguish the tones.

Hence we still call it simple *counter-point*, when a note of the bass answers precisely to that of the treble; and figurative *counter-point*, when a note is syncopated, and one of the parts makes several inflexions of the voice or tone, while the other only makes one.

We still use a point to raise the value of the note, and prolong its time by one half; *e. gr.* a point, added to a semibreve, makes it, instead of two minims, equal to three.

In the old music, a point added to a *binary* note, or one that was only equal to two others of any kind, was called the *point of perfection*, as triple time was then called *perfect*, and common time *imperfect*.

A point, in the art of fugue, generally implies a new subject of imitation in a regular fugue, and resembles an episode in an epic poem.

The Italians call the principal theme of a fugue *foggetto*, subject, as we do; but a new point is by them generally termed *attacco*; which see.

POINT d'Orgue, Fr., or Point de Repos, is a pause \frown upon a note in the base, equivalent to *tasto solo* in Italian music; when the treble part, as in Corelli's solos, is al-

lowed to wander about in double or single stops, after the manner of a cadenza or close, till the terminating shake preceding the final note. A point covered with a semicircle over any note, simply implies a pause; and over the last note of a movement, it implies its final termination. See CORONA.

POINTS, whether ever used in the Greek language as musical notes, see NOTATION.

POINT, in Navigation and Geography. *Points of the horizon, or of the compass,* are certain points, formed by the interfections of the horizon by vertical circles.

The number of these points, therefore, is really the same with that of the points conceived in the horizon, *i. e.* infinite; though, in practice, we only distinguish thirty-two of them.

Some use point for the interfection of a vertical circle, with a circle parallel to the horizon; and even some, for the segment of a vertical, intercepted between the meridian and horizon, or a circle parallel thereto.

The points are shewn by right lines drawn from a point assumed in a horizontal plane.

A point of the compass is popularly taken for a 32d part of the whole; or for an arc of $11^{\circ} 15'$; half of which, *viz.* $5^{\circ} 37\frac{1}{2}'$, is called a *half* point; and half of that, or $2^{\circ} 48\frac{3}{4}'$, a *quarter* point.

These points of the compass are divided into *cardinal* and *collateral*; which see. See also COMPASS.

POINT, in Optics. The point of *concourse*, or *concurrence*, is that wherein converging rays meet, more usually called the *focus*.

POINT of Dispersion. See DISPERSION.

POINT of Incidence. See INCIDENCE.

POINT of Reflexion. See REFLEXION.

POINT of Refraction. See REFRACTION.

POINT, Radiant. See RADIANT.

POINT, in Perspective, is a term used for various parts or places, with regard to the perspective plane. Such are the

POINT of Sight, or of the Eye. This is a point on a plane, marked out by a right line drawn from the eye, perpendicular to the plane. This is also called the *principal* point.

This point is in the interfection of the horizontal and vertical planes.

Some authors call this the *principal* point; and give the name *point of sight*, or *vision*, to the point in which the eye is actually placed, and where all the rays terminate. See PERSPECTIVE, and POINT of View.

POINT of Distance, is a point in the horizontal line, at the same distance from the principal point, as the eye is from the same. See PERSPECTIVE.

POINT, Third, is a point taken at discretion in the line of distance, wherein all the diagonals, drawn from the divisions of the geometrical plane, concur.

POINT, Objective, a point on a geometrical plane, whose representation is required on the perspective plane.

POINT, Accidental. See ACCIDENTAL.

POINT, Visual. See VISUAL.

POINT of View, with regard to *Building, Painting, &c.* is a point at a certain distance from a building, or other object, in which the eye has the most advantageous view or prospect of the same.

This point is usually at a distance equal to the height of the building. For an instance: to consider with judgment the whole of the famous church of the invalids at Paris, we must not stand at above three hundred and forty feet distance from it, which is nearly its height.

To be able to judge of the ordonnance of its façade or frontispiece, and the regularity of its order, the eye should only be as far off as the frontispiece is high; *viz.* a hundred feet.

But to examine the correctness of its profiles, and the spirit of its ornaments, the eye should only be distant the height of the Doric order, which is about forty feet; if it be nearer, the parts, being too much shortened, will appear out of proportion.

A vague or indeterminate point has a different effect from the point of view; in that, in looking at a building from an indeterminate point, the eye can only form an idea of the magnitude of its mass, by comparing it with other buildings adjacent to it.

POINT, *Punctum*, in *Physics*, is the smallest or least sensible object of sight, marked with a pen, point of a compass, or the like.

This is what we popularly call a *physical* point, which in reality has parts, though those parts are not here regarded. Of such points does all physical magnitude consist.

This *physical* point coincides with what Mr. Locke calls the point *sensible*, and which he defines to be the least particle of matter, or space, we can discern. He adds, that, to the sharpest eye, this is seldom less than thirty seconds of a circle, of which the eye is the centre.

POINT, in *Poetry*, denotes a brisk lively turn or conceit, usually found or expected at the turn of an epigram.

POINT, among *Sportsmen*, denotes the position of a *pointer*, when he stands seemingly fixed and immovable at the game before him: at the moment of observing which, particularly with young and unsteady dogs, the sportsman exclaims, "To-Ho;" "Have a Care!" as an injunction of steadiness to the dog that is standing, and of attention on the part of every dog in the field to the first who has observed the point.

POINT, among *Seamen*, is also used for a cape, or headland, jutting out into the sea.

They say, two points of land are *one in another*, when they are so in a right line against each other, as that the innermost is hindered from being seen by the outermost.

POINTS, in *Rigging*, are short pieces of braided cordage, plaited together as gaskets are; beginning in the middle with nine foxes, and tapering to five at the ends, and from one and a half fathom to one fathom in length. They are used to reef the courses and top-sails.

POINTS of *Cattle*, in *Rural Economy*, the parts which shew the excellencies or defects in their forms. See CATTLE.

POINT, in *Geography*, is used for *Cape*, (which see.) The principal points of this kind occur under the appellations that distinguish them, or from which they are denominated. Our limits will not allow our reciting them in this place.

POINT-BLANK, in *Gunnery*, denotes the shot of a gun levelled horizontally, without either mounting or sinking the muzzle of the piece.

In shooting point-blank, the shot or bullet is supposed to go directly forward in a straight line to the mark; and not to move in a curve, as bombs and highly elevated random-shots do.

When a piece stands upon a level plane, and is laid level, the distance between the piece and the point where the shot touches the ground first, is called the point-blank range of that piece; but as the same piece ranges more or less, according to a greater or less charge, the point-blank range is taken from that of a piece loaded with such a

charge as is commonly used in action. It is, therefore, necessary that these ranges of all pieces should be known, since the gunner judges from thence what elevation he is to give to his pieces, when he is either farther from or nearer to the object to be fired at; and this he can do pretty nearly by sight, after considerable practice. See *Pointing of a GUN*.

POINTED ARCHITECTURE, the appropriate term of a style of architecture of peculiar beauty and solemn effect, particularly in religious buildings, vulgarly called Gothic architecture. The distinctive character of this style is, that all its arches are pointed at the top, while other arches form the segment of a circle. From this peculiarity (the happy effect of intersecting circular arches) progressively grew the slender and circular columns, the aspiring pediments, the lofty steeples, the foliated finials and crockets, the flying buttresses, the meeting groins, the luxuriant tabernacles and the diversified tracery, which characterise the pointed style of architecture. It made its first appearance in England, then the richest and most polished kingdom in Europe, before the middle of the twelfth century, namely, about 1130, and very soon afterwards it found its way into the northern provinces of France, and into Scotland. It is divided into three orders, which grew up at different periods, each being richer and more complicated than the preceding one. See *GOthic Architecture*.

POINTED *Cross*, among *Heralds*, is that which has the extremities turned off into points by straight lines. Columbiere calls it *aiguise*, q. d. *sharpened*.

POINTED *Crowns*. See CROWN.

POINTED *Roof*. See ROOF.

POINTER, SPANISH. See DOG.

Pointers, forty or fifty years ago, were hardly ever seen that were not either entirely white, or variegated with liver-coloured spots; those of the then duke of Kingston's black and white excepted, which were considered as superior to every breed in the kingdom. But they are now to be seen of every description, from pure white and a flea-bitten blue or grey, to an universal liver colour, and a perfect black. Sportsmen observe, that in the choice of pointers for general use, that is, for every species of game, it is best to avoid extremes both in size and in speed. Pointers are never considered as complete, unless they are perfectly staunch to "bird," "dog," and "gun;" that is, that they stand singly to a bird or a covey; that one dog *backs* (or points instantaneously likewise) the moment he perceives another dog to *stand*; and lastly, not to stir from his *point*, upon the firing of any gun in company, provided that the game is neither sprung nor started at which he made his original *point*. The art of breaking pointers for the field was formerly thought a very mysterious and difficult business; but the process is now reduced to such simplicity, that a tolerable well-bred pointer-puppy may acquire the principles of his future excellence in the kitchen or parlour of his master, before he is taken into the field. This may be done even with two or three brace together in a large room, or small yard, with no other assistance, besides the alternate words of "To-Ho," "Take Heed," and "Have a Care;" with the small field whip in hand to impress attention, although meat should be tossed before them in every direction; when a single dog will not stir till the signal of "Hie-on" is heard, which they all eagerly obey; but are as instantly stopped at the moment of seizing their meat, by either of the cautions previously mentioned. Young dogs, having thus imbibed the principles upon which they are to act, have nature and their instinctive impulse, to point out their practice when brought

into the field. When brought into the field, they should be taught to traverse every yard of the ground (in proper lengths and at proper distances), so that none be left unbeaten; and this should be done with as few words, and as little noise, as possible. Short verbal signals, low vibrative whistles, and the motion of the hand to the right or left, are all that are useful; more will do mischief. One steady shot of this description, with a brace of pointers obedient to command, and staunch to *dog* and *gun*, will kill more game in any country, than a noisy crew with three or four brace of dogs before them. Young pointers should not be permitted to deviate from the proper rule of quartering the ground before them; that is, to cover a line of 80 yards *transversely* in the front of his master, taking 40 yards to his right, and repassing him, at the same distance to the left; and in such proportions as not to let his crossings and recrossings be more than 25 or 30 yards from each other. If a brace of pointers are in the field, they should alternately cross the same beat, by *meeting* and *passing* each other; but never beat the same way in a parallel direction.

Those who wish pointers to bring the game when killed, will find it easy of attainment, by teaching them to fetch and carry before they take the field. Previously to the beginning of the season, or about a fortnight before its commencement, each dog should have two doses of physic about four days apart; after which proper attention should be paid to the provision, which should be of a sweet and healthy kind, to preserve their organs and faculties, as much as possible, in full perfection. From the hardness and heat of the ground in the first weeks of September, it sometimes happens, that the feet become lacerated, inflamed, and sore; in which case, plentiful washing, with warm gruel and a sponge, will afford considerable relief; and in an hour or two afterwards, the application of some weak salt and water, or old white wine vinegar, will harden the surface, and probably prevent a repetition of the grievance.

POINTERS, in *Ship Building*, are braces of oak timber of a large scantling, sometimes fixed diagonally across the hold, to support the sides and beams to which they are attached by iron-straps or knees.

POINTING, PUNCTUATION, in *Grammar*. See PUNCTUATION.

POINTING, among *Seamen*, the marking on the chart in what point or place the vessel is.

All the difficulty in pointing a chart arises from our ignorance of the longitude. The pilot easily finds the latitude, by taking the height of the pole; but, for the longitude, there is no coming at it but by computation, which is always uncertain.

POINTING, in *Rigging*, tapering the end of a rope, or splice, and working over the reduced part a small close netting, with an even number of knittles twisted from the same, to prevent the end untwisting, and to go more readily through a block or hole. The ends of the strands of a cable are occasionally pointed, for the greater conveniency of splicing it to another cable.

POINTING, in *War*, the levelling or directing of a cannon, or mortar-piece, so as to play against any certain point. See *Pointing of a Gun*, and *GUNNER'S QUADRANT*.

POINTY, in *Geography*, a town of Hindoostan, in Bengal, on the side of the Ganges; 30 miles N.N.W. of Rajemal. N. lat. 25° 19'. E. long. 87° 33'.

POINTYPOUR, a town of Hindoostan, in Oude; 30 miles S.E. of Fyzabad.

POJO, a town of Sweden, in Nyland; nine miles N. of Eknas.

POIREL'-*fous-la-Roche*, a town of France, in the department of the Vendée, and chief place of a canton, in the district of Montaign; six miles N.N.W. of La Roche-sur-Yon. The place contains 1900, and the canton 9423 inhabitants, on a territory of 295 kilometres, in eight communes.

POIRETIA, in *Botany*, a genus established by the late M. Ventenat, received that appellation in honour of his countryman M. Poiret, who travelled into Barbary in 1785 and 1786. An account of that journey appeared in 1789. This gentleman has long been laboriously engaged, as the successor of the distinguished Lamarck, in the botanical part of the *Encyclopedie*, or *Dictionnaire de Botanique*. Other genera have borne the name of *Poiretia*. One of them, so called by Cavanilles in his *Icones* v. 4. 24, had previously been published as *Sprengelia*. Another, printed by the writer of the present article, in *Transf. of Linn. Soc.* v. 9. 304, being, in like manner, posterior to the *Poiretia* of Ventenat, has received, from Mr. Aiton and Mr. Brown, the name of *Hovea*, *Ait. Hort. Kew.* v. 4. 275; which is confirmed by Dr. Sims, in *Curt. Mag.* v. 39. 1624; and serves to commemorate a Polish travelling botanist, Anthony Pantaleon Hove, long employed to collect plants for the Kew garden and Sir Joseph Banks. The following account of the now received *Poiretia*, was transmitted to us by Mr. Brown. *Venten. Mem. de l'Institut* for 1807, part i. 4. —Class and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss.

Eff. Ch. Calyx bell-shaped, two-lipped; the upper lip emarginate; lower with three teeth. Standard semiorbicular, emarginate, bent back by the keel, reflexed at the sides. Wings oblong, very obtuse. Keel sickle-shaped, curved upwards. Stamens all united. Stigma capitate. Legume compressed, jointed; its joints single-seeded, separating when ripe.

1. *P. scandens*. Climbing *Poiretia*. (Glycine; Lamarck *Illustr.* t. 609. f. 2, without any description.)—This is a native of Hispaniola, and appears to be the only known species.—The *stem* is twining. *Leaves* abruptly pinnate, of two pair of wedge-shaped, or somewhat orbiculate, leaflets, full of pellucid dots. *Stipulas* awl-shaped, distinct from the *footstalks*. *Clusters* axillary, of a few small yellow bracteated *flowers*, dotted like the leaves. *Stamens* sometimes but eight. As this plant is so little known, and hitherto adopted by no one, Dr. Sims expresses his reluctance at yielding up the *Poiretia* of the Linnæan Transactions; but we agree with him that less confusion is likely to arise from this measure than the contrary. It is of no consequence, which particular genus bears the name of one botanist or the other. If our name had been an expressive or classical one, we should in such a case have strenuously contended for it, as we do in the case of *CONCIUM*, (see that article); because sense and utility ought surely to be preferred to a right of priority, which is obscure, unconfirmed, or even unknown. If such a right were absolutely to prevail, we could rake up obsolete authorities to overset abundance of names, now supposed to stand on the firmest possible foundation. This recalls to our memory another *Poiretia*, that of Gmelin, the too famous editor of the Linnæan *Systema Naturæ*. One of the anonymous genera of Walter's *Flora Caroliniana*, of which Gmelin knew nothing, was called by him *Poiretia*, nor did he dream that it was actually the original *Houstonia* of Linnæus! See *Pursh*, v. 1. 106. The authority of such a compiler is, by common consent amongst scientific botanists, reckoned as nothing; for those only who have seen and ascertained plants can have any pretensions to name them.

POIRINO, in *Geography*, a town of France, in the department of the Po; eight miles N.E. of Carmagnola.

POIS, ST., a town of France, in the department of the Channel, and chief place of a canton, in the district of Mortain. The place contains 608, and the canton 6640 inhabitants, on a territory of 105 kilometres, in 10 communes.

POISE. See COUNTERPOISE and WATERPOISE.

POISON, in *Medicine*, any thing which, whether taken into the stomach or lungs, or introduced by means of a wound, proves deleterious or fatal to animal life.

The smallness of the quantity in which these deleterious substances operate upon the living body, and a certain obscurity in their action or mode of operation, perhaps also enter into the notion of a poison. (See the word in Johnson.) These, however, are merely relative circumstances; for many of the most fatal poisons become, in fact, the most valuable remedies, and even the most grateful luxuries, by diminishing their quantity, or, which amounts to the same thing, by diluting their strength. Thus opium, henbane, hemlock, and the whole tribe of narcotic vegetables, the mineral acids, the metallic salts of mercury, and even of arsenic, have been brought to the condition of medicines, and constitute the most powerful and salutary agents in the hands of the physician; whilst alcohol or spirit, which is a speedy poison to many animals, and is fatal to man when pure, and taken in sufficient quantity, has constituted the luxury and solace of the human race, in the various modifications of wine, cyder, mead, beer, and other species of spirituous and fermented liquors, from the earliest periods of history. Then as to the obscurity of the action of poisons, it is precisely upon the same ground as the action of medicines in general: we are equally unable to state in what manner mercury cures syphilis, or sulphur removes the itch, as to point out the mode in which poisons influence the living system. Once for all, indeed, it may be here observed, that the hypotheses, which the older authors devised, upon mechanical principles, to account for the destructive influence of poisonous substances, by referring to certain *spicula*, or acrid salts, calculated to disunite the animal fibres, and decompose the fluids, and to certain organical particles or microscopic animalcules, are the mere creations of the fancy, and are totally unsupported by fact and observation. Indeed Dr. Mead, who advanced the former hypothesis, was convinced of its inadequacy to explain the phenomena; and in the later editions of his treatise on poisons, he recanted his opinion. The latter doctrine, which was maintained by Buffon, was one of the illusions of the microscope, and requires no refutation. Of late years, many experimental investigations have been instituted, which have contributed to throw much light on the mode of operation of poisonous substances, or at least to elucidate the parts of the living system through which they act. The extensive researches of Fontana brought many important facts to light in the most satisfactory manner; and the recent experiments of Mr. Brodie have confirmed his facts, and materially extended our knowledge on the subject.

It must be premised, that there are two classes of deleterious substances, which have obtained the denomination of poisons. One of these consists of such as give rise to specific diseases, when introduced into the living body, and have, therefore, been distinguished by the epithet *morbific* poisons, (to use the appellation of Mr. Pearson,) or more generally *morbid* poisons; which last term implies also, that these poisons are generally the result of disease, as well as the cause of disease in others. The poisons to which we allude are those which give rise to hydrophobia, to the

venereal disease, the yaws, itch, small-pox, and various other maladies. At present we have no evidence that these poisons originate in any individuals, except in those who have imbibed some portion of the secretions from persons affected with these maladies: but there is little doubt, that at some period these poisons have had their origin, independently of such communication; and now and then instances of analogous morbid poisons appear in individuals, under particular states of the constitution. These morbid poisons, however, are not the object of the present article; having been treated of under their proper head. (See MORBID *Poison*.) We shall here limit ourselves to the discussion of the other class of *poisons*, simply so called, and which produce speedy death, when a sufficient quantity is introduced.

The impossibility of explaining the action of all poisons upon any single mechanical principle, is obvious from this circumstance, that the same substance, which is a fatal poison to some species of the animal race, is eaten with impunity, nay is the favourite food and wholesome nutriment of others. Plenck observes, that the nux vomica, which is very deleterious to brutes, is injurious to man only in large doses; that aloes is a poison to dogs and foxes; and bitter almonds to cats, foxes, and chickens; that the phellandrium aquaticum is fatal to horses, but is eaten with impunity by oxen; that the doronicum kills dogs, but fattens antelopes, thrushes, and swallows; that the seeds of hemlock are eaten without injury by stares, those of stramonium by pheasants, those of the lolium temulentum by jays, and the roots of henbane by pigs. The cocculus indicus is deleterious to fish and lice, but it is supposed by Dr. Parr to make a salutary ingredient in the best London porter. (See Parr's London Med. Dictionary, art. *Venenum*.) The same writer affirms that a horse can take a dram of arsenic daily, and improve in his coat and condition. Dr. Withering states, that the *œnanthe crocata*, although the whole plant is poisonous to man, and the root a most virulent poison, is eaten by sheep; that the *cicuta aquatica*, one of the rankest of our vegetable poisons, and certainly fatal to cows, is greedily devoured by goats with impunity, and is eaten by horses and sheep with safety; that the *æthusa cynapium*, which is poisonous to geese, and occasions sickness in man, is eaten by cattle, sheep, goats, and swine; that elderflowers are fatal to turkeys, and its berries to poultry; and that the *convolvulus sepium*, which resembles the scammony plant in its acrid purgative qualities, when taken by man, is eaten largely by hogs without any such operation. Many other instances of a similar variation in the effects of the same substance upon different animals might be adduced, if it were necessary to extend the catalogue. See Withering's Botanical Arrangement of British Plants, in the notes, passim; Plenck, *Toxicologia seu Doctrina de Venenis*, p. 10, &c.

Poisons differ from each other in their action, likewise, in other respects. Some of those which are speedily fatal, if introduced into a wound, may be swallowed with impunity; as in the instance of the venom of the viper and other snakes, which appears to exert no influence on the stomach. Others, again, are principally deleterious by their action upon the stomach; such as the strong mineral acids, the caustic alkalies, and other chemical poisons. Whilst others are deleterious, whether applied to the inner surface of the stomach, introduced into the lower intestines, or inserted in a superficial wound; such as the powerful vegetable narcotics, tobacco, and the minerals, arsenic, barytes, &c.

All the three kingdoms of nature are productive of poisons,

sons, of which a complete catalogue has been arranged by professor Plenck, in his treatise entitled *Toxicologia*, above quoted. It may be sufficient, however, in this place, to enumerate some of the more remarkable examples of animal, vegetable, and mineral poisons; to state the phenomena or effects which they produce in the living body; to point out the nature of their action as far as that has been ascertained by experiment and observation; and to mention the antidotes, or means of counteracting their deleterious influence, where any such are known.

1. *Of animal Poisons.*—The animal kingdom furnishes examples of poison only in the classes of serpents, insects, and fishes, and the most virulent of them occur in the former, or serpent tribe. Many of this tribe, however, are not poisonous, such as the *Boa*, *Angues*, *Amphisbena*, and *Cæcilia*: the two genera of *Crotalus*, or rattle-snake, and *Coluber* (which includes the viper, the cobra de capello, the cerastes, &c.) afford the only examples of venomous snakes; nor are all the species of coluber poisonous. Serpents inflict their poison by the bite only; and for this purpose, in addition to the teeth possessed by the rest of the tribe, the poisonous ones are furnished with two or three longer teeth, or fangs, in the upper jaw, which they can extend or retract at pleasure, and which are perforated by a canal opening near their points. Through these apertures the poison is pressed out from a vesicle, or reservoir, at the root of the fangs, in which it is secreted, and is instilled into the wound which is inflicted by the bite. By poisonous insects, however, the venom is frequently inserted from the tail, which is armed with a sting, which, like the fang of the serpent, is perforated to the point, and seated over a reservoir of venom; as in the scorpion, wasp, bee, &c. but by some, as the tarantula, it is inserted by the bite. The poison of insects, even of the scorpion, is generally inflicted in such minute quantity as to be incapable of producing death in man. The sting of the smaller species, as of the wasp, &c., occasions only a local inflammation and swelling, and does not affect the constitution at large; and even the bite of the tarantula spider, respecting which so many fables have been propagated, produces only a painful and livid swelling, which, in a few days, becomes covered with a dark crust, with an occasional sleepiness, oppression about the præcordia, and pains in the joints. See Plenck, loc. cit.

The poison of serpents, however, is often fatal to man, and commonly so to the smaller animals, and has, therefore, been the subject of much interesting inquiry. Upon the more virulent poisons of the several species of rattle-snake, which inhabit America, and of the more deadly species of coluber, which are found on the same continent, and in Asia, few opportunities of making experiments have occurred. It appears, however, that the operation of these poisons is different only in degree from that of the viper, (*Coluber verus*), which, as the principal, or almost only poisonous reptile of Europe, has been the chief subject of experiment. For our knowledge of the nature and operation of the poison of the viper, we are indebted to the industry and zeal of the abbé Fontana, from whose "*Traité sur le Vénin de la Vipère, sur les poisons Américains, &c.*" we extract the following account.

The poison of the viper is a yellow viscid liquor, that flows from the fangs of the reptile when it bites. This poison is neither acid nor alkaline, nor does it contain any peculiar salts, as Mead and others maintained. It possesses no acrimonious quality, so that when it is put upon the tongue or the lips, in its pure state, it excites no sensation of any kind, no heat or pungency, nor any determinate taste, except a slight degree of astringency. In this respect

it differs materially from the venom of the bee, and other insects, which is acrid. The poison of the viper, even when applied to the eyes, excites no pain or inflammation; and it may be swallowed with impunity, as was proved by a servant of Fontana, who took it repeatedly, sometimes pure, and sometimes diluted, in various quantities, without experiencing any sensible effect. A dog also took it, with crumb of bread which had been soaked in it, and appeared to like it; but suffered nothing from its effects. It is obvious, then, that this poison does not act by any chemical or mechanical property, and that it is perfectly harmless when applied to any unbroken surface, either external or internal.

Fontana then proceeded to investigate, by a long series of experiments, the effects of the poison, when applied to various parts of the animal structure, and in various ways; and he found that the operation of the poison is considerably modified by these circumstances. Thus he produced a slight excoriation of the surface of the skin of guinea-pigs and rabbits, so as to make a very small quantity of blood exude, and then applied the poison of the viper to the excoriated parts; some suppuration, followed by an eschar, took place, but no disease ensued, and the animals were soon well from the local symptoms. He then made deeper wounds in the skin, to about half its thickness, and applied the poison; a more considerable suppuration and ulceration occurred; but the animals did not appear to suffer otherwise, continued to eat constantly, and recovered at the end of ten days. In other experiments, in which the skin was completely penetrated, but the muscles below not wounded, the animals (rabbits and guinea-pigs) died after three or four days, in some cases an encysted tumour forming in the bitten part, in others gangrene. The death, in these cases, however, was perhaps rather the consequence of the local disease, than of the action of the poison on the constitution; for Fontana found that in general, "the venom of the viper is not mortal, if it penetrates no farther than the adipose membrane." He likewise proved, that the poison applied to the surface of the muscles, when laid bare by dissection, is entirely harmless; when muscles are slightly wounded, a local inflammation, swelling, lividity, &c. occur, sometimes violently, but seldom fatally. Bites, or application of the poison to the ears, and noses, of animals, are obviously less dangerous than in those parts where the circulation is more abundant and free; and bites in the tendons are not productive of any disease, except as wounds in those parts.

When by a penetrating bite, however, the poison of the viper is inserted in a wound, in a small animal, death follows in a few minutes. The vital powers of the animal are immediately affected, independently of the irritation of a local wound, so that they will fall prostrate instantaneously, as if paralyzed, and some void their urine and excrements immediately, as if their sphincters had also become paralytic at the moment of their being bit. The fatal effect of this poison, as we shall state afterwards, appears to be in proportion to the size of the animal, and the quantity of poison inserted respectively. The great desideratum, then, is, to ascertain in what manner this rapid destruction of the living power is occasioned, or upon what organs this venom exerts its influence, and how it affects them. From the preceding negative conclusions it is to be inferred, that the poison only acts upon the vital powers, when it enters the blood-vessels; and this supposition appears to be amply confirmed by the experiments which have been instituted. The various hypotheses, however, which have been contrived to explain this mode of action, have not been adequate to that purpose, as will be evident on taking a brief view of the most plausible

of

of them, before we proceed to examine the experimental investigation.

It was believed by the chemical physiologists, that the poison, on entering the circulation, occasioned an universal coagulation of the blood, and therefore stopped its course, in a similar manner as acids are believed to coagulate it when introduced at an aperture made in a vein. But Redi and others have shewn that this universal coagulation does not necessarily take place; and the convulsions, vomiting, and death, which the injection of acids is said to produce, are occasioned by the injection of air and other extraneous matters into the blood-vessels. Not to mention, that the qualities of the poison are not acid. Others have supposed that an universal inflammation was excited by the poison. But Fontana justly observes, that the death is too rapid to be ascribed to such a cause; that there is not even feverishness present in all instances; and that no appearances of inflammation have been found after death. As to the opinion of Dr. Mead, that the salts of the poison decompose the blood, and destroy its crasis, the time in which it is effected is entirely adverse to such a supposition, and the existence of such salts is altogether gratuitous. Indeed, as we have already said, Mead ultimately discarded the doctrine, and referred the operation of the poison to the animal spirits, or nervous system. And this, in fact, is the conclusion, which an attention to the phenomena would lead us to deduce. For, to use the words of Fontana, "if we examine the symptoms that this venom produces in animals, we are easily led to believe that a disease of such a nature belongs to the class of diseases which the physicians stile *nervous*. In the course of my experiments, I have seen a pretty large dog fall down motionless, the moment after it had been bitten by two vipers. I at first thought it dead, but at length perceived some little remains of respiration, which was, however, so slight and feeble, that it could scarcely be distinguished. The dog continued in this lethargic state for more than half an hour. I have seen several others thrown by the venom into very violent convulsions. Vomiting, anxiety, and rage, occur very frequently; the motion of the heart is irregular and convulsive, and the arterial system hard and contracted. In short, they die in the midst of the most unequivocal symptoms of spasms and contractions, and, in a word, with the affections that are by the faculty termed *nervous*." Fontana on Poisons, vol. i. pt. iii. chap. 4.

It, therefore, became necessary to ascertain by experiment the actual influence of the poison upon the *nerves* themselves. Fontana made several experiments on the spinal marrow of frogs, which was laid bare, and wounded with a poisoned tooth; but from the difficulty of influencing the cold-blooded animals with the viper's venom, he could not arrive at any satisfactory conclusion. He then made his trials upon the sciatic nerve in rabbits. Having laid bare this nerve with a little dexterous dissection of the integuments, and holding the great glutæus muscle aside, he wounded the nerve in several places with a venomous tooth of the viper. The animal suffered nothing more than what the wound occasioned, and lived seven days. The sciatic nerve of another rabbit was wounded in upwards of twenty places, with the venomous teeth of two vipers. The rabbit scarcely gave any signs of feeling pain, and at the end of twenty-four hours ate, and appeared lively. It died, however, in forty-eight. The nerve was marked here and there with dark red spots; the parts about it were violently inflamed; and the blood in the auricles and heart was black and coagulated. Similar experiments were made on many other rabbits, with similar results. Other applications of

the poison were made to the sciatic nerves of rabbits, after the nerve had been completely divided; in some the poison was applied above, in others below the division, and the same results precisely took place in both these circumstances, as in those in which the nerve was poisoned, but not divided. He then put two ligatures on the same nerves of other rabbits, and wounded the portion between the ligatures with the poisoned teeth, and the same phenomena occurred as in all the preceding experiments; the livid spots in the nerves and adjoining portions of the muscles, and death in the second day, sooner or later. He then made some comparative experiments, by inflicting simple mechanical wounds on the sciatic nerve of other rabbits. "I laid bare," he says, "one of the sciatic nerves of another rabbit, and having wrapped it in linen as usual, I pierced it in several places with the point of a fine needle. The animal shrieked terribly, and died at the end of thirty-six hours. There were several dark spots in the nerve, and the parts adjacent to it were somewhat inflamed. The blood in the heart was black and coagulated." Other results were precisely similar.

The inferences from these experiments, then, are that the death of the animal, as well as the livid and red spots, were owing to the simple mechanical wound of the nerve; "that the venom of the viper, communicated to the nerves, neither occasions in any degree the disease of the venom, nor hastens the death of the animal; and lastly, that the venom of the viper is altogether harmless to the nerves, having no greater action on them than pure water. I have assured myself," the philosopher adds, "by other experiments, that it is not at all offensive to these organs."

This extraordinary result (which has been confirmed by subsequent inquirers) led to the examination of the effects of injecting into the blood-vessels the poison of the viper, without touching any solid part; when it was found that extreme pain is instantaneously excited, and frequently convulsions, and death immediately ensues. But with a view to prove still more decidedly that the poison affects the living body through the circulation only, Fontana made numerous experiments on the effects of interrupting the flow of blood in parts that were envenomed, and he found that instant amputation of the part prevented the influence of the venom. The period in which the poison is so far communicated to the system, as to render amputation useless, was found to be different in different animals, but perhaps greater, according to the size. In pigeons, it was found that at the end of fifteen seconds, the internal effect had been produced, and the *amputation* did not prevent speedy death: in guinea-pigs, amputation of the limb bitten at the end of one, two, and three minutes, preserved the life of the animal, and sometimes it was successful when delayed as long as six minutes.

But if this operation were successful, it occurred that interrupting the circulation of the part envenomed by a *ligature*, might also, if accomplished speedily, prevent the introduction of the poison into the system. Many experiments were, therefore, instituted by Fontana, by which he ascertained that, even in pigeons and small animals, which are certainly killed in a few minutes by the ordinary bite of a viper, the fatal influence of the poison is prevented by a ligature upon the limb, interrupting the circulation. The limb becomes swelled and livid below the ligature, sometimes discharging a blackish humour, and bordering apparently upon mortification. Another important inference also presented itself; for it was found that, after the ligature had remained in the limb of a pigeon a few hours (the exact length of time necessary was not fully determined), it might

be removed, and the constitution, nevertheless, was not injured by the poison.

On the whole, then, it was distinctly proved by Fontana, that the poison of the viper exerts no influence on an unbroken surface, nor on muscle, tendon, nerve, or any other of the solid parts of the living body, to which it is directly applied; but that it produces its deleterious effects exclusively when conveyed into the circulating blood. "This fluid," he says, "conveys the venom to the animal, and distributes it to its whole body. The action of the venom, and its effects on the blood, are almost instantaneous. The colour of the latter is suddenly changed, and from a bright red becomes livid and black. This first effect is succeeded by a second. The blood coagulates very suddenly in the lungs, heart, auricles, liver, and in the large veins. Sometimes the heart still continues its oscillatory motions, notwithstanding the blood it contains is, at least in part, coagulated. At other times the heart beats with greater force, as if for the purpose of stopping the principle of coagulation that exists in the blood.

"The blood, partly coagulated, and partly dissolved, produced a very violent derangement in the organs of the animal. The part bit by the viper swells instantly, and becomes gradually livid; the blood in the large veins stops and coagulates; the serous part transudes into the cellular membrane, which it entirely fills; the circulation is deranged in the viscera, diminishes by degrees, and at length ceases: its first cessation is in the lungs. In a word, the circulation is totally impeded, and the animal dies." *Loc. cit.* part iii. chap. 6.

From this view of the facts, Fontana was led to infer a principle (which some physiologists have deduced from the consideration of other facts), *viz.* that the *irritability* of muscular parts is something distinct from the *sensibility*, and not dependent upon the nervous system like the latter; and that this muscular irritability in the vessels, &c. is destroyed indirectly, but speedily, by the influence of the envenomed blood, which is thus instantaneously changed in its qualities. We shall see presently that a more accurate view of the subject has been subsequently made out.

Of the Antidotes to the Poison of the Viper and other Serpents.—Although it is chiefly on the poison of the viper that any accurate experiments have been instituted, either with a view to the discovery of the mode of its operation, or of the remedies for its deleterious effects; yet it is probable that the same principles may be transferred to the consideration of the poisons of the rattle-snakes, and the more fatal species of coluber, which differ perhaps rather in the degree of virulence, than in their nature and operation. In this country, however, the viper is the only snake whose bite is injurious, and it is satisfactory to learn from the ample experience of Fontana, that, although all the alleged antidotes appear to be destitute of the properties ascribed to them, yet that the bite of one viper is certainly not mortal to man. Animals appear to resist the poison in proportion to their size; and even middle-sized dogs generally resist the poison very well, without any remedy being administered; and the larger ones still better. "Five bites from three vipers were not sufficient to kill a dog that weighed nearly sixty pounds;" and as a man is seldom or never bit by more than one viper, so it is clear from the evidence collected by Fontana, that the chance of mortality from such a bite is not more than 1 to 100.

As in some other instances of disease, the natural tendency to recovery after these bites has obtained credit for every medicine that accident has caused to be administered in such cases. The theriacæ, the volatile alkali, the eau-de-

luce, the use of oil externally and internally, spirituous liquors, and other stimulants and sedatives, have obtained the credit of being specific antidotes to these poisons. The experiments of Mr. Oliver (related in the Philosophical Transactions, vol. xxxix. p. 310.), which appeared to countenance the favourable opinion of warm oil in the cure of these bites, were repeated at Oxford without success. (See the same vol. of the Phil. Trans. p. 394.) Linnæus, who was much disappointed in the use of oil, says that a woman, bitten by the coluber chersæa, died in great agony, though the oil was liberally administered. (*Amœnit. Academ.* vol. ii. 407, and vol. vi. p. 213.) With respect to the ammonia, the numerous experiments of Fontana demonstrated, "that the fluid volatile alkali is altogether useless, whether it is simply applied to the part bit by the viper, or swallowed by the animal at the same time," nay, he concluded, that instead of diminishing, it seemed to increase the virulence of the poison. The fat of the snake itself, which has been vulgarly deemed an antidote to its bite, is doubtless to be placed upon the same footing with the olive oil. The most rational mode of treatment, where a bite has been inflicted by a dangerous serpent, would appear to be the instantaneous application of a *tight ligature* round the limb, or round the finger or toe, where these parts happened to have received the bite.

For the information of those who may be under the necessity of exposing themselves to the venom of the more deadly serpents of America and the Indies, the following facts may be noticed, as they afford the best evidence of the existence of an antidote that we are acquainted with. Mr. Ireland, a surgeon of the English army in the island of St. Lucia, having heard of the reported efficacy of the Tanjore pill, used in India as an antidote to the venom of snakes, of which arsenic is the chief ingredient, was induced to try the liquor arsenicalis, or Fowler's solution, in some cases which occurred to his notice. He found that many of the soldiers had been bitten by the coluber carinatus, the fangs of which are from one and a half to two inches long, which inflict a considerable wound, and that *in all* the bite had been mortal in six, and from that to twelve hours from the time when it was received. Mr. Ireland administered the solution in large doses (of two drachms), which were repeated every half hour, for three or four hours. Vomiting and purging were produced, and all the patients (five) recovered. (See *Medico-Chirurgical Transactions*, vol. ii. p. 393 et seq., where the cases are related.) The efficacy of the Tanjore pill is recorded by Dr. Russell, in his *History of Indian serpents*.

Of the Poison of Fish.—A certain degree of poisonous influence is observed from some kinds of fish, in this country, in peculiar constitutions. Thus eels, salmon, herrings, and muscles, often induce a speedy and considerable disorder of the stomach, skin, and whole habit, sometimes accompanied by a high fever. Heat, sickness, and distention of the stomach, with headache, and a severe itching, pricking, and burning sensation of the skin, which is suddenly covered with a red rash, ensue soon after these articles are swallowed; and, if the stomach is not relieved by vomiting, the disorder does not entirely vanish for a day or two.

Some of the fish of the West Indian seas, however, produce a more violent and uniform effect, which has been well described by Dr. Thomas. (See *Memoirs of the Med. Society of London*, vol. v. part ii.) The fish most to be dreaded, he says, are the barracuta, yellow-bill sprat, cavallee, rock-fish, king-fish, smooth bottle-fish, and lobster. These fishes, however, are not uniformly poisonous, and the difference of their qualities is supposed to arise from the

difference of the food which they take, and, in some cases, to the circumstances of the entrails being allowed to remain in them some time after they are caught, which appear to be poisonous to animals. The rock-fish (*perca marina* of Catesby) is said to have the worst character for its poisonous quality of all the fish among the Bahama islands.

The consequences of eating this poison, Dr. Thomas affirms, are in general very alarming, and in many instances fatal. Some stomachs, however, are more susceptible of the action of the poison than others, and feel the effects of it almost immediately: the symptoms in others do not appear until two, three, or four hours after the accident; and some escape their violence altogether. The usual symptoms of fish-poison are cardialgia, nausea, severe vomiting and purging, griping pains in the bowels, cold sweats, fainting, and giddiness. The face in the mean time becomes highly flushed, and the eyes inflamed, attended with a burning heat and spasmodic twitches, which particularly affect the eyes, the sufferers often complaining that they are ready to start from their sockets. The burning which is felt in the face and eyes is extended to the palms of the hands, the tips of the fingers, and over the whole body; sometimes accompanied, and sometimes succeeded, by a miliary eruption, or by an efflorescence resembling the bite of a bug, but more extensive. The pulse for the most part is hard and frequent. This ardor of the skin, and a prickling in the hands and nose when immersed in cold water, are considered as diagnostics of the disease occasioned by fish-poison. The neck of the bladder, urethra, and sphincter ani, appear to sympathize with the skin, as the patients often complain of a similar heat in those parts, with a difficulty of making water, strangury, and afflicting tenesmus. The last and most tedious symptom, which may be rather considered as a secondary, is an acute and shooting pain in the articulations of the knee, wrist, ankles, and sometimes in the cylindrical bones, with more or less swelling. It is distressing at intervals for years after every other train of the disorder has disappeared, and is not unfrequently attended with œdema. The issue, however, is not always so favourable: the health of some who escape its fatal effects is often so much impaired, that a foundation is laid for a train of evils, and a visit to a cold climate is at last found necessary to restore vigour to their constitution.

For the cure of this disorder two indications are clearly pointed out; *viz.* to procure a discharge of the poison as speedily as possible, and to remove or alleviate the effects that result from it. The *first* indication can only be fulfilled by an active and expeditious emetic, such as the sulphate of zinc, which is alone sufficient to obviate the dangerous tendency of the poison; and with the view of more completely dispelling the cause of the disease from the digestive organs, a purgative, especially of some neutral salt, should be afterwards given. This method, Dr. Thomas observes, is practicable in robust constitutions; but in weak delicate habits, the vomiting and purging occasioned by the poison are so violent, and produce so much debility (resembling very much the disease called cholera), that it is often necessary to prescribe anodynes to allay these symptoms, even before it is certain that the stomach and bowels have been cleared of their noxious contents. For the *second* indication no positive rule can be laid down; as the treatment must be varied according to the nature and violence of the symptoms. If, after due evacuations, the symptoms of cholera still continue, which frequently happens, they should be checked by anodynes, cordials, and glysters of starch or gruel, with or without laudanum: and a liberal use of some mucilaginous drink should be recommended, as long as the strangury re-

mains. The administration of gentle diaphoretics, and especially Dover's powder, relieves the heat and irritation of the skin. The pains of the joints are sometimes very obstinate, and yield to nothing but time: relief may nevertheless be procured by decoctions of guaiacum and sarsaparilla, by wrapping the parts in flannel, and sometimes from the warm, and sometimes from the cold bath.

In the seventh volume of the Medical Facts and Observations (p. 289), edited by Dr. Simmons, Dr. Clarke observes that capsicum, or Cayenne pepper, has been known long ago to possess the power of preventing or counteracting the poisonous effects of fish. He adds, "this fish-poison seldom destroys life entirely, except the deadly poison of the yellow-billed sparrow, as it is called, which kills very speedily: but those who have eaten of the other kinds of poisonous fish are frequently reduced to the last extremity by vomiting, and life is almost extinguished before stimulants can take effect."

II. *Of Vegetable Poisons.*—The vegetable productions, which contain a matter deleterious to animal life, are very numerous. In some of them it is found naturally in such proportion, that the substance of the plant is fatal; but in many, the full effect of the poison is only obtained by the extraction of this matter in a concentrated state; as in the extracts of the poppy (opium), henbane, nightshade, &c.; in the essential oil of tobacco, bitter almonds, and the kernels of fruits; in the distilled waters of the lauro-cerastus, &c.; and in the preparations from the Upas, the Ticunas, or Woorara, employed by the Indians to poison their weapons of war. In this concentrated condition, many of these vegetable substances operate with a violence and fatality resembling the effects of the poison of the deadly serpents. They differ, however, in this respect, from the venom of those reptiles (if the experiments of Fontana are to be deemed conclusive), that they operate, when applied to the mucous membranes, with more rapidity than when introduced into wounds; as for instance, when swallowed into the stomach, or injected into the lower bowels, or even when applied to the tongue. The experiments of Fontana had taught him, that the living animal was affected through the same medium by the vegetable poisons, as by the animal venom, when they were applied to a wound; namely, through the medium of the circulation; and not by a direct influence on the nerves, the muscles, the lymphatics, tendons, or skin. He therefore inferred, that they acted, (as well as the animal poisons,) on the blood directly, and on the irritability of the muscular fibre, and not on the nervous system.

The experiments of Mr. Brodie, however, recently made under the correction of a better physiology, seem to put this question in a sufficiently clear light. They confirm the results stated by the Abbé Fontana, that vegetable poisons influence the living body, when applied to a wound, exclusively through the medium of the circulation, being conveyed to the brain only by mixing with the blood in the vessels; and that they are not conveyed through the medium of the nerves, nor of the absorbents. For a ligature upon the great vessels prevents them from producing their deleterious effects; whilst the division of the *nerves* of the part poisoned, and a ligature upon the *thoracic duct*, or general canal through which all the absorbents pour their contents into the blood, does not in the least retard or prevent the operation of the poison. (See *Philos. Trans.* for 1811.) But the effect of these vegetable poisons, when taken into the stomach, or even when put upon the tongue, is more rapid and fatal. Now, there are only two ways by which the living power can be influenced by substances applied to these

these unbroken surfaces; namely, by being absorbed into the circulation, or by the nervous sympathy between these surfaces and the common sensorium, or brain: and if we examine the facts, it will be very obvious, that it is through the latter medium that this influence is exerted, and not through the medium of the absorbent vessels.

In order, however, to comprehend fully the import of these facts, it will be proper to premise an observation or two relative to the immediate cause of death in general. It was demonstrated by the able and lamented physiologist, Bichât, that the functions of three organs only, the brain, the lungs, and the heart, are absolutely necessary to life; and that whenever the functions of one of these organs is suspended, death necessarily ensues. The stomach, the liver, the kidneys, and many other organs, are necessary to carry on the actions of the living body; but their constant action is not required; life will go on for some time during the complete suspension of their functions, which does not immediately occasion death. (See DEATH.) Secondly, the same ingenious physiologist observed, (and the observation has been confirmed by some experiments of Mr. Brodie, published in the *Philos. Trans.*.) that the influence of the brain is not directly necessary to the action of the heart; for that when the functions of the brain are destroyed, even when the head is removed, "the heart continues to contract for some time afterwards, and then ceases only in consequence of the suspension of respiration, which is under the influence of the brain." For if the lungs be alternately filled and emptied of air by mechanical means, the action of the heart may be carried on for an indefinite period, after the influence of the brain is entirely removed. We believe it has since been shewn by this indefatigable experimentalist, Mr. Brodie, that the destruction of the spinal marrow deprives the heart instantly of its powers of motion; upon which, therefore, it appears to be more immediately dependent, than upon the brain.

An examination of the facts, then, which Mr. Brodie has promulgated, will satisfactorily shew, that these poisons operate through the medium of the brain, in all instances; affecting this organ by nervous sympathy, when applied to mucous surfaces, and by being conveyed to it through the blood-vessels, when applied to a wound. And first we shall speak of the poisons applied to surfaces.

"Exp. 3.—Seven drams of *proof spirits* were injected into the stomach of a younger rabbit. Two minutes afterwards he evidently was affected by the spirits, and in three minutes more he lay on one side motionless and insensible. The pupils of the eyes were perfectly dilated; there were occasional slight convulsions of the extremities; the respiration was laborious, it was gradually performed at longer and longer intervals, and at the end of an hour and fifteen minutes had entirely ceased. Two minutes after the animal was apparently dead, I opened the thorax, and found the heart acting with moderate force and frequency, circulating dark coloured blood. I introduced a tube into the trachea, and produced artificial respiration by inflating the lungs, and found that by these means the action of the heart might be kept up to the natural standard, as in an animal from whom the head is removed.

"Exp. 4.—I injected into the stomach of a rabbit two ounces of *proof spirits*. The injection was scarcely completed, when the animal became perfectly insensible. Precisely the same symptoms took place as in the last experiment, and at the end of twenty-seven minutes from the time of the injection, the rabbit was apparently dead; but on examining the thorax, the heart was found still acting, as in the last experiment,

"Exp. 5.—One drop of the *essential oil of bitter almonds* was applied to the tongue of a young cat. She was instantly seized with violent convulsions; then lay on one side motionless, insensible, and breathing in a humid manner; the respirations became laboured, took place at longer and longer intervals, and at the end of five minutes from the application of the poison, had entirely ceased, and the animal was apparently dead: but on opening the thorax, the heart was found acting regularly eighty times in a minute, circulating dark coloured blood, and it continued to act for six or seven minutes afterwards."

It is unnecessary to prolong the detail of the experiments: it may be sufficient to state, that the same phenomena resulted, from the injection of two drops of the essential oil of bitter almonds, diffused in half an ounce of water, into the *rectum* of a cat; from the injection of the juice of *aconite* into the *rectum* of a cat; and from the application of the empyreumatic oil of *tobacco* to the tongue, and *rectum*, of cats and dogs, with the addition of sickness and vomiting in the latter cases.

Now it is obvious that the functions of the brain are immediately disordered by the influence of these poisons on the tongue, stomach, and lower bowel of animals, so instantaneously, that it is impossible that absorption should have already taken place. The complete insensibility to external impressions, the dilatation of the pupils of the eyes, and the loss of the power of motion, distinctly indicate, as Mr. Brodie observes, that the functions of the brain are suspended; respiration, which is under its influence, is imperfectly performed, and at length ceases altogether; while the heart, to which the action of the brain is not directly necessary, continues to contract, circulating dark-coloured blood for some time afterwards. There is a striking analogy, the same able physiologist remarks, between the symptoms arising from spirits and other poisons taken internally, and those produced by mechanical injuries of the brain. "Concussion of the brain, which may be considered as the slightest degree of injury, occasions a state of mind resembling intoxication, and the resemblance, in some instances, is so complete, that the most accurate observer cannot form a diagnosis, except from the history of the case. Pressure on the brain, which is a more severe injury than concussion, produces loss of motion, insensibility, and dilatation of the pupils; the respiration becomes laboured and stertorous, is performed at long intervals, and at last altogether ceases, and the patient dies."

The instantaneous influence of the poison of bitter almonds on the nervous system was experienced by Mr. Brodie himself, on applying a minute quantity to his tongue, at the end of a probe. He had scarcely touched the tongue, when he felt a very unpleasant and indescribable sensation, with a sudden feeling of weakness in his limbs, as if he had lost the command of his muscles, and he thought he was about to fall. Now the sudden operation of the poison, and its acting more speedily on the tongue, than when injected into the intestine, though the latter presents a better absorbing surface, added to the uninterrupted operation of it, when the thoracic duct is tied, leave no doubt that the brain is affected by the sympathetic communication of the nerves, and not in consequence of the absorption of the poison.

Mr. Brodie then proceeded to investigate, by experiment, the effects of the vegetable poisons, when applied to wounded surfaces. The essential oil of bitter almonds, the juice of *aconite*, the *woorara* (a poison used by the Indians of Guiana to arm the points of their arrows, and which Mr. Brodie considers the same as the *ticunas* used by Fontana),

and the *upas antiar*, a vegetable poison from Java, were the subjects of his experiments. It will be sufficient to quote his account of the operation of the first mentioned poison as an example of the whole.

“ Exp. 16.—I made an incision in the thigh of a rabbit, and introduced two drops of essential oil between the skin and the muscles. In four minutes after the application, he was seized with violent convulsions, and became insensible, and in two minutes more he was apparently dead; but the heart was felt through the ribs acting one hundred and twenty times in a minute, and it continued acting for several minutes. There were no other appearances in the limb, than would have resulted from an ordinary wound.

“ Exp. 17.—Two drops of the essential oil of almonds were introduced into a wound in the side of a mouse. Two minutes afterwards he was affected with symptoms similar to those which occurred in the last experiment, and in two minutes more he was apparently dead; but the heart continued to contract for some minutes afterwards.

“ From the experiments which I have just related,” Mr. Brodie adds, “and from others which it appears unnecessary to detail, as the general results were the same, I have learned that when the essential oil of almonds is applied to a wound, its effects are not so instantaneous as when it is applied to the tongue; otherwise there is no difference in its effects in whatever manner it is applied.” *Philos. Transactions*, loc. cit.

From these experiments, and from others in which the operation of the poisons was prevented by ligatures on the blood-vessels, but was not prevented by ligatures on the nerves, and on the great trunk of the absorbent vessels, it is fair to conclude, that these poisons affect the brain, by passing into the circulation through the divided vessels. “It is probable,” to borrow again the words of Mr. Brodie, when speaking of the woorara, “that it does not produce its effects, until it enters the substance of the brain, along with the blood, in which it is dissolved. Nor will the experiments of the abbé Fontana, in which he found the ticunas produce almost instant death, when injected into the jugular vein of a rabbit, be found to militate against this conclusion, when we consider how short is the distance, which, in so small an animal, the blood has to pass from the jugular vein to the carotid artery, and the great rapidity of the circulation; since in a rabbit under the influence of terror, during such an experiment, the heart cannot be supposed to act so seldom as three times in a second.”

From the knowledge of the fact, that these poisons act simply by suspending and injuring the functions of the brain, and that the heart continues to carry on the circulation for an indefinite time, Mr. Brodie was led to try by experiment, first, how long this action could be continued; and secondly, whether it might not, in some cases, be continued until the effects of the poison on the brain might subside, when the natural respiration might return, and the animal's life be saved. A rabbit was poisoned by the woorara, introduced in considerable quantity into two wounds. In seven minutes after the application, the hind legs were paralyzed, and in fifteen minutes respiration had ceased, and he was apparently dead. Two minutes afterwards the heart was still beating, and a tube was introduced through an opening into the trachea, by means of which the lungs were inflated. The artificial respiration was made regularly about thirty-six times in a minute, and was continued for the space of an hour and twenty-three minutes, when the pulse was beating one hundred times in a minute: there was no appearance of the recovery of the functions of the brain;

and the experiment was discontinued. While the artificial respiration was carried on, the blood in the femoral artery was of a florid red, and that in the femoral vein of a dark colour, as usual. Now, Mr. Brodie justly inferred, that as the circulation of the blood, and the usual changes in its colour, were maintained for more than an hour and twenty minutes after the poison had produced its full effects, it was evident, that the functions of the heart and lungs were unimpaired. But, that those of the brain had ceased, was proved by the continued insensibility of the animal, and by the cessation of the evolution of animal heat, to the generation of which Mr. Brodie's previous researches had proved the influence of the brain to be necessary.

In some subsequent experiments, in which less of the poison was introduced, and in which the temperature of the room was kept higher, to supply the loss of animal heat, and the artificial respiration was continued a longer time, (two hours and forty minutes,) the respiration at length became spontaneous, and recovery followed: but in others, the functions of the brain were not restored. Mr. Brodie upon this remarks, that “the circulation of the blood may be maintained in an animal, from whom the brain has been removed, for a considerable, but not for an unlimited time. We may conclude, that in the last of these experiments the animal did not recover, because the influence of the poison continued beyond the time during which the circulation may be maintained without the brain.” See *Further Experiments and Observations on the Action of Poisons on the Animal System*. *Philos. Transf.* for 1812.

Although the vegetable poisons, already mentioned, seem to affect the functions of the brain only, and through it the organs of respiration, leaving the powers of the circulation unimpaired; yet there are some vegetable poisons, namely, the two species of *upas* from Java, called *upas antiar*, and *upas tieute*, which appear to act upon the spinal marrow, and therefore upon the heart, destroying its irritability. It is extraordinary too, that, though the empyreumatic oil of *tobacco* affects the brain only, the infusion of that herb, when taken into the alimentary canal, suspends the action of the heart, producing syncope. The action of the heart was found by Mr. Brodie to cease, when this infusion was introduced into the rectum, and when the *upas antiar* was inserted in a wound, even before the animals had ceased to respire. It appears, too, from some experiments recently made at Paris, by M. Delile, with the *upas tieute*, that this poison acts upon the spinal marrow, without destroying the functions of the brain.

III. *Of Mineral Poisons*.—The action of these poisons appears to be somewhat more complex than that of the animal and vegetable poisons, and for our knowledge of the actual mode of operation of some of them we are indebted almost exclusively to the zealous physiologist, from whom so much of the foregoing information is derived, Mr. Brodie. As yet, indeed, his experiments have been limited to the effects of arsenic, barytes, tartrate of antimony, and the corrosive muriate of mercury; and it is not improbable that the acids and alkalies, and other caustic substances, may operate in a manner different from any of these.

With respect to *arsenic*, when taken into the stomach, so as to poison an animal, its obvious effects, discovered by dissection, are marks of inflammation in the stomach and bowels; and the common opinion entertained by medical men, is, that this inflammation is the cause of death, and the consequence of the actual irritation of the arsenic, in contact with the internal coat. But Mr. Brodie contends that this opinion is erroneous in both its parts. For in the first place,

POISON.

place, he has found the inflammation of the stomach, in several cases, so slight, that on a superficial examination it might have been easily overlooked; and in most of his experiments with this poison, death took place in too short a time to be considered as the result of inflammation. And, secondly, in whatever way the poison is introduced, the inflammation is confined to the stomach and intestines; and it is commonly more violent, and more immediate, when the arsenic is applied to a wound, than when it is taken internally, and it likewise precedes any appearance of inflammation of the wound. This fact was proved by an experiment, made by Mr. Hunter and Sir Everard Home, and by many repetitions of it by Mr. Brodie.

In all these experiments made with arsenic, applied in different ways and in different preparations, the results were, in all essential circumstances, the same. The symptoms, Mr. Brodie observes, may be referred to the influence of the poison on the nervous system, the heart, and the alimentary canal. With respect to the heart, he admits, that it is most probably affected only through the medium of its nerves; but he distinguishes it from the nervous system generally, because its action is so far independent of the brain, that its motion may go on undisturbed while the functions of the brain are suspended, and it may cease to contract, and the circulation be stopped, while the functions of the brain are not impaired. As of these three organs, the brain and the heart only are concerned in the functions immediately necessary to life, and as the alimentary canal is often affected only in a slight degree; so Mr. Brodie infers, that the affection of the two former must be considered as the immediate cause of death.

The symptoms observed in these experiments, as affecting these organs respectively, "were, 1st, paralysis of the hind legs, and afterwards of the other parts of the body, convulsions, dilatation of the pupils of the eyes, insensibility, all of which indicate disturbance of the brain; 2dly, a feeble, slow, intermitting pulse, indicating disturbance of the functions of the heart, whose action cannot be prolonged by artificial respiration; 3dly, pain in the region of the abdomen, preternatural secretion of mucus from the alimentary canal, sickness and vomiting in those animals which are capable of vomiting,—symptoms which arise from the action of the poison on the stomach and intestines."

As the affection of one or other of these three organs predominated, there is necessarily a considerable variety in the symptoms produced, and Mr. Brodie's observations respecting these varieties are valuable.

"In many cases where death takes place, there is only a very slight degree of inflammation of the alimentary canal; in other cases the inflammation is considerable: it generally begins very soon after the poison is administered, and appears greater or less, according to the time which elapses before the animal dies. Under the same circumstances, it is less in gramivorous than in carnivorous animals. The inflammation is greatest in the stomach and rectum; but it usually extends also over the whole intestine. I have never observed inflammation of the œsophagus. The inflammation is greater in degree, and more speedy in taking place, when arsenic is applied to a wound, than when it is taken into the stomach. The inflamed parts are in general universally red; at other times they are red only in spots. The principal vessels leading to the stomach and intestines are tinged with blood; but the inflammation is usually confined to the mucous membrane of these viscera, which assumes a florid red colour, becomes soft and pulpy, and is separable without much difficulty from the cellular coat, which has its natural appearance. In some instances there are small spots of extravasated blood on

the inner surface of the mucous membrane, or between it and the cellular coat, and this occurs independently of vomiting. I have never, in any of my experiments, found ulceration or sloughing of the stomach or intestine; but if the animal survives for a certain length of time after the inflammation has begun, it is reasonable to conclude that it may terminate in one or other of these ways."

Barytes in its uncombined state, and still more actively the *muriate of barytes*, produces similar deleterious effects on the animal frame as arsenic, whether it is taken into the stomach, or applied to a wound. Its operation is, however, less violent than that of the arsenical poisons. In animals that are capable of vomiting it operates as an emetic, and more speedily when taken into the stomach, than when introduced into a wound; but it affects the stomach less than arsenic, both in respect to the vomiting, and to the marks of inflammation which it leaves; and the intestines are scarcely inflamed by it. In many instances a thin layer of dark-coloured coagulum of blood is found lining the whole inner surface of the stomach, and adhering very closely to it, so as to have a good deal the appearance of a slough: and this is not the effect of vomiting, as it was observed only in rabbits, which do not vomit. The heart is with difficulty supported in its action by artificially inflating the lungs, after the operation of barytes. It was found, however, by Mr. Brodie, that when a probe was introduced into the spinal marrow, powerful contractions might be excited not only of the voluntary muscles, but also of the heart and intestines, by the galvanic influence, whence he inferred, that the muriate of barytes, like arsenic, affects the circulation by rendering the heart insensible to the stimulus of the blood, and not by destroying altogether the power of muscular contraction.

Emetic tartar, whether applied to a wound or taken in sufficient quantity into the stomach, produces effects perfectly analogous to those of arsenic and barytes. It is followed by paralysis, drowsiness, and at last complete insensibility; the pulse becomes feeble; and the heart continues to act a short time, and may be maintained by artificial respiration, after apparent death, but only for a few minutes. It appears, therefore, that this poison acts on the heart as well as on the brain; but that its principal action is on the latter. Both the voluntary and involuntary muscles may be made to contract after death by means of the Voltaic battery. The stomach is not always inflamed, and the intestines seldom, if ever.

Corrosive sublimate, or the oxymuriate of mercury, does not affect the living body in the same manner as the preceding mineral poisons. When taken internally in considerable quantity, indeed, it occasions death in a short time: but if it be applied to a wounded surface, it produces a slough of the parts, without affecting in any way the general system. A solution of a few grains of this poison, injected into the stomach of cats and rabbits, produced after a few minutes insensibility, convulsions, and death, and the heart was found not acting at all, or acting very feebly. The mucous membrane of the stomach, especially of the cardiac portion, was of a dark grey colour, and was easily torn and peeled off: in some parts its texture was completely destroyed, so that it appeared like a pulp, on removing which the muscular and peritoneal coats were exposed. This alteration of the texture of the internal membrane of the stomach appears to have been occasioned by its being chemically acted on by the corrosive muriate; since when it is injected into the stomach of a dead rabbit precisely the same changes are produced.

The destruction of the substance of the internal membrane of the stomach, as well as the non-appearance of any constitutional symptoms when the muriate is applied to a wound,

POISON.

wound, precludes the idea, Mr. Brodie observes, of the poison having been absorbed into the circulation. "We must conclude, then," he adds, "that death was the consequence of the chemical action of the poison on the stomach. This organ, however, is not directly necessary to life, since its functions, under certain circumstances, are suspended for hours, or even for days, without death being produced. Although the stomach was the part primarily affected, the immediate cause of death must be looked for in the cessation of the functions of one or more of those organs, whose constant action is necessary to life. From the scarlet colour of the blood in the left side of the heart, in the experiment on the rabbit, we may conclude that the functions of the lungs were not affected; but the affection of the heart and brain is proved by the convulsions, the insensibility, the affection of the pulse, and the sudden cessation of the heart's action in the first experiment; and we may, therefore, be justified in concluding, that the immediate cause of death was in both these organs. Farther, as the effects produced appear to have been independent of absorption, we may presume that the heart, as well as the brain, was acted on through the medium of the nerves. That sudden and violent injury of the stomach should be capable of thus speedily proving fatal is not surprising, when we consider the powerful sympathy between it and the organs on which life more immediately depends, and the existence of which many circumstances in disease daily demonstrate to us."

It has been shewn, then, from the numerous experiments of the abbé Fontana and Mr. Brodie, as above described, that the animal, vegetable, and mineral poisons, operate upon the nervous system, and through this medium destroy the functions of one, or all the three organs, upon which life immediately depends. The poison of serpents operates upon the nervous system only when introduced into the circulating blood, and does not influence the nerves of the stomach: it is probable, too, that it affects principally the brain, and organs of respiration, without any immediate influence on the heart; although this point was not attended to by Fontana. The vegetable poisons operate, in general, both on the sentient extremities of the nerves in the stomach and other mucous surfaces, and when introduced into the circulation, but influence different parts of the nervous system respectively. Thus the poison of the bitter almond, alcohol, aconite, woorara, the empyreumatic oil of tobacco, &c. affect the brain, whilst they leave the heart in possession of its moving powers; the infusion of tobacco appears to affect both the brain and the heart; whilst the two species of opium appear to paralyse the powers of the heart, and to exert little comparative influence on the brain, (such at least, the writer was informed by Mr. Brodie, has subsequently appeared to be the fact.) The mineral poisons, again, appear to affect the nervous system in a similar manner, but more extensively, and at the same time injure the stomach and intestines, so that their action is more complex than that of the other poisons, and the chance of recovery from their influence is much less than from the influence of the animal and vegetable poisons.

It is doubtful, indeed, whether the corrosive sublimate possesses any property that influences the nervous system, except by its primary *chemical* action on the stomach, by which the texture of this organ is injured or destroyed; and it is probable that the other *caustic* and corrosive substances, such as the strong mineral acids, and pure alkalies, operate in the same way, and not by any narcotic or directly deleterious influence upon the nervous system. Experiments, indeed, are wanting upon this subject; but an accident, which recently occurred within the knowledge of the writer of this

article, confirms, as far as one instance can be of any weight, this opinion. A child drank from a vial a small quantity of the strong sulphuric acid (oil of vitriol) by mistake, about half past four o'clock in the afternoon. Vomiting was immediately excited by the mother, by putting a finger down the throat. The child did not complain of much pain, except when she coughed or vomited; and continued perfectly sensible until nine o'clock in the evening, when she died without a struggle. The body was examined by dissection the following morning, when a large aperture was found in the greater curvature of the stomach, through which the food and other contents of the stomach had passed into the sac of the omentum. The omentum itself was blackened and reduced to a half pulpy state, by the action of the acid, but still retained a sufficient degree of consistence, to contain the substances which had passed into it. The perfect condition of all the functions of the nervous system, which continued for above five hours, and did not fail until the texture of the stomach was actually destroyed, marks the freedom from any direct poisonous influence upon the brain, and leads to the same inference which Mr. Brodie drew respecting the operation of the corrosive sublimate, that the brain ultimately suffered only from its sympathy with the injured structure of the stomach.

On the Treatment of those who have swallowed Poison.— Having examined the mode in which the different poisonous substances operate upon the living body, we are prepared to inquire briefly into the appropriate methods of treatment to be resorted to, in cases where any of them have been swallowed by accident or design. It is to be lamented, however, that we are not in possession of any substance, by which the deleterious qualities of the animal and vegetable poisons are capable of being corrected or altered; and that, although some of the mineral poisons, especially those of a corrosive or caustic nature, may be neutralized or decomposed by chemical means, yet their destructive action is generally too rapid to be materially diminished by any chemical combination, especially where they have been taken or given with an intention of destroying life. Among the ancients, many absurd ideas prevailed respecting the multiplicity and operation of poisons, which gave rise to equally unfounded notions of the number and efficacy of antidotes, which might be found to counteract their effects. It was supposed that what were denominated *slow* poisons might be prepared, so as to undermine the vital powers, and to produce death by insensible steps within a definite time; and against the operation of these, the fears and alarms of individuals were constantly on the alert, and the skill and ingenuity of the preparers of drugs were often principally directed. Whence the old treatises of pharmacy abound with recipes for antidotes of various reputed efficacy, to many of which the names of their inventors were annexed, but whose powers of resisting the action of poisons were purely imaginary. In fact, it was easy for any medicine to acquire that character, when the very existence of such poisons was equally gratuitous, and when security, which had never been endangered, was imputed to the operation of every farrago of drugs, that the caprice of the apothecary could bring together. The removal of the dread of poison may be reckoned among the many advantages, which a more extensive acquisition of the knowledge of nature has produced; for in the earlier periods of history, it was generally believed that poisons could be made to operate in the most secret and imperceptible ways; not only through the medium of the food and drink; but through that of the clothes that were worn, or even of the utensils that were touched, and of the flowers and perfumes that were smelt at. But these opinions and fears

POISON.

fears were the result of ignorance, or of the designs of half-learned individuals, who benefited by the credulity of their contemporaries.

The operation of poisons, when taken into the stomach, being generally manifest and rapid, and no actual antidote to their properties being in our possession, the principal object to be aimed at, in administering to the relief of those who may have swallowed them, of whatever nature, is to rid the stomach of them with all possible expedition. *Vomiting*, therefore, should be attempted to be excited immediately on the discovery that any poisonous substance has been taken into the stomach. As *emetic* drugs are not always at hand, the action of vomiting may be sometimes produced by putting a finger down the throat, or by tickling the internal fauces with a feather, and sometimes by a copious draught of warm water, which last, if the poison be of an acrid or corrosive nature, will also tend to weaken its injurious qualities by dilution. When an emetic is resorted to, it should be such a one as will act speedily; and with this view, instead of the antimonials or ipecacuanha, fifteen grains, or a scruple, of the *sulphate of zinc* (white vitriol) is usually given, which, in general, returns by vomiting almost instantly, and constitutes the most expeditious emetic that we possess, which is, at the same time, but slightly offensive to the stomach. Dr. Withering affirms that the distilled water of the *ranunculus flammula* is preferable to the white vitriol, inasmuch as it produces instantaneous vomiting, without exciting those painful contractions in the upper part of the stomach, which sometimes follow the use of the former. (See his *Botan. Arrang.* vol. ii. p. 504. *note.*) It often happens, indeed, when the vegetable narcotics are swallowed in large quantities, especially laudanum or solid opium, that the nerves of the stomach are so paralyzed or rendered torpid by the influence of the poison, that it is extremely difficult, if not impossible, to excite it to the action of vomiting, and, in this case, it becomes necessary to repeat the efforts to rouse it, even by more active means. In a case where six ounces of laudanum had been swallowed, and little or no evacuation produced six hours afterwards, although a drachm and half of sulphate of zinc had been swallowed, a solution of fifteen grains of the blue vitriol, or *sulphate of copper*, was administered, which in the course of a minute produced a copious discharge of fluid by vomiting; after which, by persevering in other means to counteract the torpor of the nervous system, such as constantly dragging the patient about the room, administering ammonia, assafœtida, and other stimulants, recovery was accomplished. See a case by Dr. Marcet, in the *Medico-Chirurg. Transact.* vol. i. p. 77.

Among the poisons of mineral origin, and others, which act by their corrosive qualities, the strong mineral acids, and the caustic alkalis, may certainly be deprived of their caustic power by dilution, and more especially by neutralization. Nevertheless as their action is very speedy upon the parts with which they come in contact, the effect of swallowing either a diluent or a neutralizing substance will be of little avail, if it is not immediately at hand. Where a strong acid has been known to be swallowed, however, it would certainly be advisable to administer, as soon as possible, an alkali in solution; and if caustic alkali has been taken, a diluted acid might be given. Those corrosive salts which an alkaline solution would decompose, as is the case with most of the metallic salts, might be, perhaps, in some degree disarmed of their virulence by a speedy administration of such a solution. The combinations of arsenic and barytes, which are deleterious in all their forms, and act independently of their chemical qualities, require to be treated

nearly as the vegetable poisons, in the first instance by vomiting and by dilution. By animals, which are capable of vomiting, indeed, Mr. Brodie affirms that the greater portion of the arsenic that is swallowed, is commonly rejected by spontaneous vomiting very soon after it has been taken; and whether the poison has been rejected spontaneously, or in consequence of artificial sickness, a disease which is not found in cases of poisoning by the vegetable narcotics, remains to be treated; namely, the inflammation of the stomach and bowels. In some instances, when a person has survived the immediate effects of arsenic as a poison, death has nevertheless ensued in a few days from the consequences of this inflammation; as in a case mentioned by Mr. Brodie, which occurred in St. Bartholomew's hospital, and was related to him by Mr. Earle; in which extensive ulcerations were found in the mucous membrane of the stomach and bowels after death. In a similar case, which was treated by Dr. Roget, the patient, after having swallowed sixty grains of white arsenic, had vomited profusely, and probably discharged the whole of the poison, as the vomiting was assisted by copious dilution; it did not appear, indeed, from the analysis of the fluid, vomited at the time the patient was first seen by Dr. Roget, about sixteen hours after the poison was taken, that any of it remained in the stomach. A severe train of symptoms, however, ensued, indicative of inflammation in the stomach and bowels, which demanded the use of the lancet and blisters and other evacuants; and under this treatment the patient recovered. The recovery was slow, and various untoward symptoms occurred, such as an extension of the inflammation to the lungs and the spleen, and likewise several symptoms indicative of the disturbance of the sensorium, such as coma, dilated pupils, and even convulsions. See *Medico-Chirurg. Transact.* vol. ii. p. 136.

In all cases, then, where poison has been obviously swallowed, the first step to be taken is the evacuation of the stomach by vomiting. The subsequent measures will be dictated partly by the nature of the poison, where that is known, and any neutralizing or decomposing substance is at hand; and partly by the nature of the symptoms which ensue, and which, in the case of arsenic in particular, are likely to be of an inflammatory kind, indicative of gastritis and enteritis; and in all cases, whether the species of poison can be ascertained or not, the free promotion of the vomiting, by copious draughts of warm water, should at all events be resorted to.

That part of *medical jurisprudence* which relates the evidence of the effects of poison in producing certain instances of death, would be a subject of interesting discussion; but very little that is universally applicable could be laid down here. In getting rid of the ancient notions of slow and imperceptible poisons, above alluded to, we have cut short much of the legal discussions upon these subjects. These erroneous opinions were very prevalent, even in the time of lord Bacon; for that great luminary of science himself, in his charge against the earl of Somerset, for the murder of sir Thomas Overbury, in the Tower, seems to give credit to the story of Livia, who is said to have poisoned the figs upon the tree, which her husband was wont to gather with his own hands; and he seriously states, that "Weston chased the poor prisoner with poison after poison; poisoning salts, poisoning meats, poisoning sweet-meats, poisoning medicines and vomits, until at last his body was almost come, by the use of poisons, to the state that Mithridates's body was by the use of treacle and preservatives, that the force of poisons was blunted upon him; Weston confessing, when he was tried for not dispatching him, that he had given
enough

enough to poison twenty men." Bacon's Works, vol. ii. p. 614.

There is, however, still considerable difficulty, in many cases, in deciding upon the cause of death, where poison is supposed to have been administered; for the two principal sources of evidence, the examination of the contents of the stomach, and the dissection of the body, are both liable to some uncertainty. This difficulty was strongly exemplified in the contrariety of evidence advanced at the trial, in the case of Miss Burns, at Lancaster, in 1808. (See Annual Medical Register, vol. i. art. 47, for 1808.) In such cases, the absence of any poisonous substance among the contents of the stomach, as found after death, cannot be deemed satisfactory evidence that the person did *not* die from poison: for it was proved by experiments on animals, instituted on that occasion by Dr. Bostock and others, that the oxy-muriate of mercury (corrosive sublimate) may be given, and may speedily prove fatal, and yet that not a particle of it shall be detected in the contents of the stomach after death. Again, the fact which Mr. John Hunter first pointed out, that in animals and men, who die suddenly while in health, the gastric juice is capable of acting on the stomach itself, so as to corrode its coats, renders extreme caution necessary in pronouncing upon the action of a poisonous substance on the coats of the stomach. Mr. Hunter, indeed, asserts, that some degree of this digestion or erosion of the stomach, at its great end, is very commonly observed; he says, too, "that when the stomach is actually perforated, the edges of this opening appear to be half dissolved, very much like that kind of dissolution which fleshy parts undergo when half dissolved in a living stomach, or when dissolved by a caustic alkali, *viz.* pulpy, tender, ragged." These observations evince the necessity of combining a consideration of the symptoms which preceded death, and of other appearances observed on dissection, with the actual state of the stomach, before any decision is given. The appearances of inflammation in the stomach, intestines, and other viscera, if there be any, should be carefully taken into the view; and even these appearances are deceptive, as has been recently shewn by Dr. Yelloly in numerous dissections of the stomach after violent death: for in such instances there is commonly a redness, which has been considered as inflammatory, but which is obviously independent of inflammation. (See *Medico-Chirurg. Transact.* vol. iv.) Inflammation and erosion of the stomach are, indeed, common effects of acrid poison; but they are also occasionally absent where such poison has been taken.

On the whole, therefore, no person who has not had ample experience of the appearances of the stomach after death, under various circumstances of health and disease, by frequent inspection, should presume to pronounce on the actual operation of a poison, except the presence of the poisonous substance be also detected, or a concurrence of certain symptoms, with the appearances found on dissection, should warrant such a decision.

We have deemed it unnecessary to enter into a minute detail of the symptoms occasioned by particular preparations of these poisons, as they vary much in different individuals, or to enumerate all the substances, either vegetable or mineral, which possess these deleterious properties. With respect to the mineral poisons, the reader will find an ample history in Dr. John Johnstone's "Essay on Mineral Poisons," 1795; and with regard to the vegetable, he may consult Wilmer's "Observations on Poisonous Vegetables," 1781, and Houlston on Poisons. A comprehensive catalogue of all the poisons known is contained in the "Toxicologia," of Plenck, above quoted.

POISON-*Ash*, in *Botany*. See RHUS and TOXICODENDRON.

POISON-*Berry*, a species of *Cestrum*.

POISON, *Indian*. See GECCO.

POISON, *Macassar*. See MACASSAR *Poison*.

POISON-*Nut*. See STRYCHNOS.

POISON-*Oak*. See RHUS.

POISON-*Tree*, or POISON-*Wood*, *Toxicodendron*. See RHUS.

POISON-*Tusk*. See HIPPOMENE.

POISON, *Counter*. See COUNTER-*Poison*.

POISON *Cove*, in *Geography*, a part of Carter's bay, on the W. coast of North America; where poisonous muscles were eaten by Capt. Vancouver's crew.

POISON *Island*, a small island in the Atlantic, near the coast of Africa. S. lat. 10° 6'. W. long. 15° 3'.

To POISON a *Piece*, among *Gunners*, is the same as to clog and nail it up. See NAILING.

POISONING, in *Law*, the crime of administering poison to a person, whereby he dies.

This is, of all species of deaths, the most detestable; because it can of any be the least prevented either by manhood or forethought. (3 Inst. 48.) And, therefore, by 22 Hen. VIII. cap. 9. it was made treason; and the punishment inflicted for it was, to be put alive into a cauldron of water and boiled to death. But this act was repealed by 1 Edw. VI. cap. 12.

At present it is only murder, or felony without benefit of clergy, if the party dies of the poison within a year and a day. See MURDER.

POISONING, in *War*, is considered by the law of nations as more odious than even assassination; because, when practised treacherously, the effect would be more inevitable, and the use more terrible; accordingly it has been more generally detested. Of this Grotius (b. iii. ch. 4. § 15.) has given numerous instances. The consuls Caius Fabricius and Q. Æmilius rejected with horror the proposal of Pyrrhus's physician to poison his master, and even gave notice to that prince, that he might beware of the traitor, haughtily adding, "It is not to make our court to you, that we give the information, but that we may not draw on ourselves any infamy." (Plut. in Vit. Pyrrhi.) And they say in the same letter, that it is for the common interest of all nations not to set such examples. It was a maxim of the Roman senate, that war was to be carried on by arms, and not by poison. (Aul. Gell. Nat. Attic. lib. iii. c. 8.) Even Tiberius himself rejected the proposal made by the prince of the Catti, that if poison was sent to him, he would destroy Arminius: and he received for answer, that the Roman people chastised their enemies by open force, without having recourse to wicked practices and secret machinations. (Val. Max. l. vi. c. 5. Tacit. Annal. l. ii. c. 88.) Tiberius thus made it his glory to imitate the virtue of ancient Roman commanders. This instance is the more remarkable, as Arminius had treacherously cut off Varius with three Roman legions. The senate, and even Tiberius himself, did not think that poison was to be made use of even against a deceiver, or by way of re-tortion or reprisal. Assassination and poisoning are therefore contrary to the laws of war, and equally exploded by the law of nature, and the consent of civilised people. The sovereign practising such execrable means should be accounted the enemy of mankind, and the common safety calls on all nations to unite against him, and join their forces to punish him. His conduct particularly authorises the enemy, who had been attacked by such odious means, to give him no quarter. Alexander declared, "that he was determined to pursue Darius to the utmost, and no longer

as a fair enemy, but as a poisoner and an assassin." (Quint. Curt. l. iv. c. 11.) The interest and safety of commanders and rulers, so far from countenancing such practices, should excite them to use all possible care to suppress them. It was wisely said of Eumenes, "that he did not think any general would, to gain a victory, set a pernicious example, which might recoil on himself." And it was on this same principle, that Alexander formed his judgment of Bessus, who had assassinated Darius. Q. Curt. l. vi. c. 3.

Although the use of poisoned arms is a practice that may be excused with a little more plausibility, as it has in it no treachery nor any thing that is clandestine; yet this is no less interdicted by the law of nature, which does not allow us to multiply the evils of war. War is never permitted to nations, but from necessity; and all are to refrain from methods which tend to render it more destructive, and they are even obliged to oppose them. It is therefore with reason, and agreeably to their duty, that civilized nations have classed among the laws of war, the maxim which prohibits the poisoning of arms. (Grotius, b. iii. c. 4. § 16.) And all are warranted by their common safety to suppress and punish the first who should offer to break through this law. The poisoning of waters, wells, and springs, is still more generally condemned, because, as some authors say, innocent persons, as well as enemies, may lose their lives. This, indeed, is a farther reason, but it is not the only, nor indeed the true one; for it is lawful to fire on an enemy's ship, though there may be neutral passengers on board. But though poison is not to be used, it is very allowable to divert the water, to cut off the springs, or in any other way to render them useless, that the enemy may be reduced to surrender. (Grot. ubi supra, § 17.) In the conduct of war, says the admirable Vattel, we should never forget that our enemies are men. If we are under the disagreeable necessity of prosecuting our right by force of arms, let us not destroy that charity which connects us with all mankind. Thus shall we courageously defend our country's rights without hurting those of society. Our courage will preserve itself from every stain of cruelty, and the lustre of victory will not be tarnished by inhuman and brutal actions. De Vattel's Law of Nations, b. iii. c. 8.

POISONOUS WATERS. See WATER.

POISSY, in *Geography*, a town of France, in the department of the Seine and Oise, and chief place of a canton, in the district of Versailles; three miles N.W. of St. Germain. The place contains 2437, and the canton 14,924 inhabitants, on a territory of 145 kilometres, in 17 communes.

POITIERS, a town of France, and chief place of a district, in the department of the Vienne, before the revolution the see of a bishop, and residence of the governor of Poitou. Its principal manufactures are stockings, woolen-caps, gloves, and combs. In this town are some remains of Roman antiquities. It was near this town that a battle was fought in 1356, between the English and the French, when the latter were defeated, and the king taken prisoner. The army of the English, led on by the Black prince, amounted only to 12,000 men, and the French to 60,000. The place contains 18,223 inhabitants, 10,025 in one canton, which includes 11,710, in two communes, and 8200 in another canton, including 10,573, in seven communes. The whole territory contains 150 kilometres. N. lat. 46° 35'. E. long. 0° 26'.

POITMANS DORF, a town of Silesia, in the principality of Neisse; seven miles S.W. of Grotkau.

POITOU, a province of France before the revolution, on the S. of the Loire; now forming the departments of

the Vienne, the Two Sevres, and Vendée; the capital of which was Poitiers.

POITU, a town of Sweden, in the province of Finland; 30 miles N.N.E. of Abo.

POIVRE, N., in *Biography*, a traveller, and intendant of the isles of France and Bourbon, was born at Lyons in the year 1715. He entered into the congregation of foreign missionaries, by whom he was sent to China, a great part of which empire he traversed as a philosophical observer. Having been thrown into prison in consequence of a mistake, he defended himself so well before a mandarin in the Chinese language, that he was honourably discharged. On his return to Europe he had the misfortune to lose an arm in an engagement with an English vessel, and his first observation on the accident was, that he was disabled for a painter. He was also obliged to renounce the ecclesiastical profession; but the India Company, to whom he was known as an active and intelligent person, employed him, in 1749, to establish a new branch of commerce in CochinChina. In this undertaking he displayed great talents for business, with the most scrupulous integrity. In 1766, he was sent by the duke de Choiseul as intendant to the isles of France and Bourbon, for the purpose of introducing improvements into these colonies. M. Poivre fully answered the ends of his mission. He imported a vast number of sheep from Madagascar, formed a nursery of every kind of useful trees adapted to the climate, and after many efforts naturalised the bread fruit, the clove, and nutmeg. He died at Lyons in the year 1786. As an author he published the following works: "Voyage d'un Philosophe," containing a brief account of Asia, Africa, and America, chiefly relative to agriculture: "A Memoir on the Preparation and Dyeing of Silk;" "Remarks on the History and Manners of China;" "Discourses addressed to the Inhabitants of the Isles of France and Bourbon." His sentiments are those of a friend to liberty and the happiness of mankind.

POIX, in *Geography*, a town of France, in the department of the Somme, and chief place of a canton, in the district of Amiens; 14 miles S.W. of Amiens. The place contains 751, and the canton 11,513 inhabitants, on a territory of 227½ kilometres, in 34 communes.

POKA, a town of Hindoostan, in Bahar; 30 miles N. of Bettyar.

POKARYA, a town of Bengal; 16 miles S. of Nattore.

POKE, or PORK *Physic*, in *Botany*. See PHYTOLACCA.

POKE, in *Rural Economy*, a small sack or bag for common purposes, as well as for those of containing hops.

POKE, a disease among sheep, which is much the same as the rot. See ROT.

POKECHU, in *Geography*, a town of Bengal; nine miles N. of Toree.

POKETALICO, a river of Virginia, which runs into the Kanhawa, N. lat. 38° 16'. W. long. 81° 51'.

POKFLIES, a town of Austria; 12 miles N.E. of Vienna.

POKONCA, a mountain of Pennsylvania; 22 miles N.W. of Easton.

POKRA, a river of Sclavonia, which runs into the Save; six miles S.W. of Craliovavelika.

POKRATZ, a town of Sclavonia, on the river Pokra; 16 miles E. of Craliovavelika.

POKREJE, or POKROJA, a town of Samogitia; 25 miles S.W. of Birza.

POKROPSKOE, a town of Russia, in the government of Perm; 20 miles S.W. of Kungur.

POKROV, a town of Russia, in the government of

Vladimir, on the Kliazma; 44 miles W.S.W. of Vladimir. N. lat. $53^{\circ} 24'$. E. long. $39^{\circ} 14'$.

POKROVA, or BOGORODITZ, a town of Russia, in the province of Usting, on the river Sula; 60 miles E. of Lalsk.

POKROVSKAIA, a town of Russia, in the government of Saratov, on the E. side of the Volga, opposite to Saratov.

POKROVSKOE, a town of Russia, in the government of Ekaterinoflav; 16 miles W.S.W. of Slavenfk.

POKROVSKOI, a town of Russia, in the government of Irkutsk; 32 miles S.W. of Yakutsk.—Also, a town of Russia, in the government of Archangel, on the Baga; 36 miles S. of Schenkursk.—Also, a town of Russia, in the province of Vologda; 16 miles W.S.W. of Totma.—Also, a town of Russia, in the government of Vologda; 32 miles N. of Totma.

POKTOO, a town of the Birman empire; 30 miles W. of Ava.

POL, ST., a town of France, and principal place of a district, in the department of the straits of Calais. The place contains 2949, and the canton 13,547 inhabitants, on a territory of 230 kilimetres, in 43 communes.

POL de Leon, St., a town of France, in the department of Finisterre, and chief place of a canton, in the district of Morlaix. The place contains 5038, and the canton 13,847 inhabitants, on a territory of 115 kilimetres, in seven communes.

POLA, a town of Istria, on a mountain, near a bay of the Adriatic; the see of a bishop, suffragan of Udina. The harbour, or bay, twelve miles in circuit, is formed and protected by a chain of very pleasant hills; the entrance of which, however, is too narrow for large vessels. The town, which is surrounded with walls, has four gates, and a castle situated towards the sea, on an eminence almost in the middle of the town. It was a Roman colony, and possesses many antiquities, viz. an amphitheatre, 366 feet long, 292 broad, and 72 feet high, with 145 arches, ranged in two lines; and nearly in the centre of the town are the ruins of two temples, one built in honour of L. Sergius Lepidus, by his consort Salvia Posthuma, and the other by the town of Pola, in honour of the city of Rome and Augustus. The town contains about 7000 inhabitants, whose trade principally consists in the fishery of tunny fish, carried on between the rocks near Pola; 30 miles S. of Capo d'Istria. N. lat. $45^{\circ} 5'$. E. long. $14^{\circ} 3'$.

POLA, a town of the island of Rhodes. N. lat. $36^{\circ} 14'$. E. long. $27^{\circ} 26'$.

POLA, or *Otewhei*, one of the Navigator's islands, in the S. Pacific ocean. S. lat. $13^{\circ} 52'$. W. long. $172^{\circ} 20'$.

POLA, a small island in the Mediterranean, near the S. coast of Sardinia. N. lat. $39^{\circ} 8'$. E. long. $9^{\circ} 15'$.—Also, a river of Russia, in the government of Novgorod, which runs into lake Ilmen, eight miles E. of Stara Raza.

POLA de Lena, a town of Spain, in the province of Asturia; 12 miles S. of Oviedo.

POLA, in *Ichthyology*, the name of a flat fish, something resembling the foal, but shorter and smaller; commonly called *cynoglossus* and *linguatuia*.

It is caught in the Mediterranean, and sold in Rome and Venice for the table.

POLABERG, or POLAPERG, in *Geography*, a town of Austria; 11 miles S.W. of St. Polten.

POLACCA, in *Musie*, a Polish air or tune for dancing.

POLACRE, in *Naval Language*, a merchant vessel used in the Mediterranean. These vessels have three pole masts, without tops, caps, or cross-trees, and a bowsprit of one

piece; they have bolsters fixed, as a stop to the shrouds stays, &c. The mizen-mast is sometimes not in one piece. Their rigging is light, having no top-mast shrouds, &c., but a rope ladder is fixed instead, from the mast heads to the upper part of the lower rigging. They carry the same sails as a ship, and have square yards; all of which, except the lower yards, are without horses; for they then stand upon the lower yards to loose or furl the top-sails, and upon the top-fail yards to loose or furl the top-gallant sails, as the yards are easily lowered for that purpose.

POLACRE-Settee, a vessel with three masts, usually navigated in the Levant or Mediterranean. These vessels are generally rigged with square-sails upon the main and mizen-mast, and the latteen-fail upon the fore-mast, like a xebec, (which see); and sometimes a latteen-fail upon the mizen-mast, and only square-sails on the main-mast. The main-mast always keeps the rigging of the polacre.

POLAEDRASTYLA, in *Natural History*, the name of a genus of crystals. The word is derived from the Greek πολλυς, many, εδρα, sides, the privative particle a, not, and συλος, a column; and expresses a crystal composed of many planes, and having no column.

The bodies of this genus are crystals composed of two octangular pyramids, joined base to base, and consequently the whole body consisting of sixteen planes. Of this genus there are only two known species: 1. A brown kind with short pyramids, found in considerable plenty in Virginia, on the sides of hills; and 2. A colourless one, with longer pyramids. This has yet been found only in one place, which is the great mine at Gossalaer, in Saxony, and there usually lies at great depths. Hill.

POLAND, in *Geography*, once a considerable kingdom of Europe, but now totally dismembered and divided among neighbouring states, was bounded on the N. by Prussia, Courland and Russia, on the S. by Hungary and Moldavia, and on the W. by Silesia, Pomerania, and Moravia; about 200 miles long and 560 broad. In its primitive condition, and in its utmost extent, Poland comprehended 13 provinces or districts: viz. Great Poland, called also Lower Poland, which included the palatinates of Posen or Pofnania, Kalish, Siradia, Lenciez, and Rawa;—Cujavia, containing the palatinates of Brzeskie and Wladislaw;—Masovia, including the palatinates of Czerfk and Ploczko;—Polish Prussia, including Pomerelia, the palatinate of Culm, the government of Marienburg and Ermeland;—Little Poland, containing the palatinates of Cracow, Sandomir, and Lublin;—Podlachia, or the palatinate of Bielsk;—Little Russia, or Red Russia, comprehending the palatinates of Chelm, Belz, and Lemberg;—Podolia and Braclaw;—palatinate of Kiev;—and Volhynia. To these may be added Lithuania, which was considered as a part of Poland, together with Samogitia and Courland. Of these, Great Poland, Polish Prussia, and part of Lithuania, have been seized by Prussia;—Little Poland and Red Russia were annexed to Austria; while the remainder and greater part of Lithuania, Courland, Polesia, Podolia, palatinate of Kiev and Volhynia, were seized by Russia: so that in the year 1793, Samogitia, Masovia, and Podlachia, were the only territories that remained to constitute the kingdom of Poland. Since that time Samogitia has been annexed to Russia, and the king of Prussia seized the other two. By the peace of Tilsit, it was agreed that all the part of Poland, which Prussia had added to her dominions since the year 1772, should be erected into an hereditary principality, under the title of the duchy of Warsaw, and given to the king of Saxony. Other changes are likely soon to take place, in consequence of the union and

POLAND.

and concurring operations of the allies, which will again overturn the arrangements which Bonaparte, the late emperor of France, had established. Of these we shall be able to give an account in some subsequent articles.

For an account of the productions of Poland, we refer to the articles comprehending the countries to which its several parts are annexed, as well as to the names of those districts as they occur. We shall here introduce a brief history of Poland, with an account of its various revolutions and of the cause that produced them. Poland, in the changes which it has since undergone, and in the situation in which it now appears, presents an interesting subject of enquiry to the philosopher and the politician. About a century ago it was one of the most respectable powers in Europe; but it has now not only lost its nominal existence and independence as a nation, but it is totally annihilated. By the progressive events that have terminated in its destruction, it has exhibited an almost uninterrupted scene of disorder and calamity. Sometimes overrun and pillaged by foreign enemies, and generally distracted by internal dissensions, peace and security and settled government have been, in consequence of a series of disastrous occurrences, almost unknown. Kings have been raised to the throne, and precipitated from it. Constitutions have been established, and altered, and overthrown, and removed. Some of its finest provinces have been dismembered; and foreign armies established in the republic, either to perpetuate its miseries, or to complete its subjugation. The situation of the country previously to its total extinction as a separate state, exhibited the most striking impressions of these convulsions. The principles of disorder, long ago incorporated into the frame of the constitution, have been matured and perfected by the habits of party dissention, heightened by religious animosity, and fomented by the insidious policy of the neighbouring states. Law and justice have been silenced by the strife of faction, or overwhelmed by the pressure of foreign force. The people, reduced to the lowest state of degradation and oppression, have had no interest in the measures of government, and no incitement to industry. The practice of selling the crown to the highest bidder soon introduced an almost universal venality among the nobility. Amidst the violence of faction, honour and principle have been swept away; and while almost every nation in Europe has been advancing in improvement and civilization, Poland appeared to have been long stationary, if its progress was not indeed rather retrograde. The nature of the Polish government has been, without doubt, the principal source from which the misfortunes of this country have taken their rise. From a sketch of the government of Poland, we shall perceive the weakness of the state keeping pace with what the Poles have called the freedom of the constitution. Little can be certainly known respecting the origin of the Polish government. In the Roman times Poland was chiefly possessed by the Sarmatæ or Slavons; and the Poles pretend to have their dukes from the 6th century. The description given by Tacitus of the tribes from which the Poles are, most probably, descended, the analogy of other northern nations, and the general tenour of the Polish history, tend to prove, that the great body of the people enjoyed a high degree of freedom, as well as a considerable influence on the measures of government. Although the sovereign power was generally continued in the same family, there was no established rule of hereditary succession. If a free election did not take place on every vacancy, the consent of the nation, expressed in a general diet, was always necessary to confirm the nomination of a successor to the ducal dignity. While the government remained in

this state, the people were really free; and yet the sovereign power appears to have been subject to no constitutional restrictions. Neither the prerogative of the duke, nor the privileges of the people, were defined by positive law. Custom seems to have formed the only restriction to either. The sovereign carried his power as far as he thought he could depend upon the submission of the nation; and the people sometimes exerted their right of expelling a tyrannical master, and asserting their freedom by force. The government, for a considerable time, subsisted in this undefined state. The first circumstance which seems to have had any permanent influence on the form of the government and the condition of the people, was the practice of bestowing fiefs upon the feudal principles. This institution, which is said to have been introduced into Poland about the year 820, invested the feudal lords with a species of authority over their vassals, which was eventually the more fatal, as in the time of ignorance it was not accurately defined. The introduction of Christianity was another event, which, by tending to strengthen the power of the aristocracy, concurred to produce the changes which afterwards took place in the government. The Poles embraced the Christian religion about the year 964, when the spiritual tyranny of Europe was at its height; and the despotic principles of the Roman Catholic church were received along with the Roman Catholic faith. The apostles of this church assumed in their mission a tone of authority corresponding to the high claims of their temporal head. No sooner had they established themselves in Poland than they found themselves placed in a situation highly favourable to their ambitious views. In process of time the domineering spirit of the Roman Catholic hierarchy, concurring with the arbitrary principles of the feudal system, gave an easy victory to the clergy and nobility over the liberties of the people: the people of course felt the consequence of these institutions in the extinction of their political privileges. They were excluded from the diet of election: the nobility and clergy reserving to themselves the sole right of regulating the succession to the sovereignty. The abridgment of personal liberty soon followed the loss of political importance; and oppressions were multiplied: they were gradually deprived of the rights of men, as well as of those of citizens. The law being too weak, or too corrupt to afford them relief, they sunk into a state of servitude, from which they never afterwards emerged. This will be sufficiently evident in the progress of their history. Their sovereigns are usually ranged in four classes or periods; *viz.* those of the house of Lesko, of Piast, of Jaghellon, and of different families. The first period is considered as fabulous: and the best Polish historians usually commence their narratives at the second era; and the early part even of this, which is dated A.D. 842, has much the air of romance. Destitute of letters, and immersed in Pagan superstition, faithful accounts are not to be expected from such people. The authenticity of the Polish annals cannot be dated earlier than the accession of Miecslaus II., the fourth sovereign of the line of Piast in 964. During the whole of this period, as some writers say, the monarchy was elective, and the sovereign power limited; but according to others, the crown was hereditary, and its authority absolute. The fact seems to have been, in accordance with both these statements, that the crown continued in the same family, and therefore seemed to be hereditary; but it had an elective appearance, because, on the death of the king, his successor was formally nominated and recognized in an assembly of the nobility and clergy of the realm. Towards the close of this second period, A.D.

1347, Casimir the Great restrained the turbulence of the principal barons, and granted certain immunities to the nobles and gentry. (See CASIMIR, surnamed the *Great*.) If Casimir had been succeeded by a line of hereditary monarchs, the barons would not have recovered their former ascendancy, and the feudal system would have been gradually annihilated in Poland as in other countries of Europe. But his nephew and successor Louis, king of Hungary, being a foreigner, was obliged to ratify certain conditions, which circumscribed the prerogative of the crown, and increased the power of the barons and inferior nobles. He agreed that no taxes should be imposed without the consent of the nation; and that in case of his demise without male heirs, the privilege of appointing a sovereign should revert to the body of nobles.

The third period begins with the death of Louis in 1382, when the Poles set aside his son-in-law Sigismund, and raised to the throne Ladislaus Jaghellon, duke of Lithuania, who confirmed all the stipulations of Louis. He was succeeded by his son Ladislaus III., and Ladislaus by his brother Casimir, who introduced further innovations unfavourable to royal prerogative. One of the principal events in this reign, which gave occasion to more important revolutions in the Polish government, was the convention of a national diet invested with the sole power of granting supplies. On this account the reign of Casimir has been considered by the popular party as the era, at which the freedom of the constitution was permanently established. His second son and successor, John Albert, assented, without hesitation, to all the immunities extorted from his predecessors, and swore to the observance of them in a general diet held at Patrikau, in 1469. His brother and successor, Alexander, declared in 1505, the following limitations of sovereign authority to be fundamental laws of the kingdom: the king cannot impose taxes; nor require the feudal services; nor alienate the royal domains; nor enact laws; nor coin money; nor alter the process in the courts of justice. The first attempt towards establishing a free election of the king was brought forward in the reign of Sigismund Augustus, son and successor of Sigismund I., who had succeeded Alexander: he was constrained in 1550 to agree, that no future monarch should succeed to the throne unless freely elected by the nation. During the Jaghellon line, which terminated with Sigismund Augustus, the sovereigns, although formally raised to the throne by the consent of the nation, still rested their pretensions upon hereditary right, as well as upon this consent, always styling themselves *heirs* of the kingdom of Poland.

The fourth period commences from the demise of Sigismund Augustus A.D. 1572, when all title to the crown from hereditary right was formally abrogated, and absolute freedom of election established. At this era a charter of immunities was drawn up in a general diet, to be ratified by the new sovereign before his election. (See PACTA CONVENTA.) Henry of Valois secured his election, partly by private bribes to the nobles, and partly by promising an annual pension to the republic from the revenues of France. His example was followed by each succeeding sovereign, who, besides an unconditional ratification of the "Pacta Conventa," purchased the crown by a public largess and by private corruption, circumstances which endeared an elective monarchy to the Poles. Under Stephen Bathori, the regal power was farther circumscribed by the appointment of 16 resident senators chosen at each diet to attend the king, and to give their opinion in all matters of importance, which prevented him from issuing any decree without their consent. Another fatal blow was given to the prerogative in 1578,

by annihilating the supreme jurisdiction, or the power of judging in the last resort the causes of the nobles, except such as arose within a small distance from the royal residence. The turbulent reign of John Casimir was marked by the introduction of the "Liberum Veto," or the power which each nuncio claims or exercises of interposing a negative, and, in consequence of that interposition, of breaking up the diet; a privilege which the sovereign himself does not possess, and which has principally contributed to destroy the true balance of the Polish constitution. But the king was still the fountain of honour, and besides the principal dignities and offices of the republic, he bestowed the "Starosties," or royal fiefs, which are held during the life-time of the possessor. Hence he still maintained great influence in the councils of the nation; but this last solitary branch of royal prerogative was wrested from the crown at the establishment of the permanent council A.D. 1733. From the preceding detail it appears, that from the time of Louis the nobles continued to diminish the regal authority, and to augment their own privileges. It also appears, that though the Poles were accustomed to boast of their liberty, they were by no means free. Their liberty was, in reality, a turbulent system of aristocratic licentiousness, where a few members of the community were above the controul of the law, and the majority excluded from its protection. The history of this country evidently shews, that the Poles were more free at home, and more independent and flourishing abroad, when the sovereign had greater authority, when the nobles assisted at the diets without the privilege of dissolving them, and when they submitted themselves and their peasants to the jurisdiction of the king.

On the demise of Augustus III. Stanislaus Augustus, son of count Poniatowski, the friend and companion of Charles XII. was supported in his pretensions to the crown by the empress of Russia and the king of Prussia, and also aided by a party among the nobles, and also recommended by his great personal accomplishments, was raised to the throne in 1764, in the 22d year of his age. He possessed talents, and virtues, which were calculated to rescue Poland from its deplorable state, if the defects of the constitution had not fettered his exertions for the public good. But all flattering prefaces were disappointed by the factions of a turbulent people, fomented by the intrigues of the neighbouring powers; and the most amiable of the Polish sovereigns was doomed to experience the dreadful effects of that excessive liberty, or rather licentiousness, which is inconsistent with the existence of a well-regulated government. The body of Polish religionists, called "Dissidents," make a principal figure in the subsequent commotions of this reign. (See DISSIDENTS.) In consequence of the indulgences granted to the Dissidents, at an extraordinary diet convened in 1768, a general dissatisfaction prevailed among the Roman Catholics, and several confederacies were formed in defence of the sacred Catholic faith. Poland became a scene of bloodshed and devastation; and the confederates, secretly encouraged by the house of Austria, assisted by the Turks, and supplied with money and officers by the French, protracted hostilities from the dissolution of the diet in 1768 to the division of Poland in 1772. Among other acts of cruelty which were perpetrated by the confederates, one, which was meditated, but not accomplished, was the assassination of the king. A period was now approaching which teemed with an event that disgraces the history of Europe. Treaties upon treaties, and negotiations upon negotiations, guaranteed to Poland the possession of her territory; and at the king's accession the three powers that dismembered her provinces

provinces solemnly renounced all right to any part of the Polish dominions; but treaties and guaranties afford no security against interest and ambition. The natural strength of Poland, if properly exerted, would have formed a more certain bulwark against the ambition of her neighbours than the faith of treaties; and it is worthy of remark, that of the three partitioning powers, Prussia was formerly in a state of vassalage to the republic; Russia once saw her capital and throne possessed by the Poles, under Sigismund III. whose troops got possession of Moscow, and whose son Ladislaus was chosen great duke of Muscovy by a party of the Russian nobles; and Austria was indebted to John Sobieski, king of Poland, who, in 1683, compelled the Turks to raise the siege of Vienna, and delivered the house of Austria from the greatest dangers it ever experienced. "The partition of Poland," says Mr. Coxe, whose account of this infamous transaction we shall give in his own words, "was first projected by the king of Prussia. Polish or Western Prussia had long been an object of his ambition; exclusive of its fertility, commerce, and population, the local situation rendered it highly valuable; it lay between his German dominions and Eastern Prussia, and while possessed by the Poles, cut off all communication between them. During the course of the seven years war, Frederic experienced the most fatal effects from this disunited position of his territories. By the acquisition of Western Prussia, his dominions would be rendered compact, and his troops in time of war be able to march from Berlin to Königsberg without interruption. The period was now arrived, when the situation of Poland seemed to promise the attainment of this favourite object. He pursued it, however, with all the caution of an able politician. On the commencement of the troubles, he shewed no eagerness to interfere in the affairs of this country, and although he concurred with the empress of Russia in raising Stanislaus Augustus to the throne of Poland, yet he declined taking an active part against the confederates. Afterwards, in 1769, when the whole kingdom was convulsed with civil commotions, and desolated by the plague, he advanced his troops into Polish Prussia, and occupied that whole district, under pretence of forming lines to prevent the spreading of the infection.

"Though completely master of the country, and not apprehensive of a formidable resistance from the disunited Poles; yet, aware that the security of his new acquisition depended upon the concurrence of Russia and Austria, he planned the partition. He communicated the project to the emperor, by whom it was readily adopted, either during their interview at Nies in Silesia, in 1769, or in the following year, at Neustadt in Moravia. Joseph who had secretly encouraged the confederates, and even commenced a negotiation with the Porte against Russia, now suddenly altered his measures, and increased his army towards the Polish frontiers. The plague presenting to him, as well as to the king of Prussia, a specious motive for stationing troops in the dominions of the republic, he gradually extended his lines, and, in 1772, occupied the whole territory, which he has since dismembered. But, notwithstanding this change in his sentiments, his real views upon Poland were at first effectually concealed; and the confederates imagined that the Austrian army was advancing to act in their favour.

"Nothing remained towards completing the partition, but the accession of the empress of Russia, who was too discerning a politician not to regard with a jealous eye the introduction of foreign powers into Poland. Possessing an uncontroled ascendancy over the whole country, she could propose no material advantage from the formal acquisition

of a part, and must purchase a moderate addition to her territory by a considerable surrender of authority. Frederic, well acquainted with the capacity of the empress to discern the true interests of Russia, forbore opening any negotiation on the subject of the partition, until she was involved in a Turkish war. At that crisis he dispatched his brother prince Henry to Petersburg, who suggested to the empress that the house of Austria was concluding an alliance with the Porte; that nevertheless the friendship of that house was to be purchased by acceding to the partition, upon which condition the emperor would suffer the Russians to prosecute the war without interruption. Catharine, anxious to push her conquests against the Turks, and dreading the interposition of the emperor; perceiving likewise, from the intimate union between the courts of Vienna and Berlin, that she could not prevent the intended partition, closed with the proposal, and selected no inconsiderable portion of the Polish territories for herself. The treaty was signed at Petersburg in the beginning of February 1772, by the Russian, Austrian, and Prussian plenipotentiaries.

"As the troops of the three courts were already in possession of the greater part of Poland, the confederates, hemmed in on all sides, were soon dispersed; and Europe waited in anxious expectation. Yet the partitioning powers proceeded with such profound secrecy, that even after the ratification of the treaty, only vague conjectures were entertained at Warsaw concerning their real intentions; and the late lord Cathcart, the English minister at Petersburg, obtained no authentic information of its signature, until two months after the event.

"The first formal notification of any pretensions to the Polish territory was in September 1772, announced to the king and senate assembled at Warsaw, by the imperial ambassador, which was soon followed by the memorials of the Russian and Prussian courts, specifying their respective claims. It would be tedious to enter into a detail of the pleas urged by the three powers in favour of their several demands; it would be no less uninteresting to lay before the reader the answers and remonstrances of the king and senate, as well as the appeals to the other states which had guaranteed the possessions of Poland. The courts of London, Paris, Stockholm, and Copenhagen, remonstrated; but remonstrances without assistance were of no effect. Poland submitted to the dismemberment, not however without the most violent struggles, and, for the first time, felt and lamented the fatal effects of faction and discord."

According to the will of the three courts a diet was convoked by the king to be held on the 19th of April 1773, when the partitioning treaty, after considerable opposition on the part of the Poles and under the enforcement of threats and bribes by the three powers, was finally ratified.

Of the dismembered countries, the Russian province was the largest, the Austrian the most populous, and the Prussian the most commercial. The province allotted to Russia comprised Polish Livonia, that part of the palatinate of Polotsk, which lies to the east of the Duna, the palatinates of Vitepsk, Miecislaw, and two small portions to the N.E. and S.E. of the palatinate of Minsk: this tract of land (Polish Livonia excepted) is situated in White Russia, and includes at least one-third of Livonia. The Russian limits of the new province are formed by the Duna, from its mouth to above Vitepsk; from thence by a straight line running directly south to the source of the Drug near Tolitzin, by the Drug to its junction with the Dnieper, and, lastly, by the Dnieper to the point where it receives the Sotz. This territory is now divided into the two governments of Polotsk and Mohilef: the population amounts to

POLAND.

pendent kingdom, contains several navigable rivers, flowing in all directions, and conveying its exports to the havens of the Baltic. By means of the Vistula and its tributary rivers, the productions of the palatinates of Cracow, Lublin, and Masovia, are sent to Thorn and Dantzick. By the Niemen, the commodities of Lithuania are transported to Memmel, and by the Duna those of Eastern Lithuania and White Russia to Riga. The chief exports are all species of grain, hemp, flax, cattle, malts, planks, timber for ship-building, pitch and tar, honey, wax, tallow, potash, and leather: the imports are foreign wines, cloths, stuffs, manufactured silks and cotton, fine linen, hardware, tin, copper, silver and gold, glass ware, and furs. From the various productions and great fertility of the soil, the trade might have been carried to a considerable height; but many causes tended to suppress the spirit of commerce. The nobles were degraded if they engaged in traffic. The burghers of the large towns were not sufficiently rich to establish manufactories, and either through want of industry, or dread of excessive extortions from the principal nobility, left the retail trade in the hands of foreigners and Jews. The inhabitants of the small towns, exposed to greater oppressions, were still more disqualified from pursuing any branch of commerce. The peasants being slaves, and the property of their master, could not remove from the place of their nativity without his consent. As the Poles drew from foreign countries the greater part of the manufactured goods necessary for home consumption, the specie which it exported exceeded the imported more than 20,000,000 Polish florins, or 555,555*l*. Poland was formerly called the granary of the North; but through neglect of cultivation, it lost this character; the exportation of corn not corresponding to the nature of the soil, or the extent of its provinces, which, properly improved, would have been capable of supplying half Europe with grain. The inattention of the Poles to the natural advantages of their country, has been exemplified in the following instance, as well as many others. By means of the Notez, a river of Great Poland, which falls into the Oder, the Poles might have conveyed grain into Silesia, and down the Oder into other parts of Germany; but they never attempted the navigation from an ill-founded notion of its impracticability. But the king of Prussia had no sooner acquired possession of the country watered by the Notez, but it was instantly covered with vessels.

The king had a corps of near 1000 troops in his own pay, consisting chiefly of Ulans, or light horse, who furnished his escort. These Ulans are chiefly Tartars, many of them Mahometans, and distinguished for their fidelity. The armies of Poland and Lithuania were independent of each other, and separately commanded by the respective great generals. In 1778, that of Poland consisted of 11,438 effective men; and that of Lithuania of 6987; making a total of 18,425. In 1790, when the Poles were preparing to establish a new constitution, and to render themselves independent of foreign powers, their army is stated by count Mofynski to have consisted of 65,074 men.

The Poles appear, by the description of Mr. Coxe, to have been a lively people, and to have used much action in their conversation. In salutation they commonly incline the head, and strike the breast with one hand, while they stretch the other towards the ground; but when a common person meets a superior, he bows his head almost to the earth, at the same time waving his hand, with which he touches the leg, near the heel, of the person to whom he pays his obeisance. The men of all ranks generally wear whiskers, and shave their heads, leaving only a circle of hair upon the

crown. The summer dress of the peasants consists of a shirt and drawers of coarse linen, without shoes or stockings, and round caps or hats. The women of the lower class wear upon their heads a wrapper of white linen, under which their hair is braided, and hangs down to the middle. The dress of the higher orders, both of men and women, is extremely elegant; that of the gentlemen being a waistcoat without sleeves, with an upper robe of a different colour, which reaches below the knee, and is fastened round the waist with a sash or girdle: the sleeves are in warm weather tied behind the shoulders: in summer the robe is of silk; in winter, of cloth, velvet, or stuff, edged with fur; a sabre is a necessary appendage of the dress as a mark of nobility. They wear fur-caps or bonnets, and buskins of yellow leather, the heels of which are plated with iron or steel. The dress of the ladies is a simple polonaise, or long robe, edged with fur. The Poles in their features, aspect, customs, dress, and general appearance, resemble Asiatics rather than Europeans, and are unquestionably descended from Tartar ancestors. Mascow, a German historian, well versed in the antiquity of nations, observes, that the manner in which the Poles wear their hair is a striking token of their origin. As early as the fifth century, some nations, comprehended under the name of Scythians, had the same customs.

The earliest coin of Poland is that of Boleslaus I. son of Micislaus, already mentioned: it was struck in 999, probably soon after the introduction of coining into Poland: it bears no head of the sovereign, but the Polish eagle on one side, and a crown on the reverse. Poland had formerly three universities, one at Cracow, another at Wilna, and a third at Posen. The Polish language is derived from the old Slavonic; but it very much differs from all the other languages having the same source. The German and also the Latin languages are much used in Poland. The religion formerly professed in Poland was the Roman Catholic; a decree of the Pacification diet, held in the year 1736, enjoining that no person should be elected king of Poland, or great duke of Lithuania, without first making a solemn profession of the Roman Catholic religion. The Dissidents are composed of Lutherans, Calvinists, and Greeks. (See DISSIDENTS.) The Jews were indulged with great privileges, and were so numerous, that Poland was styled the paradise of the Jews. Their number is supposed to have amounted to two millions. The mode of punishment for atrocious crimes was beheading or hanging; lesser delinquencies were punished by whipping, hard labour, and imprisonment; the nobles never suffered any corporal punishment, but were liable only to imprisonment and death. Torture was abolished in 1776, by an edict of the diet, introduced by the influence of the king; a regulation which evinces his judgment no less than his benevolence. For other particulars, which it is now unnecessary to detail, we refer to Coxe's Travels in Poland, &c., vol. i.

The Poles have a national melody peculiar to their own country in music. What is called a *Polonese*, or *Polacca*, in the rest of Europe, is always in triple time, and resembles our hornpipe in that measure, except that the close is made on the second note of the bar instead of the first. All the national music of Poland that we have seen is in this measure, but played faster for dancing than singing.

During the time that the electors of Saxony were kings of Poland, those splendid princes introduced a good Italian and German taste at Warsaw, and had operas performed there in great perfection.

POLAND, a town of America, in the county of Cumberland, and province of Maine; 30 miles N. of Portland.

The

The northern part of the town is now *Minot*. It has 2870 inhabitants.—Also, a town of the duchy of Carniola; 6 miles S.S.E. of Gottschee.

POLANGEN, or **POLENGEN**, a small town, or rather village, of Poland, in the country to which it gives name, situated near the sea-shore, famous for the amber collected near it, and which constitutes an article of commerce.

POLANIECZ, a town of Poland, in the palatinate of Sandomirz; 28 miles S.W. of Sandomirz.

POLAR, something that relates to the poles of the world. In this sense we say, polar virtue, polar tendency, &c. See **POLARITY**.

POLAR, or *White Bear*, in *Zoology*, a species of bear, *URSUS Maritimus*, (which see,) with a long head and neck, short round ears, end of the nose black, large teeth, hair long, soft, white, and tinged in some parts with yellow, and limbs of great size and strength. This animal, which grows to a great size, so that the skins of some are thirteen feet long, is confined to the coldest part of the globe; being unknown, except on the shores of Hudson's Bay, Greenland, and Spitzbergen. In summer the white bears make their residence on islands of ice; they swim with great agility for six or seven leagues, and are excellent divers. Their winter retreats are in dens under the snow or the fixed ice of the frozen sea. Their food is fish, seals, and the carcases of whales, and human bodies, which they will greedily devour; and they are so fond of human blood, that they will attack companies of armed men, and even board small vessels. On land they live on birds and their eggs. They bring two young at a time, and their mutual attachment is so strong, that they would die sooner than desert one another. Their greatest enemy is the morse. The flesh is white, and said to taste like mutton; the fat is melted for train oil, and that of the feet used in medicine: but the liver is very unwholesome. Pennant.

POLAR Circles. See **Polar CIRCLES**.

POLAR Dials, are those whose planes are parallel to some great circle passing through the poles, or to some one of the hour-circles; so that the pole is neither elevated above, nor depressed below the plane.

Such a dial, therefore, can have no centre, and consequently its style, sub-style, and hour-lines, are parallel.

This, therefore, will be an horizontal dial to those who live under the equator or line.

POLAR Dial, *To construct a*. See **DIAL**.

POLAR Projection, is a representation of the earth, or heavens, projected on the plane of one of the polar circles. See **PROJECTION**.

POLAR Star, or *Black Ribband*, *Order of the*, an order of knighthood in Sweden, was instituted by Frederic I. in 1748, and with regard to the election of knights, is subject to the same regulations as the orders of the *Seraphim* and the *Sword*—which see. This order consists of 48 knights, exclusive of foreigners, and six for the clergy, and 24 commanders, exclusive of four for the clergy, besides the senators of the realm, and knights of the *Seraphim*, who are also commanders of this order. Princes of the blood royal of Sweden are born knights, and may receive the ensigns of the order, whenever the sovereign of the order thinks proper. The commanders wear broad black ribbands round their necks, with the ensign of the order, or great cross, pendent from them. The knights wear a smaller ensign of the order, pendent to a black ribband at their button-hole. The collar of the order is of gold, composed of chased ornaments, linked together with chains, encompassing mullets of five points, enamelled white, edged with gold, and two letters F, back to back, enamelled blue, edged

with gold, alternately the letters crowned with the regal crown of Sweden, richly chased; to the centre hangs a star of gold, of eight points, enamelled white, edged with gold; on the centre a circle enamelled blue; thereon a star of five points, enamelled white, encircled with the following motto: *NESCIT OCCASUM*; in gold, between the angles, four ducal crowns; between the two upper points of the star a regal crown of Sweden, by which it hangs to the collar. This order, before the institution of that of *Vasa*, was conferred on men of letters.

POLARITY, the quality of a thing considered as having poles.

By heating an iron bar, and letting it cool in a vertical posture, it acquires a polarity. The lower end becomes the north pole, the upper the south.

Iron bars acquire a polarity, by being kept a long time in an erect posture, even without heating. Thus the bars of windows, &c. are frequently found to have poles. Nay a rod of iron acquires a polarity, by the mere holding it erect; the lower end, in that case, attracting the south end of a magnetic needle, and the upper, the north end. But these poles are mutable, and shift with the situation of the rod. See **MAGNET**.

Some modern writers, particularly Dr. Higgins, in his *Philosophical Essay concerning Light*, have maintained the polarity of the parts of matter, or that their simple attractions are more forcible in one direction, or axis of each atom, than in any other.

POLAROM, in *Geography*, a town of Hindoostan, in the circar of Rajamundry; 18 miles N.N.W. of Rajamundry.

POLCENIGO, a town of Friuli, on the borders of the *Trevifan*; 23 miles N. of *Trevigio*.

POLCH, a town of France, in the department of the Rhine and Moselle, and chief place of a canton, in the district of Coblenz. The place contains 1200, and the canton 4255 inhabitants, in 15 communes.

POLDER, a town of Africa, on the Gold Coast, in the canton of Agouna.

POLE, **REGINALD**, in *Biography*, cardinal, distinguished as a statesman, was born in the year 1500. He was distantly related to Henry VII. and Edward IV. Having laid the foundation of a good grammatical education under the Carthusians of the monastery at Sheen, he was removed to Magdalen college, Oxford. At a proper time he entered into deacon's orders, and at an early age had several benefices conferred upon him, through the favour of Henry VIII. In 1519 he quitted Oxford, and going to Italy, he took up his abode at Padua, then in very high reputation for polite literature. Here he contracted an intimacy with Bembo, and other distinguished characters. His progress in learning was proportionate to the opportunities that he enjoyed. He returned to England in 1525, and was received at court in such a manner, as might have led him to form the highest expectations with regard to preferment. For the present he chose to pass his life in retirement, after which he went to Paris, on the pretext of pursuing his studies; but the real cause was, that he might not be involved in those disputes which he foresaw would result from the king's pretended scruples concerning his union with Catharine of Arragon, his brother's widow. After he had passed some time at Paris, he received a requisition to concur with the king's agents in procuring the decision of the university of Paris in favour of the illegitimacy of his marriage, and the propriety of a divorce. As this opinion was contrary to the sentiments of Pole, he endeavoured to extricate himself by pleading his unsuitness for such a business; but he could not thereby escape the

the displeasure of the king. Upon his return he retired to Sheen, where he spent two years more free from molestation. Henry was now outrageous at the delays respecting the divorce, and throwing himself upon the support of his own people, it became an important step to gain over a person of Pole's rank and reputation. The king demanded an interview, but he was unable to shake his resolution, and though he was dismissed with tokens of regard, he thought it prudent to withdraw to the continent. He lived successively at Avignon, Padua, and Venice, cultivating friendships with the most eminent characters for learning and piety. In the mean time Henry had proceeded to extremities in his favourite plans. He had divorced Catharine, married Anne Boleyn, and revenged himself of the Roman see, by declaring himself head of the English church. He procured a book to be written in defence of this title, by Dr. Sampson, bishop of Chichester, which he caused to be transmitted to Pole, hoping, perhaps, that he might be convinced by the arguments made use of by the prelate. So far from this, Pole drew up a treatise, "De Unitate Ecclesiastica," in which he treated Sampson and the king with great harshness, and perhaps indecency. Henry dissembled his anger, and invited him to England, but Pole was much too wary to put himself in his power. The king, thus foiled in his plans, kept no measures with him, but withdrew his pension, alienated his preferments, and caused a bill of attainder to be passed against him. In the mean time pope Paul III. raised him to the cardinalate, and sent him as his nuncio to France and Flanders. He was afterwards employed by the pope in negotiating a peace between the emperor and the king of France, and endeavouring to engage them in a religious war against England. Upon the failure of these designs, he was sent a legate to Viterbo, where he remained till 1543. In that year he was appointed one of the three papal legates to the council of Trent; and when it was actually assembled, he attended upon its deliberations as long as his health would permit. In this council he zealously maintained the doctrine of justification by faith, which was so prominent a feature in the opinions of the reformers, that on this and other accounts he incurred some suspicion of being too favourable to Protestantism, but he had given such decided proofs of his attachment to the papal see, as would not suffer his faith to be doubted. He was therefore confidentially employed in the political affairs of the Roman court during the life of Paul, and at that pontiff's death, in 1549, he was seriously thought of as his successor. He was indeed twice nominated, and at the second time actually waited upon late at night by the cardinals to perform the ceremony of adoration. But some scruples which he manifested on account of the lateness of the hour obliged them to return, and before the morning the cardinals changed their minds, and thus he missed the papal crown, which probably was not very much the object of his desire. After this, for some time, cardinal Pole spent his time in retirement at a monastery of Benedictines, till the death of Edward VI. This event, and the still more important one of the accession of Mary, excited the warmest hopes of the restoration of the Romish religion in England, and cardinal Pole was looked up to as most likely to have effect in producing this change. Mary invited the cardinal to return to England, and he was invested by the pope with the office of legate to the holy see, but the jealousy of the emperor caused obstacles to be thrown in his way, so that he should not arrive till after the marriage of Philip with the queen; Pole himself, who, though a cardinal, was only in deacon's orders, having been thought of for a husband to Mary.

Previously to his arrival, an act of parliament was passed

to reverse the attainder laid upon him by Henry VIII., and in November 1554 he landed at Dover, and was brought to London, where he appeared in his legatine capacity. The cardinal was naturally humane, and became an advocate for lenient measures, in endeavouring to extirpate heresy, in opposition to the infuriate zeal and cruelty of Gardiner. His plans were overruled, and it is certain he afterwards acquiesced in many of the worst acts of this most bloody reign. He was satisfied of the right and obligation of the church to make use of fire and sword to extirpate heresy, and he himself was actually invested with the spoils of the martyred Cranmer. In 1556, having been first ordained priest, he was consecrated archbishop of Canterbury. In the same year he was elected chancellor of the universities of Oxford and Cambridge, both of which he visited by his commissioners, and purged from all stains of heresy. He made some statutes for these seminaries of learning, which greatly increased their reputation. He manfully opposed, though without effect, the queen's design of involving the nation in a war with France, in order to oblige her husband. He was now deprived by the pope of his legatine power, which probably very much affected his spirits, and the death of the queen, that almost immediately afterwards followed this event, with the prospect not only of impending ruin to the Catholic cause, but likewise of retaliation to its zealous adherents, so much affected the cardinal, that either through anxiety or terror, he died a few hours after her majesty, at the age of 58. His body lay forty days in state at Lambeth, after which it was carried in great funeral pomp to Canterbury, and interred on the north side of Thomas à Becket's chapel. Over his grave was erected a tomb, with the following short inscription, *Depositum Cardinalis Poli*. He was, says his biographer, a learned, eloquent, modest, and humble man, of exemplary piety and charity, as well as a generosity becoming his birth. Though by nature he was more inclined to study and contemplation than to active life, yet he was prudent and ready at business, so that he would have been a finished character, had not his superstitious devotion to the see of Rome carried him, against his nature, to commit several cruelties in persecuting the Protestants. After all, he does not appear to have been a man of commanding talents or decision of character, and his reputation has been considerably indebted to his noble birth and rank. His works, which are theological and controversial, are enumerated and described in a note in the article in the *Biographia Britannica*, to which our readers are referred.

POLE, *Polus*, Πόλος; formed from *πολεω*, to turn, in *Astronomy*, one of the extremities of the axis, on which the sphere revolves.

These two points, each 90 degrees distant from the equator, are called, by way of eminence, *the poles of the world*.

Wolfius defines the poles, those points on the surface of the sphere, through which the axis passes; of which that visible to us, or raised above our horizon, is called the *arctic* or *north* pole; and its opposite, the *antarctic* or *south* pole.

POLE, in *Geography*, is the extremity of the earth's axis, or one of the points on the surface of our globe, through which the axis passes. See EARTH.

Such are the points P, Q, (*Plate I. Geography, fig. 9.*) of which that elevated above our horizon is called the *arctic* or *north* pole; and its opposite, Q, the *antarctic* or *south* pole.

Dr. Halley shews, that the solstitial day, under the pole, is as hot as under the equinoctial, when the sun is in the zenith; in regard, all the twenty-four hours of that day

under the pole, the sun-beams are inclined to the horizon in an angle of $23\frac{1}{2}$ degrees; whereas, under the equinoctial, though the sun becomes vertical, yet he shines no more than twelve hours, and is absent twelve hours. Besides, that, for three hours eight minutes of the twelve hours during which he is above the horizon there, he is not so much elevated as under the pole. See HEAT, in *Geography*.

The altitude or elevation of the pole is an arc of the meridian intercepted between the pole and the horizon. To find this elevation is a very popular problem in astronomy, geography, and navigation; this and the latitude of the place being always the same. See ELEVATION of the Pole.

POLE, to observe the Altitude of the. With a quadrant observe both the greatest and least meridian altitude of the pole-star.

Subtract the least from the greatest, and divide the difference by two; the quotient is the star's distance from the pole; which, added to the lesser altitude found, gives the elevation of the pole required. See LATITUDE.

Thus M. Couplet, the younger, at Lisbon, in 1697, in the end of September, observed the greatest meridian altitude $41^{\circ} 5' 40''$; the smallest $36^{\circ} 28' 0''$, the difference of which is $4^{\circ} 37' 40''$; one half of which, $2^{\circ} 18' 50''$, added to the less, gives $38^{\circ} 46' 50''$, the altitude of the pole of Lisbon.

The altitude of the pole, together with the meridian line, being the basis of all astronomical observations; to determine it with the greatest accuracy, the meridian altitude must be corrected from the doctrine of refractions, hereafter to be delivered.

By means hereof, M. Couplet, subtracting $1' 25''$ in the proposed example, leaves the corrected altitude $38^{\circ} 45' 25''$.

Hence, 1. The altitude of the pole being subtracted from 90° , leaves the altitude of the equator.

2. If the greatest meridian altitude of this star exceed the altitude of the equator, the latter, subtracted from the former, leaves the declination of the star northward; if the altitude of the star be less than that of the equator, the former, subtracted from the latter, leaves the star's declination southward.

Dr. Hooke, and some others, imagined the height of the pole, and the position of the circles in the heavens, in respect of those on the earth, to be changed from what they anciently were. But M. Cassini thinks there is no ground for such a surmise; but that all the difference we now find in the latitude of places, &c. in respect of the ancient accounts, arises from the inaccuracies of the ancient observations.

Indeed, it is no wonder they should err in their observations, considering what instruments they used. He adds, it is probable there may be some variations in the height of the pole; but, he thinks, this never exceeds two minutes; and that even this will vanish, after it is arrived to its highest difference.

POLE, in *Spherics*, is a point equally distant from every part of the circumference of a greater circle of the sphere; as the centre is in a plain figure. See SPHERE.

Or, pole is a point 90° distant from the plane of a circle, and, in a line passing perpendicularly through the centre, called the axis.

The zenith and nadir are the poles of the horizon. The poles of the equator are the same with those of the sphere or globe.

POLES of the ecliptic are two points on the surface of the sphere, $23^{\circ} 30'$ distant from the poles of the world,

and 90° distant from every part of the ecliptic. For the true distance of the poles, or measure of the obliquity of the ecliptic; see ECLIPTIC.

POLES, in *Magnetics*, are two points in a loadstone, corresponding to the poles of the world; the one pointing to the north, the other to the south.

If the stone be broken in ever so many pieces, each fragment will have its two poles. If a magnet be bisected by a line perpendicular to the axis, the two points, before joined, will become opposite poles, one in each segment.

To touch a needle, &c. that part intended for the north end is touched with the south pole of the magnet, and that intended for the south end with the north pole.

A piece of iron acquires a polarity, by only holding it upright; but its poles are not fixed, but shift, and are inverted as the iron is. A fixed north pole may be made all the ways a fixed south pole is made; but not *vice versa*: and whatever way we get a fixed south pole, it is always weaker than a fixed north pole got the same way. Fire destroys all fixed poles; but it strengthens the mutable ones.

The end of a rod being heated, and left to cool northward, Dr. Gilbert says, becomes a fixed north pole; if southward, a fixed south pole: yet this doth not hold in all cases. If the end be cooled, held downward, or to the nadir, it acquires somewhat more magnetism than if cooled horizontally towards the north; but the best way is to cool it a little inclined to the north. Repeated ignitions do not avail to this purpose any more than a single one.

Dr. Power says, that if we hold a rod northwards, and hammer the north end in that position, it will become a fixed north pole; and contrarily, if you hammer the south end. What is said of hammering is to be likewise understood of filing, grinding, sawing; nay, a gentle rubbing, provided it be continued long, will produce poles. The more heavy the blows are, *ceteris paribus*, the magnetism will be the stronger. A few hard blows do as much as many.

Old drills and punches have all fixed north poles, because almost constantly used downwards. New drills have either mutable poles, or weak north poles. Drilling with such a one southward horizontally, it is a chance if you produce a fixed south pole, much less if you drill south downwards; but if you drill south upwards, you always make a fixed south pole.

A weak fixed pole may degenerate into a mutable one in a day, nay, in a few minutes, by holding it in a position contrary to its pole. The loadstone itself will not make a fixed pole in any iron. It is required the iron have a length, if it be thick.

Mr. Bailard tells us, that in six or seven drills made before his face, the bit of each became a north pole, merely by hardening. See MAGNET, and MAGNETISM.

POLES, under bare, in *Sea Language*, is the alarming situation of a ship in a storm, when, owing to the violence of the wind, no part of the sails can be set.

POLE of a Glass, in *Optics*, is the thickest part of a convex, or the thinnest of a concave glass.

If the glass be truly ground, the pole will be exactly in the middle of its surface.

This is sometimes also called the *vertex* of the glass.

POLE, in *Surveying*, is a measure containing sixteen feet and a half; called also perch, and sometimes rod. See PERCH.

A woodland pole is 18 feet, a forest or plantation pole is 21 feet, a Cheshire is 24 feet, and a rope is 20 feet.

POLE, in *Agriculture*, a small thick piece of wood, such as a straight bough or young tree. It is useful for various purposes of husbandry, as the making of stakes, hurdles, and

and various other purposes. Many different sorts of wood are used in this intention.

POLE-Axe, a sort of hatchet nearly resembling a battle-axe, used very dextrously by British sailors, having a helve or handle about two feet long, the blade whereof is formed like that of any other hatchet, being furnished with a sharp point or claw, bending downwards from the back of its head.

Some derive its appellation from its being much used in Poland, and say, that its true name is Polish-axe; some again deduce it from its supposed use, which was to strike at the head or poll; and others say it is called a pole-axe, from its being fixed on a long pole or handle. In later times, both battle-axes and pole-axes were more used for the state guards of princes and generals, than for the common purposes of war. The Welch "glaive" is a kind of bill, sometimes reckoned among the pole-axes. They were formerly much in use.

The use of the pole-axe is to cut away and destroy the rigging of the enemy, when endeavouring to board. Sometimes it is successfully used in boarding the enemy, when her sides are above those of the boarder. This is executed when endeavouring to enter at different parts of the ship's length, at which time the pole-axes are forcibly driven into her side, one above another, so as to form a sort of scaling-ladder.

POLE-Cat, *Mustela Putorius* of Linnæus, in *Zoology*, the name by which authors call a creature of the weasel kind, but larger than the common weasel, and remarkable for its stinking smell. It is also called *fitchet*. See *MUSTELA Putorius*.

A method of taking the pole-cat is to set box-traps in the bottom of ditches, or under walls or pales, with the ends of the traps fenced up, for four or five yards *aslant*, and two or three yards wide at the entrance, with earth, bushes, or broken pales, so that the vermin shall not pass without entering the traps. This is the method used by warreners. When the traps are so placed, a trail of rabbits' paunches should be drawn from one trap to another, and the baits are red herrings half broiled. Each end of the traps is to be rubbed with them, and a part of the herring is to be afterwards hung upon the nail over the bridges of the traps. This is a mode that will cause great destruction amongst them. A thin bag, sufficiently large to admit an end of the trap, is to be provided and slipped over it, when any of the traps are sprung, and by rattling at the other end of the trap, the creature will spring into the bag; for without this precaution, if it be a wild cat, the moment the light is admitted, it will fly in the face of the person opening it. By having both ends of the box-traps painted white, and rubbed over with the entrails of any animal, the hares will be deterred from entering, at the same time it will allure the vermin to go into the traps.

POLE-Cat, *American*, or striated weasel of Pennant, the conepate of Buffon, called *skunk*, is the *Viverra putorius* of Linnæus, with rounded ears; head, neck, belly, legs, and tail, black; the back and sides marked with five parallel white lines; one on the top of the back, the others on each side; the second extends some way up the tail, which is long and bushy toward the end. This animal, which is about the size of the European pole-cat, inhabits North America; when attacked, it bristles up its hair, and flings its body into a round form: its vapour is horrid. Pennant. See *VIVERRA Putorius*.

POLE, *Hop*, in *Agriculture*, a sort of pole much used in the cultivation of hops, for supporting the bine. The poles of ash, oak, willow, poplar, chestnut, and various other

sorts of wood, are employed in this way. The ash, oak, and chestnut, are probably the most valuable. In this intention, they are usually prepared by having the bark removed, and being sharpened at the thick end. Great care should be taken of them after they are separated from the bine, by having them properly stacked up in some dry situation. The prices of poles of this sort have lately increased in a high degree.

POLE-Masts, in *Ship Building*, are those made of single trees, in contradistinction to those made of several trees joined together, called "made-masts."

POLE-Star, or *Polar-Star*, is a star of the second magnitude, the last in the tail of *Urfa Minor*, or the *Little Bear*.

The nearness of this star to the pole, whence it happens that it never sets, renders it of great service in navigation, &c. for determining the meridian line, the elevation of the pole, and consequently the latitude of the place, &c.

Mr. Pond, the present astronomer royal, has published a table of the north polar distances of 44 of the principal fixed stars; which table he conceives to be much more accurate than any that has hitherto been offered to astronomers. The maximum of error he thinks seldom exceeds half a second, and only in four cases amounts to one second; *e. gr.* the polar star in summer is $1^{\circ} 41' 22''.07$, and in winter $1^{\circ} 41' 21''.47$ from the north pole of the heavens.

POLE of a Wheel-Carriage. See *PERCH*.

POLEDNISKOI STANITZ, in *Geography*, a town of Russia, in the government of Irkutsk, on the Lena; 12 miles N.E. of Vitimskoi.

POLEGIO, or *POLESE*, a town of Switzerland, in the bailiwick of Riviera; six miles N.N.W. of Bellinzona.

POLEIN, in our *Ancient Customs*, a sort of shoe, sharp or picked at the point.

This fashion was first taken up in the time of king William Rufus; the picks being made so long, that they were tied up to the knees, with silver or golden chains.

They were forbidden by stat. an. 4 Edw. IV. cap. 7. "Tunc fluxus crinium, tunc luxus vestium, tunc usus calceorum cum arcuatis aculeis inventus est." Malmsh. in Will. II.

POLEMARCHUS, *Πολεμαρχος*, among the Athenians, a magistrate who had all the strangers and sojourners in Athens under his care, over whom he had the same authority that the archon had over the citizens.

It was the duty of the polemarchus to offer a solemn sacrifice to Enyalus, said by some to be the same with Mars, but by others to have been only one of his attendants; and another to Diana, surnamed *Αγροτις*, in honour of the famous patriot Harmodius. It was also the business of the polemarchus to take care that the children of those who had lost their lives in their country's service, should have a competent maintenance out of the public treasury. Potter.

POLEMICAL, *Πολημικοι*; from *πολεμος*, *war*, *battle*, an epithet applied to books of controversy, especially those in divinity. Hence also we say, polemical divinity, for controversial, &c.

POLEMO, in *Biography*, an eminent Platonic philosopher, and the third director of the academy, after the death of its founder, was descended from a good family, but in his youth he led a very dissipated life, from which he was suddenly reclaimed in the following extraordinary manner; returning from his revels, one morning, soon after sunrise, in a loose dress, crowned with garlands, and intoxicated with wine, as he passed by the school of Xenocrates, he saw him surrounded by his disciples. He rushed into the school without ceremony, and took a place among the young philo-

philosophers. Astonished at this rude Behaviour, all the assembly shewed signs of resentment, excepting Xenocrates, who went on discoursing to his audience. With the greatest presence of mind, he changed the subject on which he was treating, to those of temperance and modesty, which he recommended with such force of argument, and persuasive eloquence, as flashed instant conviction in Polemo's mind. He felt the folly and criminality of his own conduct, and ashamed of the figure in which he appeared, he took the garlands from his head, drew his cloak about him, and assumed a sedate and thoughtful aspect, and from that moment resolved to renounce his licentious pleasures, and devote himself to the study of philosophy. After this he practised the severest austerities and the most hardy fortitude. From the 30th year of his age to his death he drank only water; upon every occasion he preserved a steady and unmoved gravity of countenance; and that he might, at the same time, keep his mind undisturbed by passion, he accustomed himself to speak in an uniform tone of voice, without elevation or depression. He was, however, possessed of a gentle, obliging, and generous temper, and such was the progress which he made in his philosophical studies, that he surpassed all his fellow disciples in the school of Xenocrates, and on the death of that philosopher, succeeded him in the chair of the academy, about the year 313 B.C. He took great delight in solitude, and passed much of his time in a garden near the school. He died of a consumption, at an advanced age, about the year 270 B.C., highly respected for his great integrity by the Athenians. He was, in his sentiments, a strict adherent to the doctrines of Plato. See PLATONISM. Enfield Hist. Phil.

POLEMONIA, in *Botany*, the eleventh order of Jussieu's eighth class, thus named from one of the best known genera it contains. For the characters of that class, see GENTIANÆ. The order is thus defined.

Calyx divided. *Corolla* regular, five-lobed. *Stamens* five, inserted into the middle of the tube. *Style* one. *Stigma* three-fold. *Capsule* surrounded by the permanent calyx, of three cells and three valves, with many seeds; the partitions from the middle of each valve, meeting the edges of a triangular central receptacle. *Stem* either herbaceous or shrubby. *Leaves* alternate or opposite. *Flowers* terminal or axillary.

The genera in Jussieu are *Phlox*, *Polemonium*, *Cantua* and *Hoitzia*; to which is to be added *Ipomopsis* of Michaux; see that article.

POLEMONIUM, an ancient name, derived from πολέμος, war, because, according to Pliny, book 25, chap. 6, kings had contended for the honour of its discovery. Another of its names, *Philetaria*, has a similar meaning. The inhabitants of Cappadocia, in allusion to its "thousand virtues," called the plant *Chiliodynamia*. Happy should we be to ascertain this inestimable herb! Pliny says, "the root is thick, with slender branches, or twigs, from whose summits hang bunches of black seed. In other respects it resembles rue, and grows on hilly ground." We must be content to describe the *Polemonium* of modern botanists, which answers but very slightly to the account of Pliny, and certainly has no virtues to entitle it to distinguished notice.—Linn. Gen. 87. Schreb. 117. Willd. Sp. Pl. v. 1. 886. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 234. Ait. Hort. Kew. v. 1. 342. Pursh v. 1. 124. Juss. 136. Tourn. t. 61. Lamarck Illustr. t. 106. Gært. t. 62.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Campanacæ*, Linn. *Polemonia*, Juss.

Gen. Ch. *Cal.* Perianth inferior, cup-shaped, of one leaf, divided half way down into five acute segments, permanent. *Cor.* of one petal, wheel-shaped; tube shorter than the

calyx, closed by five valves situated in its upper part; limb five-cleft, ample, nearly flat, the segments roundish and obtuse. *Stam.* Filaments five, inserted into the valves of the tube, thread-shaped, inclining, shorter than the corolla; anthers roundish, incumbent. *Pist.* Germen superior, ovate, acute; style thread-shaped, the length of the corolla; stigma in three revolute segments. *Peric.* Capsule ovate, with three obsolete angles, three cells, three valves, bursting at the top, invested with the calyx; partitions contrary to the valves. *Seeds* numerous, irregular, sharpish.

Ess. Ch. Corolla in five deep segments. Stamens inserted into five valves closing the bottom of the corolla. Stigma three-cleft. Capsule superior, of three cells.

1. *P. cæruleum*. Common Greek Valerian, or Jacob's Ladder. Linn. Sp. Pl. 230. Engl. Bot. t. 14. Fl. Dan. t. 255. (*Valeriana græca*; Ger. Em. 1076.)—Leaves pinnate, with numerous leaflets. Flowers erect.—Native of woods, in the mountainous parts of Europe, and the north of Asia. It is perennial, flowering in June, and forms the frequent decoration of many a country garden. The English name, like the Latin or Greek one, is founded in confusion and error, for the plant is not known in Greece, nor has it any thing in common with Valerian, except the pinnated leaves. The root is fibrous. Herb smooth, two feet high, paniced and leafy, not branched. Flowers numerous, terminal, of a delicate purplish blue, often varying to white, each about an inch wide. Gmelin, in his Fl. Sibirica, v. 4. t. 50, has figured a downy variety.

2. *P. reptans*. Creeping Greek Valerian. Linn. Sp. Pl. 230. Willd. n. 2. Ait. n. 2. Pursh v. 1. 151. (*Polemonium*; Mill. Ic. v. 2. t. 209.)—Leaves pinnate, with about seven leaflets. Flowers drooping. Root creeping. Native of North America, from Pennsylvania to Carolina, on the sides of rich hills, flowering in April and May. Miller cultivated this species, and it is preserved, for variety's sake, in curious gardens, but it yields to the former in beauty. The chief difference consists in the creeping root, more lax and spreading habit, fewer leaflets, and drooping flowers. The colour of the corolla, naturally a light blue, often varies to white.

These two are the only certain species. *P. dubium*, Linn. Sp. Pl. 231, is *Phacelia parviflora*, Pursh v. 1. 140; a small annual plant, found on rocks in Virginia; see PHACELIA. *P. Nyctelea*, Linn. Sp. Pl. 231, is ELLISIA; see that article. *P. roelloides* and *campanuloides*, Linn. Suppl. 139, are two Cape plants, imperfectly known to us, which have no appearance of belonging to *Polemonium*, but rather to *Campanula*, or some of its allies.

POLEMONIUM, in *Gardening*, contains plants of the fibrous-rooted, herbaceous, flowering, perennial kind, of which the species cultivated are, the common polemonium (*P. cæruleum*); and the creeping polemonium, or Greek valerian (*P. reptans*).

There are varieties of the first sort with white flowers, with variegated flowers, and with variegated leaves.

Method of Culture.—These plants may be increased by seeds, and parting the roots in both the sorts.

The seeds should be sown in the spring, upon a bed of light earth, and when the plants are pretty strong, they should be pricked out into another bed of the same earth, four or five inches asunder, shading and watering them until they have taken new root; keeping them clear from weeds until the beginning of autumn, and then transplanting them into the borders of the pleasure-ground. The plants are not of long duration; but by taking them up in autumn, and parting their roots, they may be continued some years; but

but the seedling plants flower stronger than those from offsets.

The varieties can only be continued by parting the roots at the above season. They should have a fresh light soil, which is not too rich, as the roots will be apt to rot in winter, and the stripes on the leaves to go off.

The second sort may be increased by feeds or offsets in the same manner, and is equally hardy, but much less beautiful.

They afford ornament among flowery plants in the borders and other parts.

POLEMOSCOPE, in *Optics*, an oblique kind of perspective glass, contrived for the seeing of objects that do not lie directly before the eye.

It was invented by Hevelius in 1637, who gave it this name, from the Greek *πολεμος*, *battle*; because it may be of use in war, in engagements, duels, &c. for discovering what the enemy is doing, whilst the spectator lies hid behind any obstacle.

Of this kind, are those now known among us under the name of ogling-glasses, or opera-glasses, through which one sees a person, in appearing to look at another.

POLEMOSCOPE, *Construction of the*. Any telescope will be a polemoscope, if the tube be but crooked, like a rectangular siphon A B D M (*Plate XVII. Optics, fig. 12.*), and between the object-glass A B, and the first eye-glass G H, (if there be several,) be placed a plain mirror, in such manner as that the mirror is inclined to the horizon at an angle of 45°, and its reflected image found in the focus of the eye-glass G H.

For, by this means, objects, situated over-against the lens A B, will appear the same as if the mirror K were away, and the object glass, with the objects, were directly opposite to the eye-glasses.

If it be desired to look in an O, not at M, another plain mirror, N, must be added.

POLENI, JOHN, marquis, in *Biography*, a learned mathematician, who flourished in the 18th century, was born at Padua in the year 1683. He was appointed professor of astronomy and mathematics in the university of his native city, and filled that post with high reputation. In three instances he gained prizes from the Royal Academy of Sciences, and in 1739 he was elected an associate of that body. He was also a member of the academy of Berlin, a fellow of the London Royal Society, and a member of the Institutes of Padua and Bologna. As he was celebrated for his skill and deep knowledge of hydraulic architecture, he was nominated by the Venetian government, superintendant of the rivers and waters throughout the republic; other states also applied to him for advice, in business belonging to the same science. He had paid particular attention to the study of civil architecture. During the pontificate of Benedict XIV., he was sent for to survey the state, of which fears were entertained, of St. Peter's church at Rome. After a minute examination, he drew up a memoir on the damages which the church had sustained, and the repairs proper to be undertaken. He died at Padua in 1761, at the age of 78. He was distinguished by a lively penetrating genius, profound scientific knowledge, and an excellent memory. He held a correspondence with the most distinguished mathematicians of the age, *viz.* with sir Isaac Newton, Leibnitz, the Bernouillis, Wolff, Cassini, Gravefande, Muschenbroeck, Fontenelle, and others. The marquis did not, however, confine his studies to the mathematical sciences properly so called: he was a zealous, intelligent, and industrious antiquary; and the learned world is indebted to him for a valuable supplement to the grand col-

lections of Grævius and Gronovius, in this department, consisting of five vols. folio.

POLENKA, in *Geography*, a town of Lithuania, in the palatinate of Novogrodek; 35 miles S. of Novogrodek.

POLESCHOWITZ, a town of Moravia, in the circle of Hradisch; six miles S.W. of Hradisch.

POLESIA, a name given to the palatinate of Brsefskie, or Brzesk; which see.

POLESINO de Rovigo, a province of Italy, situated between the Ferrarese and Paduan, 42 miles long and 12 broad, encompassed or intersected by the Po and Adige. The soil is generally rich and fertile, the marshy parts excepted, but the arable land is, in some places, lower than the bed of the Adige, which occasionally breaks through its dikes, and inundates the country, thus favouring the culture of rice. This district abounds in corn, maize, flax, hemp, fruit, and silk; and by means of its luxuriant pasture grounds, the breeding of black cattle, and of horses, is in a prosperous state. In the time of the Romans, this territory was thinly inhabited, and was known by the appellation of the "Adrian Marshes," or "Paludes Padusæ," from their extending to the district of Padua. After passing under the dominion of several masters, the Polesin of Rovigo was at length appropriated by the state of Venice, in consequence of the treaty of peace concluded in 1484. The part of the Polesin, situated on the right bank of the river, contains 3 towns, 1 borough, 55 villages, and about 9000 inhabitants. The chief place is Rovigo.

POLETA, in our *Ancient Law Books*, signifies the ball of the foot. "Tres ortilli scindantur de pede anteriori sine poleta." Matt. Par. anno 1215.

POLETÆ, *Πολεταί*, among the Athenians, ten magistrates, who, together with three that had the care of the money allowed for shows, had the power of letting out the tribute-money, and other public revenues, and selling confiscated estates; all which bargains were ratified in the name of their president. Besides this, it was their office to convict such as had not paid the tribute called *Μετρίκιον*, and sell them by auction. Potter.

POLETO, in *Geography*, a town of Italy, in the department of the Mincio; 12 miles E.S.E. of Mantua.

POLEY-GRASS, in the Linnæan system of *Botany*, is a species of lythrum.

POLEY-Mountain. See **TEUCRIUM**.

Several species and varieties of polium, erect and procumbent, with white, yellow, and purplish flowers, have been received in the shops. But the poley-mountain of Candy has been commonly understood as the officinal sort, which is procured dry from the island Candy; and the poley-mountain of Montpellier is allowed to be of the same quality. The leaves and tops have a moderately strong aromatic smell, and a disagreeable bitter taste; they are recommended as corroborants, aperients, and antispasmodics; but are at present scarcely otherwise made use of than as an ingredient in mithridate and theriaca. Lewis.

POLGHA, a name by which some authors have called the cocoa-nut tree, or palma Indica nucifera of other writers.

POLHEM, CHRISTOPHER, in *Biography*, a celebrated Swedish engineer, descended from an Hungarian family, was born at the town of Visby in 1661. By the death of his father he was left, at a very early age, without any other resource than what he might derive from his own talents. For some years he found employment as a clerk, or collector of rents, but having a strong turn for mechanics, he employed all his leisure time in studying the principles of that science. He also established a carpenter's, turner's, and

and smith's shop, and manufactured a number of curious and useful articles, as jacks, clocks, dials, &c. He took great pains to acquire a knowledge of the Latin language, and when he had made some progress in it he was admitted to the university of Upsal. After remaining there some time he proceeded to Stockholm, with the view of getting employment as a surveyor. He found himself unable to pass the examination necessary for the office, and returned to Upsal, where he renewed his studies with so much diligence, that he was shortly qualified to overcome every obstacle to his wishes. In 1690 he constructed for the royal college of mines, the model of an ingenious machine applicable to mining purposes, which afforded a striking proof of his extraordinary genius and talents. As a reward for this service, Charles XI. gave him a pension of 500 silver dollars *per annum*, and appointed him an engineer of the mines. In 1694 he set out on a foreign tour, for the purpose of improving himself in mechanical knowledge, and at Paris constructed a clock which indicated the Turkish, Jewish, Babylonian, and other hours, according to the mode of reckoning time adopted by the different nations of Europe. After this, he invented various machines, all of which were adapted to purposes of utility, and did great credit to his genius and talents. In 1707 he was invited by the elector of Hanover, afterwards George I., to visit that country, that he might improve the machinery in the mines of Hartz forest; he was urged to remain here, but his attachment to his native country induced him to decline the offer. In 1712, he began at Carlscrona the celebrated docks, hollowed out with immense labour in the solid rock, which are still the admiration of travellers, and about the same time he undertook the canal of Trollhetta, which formed part of a plan, long projected by the Swedes, of uniting the Baltic and German ocean by an inland navigation, not only to improve the interior trade, but to prevent that interruption to their foreign commerce which is always the consequence of a war with Denmark. In 1716 Polhem was ennobled, and in the same year was appointed a member of the council of commerce; for his patriotic views were directed also to the improvement of the Swedish manufactures, and every thing connected with that branch of industry. He was a great improver of the machinery used in the manufacture of iron, steel, copper, and brass; he carried the woollen trade to a high degree of perfection, and enriched every part of domestic economy with new and useful inventions. In early life he had to struggle with a great variety of obstacles, but in its later periods he met with the rewards due to his merit. In 1748, he was appointed a knight and commander of the order of the Polar star. He was one of the most distinguished members of the Royal Academy of Sciences at Stockholm, and contributed many valuable papers to its Transactions. Polhem died in 1751, in the ninetieth year of his age. The following works are referred to as containing an account of some of his machines. "A Short Description of the principal mechanical Inventions of C. Polhem, with cuts;" and "Swedenborg's Dædalus Hyperboreus." Gen. Biog. Coxe's Travels in Russia and Sweden.

POLI, in *Geography*, a town of Campagna di Roma; three miles N. of Palestrina.

POLIA, in *Botany*, *πολια*, hoary, in allusion to its white aspect, Lourei. Cochinch. 164, is our *Hagea indica*. See HAGEA.

POLIA *Lithargirus*, a term used by Dioscorides to express the white litharge, which we call litharge of silver.

The proper sense of the word *polia*, is hoary, or grey, and it very well expresses the colour of this substance; but the commentators have not been satisfied with this obvious

meaning, but have made it *pelia*, and some of them *scelia*. See LITHARGE.

POLIANTHES, in *Botany*, a name given by Linnæus, and therefore we must accept his own explanation of it, which is, "*πολις*, a town, and *ανθος*, a flower;" because this plant is so generally cultivated and sold in towns, for the sake of its elegance and fragrance. The French know the flower by the name of Tubereuse; the English call it Tuberose; both words taken from the Latin appellation which it first obtained, of *Hyacinthus tuberosus*. Some write *Polyanthes*, as Linnæus originally printed the generic name; and suppose the etymology to be from *πολυς*, many; but the abundance of flowers is not such as to countenance this explanation.—Linn. Gen. 169. Schreb. 225. Willd. Sp. Pl. v. 2. 164. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 2. 281. Juss. 56. Lamarck Illustr. t. 243.—Class and order, *Hexandria Monogynia*. Nat. Ord. *Coronarie*, Linn. *Narcissi*, Juss.

Gen. Ch. *Cal.* none. *Cor.* of one petal, inferior, funnel-shaped; tube oblong, incurved; limb in six ovate, spreading, equal segments. *Stam.* Filaments six, thick, obtuse, erect, at the top of the tube; anthers linear, longer than the filaments. *Pist.* Germen roundish, in the base of the tube; style thread-shaped, rather shorter than the corolla; stigma three-cleft, thickish, bearing honey. *Peric.* Capsule roundish, with three blunt angles, wrapped up in the lowest part of the corolla, of three cells and three valves. *Seeds* numerous, flat, semicircular, disposed in double rows.

Ess. Ch. Corolla funnel-shaped, incurved; its limb in six equal segments. Filaments inserted into the mouth of the tube, erect. Capsule invested with the base of the corolla.

1. *P. tuberosa*. Common Tuberose. Linn. Sp. Pl. 453. Willd. n. 1. Ait. n. 1. Redout. Liliac. t. 147. (*Hyacinthus indicus, tuberosa radice*; Clus. Hist. v. 1. 176. *H. indicus, tuberosus*; Ger. Em. 115. Rudb. Elyf. v. 2. 38. f. 3. 39. f. 4. *Amica nocturna*, or Sandal Malam; Rumph. Amboin. v. 5. 285. t. 98.)—The only known species, of which Rudbeck figures a larger and a smaller variety. It is usually supposed to be a native of the East Indies, but Redouté has lately advanced some reasons for believing it originally came from South America. Simon de Tovar communicated the Tuberose to Clusius, in 1594, as an "Indian plant;" which vague expression may as well refer to the West as the East Indies. The authors of the *Flora Peruviana* mention it as wild in Peru; while, on the other hand, Rumphius relates, that it was unknown in Amboina before the year 1674, having been carried thither from Batavia. It is very likely to have been transported from Holland to the latter settlement. Father Minuti is however recorded by Plumier, Nov. Gen. 35, as having brought this plant from the East Indies, to the south of France; but this was not less than fifty years after Clusius had obtained his. Its constitution is more like a Peruvian plant, than one of Ceylon or Java. In the south of France the roots increase and blossom freely, and the north of Europe has usually been supplied every year from that country, or from Italy and Portugal, with such as were fit for planting in pots, or for forcing; that being the only means of having good flowering plants in England, notwithstanding what has sometimes been related on the subject. The root is perennial, tuberous, somewhat creeping. *Stem* simple, erect, round, leafy, a yard or more in height. *Leaves* scattered, linear-lanceolate, taper-pointed, sheathing, smooth, pale, and rather glaucous. *Flowers* several, in a terminal, oblong, bracted spike. Their colour is white, sometimes tinged with a blush of pink; their odour rich

and delicious, most powerful at night, resembling the flavour of ginger, with great sweetness. The double-flowered variety is most esteemed.—Linnæus originally referred his *Crinum africanum*, now *Agapanthus umbellatus*, to this genus. Willdenow has a *Polianthes pygmæa*, which is our *Maffoni ensifolia*. See MASSONIA.

POLIANTHES, in *Gardening*, contains plants of the bulbous-tuberous rooted, herbaceous, flowering, perennial, exotic kind, of which the species cultivated is the tuberose, or Indian tuberous hyacinth (*P. tuberosa*).

There are varieties of this with a double flower, with striped leaves, and with a smaller flower. The last is frequent in the south of France, whence the roots have been often brought here early in the spring, before those roots have arrived from Italy, which are annually imported; the stalks of it are weaker, and do not rise so high, and the flowers are smaller than those of the common sort, but in other respects it is the same.

The Genoese are the people who cultivate this plant to furnish all the other countries where the roots cannot be propagated without great trouble and care, and thence the roots are annually sent to this and other countries. In most parts of Italy, Sicily, and Spain, the roots thrive and propagate without care where they are once planted.

It has been long cultivated in this country for the exceeding beauty and fragrantcy of its flowers.

Method of Culture.—These plants are chiefly increased by offsets from the roots.

The blowing roots that are annually brought from abroad, for sale, are mostly furnished with offsets, which should be separated previously to planting; those also raised here in the garden are frequently furnished with offsets, fit for separation in autumn, when the leaves decay. They should be preserved in sand during the winter, in a dry sheltered place; and in the beginning of the spring, as March, be planted out either in a bed of light dry earth in the full ground, or, to forward them as much as possible, in a moderate hot bed, sheltering them in cold weather either by a frame and lights or with mats on arched hoops, letting them enjoy the full air in mild weather, giving also plenty of water in dry seasons during the time of their growth in spring and summer.

They should remain in this situation till their leaves decay, in autumn; then they should be taken up, cleaned from earth, and laid in a box of dry sand, to preserve them till spring following, at which time such roots as are large enough to blow may be planted and managed as directed below, and the smaller roots planted again in a nursery-bed, to have another year's growth; afterwards planting them out for flowering.

The roots of these plants are mostly sold at the rate of about twelve or fifteen shillings *per* hundred, care being taken always to procure as large roots as possible, as on this depends the success of having a complete blow.

In order to blow them in a perfect manner, they require artificial heat in this climate, and should be planted in pots, and plunged in a hot-bed, under a deep frame, furnished with glass lights; or placed in a hot-house, where they may be blown to the greatest perfection, with the least trouble.

The principal season for planting them is as above; but in order to continue a long succession of the bloom it is proper to make two or three different plantings, at the interval of about a month.

Where dung hot-beds are employed, six inches depth of earth, or old tan, should be laid, in which to plunge the pots; but if bark or tan be used, no earth is necessary, as

the pots may be plunged immediately into the bark. Having the hot-beds ready, and the roots provided, and some proper sized pots, twenty-fours, one for each root, fill the pots with light rich earth; and after having divested the roots of all loose outer skins, and all offsets, plant one in each pot, in depth, so as the top of the root be about an inch below the surface of the earth, plunging all the pots in the hot-bed close together, or so that the bed may contain the number required; and as soon as they are all thus placed, put on the lights of the frame.

In the hot-house method, the pots of roots, as above, should be plunged to their rims in the bark-bed, or placed in the front part of the house; but the former is the better method.

They afterwards require to have a portion of fresh air daily admitted, by tilting the upper ends of the lights, keeping them close down in the night; also moderate waterings, which however should be applied very sparingly, till the roots begin to shoot, when repeat them moderately as occasion may require, taking care when the shoot begins to advance to admit fresh air more freely, in proportion, to strengthen the stems, according as they advance in height; and when they have risen near the glasses, it is proper to deepen the frame, either by the addition of another at top, or by raising it at bottom six or eight inches, in order to give the stems sufficient room to shoot to their full stature, repeating this once or twice, as the growth of the plants renders it necessary, still assisting them with plenty of water, and a large portion of fresh air daily, either by raising one end of the lights as above; or when the plants are advanced some tolerable height, and in the warm season the lights may be taken away entirely, occasionally, in fine mild days, which will strengthen and inure them gradually to the full air: but always draw on the lights again towards the evening, or at the approach of a sharp air, cold blasts, or heavy rains; but as the summer approaches begin to expose them fully, only giving occasional shelter in cold nights or very wet weather, either by the glasses, or mats supported on hoop arches, till they begin to flower, which will be about the middle or latter end of June, or beginning of July; when the plants in their pots may be removed where wanted; either to adorn any of the garden compartments, or any apartment of the house, a tall straight stake or stick being placed to each plant to fasten the stem to, for support.

The plants must still be duly supplied with water all the time of their bloom, as every other day, or oftener, in very hot dry weather.

Sometimes roots, when planted in May in the full ground, will shoot tolerably strong, and produce flowers in autumn.

They are highly ornamental, but especially the single and double sorts, among other tender potted plants. The dwarf and variegated sorts also afford a fine variety.

POLICANDRO, in *Geography*, an island in the Grecian Archipelago, about seven or eight leagues distant from the isle of Milo. It formerly bore the name of "Pholegandros," and to this the poet Aratus adds the epithet *ferrea*, thus by a single word suggesting an idea of its soil, which is rugged, stony, and, as it is were, composed of iron. The coast affords no harbour; its population is not numerous, and confined in a village enclosed by walls, near which rises a rock of tremendous aspect. Its vines yield good wine; but agriculture finds few spaces fit for cultivation. Some few districts yield corn and cotton, and with the latter commodity tolerably fine cloths are manufactured. Game delights in this rugged soil, and birds of passage make it their principal rendezvous in their regular migrations. N. lat. 36° 37'. E. long. 24° 59'.

POLICANY, a town of Lithuania, in the palatinate of Braflaw; 21 miles S.W. of Braflaw.

POLICASTRELLA, a town of Naples, in Calabria Citra; 15 miles N.W. of Bisignano.

POLICASTRO, a town of Naples, in Principato Citra, on the coast of the Mediterranean, the see of a bishop, suffragan of Salerno; 80 miles S.S.E. of Naples. N. lat. $40^{\circ} 8'$. E. long. $15^{\circ} 30'$.—Also, a town of Naples, in Calabria Ultra; nine miles W.S.W. of St. Severina.—Also, a town, called “Paleo-Castro,” on the N. coast of the island of Candy; 15 miles E.S.E. of Settia.

POLICE, not improbably from *πολις*, a city. The term public police and economy is applied by Blackstone to signify the due regulation and domestic order of the kingdom: but is more generally applied to the internal regulations of large cities and towns.

The police of the metropolis is a system highly interesting to be understood; but the vast proportion of those who reside in the capital, as well as the multitude of strangers who resort to it, have no accurate idea of the principles of organization, which move so complicated a machine.

That part of the system, which may be denominated municipal police, and which consists of paving, watching, lighting, cleansing, and removing nuisances, is chiefly under the management of parochial commissioners.

To administer that branch of the police, which is connected with the prevention, suppression, and punishment of crimes, twenty-six magistrates, namely, the lord mayor and aldermen, sit in rotation every day, and take cognizance of all complaints arising within the jurisdiction of the city of London.

For every other part of the metropolis twenty-seven stipendiary magistrates are appointed; three at Bow-street, Covent Garden, under a jurisdiction long established, and twenty-four by 32 stat. Geo. III. cap. 53. (generally called the Police Act), extended and enlarged by subsequent acts.

These twenty-four have eight different offices assigned to them at convenient distances in Westminster, Middlesex, and Surrey, *viz.* one in Queen-square, Westminster; one in Great Marlborough-street; one in Hatton-garden; one in Worship-street, Shoreditch; one in Lambeth-street, Whitechapel; one in High-street, Shadwell; one in Union-street, in the borough of Southwark; and one in Wapping; which last is under a separate act of parliament, and the attention of the magistrates there is almost entirely confined to the cognizance of offences, either committed on the river Thames, or connected with maritime affairs.

The duty of the magistrates at these offices extends to several important judicial proceedings, where, in a variety of instances, they are empowered and required to hear and determine in a summary way, particularly in cases relating to the customs, excise, coaches, carts, pawn-brokers, persons unlawfully pawning the property of others, and a variety of other matters under penal statutes.

Their duty also extends to many other objects, such as in considering the cases of persons charged with being disorderly, persons brought for examination under charges of treason, murder, felony, frauds, and misdemeanors of every description,—all which unavoidably impose upon every magistrate a weight of business, requiring great exertion and attention to the public interest in the due execution of this important trust.

At each of these offices there are three magistrates established, two of them attend every day except Sunday, and one every evening; two clerks, an office-keeper, a mes-

senger, and from eight to twelve constables, are also attached to each. The Thames police, from the nature of the duty, has a considerable number of constables, surveyors, watermen, and watchmen.

The establishment of the public office in Bow-street is upon a more enlarged scale than any of the others; besides the usual number of constables, there are one hundred foot patrols under proper conductors, who perambulate every evening the environs of the metropolis for two or three miles outwards; and there are also forty horsemen, who go a farther distance of from ten to fifteen miles on the roads leading into London: both these are armed, and are under the direction of the chief magistrate of Bow-street.

POLICHNA, in *Ancient Geography*, a town of Asia Minor, in the Troade, near Palæcepsis, on the summit of mount Ida. Strabo.—Also, a town of the Peloponnesus, in the Argolide, which, according to Polybius, was taken by Lycurgus.—Also, a town of the island of Crete.—Also, a small town of the island of Chios.—Also, a town of Sicily, in the vicinity of Syracuse. Diod. Sic.

POLICOLE, in *Geography*, a town of Hindoostan, in the circar of Ellore; 40 miles N.E. of Masulipatam.

POLICORN, a mountain of Naples, in Abruzzo Ultra; 15 miles S. of Lanciano.

POLICY, or **POLITY**, *Πολιτεία*, the laws, orders, and regulations, prescribed for the conduct and government of states and communities.

The word is of Greek original, being derived from the Greek *πολις*, *civitas*, *city*, or *state*.

In the general, policy is used in opposition to barbarism. Different states have different kinds of policy: thus the policy of Athens differed from that of Sparta.

Loyseau observes, that policy properly signifies the course and administration of justice in a city. The direction of the policy of London is in the hands of the lord mayor.

At Paris they have a *chamber of policy*, where people are verbally accused for contraventions of policy.

Some divide policy into two parts, *agoranomy*, that relating to affairs of merchandize; and *astynomy*, that concerning the civil and judiciary government of the citizens. Some add a third branch, *viz.* what relates to the ecclesiastical government.

Richard Hooker has a fine treatise of the laws of ecclesiastical policy.

In much the same sense is used the modern term *police*, or *public economy*, to denote the due regulation and domestic order of the kingdom: by which the individuals of the state, like members of a well governed family, are bound to conform their general behaviour to the rules of propriety, good neighbourhood, and good manners; and to be decent, industrious, and inoffensive, in their respective stations. The class of crimes against the public police of a country comprehends those which amount to felony, as clandestine marriages, bigamy, and polygamy: those of idle foldiers and mariners, wandering about the realm, and gypsies; and others, whose punishment is short of death, as common nuisances, idleness, luxury, gaming, and the destroying of game. See **POLICE**.

POLICY of Insurance, or *assurance of ships*, is a contract or convention in writing, by which a person takes upon himself the risks of a sea-voyage; obliging himself to make good the losses and damages that may befall the vessel, its equipage, tackle, victualling, lading, &c., either from tempests, shipwrecks, pirates, fire, war, reprisals, &c. in part or in whole, in consideration of a certain sum of seven, eight,

POLICY.

eight, or ten *per cent.* more or less, according to the risk run; which sum is paid down, or supposed to be paid, to the insurer by the insured, upon his signing the policy.

The origin of these insurances has been erroneously ascribed to the Jews, at the time they were expelled France, in 1182; who are said to have used this as a means to facilitate the transporting of their effects. (For the history and practice of *MARINE INSURANCES*, see that article.) The term policy is said to be Spanish, and to be derived from *poliça, schedule*; but the practice comes from the Italians and the Lombards; who, again, derived it originally from the Latin *pollicitatio, promise*. Some writers have deduced the term *policy* from the Italian, “*polizano di assicurazione*,” or “*di securanza*,” or “*di securta*,” which signifies in that language a “note or bill of security,” or indemnity. Some say the merchants of Marseilles were the first who set on foot this kind of commerce.

Anciently policies were given by word of mouth, called *policies of credit*; it being supposed the insurer would enter them in his ledger; but of late, they have been made constantly in writing.

Policies, with reference to the *reality of the interest* of the insured, are distinguished into *interest* and *wager* policies. With reference to the *amount* of the interest, they are distinguished into *open* and *valued*.

An *interest* policy is where the insured has a real, substantial, assignable interest in the thing insured; in which case only it is a contract of indemnity.

A *wager* policy is a pretended insurance, founded on an ideal risk, where the insured has no interest in the thing insured, and can therefore sustain no loss by the happening of any of the misfortunes against which the insurance is made. Insurances of this sort are usually expressed by the words “interest, or no interest,” or “without further proof of interest than the policy,” or “without benefit of salvage to the insurer.” An *open* policy is where the amount of the interest of the insured is not fixed by the policy; but is left to be ascertained by the insured, in case a loss should happen. A *valued* policy is where a value has been set on the ship or goods insured, and that value inserted in the policy, in the nature of liquidated damages, in order to save the necessity of proving it, in case of a total loss; for by allowing the value to be thus inserted in the policy, the insurer agrees, that it shall be taken as there stated. This value is, or ought to be, the real value of the ship, or the prime cost of the goods, at the time of effecting the policy. Cases, however, may occur, in which it is difficult to fix the value of the thing insured at the time, when it is necessary to make the insurance; and in such cases, the insured must fix a value according to his best means of ascertaining it; and hence it is become customary to insert a clause of valuation in the policy, which specifies a given sum as the value of the thing insured. The value in such policy should be only the prime cost. If the thing insured be undervalued, the merchant himself runs the risk of the deficiency: but if it be much overvalued, it must be done with a bad view; either to a fraudulent loss, or to game contrary to the statute 19 Geo. II. c. 37. Upon a valued policy, the insured needs only to prove *some* interest, the amount being admitted. But though a *valued* policy is distinguishable from a *wager* policy in this, that the former is founded on real interest, the amount of which is agreed by the policy, in the latter the insured has avowedly no interest at all; yet it must be owned, that a *valued* policy evidently partakes of the nature both of a policy on interest and of a wager. It

supposes on the one hand a *bonâ fide* interest in the insured, and on the other, this interest is not always expected to be exactly commensurate with the amount of the insurer's obligation. There is, indeed, a real interest; but this frequently falls short of the nominal value in the policy; and it too often happens, that wager policies are effected under colour of a small interest, and in the form of valued policies, and thus the beneficial effects of the stat. 19 Geo. II. c. 37. are defeated: the value in the policy ought, therefore, only to be considered as *prima facie* evidence of the interest of the insured, and may be disputed by the insurer. With us in England, if a valued policy be meant as an indemnity, the amount of the valuation will not be very scrupulously investigated; but if the interest proved be a mere cover for a wager, the policy will be void. The only difference between an *open* and a *valued* policy is in the case of a total loss. In the former the value must be proved; in the latter it is admitted. But in the case of a partial loss, the like inquiry into the true amount of such loss is to be made, whether the policy be open or valued. The business of insurance, and of getting policies effected, is usually transacted by persons who make this their profession, or who are called *Insurance Brokers*. See that article.

The form of the policy, similar to that now in use, was probably introduced into England by the Lombards; and it has continued without any very material alteration. This instrument is always construed by courts of justice according to the intention of the parties, and so as that the indemnity of the insured, and the advancement of trade, which are the great objects of insurance, may be attained. The construction should also be conformable to the course of the trade in the place where the insurance is made. In case of doubtful or obscure clauses, the interpretation should be according to the rules of the common law, because the parties must be presumed to make their agreements subject to that law.

The usual requisites of a policy are ten; and they are as follow. The *first* is the name of the insured, his agent or trustee. Inconvenience having been experienced from having marine insurances in blank, as to the name of the insured, which used formerly to be the case, the utility of the contrary practice was suggested about the year 1785; and the legislature was induced, with a view of remedying these inconveniences, to pass the stat. 25 Geo. III. c. 44. which directs, that where the insured resided in Great Britain, his name, or that of his agent, should be inserted in the policy, as the person interested; and where he resided abroad, the name of his agent should be inserted. This act, however, was repealed by the stat. 28 Geo. III. c. 56, which provides, that the names or firm of the persons interested, or the name of one of them, or the name of the person who gives or receives the order to insure, shall be inserted. This act ought to be construed liberally and according to its true intent and meaning; and, therefore, if a consignee refuse to accept a cargo of goods, or to accept bills of exchange for the amount, the general agent of the consignor becomes in effect the consignee, and may insure in his own name. A general agent may insure without an order for that purpose, when it is for the interest of his correspondent that he should do so. A debt, which would have given a “lien” on the thing insured, gives an insurable interest; and a contingent and reasonable expectation of interest is sufficient to entitle the party to insure. If the name of the broker effecting the policy be inserted in it, it is a sufficient compliance with the 28 Geo. III. c. 56, though he be not described therein as an agent; so,

POLICY.

though it should appear that the agent named in the policy be not *general* agent, but only agent for that particular purpose.

The *second* requisite is the insertion of the names of the ship and of the master. In a policy on goods the ship must be named; and the ship cannot be changed, but from necessity, or with the consent of the insurer. It often happens, however, that, in the trade carried on with distant countries, particularly in time of war, it is uncertain by what ships goods may be sent from thence to Europe. It is, therefore, of great importance to the merchant to be at liberty to avail himself of the first vessels that may offer for that purpose, and to make his insurance on the goods on board such vessels; and in such case, the policy is upon the goods, "on any ship or ships;" and this is now so well established, both by usage and authority, that the legality of it is indisputable. It is necessary also that the *species* of the vessel should be truly named: accordingly if the ship be a privateer or letter of marque, she should be described as such. The name of the *master* must likewise be specified: but the owner may change the master, so that the following words are always added in our policies, "or whosoever else shall go for master in the said ship;" but this ought not to be done unnecessarily.

The *third* requisite is the subject matter of the insurance, whether it be goods, ships, freight, respondentia, bottomry securities, or other things. There are, however, certain articles, which, though they may properly be called goods, are not comprehended under the general denomination of goods, wares, and merchandizes in the policy; and therefore the insurer is not liable for any loss upon these articles, unless they be specifically named: such are the master's clothes, and the ship's provisions. Neither are goods lashed to the deck comprehended under the name of goods, unless they be particularly described, because they are exposed to greater danger than goods usually are, and consequently the premium for insuring them is greater. Money, jewels, or bullion, may be insured under the denomination of goods; but the insurance is not liable for the risk of a clandestine exportation of these articles. A distinction has been generally made between money, jewels, rings, trinkets, &c. which are a part of the *cargo*, as articles of commerce, and such as are merely *personal*, and are not meant to be disposed of as such. The jewels and ornaments which are worn by persons on board, and which are not considered as forming part of the cargo, nor liable to contribute to a general average, would not be considered as included in a general policy on goods. An insurance on a ship does not comprehend both ship and cargo: and, therefore, if a merchant insure a ship generally, and she then happen to be laden, the insurer, in case of loss, shall answer only for the ship, but not for the goods.

The *fourth* requisite in a policy is a description of the voyage, with the commencement and end of the risk. This is of such importance, that if a blank be left either for the place of departure or of destination, the policy will be void. In our ordinary policies, the continuance of the risk on goods is generally expressed to be "from the loading thereof on board the ship," and to continue "until the same be discharged and safely landed" at the port of delivery. Upon the *ship*, on an outward voyage, it is sometimes from "her beginning to load" at some particular place, or "at and from" such place; sometimes "from a particular day." On a homeward voyage, it is generally made to commence "on the ship's arrival" at a particular place abroad, or at and from such place; and it continues "till

she arrives" at her place of destination, "and is there moored twenty-four hours in good safety." A ship is enabled, by certain additional provisions, to touch, stay, trade, &c. at certain places out of the direct course of the voyage, without incurring the guilt of a deviation. Privateers and vessels which are constantly employed in the coasting trade, are insured sometimes for a term; but by stat. 35 Geo. III. c. 63. §. 12. this term must not exceed 12 calendar months; if it exceed that time, the policy will be void.

In policies for time the commencement and termination of the time should be distinctly specified; but if these should not be precisely stated, it will be sufficient if it can be collected from the construction of the policy and the intention of the parties. If the port or ports of the ship's destination be untruly set forth in the policy, the contract will be void, whatever may have been the original *intention* of the insured at the time when the insurance was effected; if, in fact, the ship sail on a voyage different from the voyage insured, the policy is discharged; not, perhaps, on the ground of a wilful misrepresentation, but because the ship never sailed on the voyage described in the policy, and there is no inception of the risk insured against. But it has been holden, in a subsequent case, that though there be a *previous design* to touch at a port out of the usual course of the voyage insured, and the ship be even furnished with clearances for that port; yet, if the "termini" of the intended voyage be the same as those of the voyage mentioned in the policy, this shall be considered only as an *intention to deviate*. If, indeed, the ship has liberty in the policy to touch at a place where it is not intended she shall go, yet the policy will be good. If from a certain point in a voyage there be several tracks, of which the captain usually elects which he will pursue; but a particular track is *prescribed to him* by the insured: this should be mentioned in the policy, otherwise it would be void.

Fifthly. The various perils against which the insured means to be protected, must be distinctly enumerated in the policy. These are generally expressed in a form of words which have been long in use, and which afford full protection against every accident or misfortune that can possibly happen in the course of any voyage, and for which it is meant that the insurer shall be answerable. There are, however, certain losses which are not comprehended in the usual words of the policy: such are injuries occasioned to goods by bad stowage, by being exposed to wet, by theft, and embezzlement of the master or mariners, &c. In all our policies are inserted the words "lost, or not lost," by which the insurer takes upon himself, not only the risk of future loss, but also the loss, if any, that may already have happened.

The *sixth* requisite in a policy respects the powers of the insured in case of misfortune. It was formerly doubted whether the insured might use his endeavours to recover the goods which had been lost, or in preserving such as had been saved, without waving his right to abandon. In order to obviate this doubt, a clause was introduced into the policy to enable the insured, in case of any loss or misfortune, to employ all necessary means for the defence, safeguard, and recovery of the goods or ship insured, without prejudice to the insurance, and at the charge of the insurers, to which they bind themselves to contribute in proportion to their respective subscriptions.

Seventhly. The next clause in the policy is that by which the insurers bind themselves to the insured for the true performance of their contract, and confess themselves paid

POLICY.

the consideration or premium, by the insured, after the rate specified. In practice the premium is not always paid when the policy is underwritten. Insurances are generally effected by the intervention of *brokers* (see that article), and open accounts are usually kept between them and the underwriters, in which they make themselves debtors for all premiums. It is laid down, by usage of trade, that the insurer is to look to the agent who is employed to effect the policy for his premium: but whether the insured himself or the agent is liable, the insurer may receive the premium, and "indebitatus assumpsit" will lie for it, notwithstanding the formal acknowledgment of the receipt of it in the policy, which is not inserted there as conclusive evidence of the actual payment of the premium, but to preclude the necessity of proving it in case of loss. However, the payment or non-payment of the premium can have no effect upon the insurance. The rate of the premium must always depend on the agreement of the parties; and therefore the premium, whatever it may be, is always reputed to be just and fair, if there be no fraud or surprise on either side. If the nature of the risk be fairly and fully declared by the insured, the insurer can never dispute the payment of a loss, on the ground of the smallness of the premium.

Eighthly. The common memorandum follows for confining the insurances to their only proper object, namely, an indemnity against real and important losses arising from the perils of the sea; and to obviate all subjects of litigation about trivial losses, and losses arising from the perishable quality of the goods insured. Accordingly this memorandum constantly stipulates, in all our policies, that in the case of certain enumerated articles, of a quality peculiarly perishable, the insurer shall not be answerable for any partial loss whatever; that, in the case of certain others, liable to partial injuries, but less difficult to be preserved at sea, he shall only be liable for partial losses above 5 *per cent.*: and that, as to all other goods, and also the ship and freight, he shall only be liable for partial losses above 3 *per cent.* But in this memorandum there is an exception of all losses, however small, of the nature of "general average," or when the ship is stranded: but this last exception is only found in the policies of private underwriters.

The *ninth* requisite is the date and subscription. The sum insured is generally placed after the signature, in the underwriter's hand-writing, and in words at length, not in figures, which are easily altered or changed. But it is not indispensably necessary that the sum should be specified in the policy. An insurer may bind himself to pay the value of the effects insured, or a given proportion of it, without fixing that value in the policy. A policy of insurance, like every other contract in writing, should have a date. This date seems, when compared with the dates of facts connected with the transaction, to discover whether there be reason to suspect any fraudulent concealment, at the time of any of the subscriptions to the policy. Each underwriter puts the date to his own subscription.

The *tenth* or last requisite of the policy is the stamp. The statute of 35 Geo. III. c. 63. imposes upon every 100*l.* insured, a duty of 2*s.* 6*d.*, and so progressively for every sum insured, and for a less sum than 100*l.*, the like stamp of 2*s.* 6*d.*; and for every fractional part above 100*l.* or any progressive sums of 100*l.* each, a like duty of 2*s.* 6*d.*; and where the premium *bonâ fide* paid, or contracted for, shall not exceed the rate of 10*s.*, and the sum insured amounts to 100*l.*, a duty of 1*s.* 3*d.*, and so progressively for every 100*l.* and the fractional part of every 100*l.* insured. Provided that where the premium shall not exceed 10*s.* *per*

cent., and the sum insured amounts to 200*l.* or upwards, a stamp of 2*s.* 6*d.* may be used for every 200*l.* insured, instead of stamps of 1*s.* 3*d.* for every 100*l.* Where the sum insured on homeward voyages exceeds the interest of the insured by 1000*l.* where the stamp is 1*s.* 3*d.* *per cent.*, or 500*l.* where it is 2*s.* 6*d.*, the excess of duty may be allowed. Every contract shall be deemed a policy, which shews the premium, risk, sum insured, and names of insurers. No policy of a ship is to be for a longer term than twelve months: nor shall any such insurance be available in law unless duly stamped, and no policy is to be stamped after the insurance shall be printed or written. Any person effecting such insurance, or paying any premium, or contracting for such insurance, unless it be printed or written, &c. duly stamped, shall forfeit 500*l.*: and brokers negotiating such insurances shall forfeit the same sum: nor shall any brokerage be charged, unless such insurance be printed or written, and duly stamped. Any person insuring without a stamp, or concerned in any fraud to evade the stamp duties, shall forfeit 500*l.* The two law-insurance companies, *viz.* the London Assurance and the Royal Exchange Assurance companies, may make agreements for insurances on unstamped labels, provided the policies be made out in three days after. Any alteration may be made in the policy, before notice of the end of the risk, if the premium exceed 10*s.* *per cent.* The act contains other regulations, which it is not necessary for us to recite. By the statute 41 Geo. III. c. 10. §. 1. all the duties imposed by the above act are doubled. (See STAMP.) The general form of the policy, which has been for many ages nearly the same, is never altered but with the utmost caution, and upon very great consideration; nor can it be altered except by the consent of all parties, or by the authority of a court of equity, or perhaps a court of law, and then only in a case where something has, by mistake or fraud, been inserted or omitted contrary to the manifest intention and the real agreement of the parties; and a case of this sort must be made out by unquestionable testimony to warrant such an alteration. When an underwriter agrees to alter the policy in order to correct a mistake, he shall not afterwards object that he ought to have had an increase of premium. Marshall's Treatise on the Law of Insurance, vol. i.

POLICY of Insurance, or Assurance of Houses, is an instrument formed on the model of that for vessels; by which a person, or community of persons, take on themselves the risks and damages that may befall houses, their furniture, in whole, or in part, &c. from fire, on consideration of a certain sum, or sums, to be paid by the assurer, according to the terms of the agreement.

The insurance from fire is now a popular species of commerce; and we have a number of societies erected into corporations for that purpose. See INSURANCE.

Policies against fire are subject to a stamp of 3*s.* if under 1000*l.*, and 6*s.* if 100*l.* or upwards; and also to a yearly duty of 2*s.* *per cent.* on the sum insured. 37 Geo. III. c. 90.

POLICY of Insurance of Lives, is an instrument by which a society of persons, erected into a corporation, &c. oblige themselves to pay a certain sum of money, or an equivalent annuity, upon the death of a person whose life they assure, in consideration of a certain premium, either in a gross sum, or by annual payments, to the person for whose benefit the insurance is made, whenever the death of the person insured shall happen, if the insurance be for the whole life, or in case this shall happen within a certain period, if the insurance be for a limited time.

The policy is under the seal of the office, and entitles the person in whose favour it is granted, to make good his claim, according to the tenor of the articles, or by-laws, of the society. See ASSURANCE on Lives, and STAMP.

POLICY, *Officers of.* See OFFICER.

POLICY, in *Letter Foundery*, is sometimes used for a rule that regulates the number of letters of each kind in a complete font; *i. e.* to determine how many, in proportion to the whole set, there are to be of each particular kind.

For instance, in a font of a hundred thousand characters, there are to be five thousand for *e*, a thousand for *a*, three thousand for *m*, thirty only for *k*, as many, or a little more, for *x*, *y*, and *z*; and in proportion for the other letters, the great and small capitals, the initial letters, points, commas, double letters, &c. See LETTER FOUNDERY.

POLIDE, formed of *πολις*, *city*, and denoting the patroness of a town or city, in *Mythology*, an epithet given to Minerva, under which title she had two temples; one at Erythres, in Achaia, and another at Tegea, in Arcadia.

POLIDORO, DA CARAVAGGIO, in *Biography*. See CALDARA.

POLIEA, *Πολιεια*, in *Antiquity*, a solemnity of Thebes in honour of Apollo, surnamed *Πολιος*, *i. e.* grey, because he was represented in this city (contrary to the practice of all other places) with grey hairs. Potter.

POLIEUS, formed of *πολις*, *city*, and denoting the protector of a city, in *Mythology*, a name under which Jupiter had a temple in the citadel of Athens.

POLIGNAC, MELCHIOR DE, cardinal, in *Biography*, a statesman and man of letters, born in 1661, was second son of the viscount de Polignac, a branch of one of the most illustrious families in that province. Being destined for the church, he was sent, at an early age, to Paris, and placed in the college of Clermont. He soon made himself acquainted with the systems of Aristotle and Descartes, and maintained the truth of both, with vast applause, in two theses, which he publicly defended in two successive days. He obtained equal reputation in his theological exercises. He was not formed less to shine as a man of the world than as a student, and was received in the politest circles in Paris. "Of all men I know," says Madame de Sevigné, "he appears to me one of the most agreeable. He knows every thing, he talks of every thing; he has all the softness, the vivacity, the complaisance, that can be desired in social intercourse." The cardinal de Bouillon took him to Rome in 1689, and employed him not only in the election of the new pope Alexander VIII., but in the accommodation of the differences which had arisen between the courts of France and Rome. On these occasions he displayed a talent for negotiation that equally obtained the applause of the pontiff, and of his own sovereign Lewis XIV. In 1693 he was appointed by the king ambassador to Poland, where the declining health of John Sobiesky rendered it necessary that measures should be taken for the support of the French interest in the approaching election to that crown. His want of success obliged Lewis to appear dissatisfied with his conduct, and he was ordered to his abbey, where he occupied himself with literature, and where he composed his "Anti-Lucretius." In the mean time he was not inattentive to the recovery of the royal favour, and upon the succession of the duke of Anjou to the crown of Spain, he wrote to Lewis in the following terms: "Sire, if your majesty's prosperity does not put an end to my misfortunes, at least it makes me forget them." Shortly after this courtly epistle he was recalled to court, where he was received very graciously, and appeared with more splendour than before. He was employed again in various important

political missions, and was at length, as a reward for his many services, elevated to the cardinalate, and was in the same year, 1713, made master of the chapel royal. After the death of Lewis XIV., the cardinal connected himself with the enemies of the regent, and was exiled, in 1718, to the abbey of Anchin, whence he was recalled in 1721. The monks of the abbey, who had been intimidated on his coming among them, were so captivated by his affability and generosity, that they wept at his departure. In 1724 he went to Rome, to assist in the election of Benedict XIII., and remained eight years in that city as minister of France. During this period he was nominated to the archbishopric of Auch, and made commander of the order of the Holy Ghost. He died at Paris in 1741, at the age of 80. As an author, he is chiefly known and remembered by the "Anti-Lucretius," which was first published in 1747. It has gone through many editions in the original Latin, and has been translated into the French and other modern languages. The original is distinguished for the purity and elegance of its diction, and the happy turn of its expressions. It is successful in confuting the absurdities of the Epicurean system, but it substitutes in their place the reveries of Descartes, in opposition to the true principles of Newton. Cardinal Polignac was possessed of a general taste for science, literature, and the fine arts: he was a member of the French Academy, that of Sciences, and that of Inscriptions and Belles Lettres. He had a large collection of antiquities dug up from the ruins of Rome: at one time he had formed a project of diverting the course of the Tyber, in order that strict search might be made for the relics contained in its bed. His private affairs fell into great disorder, and he died very much in debt. Moryer.

POLIGNAC, in *Geography*, a town of France, in the department of the Upper Loire; 6 miles N. of Puy.

POLIGNANO, a town of Naples, in the province of Bari, on the coast of the Adriatic, the see of a bishop, suffragan of Bari; 17 miles E. of Bari. N. lat. 41° 12'. E. long. 17° 14'.

POLIGNY, a town of France, and chief place of a district, in the department of the Jura; 9 miles N.N.E. of Lons le Sauniers. The place contains 5293, and the canton 14,678 inhabitants, on a territory of 252½ kilometres, in 30 communes. N. lat. 46° 50'. E. long. 5° 47'.

POLIIFOLIA, in *Botany*, a name given by Buxbaum, in the Petersburg Transactions for the year 1727, to the plant subsequently called by Linnæus *Andromeda polifolia*. See ANDROMEDA, and POLIUM.

POLINA, in *Geography*, a town of European Turkey, in Macedonia; 30 miles S.E. of Saloniki.

POLINARA, a town of Naples, in Calabria Citra; 11 miles N. of Bisignano.

POLING, in *Internal Navigation*, a term of the same import with setting, shoving, or pushing a boat along with poles, &c.

POLINIÈRE, PETER, in *Biography*, a French mathematician, who flourished in the 18th century, was born at Coulouce, near Vire, in Lower Normandy, in the year 1671. He was educated partly at Caen, and partly at Paris; at the latter he applied himself particularly to the study of mathematics. Here he published a work, entitled "Elements of the Mathematics," which, whatever might have been its merit then, has long since been superseded by other publications. In 1709 he published "Experiments in Natural Philosophy," which work met with so much success, that it was translated into several languages. He afterwards republished it 2 vols. 12mo. He was the first person appointed to deliver lectures on experimental philosophy

lofophy in the univerfity of Paris, and had the honour of delivering one courfe before the king. He retained the office of lecturer upwards of thirty years, and his labours were, at laft, terminated by a fudden death, in 1734, when he had attained the age of 63. He is characterifed as a man of clofe and indefatigable application, and affociated with fcarcely any perfons but men of fcience. He refided principally at Conlonce, and came annually to Paris, where he remained no longer than till he had gone through his courfe of lectures. Moreri.

POLIOPTRUM, in *Optics*. See POLYOPTRON.

POLIOPUS, in *Ornithology*, a name given by Aldrovand, and fome other authors, to the grinetta, a fmall bird of the moor-hen kind.

POLIPUT, in *Geography*, a town of Hindooftan, in the Carnatic; 5 miles S.E. of Bomrauzepollam.

POLISHER, an instrument, called alfo a burnifher, ufed for polishing and burnifhing gold, filver, and other metals, when gilt or filvered; and matters of other kinds, proper to take a polish.

The polifher is different in the different arts and manufactories. The gilders ufe an iron polifher, to prepare their metals before gilding; and the blood-ftone, to give them the bright polifh after gilding.

The polifher ufed by the makers of furs, bits, &c. is part iron, part fteel, and part wood. The inftrument confifts of an iron bar, with a wooden handle at one end, and a hook at the other, to faften it to another piece of wood held in the vice, while the operator is at work. In the middle of the bow, withinfide, is what they properly call the polifher; which is a triangular piece of fteel, with a tail, by which it is rivetted to the bow. What the cutlers call their polifhers are a kind of wooden wheels, for grinding, made of walnut-tree, an inch thick, and of a diameter at pleafure. They are turned by the great wheel; and it is on thefe they polifh and fmooth their works with emery and putty.

The polifhers ufed in the manufacture of glafs are very different from all thefe. They confift of two pieces of wood; the one flat, covered with old hat; the other long and half round, faftened on the former, whofe edge it exceeds, on both fides, by fome inches: which ferve the workman to take hold of, and to work it backwards and forwards by.

The polifhers ufed by fpectacle-makers are pieces of wood a foot long, feven or eight inches broad, and an inch and a half thick, covered with old caftor hat, on which they polifh the fhell and horn frames their fpectacle glaffes are to be fet in.

POLISHING, the art of giving a glafs or luftre to a thing; particularly a precious ftone, marble, glafs, a mirror, or the like.

For grinding and polishing fteel, the grindftones that are ufed are made to revolve, either vertically or horizontally, with a velocity fo great, as to defcribe fometimes as much as fixty feet in a fecond. The fteel is alfo, in fome cafes, drawn backwards and forwards horizontally on a circular furface; and in order that the action may be equally diftributed throughout the furface, it is allowed to revolve on an axis by means of the friction: its motion being confined to one direktion by the action of a catch. Various fubftances, chiefly of mineral origin, are alfo ufed, on account of their hardnefs, as intermediate materials, for grinding and polishing others. Thefe are diamond duft, corundum, emery, tripoli, putty, glafs, fand, flint, red oxyd of iron, or crocus martis, and prepared chalk. Thefe are fometimes applied in loofe powder, and fometimes fixed on wood, leather, or

paper. Cuttle-fifh bone and feal-fkin are furnifhed by the animal kingdom; and Dutch rufhes by the vegetable; thefe are employed chiefly in polishing wood or ivory. Marble is made fmooth by rubbing one piece on another, with the interpofition of fand; the polishing blocks are fometimes caufed to revolve by machinery in a trough, in which the marble is placed under water, and are drawn at the fame time gradually to and from the centre; or the flab itfelf, with the frame on which it refts, is drawn flowly backwards and forwards, while the blocks are working in it. (See *Polifhing of MARBLE*.) Granite is polished with iron rubbers, by means of fand, emery, and putty: but it is neceffary to take care, during the operation, that the water, which trickles down from the rubbers, and carries with it fome of the iron, may not collect below the columns, and ftain them; an inconvenience which may be wholly avoided by employing rubbers of glafs.

For the method of grinding and polishing optical lenfes, fee GRINDING, LENS, and MIRROR.

POLISHING of *Glaſſes, Lenfes, &c.* fucceeds the grinding of them.

The polishing of a mirror is the laft preparation given it with emery or putty.

For an account of the methods recommended by various authors for polishing glafs and metals in the conftruction of telefcopes, &c. fee GRINDING.

For the polishing of diamonds, &c. fee LAPIDARY; fee alfo DIAMOND, and GEMS.

When plates of glafs for looking-glaffes and mirrors are prepared in the manner ftated under *LOOKING-Glaſſes* and *MIRROR*, the next procefs is that of polishing both fufaces to that perfect brightnefs which is obfervable in finifhed mirrors, fo that the rays of light may pafs through unimpaird to the filvering on the pofterior furface, and be reflected again from thence, according to the laws of catoptries. The fubftance ufed to give this laft polifh is colcothar, imported from this country, and called "rouge d'Angleterre," or "Potée." It is the refidue left in the retorts of the aquafortis-makers, and when well washed and levigated confifts of little elfe than a red and perfect oxyd of iron. The polishing inftrument is a block of wood covered with feveral folds of black cloth with carded wool between each fold, fo as to make a firm elastic cuſhion. This block has a handle for the workman to hold; for the whole of this part is done by hand and not by machinery, as the latter would work too uniformly, and not allow of that variation of preffure and thofe finifhing touches which are required to bring every part of the glafs to exactly the fame height of polifh. But to increafe the preffure of the polifher, without fatiguing the workman, the handle is lengthened by a wooden fpring bent to a bow, and three or four feet long, which at the other extremity refts againft a fixed point in a beam placed above. The plate being fixed on the table by plaſter, he then moiftens the polifher with a wet brush, covers it with colcothar, and begins his operation by working it backwards and forwards over the furface of the plate. Much practical ſkill and dexterity is required to give an uniform and high degree of polifh over the furface of a large plate, as it muft be done by feparate portions, and the finifhing touches given with great care. The glaffes of moderate fize are completed in four portions from corner to corner, the centres of which intermingle fo as to leave no part untouched, but the larger glaffes require additional polishing in the centre. When one fide is completed, and the reverfe is about to be done, the polifhed fide, now the undermoft, is entirely covered with the red colcothar, to prevent the dazzle reflected from the white plaſter, which would

would prevent the workman from judging so accurately of the state of the surfaces on which he is employed. When both sides of the glass are thus brought to the same perfection of polish, the operation is finished by inspecting the glass, first cleaning both surfaces, and laying it, each side alternately upwards, upon a dark blue or black cloth, admitting only a moderate light, and if any part appear less highly finished than the rest it is retouched by a small hand-polisher and colcothar as before.

When a number of smaller pieces of glass, such as are used only for chamber or similar mirrors are to be polished, they are laid together on the table, and several of them polished at a time. But as these consist of pieces often of unequal thickness, though their surfaces have been rendered perfectly flat by the previous grinding, if they were simply placed side by side, and fixed on the table by plaster as usual, the polisher would not work well over such a variety of heights, and would act chiefly on the edges of each piece of plate. Therefore they are all first arranged on a large smooth plate, finished all but the polishing, and previously wetted, and plaster is poured upon them by which they are fixed together, and then when taken off, the surfaces which were in contact with the plate are perfectly level with each other, and the polishing goes on with the same ease as on an entire plate.

For an account of the next operation, which is that of *Silvering*, see that article, and *LOOKING-Glasses*.

POLISHING of Copper-Plates. See *COPPER Plates*.

POLISHING of Shells. See *SHELLS*.

POLISHING, Water. See *JAPANING*.

POLISMA, in *Ancient Geography*, a town of Asia Minor, in the Troade, upon the banks of the river Simoente. Strabo.

POLISTENE, in *Geography*, a town of Naples, in Calabria Ultra; 16 miles S.E. of Nicotera.

POLITI, ALEXANDER, in *Biography*, a learned Italian, was born at Florence in 1679. He was educated at the Jesuits' seminary, and became distinguished by his ardour in literary pursuits. At the age of fifteen he entered a college life, in order that he might complete his philosophical studies. He repaired to Rome for the study of theology, and on his return in 1700, was appointed professor of rhetoric at the same college in which he had studied, and afterwards of philosophy. In 1708 he published a compendium of the Peripatetic philosophy. After this he published a work entitled "De Patria in Testamentis condendis Potestate." His favourite study was Greek literature, and the author to which he devoted the labour of many years was Eustathius, the commentator on Homer. Having resolved to illustrate and translate his works into Latin, he began to execute his design in 1716, but it was not till 1730 that he was able to publish the first volume of his version of Eustathius's Commentary on the Iliad, which he dedicated to John Gaston, duke of Tuscany. The second volume he inscribed to pope Clement XII., and the third to Lewis XV. In consequence of this work he was appointed to the Greek professorship in the university of Pisa in 1733, and in a short time he was elected professor of eloquence. In the exercise of the duties of this office he was attended by a great confluence of auditors, who were attracted by the fame of his Latin orations on various occasions, many of which he published. Six of them were peculiarly calculated for popularity, being eulogies of the same number of towns in the Tuscan territory. In 1741 he published a Latin version of Eustathius's Commentary on Dionysius Periegetes, followed by two books of animadversions upon Dionysius and Eustathius. As his last work he undertook the laborious task of a new

edition of the Roman Martyrology, of which he published the first volume in 1751. In the following year he died, having completed his seventy-second year. Besides the writings above mentioned, he published "Epistola de Curibus Antiquorum," in the preface to the works of Meursius, printed at Florence: he was author likewise of other orations and treatises. His style is copious, fluent, warm, and enriched with a variety of erudition. Gen. Biog.

POLITIANO, ANGELO, an eminent man of letters, was born in 1454, at Monte Pulciano, in the Florentine territory, called in the Latin Mons Politianus, whence he derived the appellation by which he is usually known. He was sent for education at an early age to Florence, where he obtained the patronage of the family of Medici, particularly of Lorenzo, who admitted him as an inmate of his palace. He had the advantage of able instructors, and his progress was extremely rapid, especially in classical literature and poetry. His Latin epigrams, written when he was only thirteen years old, and his Greek at seventeen, caused him to be looked upon as the wonder of the school; and his Italian *stanze* on the tournament of Giuliano de Medici, one of the best pieces of vernacular poetry of that age, procured him general fame, and the particular regard of that illustrious house. He soon began to distinguish himself as a critic and original writer, and was at the age of twenty-nine made professor of Greek and Latin eloquence. In this situation he formed many scholars, who became eminent in literature: his lectures were not only well attended by the natives, but his celebrity attracted foreigners from all parts to Florence. Various honours and emoluments were conferred upon him; he entered into holy orders, and took his degrees in canon law. After this he was one of the ambassadors sent by the Florentines to do homage to pope Innocent VIII. at his election in 1485, and he was at this time in habits of correspondence with several crowned heads, and men of high rank, as well as with the principal literary characters of the age. Above all, as being to him of the most importance, he was honoured with the perpetual friendship and patronage of Lorenzo de Medici, who entrusted him with the education of his children, and the care of his library and museum, and assigned to him a constant residence in his own house. Politiano was unquestionably one of the most learned men of that age. He wrote elegantly in the Italian, Latin, and Greek, and was also versed in the Hebrew. He composed with equal facility and purity in prose and verse, and in the dignified and familiar style. He was an industrious and skilful collector of ancient MSS., and gave important assistance to the visitors in the early period of typography. In Italian poetry he may claim the rank of an inventor; for his "Orfeo," a dramatic composition represented at Mantua, and written in two days at the desire of cardinal Francesco Gonzaga, was the earliest example of that combination of music and lyric poetry with tragic action, which has since become famous under the name of the Italian opera. Politiano with all his literary excellencies was the slave of immoralities that have disgraced his memory: he was openly accused of infamous propensities, and of the total want of religion. Both these accusations were greatly exaggerated, in consequence of his own intractable and arrogant disposition, which involved him in perpetual quarrels. He, however, retained the kindness of his illustrious patron so long as the latter lived, and at his house at Fiesole, he composed his elegant and rural poem entitled *Rusticus*. Politiano did not long survive his patron, dying at the early age of 40. He is said to have died like a good Christian, of which the chief proof is, that he requested to be buried in the habit of a monk. The works of Politiano are translations of various Greek

Greek authors, Greek epigrams, Latin epistles, poems, and philosophical treatises; a history of the conspiracy of the Pazzi in Latin; Italian poems; and a volume of Miscellanies, containing explanations and corrections of a great number of passages in the Latin classics, displaying very profound erudition. Roscoe's Life of Lorenzo de Medici.

The "Orfeo," of Politiano, a poem for music, was certainly the first attempt at a musical drama in Italy, which was afterwards perfected by Apostolo Zeno, and Metastasio. We shall, therefore, present our readers with an account of it, as lately published in the seventeenth volume of the "Parnaso Italiano," where it is said to be a beautiful piece of poetry, written by the elegant pen of Politiano in the dawn of dramatic representation.

To this drama there is an argument in verse. The piece is in five acts, and founded on the ancient fable. Aristæus, a shepherd, the son of Apollo, loved Eurydice, the wife of Orpheus, in so violent a manner that he pursued her in the fields, and in her flight from him she was stung by a serpent, of which she died. Orpheus by singing so softened the infernals, that they suffered her to depart, on condition that he would not look behind him. But not obeying this injunction, she was forced back to hell. Upon his grief, and resolution never to love another female, the Thracian women tore him to pieces.

Atto primo, Pastorale.

Part of the first scene seems to have been declaimed; though it is in verse, in *terza rime*; but the rest is called canto di Aristeo.

"Udite, felle, mie dolce parole,
Poichè la bella ninfa udir non vuole."

These two lines are the burden of his song, which is beautifully pastoral.

Atto secondo, Ninfale.

Aristæus, a dryad, and chorus of dryads.

This is beautiful poetry, consisting of complaints for the death of Eurydice.

Atto terzo, Eroico.

Orpheus comes in singing the following Latin verses, accompanying himself on his lyre.

Orpheus. "Musa, triumphales titulos, et gesta canamus.
Herculis, et forte monstra subacta manu.
Et timidæ matri pressos ostenderit angues
Intrepidusque fero riferit ore puer."

Then the dryad tells the sorrowful tale of Eurydice's death. This act seems all to have been sung. A satyr follows the afflicted Orpheus to see whether the mountains are moved by his song.

Atto quarto, Nigromantico.

Orpheus visits the infernal regions; himself, Pluto, Proserpine, Eurydice, and Tefiphon, are the interlocutors.

"E' vien per impetrar mercede o morte
Dunque m' aprite le ferrate porte."

The whole of this act is admirable, and all the interlocutors speak in character.

Atto quinto, Bacchanale.

Orpheus, one of the Menades (not Thracian women), and chorus of Menades, who tear him to pieces.

The whole of this drama, which, from its brevity, seems

chiefly to have been sung, is admirably calculated for impassioned music of every kind.

First act, one hundred and twelve lines; second, eighty-two; third, forty-four; fourth, one hundred and seventeen; fifth, seventy-eight; in all four hundred and thirty-four verses.

Politiano was always passionately fond of music, and is said to have died playing on the lute.

POLITICAL, πολιτικός, formed from πολις, *city*, something that relates to policy, or civil government.

In this sense we say, political interests, political views, political discourses, &c.

POLITICAL Arithmetic is the application of arithmetical calculations to political uses and subjects, as to the revenues, number of people, extent and value of land, taxes, trade, &c. in any nation. These calculations are generally made with a view to ascertain the comparative strength, prosperity, &c. of any two or more nations: that is, of their wealth. Political arithmetic does not determine in what national wealth consists, but estimates the value of whatever passes by that name, and distinguishes the proportions by which the component articles may be applied to purposes conducive to the safety or prosperity of the community. It will be readily allowed, that in the application of arithmetic to the subjects of **POLITICAL Economy**, (which see,) it loses much of its precision from the fluctuating nature of all kinds of property, both with respect to distribution and value, the state of which it is one of its chief objects to estimate; it retains, however, a sufficient degree of certainty to become an interesting object to every person who wishes to acquire a just idea of the resources either of the community to which he belongs, or of other nations.

On this subject, if the particulars assumed as facts could be obtained correct, the deductions obtained from them would be nearly as determinate and invariable as in any other branch of arithmetic; but as the former cannot be perfectly depended upon, the latter will necessarily be only approximations to the truth. Such approximations, however, may be sufficient for most purposes of practical utility.

Political arithmetic has been much cultivated, of late years, in many parts of Europe, particularly in our own country, in France, and Germany; but as its application, however varied in different places, is very similar, it will be our business in the following article, and in that under the word **POPULATION**, to endeavour to illustrate the subject, by attempting to determine the state of the national wealth of Great Britain at or about the commencement of the present century.

POLITICAL Economy is the science in which the wealth of nations is considered. Its object is to ascertain, in the first place, in what wealth consists, and then to explain the causes of its production, its increase and diminution, and the principles on which it is distributed through the different orders of society. It likewise endeavours to point out the tendency which any political regulations may have to favour or injure the productions, or most advantageous distributions of wealth.

The writers on political economy have been arranged in two great classes, the former composed of those who regard commerce, and the latter of those who regard agriculture as the principal source of national wealth. Almost all the old writers belong to the former class. Of our own countrymen, the most considerable are Dr. DAVENANT, and sir JOHN STEWART, (see their articles,) and their principles are interwoven in Anderson's "History of Commerce." The commercial system of political economy is very ably examined, explained, and illustrated in the "Wealth of Nations," by

by our countryman Dr. Adam Smith. The agricultural system is of comparatively recent origin. It was first brought into notice by M. Quesnai, a celebrated French physician, and his ideas have been adopted and diffused by several very able writers, particularly in a work, by Mercier de la Rivière, entitled "L'Ordre Naturel de Sociétés Politiques." The writings of Quesnai have been published, commented upon, and illustrated, in a work entitled "Physiocratie," by Dupont de Nemours. The followers of Quesnai, who are commonly great enthusiasts in behalf of the system of their leader, are known, throughout Europe, under the denomination of "Economists." The most important work, by much, on political economy, is the treatise on the "Wealth of Nations," to which we have already referred, and shall have recourse, in this article, again and again. Some errors may have been discovered in the arguments, but they are trifling in comparison of the great excellence of the treatise as a whole, so that it still deserves the praise that has frequently been bestowed upon it, as a work at once original, accurate, and profound, as just in its general principles, and perspicuous in its illustrations.

A striking and very important difference between the systems of political economy, as detailed a century ago, and that introduced by Adam Smith, consists in this, that the former are calling, upon all occasions, for the regulation and controul of laws; regarding the legislature as best qualified to estimate the value of any particular branches of trade, or modes of conducting business; while by the latter the merchant is supposed to be the best judge of the most eligible method of conducting his own affairs. The former has been rightly denominated a system of restrictions and encouragements, in which little is left to the choice and sagacity of individuals: in the latter it is supposed that national wealth, which is the aggregate of individual wealth, will increase most rapidly, where, while private property is rendered sacred by the laws, talent and enterprise are under the least possible restraint. Having spoken thus generally on the subject, we shall advance to particular details, beginning with an enquiry into

The Nature and Effects of Wealth.—Whatever be the nature of wealth, notwithstanding what has been said of it by moralists and divines, it cannot be denied that it is the object of the ambition of individuals and nations, the cause of their quarrels and contentions, and not unfrequently the reward of violence, of fraud, and injustice.

Some writers, as sir William Petty, state the wealth of a nation to consist in the totality of the private property of its individuals; others in the abundance of its commodities. Some, distinguishing *public* from *private* wealth, assign to the former a value in use, but no value in exchange; and to the latter an exchangeable value, but no value in use; and these make public wealth to consist in the exchangeable value of the net produce. Others say that wealth consists of all the material commodities which man may use to supply a want, or to procure an enjoyment either to his sensuality, his fancy, or his vanity. One defines wealth to be whatever is superfluous. M. Canard, a modern French writer, in his "Principes d'Economie Politique," calls wealth the accumulation of superfluous labour; and the earl of Lauderdale, who, like the French economists, distinguishes individual riches from public wealth, submits "that the latter may be defined to consist of all that man desires as useful or delightful to him, and the former to consist of all that man desires as useful or delightful to him, which exists in a degree of scarcity." This definition has been ably controverted in the Edinburgh Review, vol. iv. The common apprehensions, wealth, in the simplest and most general acceptance of the term, consists in the surplus of

produce above consumption, or of income above expenditure. The extent both of public and private wealth depends, it should seem, on the accumulation of this surplus, and on the manner in which it is managed and applied. When individuals and nations have not enough to supply their wants, they are poor; when their means are adequate to all their wants, they are equally removed from poverty and wealth: and when they have a surplus left, after supplying all their wants, this surplus constitutes wealth.

The passion for wealth is universal, and the history of man and civil society shews that it is always active and enterprising. It is the spring of almost all our actions. The passion for wealth is not peculiar to mankind exclusively, vestiges of it are found among some species of the brute creation, but there is this difference between them. "In the brute creation, the propensity is limited; in men, it seems to be without bounds. It has not influenced animals to advance one step beyond the instinct that directs them for means to self-preservation, while, in men, it has been the principle and promoter of intellectual faculties, of liberal and mechanical talents, of ingenious and active industry: it has afforded mankind ample means and vast resources; secured them against want, procured them conveniences, comforts and enjoyments the most exquisite; and extended, as it were, the dominion which nature destined for man, so that the distance which separates mankind from the animal creation might be measured by the distance of the most refined enjoyments from the ordinary wants, or, in other words, by the distance of wealth from poverty."

This passion for wealth, which nature designed for the most useful and beneficial purposes, has long been a constant source of disorder, violence and calamities, among individuals and nations. Ancient history, and the records of the middle ages, continually exhibit the passion for wealth, as an obstacle to the safety, the liberty, and happiness of individuals: to the independence and prosperity of nations, and to the increase and welfare of mankind: it was ever arming men against men, cities against cities, and people against people. We cannot stop to adduce facts in proof of these assertions: to those conversant in history there is no need of amplifying: they already know what course the passion for wealth formerly followed, and the share which it had in the elevation and decline of the states to which we have referred.

Modern nations are not less addicted to the passion for wealth, than the nations of antiquity, and of the middle ages; but they have been more enlightened or more fortunate in the direction which they have given to that passion; and wealth, it has been assumed, has been as productive of public and private prosperity, as it had been before of general and individual distress. Produced by labour, it rendered men attentive to the means of augmenting the productiveness of labour. They soon perceived that the free labourer who works for profit, multiplies the produce he consumes during labour; while the slave or bondman scarcely replaces what he consumes. Wealth, produced by labour, maintains nine-tenths of the people, the strength, energy, and dexterity, with which man is endowed by nature; and it develops in the remaining tenth, those faculties of the mind which seem beyond the sphere of humanity, and which bring man, as it were, nearer to the divine nature. Produced by labour, wealth banishes idleness, and the vices unavoidably connected with idleness; it renders man laborious, patient, economical, and at the same time adorns him with those precious qualities, the sources of individual, domestic, and social virtues. It binds the natives of the same land by the most powerful ties, mutual wants, and reciprocal

cal services. It has rendered nations more powerful, because every individual member is interested in the success of national affairs; all bear their weight, and all share in the advantages which they procure. This community of good and evil, to which the circulation of wealth calls every individual of the nation, affords the greatest strength which the social compact possibly can or ever did produce. This stimulus is active among industrious and commercial nations, and its strength and intensity can never be impaired or lost. Whatever may be the stock of riches accumulated through labour, it impoverishes no one; on the contrary, it enriches every individual: it is the instrument of general wealth; it increases the mass of labour, and the sum of its produce; and, consequently, augments the resources of the laborious, and the treasures of the rich. The effects of wealth produced by labour are felt alike by the nations that compose the great family of mankind, and by the individuals who compose each national family. In this system, it is the interest of all to labour, the one for the other, and to increase the stock of general wealth. The labour, industry, and commerce of every individual is useful to all, whatever portion of the globe they may inhabit. The more extensive agriculture of one country is beneficial to all laborious, manufacturing, and trading nations; it increases the produce destined for general consumption, which, in its turn, augments population; and this augmented population affords new consumers of the productions of the industry of every nation. Thus all nations share in the prosperity of each, and the portion of each is proportioned to its labours, manufactures, and commerce.

Of the various Systems concerning the Sources of Wealth.—The most ancient system concerning the sources of wealth, derives wealth from foreign commerce; that is, from that commerce in which one nation sells more to other nations than it purchases, and is paid for the surplus of its sales over its purchases in precious metals. This doctrine was adopted, without any limitation, by the authors who first wrote upon political economy in England, Italy, and France, and up to the middle of the eighteenth century; and it still prevails in the opinions of most individuals, nations, and governments; almost all consider commerce as the true way to grow rich, and by commerce they understand the exchange of commodities with foreign nations. In proof of which, it is said, with reference to Phœnicia, Alexandria, Carthage, Rome, &c., that if we ascend ever so high in the history of wealth, we find that wealth always followed the direction of foreign commerce, and remained faithful to its banners and ships. The question is, How does commerce enrich a country? By what channels does it pour its benefits? And how is the productiveness of commerce to be increased, and its prosperity insured? Most writers supposed that foreign commerce enriches a country by the plenty of gold and silver which it causes to circulate, and hence governments endeavoured to retain the precious metals, or to invite them by encouraging national manufactures, by directly or indirectly prohibiting the produce of foreign industry, or by procuring to the produce of national industry an easy and even privileged introduction into foreign countries. Such is the system which places the source of wealth in foreign commerce, and which, on that account, has been called the mercantile system. Davenant, though a partisan of the mercantile system, did not, like many of its advocates, limit its advantages to the abundance of precious metals which it accumulates in a country; he lays it down as a principle, that every trade is advantageous, provided its returns be more considerable than its exports, even though the returns should consist in perishable commodities.

The mercantile system was general, till some discussions took place on the forced lowering of interest, and an excessive paper circulation led to the inference, that gold and silver, which till then had been considered as true wealth, are only the instruments of its circulation; and this view of the subject, almost as soon as it was started, gave birth to fresh enquiries into the nature of wealth. It was now that M. Quesnai acquired great celebrity by the new views of his "Theory of the Sources of Wealth." He does not place the source of wealth in commerce, because all its operations are limited to the conveyance of the produce of the soil and industry from one place to another. Neither can industry aspire to this eminent prerogative; because it only transforms the territorial produce into different shapes, without adding any thing to its quantity; and because its productions are only the material representatives of the produce of the soil, which the manufacturer has employed or consumed. Land alone, according to this system, is the true source of wealth, because it produces every thing that man desires for the supply of his wants, for his enjoyments, his pleasures and his fancies; and because it constantly reproduces a quantity superior to what has been consumed to effect its reproduction. This excess of reproduction, this gratuitous gift of the soil, this net produce, is the only fund that can be employed to encourage the progress of labour, to reward its success, to promote improvements, and indefinitely to increase the sum of public and private wealth.

Agricultural labour, by a necessary consequence, is the only productive one; all other labours are barren and unproductive. By another consequence not less just, the surplus of the produce of the soil above all expences to obtain it, being a gratuitous gift of the land, ought to belong to the land-owners; they alone can distribute it to the other classes of the community, a circumstance that gives them the character of paymasters, and to those who receive it the character of mercenaries. On this respective paying and being paid, the economists built the relative rights of governors and governed. They asserted, that the land-owners, as paying, ought alone to share in the government; and that all those who are paid, cannot take any part in it without an evident and manifest usurpation; and finally, M. Quesnai maintained, that the net produce being the sole disposable wealth, the public revenue can only be derived from part of this produce; that the act of sharing in the net produce renders government a co-proprietor of the soil; and that this co-proprietorship constitutes its rights to government, which right is limited by its co-proprietors.

At this period, the principal writers on political economy, and who defended the mercantile system, were Genovesi, Beccaria, Carli, and Verri, all Italians, who made wealth depend on the unlimited liberty of foreign commerce, and triumphantly refuted the system of the French economists. At this time the Italians very much surpassed the writers of the rest of Europe in the science of which we are treating, and they kept this superiority till Adam Smith enquired into the nature and causes of the wealth of nations, and combating the mercantile and agricultural system with weapons equally formidable, assumed other principles, and was, as it were, the creator of the science.

Notwithstanding the high rank which Dr. Smith holds, lord Lauderdale has asserted, that he had no fixed opinion as to the sources of national wealth, and quotes some passages from his celebrated work in defence of this assertion. In one place Adam Smith says, "that the annual labour of every nation is the fund which originally supplies it with all the necessaries and conveniences of life, which it annually consumes, and which consist always either in the immediate

produce of that labour, or in what is purchased with that produce from other nations." In another place, he says, "lands, mines, and fisheries, replace with profit not only the capitals employed on them, but all other capitals employed in the community;" in a different part of his work, it is stated, "that the real wealth of a country consists in the annual produce of its land and labour;" then, "that the land and capital stock are the two original sources of all revenue, both private and public; capital stock pays the wages of productive labour, whether employed in agriculture, manufactures, or commerce;" and lastly, he asserts, that we ought to consider "land, labour, and capital, as being all three sources of wealth; for whoever derives his revenue from a fund that is his own, must draw it either from his labour, his stock, or his land." These passages are, no doubt, difficult to reconcile; nevertheless, upon an attentive review of the whole work, it seems certain, that he placed the source of wealth in labour, which fixes and realises itself in some particular subject, that lasts for some time, at least, after that labour is past, whose power is augmented by sub-division, which is developed by trade, improved by competition, and proportioned to the extent of the market, capital, and wages.

Ever since Dr. Smith published his great work, no other theory has been proposed, and though he may not have assigned the limits of the science, nevertheless he has so well determined its principles, that it will be impossible to miss or go astray from the doctrine which he means to establish. Lord Lauderdale, who has criticised some fundamental points of Dr. Smith's, derives wealth from land, labour, and capital; and he goes farther, he attempts to determine the share of each of these sources in the formation of public wealth.

Such are the various systems concerning the sources of wealth. Though they appear at variance, their difference is little more than nominal, and of very little importance to the science. The partisans of the mercantile system do not assert, that the precious metals which are accumulated by commerce, in a country, are not derived from the produce of land, labour, and capital; they even take it for granted that it is so. Again, the French economists do not pretend to believe, that the soil spontaneously yields wealth, so far from it, that they allow, if land be the source of wealth, it is agriculture that multiplies it; and by agriculture they understand the labour and capital of the husbandman; they even admit that the exchangeable value of the agricultural produce is the measure of wealth of a nation; and that this exchangeable value can only be obtained by the free concurrence of the home and foreign trade; in this way the economists themselves derive wealth from land, labour, capital, and commerce. By placing the source of wealth in labour, which fixes and realises itself in some permanent object, Dr. Smith likewise admits the co-operation of land, labour, capital, and commerce. Finally, the system of the earl of Lauderdale differs from the other systems only as far as his lordship assigns a particular importance to capital. In every other respect the noble lord coincides more or less with the agricultural system, and the system of labour.

Thus, it is evident, that it is not properly concerning the sources of wealth that the different systems vary; they all, in fact, acknowledge that wealth is produced by the concurrence of labour, land, capital, and commerce; they chiefly differ respecting the more or less important share which they assign to each of these causes; in this consists their difference, and in this lies all the difficulty of the science. The problem to be resolved is this: of the three

causes, labour, capital, and commerce, which is best calculated to produce public and private wealth?

Of the various Systems concerning Labour, as a Source of Wealth.—In every system of political economy, labour has the greatest share in the formation, increase, and preservation of wealth. If the labourer find the precious seeds of wealth in the spontaneous gifts of the soil, he fertilises, multiplies, varies them by his activity, his skill, and his industry; and obtains results so new, so different, and so remote from their nature, that he may almost be regarded as the creator, rather than as the co-operator in obtaining wealth, and hence Canard defines wealth to be "an accumulation of superfluous labour."

On this subject many interesting questions occur: Is this productiveness of wealth exclusively reserved to one, peculiar to a few, or common to all sorts of labour? Is there, among the different kinds of labour, any one more especially productive, and favourable to the progress of wealth? Is agriculture more conducive to wealth than manufactures and commerce? What are the means of rendering these different labours more productive and more profitable? Which are the obstacles that oppose their progress and impede their success? These questions it will be interesting to investigate and appreciate, as far as the nature of our work will allow.

The economists assign, exclusively, to agricultural labour the power of producing wealth, and regard every other kind as barren and unproductive. They do not deny the usefulness of what they call unproductive labour,—they only limit its utility; and assert, that with regard to manufactures, this utility consists in the adaptation of the agricultural produce to consumption; with regard to commerce, in its conveyance to the consumer; and with regard to sciences, literature, and the arts, in their power of defending, protecting, and encouraging all kinds of labours, in multiplying the enjoyments of life, and in extending and improving the moral and intellectual faculties of man; services which, notwithstanding their importance, only modify, or transport the agricultural produce, add nothing to its quantity, and yield no new produce; whence they infer, that agricultural labour is the only productive one. This system was not adopted by any English or Italian writer of celebrity; of late years it has met with an able defender in Garnier, a French senator, who translated the *Wealth of Nations* into his own language, for the purpose of writing notes and comments, which he trusted would render the system of the economists triumphant over the doctrines of Smith, and all the writers who have opposed his favourite opinion. In our country, at a still later period, the economists have found a most ingenious advocate, in Mr. William Spence, at least to their main principle, that the soil is the grand source of wealth. See his tracts, entitled "*Britain Independent of Commerce;*" and "*Agriculture the Source of Wealth to Britain.*"

In the present state of civilization, we know labour only through the exchange of its produce; in this exchange, every labourer, every family, every nation, find means of supplying their wants, procuring some comforts, and reaching a more or less elevated point of prosperity, power, and happiness. Hence labour appears to contribute to wealth, merely through its produce being exchanged, and by this exchange alone, its particular and general properties ought to be estimated. But the French economists consider it very differently; they divide it at once into productive and unproductive. The value of labour cannot be separated from the exchange of its produce; for if the produce of labour be not exchanged, every individual would be reduced to work to procure the articles necessary for his food, his raiment,

ment, and his dwelling; and under such circumstances, ages must roll away, before the unexchanged labour of individuals would produce any wealth. Agricultural labour, then, cannot alone be productive of wealth; and if, like all other kinds of labour, it co-operate in the creation of wealth, merely by the exchange of its productions; if it has no value, but through this exchange, it cannot be called the only productive labour, in opposition to all other kinds.

Of agricultural produce, one part is destined to replace that which has been consumed by the husbandman during his labour; this part has no value of its own, it is merely the instrument of agriculture destined to supply absolute and indispensable wants, and cannot contribute to the formation of wealth. The other, called the net produce, has no value as long as it remains in the hands of the husbandman. His stock, as stock, is no wealth to him; it is only when this net produce departs from him to be consumed by others, that it becomes useful, obtains a value, and forms one of the elements of wealth. There are only two ways by which this net produce can be transmitted to others, *viz.* by a free gift, or by a cession against an equivalent. "The former," says a good writer, "cannot be practised for any length of time, and has not yet contributed to the wealth of any nation. Hospitality among those who are on the lowest steps in the scale of civilization, benevolence among those who are more civilized, and charity among those whose civilization is heightened by religion, have never been of great assistance to augment the population, wealth, or power of any nation." The second way, the cession of the net produce against an equivalent, alone confers a value upon agricultural labour; but in this case its value is relative, and, like the value of all other labour, is dependent on its being exchanged.

Dr. Smith, who refuted the position of the exclusive productiveness of agricultural labour, in a great measure, without, probably, being aware of it, by accusing of unproductiveness any labour which, after it is over, does not fix and realise itself in some permanent object; by denying the productive faculty to any labour which does not terminate in a material and permanent produce, and by supposing that wealth depends on the numerical proportion between the individuals employed in what he calls useful labour, and those who are not usefully employed, in fact, supported the principle which he had overthrown. On this account he wished to reduce the number of labourers who are not usefully occupied, and to increase that of those who are usefully employed, not reflecting that could this be accomplished, the formation of wealth would be impossible, because consumers would be wanting for the commodities produced, and then in future that which was not likely to be consumed would not be produced. Hence labours exclusively devoted to luxury, pomp, and even the most frivolous expences, are productive; because they co-operate to increase the population and wealth, and contribute to the splendour and power of states. Care must, however, be taken not to stretch this principle beyond its true limits; but so long as productive labours pay freely and spontaneously for what may be called frivolous labours, there is no fear of their extending beyond the boundaries which private and public wealth require; and it is on this account, that every kind of labour is productive, and contributes more or less efficaciously to the increase of public wealth, because it necessarily occasions the productions with which it is paid.

The question now occurs, as to the kind of labour, if any, which is most productive, and most favourable to the growth of wealth. This enquiry is of great importance; it is the

foundation of the science, since labour has the greatest share in the formation, increase, and preservation of wealth. "It is remarkable," says M. Ganilk, "that almost every writer on this controversy has regarded the labour, which is preferred in his own country, as the most productive. Thus, with the exception of Adam Smith, the English writers assign the first rank to commerce and manufactures. Dr. Smith not only placed agriculture above commerce and manufactures, but he attempted to assign different degrees of productiveness to different labours, and in his scale arranged agriculture at a very great distance above all other labours. In France, where agriculture has always predominated, the writers on political economy have generally granted agriculture the precedency before commerce and manufactures. In Italy, opinions have been divided, and according as they inhabited either the interior or the maritime provinces, the writers on subjects connected with political economy have extolled agriculture, or manufactures and commerce. It may, in this state of things, be worth while attempting to determine whether agriculture, or commerce and manufactures, are most conducive to the advancement of public and private wealth, to the welfare of individuals, the prosperity of nations, and their absolute and relative power; that is, to determine which of these labours obtains the greatest value for its produce on its being exchanged, which circumstance is, at once, the promoter, regulator, and arbitrator of wealth.

By means of agriculture, men may succeed in procuring corn and cattle for their food, and raw materials for their clothes and habitations, but here the progress of wealth stops: they would not think of producing any surplus, or of accumulating any stock. Or supposing that a surplus had been stored up, they would have no inducement to cede this to others, to whom idleness or accidents should have rendered it necessary, because no equivalent could be obtained, all agricultural productions being uniform and identical in the same country. But suppose the combined progress of agriculture and population should lead to the division of labour, and the separation of the labouring classes, what, under such circumstances, would be the growth of public and private wealth? As agricultural productions afford the means of subsistence, the wages of all labour, they would be distributed in proportion to the wants of the husbandmen, and the progress of agriculture; consequently, the share of the industrious classes would be small, and would not allow them to extend, to prosper, or to aspire to a free and independent condition. Supposing even that agriculture could by itself, as it has been asserted with regard to Egypt, China, and North America, raise a numerous, rich, and flourishing population, it would not be productive of any great moral and political virtues, of the energy, public spirit, and eminent qualities, which alone form really great nations, and render their inhabitants illustrious. Neither could a mere agricultural nation possess any means of resistance against foreign invaders, of power, and grandeur; hence we see the deficiency of the agricultural system with regard to political independence, national power, and public wealth. These defects equally shew themselves in the small extent of general labour, in the insulated condition of individuals, in the weakness of government, and in national impotency and general indifference; of course agriculture cannot be considered as the most productive of all labours, much less as forming "the natural constitution of a government the best adapted to the human race."

Do manufactures and commerce afford the advantage which seem to be denied to agriculture? If it be said that men begin by tilling their lands before they build ships

to go in search of new lands beyond seas; it may be answered, that those who are forced to devote themselves to maritime commerce, soon acquire that industry, the offspring of want, which does not stimulate other nations. This industry acquires great superiority, when labour is subdivided, when the manufacturing and trading classes, breaking the fetters which kept them enchained to agricultural classes, labour without waiting for the demand, submit their productions to commercial exchanges, and derive from the equivalents obtained in return, their subsistence, their comforts, and their wealth. Their economical notions then take a new course, their relations become complicated; the results of their commerce are lost in an obscurity so profound, that they are not always clear to the most acute and best exercised understandings, and their advantages and inconveniences are frequently mistaken.

As soon as the labouring classes, whether agricultural, or manufacturing and commercial, carry to market the surplus of their produce above their consumption, and exchange one for the other, general industry receives a fresh impulse, follows another direction, and attains a higher destiny. The producer does not wait for the produce being consumed before he reproduces more; neither does he limit his productions to the local consumption, or to his present and actual wants. In this system, every producer is a consumer; all productions are thrown into the scales of a general exchange, and commerce begets general production by general consumption. The labour of the husbandman is no longer confined to his necessary subsistence: he labours for a surplus, to be enabled to purchase objects, the sight of which, in the market, may inspire him with the desire of possessing them. The industrious do not now wait for orders to labour; they create, invent, perfect the means of rendering life convenient, comfortable, and agreeable; of multiplying enjoyments and satisfying every desire. They are no longer reduced to a mercenary hawking, but collect and preserve in their warehouses the surplus of productions which have not met with any demand, and endeavour to provide consumers for it on every point of the globe. In this way the trading classes produce, preserve, and multiply wealth.

Riches do not now consist in the proportion of produce to wants, of income to expenditure, of production to consumption; but in the accumulation of a surplus stored up for unforeseen wants and enjoyments. This surplus is a resource for the existing population against the uncertainty of the seasons, and it acts as a premium for their increase. Individuals are multiplied in proportion to the surplus that is accumulated, and nations prosper in the compound ratio of the mass of their surplus and the increase of their population, and public wealth results from the exchange of the surplus produce of general labour.

If property, the accumulated surplus of labour, be the spring of labour and wealth, the foundation of social order, and the support of public and private prosperity; how much must its power have been augmented by the abundance of gold and silver, which caused property to reach even the poorest classes of the community, which might be kept or transmitted, stored up or used at the call of their passions and dispositions, and according to the circumstances in which they were placed. By diffusing the advantages of property among the labouring classes, the precious metals served as a sort of bond of union, ranking them with the other classes, under the general name of proprietors. Thus greater degrees of civilization were obtained, and the people, otherwise but a few degrees above barbarism, became inspired with sentiments of justice and mutual benevolence. Now the effects which we have described as necessarily resulting from

the plenty of precious metals, considered merely as merchandize, belong exclusively to manufactures and commerce, and could not have taken place in the agricultural system, which shews at what a distance those two kinds of pursuits are from each other, and how greatly their reciprocal influence on labour and wealth differs. "How confined," says M. Ganilk, "the action of agriculture, which has nothing but wages to offer to manufactures and commerce, and builds upon the portion of its produce destined for such wages all its hopes of wealth. How extensive, on the contrary, the action of manufactures and commerce, which puts all the powers of labour into motion, multiplies its produce by exchanges, and redoubles their efforts in proportion to their success. In the agricultural system, labour is paid for by the idle land-owner, who fancies himself the richer for having less to pay: in the mercantile system, labour rewards labour; and even the idleness of the wealthy it never receives without giving, nor gives without receiving. The universal exchange of the produce of labour enables nations, reciprocally, to encourage each other to fresh labour by the hopes of new enjoyments; immense deserts, which nature had doomed to everlasting sterility, are peopled, cultivated, and fertilized."

This superiority of manufactures and commerce over agriculture, is proved by the history of wealth among all ancient and modern nations. Tyre, Sidon, Corinth, Athens, Syracuse, and Carthage, in ancient times acquired, by their industry and commerce, riches of which there is no example in any agricultural nation; and their wealth raised them to a degree of power and consideration to which their territory and population would not have allowed them to aspire. In the middle age, Constantinople, by her industry and commerce, preserved the wealth acquired by her arms; her riches protected the people against the attacks of the Barbarians; prolonged her resistance, and retarded her fall. In modern times, Venice, Genoa, Florence, the Hanseatic towns, Holland, and England, have at different periods alternately acquired, by manufactures and commerce, riches which have enabled them to act an important part in the political world, and even placed some of them, as our own country, in the rank of preponderating powers. With respect to Holland, Davenant observes, its territory contains only from eight to nine millions of acres: her population does not exceed two millions, and yet what a figure did she make in the seventeenth century! what wars did she sustain! what forces did she resist, and to what power did she attain! She is subject to frequent invasions: her harbours are bad: she annually spends immense sums not to be swallowed up by the sea; and all these difficulties have been overcome by her indefatigable industry, and her gains from commerce.

In comparing the advantages of agriculture with those of commerce and manufactures, it has been observed that agricultural produce is common to all countries, and has every where to struggle against a general competition; while commerce and manufactures are peculiar only to some countries, and some governments, and have of course no general competition to encounter. Agriculture does not require any great talents; nature performs a great part of the work: its improvements are slow, and the discoveries by which they may be hastened are soon known to all agricultural nations. The case is different with manufactures and commerce; they require a certain degree of intelligence, are continually improved, reach to a degree of superiority difficult to be attained, and rarely lose the superiority which they have once acquired. Agriculture is subject to accidents: the risks of industry and commerce are less numerous, and less fatal. Agriculture cannot extend its produce

duce beyond the extent of the territory and agricultural population; neither can it accumulate large quantities of its productions, because they would require immense costly buildings, and because they rapidly perish. Manufactures and commerce may multiply their productions without increasing the number of hands employed, and frequently even by diminishing their number. These productions may be stored up, at comparatively small expences, in proper warehouses, without any fear of their decaying before they are sold. Their consumption finds no limits but in the numbers of mankind, and in the progress of general wealth; that is to say, it is unlimited. Lastly, agriculture cannot build great hopes on the improvements of its methods. Notwithstanding the encouragements which have been bestowed upon agriculture by governments, and the efforts of learned societies, it has not, among the most enlightened nations, advanced much beyond the point at which it remains among the most ignorant; while the improvements of manufactures and commerce have been uninterrupted within the three last centuries, and promise still greater success from the discoveries of the arts, and the development of all the productive powers of labour.

Hence it is inferred, that without monopoly, or particular privileges, manufactures and commerce contribute more efficaciously than agriculture to the progress of wealth, and give to manufacturing and trading nations an absolute preponderance over agricultural nations.

It has, however, been said, that manufactures and commerce have only a temporary and precarious superiority over agriculture, and that the progress of knowledge and the arts are calculated not only to re-establish the equilibrium between those different labours, but even to incline the scales in favour of agriculture. To this it has been replied, an agricultural nation cannot become a trading and manufacturing one, but by the slow and uncertain progress of time, by the growth of local wealth, and the improvement of knowledge and the arts, or by a concurrence of circumstances over which they have no controul, and on which they cannot rely. If they attempt to force the natural order of things, and all at once to appropriate to themselves the benefits of manufactures and commerce, they cannot accomplish this but by taking from agriculture part of the hands and capital which caused it to flourish; that is, by injuring in a most material degree that upon which their subsistence depends. On the other hand, the unskillfulness and inexperience of new manufacturers and merchants yield, for a long time, none but productions of inferior value, and which, of course, cannot stand the competition in the general and particular market. The attempt, therefore, of transforming at once part of an agricultural nation into manufacturers and traders, is equally prejudicial to agriculture, manufactures, and commerce, and is accordingly productive of the decay of national wealth.

On the other hand it may be said, that so far from having any thing to apprehend from the progress of manufactures and commerce among agricultural nations, this progress would afford manufacturing and trading nations new means of prosperity and wealth; because when an agricultural country, supplied by foreign manufactures, establishes national manufactures to supply herself, and to share in the benefits of the general market, she gives to her labour and capital a direction more useful and more profitable than before, and consequently becomes richer by all the profits derived from her new manufactures and trades. The new demand, thus created, of the produce of ancient industry necessarily raises its price, increases the gains of the ancient producers, favours their manufactures and commerce, and

accelerates the growth of general wealth. The increase of national wealth occasions a larger importation of foreign productions, and these imports are necessarily an increase of wealth to the producing nations: hence the introduction of manufactures and commerce among agricultural nations, which is to them an increase of wealth, cannot be prejudicial to the prosperity of manufacturing and trading nations.

The trade of nations with each other has been too frequently regulated by the example of the individual trade of a country; and as it is found that the number of manufacturers and traders of a village or town cannot be increased, without every one of them suffering more or less from the competition, it was inferred that the same thing would happen to manufacturing and trading nations, in proportion as their numbers increased in the world. But the cases are essentially different. The industry and trade of a village or town draw all their means of getting rich from the wealth of the place, and can prosper only in proportion to this wealth, and its increase, over which they have no controul. Thus confined, trade and industry are merely passive, and destroyed by their own efforts. But this is not the characteristic of manufactures and trade generally: they act a more important part in the formation of wealth, and so far from being burdensome, they are its firmest support. Wherever they enjoy all their elasticity, they bestow productiveness upon existing wealth, accelerate its progress, and carry it to the highest pitch which it can attain; they assign to labour the most beneficial direction, to capital the best employment, and to the circulation of produce the most rapid and most profitable activity.

“When sir Richard Arkwright,” says M. Ganilk, “invented the cotton spinning machine, he shortened that kind of labour by two-thirds, and rendered it twenty times more productive than it had been before: he improved the manufacture of cotton, so as to make it an object of luxury to the rich; and lowered its price, so as to enable the less fortunate class to wear better garments: in short, he insured to this kind of industry a superior value in exchange over the other productions of general industry; and the result of his invention was less labour, and more produce, smaller expences, and greater value. This saving in labour and expence, this increase of produce in value and quantity, is a real increase of public and private wealth, and in every respect assimilates the skilful mechanic, to whom it owes its birth, to the husbandman, who, by his labour, increases agricultural produce. What is here observed concerning sir Richard Arkwright, applies to all who have made any improvements in science, manufactures, and arts, from the invention of the plough to the spinning machine. They all were creators of wealth in the ratio of the expence saved in the performance of labour, or of the higher value given to its productions.”

Commerce is exactly on a par with manufactures, and contributes in the same manner to the growth of wealth. Merchants, by following navigators on all coasts, and travellers in all climates, to open commercial communications with their inhabitants, by bringing to market the produce of unknown countries, and in exchange for this, which is of no value to the owners, giving them other useful and agreeable productions, are actually creators both of this new produce, and the equivalents which serve to pay for it, and augment public and private wealth by the whole value of this produce, and its equivalents. There is, therefore, a kind of industry which is not paid for by local wealth, which draws its wages from the wealth which it creates, and which can never obstruct any kind of manufactures; which can neither be impoverished by, nor impoverish any: all

all may prosper by each other's side, lend each other mutual support, and be so much more beneficial to general wealth as they are more numerous.

The superiority of the mercantile over the agricultural system, is particularly manifest with regard to political power and independence. In the mercantile system, the manufacturing and trading classes are able to spare, for the service of the country, a great number of young men, without any prejudice to general labour. The diminution of workmen is repaired by more exertion, more assiduity, and a better employment of time on the part of the other labourers. And should the produce be diminished, its value is increased by its scarcity, the national income always remaining the same. Even in war, manufacturing and commercial nations find in their foreign relations, in the circulation of their produce in all parts of the globe, and in their credit, facilities and resources from which agricultural nations are debarred: so that, on the whole, we may conclude, that if labour has the greatest share in the formation and progress of general wealth, their productiveness is not the exclusive lot of any particular labour, but is common to labour in general, and eminently connected with manufactures and commerce. This concurrence of labours is calculated to produce wealth, without any other pre-eminence than that which is obtained by the exchange of their productions. By this system all follow their own inclinations, develop and improve their own faculties, encourage and improve each other by a noble emulation, and are every instant of time reminded of their need of each other. Though scattered over the globe, speaking different languages, and following different customs, men are no longer strangers to each other; they labour one for the other; they correspond together, although separated by deep seas, severe climates, inaccessible mountains, and inhospitable deserts, and thus the produce of general labour is circulated all over the world.

We are now to enquire into the *causes which invigorate labour, improve its powers, and meliorate its produce*. Dr. Smith ascribes all its improvements to the division of its parts, or the confiding to several hands the different branches of the same labour, which gives each labourer more dexterity, avoids the loss of time occasioned by the change of labour, and is conducive to the invention of machines which shorten and facilitate labour, and enable one individual to perform the labour of many. On this principle the writer just referred to reared his system of political economy, and it has generally been considered as one of the facts which have most accelerated the progress of political economy, and most contributed to the celebrity of its author. But the earl of Lauderdale has controverted the principle: he contends, in the first place, that the idea of the effects of the division of labour is not new; that it has been recognized from the days of Xenophon; and that on this principle professions in ancient times had been made hereditary: he adds, that the great number of distinct operations that contribute towards the formation of some of the most trifling manufactures, as pin-making, is not derived from any degree of habitual dexterity, or from the saving of time as results of the division of labour, but from the circumstance of supplanting and performing labour by capital. Without the machinery, which the faculty that man possesses of supplanting labour by capital introduces, no great progress could have been made in the rapidity with which pins are formed; and one man, with the use of this machinery, though he goes through and performs all the operations himself, must manufacture more pins in an hour, than would be formed in a month, or a year, by any number of men among whom labour could be divided, if unaided by the circumstance of part of

their labour being supplanted and performed by capital. The noble earl produces facts in support of his position, and concludes generally, "that it is to the introduction of some sort of machinery; to the effect of the application of chemistry to manufactures; and to the increase or command of capital enabling the manufacturers to reduce the price of manufactured commodities, that we are indebted for the wealth and comforts generally enjoyed by civilized society."

It is of no consequence to the general question whether the effects of the division of labour were or were not known to the nations of antiquity, but it is important to enquire whether machinery or the division of labour be more conducive to develop the energies of the labourer, improve his faculties, and increase his produce. The division of labour imparts to the workman not only greater facility, dexterity, and intelligence, to perform the business which he has undertaken, but it distributes every part of the labour in the manner best calculated to hasten and improve its performance: so that if it even were true that the labourer receives greater assistance from machinery than from the division of labour, yet it would appear, that with regard to labour in general, the distribution of the different parts of labour renders services superior to those of machinery. Hence the division of labour appears to be entitled to be compared with the direction of labour. Machines may be more diligent, more active, and less expensive labourers: but the division of labour is the undertaker that directs them, regulates their motions, and guides them to their end by the straighter and, of course, the shortest line. The division of labour prepares the links of that immense chain which connects individuals with individuals, families with families, nations with nations, and converts the whole world into a single workshop,—a general manufactory. If, however, the division of labour be so advantageous in manufactures and commerce, the thing is not at all evident in agriculture. It is still a subject of debate, whether large or small farms are more beneficial to a country. Dr. Price, in his *Reversionary Payments*, said there was no maxim of political economy more true than this, that the division of property, that is of land, into small farms, increased population, and, of course, the strength of the country. Arthur Young, in his *Political Arithmetic*, assumes that it is not the number of people, but their wealth which constitutes power; and that population ought to be subordinate to agriculture, so that the abundance of produce should constantly precede the increase of population. As it is admitted that large farms yield a larger quantity of produce, than they would if divided into small ones, or what is the same, they yield an equal produce at less expence; should this saving of costs be obtained at the expence of the husbandmen, so as to diminish their number, population even would not be a sufferer, and wealth would be a considerable gainer. The husbandmen who are become useless to agriculture, still find subsistence in its produce, but being obliged to reproduce, at least, its equivalent by other labour, general wealth is increased by the total sum of this equivalent, and thus it is inferred, that with regard to population and wealth, the division of labour applied to agriculture, or the system of small farms, is as hurtful as it is beneficial in its application to manufactures and commerce.

To enquire into the actual utility of machines, of which lord Lauderdale speaks so highly, we must distinguish between machines that perform labour beyond the strength of man, and those that perform labours which man is capable of performing. With regard to the former, they are always profitable, and can never be prejudicial, since they afford

productions

POLITICAL ECONOMY.

productions which exceed human strength and dexterity, and could not exist without their aid. With respect to those machines which barely supplant the labour of man, it has been remarked, that they are not prejudicial to nations whose prosperity is on the increase, because they merely supply the want of hands; but nations whose wealth is stationary, or retrograding, have no need of them. This distinction does not seem to rest on any solid foundation, if it be considered that they are not introduced suddenly, but slowly and partially, and the labourer, who through the erection of machines is deprived of his usual employment, likewise obtains his wages from new manufacture, the establishment of which every where follows the increase of productions and general wealth, and thus the labourer is not likely to suffer by the introduction of machines, whatever may be the state of the country. To this it may be added, that if any thing can arrest the decline of a country, and restore her to prosperity, it would be the use of machinery, and the concentration of small farms into large ones, because they would augment the produce of her labour, and diminish its cost. And wherever there is an increase of produce at a smaller expence, there is an increase of wealth, and an increase of wealth is uniformly followed by an increase of population.

It has been asserted, that wealth acquired by industry may be useless to the increase of the industrious population, and even augment to their prejudice the agricultural population, by which they are supplied with the raw produce of agriculture. But in reply it is said, that an agricultural country increases her raw produce only as far as trading countries insure its sale. The increase of the wealth and population of agricultural nations depends, therefore, on the industry and population of the manufacturing ones. But in what proportions does the increase of wealth and population take place in both countries? It has been said by Garnier, that one day's labour in the manufacturing country, is equivalent to two or three days' labour in the agricultural country; therefore, while the wealth and population of the agricultural country are increased in the proportion of one to three, the wealth and population of the manufacturing country augment in the proportion of three to one. Again, the raw produce of an agricultural country is not by any means so well calculated to increase population as a manufactured produce; for the raw produce does not remain with agricultural nations: it passes over to the manufacturing nations. This raw produce is food for population, while the manufactured produce serves at the most as raiment and household furniture to agricultural nations. In this exchange of food for garments, the population that gets the food in a triple proportion to that which gets clothing, must necessarily increase in a triple proportion; because it is food and not clothing which augments population. This result, which cannot be disputed, ought to teach agricultural nations the necessity of turning their attention to manufactures and commerce, on account of their superiority over agriculture.

The inference deducible from what is gone before is, if our reasoning be conclusive, that the means of increasing the power of labour, of augmenting its produce, and meliorating its quality, consists, with regard to agriculture, in large farms; and with regard to manufactures and commerce, in the division of labour and the use of machinery. These means give to labour the highest degree of utility which it is capable of attaining, particularly if their effect be not impeded or destroyed by various obstacles, so much the more fatal as opinions are divided concerning their influence. These obstacles, said by some philosophers to be prejudicial to the progress of labour, and by others considered as bene-

ficial, are, the slavery of the labourer, apprenticeships, corporations, and low wages. On these subjects we cannot enlarge, but shall give certain statements illustrative of our subjects, chiefly taken from some admirable papers published in the beginning of that useful and respectable work entitled the "Monthly Magazine," by the late Mr. J. J. Grellier, once an able contributor to the New Cyclopædia. Assuming from the parliamentary returns of the population of Great Britain, including the army and navy, at 10,820,370, he endeavoured to distinguish, as nearly as he was able, the proportion of those who subsist by the labour of others, to those by whom they are supported; and of the unproductive, though, in most instances, useful labourers, to those on whose labour the annual produce, and consequently all additions to the national stock, depend.

It appears, that of the whole number of persons living, more than one-fourth are children under ten years of age, who therefore contribute little or nothing to their own maintenance; for though in a few manufactures, children under this age are employed, they are more than counterbalanced by the greater number who remain unemployed for several years beyond the age of ten. After deducting 2,705,092, it will be found, that one in about 28 of the remainder, or 289,831, are incapacitated by old age or infirmities from useful labour, including all persons in hospitals, &c. and most of the inhabitants of alms-houses, and other charitable establishments. But of those who are supported by the labour of others, or by the property of others, which comes to the same thing, there are many who follow a species of employment, by which they obtain this property, which employment is, however, of no benefit to the country, as it is not only unproductive, but useless, and in many instances injurious to the community; such are gamblers, swindlers, thieves, prostitutes, beggars, gipsies, &c. whose aggregate number, according to Mr. Colquhoun's estimate for the metropolis, probably exceeds considerably 150,000. The convicts and prisoners confined in the different prisons of Great Britain, and on board hulks, are usually about 10,000 persons, whose labour is lost to the community, for the work which is performed in some of our gaols scarcely deserves mention. There is also a class of a very different description, who are supported by the labour of others: this is the nobility and gentry, whose exemption from labour is considered as a part of their honour and distinction; some, it is true, hold employments under the government, and a few are engaged in agriculture or trade; but the majority, who subsist on the income they possess, without following any useful occupation, is probably not less than 5000.

These numbers include persons of both sexes, and are all rather below the truth than beyond it; they amount together to 3,159,923 persons, and being deducted from the whole population of 10,820,370, shew the number of those who work to be 7,660,447. But it is well known, that of those who gain a subsistence by their labour, many follow employments which, though more or less necessary and useful, do not, in the least degree, increase the quantity or value of the produce of the country; the number of these unproductive labourers is nearly as follow:

The army, officers and privates, including half-pay, commissaries, agents, &c.	} 200,000
The navy, ditto	} 127,000
Officers and clerks employed in collecting the revenue, and in other offices under government	} 6,500
	<hr style="width: 100%;"/>
Carry over	333,500

POLITICAL ECONOMY.

Brought forward -	333,500
Clergy of the church of England and Scotland -	18,000
Ditto, dissenters of every denomination - -	14,000
Schoolmasters (exclusive of clergymen) and } Schoolmistresses - - - - - }	20,000
Judges, counsel, attornies, sheriff's officers, jailors, } and all persons employed in the execution of } the laws, except constables, headboroughs, &c. }	14,000
Players, musicians, dancing masters, &c. -	5,000
Women supported by their husbands' labour -	500,000
Female servants of all descriptions - - -	650,000
Male servants - - - - -	150,000
	1,704,500

It must be confessed that the number of some of these classes of persons cannot be ascertained with much precision: this, however, is of no great importance, if the total is not far from the truth, as the object is chiefly to shew the proportion of productive to unproductive labourers; the latter may be distinguished according to the following statement:

Merchants, brokers, factors, and others depend- } ing on foreign trade - - - - - }	25,000
Clerks to ditto, and in the offices of commercial } companies - - - - - }	40,000
Seamen in the merchants' service, including the } coasting-trade and fisheries - - - }	144,000
Lightermen, watermen, &c. - - - - -	3,500
Persons employed in the different manufactures	1,800,000
Mechanics not immediately belonging to the } manufactures, such as carpenters, bricklayers, } masons, wheelwrights, shipwrights, boat- } builders, &c. - - - - - }	50,000
Painters, engravers, carvers, and other artists -	5,000
Shop-keepers, viz. butchers, bakers, publicans, } fishmongers, poulterers, pastrycooks, grocers, } chandlers, pawnbrokers, apothecaries, &c. }	150,000
Farmers, graziers, and all other persons em- } ployed in agriculturre, including millers, } mealmen, farriers, horse-doctors, &c. - }	2,000,000
Wives and families of most of the above classes } assisting in their occupations, or following } other employments of profit - - - }	1,738,447
Total -	5,955,947

The whole population of the country will thus appear to consist of nearly the following proportions:

Supported by others' labour - - - - -	3,159,923
Unproductive labourers - - - - -	1,704,500
Productive labourers - - - - -	5,955,947
Total -	10,820,370

It thus appears that the whole of the people depend for subsistence, and all the conveniences of life, on the labour of little more than one-half; and the increase or decrease of this number, and of the effect produced by the individuals who compose it, is the measure of the increase or decline of national strength. Of the unproductive labourers, or those who gain a subsistence by defending, instructing, or serving others, the greater part are highly useful to the community, and in the present state of society a nation could not exist without them; but as they do not contribute to the production of any of the necessaries of life, or articles of commerce, it is evident that they depend entirely on the exer-

tions of the productive labourers, who are the source not only of the general subsistence, and of the means of commerce, but of all accumulation of stock, which is, in fact, the surplus of former produce beyond the consumption. The power of acquiring national wealth, therefore, depends principally on the proportion of productive labourers to the whole number of inhabitants; for though the population of a country should have greatly increased, if it had been chiefly by an addition of idle hands, the produce would remain the same, and the consumption being much greater, the country must become poorer: but it likewise depends, in a great measure, on the facility with which labour is performed; for if a country contained only half the number of labouring inhabitants, with the same number of other persons it had at a former period, but this half, by means of machinery and other improvements, could produce the same effect as the whole number before, such a country would become considerably richer, though the total population was diminished, and the proportion of unproductive to productive persons increased; for there would be the same supply and a much less consumption: and wherever the produce or supply exceeds the consumption, there will be an acquisition of stock; for, unless the surplus could be reserved for some useful or desirable purpose, it would soon cease to be produced, by the supply falling to the level of the demand for consumption. The surplus reserved, or converted into stock, is a fund for supporting an increase of exertion, or for supplying the means of future enjoyment.

We now proceed to consider a second important subject in the science of political economy, viz. the various systems concerning capital. On this topic, the theory of Dr. Smith is, without dispute, new. The subject, before his time, was not at all understood. The writers on political economy made capital consist entirely of metallic currency, and derived it from foreign commerce; hence their system was denominated the mercantile system. The French economists, who substituted the agricultural system, acknowledged no other capital than the advances on cultivation. Dr. Smith took a larger view of the subject; and capital, according to his theory, consists in the advances and prime materials of all kinds of labour—in the improvements of soil—in the implements and machines for the purposes of agriculture, manufacture, and trade, which, of course, comprise both metallic and paper currencies—and likewise in commodities reserved for general consumption. The latter may fairly be objected to, though our limits do not allow us to enter on the subject; yet it cannot but be matter of surprise that the doctor should enumerate with capital, commodities reserved for consumption, and incapable of being accumulated. Some modern French authors assign to land, mines, and fisheries, which they regard as instruments of production, the rank of capital; but lord Lauderdale limits capital to the instruments and machines adapted to shorten and facilitate labour. The author to whom we have frequently referred, and shall refer again and again, M. Ganilk, defines CAPITAL to consist in the accumulation of the produce of labour, and he adds, that “according to this definition, lands, mines, and fisheries, in their original state, would not be comprised among capitals; and stripped of the improvements, instruments, and machines which render them productive, they scarcely deserve to hold a place in the capital stock of a nation. Their spontaneous produce is but the smallest part of the general produce of labour, and cannot contribute any separate article in the wealth of nations. If we deduct from agricultural produce the part which is due

to cultivation; from the produce of fisheries, that which is due to the implements and tools for fishing, and particularly to the art of salting, drying, and curing fish; and from the produce of mines, that which is due to the aid of machines and extraordinary labours; there remains so little, that there is no danger of erring in ranking them among the produce of labour, and admitting them only as such among capital."

Capital offers three different considerations, equally interesting to the science, to its progress, and to its results; *viz.* its formation, employment, and influence upon public and private wealth. According to Quesnai, capital is derived from economy in the costs of agricultural labour; from the savings in the expences of the land-owners, as far as those savings are applied to improve the soil; and from the increased price of commodities through foreign trade: and, therefore, nothing contributes to the formation of capital, but the saving of the net produce, when employed in agricultural improvement. And Dr. Smith derives capital from the greater or smaller quantity of productive labour relatively to unproductive labour; from the proportion of the productive to the non-productive consumers; and from economy in private consumption: and he adds, *capital* is increased by parsimony, and diminished by prodigality and misconduct. In one principle, Quesnai and Smith agree, the one faithful to the agricultural system, and the other to his system of productive labour; they both regard none but the savings applied to agricultural or productive labours as proper to form capital. In whatever way economy may be effected, it leaves at liberty a sum of produce which is consumed by the idle, or by the labouring classes. If by the latter, it serves to pay for more labour, or for useful labour to be better done. Increased or improved labour gives more or better productions, and consequently more wealth. Higher wages, at the same time, procure more comforts to the labouring class; and more comforts become the cause of a greater population. Thus the savings consumed by the labouring classes evidently increase both wealth and population. When the savings are consumed by the idle classes, they serve to employ a greater number of individuals in labours of luxury: and it matters little whether the savings be made by the idle classes, or whether they be borrowed by them from the labouring class. In the first case, the savings serve only to augment the population; in the second, the savings of the labouring class are exchanged for the capital of the idle classes; and this exchange is not at all injurious to the national capital; it simply effects a change of capitalists, which is perfectly indifferent to the formation of capital and wealth, and is in no-wise prejudicial to population. It seems, therefore, clear that Quesnai and Dr. Smith were mistaken in assuming that savings cannot contribute to the formation of capital, except they are applied to agricultural or to productive labour. They clearly contribute to the formation of capital, though they are employed in labours of luxury. This kind of labour, the least beneficial, indeed, to wealth, constantly and infallibly replaces the savings by which it is paid, and constantly produces the population which is maintained by these savings. Hence it is given as an axiom, that *capital is always derived from economy, and can neither be formed nor increased otherwise than by economy.* This system has been opposed by the earl of Lauderdale, who makes the property of a society chiefly occupied in agriculture, to consist in the land which he cultivates—the stock he reserves for immediate and remote consumption—and his *capital*, which consists of the animals or machines which he employs to save labour in the cultivation of his farm, or in the convenient consumption of its produce. If, however, wealth result from the accumulation of the

surplus of the produce of labour over consumption, it may certainly be increased by other means than by those mentioned by the noble lord, *viz.* by economy, which he seems to hold in great contempt.

Suppose a nation accumulate a certain sum annually, it is either distributed to individuals, whose situation is rendered more comfortable, and who pay for it with more or better labour—and in this case it acts as an encouragement to labour and industry, and multiplies the means of public and private wealth; or it is given to individuals taken from the labouring and industrious classes, to be employed in the service of the idle and rich: in that case also it increases population by all the individuals it maintains. Such is the natural effect of economy, and of an increased produce; both contribute to the progress of population and wealth. There are no limits to this progress, but in the utmost extension and improvement of agriculture, manufactures, commerce, population, and civilization all over the world. People, therefore, ought never to relax in endeavouring to increase their produce, and being economical in their consumption. It is certain that consumption is the measure of production, for a produce that finds no consumer, is not long reproduced. It must not, however, be inferred, that an abundant, and even an over-abundant produce is not consumed. The abundance of productions is always an excitement to a greater consumption; and as abundance, is wealth. Wealth in its turn affords the greatest possible means of consumption. Production is limited by consumption; when the consumer does not like the commodities produced, or when he is unable to pay their price. The producer is every where obliged to consult the taste and faculties of the consumers, and it is when he is mistaken in these two respects, that non-consumption is detrimental to reproduction. Produce will always be consumed, provided it suits the consumers, and they have the means of paying for it. Abundance and cheapness are the springs of consumption and reproduction; and as economy necessarily produces both, it follows that economy is beneficial to both.

If this reasoning be correct, it is not possible that capital can, according to the theory of the earl of Lauderdale, consist only in machines and instruments proper to shorten or facilitate labour, because an economy which tends to multiply such a capital beyond real wants would be injurious instead of beneficial. Hence the capital recommended by the best writers, consists in the advances and raw materials necessary to all kinds of labour; in the improvements of the soil; in the instruments and machines proper to facilitate labour; and in the produce kept in store for present, future, and distant consumption. In this way the means of labour are increased; the soil is rendered more productive; the productions of industry are more abundant; of a better quality, and at a lower price; and their very abundance is a premium to augment population, and means of private and public wealth. Thus economy, by extending every branch of capital, has the same effect as the productiveness of the soil, the progress of industry, and the speculations of commerce. It augments public and private wealth; and it is economy and not industry which increases the capital of a nation.

We are now to enquire in what manner capitals are employed. M. Quesnai mentions the following ways: 1. In the original advances, which have cleared the ground: 2. In the annual advances, which reward the labour of the husbandmen, preserve the original advances, and provide against accidents: 3. The advances which serve to pay for the raw materials and wages of labour: and 4. The advances of the merchants who defray carriage and warehouse expences. Dr. Smith took a more enlarged view of the subject; he devotes one part of the capital to immediate consumption,

sumption, consisting of food, clothing, household furniture, houses, &c.; a *second* part he calls fixed capital, which affords a revenue without circulation or changing masters; this consists in useful machines which abridge labour—in buildings that procure a revenue not only to the proprietor, but to those who pay rent for them—in the improvements of land—and, lastly, in the talents of all the inhabitants of the society. The third and last portion is the circulating capital, and is composed of money—of the stock of provisions, from the sale of which a profit is expected—of the materials, whether rude or partly manufactured—and fourthly, of work ready for sale, but not disposed of.

The difference of opinion between M. Quesnai and Adam Smith is the consequence of their different theories concerning the source of wealth; which one places in agriculture, and the other in any labour which fixes and realises itself in some permanent object.

That part of the capital stock which Adam Smith denominates the circulating capital, is nearly the same with that which M. Quesnai calls annual advances. Both intend this part of the capital stock of a country to provide for the divers wants of agriculture, manufactures, and commerce; they only differ in so far as Adam Smith admits the metallic currency of the country into the circulating capital, which is not mentioned by Quesnai. But the theory of circulation, of which a metallic currency is the principal instrument, had made but small progress at the time the French economists wrote, and its benefits could not easily be foreseen; nor its extent, resources, and results calculated.

Dr. Smith says, that the metallic currency of a country forms part of her circulating capital, and is not only of no benefit to wealth, but even burthensome to it as an object of expence. Other writers on this subject imagine, that money operates in the same manner as other machines employed in agriculture, manufactures, and commerce, and tends like them to shorten labour, and is productive of whatever the exchange of commodities costs, less than what it would have cost without the assistance of money. Of this number is the earl of Lauderdale, who has treated the subject in a very luminous manner, and who explains, in a novel and ingenious method, the operation of money in the interchange of the produce of labour. For his lordship's reasoning and illustrations on this subject, we must refer our readers to the third chapter of the "Inquiry into the Nature and Origin of Public Wealth." Money, says the noble lord, is of use to mankind in two different capacities, as an instrument of exchange, and as a practical standard, by which the value of all commodities is measured and expressed: it will be easily understood how this part of the national capital employed in these two duties is profitable, when we reflect what would be the effect of withdrawing from any society, that part of the capital which is employed in conducting the circulation of goods, and in forming a practical standard by which the value of commodities is measured; for the moment this portion of the national capital is abstracted from any society, the exchange of those things which one man produces with greater ease, for those which another can produce with more advantage, must be conducted by barter. Thus, if a farmer who had more wheat than he wanted, and who meant the surplus to supply his family with other necessaries, wanted a pair of shoes, he must carry a portion to a shoemaker in order to negotiate an exchange, but the shoemaker is already supplied with as much wheat as he wants; the farmer must either seek another shoemaker, or ascertain what articles of consumption the first wants, in order to make a third or a fourth exchange before he could get his shoes. This single instance, which any reader can easily conceive and follow into all its conse-

quences, will explain the labour that must attach to every person, if the circulating capital of a country were obstructed, in endeavouring to supply his wants by parting with his superfluities. Thus coin, employed as a circulating capital, has been eagerly sought after, not for its own sake, or for the sake of the gold and silver it contains, but merely on account of the labour it supercedes. It not only, however, requires a certain portion of labour to acquire, but also to carry about when procured. To prevent this, various modifications of banks have been introduced. Hence the question, do bills of exchange, paper-money in general, and public stocks form capital; and if so, are they part of the *fixed* or *circulating* capital? They seem entitled to be regarded as capital, because they perform the functions of capital; on the other hand they ought not to be regarded as capital, because they have no value of their own, and only represent a mortgage, which itself constitutes a part of capital. Bills of exchange represent the merchandise which they cause to circulate. The mortgage of private promissory notes, consists in the moveable and immoveable goods of the debtor; and public funds or stocks have their mortgages in a particular branch of the revenue. This merchandise; these moveable and immoveable goods; and this branch of public revenue, constitute part of the *fixed* capital, of the *circulating* capital, and of the *stock* reserved for immediate consumption.

The effect of *hoarding* has been considered as a fit subject of consideration in the science of political economy, though overlooked in the "Wealth of Nations." Metallic currency is, as we have seen, a mere instrument, proper to circulate the produce of labour, whatever this produce may be. Abstracted from this destination by being hoarded, it becomes like a merchandize that is not in commerce; and which, so long as it remains out of it, has no value or use for any one. It is, in fact, as if it did not exist, as if it were still buried in the bowels of the earth. When hoarding is the effect of a passion for gold and silver, it is of little importance with regard to wealth, because it is never attempted to any great extent. The only mischief that arises from it is, that it occasions a little more expence to the nation in the purchase of precious metals. Hoarding becomes of public importance only when it takes place in consequence of political causes or mal-administration, when the minds of men are uneasy about public affairs. Instances of such kind of hoarding are met with wherever government respects not persons and property, nor causes them to be respected; and in times of political commotions. Against this calamity political economy affords no remedies: science loses its power; and all those measures, which political economy disavows, are but miserable palliatives which aggravate the evil, and delay its cure, or render it impracticable.

Capital stock, considered as *fixed* capital, as *circulating* capital, and as capital destined for immediate consumption, provides for the wants of labour, contributes to its progress in proportion to its own increase, and always affords an exact measure of the progress of national wealth. There is a fourth employment of capital, by its being lent out to interest, either to private individuals or to the public. Writers on political economy are not all agreed respecting either the utility or disadvantages of this kind of employment of capital. Without entering into the discussion here, we shall refer to the article BANK, also to the latter part of our article INTEREST; LOAN-banks; LOMBARDS; likewise DEBTS, *National*, and FUNDS, *Public*.

In considering the influence of capital on the progress of public wealth, Dr. Smith asserts, that "capitals of equal value will put into motion very different quantities of productive labour, and augment in different proportions the value

value of the annual produce of the land and labour of the society to which they belong, according as they are employed either in procuring the rude produce for use and consumption; in manufacturing and preparing that rude produce for immediate use; in transporting either the rude or manufactured produce from the places where they abound to those where they are wanted; or, lastly, in dividing particular portions of either into such small parcels as suit the occasional demands of those who want them." He accordingly assumes that no equal capital puts in motion a greater quantity of productive labour than that of the farmer, because nature performs seldom less than a fourth, and frequently more than a third of the labour; and no equal quantity of productive labour employed in manufactures can ever occasion so great a production. Next to the capital of the farmer he ranks that of the manufacturer, "who augments the value of the raw materials, which he employs by the wages of his different workmen, and by his own profits on the wages, materials, and instruments of trade. To the capital of the wholesale merchant he assigns the last rank, because it augments the price of his goods only by the value of his profits and the wages of the carriers. He then considers the difference according to the different sorts of wholesale trade in which any part of the capital is employed. The capital employed in the home trade is the most lucrative, because its returns are most frequent; the capital employed in the foreign trade of consumption is less productive than that employed in the home trade, because the profits are shared between the native merchant and the foreign one: but the capital employed in the carrying trade is the least productive of all, because it is altogether withdrawn from supporting the productive labour of the country to support that of some foreign countries.

Dr. Smith's theory on this part of the subject has been ably combated by M. Ganilk, who admits that nature does a considerable part of the farmer's labour, because the produce of labour is not valued by what it cost, nor by its use, but by its *value in exchange*; of course it matters little whether the agricultural produce costs more or less to be raised, if it has not a greater value in exchange. It is, therefore, neither this nor that particular produce which constitutes wealth: it is the exchangeable value of all produce; and the capitals which confer the greatest exchangeable value upon the produce of a country, are the most useful and most favourable to the wealth of that country. Capitals employed in manufactures and commerce are eminently possessed of that faculty, because they afford the produce most in request, and find consumers and commodities in exchange for it in every part of the globe. The nation which employs its capital in manufactures and commerce, is therefore nearer the source of wealth, than the nation which employs it in agriculture, and which, in truth, can derive no wealth but from the prosperity of manufactures and commerce. Besides, the characteristic of the mercantile system is every where to stimulate labour, to accumulate its produce, and to increase wealth; hence the mercantile system is as preferable to the agricultural system, with regard to the employment of capital, as with respect to the nature and effects of labour; and the greater their progress in manufactures and commerce, the nearer will they be to wealth, and their wealth will be so much larger, the more capital they employ in manufactures and commerce. This result is also obtained from the propensity of man to exchange commodities, and from his fondness for all those enjoyments which can be had only by means of such exchanges. It has also been asked, if, in spite of those institutions which oppose the development of industry and commerce, it is not still to manufactures, commerce, and the arts, that the most in-

dustrious, the most ingenious individuals, those whom nature and education have endowed with most talents and faculties, devote themselves? and is not agriculture the lot of men the least endowed by nature, and the least disposed to occupations which require dexterity and talents. This tendency of men to industry and commerce, renders it impossible to be blind to their advantages, or even for a moment to give so decided a preponderance in favour of capitals being employed in agriculture. The most profitable capitals are not those which put most labour, but the most useful labour, into motion; not those which employ most, but the most skilful individuals; not those which yield the largest, but the most valuable produce: consequently the most profitable capitals are those employed in manufactures and commerce. Such is the theory of M. Ganilk.

With regard to the profit of stock, the rule which directs us in the research is, according to Dr. Smith, the rate of interest of money in a given country, and at a given time. As the usual market-rate of interest varies in any country, we may be certain that the ordinary profits of stock must vary with it, must sink as it sinks, and rise as it rises: hence Dr. Smith draws various consequences relative to the progress of wealth in France, England, Holland, and Mexico. This rule is, however, liable to several exceptions, which render its application uncertain. In general, the profits of stock decrease in proportion to the increase of wealth, and augment in proportion to its decline. When a country possesses the sum of capital which it wants, the profits of stock are very low. From this doctrine the following corollary has been drawn, *viz.* that the operations of governments, when not conducted with knowledge and prudence, may have the most distressing influence on all the relations of a country, individual, social, and foreign. If government derange the natural rate of the interest of money, the private interests of all suffer: the land-owner is sacrificed to the capitalist, or *vice versa*; agricultural, manufacturing, and commercial undertakings are carried on beyond, or stop short of their means; and in both cases labour is a sufferer, and wealth declines. Again, if government do not avail itself of the new methods which the science of capital has introduced in other countries, the nation over which it rules labours with equal capital under a great disadvantage in its dealings with other nations, and for a length of time contributes to enrich them at its own expence. The employment of capital is one of the most difficult branches of the science of public administration; and whatever governments may do, capital always has a great value wherever national wealth declines, and it constantly loses its value in proportion to the increase of public wealth.

We shall now briefly consider the various systems relating to the circulation of the produce of labour by means of commerce, which is the only method by which nations attain wealth, splendour, and power. "Trade," according to Dr. Davenant, "is the living fountain whence we draw all our nourishment. It disperses that blood and those spirits through all the members, by which the body politic subsists. The price of lands, value of rents, manufactures, &c. rise and fall as it goes well or ill with our foreign trade." "The greatness of a state, and the happiness of its subjects, are," says Mr. Hume, "generally allowed to be inseparable with regard to commerce." M. Quesnai observes, "Like sale, like production." An able Italian writer on political economy, M. Genovesi, says, "The end of social economy is, 1st, increased population; 2d, wealth; 3d, natural and civil happiness; 4th, the grandeur, glory, and welfare of the sovereign. Of all the means of attaining this end, there is not one more efficient than commerce, which avails itself of human avidity, as the

most powerful promoter of all social advantages." To these testimonies in favour of the circulation of produce, by means of commerce, we may add that of our countryman, Dr. Adam Smith. "As it is the power of exchanging that gives occasion to the division of labour, so the extent of this division must always be limited by the extent of that power, or the extent of the market." Hence the importance of commerce, or of the circulation of the produce of labour. In this point all writers on political economy are unanimous; but with regard to the principle, nature, progress, and effects of this beneficial circulation, opinions are very various. The origin of commerce is sought for, by some, in the avarice of mankind; by others, in their propensity to barter, and exchange one thing for another; and by others, in their variety. The same sort of uncertainty prevails respecting the laws which determine the respective value of the produce exchanged by commerce, concerning the influence of money and credit upon commerce, and concerning the most useful and profitable mode of commerce.

Without attempting to decide upon the origin of commerce, we may observe that no one parts with the produce of his labour, and puts it into circulation, but in the expectation that it will procure him more food, or greater conveniences, comforts, and enjoyments: hence the farther circulation extends, or the larger the market, and the more that market offers varied productions and new enjoyments, the more does labour increase in intensity and activity, the more its produce multiplied, and wealth enlarged and augmented. The sources of the circulation of the produce of labour may be traced in the passion for enjoyment, in the efforts of commerce, and in the genius of the arts. To their united action commerce owes its impulse, its progress, and its success.

The value of produce is regulated by the wants of the consumers, and their means of supplying them; by the demand for commodities, and their abundance and scarcity; by labour, &c. Most writers on this subject are of opinion, that things have no other value than what is fixed by the demand for them, and their abundance or scarcity. One writer observes, that the words *price*, *worth*, *value*, are relative terms, because things have no price or value but relatively to man: wherever there are no men, there are no values; but man assigns no value to things, but as he wants them. By another person it is said, that the sole capability of being exchanged, combined with the greater or smaller natural abundance of things, and with a more or less ardent desire to be possessed of them, forms the basis of what mankind denominate value. The price of things, according to another author, is composed of two elements—their utility and their scarcity: of course their value increases with their scarcity, and diminishes with their plenty. Dr. Smith observes, "that the value of any commodity to those who possess it, and who want to exchange it for some new production, is precisely equal to the quantity of labour which it can enable them to purchase or command: whence he infers that labour is the real measure of the exchangeable value of all commodities." The earl of Lauderdale opposes this doctrine. He maintains that a perfect measure of value is impossible: for as nothing can be a real measure of length and quantity, which is subject to variations in its own dimensions; so nothing can be a real measure of the value of other commodities, which is constantly varying in its own value. But things may alter in their value in three different ways: 1st, in respect to different periods of time; 2d, in different countries; 3d, in different parts of the same country. Labour is not only subject to all the usual sources of variation, but possesses the characteristic of varying at the same time and place: hence labour cannot be a standard. Money and corn are not better calculated than labour to fix

the value of things for distant times. As then the value experiences a rise and fall perfectly similar to the rise of the price of commodities, and as this variation in their respective values proceeds from the same cause, that is, from the proportion of the demand to their abundance or scarcity, there is no difference between their values: both are alike liable to vary, and consequently both are alike unfit to form an invariable measure of value; so that it is the exchangeable value which ultimately gives to every producer the equivalent of what his commodity cost to produce, and consequently secures the producers against loss. Beyond this the profits on productions of labour are unequal. This inequality of profits is indifferent with regard to home-trade: for the superiority of certain labours and employments of capital cannot be of long duration, because those which are least favoured go over to the most favoured ones, and by their competition re-establish a certain proportion between the profits of all labours and employments of capital. But it may be asked, is the inequality of profits in the exchange of home for foreign produce equally harmless? The question has been ably discussed, and decided affirmatively, with the observation that there is but one motive that should induce a nation to prohibit the importation of the produce of other countries; that is, when the government of our own country is so defective, that none of our home productions can stand a competition with foreign productions, even in the home market; when national industry is not capable of being stimulated by the rivalry of foreign industry; and when the people abandon themselves to sloth and misery. With this single exception, foreign commerce or general circulation is beneficial, useful, and profitable to all, and contributes, if not with equal, at least with certain, success to the progress of wealth.

In treating of the wealth of nations, which is the great object of political economy, we shall not omit the computations that have been given of what has been denominated the national stock or capital, that is, of the existing surplus which has been accumulated. In this part of our discussion we shall extract largely from Mr. Grellier's papers, already referred to. Previously to an enquiry into its increased amount, as taken at the commencement of the present century, we may cite the estimate of sir William Petty, whose computation of the wealth of England and Wales, in 1664, is as follows:

Value of land: 24 millions of acres, yielding 8 millions of pounds <i>per annum</i> , at 18 years' purchase	} 144,000,000
Houses, reckoning those within the bills of mortality, equal in value to one-third of the whole	} 30,000,000
Shipping: 500,000 tons, at 6 <i>l.</i> <i>per ton</i>	- 3,000,000
Stock of cattle on the 24 millions of acres, and the waste, including fisheries, warrens, &c.	} 36,000,000
Gold and silver coin (at that time scarce)	- 6,000,000
Wares, merchandize, plate, furniture, &c.	- 31,000,000
	<hr/>
	£250,000,000

"In comparing this estimate with similar accounts for the year 1800, or thereabouts, it must be remembered, that a great alteration has gradually taken place in the nominal value of all commodities, which, with respect to the above period, appears, from a table formed by sir G. S. Evelyn, to be in the proportion of about five to fourteen; the total of the wealth of England and Wales, in 1664, would

POLITICAL ECONOMY.

would therefore have amounted to 700,000,000*l.*, according to the present value of money.

“ The value of land has progressively increased, in consequence of improvements in cultivation, and the increased consumption of the produce of land. Before England became a trading nation, the general price of land was twelve years’ purchase. At the beginning of the last century but one it sold for about sixteen years’ purchase: sir W. Petty valued it at eighteen years’ purchase; and at the commencement of the last century, it had advanced to twenty years’ purchase. About the year 1730, it had risen to twenty-five years’ purchase; and at present is from twenty-eight to thirty years’ purchase. The increase of the number of years’ purchase paid for land, is the most obvious proof of its augmented value; but it does not shew the whole augmentation of the national wealth on this account, which in part arises from the increase of the total rental beyond the advance that is caused merely by the difference in the value of money. This real increase of the rental proceeds from a greater proportion of land being brought into cultivation, and that which was before cultivated being improved. The whole landed rental of England and Wales, and the Lowlands of Scotland, was stated by sir W. Petty at about 9,000,000*l.*; and it cannot be supposed that, if he had included the Highlands of Scotland, he would have made the rental of the whole island more than 9,500,000*l.* G. King and Dr. Davenant, in queen Anne’s reign, stated the rental of England and Wales at 14,000,000*l.*; and it may be presumed this was nearly the truth at the time: but it soon began to appear too low; and between twenty and thirty years ago it was generally reckoned at 20,000,000*l.* At present, however, it considerably exceeds this sum.

“ The chief difficulty of forming an estimate of the land rental consists in assigning an average value to the different descriptions of land. The total number of acres in England and Wales has been computed by sir W. Petty to be 28,000,000; by Dr. Grew, 46,000,000; by Dr. Halley, 39,938,500; by Mr. Templeman, 31,648,000; by Mr. Arthur Young, 46,16,000; and by the Rev. H. Beeke, 38,498,572. Mr. Beeke’s calculation appears to be by far the most accurate: it is therefore taken as the foundation of the following statement; the proportions cultivated for different purposes being nearly as given by Mr. Middleton, in his View of the Agriculture of the County of Middlesex:

	Acres.
Wheat - - - - -	3,160,000
Barley and rye - - - - -	861,000
Oats and beans - - - - -	2,872,000
Clover, rye-grass, &c. - - - - -	1,149,000
Roots and cabbages cultivated by the plough	1,150,000
Fallow - - - - -	2,297,000
Hop-grounds - - - - -	36,000
Nursery-grounds - - - - -	9,000
Fruit and kitchen-gardens, cultivated by the spade	41,000
Pleasure-grounds - - - - -	16,000
Land depastured by cattle - - - - -	17,479,000
Hedge-rows, copses, and woods - - - - -	1,641,000
Ways, water, &c. - - - - -	1,316,000
Cultivated land - - - - -	32,027,000
Commons and waste lands - - - - -	6,473,000
Total acres in England and Wales - - - - -	38,500,000

“ If the commons and waste lands are considered as equal in annual value to only one million of cultivated

acres, the whole may be taken at 33 millions. The average rent has been stated at 15*s.* per acre, which appears to be a moderate computation, and makes the rental amount to 24,750,000*l.*, the value of which, at 28 years’ purchase, is 693,000,000*l.* The number of cultivated acres in Scotland is upwards of 9,690,000; and of uncultivated, about 11,310,000: a great part of the latter is of very little use; but if it is wholly excluded, and the cultivated part rated at an average of 10*s.* per acre, which makes 4,845,000*l.* per annum, the total rental of the island will be 29,595,000*l.*, and the value of the land 828,660,000*l.* This must be understood as including the value of tythes, it being unnecessary in this point of view to distinguish between the rent paid to the landlord, and the part paid to the tythe proprietor.

“ The value of the houses of Great Britain is perhaps more difficult to ascertain than that of the land: but the following statement of their rent, founded on the number returned under the population act, will not be thought too high:

100,000 houses, at 30 <i>l.</i> per annum	-	£3,000,000
500,000 - - - - - 10 <i>l.</i> - - - - -	-	5,000,000
250,000 - - - - - 5 <i>l.</i> - - - - -	-	1,250,000
600,000 - - - - - 2 <i>l.</i> - - - - -	-	1,200,000
425,000 - - - - - 1 <i>l.</i> 10 <i>s.</i> - - - - -	-	637,500
1,875,000	-	Total rent - £11,087,500

“ The total rent, if valued at only 18 years’ purchase, makes the value of all the houses in Great Britain 199,575,000*l.*

“ In order to form an idea of the value of cattle and farming-stock on the land, we may consider the black cattle and calves, sheep and lambs, swine, pigs, and poultry, annually consumed in London, as worth 6,000,000*l.*, which cannot be more than a seventh part of the whole consumption, amounting therefore in value to 42,000,000*l.*; but the whole number of cattle existing must be more than double the quantity brought to market; so that, including horses, asses, cows kept for milk, and oxen employed in agriculture, the whole value of the cattle cannot be less than 90,000,000*l.*

“ Taking the annual consumption of grain of all sorts at 16,000,000 quarters, which is probably below the truth, we may presume, that in general there is at least three or four months supply on hand, which, at only 35*s.* per quarter, will amount to at least 7,000,000*l.* The value of hay and straw, and all kinds of fodder, and of all implements of husbandry, cannot be less than five or six millions, and with the former sum cannot be less than 12,500,000*l.* The total value of cattle and farming-stock is therefore 102,500,000*l.*

“ The value of the shipping belonging to Great Britain may be calculated with more accuracy. It appears from the accounts laid before parliament, that, exclusive of Ireland and the plantations, the number of vessels in the merchants’ service, belonging to Great Britain, on the 30th September 1804, was 17,809; and the amount of their tonnage, 2,018,999 tons; taking it at 2,000,000, at 8*l.* per ton, it makes 16,000,000*l.*, which is certainly below the real value. The shipping of the navy may at least be estimated at 4,000,000*l.*; making with the former sum, 20,000,000*l.*; to which some addition should be made for the value of ships building in all the dock-yards, and for small craft employed on the rivers and canals.

“ The quantity of money in the country has at different times been a subject of dispute, and has never been determined with precision. It was, however, pretty well ascertained by the re-coinage in the years 1773, 1774, and 1776. The value of the light gold delivered into the bank under the different proclamations, amounted to 15,563,593*l.*; and it

POLITICAL ECONOMY.

was generally admitted that somewhat more than two millions of heavy guineas remained out in circulation, which, with the silver and copper coin, made the whole at that time about 20 millions; at which sum Mr. Chalmers estimated it in the year 1786. Including the cash in the coffers of the bank it appears, that at the time of the re-coinage the whole money in the country was rather above than under the sum just stated; and from the sums annually coined since that time, it might be presumed that the quantity in circulation at present was considerably greater. Mr. Rose has stated it at no less than 44,000,000*l.*; but though our commerce has considerably increased, it will hardly be thought, considering the far greater quantity of small bank notes in circulation, that, if 20 millions of coin were sufficient in 1776 or 1786, we can at present have occasion for more than 25 millions at the utmost.

“Of the value of the merchandize and manufactures usually in the hands of the merchants, wholesale dealers, shopkeepers, and manufacturers, it is very difficult to form a satisfactory idea. The total amount of the imports in the year 1804 was 29,201,490*l.*, and of the exports 34,451,367*l.*, according to the Custom-house accounts; but it has long been known that these accounts are considerably below the true value, and particularly since passing the Convoy act, in the execution of which it has appeared that the declared value of British manufactures exported is about 71 *per cent.* greater than the value in the inspector-general's register; and, with respect to the foreign merchandize imported, the difference on the whole may not be much less; for it is certain that some of the articles are at present considerably more than 71 *per cent.* above the value at which they are rated. Taking the whole, however, as rated only 60 *per cent.* under the present values, the annual amount of foreign trade will be 101,844,571*l.*, to which some addition should be made for smuggled goods. It was the opinion of a numerous meeting of merchants in the year 1797, that there is at all times at the least two months supply of export and import merchandize in the custody of the merchants and traders, which, according to the above total, will amount to 16,974,095*l.*; to which some addition should be made for property in the hands of foreign merchants, on account of the merchants of this country generally giving longer credit than they are allowed from other countries. But though the value of goods in the hands of merchants and wholesale dealers appears so considerable, it must be exceeded by the goods in the hands of the manufacturers and of retail traders; for though many of our principal manufactures depend greatly on foreign trade, their main support is the home consumption. The official value of British produce and manufactures exported in the year 1804, was 23,935,793*l.*; but the real value, as far as it can be ascertained, amounted to 40,349,642*l.* This, it may be presumed, cannot be more than half of the whole produce of our manufactures, which will thus amount to 80,699,284*l.*, of which but a small proportion is included in the value before-mentioned in the hands of the merchants; which consists chiefly of foreign merchandize and materials for the different manufactures, as they can generally obtain manufactured goods for exportation at a short notice, deducting, however, 3,000,000*l.* on this account; of the remainder it is probable that there is much more than three months supply in the hands of the manufacturer, in different stages from the raw material to finished goods, and in the possession of retail traders, who, in many branches, are obliged to keep a large assortment; but taking it only in this proportion it amounts to 19,424,821*l.*

“There still remains to be valued that part of the property of individuals which consists in household furniture, wearing apparel, plate, jewels, and trinkets, books, provi-

sions, fuel, carriages, &c.; with respect to which the most that can be done is to form a conjecture that shall be generally admitted as not exceeding the truth; and certainly this general kind of property, of which every individual must possess or enjoy the use of some share, will not be thought over-rated at three times the yearly rent of the houses which contain it, or 33,262,500*l.* in all Great Britain.

“Having thus valued the different descriptions of stock, or actual capital, its total amount will appear as follows:

Value of the land of Great Britain	£ 828,660,000
Houses	199,575,000
Cattle, and all kinds of farming stock	102,500,000
Shipping; navy and merchant ships	20,000,000
Money	25,000,000
Goods in the hands of merchants and whole- sale dealers	16,974,000
Goods in the hands of manufacturers and retail traders	19,424,000
Furniture, apparel, &c.	33,262,000
Total	£ 1,245,395,000

“Upon this capital all other species of wealth, whether consisting in the securities of government or individuals, or of any other description, ultimately depends; for private and public loans, in which mode a great part of the property of many persons is invested, implying an obligation on the part of the borrower to repay at a future period a certain sum of money which is the measure and representative of all other species of property, or to pay an income arising from this sum till the capital is repaid, the borrower is no otherwise richer than by the greater income he can make from the money than what he agrees to pay for it; as the capital, in whatever manner he invests it, still belongs to the lender, who, though he may not, by the laws of the country, be permitted to take possession of the property into which his money had been converted, may, if necessary, bring it to sale, for the purpose of re-converting it into the sum equivalent to what he had lent. If, therefore, the whole of the land, houses, cattle, and all other articles composing the wealth of the country, was in the hands of one half of the inhabitants, who had borrowed the above sum of 1,245,395,000*l.* from the other half, it is evident that the whole real capital of the country would in fact be the property, not of those in possession of it, but of those to whom they were indebted. This is the case with respect to a considerable part of the capital part of Great Britain; and the debts of the government have greatly contributed to bring it into this state; for though these debts are not contracted under an obligation to repay the principal at any fixed period, they rest on the right which the government possesses, to claim, if it should ever be necessary, a portion of the general property sufficient for this purpose, and, till that time, to raise sufficient contributions to pay an annuity equivalent, in value, to such principal.

“The above estimate shews that, notwithstanding the expensive wars in which the country has been engaged, which, by drawing much money out of the country, has greatly diminished the profits that would otherwise have remained, there has been a great accumulation; though, at the same time, the people in general appear to live in a much more expensive manner than their ancestors. We have seen that, in the year 1664, the whole national capital did not exceed 700,000,000*l.*, according to the present value of money; there has, therefore, been an average gain since that time of nearly four millions *per annum*, a very considerable part of which must have arisen from foreign commerce; for com-

merce

merce would not be carried on without gain; and whatever profits have been saved or converted into stock, must appear in the foregoing account; even the increased value of the land and houses is in a great measure owing to the assistance of capitals acquired in trade.

“The great increase of the annual income is a further proof, that there must have been such an accumulating surplus as is here stated. Sir W. Petty computed the whole income of the country to be 42,000,000*l.*; Mr. G. King estimated it at 43,500,000*l.*; Mr. Davenant, in 1701, stated it at 49,000,000*l.* These accounts are exclusive of Scotland; but after making a sufficient addition on this account, it will appear that there has been a very considerable increase. Sir John Sinclair, in 1783, observed, that the income of the country arising from lands, commerce, and manufactures, was commonly calculated at 100,000,000*l.*, which he considered rather a low valuation; and there can be little doubt that of late years the profit derived from each of these sources has been greatly augmented.

A part of the national stock or capital produces no income; such as the money in circulation, furniture, apparel, &c.; and, on the contrary, much income arises without capital, being solely the recompence of labour. A very considerable proportion arises from capital and labour united, such as that of most farmers, merchants, and retail dealers; and the difficulty of distinguishing, in many cases, that part of the income of individuals, which is the wages of their labour, from the part which should be considered as the profits of their capital, must render every attempt to particularize the amount of the different branches of income liable to objections. The following statement is, however, presumed to be not very inaccurate:

From rent of lands	-	-	29,595,000
From rent of houses	-	-	11,087,000
Profits of farming, or the occupation of the land	-	-	6,120,000
Income of labourers in agriculture	-	-	18,000,000
Profits of mines, collieries, and inland navigation	-	-	2,000,000
Profits of shipping in the merchants' service, and small craft	-	-	1,000,000
Income of stock-holders	-	-	18,925,000
From mortgages and other money lent on private securities	-	-	2,500,000
Profits of foreign trade	-	-	11,250,000
Profits of manufactures	-	-	13,300,000
Pay of the army and navy, and seamen in the merchants' service	-	-	5,500,000
Income of the clergy of all descriptions	-	-	2,200,000
Income of the judges, and all subordinate officers of the law	-	-	1,800,000
Professors, schoolmasters, tutors, &c.	-	-	600,000
Retail traders not immediately connected with foreign trade, or any manufacture	-	-	6,000,000
Various other professions and employments	-	-	2,000,000
Male and female servants	-	-	2,000,000
		Total	£133,877,000

“Of this annual sum, the part drawn from other countries by commerce, is stated at 11,250,000*l.*, which is founded on a supposition, that the capital employed cannot be less than 75,000,000*l.*; and that the profits thereon, including those of all persons immediately depending on foreign trade, may be taken at 15 per cent. It must not however be supposed, that the nation receives an accession

of wealth to the amount of 11,250,000*l.* annually from this source: whatever payments are made to other countries for the dividends on the share foreigners hold of the public debts, or as subsidies to their governments, or spent therein in the maintenance of troops, or by British subjects occasionally resident there, operate to the diminution of this profit in a national view. The actual wealth, which the country acquires by its intercourse with other nations, may be very different from the profits of the individuals concerned in trade; as a sum equal to a great part, or even the whole, of such profits, may be sent abroad in the various ways just mentioned. The balance of trade in favour of the country has usually been estimated by the excess of the exports beyond the imports, and a comparatively small amount of the latter has been considered highly desirable. This is a concise mode of determining a very important point. But even if the Custom-house accounts were much better adapted to the purpose than they are, the justness of the conclusions thus drawn from them would be very doubtful; for it may be easily shewn that in many cases, if the imports even exceeded the exports, there might notwithstanding be a considerable gain. Thus, supposing the merchants of this country to purchase British manufactures for exportation, on their own account, to the value of 20,000,000*l.*, the net proceeds thereof in the countries to which they are exported cannot be considered as less than 22,000,000*l.*; and this sum being invested in foreign produce, and imported into this country, will amount, after repaying the duties and all expences, to at least 24,200,000*l.*, returning the merchants the capital originally advanced, with a profit of 21 per cent. In like manner, whenever the merchandize imported in return for any quantity exported is of greater actual value in this country, or yields a greater price, after allowing for all charges and the interest of the capital employed, the surplus must be an addition to the wealth of the country; and if the whole of the foreign trade was of this description, the excess of the imports would shew the profit or the wealth acquired by the exchange of commodities with other nations.

“It has been shewn, that the total income of the country is at present upwards of 133,000,000*l.*; and that it cannot be less than this sum, may be inferred from the general expenditure. Sir W. Petty reckoned the average expence of men, women, and children, in England and Wales, at 6*l.* 13*s.* 4*d.* per annum, for food, housing, clothes, and all other necessaries; Dr. Davenant took the average expence at 7*l.*, which, according to the difference in the value of money, is equal to upwards of 16*l.* for each person at present. Mr. Jonas Hanway, about 35 years ago, estimated the expence of the people of England and Wales on an average about 9*l.* each; but this must be too low at present: and the following estimate will probably approach nearer to the truth, with respect to the mere expence of subsistence, or of eating and drinking, particularly as we are not to consider what is absolutely necessary for support, but what is actually expended in this way:

300,000 persons at 16 <i>d.</i> per day	£	7,300,000
700,000 — 12 <i>d.</i> —		12,775,000
1,500,000 — 9 <i>d.</i> —		20,531,250
2,000,000 — 6 <i>d.</i> —		18,250,000
2,500,000 — 4 <i>d.</i> —		15,208,333
2,000,000 — 2 <i>d.</i> —		6,083,333
1,500,000 — 1 <i>d.</i> —		2,281,249
		£82,429,165

“When

POLITICAL ECONOMY.

“When the price of most of the necessaries of life is considered, it will not be thought that the expence of subsistence is over-rated in the lowest classes; and if this is admitted, it cannot be too high in the other classes, when it includes strong beer, spirits, wine, and a variety of luxuries. To the expences of living must be added, those of house-rent, clothing, and superfluous expences, in order to arrive at the whole actual expenditure. The first of these articles has been stated at 11,087,500*l.*; and allowing for the rent of shops, warehouses, and other buildings appropriated wholly to trade, it may be taken at 9,500,000*l.* The expence of clothing, including every article of dresses, or personal decoration, will, on a very moderate computation, amount to 26 millions, *viz.*

150,000 persons at	20 <i>l.</i>	per annum		3,000,000
300,000	—	12 <i>l.</i>	—	3,600,000
750,000	—	8 <i>l.</i>	—	6,000,000
1,300,000	—	4 <i>l.</i>	—	5,200,000
2,800,000	—	30 <i>s.</i>	—	4,200,000
4,000,000	—	20 <i>s.</i>	—	4,000,000
1,500,000	—	0		
<hr/>				
10,800,000				£26,000,000
<hr/>				

“With respect to superfluous expences, when the sums spent by the nobility and people of fashion in plays, operas, concerts, routs, gambling, horses, carriages, and other amusements and luxuries, are considered, it will certainly be thought a very moderate assumption, that, including what is spent by others on objects more rational, though not absolutely requisite, there is half a million of persons who, one with another, spend 25*l.* per annum in unnecessary expences, making 12,500,000*l.* The total expence will then be:

For subsistence	-	-		82,400,000
For house-rent	-	-		9,500,000
For clothing	-	-		26,000,000
For miscellaneous expences	-	-		12,500,000
<hr/>				
Total				130,400,00
<hr/>				

“The difference between this expenditure and the general income, shews the annual gain of the country, or the sum applicable to the extension of commerce, the reservation of a greater quantity of foreign articles, the increase of shipping and buildings, agricultural or mechanical improvements, or other augmentations of the general stock. Without such a surplus, few improvements could be carried on, nor could there be any increase of wealth; and if this latter circumstance is thought essential to national advancement, it becomes an object of much importance, that the expences of the government should be restrained within such bounds, and provided for in such manner, as to intrench as little as possible on the annual surplus that would otherwise be converted into permanent capital.”

With regard to the influence of money and credit upon the circulation of the produce of labour, we refer the reader to our articles MONEY, PAPER Currency, BANK, and CREDIT. For various other topics connected with this interesting and important subject, the reader may examine different other articles in the course of our volumes, particularly EXCHANGES, PAR of Exchange, COLONIES, COMMERCE, and CORPORATIONS.

We shall conclude the article with some account of the various systems concerning national income and consumption. All systems of political economy agree in making national income to consist in the produce of annual labour. The sponta-

neous productions of the soil, of mines, and the waters, are not very considerable, and moreover require a certain portion of labour to be brought to market. Income is either private or public. The produce of general labour, whether in the hands of individuals, where it forms private income, or diffused all over the country in the shape of national income, is partly consumed by the producer, and partly exchanged with the view of consumption. If the produce consumed in the place where it was produced be abundant, its plenty contributes alike to public and private wealth; but if that produce be rare, its scarcity impoverishes the individual and the public. With regard to the produce exchanged by the producers, if the exchange takes place with a foreign country, its abundance turns it to the benefit of the foreigners, who purchase it with the same values which they used to give for it, unless the foreign country should have been favoured with a like abundance in its own produce; because in that case plenty is equally beneficial to the foreigners and natives, and in both cases private and public wealth remains the same. But if the produce exchanged with the foreign country be scarce, the foreigners are sufferers by this scarcity. Finally, if the exchange of national produce take place at home, its plenty becomes beneficial to the consumers, without loss to the producers, because the latter always receive the same value which they usually received from the consumers. But in case of scarcity, the loss is to the consumer, yet without any benefit to the producer, because the consumer can only give him the usual value: therefore in both cases there is neither loss nor profit for private and public wealth. But when the abundance or scarcity is excessive and extraordinary, it is more or less fatal to the producer or consumer, still without effecting any difference between public and private wealth, because what the one loses the other gains: and public wealth, which consists of individual riches, experiences no change from the loss of the producers and the gain of the consumers. It seems to be of great importance that governments should be fully convinced of the identity of public and private wealth, because it is on this truth that the maintenance of social order, the progress of public wealth, and the melioration of mankind do, in a measure, depend.

The produce of annual labour, whether considered as private or national income, is distributed in the shape of wages, of labour, profit of stock, or rent of land, and the distribution is regulated by the progressive, stationary, or retrograde state of national wealth. When wealth is progressive, more produce of the annual labour is distributed in wages of labour, profit of stock, and rent of land: when it is stationary, a smaller quantity of that produce goes to the labourers as wages, and to the landholders as rent; and the profit of stock remains as before; but when it is retrograde, the wages of labour sink so low, that they are scarcely adequate to supply the most urgent wants of the labourers; rents also suffer a considerable diminution, but the profits of stock experience a rise corresponding with the decline of national wealth.

Consumption bears a necessary and indispensable proportion to the national income, but that proportion has not yet been invariably fixed. The French economists think that consumption ought to be equal to the income, and they allow no economy but in that part of the annual income reserved for the land owners as the net produce of their lands. But according to Dr. Smith, consumption ought to be inferior to income, and it is on the surplus of income that he chiefly founds the progress of national wealth: and he assumes that parsimony and not industry is the immediate cause of the increase of capital. There are some authors who condemn economy;

economy; who regard consumption as the measure of re-production; and maintain that the people are the richer the more they spend, whence luxury would become the most powerful spring of wealth. When an individual consumes more than his income, the surplus must be taken from his capital, which is gradually diminishing, and the diminution of the capital diminishes his income in the same proportion: and if he go on upon this plan, the time will come when that individual, having neither income nor capital left, is obliged to labour for his subsistence, or to be indebted for his maintenance to public charity. What is true of one individual is equally so of several, and even of a whole nation, and the excess of consumption above income may therefore occasion the ruin of nations as it does the misery of individuals. It was so understood among the ancients, who not only recommended economy, but honoured parsimony very highly, and imputed to luxury the decay of morals, the ruin of private fortunes, and the loss of the state. A distinction ought, however, to be made between individuals and the state; for though the expenditure of individuals should absorb their income, it may, so far from being prejudicial to national wealth, even contribute to its increase. The desire of comforts, the love of pleasure, &c. are powerful incitements to labour, and induce the labourer to multiply the produce of his labour; and in that case he labours more in proportion as he consumes more, and he becomes richer as his expences are more considerable. In this particular instance those are right who praise luxury and attribute to it a large share in the increase of wealth, and also in the civilization of individuals and nations; but neither individuals nor nations can enjoy a solid and permanent prosperity, unless when private and public consumption does not absorb the general income, and when the surplus produce, that is annually accumulated, goes to augment the sum of labour, raise the wages of labourers, increase population, develope industry, multiply wealth, and place public power on the immoveable basis of population and wealth.

We may farther observe, that after the produce of the annual labour of every country has been reduced to its true value by its interchange with the produce of all countries, it has no longer any influence upon wealth, but with regard to its distribution and consumption. The national produce is distributed to the *land owners* in the shape of *rents*; to the *capitalists* as *profits of stock*; and to all who participate directly or indirectly in *labour*, in the shape of *wages*. This distribution is more or less favourable to the progress of public and private wealth, according as stipulations in all private contracts are more or less free. All measures that alter the direction of this distribution, and infringe upon its natural proportions, oppose more or less obstacles to wealth, and may even prove fatal to its existence. Independently of the distribution of the produce of labour to the land owners, the capitalists, and the labourers, a part must be taken from this produce for government and the servants of the state, which also has a considerable influence upon wealth. The consumption of the produce allotted to each individual, by the rents of land, the profits of stock, and the wages of labour, is subject to two laws: 1. The consumption of the annual produce must be inferior to the total quantity of that produce. A part should be saved for the increase of the capital stock; for unforeseen wants; and a progressive population. This economy acts as a safe-guard against the blasts of fortune, and is a certain pledge of grandeur and prosperity: and so long as the consumption of public and private revenue does not absorb the whole produce of general labour, wealth is progressive, nations prosper, and are, in truth, advancing to the highest degree of power and splendour.

2. Consumption is more or less useful to the progress of wealth, according as it is or is not directed to solid and lasting enjoyments.

To conclude in the words of Mr. Ganilh: "In the economical system of modern nations, general labour is the spring of wealth, and general economy the only way of increasing the funds and the resources of labour; of developing its power, its faculties, and its genius; and of giving it a constant and unlimited progression. The general interchange of the produce of labour, by affording to the labouring classes new, varied, and inexhaustible enjoyments, stimulates their activity, excites their industry, encourages their efforts, and raises them to the highest degree of energy and industry, and the extent of a more or less beneficial consumption of the whole productions extends or narrows the bounds of wealth and opulence.

"Wealth, in the modern system of political economy, is the work of all men, of all nations, and, as it were, of the whole human race; the reward of all individual efforts; and the end of private and general ambition. When all are rushing to the same end, the rights of all are respected, the interests of all attended to, and the conveniences of all consulted. All advance by the side of each without elbowing, without injuring, without crushing each other. All are benefited by their reciprocal efforts, and all owe their successes to their general co-operation. To this admirable system, civilization is indebted for its progress; and when better understood, it will prove its most vigilant safe-guard and its firmest support."

POLITICAL Criticism. See CRITICISM.

POLITICAL Liberty. See LIBERTY.

POLITICAL Power, in *Matters of Government*, is, according to Mr. Locke (*Of Government*, b. ii. c. 1. § 3.) a right of making laws with penalties of death, and consequently all less penalties, for the regulation and preservation of property; and of employing the force of the community in the execution of such laws, and in the defence of the commonwealth, from foreign injury; and all this only for the public good. The principle upon which this kind of power is founded, is this, that it is every person's interest to give up his own judgment as to his property and his right of self-defence to the regulations of laws and magistrates; since in this way the preservation of property and the safety of every person are best consulted. Reason teaches all the members of society, to submit the strength of the whole to the direction of proper persons, to be by them exerted in its defence. Thus the reason of the thing, the consent of the several members, express or tacit, and the authority of the Creator, obliging to what is for the common good, concur to establish political power, and to make submission to it a duty.

POLITICS, POLITICE, πολιτικη, from πολις, *civitas*, *state*, the first part of economy, or ethics, consisting of the governing and regulating of states, for the maintenance of the public safety, order, tranquillity, and good morals.

Lord Bacon divides politics into three parts, with regard to the three grand ends thereof, or the three offices incumbent on those who have the administration; *viz.* the *preservation* of the state; the *happiness* and *flourishing* of the state; and the *enlargement* of its bounds.

The two first parts, he observes, are well handled by several authors; but about the third there is a deep silence. He ranks this, therefore, among the number of the desiderata, and gives us a specimen of an essay to supply it.

We have several systems of politics by Aristotle, Machiavel, Doria, Lipsius, &c. in which last there is nothing but

particles and conjunctions of the author's own; the body of the book being all quotations.

POLITICS, *Academy of*. See ACADEMY.

POLITIUM, in *Ancient Geography*, a town of Italy, belonging to the Marrucini. Diod. Sic.

POLITTOOR, in *Geography*, a town of Hindooftan, in the Carnatic; seven miles N. of Conjeveram.

POLITORIUM, in *Ancient Geography*, a town of Italy, in Latium, and in the first region of it, according to Pliny. Livy says, that it was taken by king Ancus.

POLITSCHANO, in *Geography*, a town of the duchy of Stiria; four miles S. of Windisch Weiftritz.

POLITY, or POLICY. See POLICY.

POLITZ, in *Geography*, a town of Anterior Pomerania, near the Frisch Haff, celebrated for its hops; eight miles N. of Old Stettin. N. lat. $53^{\circ} 36'$. E. long. $14^{\circ} 40'$.—Also, a town of Bohemia, in the circle of Konigingratz; four miles W. of Branau.

POLITZKA, a town of Bohemia, in the circle of Chrudim; 20 miles S.E. of Chrudim. N. lat. $49^{\circ} 40'$. E. long. 16° .

POLIUM, in *Botany*, from *πολιος*, hoary, an old name for a pretty mountain plant, of which there are many varieties, or perhaps species, comprehended by Linnæus under his *Teucrium Polium*. The heads of flowers are hoary, and the backs of the leaves snow-white. The whole herb is bitter and strongly aromatic, esteemed useful for keeping away moths from clothes and furniture, whence it has sometimes obtained the appellation of *Tinearia*. See TEUCRIUM.

POLIVO, or BURNT Island, in *Geography*, an island of the Archipelago, which lies to the E. of Argentiera, and is separated from it only by a channel a quarter of a league wide. It formerly belonged to individuals of Milo and Argentiera, who had flocks on this island; but fearing to turn it to account lest they should attract the attention and extortions of the Turks, they were endeavouring to dispose of their interest in it, when Sonnini visited it. This island, occupied only by flocks, is four or five leagues in circumference, and, about one-fourth of the soil excepted, capable of cultivation. The uncultivable part consists of hills, partly covered by rocks, between which grow various plants and shrubs; and these hills, though not cultivated, would not be unproductive; flocks would find there abundance of food; and lentisks and junipers would yield wood and oil. Nature has planted between the rocks bulbs of saffron, in the midst of other vegetable productions, useful, though wild. In the bosom of the rocks are found carnellians of several colours, but mostly of a yellow-orange colour, and agates of a yellow and transparent grey, which may be considered as a species of fardonix. An excavation, supported by posts, indicates ancient mineralogical labours, and it might be possible to renew them with advantage. To the culture of various species of corn, cotton, &c. and to the collection of wood, might be added the rearing of bees, and wax in the Levant is known to be a profitable article of trade. The situation of Polivo at the entrance of the Archipelago, in the vicinity of a great number of islands, forming a road, the common anchoring place for vessels that navigate in these seas, would give birth to an infinite number of commercial speculations, which could not fail to be very productive. On the west, facing Argentiera, are two coves, into one of which ships can enter. The Europeans call Polivo by the name of "Burnt Island," because the Venetians, during the long wars which they had to maintain against the Turks, destroyed by fire the olive trees with which it was covered. These trees indicate the goodness of the soil, and the small number, still

cultivated on the west coast, opposite to Argentiera, produces abundant crops.

POLIZZI, a town of Sicily, in the valley of Mazara; 15 miles E. of Cefalu. N. lat. $37^{\circ} 47'$. E. long. $14^{\circ} 10'$.

POLKOWITZ, a town of Silesia, in the principality of Glogau, containing two churches; 10 miles S. of Gros Glogau. N. lat. $51^{\circ} 29'$. E. long. $16^{\circ} 5'$.

POLL, a term used in ancient writings for the head.

The word is, doubtless, formed from *pole*; this part being, as it were, the pole of the microcosm.

Hence, to poll is to enter down the names of persons who give their votes, or voices, at an election.

POLL Deed. See DEED.

POLL-Evil, in *Veterinary Science*, a name given to an abscess formed near the head of a horse, about the junction of the first vertebra of the neck. It commonly proceeds either from a blow or hurt received on the head, either by striking it against the ceiling of a low stable, or by the pressure of old harsh harness halters. Upon the first discovery of it repellents may be used, such as fomentation with hot vinegar and a sponge, followed by a slight application of camphorated spirits. The most effectual method, it is said, of dispersing the tumour in the first stage of the disorder, is that of anointing the inflamed parts with blistering liniment. But for expediting suppuration, the best applications are hot fomentations with gruel, succeeded by emollient poultices of linseed powder, milk, and a small quantity of turpentine well incorporated, or bread, milk, and white lily-root, bruised to a paste and applied of a proper warmth. When suppuration has taken place, and the matter can be distinctly felt, an opening must be made as near as possible to the inferior part of the abscess, and a seton be introduced through the whole extent of the cavity which should be frequently moved, and washed with spirits of turpentine. The healing process may be aided by daily injecting the following lotion into the cavity of the abscess: *viz.*

Take muriated quicksilver and vitriolated copper, of each in powder two drachms, and of boiling water, one pint; when cold, add two ounces of tincture of myrrh, and mix them.

If sinuses be formed, and the lotion be not sufficient to heal the parts, the parts must be laid open by an incision through their whole extent, and the following dressing may be used: *viz.*

Take of red precipitate, in powder, half an ounce, ointment of yellow resin, two ounces, and oil of turpentine, half an ounce, and mix them.

Over this dressing lay a large pledgit of tow, spread with any simple ointment. In the further process, let the wound be kept clean, and the treatment be such as is usual in simple wounds.

POLL Taxes. See CAPITATION.

POLLS, *Challenge to the*. See CHALLENGE.

POLLA, in *Geography*, a town of the duchy of Stiria; six miles W.N.W. of Hardeberg.—Also, a town of Naples, in Principato Citra; four miles S. of Cangiano.

POLLACK, in *Ichthyology*, a name which we give to two different fish of the *afellus* or *gadus* kind, with the different epithets of *raw* and *whiting*. The raw-pollack is the same species that in some parts of England is called the cole-fish, and is the *afellus niger*, or *gadus carbonarius*, of authors. The other is called the whiting-pollack, and is the *afellus virefcens* of Willughby and others; and the *gadus pollachius* of Linnæus. See GADUS.

The whiting-pollack is common on many of our rocky coasts, and numbers of them are seen in summer sporting on the surface of the water, which are often taken with a

goose's feather fixed on the hook. They do not grow to a large size, and are a good fish for the table.

POLLAJUOLO, ANTONIO and PIETRO, in *Biography*. These brothers were born at Florence of low parentage, Antonio in 1426, and Pietro in 1428; and as their father was unable to give them a liberal education, Antonio was placed with Bartoluccio Ghiberti, a very eminent goldsmith, and Pietro became a disciple of Andrea del Castagno. Antonio followed his trade with the highest credit, and designed extremely well in metals, and in wax; having performed many very estimable works in both. But as Pietro had at the same time rendered himself considerable, and was in great reputation for his performances in oil-colours, Antonio quitted his original profession to learn design and colouring from his brother; and they ever after associated in all those works which they executed in Florence, and several other cities in Italy.

Pietro had been taught the secret of preparing his colours with oil, by his master Castagno; and having communicated that knowledge to Antonio, these artists improved it daily by their practice, and distinguished themselves exceedingly for portrait painting, as well as for history. Pietro in particular painted the portraits of Poggio, who wrote the history of Florence, and of many of the nobility, in a size as large as life, which procured him the greatest applause. Among the historical subjects which they jointly executed, are mentioned some of the Labours of Hercules, painted in the Medicean palace; and in the chapel of the family Pucci, à Servi, there yet exists a picture, by the hand of Antonio, of the Martyrdom of St. Sebastian, one of the best performances of the fifteenth century, if not in colour, superior in composition to the productions of that epoch.

These brothers lived in high esteem and great affluence; and they died in the same year, not more rich in fortune than in reputation. Few months intervened between the death of the one and the other; and they were both buried in the same tomb, in the church of St. Pietro in Vincula, at Rome. Fufeli's Pilkington.

POLLAM, in *Commerce*, a weight at Madras, and other parts of the East Indies; 320 of which are equal to 3200 pagodas = 8 vis = 1 maund.

POLLARD, among *Hunters*, a stag, or male deer, which has cast its horns.

POLLARD, in *Planting*, a term applied to a tree that has been frequently polled or lopped, and its top taken off, or headed down to the stem, for the purpose of fire wood, or small poles for hurdle wood, and other similar uses, as well as for hop poles, &c. It is a term most commonly in use in the southern and eastern districts of the kingdom. But though much wood of this small sort may be provided in this way, the practice has been highly reprobated, not only as being destructive of good timber, but as a barbarous system which disfigures and renders the appearance of the country disagreeable.

In the Survey of Middlesex, after remarking that the hedge rows in that county are sometimes disfigured by pollard trees; but in no degree equal to what they are in some other counties; it is observed, that hedge rows in no district are so barbarously used by the tenants, or reflect so much want of attention on the part of the landlords, as those in Norfolk and Suffolk. Numerous are the fields in those counties whose hedges are filled with pollards of every age, under perhaps two hundred years, of no value to the tenant, and worth to the landlord only a twentieth, or thirtieth part of what those identical trees would have been worth, had they been protected from the spoliation of the farmer's axe. Including interest on the value of such trees, the

amount would have been at least an hundred times more than it is.

And instances are not wanting in every county, of pollard oaks abounding in hedge rows; which, had they been protected till grown into trees, and sold in their prime, including interest on their produce, would now have brought three times more money than the freehold would sell for which produced them. But, for want of such protection, they at present disfigure the estates on which they stand; and are only of a comparatively trifling value. Consequently, the owners of such estates have lost the greater part of their property by the knavery of their tenants; the want of skill and diligence in their agents; and of attention or discernment in themselves. It is suggested, that the best remedy for this evil would be, for landlords to cut down all the pollards over the whole extent of their properties; and to sell them for what they would fetch. They would produce, on some estates, a considerable sum, which, at compound interest, would double itself every fifteen years. But the longer the pollards stand, the less valuable they will be. In the next place, a covenant should, it is contended, be entered into by the tenant, not to *top* any tree (nor to *lop* it to any greater height than ten or fifteen feet from the ground) under a penalty of five pounds for each offence; which sum the landlord would be entitled to receive of the tenant for every pollard discoverable at any time upon his estate. Any tree recently pollarded, would be positive evidence against the tenant; who should be invariably required to pay the penalty; and, when that is done, the landlord should cut the pollard down. If this method were adopted, and the young trees thus carefully protected, the estates would increase in beauty and value every year. In a *national* point of view, this matter is of still greater importance, as it is not conceivable, without the help of calculation, what an immense loss of timber is sustained in this way.

Where pollard trees abound in hedge rows, they are in general cropped or cut over once in from about nine to fifteen years, the advantage of which mostly belongs to tenants. It is a work that should be carefully performed, the branches being taken off by a clean cut, and be constantly finished by the latter part of February, if possible to be done.

POLLARD, in *Rural Economy*, a term applied to the fine bran or inner husk of wheat. It is a substance much used in the southern districts in feeding hogs and different sorts of domestic animals.

POLLARD is a name given by some historians to a sort of base money current at one time in Ireland, and called more usually *crocards*.

These were coins of France, and other nations, which passed in Ireland as pennies, though really not worth quite half so much. They were made of copper, with a very small admixture of silver.

It was in the reign Edward I. appointed lord of that kingdom in the life-time of his father Henry III. that the use of false and counterfeit money of this kind was so extremely common in Ireland. While his father reigned in England this prince never extended his power so far as to set up any mint, or coin any money in Ireland; but at his accession to the crown he found his treasury empty, and the current coin of his kingdoms in a very bad condition; his absence of near two years after his father's death having so encouraged the clippers and coiners of money, that little but clipped or counterfeit money of the kingdom was to be met with; and five or six different sorts of base and mixed money had been imported privately, and uttered in England and Ireland as pennies, though they were not half the value of the penny sterling.

These were the crocards and pollards, called also mitres, lionines, rosaries, and by the like names, according to the things marked in the impressions. To remedy this evil, and restore the current coin of the kingdom to its ancient purity and value, this prince established a certain standard; and as the base money was an admixture of a very small quantity of silver, with a great deal of copper, he ordered that there should be in every pound of money weighing twelve ounces, eleven ounces and two penny-weights and a quarter of pure silver, and only seventeen pence halfpenny farthing alloy.

The said pound to weigh twenty shillings and three pence in account; the ounce twenty pence; and the penny twenty-four grains and a half. According to this regulation, the money of Ireland was also ordered to be made, and a new kind of money was struck there in the year 1279, under Stephen de Fulbourn, bishop of Waterford, and lord deputy of Ireland. The pieces coined at this time in Ireland were groats, or four-pennies, halfpence, and farthings; and as these were the same in value, as to weight, with the English coins, they would go equally in England and Ireland; and in the twenty-ninth year of the reign of the same prince, that is, in 1300, the crocards, pollards, and other base money, were decried; and it was made death, with confiscation of goods, to import any of them.

By this means the circulation of the base and mixed money was in a great measure stopped, and four new furnaces were erected in the mint of Dublin, to supply the great demand that there was for good money; and Almander Norman de Line was appointed master of the coiners. This was the beginning of good money in Ireland; and in the year 1304, there were sent over from England twenty-four stamps for coining of money there, *viz.* three piles with six crosses, for pennies; three piles with six crosses, for halfpence; and two piles with four crosses, for farthings. In the old way of coining with the hammer, before the mill and screw were invented; two kinds of punchions were in use, the one called the cross, upon which was engraved the head of the prince; and this was so called, because anciently a cross was the figure struck on this side of coins instead of the head of the prince: the other, called the pile, contained the arms, or some other figure, to be struck with an inscription on the back, or reverse of the coins. The pennies and halfpence struck in this king's reign, have the king's head in a triangle full-faced. The best preserved of them, found at this time, weigh twenty-two grains the penny: and the halfpence from ten grains to ten and a half. The farthings are so scarce, that it is very rare to meet with one in the collections of the most curious. Simon's Hist. of Irish Coins, p. 15.

POLLARD, in *Ichthyology*, a local name for the young and small fish of the cole-fish, or rawling-pollack kind. It is used in Cornwall, &c.

POLLAROLI, CARLO FRANCESCO, in *Biography*, one of the most voluminous composers of operas at Venice; who, from 1689 to 1729, when he died, composed more than a hundred lyric dramas for that city, which seem all to have been well received. His son Antonio, maestro di cappella of St. Mark's cathedral, was an eminent musician, and a composer of several operas for the Venetian theatres.

POLLAY, in *Geography*, a town of Hindoostan, in Bahar; 25 miles S.W. of Patna. N. lat. 25° 21'. E. long. 85°.—Also, a town of Hindoostan, in the circar of Ruttunpour; 10 miles N.E. of Ruttunpour.

POLLE, a town of Westphalia, in the principality of Calenberg, on the Weser, with a ferry; 20 miles S. of Hameln.

POLLEAR, or POLEYAR, in *Hindoo Mythology*, a name of the god of prudence and policy. He is always represented with the head of an elephant, and generally with four arms, otherwise as a man; sometimes mounted on a rat or mouse, or with that animal beside him, it being deemed in India a very sagacious animal, and the elephant proverbially so. He is deemed the offspring of Siva and Parvati, and is often seen with the sectarial marks on his forehead, that distinguish the grand division of Saivas; such as horizontal lines, a crescent, &c. His commonest name is Ganefa; that at the head of this article being of local usage, on the coast of Coromandel chiefly. He is also classically called Ganyaka; and vulgarly, among the Mah-rattas and low people, Ganpatty. His name of Ganefa is derived by sir W. Jones from *gana*, an assemblage of gods, and *isa*, meaning lord; denoting him to be the superior of such assemblages, of which Hindoo books enumerate nine, each consisting of eight deities. He is invoked by Hindoos of many, if not of all, sects in the outset of any business: if a person build a house, an image of Ganefa is previously propitiated by ceremonies detailed in their rituals, and set up at or near the spot: if he write a book, Ganefa is saluted at the commencement, as he is also at the top of a letter, with *Sri Ganefa namah*, praise to the divine Ganefa, or some such phrase, or a character denoting it. Setting off on a journey, Ganefa is implored to protect him; and for the accommodation of travellers his image is frequently seen by the road side, especially where two roads cross; but sometimes it is little else than a stone rudely chiselled into something of a conical form, or like an elephant's head, with oil and red ochre daubed over it, decorated perhaps with a chaplet of flowers by some pious neighbour or traveller. It is common to see a figure of the god of prudence over bankers' and other shops; and upon the whole there is perhaps no deity in the Hindoo Pantheon, as copious as that of Rome, oftener seen and addressed.

There are several coincidences in the characters of Ganefa and Janus: to both were ascribed a character of wisdom; and when he is described as considered by the Romans "the god who presided over the beginning of all undertakings, receiving the first libations of wine and wheat, and the preface of all prayer," the description answers to both.

Besides the usual adoration paid to Ganefa associated with other gods, there is, it is said, a sect of people who exclusively or chiefly worship him. They are called Ganapatya. He has been frequently incarnated, and Hindoo books contain numerous legends of his metamorphoses and adventures, heroic and amorous. Under the article MURABA of this work, an instance is given of existing superstition connected with this deity, scarcely to be paralleled out of Asia.

The worship of Ganefa we may conclude to have been long as well as extensively a usage, for he is seen frequently sculptured in the Elephanta and other ancient caves. In the Puranas are many extravagant relations respecting him. Although usually considered as the offspring of Siva, it is said in the Siva Purana that he was formed by Parvati of fair proportions, of the excrementitious particles and impurities of her own body, without the intervention of her lord, which so enraged him, that on one occasion he cut off the head of Ganefa, in place of which an elephant's was substituted. Sometimes he is seen in pictures with but one husk, and legends, similarly extravagant, are given to account for this. Such of our readers as desire more of these fables, we refer to the Hindoo Pantheon, where many particulars and plates of Ganefa are given. Under the article PARASU RAMA of this work, that hero is mentioned as the *cutter-off* of the head of Ganefa.

POLLEE, in *Geography*, a town of Hindoostan, in Orissa; 12 miles E. of Sonepour.

POLLEN, in *Botany* and *Vegetable Physiology*, a Latin word, expressive of any fine powder, but originally of the light volatile dust of a mill; and now technically applied to the powdery particles, discharged by the anthers of flowers. These are thrown out, chiefly in warm dry weather, when the anther bursts, either by the contraction of its coat, or by some appropriate opening, or pore. The pollen, though a fine powder in appearance, and light enough to be wafted along by the air, has a peculiar and appropriate structure, sometimes very different in different plants. Each grain is commonly a membranous bag, round or angular, rough or smooth, which remains entire till it meets with any moisture, when it bursts with great force, discharging a most subtile vapour. The moisture naturally destined to produce this explosion, is the honey-like exudation of the stigma, by which means it takes place in the only situation where the requisite purpose can be answered, of impregnating the germen. (See *FECUNDATION of Plants*.) If the pollen meets with wet before it arrives at the stigma, a premature bursting, and loss of its contents and virtues, are the consequences. Nothing can be a more exquisite hygrometer than the membranous part of the pollen. This appears by the intelligent remarks of Mr. Luke Howard, of Plaistow in Essex, published in *Transf. of Linn. Soc.* v. 6. 65. To that gentleman we are indebted for the information that the pollen of the Hazel-nut, and some other plants, consists of several cells. The various movements which he describes, in pollen floating in mixtures of spirits and water, are probably to be attributed, not to any sort of irritability, but to the impetus given to each bag by the discharge of its contents; as well as to the compound agitation, caused by the hygrometrical effect of the water absorbed by the membrane, and the dissolving or separating action of the spirits upon its substance, which, from the inflammability of some kinds of pollen, appears to partake of a resinous nature.

In many plants of the natural orders of *Orchidea* and *Consortia*, as well as in the genus *Mirabilis*, the pollen seems of a glutinous nature, or rather of an elastic or spongy texture, saturated with a fluid. This fluid appears nevertheless to be analogous to the more elastic impregnating vapour of ordinary pollen. In some of the *Orchidea* it becomes, after a while, as Mr. Brown has observed, of a waxy nature. Such pollen is gradual in performing its office, attaching itself to the stigma, and remaining there in its original mass, not flying in dispersed particles, and in a casual manner, through the air, to impregnate stigmas of distant flowers.

The pollen of plants that blossom under water must be of a very different nature from that which flies through the air, and which with the touch of any moisture is destroyed. We can easily conceive that submersed vegetables may be provided with a still more glutinous, or resinous, pollen, only so far soluble in water as may answer the purpose of its communication with the stigmas; while, in like manner, the secretion of the latter must be of a different nature from that of ordinary plants, lest it should be weakened, or washed away, by the circumambient fluid.

POLLEN, in *Agriculture*, a provincial word applied to the hen-roost. It is sometimes written pollen and hen-pollen.

POLLEN *Thuris*, in the *Materia Medica*, a term used by the Latin writers to express the *manna thuris*, or *manna libanotis*, of the Greeks, but that very improperly; for the word *pollen thuris* properly signifies the frankincense reduced to a powder; but this was not what the ancient Greeks called *manna thuris*, but the small fragments which were

broken off from the large pieces, in the gathering or packing up. See *LEPTOS Libanotis* and *FRANKINCENSE*.

POLLENECA, POLENZA, in *Ancient Geography*, a town of Italy, in Etruria, N. of Augusta Vagiennorum, at the confluence of the Stura and the Tanarus. Suetonius, in his life of Tiberius, mentions it as an ancient and municipal city.

POLLENFELD, in *Geography*, a town of Bavaria, in the principality of Aichtatt; 3 miles N.E. of Aichtatt.

POLLENTIA, in *Ancient Geography*, a town of Italy, in the interior of Liguria; situated, according to Pliny, near the Alps, furnamed Potentia, and S.E. of Afta.—Also, a town of Italy, in the Picenum, with the title of a Roman colony, according to Livy.—Also, one of the chief towns of the Greater Balearic isle, situated towards the N.E., and bearing, as Strabo says, the title of a Roman colony.

POLLENZA, or PUGLIANZA, in *Geography*, a town situated on the N. of the island of Majorca, anciently *Pollentia*. This ancient little town was built, as it is said, with a view of replacing a Roman colony, founded in that situation, and on that account called Colonia. It evidently appears by aqueducts and other remains to have been formerly of greater extent than it is at present: it is a league from the sea, in a plain protected from the north winds by several high hills. The interior is well built, and the population amounts to nearly 6000 inhabitants, who are in easy circumstances. The parish church is consecrated to our Lady of the Angels, and is built in a good style of architecture; it has a prior and 19 beneficiaries, appointed by the order of Malta, who have the same jurisdiction with that formerly exercised by the Knights Templars, to whom it belonged. Here are a convent of Dominicans, an unfinished monastery of Jesuits, a military hospital, and two chapels or oratories. The moorings in the port of Pollenza are of sufficient depth to admit ships and galleys; they are sheltered from all winds, and defended by a tower with artillery. The environs are well cultivated; here are vines, olive-trees, and large flocks of sheep: the principal productions are oil and wine; the latter, called "Montona," is exquisite, and particularly valued. Near Pollenza stands an insulated mountain, on the top of which is a chapel consecrated to the Holy Virgin; and on the N. are the ruins of the castle of Pollenza. Towards the N.E. the isle is terminated by a point advancing very far out into the sea, and forming the cape of Fromentor. To the N.W. is *Palamera*, which see. After traversing some lofty mountains, thought to be the highest in the island, on the W. of Pollenza, you arrive at Soller, a small port, with a narrow and difficult mouth, protected by a battery of several guns, at which the ships receive their cargoes of oranges, which they export to foreign countries. Pollenza is distant 26 miles N.N.E. from Majorca. N. lat. 39° 51'. E. long. 3° 1'.

POLLEX, in *Anatomy*, the thumb. Pollex pedis is used for the great toe; but the expression is incorrect, since that member cannot be moved in opposition to the other toes, as the thumb may in opposition to the fingers. The proper word is hallux. See *EXTREMITIES*.

POLLIA, in *Botany*, so named by Thunberg, after his great patron I. van der Poll, a burgomaster of Amsterdam, one of those who promoted his voyage to Japan; as appears by the preface to his *Flora* of that country, p. 13.—Thunb. *Nov. Gen.* 11. *Jap.* 8. Schreb. 223. Murray in *Linn. Syst. Veg.* ed. 14. 332. Willd. *Sp. Pl.* v. 2. 149. Juss. 45.—Class and order, *Hexandria Monogynia*. Nat. Ord. *Enfatae*, Linn. *Junci*, Juss.

Gen.

Gen. Ch. reformed. *Cal.* Perianth of three obovate, obtuse, concave, coriaceous, permanent, finally reflexed leaves. *Cor.* Petals three, alternate with the calyx and about the same length, oblong, membranous, ribbed, withering. *Stam.* Filaments six, inserted into the receptacle, capillary, incurved at the summit; anthers of two roundish lobes. *Pist.* Germen superior, globose, sessile; style slender-awlshaped, incurved; stigma simple, obtuse. *Peric.* Berry globose, coloured, polished, accompanied by the reflexed calyx and withered petals. *Seeds* numerous, about twenty, angular.

Ess. Ch. Calyx of three leaves. Petals three. Filaments simple. Berry with many seeds.

1. *P. japonica*. Thunb. Jap. 138. Jamma Mioga of the Japanese.—The only known species, found near Nagasaki in Japan, as well as in the isle of Java. *Thunberg*. It flowers in September, but is as yet a stranger in the gardens of Europe, nor has a figure of this rare plant ever appeared. We have a specimen from its discoverer, the whole aspect of which justifies the sagacious determination of Jussieu, respecting its natural affinity. It ranges near *Tradescantia*, both in the natural and artificial systems; nor is it related, as has been suspected, to *Asparagus* or *Dracena*. The stem is erect, about two feet high, but little branched, angular, jointed, clothed with short, dense, recurved, rigid pubescence. *Branches* alternate, short. *Leaves* crowded about the lower part of the stem; widely scattered above; alternate, elliptic-lanceolate, a foot long, entire, tapering at each end, with a strong mid-rib, and several smaller parallel lateral ones; both surfaces very minutely roughish. *Footstalks* clasping the stem, membranous, ribbed, hairy, abrupt. *Flower-stalks* corymbose, placed about four in a whorl; rough with short reflexed hairs, of few flowers; the partial ones smooth, white, and thickened upwards. *Braætes* membranous, white. *Flowers* snow-white, the size of *Asparagus* blossoms. *Berry* as big as a large pea, its outer surface, even in a dried state, of the most beautiful polished blue, like that given by heat to steel. Internally it is white, and seems to be divided into three cells.

POLLICHIA, a most distinct and curious genus, thus named by Dr. Solander, in honour of John Adam Pollich, M.D. author of an excellent Flora of the Palatinate of the Rhine, in three volumes octavo, full of ample and scientific descriptions. He died in 1780.—Ait. Hort. Kew. ed. 1. v. 1. 5, and v. 3. 505. ed. 2. v. 1. 11. Schreb. 782. Willd. Sp. Pl. v. 1. 23. Mart. Mill. Dict. v. 3.—Class and order, *Monandria Monogynia*. Nat. Ord. *Holeracea*, Linn. *Amaranthi*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, pitcher-shaped, with five furrows and five teeth, permanent; its mouth bordered with an elevated pellucid ring. *Cor.* Petals five, very small, inserted into the ring, alternately with the teeth of the calyx. *Stam.* Filament solitary, incurved, inserted into a fissure in the ring, next to one of the teeth of the calyx, which it scarcely equals in length; anther roundish, incumbent, of two lobes. *Pist.* Germen in the bottom of the calyx, ovate; style thread-shaped, cloven, the length of the calyx; stigmas two, divaricated, obtuse, fringed. *Peric.* none, except the permanent thickened calyx. *Seed* solitary, ovate, filling the cavity of the calyx. *Recept.* of several aggregate scales, sometimes compound; each roundish, fleshy, bearing on its disk a solitary flower, and at length becoming very juicy, pellucid and coloured, supporting the ripened fruit.

Ess. Ch. Calyx of one leaf, with five teeth, permanent. Petals five. Seed one. Scales of the receptacle pulpy, aggregate, supporting the fruit.

1. *P. campestris*. Whorl-leaved Pollichia. Smith Spicil. 1. t. 1. Willd. n. 1. Ait. n. 1.—The only-known species; discovered in sandy fields at the Cape of Good Hope by colonel William Patterfon, who sent its seeds to the late countess of Strathmore and to Kew, in 1780. The plant is biennial in the greenhouse, flowering in autumn. *Root* fibrous. *Stems* numerous, twelve or eighteen inches long, decumbent, branched, leafy, rather shrubby, round, invested with scattered white down. *Leaves* about six in a whorl, unequal, spreading, sessile, linear-lanceolate, entire, tapering at each end, about an inch long, smooth, glaucous, scarcely fleshy. *Stipulas* numerous, small, membranous, lanceolate. *Flowers* in small, axillary, sessile, opposite green heads, at almost every whorl, numerous, small, with white petals. *Fruit* a larger head of crowded, juicy, sweet, pearly-white scales, each supporting a brown calyx, containing one seed.

No genus can be more curious and distinct. It differs from *Blitum*, not to mention other marks, nearly as *Broussonetia* differs from *Morus* (see PAFYRIUS); the fruit or seed being elevated on an enlarged pulpy receptacle, instead of being enveloped in the calyx, become juicy and coloured like a berry. In *Broussonetia* indeed the calyx remains at the bottom of the pulpy receptacle; in *Pollichia* it is elevated upon that part.—Dr. Solander, in his description, overlooked the five white petals; and Willdenow, not having seen the *Spicilegium*, where alone a full description and coloured plate of this plant have appeared, unavoidably copied the error; which also escaped Mr. Dryander in editing the new edition of *Hort. Kew*.

POLLICIPES, the *Toe-shell*, in *Natural History*, the name of a genus of shells, the characters of which are these: they are multivalve flat shells, of a triangular figure, each being composed of several laminæ, which end in a sharp point. They stand upon pedicles, and are furnished with a great number of hairs. We have only one known species of this genus, and this always found in large clusters.

POLLICIS ABDUCTOR, in *Anatomy*. See ABDUCTOR.

POLLICIS Adductor. See ADDUCTOR.

Extensor POLLICIS Brevis, and Longus. See EXTENSOR.

Flexor POLLICIS Brevis, and Longus. See FLEXOR.

POLLINA, in *Geography*, a river of Sicily, which runs into the sea; 10 miles W.N.W. of Mistretta.

POLLINCTORES, among the *Ancients*, an appellation given to those who washed and anointed the dead.

POLLINCTURA, a word used by some authors to express the embalming of dead bodies.

POLLING, in *Gardening*, the operation of dispersing the worm-casts all over the walks, with long ash-poles: this, besides destroying worm-casts, is very beneficial to the grass of the walks. See GRASS-walks.

POLLIO, C. ASINIUS, in *Biography*, an eminent Roman, was born about the year B. C. 76. Although he was descended from an obscure family, he raised himself by his merit to the highest offices in the state. He was consul with Domitius Calvinus, in the year 40 B. C., triumphed over the Dalmatians, and performed much important service to Antony in the civil wars. After this he was regarded as a friend by Augustus, and was looked upon as one of the most illustrious persons of his time. He obtained celebrity as a literary character, ranked very high as an orator, and composed a history of his own times. Horace addresses to Pollio the first ode of his second book, and begins it with an allusion to his intended history of the civil wars. Virgil also, in his third eclogue, records his gratitude to Pollio as the favourer of the muse, and to him he inscribes his fourth eclogue. Pollio was a severe and jealous critic, and some

of his strictures are recorded upon the writings of Livy, Sallust, Cæsar, and Cicero. To the well-earned glory of the latter he was exceedingly inimical. His own style is represented by Quintilian as studied, weighty, and expressive, but hard and abrupt, and approaching more to that of the earlier writers, than to the polish and sweetness of Cicero and his contemporaries. He was a man of extensive erudition and great industry. He wrote a Narrative of Roman affairs; a Grecian history; and likewise composed tragedies in the Greek language. He is said to have been the first who founded a library in Rome for the public use, to which laudable purpose he devoted the spoils he had taken in war. Of his writings nothing remain, excepting a few passages quoted by other authors. He died about the year four of the Christian era, at the age of 80.

POLLIOR, or BELIOR, in *Geography*, an island in the PERSIAN gulf, which see.

POLLIPLE'S ISLAND, a small rocky island, at the N. entrance of the Highlands in Hudson's river.

POLL-MONEY, or CAPITATION, a tax imposed by authority of parliament, on the person, or head, either on all indifferently, or according to some known mark of distinction; as quality, calling, &c.

Thus, by the statute 18 Car. II. every subject in the kingdom was assessed by the *head*, or *poll*, according to his degree; every duke 100*l.*, marquis 80*l.*, baronet 30*l.*, knight 20*l.*, esquire 10*l.*, &c. and every single private person 12*d.*

This was no new tax, as appears by former acts of parliament; particularly that anno 1380, where, *quilibet tam conjugatus quam solutus, utriusque sexus, pro capite suo solvere cogebatur*. Walsing. See CAPITATION.

Camden, in his Remains of Coins, says, there was anciently a personal tribute called *capitatio*, or *poll-silver*, imposed on the poll, or person, of every one; on women from the age of twelve years, and on men from fourteen.

POLLOCK, in *Geography*, a town of North Carolina; 35 miles E.S.E. of Halifax.—Also, a town of North Carolina; 13 miles S.W. of Newbern.

POLLOCK Harbour, a harbour on the west coast of Mindanao. N. lat. 7° 15'. E. long. 124° 42'.

POLLOCKSHAW, a manufacturing town of Scotland, in the county of Renfrew; 5 miles E. of Paisley.

POLLS, a town of the duchy of Stiria; 5 miles N. of Judenberg.—Also, a town of South Carolina; 18 miles W.N.W. of George-town.

POLLUCTUM, among the Romans, a feast kept in honour of Jupiter Dapalis, Hercules, &c. at which sacrifices were offered to the gods.

POLLUTION, POLLUTIO, the act of profaning a temple, or other holy place.

The Romanists hold a church to be polluted by the effusion of blood, or of seed, therein; and require its being consecrated anew.

The Jews were held polluted by the touching of a dead body, or of the menses of women; and were to be purified in form. See the laws relating to it in Leviticus.

The Indians are so superstitious on the head of pollution, that they break all the vessels which those of another religion have drank out of, or even only touched; and drain all the water out of a pond a stranger has bathed in.

POLLUTION, or *Self-Pollution*, is also used for the abusing or defiling of one's own body, by means of lascivious frictions and titillations, raised by art, to produce emission.

We read in Scripture, that Onan, and, as some critics also think, Er, were severely punished for having polluted themselves by spilling their seed on the ground; whence the crime has been denominated, by some, *Onania*.

Of pollutions, some are *voluntary*, others *involuntary*, and *nocturnal*.

POLLUTION, *Pollutio Nocturna*, in *Medicine*, the name of a disease, which consists in an involuntary emission of the seed in the night, in time of sleep. This, in different persons, is very different in degree; some being affected with it only once a week, a fortnight, three weeks, or even a month, and others being subject to it almost every night.

The persons most subject to this are young men of a sanguineous temperament, and who feed high, and lead a sedentary life. When this happens to a person but once in a fortnight or a month, it is of no great consequence; but when it happens almost every night, it greatly injures the health; the patients look pale and sickly. In some the eyes become weak and inflamed; sometimes they are affected with violent defluxions, and usually, at last, are circled round with a livid appearance of the skin.

The distemper is to be cured rather by a change of life than by medicines. When it has taken its rise from high diet and a sedentary life, a coarser food and the use of exercise will generally cure it; but if any medicines are to be given, nitre alone will do more than almost all the rest. This may be taken in large doses, a scruple at a time, with very little liquid with it, and must be continued for some time at night going to rest. The root of the water-lily is greatly recommended by some in this case; and by others, the seeds of the agnus castus; but it is very doubtful whether they have either of them any effect.

Persons subject to this disease must never take any stimulating purges, and must avoid, as much as possible, all violent passions of the mind; and though exercise is recommended in moderation, yet if this be too violent, it will rather increase the disorder than do any thing towards its cure.

The Romish church puts up prayers, in the close of the evening office, to be preserved from nocturnal pollutions.

POLLUTRI, in *Geography*, a town of Naples, in Abruzzo Citra; 9 miles S.E. of Lanciano.

POLLUX, in *Astronomy*, the hind twin, or the posterior part of the constellation Gemini.

POLLUX is also a fixed star of the second magnitude, in the constellation Gemini, or the Twins.

POLLUX is also used in *Meteorology*. See CASTOR.

POLLUX, in *Mythology*, the name of a demi-god, supposed to be the son of Jupiter and Leda, who had a temple in the city of Teraphne, in Laconia, where was also a sacred fountain, called Polydocea, or the fountain of Pollux.

POLLUX, JULIUS, in *Biography*, a grammarian, who was born at Naucratis in Egypt, and flourished in the reign of Commodus, about the year 180. He wrote an epithalamium for that emperor, and opened a school for rhetoric at Athens. He was author of a dictionary, or "Onomasticon," which is extant, and is a valuable aid to the study of the Greek language, and the elucidation of its writers. The best edition of this work is that of Hemsterhuys, 2 vols. folio, Gr. et Lat. 1706. Another author of the same name, but much posterior, wrote a "Chronicon," in Greek, from the creation to the reign of the emperor Valens. Of this there is an edition by Hardt, printed at Leipzig in the year 1792.

Pollux, in his "Onomasticon," treats of music; and in the 4th chapter of his second book, "De voce, aut his quæ a voce derivantur;" ch. 7. lib. 4. "De poetis et cantilenis gentilitiis," of poetry and graceful melody; ch. 8. "De instrumentis musicæ;" of musical instruments invented by different people; of the pulsatile, stringed, and pneumatic kind;

kind; of the music of Olympus, and of the musical contentions at the Pythic games.

POLNA, in *Geography*, a town of Bohemia, in the circle of Czaflau; 22 miles S. of Czaflau. N. lat. $49^{\circ} 30'$. E. long. $13^{\circ} 35'$.

POLNO, a town of Hinder Pomerania; 75 miles W.S.W. of Dantzic. N. lat. $54^{\circ} 3'$. E. long. $16^{\circ} 27'$.

POLNOVATSKOI, a town of Russia, in the government of Tobolsk; 36 miles E. of Berezov.

POLO, MARCO, in *Biography*, a celebrated traveller of the 13th century, was born about the year 1250. His father Niccolo, and uncle Matteo, were two citizens of Venice, who sailed to Constantinople in the reign of the emperor Baldwin II., and in that city Marco was born. The two brothers sailed across the Euxine to Armenia, whence they travelled by land to the court of a considerable Tartarian lord, named Barka. By him they were favourably received; but after a year spent at his capital, they went to Persia, where they remained three years, whence they accompanied a messenger going to the court of Kublai, grand khan of the Tartars, and arrived after a year's journey. Here they were favourably received by the powerful monarch, who was curious in his inquiries concerning the affairs of Europe, and the Christian religion. They gained his confidence so completely, that he determined to dispatch them as his ambassadors to the pope, with the request that he would send persons to instruct his people in the true faith. They set out, and in three years, *viz.* in 1269, reached Italy. At this time there was a vacancy in the popedom, and the brothers remained at Venice two years before it was filled. At length they obtained letters for Kublai from Gregory X., taking with them young Marco, and accompanied by two friars of the order of preachers, they again departed for the east. On their arrival in Armenia, they found the sultan of Babylon at war with that province; on which account the friars refused to advance, but no sense of danger could prevent the Venetians from proceeding on their course; and after a journey of three years and a half, in the midst of dangers and disasters, they came to a city in which Kublai then resided. He was much pleased with their return, and received with the most profound respect the letters of the pope, and a present of some oil from the lamp burning before the holy sepulchre at Jerusalem. To Marco he paid the greatest attention, and the young man in a very short time acquired four different languages of that country, and made himself so acceptable to the khan, that he was employed in various missions to different provinces. In every situation he diligently noticed the manners and customs of the countries of the people among whom he resided; and from the facts which he collected, he afterwards composed his book of travels.

After a residence of 17 years at the court of Kublai, the Venetians were extremely desirous of returning to their native land, and at length obtained permission to accompany the ambassadors of a king of India, who had come to demand a princess of the khan's family in marriage for their sovereign. It was a voyage of 18 months through the Indian sea, before they arrived at the court of this king, named Argon. Thence they travelled to Constantinople, and finally reached Venice in 1295. They returned rich in jewels and valuable effects, after an absence of 26 years, which had so altered them, that they were obliged to make a display of their wealth to procure a reception from their relations. In a very short time, news came to Venice, that the Genoese were approaching with a powerful armament; on which account, a number of galleys were immediately fitted out to oppose them, and Marco Polo was appointed

to the command of one of them. In an engagement that ensued he was taken prisoner, and carried to Genoa. He was, however, well treated, sent for his papers, and employed himself in writing an account of his travels. After this he obtained his liberty, but of his subsequent history nothing is known. His work was probably composed in the Venetian dialect, and from this several versions have been made into the Italian and Latin languages. The best Latin translation is that of Andrew Muller, 1675. It has also been translated into several modern languages. Of the veracity of his relations very different opinions have been given; but in what he asserts from his own knowledge, he seems in general deserving of credit; and perhaps to him Europeans owe the first distinct account of the remoter parts of Asia. *Univer. Hist.*

POLO, in *Geography*, an island in the Pacific ocean, about 50 miles in circumference. N. lat. $14^{\circ} 55'$. E. long. $122^{\circ} 28'$.—Also, a small island in the East Indian ocean, near the N. coast of Samar. N. lat. $12^{\circ} 14'$. E. long. $121^{\circ} 33'$.—Also, a small island in the East Indian sea, near S. coast of Bool. N. lat. $9^{\circ} 40'$. E. long. $124^{\circ} 5'$.

POLOK, a town of Poland, in Podolia; 54 miles N.W. of Kamniec.

POLOLAMOI, a town of Russia, in the government of Olonetz; 100 miles W.S.W. of Kemi.

POLOMA, a town of Africa, in the kingdom of Aweri, on the sea-coast, at the mouth of the river Formosa, inhabited by fishermen; 12 miles S.S.W. of Aweri.

POLOMEN, a town of Prussia, in Natangen; 8 miles N. of Lick.

POLONGHERA, a town of France, in the department of the Stura, on the Po; 13 miles S. of Turin.

POLONHIR, a river of Thibet, formed by the union of several small streams, 20 miles E. of Tchontori, which loses itself in lake Hara.

POLONIA, a river of European Turkey, which runs into the Adriatic, at Pirgo, in the province of Albania.—Also, a small strait that forms the separation of the islands of Milo and Argentiera, called by the Greek navigators the "Pas de Pologne." This passage is too dangerous to be frequented by shipping. At the entrance of this strait, on the coast of Milo, which faces the N.E., is extracted a sort of Cimolian earth, differing very little from that of Argentiera; boats come and load with it, in order to convey it to the other islands of the Archipelago: this earth is even said to be preferred to the true Cimolian earth for washing, but that it is not so proper for scouring and taking out spots. The Greeks call it "pilo," which merely signifies clay.

POLONIA, a town of European Turkey, in Albania, the see of a Greek bishop; 20 miles N. of Valona.

POLONNE, a town of Russian Poland, in Volhynia; 115 miles W. of Kiev.

POLORE, a town of Hindoostan, in the Carnatic; 26 miles S.S.W. of Arcot. N. lat. $12^{\circ} 30'$. E. long. $79^{\circ} 15'$.

POLOROTOVA, a town of Russia, in the government of Irkutsk; 24 miles S. of Kirensk.

POLOTSK, a city of Russia, and capital of a government, to which it gives name, situated on the Duna; 168 miles S.E. of Riga. N. lat. $55^{\circ} 32'$. E. long. $28^{\circ} 20'$.

POLOTSKOE, a government of Russia, bounded on the N.E. by the government of Pskov, on the N.W. by that of Riga, on the S.E. by those of Smolensko and Mogilev, and on the S.W. by Lithuania; about 160 miles in length, and 60 in breadth. This country was formerly

formerly a part of Lithuania: its capital is Polotsk. N. lat. 55° 10' to 56° 16'. E. long. 25° to 31°.

POLPHOS, a word used by some authors to express a bulb or bulbous root.

POLPOCH, in *Zoology*, a species of serpent, said to be found in Yucatan, a country bordering upon New Spain. It can bite with the mouth, and sting with the tail.

POLRITTEN, in *Geography*, a town of Prussia, in Ermeland; 6 miles S. of Heilsberg.

POLTANA, a town of Naples, in Abruzzo Citra; 9 miles S. of Lanciano.

POLTAVA, or PULTAWA, a town of Russia, in the government of Ekaterinoflav, on the Vorekla. This town,

with its regular fort, is subject to a commandant, who resides here. The burghers carry on a considerable trade to the Crimea, and through Poland to Germany. The town is but indifferent, being built after the manner of the Cossack towns; however, it was rendered famous by the siege of the Swedes in 1709; at last it fell into the hands of the Russians, after the defeat of Charles XII. near this place. On an eminence without the town stands a monastery, where the king of Sweden had his head quarters; 84 miles N.N.W. of Ekaterinoflav. N. lat. 49° 30'. E. long. 34° 14'.

POLTIN, or POLPOLTIN, in *Commerce*, a Russian silver coin. The poltin is = 50 copecks, and the polpoltin = 25 copecks.

	Assay.		Weight.			Contents in pure Silver.	Value in Sterling.	
	oz.	dwt.	oz.	dwt.	gr.	grains.	s.	d.
Poltin, or half ruble, of the empress Ann -	W.	1 10	0	7	21	151.2	1	9
Ditto of the empress Elizabeth - -	W.	1 8	0	8	2	156.9	1	10
Ditto of Catharine II. - - -	W.	2 4	0	7	18	137.9	1	7 $\frac{1}{4}$
Ditto of Paul - - - -	W.	0 15	0	6	18	139.8	1	7 $\frac{1}{2}$
Ditto of Alexander (1804) - - -	W.	0 14	0	6	13 $\frac{1}{2}$	136.5	1	7
Polpoltin, or $\frac{1}{2}$ ruble, old - - -	W.	2 6	0	4	1	71.2	0	10
Ditto of Paul - - - -	W.	0 18 $\frac{1}{2}$	0	3	7	67.3	0	9 $\frac{1}{2}$
Ditto of Alexander (1802) - - -	W.	0 13 $\frac{1}{2}$	0	3	9 $\frac{1}{2}$	70.8	0	10

N. B. W. denotes worse than the English standard.

The poltin, or half ruble, bears the same impressions as the ruble, according to the period at which it was coined, except that the inscription contains the word "POLTINA," instead of "RUBLE:" and the quarter ruble is marked "POLUPOLTINICK."

POLTROON, or POLTRON, a coward, or dastard, wanting courage to perform any thing great or noble.

The word we borrow from the French, who, according to Salmafius, derive it à *pollice truncato*; because, anciently, those who would avoid going to the wars, cut off their thumbs.

But Menage, with more probability, derives it from the Italian *poltrone*, and that from *poltro*, a bed; because timorous pusillanimous people usually take pleasure in lying a-bed. He adds, that the Italian *poltro* is again derived from the German *polster*, a pillow, or cushion.

Others choose to derive the word from the Italian *poltro*, *colt*; because of that creature's readiness to run away.

POLTROON, in *Falconry*, is a name given to a bird of prey when the nails and talons of his hind toes are cut off, in which his chief force and armour lay; in order to intimidate him, and prevent his flying at great game.

POLTURAT, in *Commerce*, a copper coin of Hungary, which sometimes contains a little silver. A polturat is accounted = 6 pfenings, and a creutzer is 4 pfenings.

POLTZIN, in *Geography*, a town of Pomerania, near which are some medicinal springs and baths; 32 miles S.E. of Colberg. N. lat 53° 46'. E. long. 16° 4'.

POLTZNITZ, a river of Saxony, which runs into the Elster, at Elsterwerda.

POLVERINE, the calcined ashes of a plant; a substance of the nature of our pot-ashes, or pearl-ashes.

It is brought from the Levant and Syria; but in the glass trade, though it be of the nature of the other ashes they use, it is always to be preferred to any other. The barilla, or pot-ashes of Spain, yield more pure salt than the pulverine of the Levant, but the glass made with it has always

some tinge of blueishness: that made with the pulverine is ever perfectly white, and this is the substance that ought always to be used for the finest crystal. See GLASS.

POLUKSHA, in *Commerce*, a copper coin of Russia = $\frac{1}{4}$ copeck.

POLURA, in *Ancient Geography*, a town of India, on this side of the Ganges, between the first and second mouth of that river, on the western side of it. Ptolemy.

POLURA, in *Geography*, a town of Walachia; 20 miles N.E. of Tergofyl.

POLY, a town of Hindoostan, in Vissapour; 20 miles N.W. of Sattarah.

POLYACANTHA, in *Botany*, a name adopted by Vaillant, for a genus of the thistle family, expressive of its numerous thorns. This genus is included under the *Cnicus* of Linnæus.

POLYACOUSTICS, compounded of *πολυς*, *much*, and *ακουω*, *I hear*, instruments contrived to multiply sounds; as multiplying-glasses, or polyscopes, do the images of objects. See PHONICS.

POLYADDEN POINT, in *Geography*, a cape in the English Channel, on the S. coast of Cornwall; 2 miles W. of Deadman's Point.

POLYADELPHIA, in *Botany*, from *πολυς*, *many*, and *αδελφοι*, *a brother*, the 18th class of the artificial-system of Linnæus, is distinguished by having the stamens united into many, or at least more than two, sets or parcels. See DIADELPHIA.

The orders are not distinguished by Linnæus with his wonted accuracy or consistency, he having adverted only to the number of the stamens, not to their insertion. The writer of the present article has therefore proposed the following arrangement. See *Introd. to Botany*, ed. 3. 340.

Ord. I. *Dodecandria*. Stamens, or rather anthers, from twelve to twenty, or twenty-five, their filaments unconnected with the calyx. To this belongs *Theobroma*, the Chocolate; as well as *Bubroma* of Schreber, and *Abroma* of Jacquin; likewise *Monsonia* and *Citrus*. The latter has about nine-

teen or twenty stamens, combined variously and unequally in several distinct parcels, which are all inserted into the receptacle; and not by any means into the calyx, as the character of the class *Icosandria*, and consequently of every order so named, requires.

Ord. 2. *Icosandria*. Stamens numerous, their filaments inserted (in several parcels) into the calyx. To this is to be referred *Melaleuca* and its allies, a genus erroneously placed by Linnæus in the next order.

Ord. 3. *Polyandria*. Stamens numerous, unconnected with the calyx, of which *Hypericum* is the principal genus. See also *Durio*, *Glabraria* and *Lubea*, all which properly belong to this class and order.

POLYÆGOS, in *Ancient Geography*, one of the Cyclades, situated very near the E. of the isle of Melos, and S.E. of Cimolis.

POLYÆNUS, in *Biography*, a native of Macedon, flourished about the year 180, and wrote in Greek a work on "Military Stratagems," which he dedicated to the emperors M. Antoninus and Verus. It is characterised as an entertaining performance, written in an easy and elegant style, and though in many respects it is trifling, it contains some curious information. It was first published in 1589. An improved edition was given by Masvicius in 1690, and another by Murfinna in 1756.

POLYANDRIA, in *Botany*, from *πολυς*, many, and *ανδρ*, a man, the 13th class of the Linnæan artificial system, characterised by having numerous stamens, from twenty to any greater number, inserted into the receptacle, and not at all connected with the calyx, which often falls off as soon as the flower expands. By this mode of insertion the class is essentially distinguished from the 12th, ICOSANDRIA; see that article. A most essential difference exists between the plants composing these two classes. Those of the *Polyandria* scarcely produce any pulpy or eatable fruits, but are in all their parts frequently of an acrid or narcotic quality. The class however being of a more artificial and heterogeneous nature than the *Icosandria*, no absolute rule can be laid down on this subject.

The orders are distinguished by the number of styles. *Monogynia*, the first, subdivided according to the number of petals, abounds with stately exotic trees, and other plants, with handsome flowers. The five following Linnæan orders, *Digynia*, *Trigynia*, *Tetragynia*, *Pentagynia*, and *Hexagynia*, might be most conveniently united into one, perhaps under the name of *Pentagynia*, as we have recommended under *Icosandria*. Possibly the term *Heterogynia* might be eligible for such an order, as different species of several of its genera disagree in the number of their styles. *Polygynia*, the last order of the present class, has numerous styles, and is furnished with abundance of handsome and important genera, beautiful in their flowers, but often very acrid or poisonous in their qualities.

POLYANDRIA is likewise the name of a considerable order in the class *Monadelphia*, consisting chiefly of the columiferous, or mallow, tribe. There are also orders under the same denomination and character, in the classes *Polyadelphia*, *Monoecia*, and *Dioecia*; as well as in that of *Gynandria*, according to Linnæus; but of the latter no certain example can, on correct investigation, be found.

POLYANDUS, in *Ancient Geography*, a town of Asia, in Armenia Minor, and in the prefecture called Cataonia. Ptolemy.

POLYANTHEA, a collection of common-places in alphabetical order; of great service to orators, preachers, &c. of the lower class.

The word is formed from the Greek *πολυς*, much, and

ανθος, flower; and is much of the same significance with *anthology*, or *florilege*.

The first author of the *polyanthea* was Dominic Nanni de Mirabellio, whose labour has been improved on by Barth. Amantius, and Franc. Torsius; and since these, by Jos. Langius, under the title of "*Polyanthea nova*," 1613.

POLYANTHEMUM, in *Botany*, a name given by some authors to the water crow-foot, from its great number of flowers.

POLYANTHES, in *Botany* and *Gardening*. See POLIANTHES.

POLYANTHUS, or POLYANTHIUM, compounded of *πολυς*, much, and *ανθος*, flower, a garden flower, of the primrose kind. (See PRIMULA.) The word is also used, in general, to denote a plant which bears or produces several or more flowers.

POLYANTHUS-Narcissus. See NARCISSUS.

POLYBIUS, in *Biography*, an eminent Greek historian, was born at Megalopolis, in Arcadia, about the year 203 B.C. His father was Lycortas, a prætor of the Achæan republic, and an intimate friend of PHILOPOMEN, (see his article). He was brought up to arms and public affairs, and at the age of twenty-four, he was one of the deputies sent by the state to negotiate with Ptolemy Epiphanes. After this he was employed in various other embassies, and at length, when the Romans found it necessary no longer to preserve appearances with the Greeks, he was one of the thousand suspicious persons demanded of the Achæans as hostages to be detained under custody in Italy. Polybius was kept in close custody at Rome, and not suffered to plead before the senate in favour of his countrymen. By his learning, virtue, and talents, he ingratiated himself with many of the most eminent senators, especially with the two sons of Paulus Æmilius. Through the interest of the latter, the exiles, after seventeen years absence from their country, were permitted to return to Greece, but only three hundred survived to enjoy that liberty. Polybius himself not wishing to see his native land in its humiliated state, chose to remain at Rome, and attach himself to the service of Scipio Æmilianus, whom he accompanied into Africa, and materially aided by his counsel. After this he was witness to the sack and destruction of Corinth, and of the reduction of Achaia to the condition of a Roman province. Amidst these dreadful scenes he displayed noble traits of patriotism and disinterestedness, which obtained for him so much credit, that he was entrusted with the care of settling the new form of government in the cities of Greece, which office he performed to the satisfaction both of the Romans and the Greeks. The people of Achaia erected several statues to his honour. He accompanied Scipio to the siege of Numantia; and upon the subsequent death of his great friend and benefactor, he retired to his native country, where he died, in consequence of a fall from his horse, at the age of eighty-two. During a long period of his life he employed his leisure and opportunities in composing a history from the beginning of the second Punic war, to the subversion of the Macedonian kingdom, a period of fifty-three years. It was comprised in thirty-eight books, besides two introductory ones, containing an abridgment of the Roman history from the taking of Rome by the Gauls. The history of Polybius has been styled the Catholic or Universal History, because though chiefly devoted to Roman affairs, yet it relates the contemporary transactions in several other countries. Only a very small part of this work remains, viz. the first five books, which are entire, and considerable fragments of the twelve following. No historian of antiquity is more valuable for the accuracy and

and fidelity of his narrations, and the abundance of his information. His style is not to be commended, and he is one of those authors who are read exclusively for their matter. He has been closely copied in many parts by Livy. Marcus Brutus was so fully sensible of his value, that he studied him even in the midst of his most anxious engagements. The editions of Polybius that are most esteemed, are Casaubon's, Paris, 1609. fol.; Gronovius's, Amst. 3 vols. 8vo. 1670; and Schweighauser's, Leipf. 9 vols. 8vo. 1789-93.

POLYCARDIA, in *Botany*, a name of Jussieu's, composed of *πολυ*, many, and *καρδια*, a heart, and suggested by the inversely-heartshaped figure of the numerous leaves that bear the flowers, whose midrib is, by that circumstance, arrested in its growth, and the sides protruded, in two lobes, beyond it.—Juss. 377. Willd. Sp. Pl. v. 1. 1121. Lamarck Illustr. t. 132.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Rhamni*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, flat, very small, in five rounded unequal segments. *Cor.* Petals five, rounded, spreading, sessile, equal. *Stam.* Filaments five, awl-shaped, much shorter than the petals, opposite to the segments of the calyx; anthers roundish, two-lobed. *Pist.* Germen superior, roundish; style columnar, very short; stigma notched. *Peric.* Capsule ovate, slightly furrowed, of five thick, woody, at length flattened valves, and as many cells; the partitions narrow, from the centre of each valve. *Seeds* few, oblong, inserted at the base of the partitions, on each side, each seed half enclosed in a cup-like lacinated tunic.

Ess. Ch. Petals five, rounded, spreading. Stigma notched. Capsule ovate, woody, with five flattened valves. Seeds with lacinated tunics.

Obf. Jussieu remarks, that the capsule has occasionally but three or four valves, and as many cells; which almost reduces this genus to *Celastrus*, unless the woody and flattened valves may keep it distinct. We propose it here for the sake of enquiry. Commerçon appears to have chosen this shrub to perpetuate his own memory, having in his herbarium marked the specimens *Commerçonia*. Willdenow applied a vile specific name, which we do not think it incumbent on us, in defiance of all principle and harmony, to retain, it having been no where else received.

1. *P. epiphylla*. (*P. madagascarensis*; Willd. n. 1.)—Gathered in Madagascar, by Commerçon, some of whose specimens, in flower and fruit, are before us. The stem is shrubby, with round smooth branches. Leaves scattered, stalked, two or three inches in length, elliptic-oblong, bluntish, entire, thick-edged, coriaceous, smooth, single-ribbed, obscurely veined; tapering at the base, into a channelled footstalk about an inch long. Some leaves, which Jussieu terms winged flower-stalks, are stopped at about the middle of their growth by producing fructification at their apex, beyond which each side of the leaf is afterwards gradually extended into a rounded lobe, rendering the whole inversely heart-shaped. In the sinus thus formed stand three or four sessile flowers, much like those of an *Euonymus*. The capsules are ovate, hard, smooth, three quarters of an inch long, externally dark brown, internally pale and shining. Lamarck's plate represents every part with great fidelity; but we wonder how he, who has omitted to figure *Celastrus*, because of its near affinity to *Euonymus*, could retain the present as a distinct genus. Willdenow's description is evidently made from Lamarck's engraving.

POLYCARP, SAINT, in *Biography*, an apostolical Christian father and martyr, supposed to be a native of Smyrna, in Asia Minor, and born during the reign of Nero.

He was a disciple of the apostle John, by whom he was instructed in the truths of the Christian religion, and appointed bishop of Smyrna. By some he is thought to have sat under the instructions of some other of our Lord's apostles; there seems no doubt that he conversed with several who had heard and seen our Lord, and by many he is thought to have been the angel of the church of Smyrna, to whom the epistle in the second chapter of the book of Revelation was directed to be sent; and those who have carefully investigated the subject, generally admit, that the character and circumstances which St. John ascribes to that angel, seem to agree very exactly with those of Polycarp. In a few years after the death of the apostle John, Ignatius, who had been condemned to suffer death at Rome, having in his voyage been permitted to land at Smyrna, was visited by Polycarp, who comforted and encouraged him under his sufferings. Some years after this, a controversy having arisen between the Eastern and Western churches respecting the proper time for celebrating Easter, Polycarp took a journey to Rome to confer with Anicetas, bishop of that city, on the subject, and, if possible, to terminate the warm disputes which it had occasioned. Though this conference did not produce the desired effect, Polycarp and Anicetas agreed in this, that the bonds of charity were not to be broken on account of the controversy. While Polycarp continued at Rome, Irenæus informs us, that he made many converts, to the simplicity of Christian doctrine, which he had learned from the apostles, from among the followers of Valentinus and Marcion. Some years after the return of Polycarp from Rome, and under the reign of the emperor Marcus Aurelius; the Christians were persecuted in all parts of the Roman empire with unrelenting rigour; and many were called upon at Smyrna, among other places, to seal their profession with their blood. In this persecution Polycarp suffered martyrdom. His martyrdom happened, according to bishop Pearson, who supposes it to have taken place under Antoninus the Pious, in the year 148. St. Jerom, in his work of Illustrious Men, speaks of Polycarp "as the prince of all Asia, inasmuch as he had seen and been taught by some of the apostles, and those who had seen the Lord." Afterwards he adds, "in the reign of Marcus Antoninus and L. Aurelius Commodus, in the fourth persecution after Nero, he was condemned to the flames at Smyrna, the proconsul being present, and all the people demanding his death. He wrote to the Philippians a very useful epistle, which to this day is read in the assembly of Asia." The judicious Lardner feels that there is great difficulty in ascertaining the exact period of his martyrdom: "We have," says he, "the relation of his martyrdom in a letter of the church of Smyrna to the church of Philadelphia, and other churches. In this relation Polycarp says to the proconsul; 'Eighty and six years have I now served.' Understand this of his life; and according to every calculation of the time of his death, he lived a good while in the first century. Understand it of his Christianity, as Tillemont does, and being martyred, as he says, in 166; his conversion to Christianity happened in the year 80. Understand it of his serving Christ in the ministry; and he was bishop of Smyrna from the year 84, according to Basnage." Lardner himself thinks, the martyrdom of Polycarp happened about the year 169. Great pains were taken to make him recant, but he refused; and when told if he persisted in his obstinacy he should be burnt alive, he exclaimed, "Thou threatenest me with fire, which burns for an hour, and is then extinguished; but thou art ignorant of the judgment to come, and of the fire of everlasting punishment, reserved for the wicked in the other

world: why dost thou delay?" Finding him immoveable, the proconsul ordered proclamation to be made three times, that Polycarp had persisted in professing himself a Christian; after which, on the unanimous demand of the infuriated multitude, he was sentenced to be immediately committed to the flames. Polycarp is supposed to have written several epistles to the neighbouring churches to confirm them in their Christian faith, and some others to exhort and encourage the brethren to persevere in the truth. These pieces are all lost, excepting his short "Epistle to the Philippians," which is thought to have been written soon after the death of Ignatius, and consists of admirable precepts, counsels, and exhortations, intermixed with numerous quotations from the books of the New Testament, and written with great elegance and simplicity. This epistle has frequently been reprinted; archbishop Usher published it, in Greek and Latin, at Oxford in 1648: and English editions of it have been given by archbishops Wake and Cave. See Lardner, vol. ii. edition 1788.

POLYCARPÆA, in *Botany*, see **HAGÆA**. This genus ought probably to be united with **POLYCARPON**, see that article; for Mr. Ferdinand Bauer's discovery of the variability of number in the latter, with respect to the stamens and pistil, removes the distinction between those two genera. Some flowers of *Polycarpon tetraphyllum* are shewn by him to assume the essential characters of *Hagæa*.

POLYCARPON, from *πολυς*, many or much, and *καρπος*, fruit; a name applied to various plants, but now appropriated to the present, which forms a genus, and to which it is as suitable as to any.—Linn. Gen. 42. Schreb. 58. Willd. Sp. Pl. v. 1. 490. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 162. Fl. Græc. Sibth. v. 2. 4. Ait. Hort. Kew. v. 1. 184. Juss. 299. Lamarck Illustr. t. 51. Gært. t. 129.—Class and order, *Triandria Trigynia*. Nat. Ord. *Caryophyllei*, Linn. Juss.

Gen. Ch. Cal. Perianth inferior, of five ovate, concave, keeled, pointed, permanent leaves. Cor. Petals five, much shorter than the calyx and alternate with it, obovate, obtuse or emarginate, withering. Stam. Filaments three, thread-shaped, half the length of the calyx; anthers erect, roundish, of two lobes. Pist. Germen superior, ovate; styles three, spreading, very short; stigmas obtuse. Peric. Capsule ovate, of one cell and three valves, enclosed in the permanent calyx. Seeds numerous, small, kidney-shaped.

Obs. Mr. Ferdinand Bauer, the excellent artist, and travelling companion, of Dr. Sibthorp, observed the stamens to be, in some flowers, five, while the style in such was simple and undivided; probably imperfect. See **POLYCARPÆA**.

Ess. Ch. Calyx of five leaves. Petals five, obovate, minute. Capsule superior, of one cell and three valves. Seeds numerous.

1. *P. tetraphyllum*. Four-leaved All-seed. Linn. Sp. Pl. 131. Sm. Fl. Græc. Sibth. t. 102. Engl. Bot. t. 1031. (*Anthyllis marina incana alfinefolia*; Ger. Em. 622. *Paronychia altera*; Matth. Valgr. v. 2. 389.)—A very common weed in dry sandy waste ground, throughout the south of Europe, and north of Africa, flowering all through the summer, as well as in mild winter, or spring, weather. With us it is scarcely found except on the coasts of Devonshire and Dorsetshire. At Rome it occurs in the streets, and on the steps of buildings. Dr. Sibthorp observed it by way-sides, throughout the Archipelago. The root is annual, simple, branched copiously below. Stems numerous, spreading on the ground in every direction, from two to six inches long, branched, divaricated, zigzag,

leafy, round, smooth, often purplish. Leaves generally four together at each joint, obovate, entire, smooth, single-ribbed, rather fleshy, with very short footstalks. Stipulas opposite, lanceolate, acute; membranous, torn. Panicles copious, terminal, repeatedly forked, many-flowered. Bractees like the stipulas, in pairs at each subdivision. Flowers small, inodorous. Calyx green, pale at the edges. Petals white.

POLYCEPHALON, *πολυκεφαλον*, in *Antiquity*, a kind of poetry, for the nature and origin of which see Mem. de l'Acad. Roy. des. Insc. vol. xiv.

POLYCEPHALOS, in *Botany*, so called by Forskall, Ægypt-Arab. 154, from its numerous heads of flowers. See **SPILÆRANTHUS**.

POLYCHREST, *πολυχρηστος*, compounded of *πολυς*, much, and *χρηστος*, useful, in *Pharmacy*, a medicine that serves for many uses, or that cures many diseases.

POLYCHREST, *Sci.* See **SAL-Polychrest**.

POLYCHROA, in *Botany*, a genus of Loureiro's, with which we are unacquainted, named by him from *πολυς*, many, and *χρως*, colour, in allusion to the particoloured foliage.—Lour. Cochinch. 559. Willd. Sp. Pl. v. 4. 393.—Class and order, *Monocia Pentandria*. Nat. Ord. *Holeraceæ*, Linn. *Amaranthi*, Juss.

Gen. Ch. Male flowers underneath, on a long common stalk. Cal. Perianth bell-shaped, in five nearly ovate, incurved, keeled, coloured segments. Cor. none. Stam. Filaments five, swelling, pellucid, spreading, longer than the calyx; anthers somewhat arrow-shaped.

Female flowers nearly sessile, above the male, on the same plant. Cal. Perianth inferior, in five deep, erect, awl-shaped, permanent segments. Cor. none. Pist. Germen oblong; style none; stigma obtuse. Peric. Capsule ovate, of one cell. Seed solitary, ovate, smooth.

Ess. Ch. Male, Calyx bell-shaped, five-cleft. Corolla none.

Female, Calyx in five deep segments. Corolla none. Stigma solitary, sessile. Capsule with one seed.

1. *P. repens*. Lour. n. 1. Willd. n. 1.—Native of moist rocks about fountains in China and Cochinchina, in which countries it is also cultivated for its beauty. The root is perennial. Stems herbaceous, creeping extensively, round, red, juicy, branched, throwing out short lateral radicles. Leaves alternate, oblong, somewhat crenate, variegated with green, white, and red, obtuse; heart-shaped and unequal at the base. Stipulas in pairs, acute. Flowers red and white, in small axillary clusters.

POLYCHROITE, in *Chemistry*, a name given by Bouillon Lagrange and Vogel, to the colouring matter of saffron, formerly considered as extractive, but which is now thought to be a peculiar vegetable principle. In order to obtain it, we have only to digest saffron in water, evaporate the liquid to the consistence of a thick syrup, and digest this residue in alcohol. When the alcohol is evaporated, polychroite remains behind in a state of purity.

The properties of this substance are as follow:

It has a very intense yellow colour; its taste is bitter, similar to that of saffron, and it has an agreeable smell:—it dissolves readily in water and alcohol, but scarcely in ether, and not at all in fat and volatile oils:—when the solution of polychroite is exposed to the light, it gradually loses its colour: its colour is likewise destroyed by oxymuriatic acid; the addition of a few drops of sulphuric acid changes its colour to an intense and beautiful blue; nitric acid in like manner renders it green:—it combines with lime, potash, and barytes, forming with these bases soluble and insoluble compounds:—when sulphate of iron is dropped

dropped into a solution containing it, a dark brown precipitate is formed:—it stains cloth of an intense yellow colour:—when distilled, it yields an acid liquid, a yellow-coloured oil, and carbonic acid gas, and carburetted hydrogen gas; the acidulous liquid contains ammonia: the charcoal, when incinerated, leaves traces of carbonate, sulphate, and muriate of potash, of carbonates of lime and magnesia, and of iron. *Ann. de Chim.* vol. 80.

POLYCLETUS, in *Biography*, a famous sculptor of antiquity, was a native of Sicyon, and flourished about the year 430 B.C. He was supposed to have carried the art to the highest degree of perfection, at least as far as the excellence of single figures could go. One of his figures, representing a life-guard of the king of Persia, was performed in such exact proportions, that it was called *the rule*, and artists came to study it as a model. He made the statue of a boy, which was estimated at a hundred talents, or perhaps nearly 20,000 pounds, according to our mode of reckoning. The emperor Titus had two naked boys playing at a game by his hand, which was considered as a perfect performance. It was peculiar to him, that he formed almost all his figures supported on one thigh, which made them appear deficient in variety.

POLYCNEMUM, in *Botany*, *πολυκνέμων* of the Greeks, from *πολυς*, many, and *κνήμη*, a leg, a name adopted by Linnæus, for the present genus of little slender-stalked plants.—*Linn. Gen.* 25. *Schreb.* 33. *Willd. Sp. Pl.* v. 1. 192. *Mart. Mill. Dict.* v. 3. *Ait. Hort. Kew.* v. 1. 79. *Juss.* 84. *Lamarck Illustr.* t. 29. *Gærtn.* t. 128.—Class and order, *Triandria Monogynia*. *Nat. Ord. Holeraceæ*, *Linn. Atriplices*, *Juss.*

Gen. Ch. *Cal.* Perianth inferior, of five ovate, erect, pointed, permanent leaves. *Cor.* none. *Stam.* Filaments three, sometimes but two, capillary, shorter than the calyx; anthers of two lobes. *Pist.* Germen roundish, superior; style very short, cloven; stigmas obtuse. *Peric.* Capsule ovate, depressed, and bordered at the summit, pointed with the permanent style, membranous, thin, without valves, and not bursting. *Seed* solitary, kidney-shaped, stalked.

Obs. The leaves of the calyx are said, by Pallas and Schreber, to vary in number, from two to five, and the stamens from one to five; the style is also, in some instances, double. Linnæus seems latterly to have taken the bractæas for a calyx, the perianth for a corolla, in which he is followed by Willdenow and Hort. Kew.

Ess. Ch. Calyx of five leaves. Corolla none. Style divided. Capsule membranous, not bursting. Seed one.

1. *P. monandrum*. “Pallas Travels, v. 1. append. n. 94. t. G. f. 1.” *Willd. n. 1.*—Stamen one. Leaves linear, acute. Stem erect.—Gathered by Pallas in Siberia, on a dry saltish soil, below the entrenchment of the Calmucks. Perennial. We have seen no specimen.

2. *P. sclerospermum*. Pallas Travels v. 3. append. n. 84. t. M. f. 2. e, E. *Willd. n. 2.*—Stamens two. Leaves cylindrical, fleshy. Stem erect, branched.—Native of muddy salt places, in the drier parts of the Siberian desert, not uncommon, flowering before August, and ripening seed in October. The root is annual. *Herb* from four to ten inches high, much branched, spreading, glaucous, succulent, brittle though rigid. *Leaves* scattered, sessile, cylindrical, awl-shaped, tipped with a spine, fleshy. *Flowers* axillary, solitary, sessile, with a pair of awl-shaped bractæas. The germen and calyx harden into a sort of nut, and the seed is spiral.

3. *P. arvense*. *Linn. Sp. Pl.* 50. *Willd. n. 3.* *Ait. n. 1.* *Jacq. Austr.* t. 365. (*Anthyllis altera italorum*; *Ger. Em.* 623.)—Stamens three. Leaves awl-shaped, tri-

angular. Stem diffuse.—Native of fields in the southern parts of Europe, unknown in England, except in curious botanic gardens. A small annual herb, with no pretensions to beauty. The stem is branched and spreading from the bottom, to the extent of a span. *Leaves* numerous, scattered, slender, rigid, an inch long, with axillary tufts of smaller ones. *Flowers* very small, axillary, sessile, whitish, with a pair of pale divaricated bractæas to each.

4. *P. falsum*. *Willd. n. 4.* (*P. triandrum*; Pallas Travels v. 1. append. n. 95. t. G. f. 2, and H. f. 1.)—Stamens three. Leaves thread-shaped, fleshy, sheathing. Stem diffuse.—Found by Pallas in moist, sandy, rather salt situations in Siberia. Perennial. The leaves are thicker and more fleshy than in the last, fringed at their base, and somewhat recurved. The young branches are silky.

5. *P. oppositifolium*. Pallas Travels v. 1. append. 98. t. H. f. 2.—Stamens five. Leaves opposite, fleshy, semi-cylindrical. Stem erect. Gathered by Pallas in salt marshes, about the Caspian sea. Annual. We have seen no specimen.

POLYCOMBUS, a name given by Neophytus and others to the common knot-grass, more usually called *polygonum*.

The name *polycombis* is formed of the Greek *πολυς*, many, and *κομβος*, a joint; and as it is usually applicable to this, and all the other jointed plants, it is used by some for the name of the several species of equisetum, or horsetail, as the word *polygonum* is.

Neophytus describes one species of this, which he says is called *oreon*, from its growing in mountainous places. This, he says, looks like a young reed, and has several joints in the main stalk, which are received into one another as so many cups or boxes: he adds, that the leaves are like those of the pine-tree. What he calls the leaves, are probably the tender branches; and then this description will agree very well with our great marsh horsetail, which grows in wet places in mountainous countries, and about the springs in our hills. This is the horsetail to which the greatest virtues are attributed by this author; but the whole account of the hippuris, polygonum, and equisetum, is so confused, that there is little to be learnt from what the ancients say of them, without repeating the trials of their virtues.

POLYCRATES, in *Biography*, a celebrated bishop of Ephesus, who flourished towards the close of the second century, was the eighth Christian bishop of his family, and is spoken of by Jerome as a person of considerable abilities and authority, who flourished under the reign of the emperor Severus. About the year 196, he called a numerous synod of the bishops of Asia, concerning the existing controversy about the time of celebrating Easter, which was then kept by the churches of Asia Minor on the fourteenth day of the moon, on whatever day of the week it happened; but by the Romans, and most other churches, on the Lord's day following. Victor, bishop of Rome, required the bishops of Asia to follow the custom of other churches. Polycrates, having consulted the bishops of Asia, wrote a letter, with their approbation, to Victor and the church of Rome, declaring their resolution to keep Easter at the time they had hitherto observed it: upon this Victor excommunicated all the churches of Asia, and those in the neighbourhood. The letter which Polycrates sent to Victor is no longer extant, but there are two fragments of it preserved by Eusebius, containing allusions to passages in the New Testament, or quotations from them, which Dr. Lardner has brought to confirm

confirm the authenticity of the Christian scriptures. Lardner, vol. ii. edition 1788.

POLYCROTA, in the *Naval Architecture of the Ancients*, a word used to express such of their galleys as had three, four, five, or more tiers of rowers, seated at different heights; they were distinguished by this term from the *monocrota*, or those which had only single rows of oars. The number of rows of rowers in the polycrota galleys has given occasion to some to suppose those vessels of such a height from the water as is scarcely credible; we have, however, no warrant for this, but the commentators have given occasion to the opinion, from their not having been able to stow the rowers in less room, and have measured the height of the vessel by their own skill in this sort of architecture, not by that of the people who built them. Meibomius has found a way to take off a great deal from the imaginary height of these galleys. He has two inventions to answer this purpose; by the first of them, he shews how the lateral rowers may be so placed, that he who sits behind another may move his hands and oar under the seat of the rower who sits next before him; by which means three lateral rowers, which, according to Scaliger's way of reckoning, would require thirteen feet and a half, will be placed in the height of seven feet and a half.

By the second invention, he finds out a place in the vessel for almost half the number of rowers; forasmuch as on the sides of the aforesaid rowers, he places others in the middle of the ship, upon transra or transverse seats, which he imagines thrust out their oars under the seats of the lateral rowers; by this contrivance he has gained no less than nine feet in the height of a quinqueremis. The different series of rowers were called by different names; the *thalamitæ* were those who sat in the lowest row; the *zygitæ* were those who sat in the transra, or cross seats; and the *thranitæ*, those who sat uppermost of all in the vessel.

The most surprising account of a polycrota vessel among the ancients, is that said to have been built by Philopater, of forty tiers of rowers. The next to this is that of Ptolemy Philadelphus, which is said to have had thirty tiers; and in these there sat more than three thousand rowers. It has been disputed by many, whether such immense vessels as these were ever built, or ever could be used if built. The monstrous height they have been calculated to be of, according to the schemes of the generality of commentators, has rendered it incredible, that there were ever any such; but Meibomius has found out such convenient ways of placing the rowers in them, and has taken off so great a part of this imaginary height necessary in them, that he is clearly of opinion, that there were such vessels actually built and used.

The triremis, according to the computation of this author, contained two hundred men; of which one hundred and eighty were rowers, and the rest were mariners; so that the Athenian fleet, of which Conon was commander, consisting of one hundred and eighty triremes, had in it six and thirty thousand men. The quinqueremis of these times contained four hundred and twenty men, three hundred of whom were rowers, and the rest soldiers; so that there are three stupendous things to be observed in regard to the Roman fleet at Messina and the Carthaginian at Lilybæum: one is, that the former consisted of three hundred and thirty, and the latter of three hundred and fifty vessels, most of which were quinqueremes, which, according to the most accurate computation, were a hundred and fifty feet long; the number of men they contained was, in the Roman, one hundred and thirty thousand, and in the Carthaginian, one hundred and fifty thousand. The apparatus and provisions necessary

for such a numerous host, are wonderful in these early days of shipping, and the accounts would be doubted, were they not given by one of the best of historians, Polybius, who wonders, as indeed he very well may, at such an amazing equipage for sea service at such a time.

POLYDIPSIA, in *Medicine*, from πολυ, much, and διψα, thirst, signifies immoderate or morbid thirst.

This excessive or morbid thirst is seldom to be considered as itself a disease, being generally a symptom of some other morbid condition, either of the stomach, or of the constitution at large. Sauvages makes three species of polydipsia, according to the different morbid affections with which it is connected. Thus, 1. Polydipsia *febrilis* is the thirst connected with a state of general fever, of which it is usually a concomitant symptom, though not so prominent as to characterise the disease. 2. Polydipsia *hydropica* is the thirst which accompanies dropsy, when it is extensive, under all its forms, in consequence of the great abstraction of the watery part of the blood from the circulating mass, which the effusion of serum into the cavities and cellular membrane occasions. And 3. Polydipsia *fluxuum* is the thirst which is the result of profuse discharges of any kind, by which the quantity of fluids in the body is much diminished, as in cases of diabetes, salivation, profuse sweating, hæmorrhages, and the like. In the case of diabetes, indeed, the immoderate thirst is often the most prominent symptom, and claims the patient's attention, before the excessive flow of urine is noticed; and when this discharge is noticed, it is often considered for some time as the mere consequence of the inordinate quantity of drink taken in; so that diabetes has been sometimes denominated polydipsia. (See **DIABETES**.) In all these cases, however, the object of medical treatment is the removal of the primary disease, of which the extraordinary thirst is symptomatic, and not of the thirst itself.

POLYDORA, in *Ancient Geography*, an island situated in the vicinity of Cyzicus, according to Pliny, Diodorus Siculus, and Steph. Byz.

POLYEDRON. See **POLYHEDRON**.

POLYEIDÆ SPHRAGIS, the name of a sort of troches or pastils greatly used among the ancients. They consisted of alum, four drachms; myrrh and aloes, of each five drachms: pomegranate-peel, and bull's gall, of each six drachms: all of which were rubbed to fine powder, and made into troches with the bull's gall, mixed with a sufficient quantity of the most austere wine.

POLYGALA, in *Botany*, an ancient name, composed of πολυ, much, and γαλα, milk, alluding to the reputed effects of the plant, on cattle that fed upon it; but to what plant the name, or the virtues, are rightly to be attributed, we are ignorant. Our common Milkwort appears to have no other claim than ancient usage to this appellation.—Lian. Gen. 364. Schreb. 482. Willd. Sp. Pl. v. 3. 871. Mart. Mill. Dict. v. 3. Sin. Fl. Brit. 752. Prodr. Fl. Græc. Sibth. v. 2. 51. Ait. Hort. Kew. v. 4. 242. Thunb. Prodr. 120. Pursh. 458. Juss. 99. Lamarek Illustr. t. 598. Gærtn. 1. 62.—Class and order, *Diadelphia Oðandria*. Nat. Ord. *Lomentaceæ*, Linn. *Pediculares*, Juss.

Gen. Ch. *Cal.* Perianth inferior, permanent, small, of five unequal, ovate, acute leaves; two of them below the corolla; one above it; and two very large, flat, coloured, like wings, at the sides. *Cor.* imperfectly papilionaceous. Standard tubular, nearly cylindrical, short, its mouth reflexed, small, cloven. Keel concave, compressed, swelling towards the extremity, near to which are attached, for the most part two, feathery, three-cleft appendages. *Stam.* Filaments eight, in two sets, both united, contained within the keel; anthers eight, simple. *Pist.* Germen oblong, superior;

POLYGALA.

superior; style simple, erect; stigma terminal, tumid, cloven. *Peric.* Capsule turbinate, somewhat heart-shaped, compressed, sharp-edged, with two cells and two valves, bursting on each side at the edges, the partition contrary to the valves. *Seeds* solitary, ovate, with a glandular scar.

Obf. Some species are called beardless, because the appendage to their keel is not of a feather-like structure. Linnæus conceived the two wings to belong to the corolla, though he rightly adverted to their situation, which is out of the line of the other petals. Schreber, whom we follow, esteems them a part of the calyx. Real wings are found in the corolla of *P. myrtifolia*.

Eff. Ch. Calyx of five leaves; two of them very large, wing-like, coloured. Capsule inversely heart-shaped, of two cells.

Polygala consists of a number of elegant species, natives of various parts of the globe, for the most part shrubs, of rather a slender habit; many of the rest are herbaceous, and some few of only annual duration. Linnæus has 24 species in his Sp. Pl. ed. 2; the 14th edition of Syst. Veg. contains 38. Willdenow has 76, the discoveries of Thunberg at the Cape having greatly enriched this genus. The whole are disposed in four sections, of which we shall give examples.

SECT. I. *Crested; (the appendage of the keel feathery).* Forty-two species.

P. vulgaris. Common Milkwort. Linn. Sp. Pl. 986. Willd. n. 6. Ait. n. 2. Engl. Bot. t. 76. Fl. Dan. t. 516. (*Polygala*; Ger. Em. 563. f. 3, 4, and 564. f. 5.)—Flowers crested, racemose. Wings of the calyx three-ribbed, obtuse, the length of the corolla, stems herbaceous, simple, procumbent. Leaves linear-lanceolate, rather acute. Common in dry gravelly or chalky pastures throughout Europe, perennial, flowering in summer. This is the only British species, and abounds among short grass, on chalky hills or dry heaths. The stems spread on the ground every way, and are three or four inches long, clothed with numerous, dark-green, smooth, entire leaves, variable in length and breadth. The flowers are usually blue, but frequently pink or white, always veined with green. Their form is singular and elegant, like little flies, and they compose long terminal clusters. The whole herb is very bitter. An infusion of it taken every morning fasting, about a quarter of a pint daily, is good for a catarrhus cough. Most authors believe this the *πολυγυλον* of Dioscorides; others have supposed his plant one of the dwarf *Coronilla*; see Matth. Valgr. v. 2. 549. He speaks of its astringent taste, but says nothing of the great bitterness, so remarkable in our *P. vulgaris*, as well as in its near relations *amara*, *major*, Jacq. Austr. t. 413, and *monspeliaca*. The two following are not among Willdenow's species.

P. venulosa. Sm. Prodr. Fl. Græc. Sibth. n. 1641. Fl. Græc. t. 669, unpublished.—Flowers crested, racemose. Wings of the calyx three-ribbed, copiously veined, shorter than the keel. Stems ascending. Leaves elliptic-lanceolate.—Gathered by Dr. Sibthorp on hills in the island of Cyprus, as well as in the countries of Argos and Laconia, flowering in May. This species is rather larger and more erect than the *vulgaris*, but less than the *major*, differing essentially from both in the great abundance of little transverse green veins, between the three ribs of the broad obovate wings. The flowers are of a pale blush-colour, with a white crest, the petals nearly twice as long as the wings.

P. glumacea. Sm. ibid. n. 1642. Fl. Græc. t. 670, unpublished.—Flowers crested, racemose. Wings of the calyx three-ribbed, slightly veined, twice as long as the

keel. Leaves taper-pointed.—Discovered by Dr. Sibthorp, who named it extemporaneously *P. cypria*, on grassy hills in Cyprus, flowering in May. The abbè Durand gathered the same at Gibraltar. Rather smaller than the foregoing, and conspicuous for the chaffy aspect of the elliptic-lanceolate green and white wings, about twice the length of the snow-white corolla; their transverse green veins are few, and do not reach from rib to rib. The stems are nearly erect. Leaves narrow, and taper-pointed. Partial flower-stalks capillary and purple.

P. paniculata. Linn. Sp. Pl. 987. Willd. n. 17. Swartz Obf. 272. t. 6. f. 2.—Flowers crested. Clusters lateral, on very long stalks. Stem herbaceous, erect, much branched upwards. Leaves linear, acute.—Native of shady hillocks, on the banks of rivers, in Jamaica, Hispaniola, &c. A slender annual species, with a panicled stem, about a foot high, rough with minute glandular pubescence. Leaves copious, smooth, narrow, hardly an inch long. Flower-stalks usually terminal at first, but soon becoming lateral; not axillary, as Willdenow defines them; each bearing a delicate cluster of small pale flowers, with permanent pink wings. Ripe capsule green, elliptical, longer than the wings. Seeds hairy.

P. bracteolata. Spear-leaved Milkwort. Linn. Sp. Pl. 987. Willd. n. 29. Ait. n. 4. Curt. Mag. t. 345.—Flowers crested, racemose. Wings of the calyx many-ribbed, pointed, obliquely ovate. Stem erect, shrubby. Leaves linear-lanceolate, smooth.—This is one of those beautiful Cape species, which contribute so much to the ornament of our more choice greenhouses. It is a smooth branching shrub, three or four feet high, flowering all summer, with usually very narrow linear leaves. Flowers in long terminal clusters, large and very handsome, the wings of the calyx being internally of the most vivid purple or crimson; externally green, veined and tinged with red. Keel green, with a white tufted crest. Each partial stalk is an inch long, with three lanceolate bracteas at the base; but these, as Willdenow remarks, are not peculiar to the present species.

P. myrtifolia. Myrtle-leaved Milkwort. Linn. Sp. Pl. 988. Willd. n. 37. Ait. n. 7. Mill. Illustr. t. 61. (*P. arborea myrtifolia*; Comm. Hort. v. 1. 87. t. 46.)—Flowers crested. Clusters short, terminal. Keel falcate. Stem shrubby. Leaves elliptic-oblong, bluntish, smooth.—Native of the Cape of Good Hope, and one of the first plants from that country introduced into our greenhouses, where it blossoms most part of the year. The leaves vary in breadth, and are sometimes obovate; their colour is a bright yellowish-green. Flowers very elegant; the inner surface of their broad wings light purple; their keel broad and rounded, pale with a rich purple tip; its appendage first three-cleft, then twice subdivided, into capillary, hardly feathery, segments. J. Miller's figure exhibits, besides the diminutive cloven standard, a pair of equally diminutive lanceolate wings to the corolla. Possibly such may be found in other species.

P. oppositifolia. Opposite-leaved Milkwort. Linn. Mant. 259. Willd. n. 39. Ait. n. 8. Curt. Mag. t. 492.—Flowers crested. Clusters short, terminal. Stem shrubby. Leaves opposite, acute, ovate, somewhat heart-shaped.—Native of the Cape; sent to Kew by Mr. Masson in 1790. This species, which vies with the two foregoing in beauty, is distinguished from them by its opposite leaves, and their broad more or less heart-shaped figure. The stem is woody and stout, much branched; the branches often downy. Flowers in short terminal clusters, constructed much like those of *myrtifolia*, but their wings are more acute, and of a less

POLYGALA.

a less bright or uniform purple. In this respect however they vary; as do the *leaves* in their shape, which is sometimes much more cordate, as well as pointed; and this variety constitutes the *P. cordifolia* of Linnæus and others. The *stem* being smooth or downy is no permanent distinction.

P. spinosa. Thorny Milkwort. Linn. Sp. Pl. 989. Mant. 437. Willd. n. 42. Ait. n. 10.—Flowers crested, axillary, solitary. Stem shrubby, with thorny-pointed branches. Leaves oval, obtuse, with a small point.—Native of the same country with the three foregoing, but of the time of its introduction here no more is recorded than that Dr. Fothergill cultivated it before the year 1780. Mr. Aiton says it flowers in January and February. The *stem* is very stout and firm, with copious short leafy *branches*, each terminated by a strong rigid spine. *Leaves* numerous, scattered, elliptical, thick, about a quarter of an inch long, on short *stalks*. *Flowers* rather smaller than the *leaves*, white, tipped with purple, drooping, on short stalks, for the most part solitary. We presume there must be some mistake in the marvellous assertion of Linnæus, given on the authority of governor Tulbagh, that the *fruit* of this species is an eatable *berry*. If so, we can only say the plant is no *Polygala*.

SECT. 2. *Beardless; (keel without a feathery appendage).* Stem rather shrubby. Twenty-four species.

P. astuans. Linn. Suppl. 315. Willd. n. 47.—Flowers beardless, racemose. Leaves lanceolate, stalked. Stem shrubby. Capsule ovate, corrugated, woody, sent by Mutis to Linnæus, from New Granada. The *stem* is shrubby, with alternate, striated, minutely downy *branches*. *Leaves* alternate, stalked, elliptic-lanceolate, obtuse with a small point, entire, minutely downy, an inch and a half or two inches long. *Footstalks* short, broad, channelled, downy, glandular as if jointed at the summit. *Clusters* several about the ends of the branches, stalked, downy. *Flowers* of a short round figure. *Wings* of the *calyx* blue. *Keel* white, beardless at the summit, but the inner parts of the flower are downy, and the *keel* itself is lined with silky hairs. *Germs* and *style* smooth. *Capsule* pendulous, smaller than a grain of wheat, ovate, thick and hard, marked with strong elevated reticulations, of two cells, with solitary *seeds*, one of which is sometimes abortive.

P. Chamæbuxus. Box-leaved Milkwort. Linn. Sp. Pl. 989. Willd. n. 53. Ait. n. 11. Schmidel Ic. 75. t. 20. Curt. Mag. t. 316. Jacq. Austr. t. 233. (Anonymos flore Coluteæ; Clus. Hist. v. 1. 105. Chamæbuxus flore Coluteæ; Ger. Em. 1597.)—Flowers beardless, scattered. Keel oblong, with a terminal pouch. Stem rather shrubby, decumbent. Leaves elliptic-lanceolate, acute.—Native of the alps of Germany and Switzerland; tolerably hardy in our gardens, flowering in May and June, and thriving best in a shady border of bog earth. The plant resembles the dwarf box used for edgings, but is conspicuously beautiful when laden with its large white *flowers*, the three-lobed extremity of whose *keel*, at first yellow, soon assumes a rich tawny brown, and finally a paler faded hue, before the *calyx* and its wings are much altered.

P. Heisteria. Furze-leaved Milkwort. Linn. Sp. Pl. 989. Willd. n. 56. Ait. n. 13. Curt. Mag. t. 340. Schneevogt Ic. t. 26. (Heisteria; Linn. Hort. Cliff. 352.)—Flowers beardless, axillary. Leaves awl-shaped, channelled, rough-edged, spinous-pointed, keeled, shorter than the flowers.—Native of the Cape, where it had long been known to the Dutch, but was not sent to England till 1787. The elegant and copious flowers are produced almost all the year long. The *stem* forms a large dense bush; its downy *branches* every where clothed with alternate sessile *leaves*,

half an inch or more in length, smooth except a marginal fringe, and laden with axillary tufts of rather smaller ones. *Flowers* sessile, solitary, longer than the leaves; their *calyx* pale, chaffy, fringed, spinous-tipped; *standard* white; *keel* rounded, of a beautiful purple, with two spreading lobes of the same colour. Some of the reputed varieties in Sp. Pl., copied by Willdenow, are species; the α is *P. stipulacea*, Linn. Mant. 260. Andr. Repos. t. 363?

SECT. 3. *Beardless.* Stem herbaceous, unbranched. Six species.

P. Senega. Rattle-snake Milkwort. Linn. Sp. Pl. 990. Willd. n. 67. Ait. n. 17. Curt. Mag. t. 1051. Woodv. Med. Bot. t. 93. Pursh 464.—Flowers beardless. Cluster terminal, stalked, solitary, tapering. Stem erect, simple, herbaceous. Leaves ovato-lanceolate.—Native of North America, on the sides of hills and in dry woods, flowering from June to August. There is a variety with whitish flowers, in a dense spike or cluster; and another with rose-coloured flowers, in a lax cluster, and narrower leaves. *Pursh.* The *root* is perennial, and somewhat woody, a celebrated Indian remedy for the bite of a rattle-snake, but now discredited. The *stems* are about a foot high, slender, clothed with scattered smoothish *leaves*, about two inches long. *Cluster* pale red, or whitish, not unlike that of a *Polygonum*.

P. lutea. Yellow-flowered Milkwort. Linn. Sp. Pl. 990. Willd. n. 68. Ait. n. 18. Pursh 465. (*P. floridana lutea*, floribus in globosum capitulum congestis; Pluk. Amalth. 175. t. 438. f. 6.)—Flowers beardless. Cluster dense, capitate, terminal. Bractæas setaceous. Stem erect, simple, herbaceous. Leaves lanceolate; the radical ones obovate.—Found in moist shady situations in North America, flowering in July and August. *Root* annual, or biennial. *Stem* slender, straight, leafy, above a foot high. *Leaves* acute, an inch long, tapering at the base. *Flowers* of a fine golden yellow, numerous, in a dense round-headed *cluster*. Mr. Pursh mentions a dwarf variety, in which all the *leaves* are spatulate, and the *cluster* larger.

SECT. 4. *Beardless.* Stem herbaceous, branched. Four species.

P. ciliata. Fringed Milkwort. Linn. Sp. Pl. 991. (*P. n. 268; Linn. Zeyl. 123.*)—Flowers beardless, in slender spikes. Stem herbaceous, branched, erect. Leaves heart-shaped. Capsules fringed with rigid teeth.—Native of the East Indies; a stranger to our gardens, nor does it appear to be any where figured. This is a branched herbaceous annual plant, a span high, the *stem* angular, and somewhat winged. *Leaves* alternate, on short stalks, heart-shaped, not ovato-lanceolate, scarcely an inch long, tipped with a little point, smooth, five-ribbed. *Spikes* long and slender, stalked, terminal; lax when in seed. *Flowers* small, variegated with pink, white, and green, much resembling those of our common Fumitories, but smaller. *Capsules* very curiously formed, abrupt, of two rounded compressed lobes, edged with little rigid obtuse teeth, like those of a clock-wheel.

POLYGALA, in Gardening, contains plants of the woody, under-shrubby, and herbaceous perennial kind, of which the species cultivated are, the myrtle-leaved milk-wort (*P. myrtifolia*;) and the box-leaved milk-wort (*P. chamæbuxus*.)

Method of Culture.—The first sort may be increased by seeds, which should be sown in small pots, filled with light loamy earth; soon after they are ripe, placing them where they may have the morning sun only till October, when they should be placed under a hot-bed frame, and be plunged into old tanners' bark which has lost its heat, where they may be defended from frost during the winter, and in the spring the pots

pots should be plunged into a moderate hot-bed, which will bring up the plants. When these appear, they should not be too tenderly treated, but have a large share of free air admitted to them; when they are fit to transplant, they should be carefully shaken out of the pots, and separated, planting each into a small pot filled with soft loamy earth, and plunged into a very moderate hot-bed, to forward their taking new root, shading them from the sun, and gently refreshing them with water as they may require. When they are rooted, they must be gradually inured to the open air, and in June they may be placed abroad in a sheltered situation, where they may remain till the middle or latter end of October, according as the season proves favourable; then they must be removed into the greenhouse; and treated in the same way as the orange-tree, being careful not to give them too much wet during the winter season.

The second sort was formerly thought difficult to raise by seeds; but at present it is readily increased by parting its creeping roots, and planting them in bog earth, on a shady border, where it thrives very well, and spawns much.

The first sort affords variety when set out among other potted plants of the greenhouse kind; and the latter in the borders, &c.

POLYGAMIA, in *Botany*, from *πολυς*, *many*, and *γαμος*, *a marriage*, the twenty-third class in the Linnæan artificial system, derives its name and character from the various distribution of its stamens and pistils, which are partly found in the same flower, and partly in separate ones, either on the same or on different individual plants of one species. Such a diversity is very prevalent among the trees of tropical climates, which are most of them more or less polygamous, as is the case also with many grasses. Yet such a character, being not always permanent, leads to much difficulty in practice. Hence some botanists have hastily abolished the class altogether. The writer of the present article first suggested a limitation of it to those genera which have a difference of structure in the accessory parts of their flowers, (the calyx, corolla, &c.) independent of the stamens and pistils; flowers so constructed being permanently distinct. If the class cannot be supported on this foundation, it must fall to the ground. *Atriplex* is thus the only British example of *Polygamia*, having some perfect flowers, (with stamens and pistils,) whose calyx is regularly five-cleft and spreading; while on the same plant are others, with pistils only, whose calyx consists of two compressed valves, greatly enlarged as the seed ripens. Yet some species of this very genus have the stamens and pistils separate in all their flowers.

The orders of the class in question are three.

1. *Monoecea*, in which the united, or perfect, flowers are accompanied with male or female, or both, all on the same individual plant, as in *Atriplex*.

2. *Dioecia*, in which the different kinds of flowers grow on two distinct individuals; there being, in that case, only male or only female flowers, besides the united ones, of which *Hippophæ* is but an occasional example. 3. *Trioecia*, having, on three separate individuals, the three different sorts of flowers, male, female, and united. Of this *Ficus* is supposed to be a solitary, and perhaps a very doubtful, example.

POLYGAMIA is the appellation of all the Linnæan orders of *Syngenesia*, (except the now abolished one, *Monogamia*,) having a word subjoined to express the kind of polygamy existing in each order. Thus; 1. *Polygamia equalis* has all the florets, in the common calyx, perfect or united, each furnished with its own efficient stamens and pistil: 2. *Polygamia superflua* has perfect florets in the disk, female ones,

equally fertile, in the circumference: 3. *Polygamia frustranea* has perfect florets in the disk, and neutral or abortive ones in the circumference: 4. *Polygamia necessaria* has male florets in the disk, female in the circumference: and lastly, 5. *Polygamia segregata* has several syngenesious flowers, with a partial calyx, all united in one general calyx, as in *Echinops*, the Globe-thistle. Willdenow has, very unadvisedly, omitted the word *polygamia* in the class *Syngenesia*, terming the orders simply *equalis*, *superflua*, &c.; adjectives, having no substantive with which they can agree but *Syngenesia*, and therefore conveying a wrong idea. We are happy to observe that the able author and editor of Hort. Kew. have not been seduced by him in this instance.

POLYGAMY, *Πολυγαμία*, formed from *πολυς*, *multus*, and *γυνή*, *uxor*, *wife*; a plurality of wives, or husbands, held by the same man, or woman, at the same time.

Polygamy is prohibited among Christians; but it was allowed among the Jews, as it is still among the Mahometans; and under all the religions that have obtained in Asia. In the kingdoms of Boutan and Thibet, polygamy is at this time almost general; one wife frequently serving all the males of a whole family, without being the cause of any uncommon disunion or jealousy among them.

The customs of the Sumatrans, as we learn from Mr. Marsden (*Hist. of Sumatra*), permit their having as many wives by "joojoo," as they can afford to purchase or maintain. "Joojoo" is a certain sum of money, given by one man to another, as a consideration for the person of his daughter, whose situation, in this case, differs not much from that of a slave to the man she marries, and to his family. Nevertheless, in Sumatra it is extremely rare, that an instance occurs of their having more than one, and that only among a few of the chiefs, which continence is in some measure owing to their poverty. In talking of polygamy, they allow it to be the privilege of the rich, but they regard it as a refinement to which the poor Rejangs cannot pretend. A man married by "semundo," or by a regular treaty between the parties on the footing of equality, cannot take a second wife without repudiating the first, for this obvious reason, that two or more persons would not be equally entitled to the half of his effects.

Montesquieu infers, that the law which permits polygamy, is physically conformable to the climate of Asia. The season of female beauty precedes that of their reason, and from its prematurity soon decays. The empire of their charms is short. It is therefore natural, as he observes, that a man should leave one wife to take another; that he should seek a renovation of those charms that had withered in his possession. But are these the real circumstances of polygamy? Mr. Marsden says, surely not. It implies the contemporary enjoyment of women in the same predicament; and he adds, I should consider it as a vice, that has its source in the influence of a warm atmosphere upon the passions of men, which, like the cravings of other disordered appetites, make them miscalculate their wants. Moreover, it ought to be considered, that the genial warmth which expands the desires of the men, and prompts a more unlimited exertion of their faculties, does not inspire their constitutions with proportionate vigour; but, on the contrary, renders them, in this respect, inferior to the inhabitants of the temperate zone; whilst it equally influences the desires of the opposite sex, without being found to diminish from their capacity of enjoyment. Whence we may infer, that if nature intended one woman only should be the companion of one man in the colder regions of the earth, it appears also intended, *a fortiori*, that the same law should be observed in the hotter; inferring nature's design, not from

the desires, but from the abilities with which she has endowed mankind.

Montesquieu has farther suggested, that the inequality in the comparative numbers of each sex, born in Asia, which is represented to be greatly superior on the female side, may have relation to the law that allows polygamy. But it is replied, that there is strong reason for denying the reality of this supposed excess. The Japan account, taken from Kæmpfer, which makes them to be in the proportion of 22 to 18, is very inconclusive, as the enumeration of the inhabitants of a great city can furnish no proper test; and the account of births at Bantam, which states the number of girls to be ten to one boy, is not only manifestly absurd, but positively false. Marsden asserts, with confidence, that the proportion of the sexes throughout Sumatra does not sensibly differ from that ascertained in Europe; nor could he ever learn from the inhabitants of the many eastern islands with whom he had an opportunity of conversing, that they were conscious of any disproportion in this respect.

But from whatever source we derive polygamy, its prevalence is attended with the practice of giving a valuable consideration for the female, instead of receiving a dowry with her. Where each man endeavours to engross several, the demand for the commodity, as a merchant would express it, is increased, and the price of course enhanced. In Europe the demand is small, whether owing to the paucity of males from continued diminution, their coldness of constitution, their corruption of manners, leading to promiscuous concubinage, or, in fine, the extravagant luxury of the times, which renders a family an insupportable burden;—whatever may be the cause, it becomes necessary, in order to counteract it, and produce an additional incitement to the marriage state, that a premium be given with the females. We find in the history of the earliest ages of the world, that when a plurality of women were allowed, by law or custom, they were obtained by money or service. The form of marriage by “Semundo,” among the Malays, which admits but of one partner, requires no sum to be paid by the husband to the relations of the wife, except a trifle, by way of token, or to defray the expences of the wedding feast. The custom of giving “joojoors” had most probably its foundation in polygamy; and the superstructure subsists, though its basis is partly mouldered away; but being scarcely tenable, the inhabitants are inclined to quit, and suffer it to fall to the ground. Moderation with regard to women destroying their principle, the “joojoors” appear to be devoid of policy. Open a new spring of luxury, and polygamy, now confined to a few individuals among the chiefs, will spread throughout the people. Beauty will be in high request; each fair one will be fought for by many competitors; and the payment of the “joojoor” be again esteemed a reasonable equivalent for possession. Their acknowledgment that the custom, under the present circumstances, is a prejudicial one, so contrary to the spirit of eastern manners, which is ever marked with a blind veneration for the establishments of antiquity, contributes to strengthen considerably the opinion already advanced.

Major Graunt observes, that the males and females brought into the world are nearly on a balance, only abating for a little excess on the side of the males, in the proportion of about 19 to 18, to make up for the extraordinary expence thereof in war, and at sea: whence it evidently follows, that nature only intends one wife, or one husband, for the same person; since, if they have more, some others must go without any at all. See MARRIAGE.

Hence he concludes, that the Christian law, which prohibits polygamy, is more agreeable to the law of nature

than the Mahometan; and we may add, than the Jewish law, which tolerated polygamy.

Dr. Percival, Phil. Transf. vol. lxvi. part i. p. 163. has very justly observed, that the practice is brutal, destructive to friendship and moral sentiment, inconsistent with one great end of marriage, the education of children, and subversive of the natural rights of more than half of the species: besides, it is injurious to population, and, therefore, can never be countenanced or allowed in a well regulated state; for, though the number of females in the world may considerably exceed the number of males, yet there are more men capable of propagating their species than women capable of bearing children; and it is a well known fact that Armenia, in which a plurality of wives is not allowed, abounds more with inhabitants than any other province of the Turkish empire.

Yet Selden has proved, in his “Uxor Hebraica,” that plurality of wives was allowed of, not only among the Hebrews, but also among all other nations, and in all ages. It is true, the ancient Romans were more severe in their morals, and never practised it, though it was not forbidden among them: and Mark Antony is mentioned as the first who took the liberty of having two wives.

From that time it became pretty frequent in the empire, till the reigns of Theodosius, Honorius, and Arcadius, who first prohibited it by an express law in 393. After this the emperor Valentinian, by an edict, permitted all the subjects of the empire, if they pleased, to marry several wives: nor does it appear, from the ecclesiastical history of those times, that the bishops made any opposition to this introduction of polygamy. In effect there are some even among the Christian casuists, who do not look on polygamy as in itself criminal. Jurieu observes, that the prohibition of polygamy is a positive law; but from which a man may be exempted by sovereign necessity. Baillet adds, that the example of the patriarchs is a very powerful argument in favour of polygamy.

But though the practice of polygamy prevailed among the patriarchs, both before and under the Jewish law, it has been doubted whether the law of Moses permitted it. (See Deut. xvii. 16. xxi. 15.) The permission, if there was any, might be like that of divorce, “for the hardness of their heart,” in condescension to their established indulgencies rather than from the general rectitude or propriety of the thing itself. However this be, the state of manners in Judea had probably undergone a reformation in this respect before the time of Christ, for in the New Testament we meet with no trace or mention of any such practice being tolerated. For this reason, and because it was likewise forbidden among the Greeks and Romans, we cannot expect to find any express law upon the subject in the Christian code.

The ancient Medes compelled their citizens, in one canton, to take seven wives; in another, each woman to receive five husbands; according as war had made, in one quarter of their country, an extraordinary havock among the men, or the women had been carried away by an enemy from another. This regulation, so far as it was adapted to the proportion which subsisted between the numbers of males and females, was founded in the reason upon which the most improved nations of Europe proceed at present.

Among the ancient Britons they had a singular kind of marriage, or rather polygamy, which is not to be found among any other people. Any number of them, as ten or a dozen, joined in a society together, which was perhaps requisite for mutual defence in those barbarous times. In order to link this society the closer, they took an equal number of wives in common, and whatever children were

born, were reputed to belong to all of them, and were accordingly provided for by the whole community.

Cæsar found among the inhabitants of this island a species of polygamy, if it may be so called, which was perfectly singular. "Uxores," says he, "habent deni duodenique inter se communes, et maxime fratres cum fratribus, parentisque cum liberis: sed si qui sunt ex his nati, eorum habentur liberi, quæ primum virgo quæque deducta est."

It has been much disputed among the doctors of the civil law, whether polygamy be adultery. In the Roman law it is called *stuprum*, and punished as such, that is, in some cases, capitally. But a smaller punishment is more consistent with the Jewish law, wherein the prohibition of adultery is perpetual, but that of polygamy temporary only. See Selden, lib. i. cap. 9. de Uxore Hebraica.

The words of Christ (Matt. xix. 9.), may be construed, says archdeacon Paley, by an easy explication to prohibit polygamy; for, if "whoever putteth away his wife, and marrieth another, committeth adultery," he who marrieth another, *without* putting away the first, is no less guilty of adultery; because the adultery does not consist in the repudiation of the first wife (for however unjust or cruel that may be, it is not adultery), but in entering into a second marriage, during the legal existence and obligation of the first.

However this passage be understood, polygamy has been as much disused and as universally prohibited in all Christian countries, as if Christianity had positively and expressly forbidden it.

In Germany, Holland, and Spain, this offence is differently punished. By a constitution of Charles V. it was a capital crime. By the laws of ancient and modern Sweden it is punished with death. In Scotland it is punished as perjury.

In England it is enacted by statute 1 Jac. I. cap. 11. that if any person, being married, do afterwards marry again, the former husband or wife being alive, it is felony, but within the benefit of clergy. The first wife in this case shall not be admitted as an evidence against her husband, because she is the true wife; but the second may, for she is indeed no wife at all; and so *vice versa* of a second husband. This act makes an exception to five cases, in which such second marriage, though in the three first it is void, is, however, no felony. 1. Where either party hath been continually abroad for seven years, whether the party in England had notice of the other's being living or no. 2. Where either of the parties hath been absent from the other seven years, within this kingdom, and the remaining party hath had no notice of the other's being alive within that time. 3. Where there is a divorce or separation *a mensa et thoro* by sentence in the ecclesiastical court. 4. Where the first marriage is declared absolutely void by any such sentence, and the parties loosed *a vinculo*. Or, 5. Where either of the parties was under the age of consent at the time of the first marriage; for in such case the first marriage was voidable by the disagreement of either party, which this second marriage very clearly amounts to. But if at the age of consent the parties had agreed to the marriage, which completes the contract, and is, indeed, the real marriage, and afterwards one of them should marry again, judge Blackstone apprehends that such second marriage would be within the reason and penalties of the act. Comment. book iv.

Bernardus Ochinus, general of the order of Capuchins, and afterwards a Protestant, published, about the middle of the sixteenth century, Dialogues in favour of polygamy,

which were answered by Theodore Beza. And about the conclusion of the last century we had at London an artful treatise published in behalf of a plurality of wives, under the title of "Polygamia Triumphatrix:" the author of which assumes the name of Theophilus Aletheus; but his true name was Lyferus: he was a native of Saxony. It has been answered by several.

In the year 1780, the Rev. Mr. Madan published a treatise, artfully vindicating and strongly recommending polygamy, under the title of "Thelyphthora; or a Treatise on Female Ruin, in its Causes, Effects, Consequences, Prevention, and Remedy, &c." Marriage, according to this writer, simply and wholly consists in the act of personal union, or *actus coitus*. Adultery, he says, is never used in the sacred writings but to denote the defilement of a betrothed or married woman, and to this sense he restricts the use of the term, so that a married man, in his opinion, is no adulterer, if his commerce with the sex be confined to single women, who are under no obligations by espousals or marriage to other men: but, on the other hand, the woman who should dare to have even but once an intrigue with any other man besides her husband, (let him have as many wives as Solomon,) would, *ipso facto*, be an adulteress, and ought, together with her gallant, to be punished with immediate death. This, he boldly says, is the law of God: and on this foundation he limits the privilege of polygamy to the man; in support of which he refers to the polygamous connections of the patriarchs and saints of the Old Testament, and infers the lawfulness of their practice from the blessings which attended it, and the laws which were instituted to regulate and superintend it. He contends for the lawfulness of Christians having, like the ancient Jews, more wives than one; and labours much to reconcile the genius of the evangelical dispensation to an arrangement of this sort. With this view he asserts, that there is not one text in the New Testament that even hints at the criminality of a polygamous connection; and he would infer from St. Paul's direction, that bishops and deacons should have but one wife, that it was lawful for laymen to have more. Christ, he says, was not the giver of a new law: but the business of marriage, polygamy, &c. had been settled before his appearance in the world, by an authority which could not be revoked. Besides, this writer not only thinks polygamy lawful in a religious, but advantageous in a civil light, and highly politic in a domestic view.

In defence of his notion of marriage, which, according to his account of it, consists in the union of man and woman as one body, the effects of which in the sight of God no outward forms or ceremonies of man's invention can add to or detract from, he grounds his principal argument on the Hebrew words made use of in Gen. ii. 24. to express the primitive institution of marriage, *viz.* בָּשָׂר וָחַיִּים, rendered by the LXX *προσκολληθησονται προς την συνικια αυτην*, which translation is adopted by the evangelist (Matt. xix. 5.) with the omission only of the superfluous preposition (*προς*) after the verb. Our translation, he says, "shall cleave to his wife," doth not convey the idea of the Hebrew, which is literally, as Montanus renders the words, "shall be joined or cemented *in* his woman, and they shall become (*i. e.* by this union) one flesh." But on this criticism, it is well remarked, that both the Hebrew and Greek terms mean simply and literally attachment or adherence; and are evidently made use of in the sacred writings to express the whole scope of conjugal fidelity and duty, though he would restrain them to the grosser part of it. See Deut. iv. 4. Joshua, xxiii. 8. Acts, v. 36.

With respect to the Mosaic law, for which Mr. Madan is a warm advocate, it was certainly a local and temporary institution, adapted to the ends for which it was appointed, and admirably calculated, in its relation to marriage, to maintain and perpetuate the separation of the Jewish people from the Gentiles. In attempting to depreciate the outward forms of marriage, this writer would make his readers believe, that because none are explicitly described, therefore none existed: and, consequently, that they are the superfluous ordinances of human policy. But it is evident, from comparing Ruth, iv. 10, 13. with Tobit, vii. 13, 14. and from the case of Dinah, related Gen. ch. xxxiv. that some forms were deemed essential to an honourable alliance by the patriarchs and saints under the Old Testament, exclusive of the carnal knowledge of each other's persons. It is also evident in the case of the woman of Samaria, whose connection with a man not her husband is mentioned in John iv. that something besides cohabitation is necessary to constitute marriage in the sight of God.

Having stated his notion of marriage, he urges in defence of polygamy, that notwithstanding the seventh commandment, it was allowed by God himself, who made laws for the regulation of it, wrought miracles in support of it by making the barren woman fruitful, and declared the issue legitimate to all intents and purposes. God's allowance of polygamy is argued from Exod. xxi. 10, and particularly from Deut. xxi. 15, which, he says, amounts to a demonstration. This passage, however, at the utmost, only presupposes that the practice might have existence among so hard-hearted and fickle a people as the Jews; and therefore wisely provides against some of its more unjust and pernicious consequences; such as tended to affect the rights and privileges of heirship. Laws enacted to regulate it cannot be fairly urged in proof of its lawfulness on the author's own hypothesis; because laws were also made to regulate divorce, which Mr. Madan condemns as absolutely unlawful, except in cases of adultery. Besides, it is more probable, that the "hated wife" had been dismissed by a bill of divorcement, than that she was retained by her husband: and moreover, it is not certain that the two wives, so far from living with the same husband at the same time, might not be dead; for the words may be rendered thus, "if there should have been to a man two wives, &c." The words expressing the original institution of marriage, Gen. ii. 24. compared with Matt. xix. 4, 5, 8, afford insuperable objections against Mr. Madan's doctrine of polygamy. (See also Lev. xviii. 18. 1 Cor. vii. 2, &c.) In a word, the several passages in St. Paul's writings, which speak of marriage, always suppose it to signify the union of one man with one woman. See Rom. vii. 2, 3.

If we appeal on this subject, from the authority of scripture to the writings of some of the earliest fathers in the Christian church, there is not to be found the faintest trace of any thing resembling a testimony to the lawfulness of polygamy; on the contrary, many passages occur, in which the practice of it is strongly and explicitly condemned. See Justin Martyr's Dial. with Trypho the Jew, Greek edit. by Thirlby, fol. p. 336. 423. 372. Clemens Alexandrin. Stromata, lib. iv. p. 312, 335, 336, edit. Heinsii, &c. Lug. Bat. fol. 1616.

We shall here adopt the words of an excellent anonymous writer, to whose critique on Mr. Madan's work we are indebted for many of the above remarks: in a word, when we reflect, that the primitive institution of marriage limited it to one man and one woman; that this institution was adhered to by Noah and his sons, amidst the degeneracy of the age in which they lived, and in spite of the examples

of polygamy, which the accursed race of Cain had introduced; when we consider how very few (comparatively speaking) the examples of this practice were among the faithful; how much it brought its own punishment with it; and how dubious and equivocal those passages are in which it appears to have the sanction of divine approbation; when to these reflections we add another, respecting the limited views and temporary nature of the more ancient dispensations and institutions of religion—how often the imperfections, and even vices of the patriarchs, and people of God, in old time, are recorded, without any express notification of their criminality—how much is said to be commanded, which our reverence for the holiness of God, and his law, will only suffer us to suppose was, for wise ends, permitted—how frequently the messengers of God adapted themselves to the genius of the people to whom they were sent, and the circumstances of the times in which they lived; above all, when we consider the purity, equity, and benevolence of the Christian law; the explicit declarations of our Lord, and his apostle St. Paul, respecting the institution of marriage, its design and limitation; when we reflect, too, on the testimony of the most ancient fathers, who could not possibly be ignorant of the general and common practice of the apostolic church; and, finally, when to these considerations we add those which are founded on justice to the female sex, and all the regulations of domestic economy and national policy, we must wholly condemn the revival of polygamy; and thus bear our honest testimony against the leading design of this dangerous and ill-advised publication. Monthly Review, vol. lxxiii. p. 338.

Polygamy, says Paley, not only violates the constitution of nature, and the apparent design of the Deity, but produces to the parties themselves, and to the public, the following bad effects: contests and jealousies amongst the wives of the same husband; distracted affections, or the loss of all affection in the husband himself; a voluptuousness in the rich, which dissolves the vigour of their intellectual as well as active faculties, producing that indolence and imbecility both of mind and body, which have long characterised the nations of the East; the abasement of one half of the human species, who, in countries where polygamy obtains, are degraded into mere instruments of physical pleasure to the other half; neglect of children; and the manifold, and sometimes unnatural, mischiefs, which arise from the scarcity of women. To compensate for these evils, polygamy does not offer a single advantage. In the article of population, which it has been thought to promote, the community gains nothing, that is, nothing compared with a state in which marriage is nearly universal; for the question is not, whether one man will have more children by five or more wives than by one, but whether these five wives would not have the same, or a greater number of children, by five separate husbands. And as to the care of the children when produced, and the sending of them into the world in situations, in which they may be likely to form and bring up families of their own, upon which the increase and succession of the human species in a great degree depend; this is less provided for, and less practicable, where twenty or thirty children are to be supported by the attention and fortune of one father, than if they were divided into five or six families, to each of which were assigned the industry and inheritance of two parents. Paley's Principles of Moral and Political Philosophy, vol. i.

POLYGAMY is also used in the *Canon Law*, for a plurality of wives, though only had successively, or one at a time: in the Romish church this disqualifies a man for the episcopate. See BIGAMY.

POLYGLOTT, Πολυγλωττος, thus called from πολυ, and γλωττιζ, tongue, language, among *Divines* and *Critics*, chiefly denotes a bible printed in several languages.

The first Polyglott bible is that of cardinal Ximenes, printed in 1515, at Alcalá de Henares; and commonly called the *Bible of Complutum*, or the *Complutensian Bible*; and contained in six volumes.

It contains the Hebrew text, the Chaldee paraphrase on the Pentateuch, the Greek version of the LXX, and the ancient Latin version.

In this Polyglott there is no other Latin version from the Hebrew, beside this last; but there is added another literal one from the Greek Septuagint. The Greek text of the New Testament is here printed, without accents, to bring it nearer to the original of the apostles, or, at least, to the most ancient copies; in which there are no accents found.

At the end is added an apparatus of grammars, dictionaries, and indices, or tables. The chief author, Ximenes de Cineros, cardinal, and archbishop of Toledo, in his dedication to pope Leo X., observes, that it was necessary to give the holy scriptures in their originals, there being no translation, how good soever, that can render them perfectly.

The second Polyglott, called the *Biblia regia*, is that of Philip II., printed by Plantin, at Antwerp, in 1751, in eight volumes, with a better paper and letter than the former, and the care of the edition imposed on Arias Montanus.

In this, besides every thing in the bible of Complutum, there are added, the Chaldee paraphrases on the rest of the Old Testament, besides the Pentateuch, with a Latin translation of those paraphrases. In this Polyglott is likewise a very literal Latin version of the Hebrew text, for the use of those who have a mind to learn the Hebrew language.

As to the New Testament, beside the Greek and Latin of the bible of Alcalá, in this edition there is added an ancient Syriac version, both in Syriac and Hebrew characters, with points, to facilitate the reading thereof to those accustomed to read Hebrew. To the Syriac is likewise added a Latin one, composed by Guy le Fevre, who had the care of the Syriac version of the New Testament.

Lastly, in the Polyglott of Antwerp is added a more copious apparatus of grammars, dictionaries, &c. than in that of Complutum; with several little treatises, judged necessary for clearing up the more difficult passages in the text.

The third Polyglott is that of M. le Jay, printed at Paris in 1645, in ten volumes, which has this advantage over that of Philip II., that it has the Syriac and Arabic versions of the Old Testament, with Latin interpretations. In the Pentateuch it has likewise the Hebrew and Samaritan text; and the Samaritan version in Samaritan characters.

As to the New Testament, beside every thing in the Polyglott of Antwerp, here is added an Arabic translation, with a Latin interpretation. But here are wanting the apparatus, and the grammars and dictionaries, which are both in the former Polyglotts; which renders this great work very imperfect.

The fourth Polyglott is that of London, printed in 1657, in six volumes, called Walton's Polyglott, from the author of the edition, Dr. Bryant Walton, afterwards bishop of Winchester.

This is, indeed, less magnificent than that of M. le Jay, with regard both to the size of the paper, and the beauty

of the characters; but is, in all other respects, preferable; being both much more ample and more commodious.

In this the Vulgate is printed according to the revised and corrected edition of Clement VIII., which is not done in that of Paris, where the Vulgate is printed as it stands in that of Antwerp, before that correction.

This likewise contains an interlineary Latin version of the Hebrew text; whereas the Paris edition has no other Latin version from the Hebrew beside the common Vulgate: again, the Greek Septuagint printed in the Polyglott is not the same with that printed in the bible of Complutum, which was retained in the editions of Antwerp and Paris, but the Greek text of the edition of Rome. To which are added the various readings of another very ancient Greek copy, called the *Alexandrian*, because brought from Alexandria.

The Latin version of the Greek of the Septuagint is that published by Flaminius Nobilius, by authority of pope Sixtus V. Add, that in this Polyglott are found some parts of the bible in the Ethiopic and Persian; nothing of which appears in any of the rest.

Lastly, this edition has the advantage of preliminary discourses, called prolegomena, on the texts, both of the originals and versions; with a volume of various readings of all the different editions.

Dr. Edmund Castell, Arabic professor at Cambridge, in 1669, published a *Lexicon Heptaglotton*, for the use of Walton's Polyglott, in two volumes, folio. See the Preface to this Polyglott.

To the number of the Polyglotts may likewise be added the two Pentateuchs, printed by the Jews of Constantinople, in four languages; but all in Hebrew characters. In one of these Pentateuchs, printed in 1551, is found the Hebrew text, in large characters; on one side of which is the Chaldee paraphrase of Onkelos, in middling characters; and on the other side, a paraphrase in the Persian, composed by a Jew, one Jacob de Tous, so called from the city where he lived. Beside these three columns, the Arabic paraphrase of Saadias Gaon is printed in small characters, at the top of the pages; and at the bottom is added the commentary of Rasch.

The other Polyglott was printed at Constantinople in 1547, in three columns like the former. The Hebrew text of the law is in the middle, a translation into the vulgar Greek on one side, and a Spanish translation on the other. These versions are both in Hebrew characters, with points to determine the pronunciation. At the top of the page is added the Chaldee paraphrase of Onkelos, and at the bottom the commentaries of Rasch.

To all these may be added, as a seventh Polyglott, the *Pfalter* published by Aug. Justinian, a Dominican, and bishop of Nebio, at Genoa, 1515, containing the Hebrew, Greek, Arabic, and Chaldee, with Latin interpretations and glosses.

There are also various other editions of the bible, either in whole, or in part, which might be ranged under the article of Polyglotts; though they are not so denominated. Such are the *Hexapla*, and *Octapla*, of Origen.

And the bible of Hutter, printed at Hamburg in Hebrew, Chaldee, Greek, Latin, German, Saxon, Italian, French, Sclavonic, Danish, &c.

POLYGLOTTA AVIS, in *Ornithology*, the name of a bird described by Nieremberg, and which, he says, he saw and heard, with admiration, singing in all tones. It is of the size of our starling.

Its back is brown, and its breast and belly white; and
near

near the neck and tail it is variegated with spots and streaks of white; its head has a streak of white, which represents a sort of crown of silver; it is mightily esteemed, and kept in cages by the Spaniards, as infinitely superior to all other birds in melody; it feeds on almost any thing that is given it, and is most fond of the warmer climates; but endures the more temperate ones without harm. Ray.

The polyglottus of Linnæus is a species of the *turdus*; which see.

POLYGON, Πολυγωνος, formed from πολυς, many, and γωνια, angle, in *Geometry*, a multilateral figure, or a figure whose perimeter consists of more than four sides and angles.

If the sides and angles be equal, the figure is called a regular polygon. For similar polygons, see SIMILAR.

Polygons are distinguished according to the number of their sides. Those of five sides are called *pentagons*; those of six, *hexagons*; those of seven, *heptagons*; those of eight, *octagons*, &c. The particular properties, &c. of each of which, see under its proper article, **PENTAGON**, **HEXAGON**, &c.

POLYGONS, general Properties of. Euclid demonstrates these which follow: 1. That every polygon may be divided into as many triangles as it hath sides.

This is done by assuming a point, as F (*Plate XI. Geometry, fig. 6.*), any where within the polygon, and thence drawing lines to every angle, F a, F b, F c, F d, &c.

2. The angles of any polygon, taken together, make twice as many right ones, abating four, as the figure hath sides. Thus, if the polygon hath five sides, the double of that is 10; whence subtracting 4, there remain 6 right ones.

3. Every polygon, circumscribed about a circle, is equal to a right-angled triangle, one of whose legs is the radius of the circle, and the other the perimeter, or sum of all the sides of the polygon.

Hence, every regular polygon is equal to a right-angled triangle, one of whose legs is the perimeter of the polygon; and the other a perpendicular drawn from the centre to one of the sides of the polygon.

Hence, also, every polygon, circumscribed about a circle, is bigger than it; and every polygon, inscribed, is less than the circle. The same likewise appears hence, that the thing containing is ever greater than the thing contained. Hence, again, the perimeter of every polygon circumscribed about a circle, is greater than the circumference of that circle; and the perimeter of every polygon inscribed, less: whence it follows, that a circle is equal to a right-angled triangle, whose base is the circumference of the circle, and its height the radius; since this triangle is less than any polygon circumscribed, and greater than any inscribed.

Nothing, therefore, is wanting to the quadrature of the circle, but to find a right line equal to the circumference of a circle.

POLYGON, to find the area of a regular. Multiply a side of the polygon, as A B, by half the number of the sides, *e. gr.* the side of a pentagon by $2\frac{1}{2}$. Again, multiply the product by a perpendicular let fall from the centre of the circumscribed circle to the side A B; the product is the area required.

Thus, suppose A B 54; and half the number of sides $2\frac{1}{2}$; the product or semiperimeter is 135. Supposing then the perpendicular F H 29; the product of these two, 3915, is the area of the pentagon required.

POLYGON, to find the area of an irregular, or trapezium. Resolve it into triangles; find the several areas of the several

triangles, see TRIANGLE. The sum of these is the area of the polygon required.

POLYGON, to find the sum of all the angles in any. Multiply the number of sides by 180° : from the product subtract 360; the remainder is the sum required.

Thus, in a pentagon, 180, being multiplied by 5, gives 900; whence subtracting 360, there remain 540, the sum of the angles of a pentagon.

Hence, if the sum found be divided by the number of sides, the quotient will be the angle of a regular polygon. Or the sum of the angles is more speedily found thus: multiply 180 by a number less by two than the number of sides of the polygon; the product is the quantity of the angles required: thus, in a pentagon, 180 being multiplied by 3, a number less by two than of its sides, the product is 540, the quantity of angles as before.

The following table exhibits the sums of the angles in all rectilinear figures, from a triangle to a dodecagon; and is of good use, both for the describing of regular figures, and for proving whether or not the quantity of angles has been truly taken with an instrument.

Number of Sides.	Sums of the Angles.	Angles of Regular Figures.	Angles at the Centre.	
III.	180°	60°	100°	
IV.	360	90	90	
V.	540	108	72	
VI.	720	120	60	
VII.	900	128	51	$35\frac{5}{7}$
VIII.	1080	135	45	
IX.	1260	140	40	
X.	1440	144	36	
XI.	1620	147	32	$43\frac{7}{11}$
XII.	1800	150	30	

This table is formed by dividing 360, the degrees in a circumference, by the number of the sides in each polygon; and the quotients are the angles at the centres; the angle at the centre subtracted from 180° leaves the angle at the circumference; and the sum of the angles is had by doubling the number of sides, subtracting 4 from the product, and multiplying the remainder by 90.

POLYGON, to inscribe a regular, in a circle. Divide 360 by the number of sides in the polygon required, to find the quantity of the angle E F D. Set off the angle at the centre, and apply the chord thereof, E D, to the periphery, as often as it will go. Thus will the polygon be inscribed in the circle.

The resolution of this problem, though it be mechanical, yet is not to be despised, because both easy and universal. Euclid, indeed, gives us the construction of the pentagon, decagon, and quindecagon; and other authors give us those of the heptagon, enneagon, and hendecagon; but they are far from geometrical strictness.

Renaldinus lays down a Catholic rule for the describing of all polygons, which many other geometricians have borrowed from him; but Wagnerus and Wolfius have both demonstrated the falsity of it.

POLYGON, about a regular, to circumscribe a circle: or, to circumscribe a regular polygon about a circle. Bisect two of the angles of the given polygon A and E, by the right lines A F and E F, concurring in F, and from the point of concurrence with the radius E F describe a circle. To circumscribe a polygon, &c. divide 360 by the number of sides required,

POLYGON.

required, to find $e F d$; which set off from the centre F , and draw the line $e d$; on this construct the polygon, as in the following problem. See CIRCUMSCRIBING.

POLYGON, on a given line $E D$ to describe any given regular. Find an angle of the polygon in the table; and in E set off an angle equal to it, drawing $E A = E D$. Through the three points A, E, D , describe a circle. In this apply the given right line as often as it will go. Thus will the required figure be described.

POLYGON, to inscribe, or circumscribe a regular, trigonometrically. Find the sine of the arc produced by dividing the semi-periphery 180 by the number of sides of the polygon: the double of this is the chord of the double arc; and therefore the side $A E$ to be inscribed in the circle. If, then, the radius of a circle wherein, *e. gr.* a pentagon is to be inscribed, be given in any certain measure, *e. gr.* 345 , the side of the pentagon is found in the same measure by the rule of three, thus; as radius 1000 is to 1176 , so is 3450 to 4057 , the side of the pentagon. With the given radius, therefore, describe a circle; and therein set off the side of the polygon as often as it will go; thus will a polygon be inscribed in the circle.

To save the trouble of finding the ratio of the side of the polygon to radius, by the canon of sines; we shall add a table expressing the sides of polygons in such parts whereof radius contains 10000000 . In practice, as many figures are cut off from the right hand, as the circumstance of the case render needless.

Number of Sides.	Quantity of Sides.	Number of Sides.	Quantity of Sides.
III.	17320508	VIII.	7653668
IV.	14142135	IX.	6840402
V.	11755705	X.	6180339
VI.	10000000	XI.	5634651
VII.	8677674	XII.	5176380

POLYGON, to describe a regular, on a given right line, and to circumscribe a circle about a given polygon, trigonometrically. Taking the ratio of the side to the radius out of the table, find the radius in the same measure in which the side is given. For the side and radius being had, a polygon may be described by the last problem. And if with the interval of the radius, arcs be struck from the two extremes of the given line, the point of intersection will be the centre of the circumscribing circle.

General analytical Investigation of the Properties of Polygons.—The most curious property of polygons is that discovered by professor Gauss, of Straßburgh, and published by him in his “*Disquisitiones Arithmeticae*” in the year 1800 . This is one of the most interesting theorems of the kind that has been discovered since that of the celebrated Cotesian theorem, and our readers, therefore, will be gratified to find here a sketch of the method which this author has pursued.

We have given above, and under the articles TRIANGLE and SQUARE, the geometrical method of inscribing in a circle a triangle, square, and pentagon: and from these it is obvious, that we may also inscribe any polygon of $6, 12, 24, \&c.$ sides, as also of $8, 16, 32, \&c.$, and of $10, 20, 40, \&c.$ sides, by the continual bisection of the arcs subtending the side of the original figure. It is also evident from other principles, that if two polygons of an unequal number of sides prime to each other can be inscribed in a circle, that the polygon whose number of sides is equal to the product of these, may likewise be inscribed

geometrically; therefore, 3 and 5 being numbers of this kind, we see that a 15 -sided polygon may be inscribed, and consequently one of $30, 60, 120, \&c.$ sides, and these were the only cases whose geometrical constructions were known before the publication of the work above-mentioned. But Mr. Gauss has added to them several others, having shewn how any polygon of a prime number of sides may be inscribed when that prime number is of the form $2^m + 1$; such are the numbers $17, 257, \text{ and } 65537$, and consequently their doubles, quadruples, &c.

Gauss's Theorem for Polygons.—It is obvious, that when the cosine or sine of the central angle of a polygon can be analytically expressed by means of quadratic equations, the same polygon may be geometrically inscribed; but when the sine or cosine cannot be expressed without a higher equation than a quadratic, as there are no geometrical constructions of such equations, no more are there any geometrical construction of the polygons depending upon them; therefore, when the former can be accomplished, the possibility of the construction is admitted, and this is what is to be understood by *Gauss's theorem*, which is a general method of exhibiting the sides of every polygon in the lowest analytical expression, which in the cases above mentioned are simple quadratics.

It has been known, since the invention of the Cotesian theorem, that the division of the circle into any proposed number of parts depends upon the solution of the general binomial equation $x^n + 1 = 0$, all the imaginary roots of the former, *viz.* of $x^n + 1 = 0$, being contained in the general

formula $x^2 - 2 \cos. \frac{(2k+1)\pi}{n} x + 1 = 0$; and of the latter,

viz. $x^n - 1 = 0$, in the general formula $x^2 - 2 \cos. \frac{2k\pi}{n} x + 1$

$= 0$, k being any integer number not divisible by n , and π representing the semi-circumference. See the demonstrations of these properties in Lagrange's *Leçons des Fonctions Analytiques*, or in Barlow's *Theory of Numbers*, p. 481 .

Assuming, therefore, the equation $x^n - 1 = 0$, and its general factor $x^2 - 2 \cos. \frac{2k\pi}{n} x + 1 = 0$, it is obvious that

if $2 \cos. \frac{2k\pi}{n}$ is known, two of the roots of the equation

$x^n - 1$ become also known, and conversely if the roots of the equation $x^n - 1$ can be found independently of the for-

mula $x^2 - 2 \cos. \frac{2k\pi}{n} x + 1 = 0$, the co-efficient $2 \cos. \frac{2k\pi}{n}$

will be determined, being equal to two of the roots from the known theory of equations; and hence it is obvious in what manner the division of the circle, or the general inscription of polygons in a circle, depends upon the solution of the equation $x^n - 1 = 0$. Our object, therefore, will be to explain the general solution of this binomial equation. 1 . All the imaginary roots of the equation $x^n - 1 = 0$, n being a prime number, are different powers of the same imaginary quantities, and, therefore, different powers of each other; that is, if r be one root of the equation $x^n - 1 = 0$, then will all the imaginary roots of this equation be contained in the series

$$r, r^2, r^3, r^4, \text{ and } r^{n-1}$$

This is evident; for since $r^n = 1$, $(r^2)^n = 1$, $(r^3)^n = 1$, &c. or $r^2, r^3, r^4, \&c.$ are each equal to 1 , which is the condition of the equation; and it may readily be shewn that these roots are all different from each other.

Hence,

Hence, again, it follows, r^n being one of the roots, or $r^n = 1$, that $r^{n+1} = r$, $r^{n+2} = r^2$, $r^{n+3} = r^3$ &c.; and therefore the series

$$r, r^2, r^3, r^4, r^5 \text{ \&c. } r^{n-1}$$

being continued beyond r^{n-1} , and r^n , will recur again in the same order, and become

$$r^{n+1}, r^{n+2}, r^{n+3}, r^{n+4} \text{ \&c.}$$

Or, if we assume, for the first root, r^a , a being any number prime to n , then we should have for our series of roots

$$r^a, r^{2a}, r^{3a}, r^{4a}, \text{ \&c. } r^{(n-1)a},$$

which being continued, will give the same series over again in precisely the same order.

Now this series, containing in it all the imaginary roots of the equation $x^n - 1 = 0$, and the sum of all the roots of every equation being equal to the co-efficient of the second term, it follows, that the sum of all these imaginary roots must be equal to *minus* the real root, which is 1, that is,

$$r^a + r^{2a} + r^{3a} + r^{4a} + \text{ \&c. } r^{(n-1)a} = -1,$$

and their continued product

$$r^a \times r^{2a} \times r^{3a} \times r^{4a} \text{ \&c. } r^{n-1)a} = +1,$$

the absolute term, these being both well-known properties of every equation.

Having said thus much, by way of introduction, which was necessary for comprehending the method pursued by M. Gauss, we will now attempt a slight sketch of his solution of the equations under discussion; but in a work of this kind, the reader will not expect to find a complete development of it, as this would far exceed the limits that can be allowed for this article.

We have shewn above, that the whole series of imaginary roots of the equation $x^n - 1 = 0$, by being continued beyond the term $r^{(n-1)a}$, will recur again in the same order as at first, also n being always supposed a prime number $n - 1$, the number of imaginary roots is an even number, and consequently a composite number; and this composite number of roots may therefore be separated into equal periods of roots, which periods may, in all cases, be so selected, as to possess the same property as the whole series, *viz.* they may be so selected, that each period being continued, the roots in each will recur again in the same order as at first, and it is on this separation of the original periods of roots into other inferior periods that the particular solution of M. Gauss depends; for when this is done, the products or the sums of any number of these periods will be equal to the sums of similar series: but the demonstration of this property is too long to be admitted into this article, and we can therefore only refer the reader to the work itself, or to those which have since been written on the same subject as enumerated at the conclusion of this article.

In order to illustrate what has been said in the preceding columns, and to shew its application to the solution of the proposed equation, we shall select two or three of the simplest cases, which will at once put the reader in possession of the method of solution, which is all that can be attempted in this place.

Let it then be proposed to find the four imaginary roots of the equation $x^5 - 1 = 0$; which answers to the division of the circle into five equal parts, or the inscription of a pentagon in a circle.

Let r represent one of the imaginary roots of this equation, then from what is said above the four roots will be r, r^2, r^3, r^4 .

Now let these roots be divided into the periods

$$\begin{aligned} r + r^4 &= p \\ r^2 + r^3 &= p' \end{aligned}$$

By the addition of the two, we have

$$r + r^2 + r^3 + r^4 = p + p' = -1;$$

and the product of them gives

$$r^3 + r^4 + r + r^2 = pp';$$

or, since $r^5 = r^{4+1} = r$, and $r^7 = r^{5+2} = r^2$, we have

$$r^3 + r + r^4 + r^2 = pp' = -1.$$

Hence we have $p + p' = -1$,
and $pp' = -1$,

the solution of which gives

$$p = \frac{-1 + \sqrt{5}}{2}, \text{ and } p' = \frac{-1 - \sqrt{5}}{2};$$

and now, having obtained the values of p and p' , we may readily find those of r, r^4 , and r, r^3 ; but this is not necessary to our inquiry, for we have seen that the general factor of the equation $x^n - 1 = 0$, is

$$x^2 - 2 \operatorname{cof.} \frac{2k\pi}{r} + 1 = 0,$$

and consequently, that $2 \operatorname{cof.} \frac{2k\pi}{r}$ is equal to the sum of

two of the roots of the proposed equation, which sum we have already found; *viz.* making $k = 1$, and $\pi = 180^\circ$, we have

$$r + r^4 = p = \frac{-1 + \sqrt{5}}{2} = 2 \operatorname{cof.} \frac{360^\circ}{5}$$

$$r^2 + r^3 = p' = \frac{-1 - \sqrt{5}}{2} = 2 \operatorname{cof.} \frac{720^\circ}{5}.$$

The roots themselves, however, if required, are contained in the two quadratics

$$x^2 - \left(\frac{-1 + \sqrt{5}}{2} \right) x + 1 = 0$$

$$x^2 - \left(\frac{-1 - \sqrt{5}}{2} \right) x + 1 = 0,$$

which, with the real root 1, complete the solution of the equation.

In this equation the four roots were decomposed into two periods, of two terms each, and it was therefore only necessary to find the sum of the two periods, and their product, which required only the solution of a quadratic equation; but when this cannot be done, that is, when $n - 1$ is such as not to consist of some power of 2, then the roots must be divided into periods, according to the factors of $n - 1$, and whatever number of periods there may be, the solution of the equation will require that the sum of them, the sum of the product of every two, of every three, &c. be known; and, consequently, the equation by which they are expressed, will rise to a dimension equal to the number of such periods.

Thus, in the equation $x^7 - 1 = 0$, since $7 - 1 = 6 = 2.3$, the series of roots will be divided into three periods, of two roots each, and the solution of the equation will depend upon the resulting cubic equation.

Here the imaginary roots being $r, r^2, r^3, r^4, r^5, r^6$, and the periods

$$\begin{aligned} r + r^6 &= p \\ r^2 + r^4 &= p' \\ r^3 + r^5 &= p'' \end{aligned}$$

POLYGON.

we must find the value of $p + p' + p''$, of $pp' + pp'' + p'p''$, and of $p p' p''$, then the cubic equation having these quantities for its co-efficients, will have for its roots the three quantities p, p', p'' .

Now, by really taking these sums and products, we find

$$p + p' + p'' = r + r^2 + r^3 + r^4 + r^5 + r^6 = -1,$$

$$\begin{aligned} p p' &= r^1 + r^2 + r^5 + r^3 \\ p' p'' &= r^3 + r^6 + r + r^2 \\ p p'' &= r^1 + r + r^6 + r^4, \end{aligned}$$

and therefore

$$p p' + p p'' + p' p'' = 2(r + r^1 + r^1 + r^1 + r^5 + r^6) = -2,$$

and in the same way we find

$$p p' p'' = -(r + r^2 + r^3 + r^4 + r^5 + r^6) = 1;$$

therefore the cubic equation containing these three values of $p p' p''$, is

$$p^3 + p^2 - 2p - 1 = 0,$$

the solution of which gives

$$\begin{aligned} p &= 1.2469796 = 2 \operatorname{cof.} \frac{360^\circ}{7} \\ p' &= -1.8019376 = 2 \operatorname{cof.} \frac{2 \times 360^\circ}{7} \\ p'' &= -0.4450420 = 2 \operatorname{cof.} \frac{3 \times 360^\circ}{7} \end{aligned}$$

which is all that is required for the division of the circle into seven parts; but the roots themselves, if required, are contained in the three following quadratics,

$$\begin{aligned} x^2 - p x + 1 &= 0 \\ x^2 - p' x + 1 &= 0 \\ x^2 - p'' x + 1 &= 0. \end{aligned}$$

Let us now attempt the solution of $x^7 - 1 = 0$, which it will appear may be effected by means of quadratic equations only, and consequently a polygon of this number of sides may be inscribed geometrically in a circle, a problem which, before the publication of the work above-mentioned, was thought to be totally beyond the reach either of geometry or analysis.

Here the 16 imaginary roots being first decomposed into the two following periods, *viz.*

$$\begin{aligned} p &= r + r^2 + r^3 + r^5 + r^6 + r^7 + r^4 + r^2 \\ p' &= r^3 + r^{10} + r^5 + r^1 + r^{13} + r^7 + r^{12} + r^5, \end{aligned}$$

we have, by the actual addition and multiplication of the two periods,

$$\begin{aligned} p + p' &= -1 \\ p p' &= -4; \end{aligned}$$

whence, $p = -\frac{1}{2} + \frac{1}{2} \sqrt{17}$, and $p' = -\frac{1}{2} - \frac{1}{2} \sqrt{17}$.

Now, let these periods p, p' , be decomposed into two others, denoted as below by q and q' , *viz.*

$$\begin{aligned} \text{period } p &\begin{cases} q = r + r^{13} + r^6 + r^1 \\ q' = r^2 + r^{15} + r^3 + r^2 \end{cases} \\ \text{period } p' &\begin{cases} q'' = r^3 + r^5 + r^{14} + r^{12} \\ q''' = r^{10} + r^{11} + r^7 + r^5, \end{cases} \end{aligned}$$

which, being added and multiplied as above, give

$$\begin{aligned} q + q' &= p = -\frac{1}{2} + \frac{1}{2} \sqrt{17} \\ q q' &= p + p' = -1; \end{aligned}$$

whence,

$$\begin{aligned} q &= \frac{1}{2} p + \frac{1}{2} \sqrt{4 + p'} \\ q' &= \frac{1}{2} p - \frac{1}{2} \sqrt{4 + p'}, \end{aligned}$$

and in the same way,

$$\begin{aligned} q'' &= \frac{1}{2} p' + \frac{1}{2} \sqrt{4 + p''} \\ q''' &= \frac{1}{2} p' - \frac{1}{2} \sqrt{4 + p''}. \end{aligned}$$

Again, subdividing these four periods, each into two others, (of which, however, one only, as the first, will be sufficient for our purpose,) we shall have the sums of each pair of roots of the equation proposed. Now,

$$\text{period } q \begin{cases} t = r + r^{16} \\ t' = r^{13} + r^1, \end{cases}$$

which, by addition and multiplication, give

$$\begin{aligned} t + t' &= q = \frac{1}{2} p + \frac{1}{2} \sqrt{4 + p^2} \\ t t' &= q'' = \frac{1}{2} p' + \frac{1}{2} \sqrt{4 + p'^2}; \end{aligned}$$

therefore the quadratic equation, containing the roots t, t' , is

$$t^2 - q t + q'' = 0,$$

whence,

$$\begin{aligned} t &= \frac{1}{2} q + \frac{1}{2} \sqrt{q^2 - 4 q''} \\ t' &= \frac{1}{2} q - \frac{1}{2} \sqrt{q^2 - 4 q''}, \end{aligned}$$

the first of which is the greatest positive root, corresponding

to the 2 cof. $\frac{360^\circ}{17}$; which, by substituting for q and q'' ,

their respective values become =

$$\frac{1}{2} \left\{ \frac{1}{2} p + \frac{1}{2} \sqrt{4 + p^2} + \frac{1}{2} \sqrt{\left\{ \frac{1}{2} p + \frac{1}{2} \sqrt{4 + p^2} \right\}^2 - 4 \frac{1}{2} p' + \frac{1}{2} \sqrt{4 + p'^2}} \right\}$$

and in this expression, by re-establishing the values of p and p' ,

we have, in numbers, $2 \operatorname{cof.} \frac{360^\circ}{17} =$

$$\begin{aligned} &\frac{1}{2} \left(\frac{1}{2} \left(-\frac{1}{2} + \frac{1}{2} \sqrt{17} \right) + \frac{1}{2} \sqrt{\frac{1}{2} (17 - \sqrt{17})} \right) + \\ &\frac{1}{2} \sqrt{\left(\frac{1}{2} \left(-\frac{1}{2} + \frac{1}{2} \sqrt{17} \right) + \frac{1}{2} \sqrt{\frac{1}{2} (17 - \sqrt{17})} \right)^2 - 4 \left(\frac{1}{2} \left(-\frac{1}{2} - \frac{1}{2} \sqrt{17} \right) + \frac{1}{2} \sqrt{\frac{1}{2} (17 + \sqrt{17})} \right)}, \end{aligned}$$

which is the true numeral value of $2 \operatorname{cof.} \frac{360^\circ}{17}$.

These examples are sufficient for throwing some light on the method of solution adopted by M. Gauss in his work entitled "Disquisitiones Arithmeticae," but those who are desirous of entering more fully into the spirit of that method, must consult the work itself, or its translation, under the title of "Récherches Arithmétiques." An explanation and illustration of the same theorem is also given by Legendre, in the second edition of his "Essai sur la Théorie des Nombres," and the same again in its most simple form in Barlow's "Theory of Numbers." From what has been said in the preceding part of this article, it appears that the equations by which the circle may be divided into a prime number of equal parts n , depend upon the factors of $n - 1$; that is, upon the subdivision of its $n - 1$ roots into periods; thus, if $n - 1 = a^\alpha, b^\beta, c^\gamma, \&c.$ then the solution will be effected by α equations of the degree a , β of the degree b , γ of the degree c , and so on; whence, if $n = 11$, because $n - 1 = 10 = 2^1 \cdot 5^1$, the solution depends upon one equation of the fifth degree and one of the second. For in this case we can only decompose the ten imaginary roots into five periods of two terms each, or into two periods of five terms each; and in the first instance it is obvious that, in order to get the sum of all the p 's, as $p + p' + p'' + p'''$, &c. the sum of the product of every two, of every three, &c. the equation must necessarily rise to the 5th degree. And if, according to the other division, the roots are resolved into two periods of five terms each, though the value of these periods would be found by a quadratic, yet this would be of no use, as we should thus have only the value of the sum of five of the roots, whereas it appears from what has been said in the preceding part of this article, that it is only by knowing the sum of two roots that the solution of the equation can

POLYGON.

be determined. It is therefore necessary in all cases to manage the division so that the final equation may be a quadratic, that is, so that the number of terms in each period in the last instance shall not exceed two, which may always be done, because $n - 1$ is always an even number; and thus, when $n - 1$ is any complete power of 2, as we can then every step divide each period into two others, it follows that the solution of such an equation may always be effected by means of quadratic equations only; and consequently a polygon of such a number of sides may be inscribed geometrically in a circle. Now, 5, 17, 257, 65537, are prime numbers of this form, and therefore each of these admit of a geometrical construction; which, with the polygons that yield to the common operations of geometry, as enumerated in the beginning of this article, form the following series of polygons, each of which possesses the same property.

Polygons of less than 100 sides admitting of a geometrical construction.

No. of Sides.	No. of Sides.	No. of Sides.
3 = trigon.	16 = 2^4	48 = 3.16
4 = 2^2	17 = $2^4 + 1$	51 = 3.17
5 = $2^2 + 1$	20 = 4.5	60 = 2.30
6 = 2.3	24 = 3.8	64 = 2^6
8 = 2^3	30 = 3.10	68 = 2.34
10 = 2.5	32 = 2^5	80 = 2.40
12 = 3.4	34 = 2.17	85 = 5.17
15 = 3.5	40 = 2.20	96 = 2.48

And to the above may be added the three consecutive polygons

$$255, 256, 257,$$

each of which is inscribable in a circle; for

$$255 = 3 \cdot 5 \cdot 17, \quad 256 = 2^8, \quad \text{and} \quad 257 = 2^8 + 1, \text{ a prime.}$$

The three next consecutive polygons that admit of a geometrical construction, are the following, viz.

$$\begin{aligned} 65535 &= 255 \times 257 \\ 65536 &= 2^{16} \\ 65537 &= 2^{16} + 1, \text{ a prime.} \end{aligned}$$

POLYGON, in *Fortification*, denotes the figure or perimeter of a fortress, or fortified place. See FORTIFICATION.

POLYGON, *Exterior*, is a right line drawn from a vertex or point of a bastion, to the vertex or point of the next adjacent bastion. Such is the line CF, *Plate I. Fortification, fig. 1.*

POLYGON, *Interior*, is a right line drawn from the centre of one bastion to the centre of another. Such is the line GH.

POLYGONS, *Line of*, is a line on the French sectors, containing the homologous sides of the first nine regular polygons inscribed in the same circle, i. e. from an equilateral triangle to a dodecagon. See SECTOR.

POLYGONAL COLUMN. See COLUMN.

POLYGONAL Numbers, are those that are formed of the sums of different and independent arithmetical series, and are termed natural, triangular, quadrangular, pentagonal, hexagonal, &c. numbers; according to the series from which they are generated.

Lineal or natural numbers are formed from the successive sums of a series of units; thus,

$$\begin{array}{lcl} \text{Units} & - & 1, 1, 1, 1, 1, 1, \&c. \\ \text{Natural numbers} & & 1, 2, 3, 4, 5, 6, \&c. \end{array}$$

Triangular numbers are the successive sums of an arithmetical series, beginning with unity, the common difference of which is 1; thus,

$$\begin{array}{lcl} \text{Arithmetical series} & & 1, 2, 3, 4, 5, 6, 7, \&c. \\ \text{Triangular numbers} & & 1, 3, 6, 10, 15, 21, 28, \&c. \end{array}$$

Quadrangular or square numbers are the successive sums of an arithmetical progression, beginning with unity, the common difference of which is 2; thus,

$$\begin{array}{lcl} \text{Arithmetical series} & & 1, 3, 5, 7, 9, 11, 13, \&c. \\ \text{Quadrangles or squares} & & 1, 4, 9, 16, 25, 36, 49, \&c. \end{array}$$

Pentagonal numbers are the sums of an arithmetical series, the common difference of which is 3; thus,

$$\begin{array}{lcl} \text{Arithmetical series} & & 1, 4, 7, 10, 13, 16, 19, \&c. \\ \text{Pentagonals} & & 1, 5, 12, 22, 35, 51, 70, \&c. \end{array}$$

And universally, the *m-gonal series of numbers* is formed from the successive sums of an arithmetical progression, beginning with unity, the common difference of which is $m - 2$.

The general form, which includes every order of polygonal numbers, is

$$\frac{(m - 2)n^2 - (m - 4)n}{2}$$

where m is the denomination of the order; therefore, making successively $m = 3, 4, 5, \&c.$ we have the following results as to the forms of polygonals.

$$m = 3 \text{ Triangular numbers} = \frac{n^2 + n}{2}$$

$$m = 4 \text{ Squares} = \frac{2n^2 - 0n}{2} = n^2$$

$$m = 5 \text{ Pentagonals} = \frac{3n^2 - n}{2}$$

$$m = 6 \text{ Hexagonals} = \frac{4n^2 - 2n}{2}$$

By means of the above general form, any polygonal number, of which the root n is given, may be readily ascertained. Thus by making $m = 3, m = 4, m = 5, \&c.$ and in each series $n = 1, 2, 3, 4, 5, \&c.$ we shall obtain the same numbers as given above, under each respective denomination. Also any polygonal number, and its denomination being given, the root of the polygon is readily obtained. For let

$$P = \frac{(m - 2)n^2 - (m - 4)n}{2}$$

represent any given polygonal, of which the denomination m is known: then

$$(m - 2)n^2 - (m - 4)n = 2P$$

$$\text{or} \quad n^2 - \left(\frac{m - 4}{m - 2}\right)n = \frac{2P}{m - 2}$$

$$\text{whence} \quad n = \frac{m - 4 \pm \sqrt{(2P(m - 2) + (m - 4)^2)}}{2m - 4}$$

which is a general form for the root of every polygonal number.

Fermat, at page 15, in one of his notes to prop. 9 of Diophantus on Multangular Numbers, has given particular rules for finding the roots of given polygonal numbers, without the extraction of the square root; but they are

of little or no use, and therefore we shall not enumerate them.

We may also find the sum of any series of polygonals by means of the foregoing general formula, for representing still the denomination of any order of polygonals by m , and for abridging make $m - 2 = d$, the common difference of the series from which they are generated; and let n be the number of terms in the series whose sum is required, then we shall have

$$\left(\frac{n^2 - 1}{6}d + \frac{n + 1}{2}\right)n = \left(\frac{n^2 - 1}{6}(m - 2) + \frac{n + 1}{2}\right)n$$

for the sum of the n terms sought.

Hence, substituting successively the numbers 3, 4, 5, &c. for m , there are obtained the following particular cases, or formulæ, viz.

Triangulars	-	$\frac{n^2 + 3n + 2}{6}n$,
Squares	-	$\frac{2n^2 + 3n + 1}{6}n$,
Pentagonals	-	$\frac{3n^2 + 3n + 0}{6}$
Hexagonals	-	$\frac{4n^2 + 3n - 1}{6}n$,
&c.		&c.

The denomination of polygonals seems to have been given to this class of numbers, from the circumstance that they may be represented by the particular figures, the names of which they bear, and the *side of the figure* is the same as what we call the *root of the polygon*. Thus

Triangles	&c.
	
Squares	&c.
	

See some particular rules for arranging the points in a note subjoined to the English edition of Euler's Algebra.

POLYGONATUM, in *Botany*, supposed to be the *πολυγονάσιον* of Dioscorides, so called from *πολυ*, many, and *γονον*, a knice, or joint, because the root consists of many joints. This appellation has been bestowed on several species of the Linnæan genus *Convallaria*, which are otherwise called Solomon's Seal, in allusion to the scars, like the impressions of a seal, left where the stems of former seasons have stood. Linnæus retains *Polygonatum* for the specific name of the species with an angular stalk, Engl. Bot. t. 280; but Matthioli seems to understand *C. multiflora* as the *πολυγονάσιον* of Dioscorides. Both are found in Greece, and both were probably confounded by the ancient, as they seem to be by the modern, inhabitants of that country, under the name in question. We have always suspected that Linnæus, in his application of it, adverted to the many angles of the stem, understanding the word as derived from *γωνια*, an angle.

POLYGOŒÆ, Juss. 82. Brown Prodr. Nov. Holl. v. 1. 413, a natural order of plants, the 28th in Jussieu's system, or the fifth of his sixth class; for the characters of which class. see LAUREL. The order is thus defined.

Calyx of one leaf, divided. *Stamens* definite in number, inserted into the lower part of the calyx. *Germen* simple, superior; styles either several, or none at all; stigmas

several. *Seed* solitary, naked; or invested with the calyx, which then assumes the appearance of being superior. *Cork* immersed in a farinaceous albumen. *Leaves* alternate, sheathing at the base, or combined with an intrafoliateous membranous sheath (or *stipula*); revolute when young. *Stem* for the most part herbaceous.

The genera are *Coccoloba*, *Atraphaxis*, *Polygonum*, *Rumex*, *Rheum*, *Triplaris*, *Calligonum*, (from which *Pallasia* of Linn. Suppl. is now acknowledged, on all hands, not to differ,) and *Koenigia*. To these, which are all Linnæan, is to be added **ERIOGONUM**; see that article. Mr. Brown remarks, that in this last-named genus there is no sheath to the footstalk, and the albumen moreover is fleshy, as well as in very small quantity; but the erect seed with its superior radicle is esteemed by him as deciding the place of *Eriogonum*, those marks serving chiefly to distinguish the order of *Polygoneæ*, from such of the *Atriplices* of Jussieu, as constitute the *Cheupodeæ* of Decandolle.

POLYGONELLA, a diminutive of *Polygonum*, applied by Michaux, Fl. Boreal-Amer. v. 2. 240, to a supposed genus, which Ventenat very properly reduces to *Polygonum*, in his Jardin de Cels, t. 65, and which Mr. Pursh suspects to be not even specifically distinct from *P. articulatum* of Linnæus. See **POLYGONUM**.

POLYGONIFOLIA of Dillenius. See **CORRIGIOLA**.

POLYGONOIDES. See **CALLIGONUM**.

POLYGONOMETRY is an extension of the science of trigonometry, having the same reference to polygons in general, as trigonometry has to triangles in particular. We owe this extension of the rules of trigonometry to L'Huillier, who published a treatise on this subject at Geneva in 1789, which, with the exception of a short chapter in vol. iii. of Dr. Hutton's Course of Mathematics, is, we believe, the only work on polygonometry at present before the public; the reader, therefore, will not be displeased to find here a statement of some of the principal propositions of this new science; at the same time it will not be expected that we should enter at great length on the subject, but merely trace the analogy between the rules of trigonometry and those of polygonometry, and exhibit the demonstrations of two or three of the most remarkable cases.

In the common cases of trigonometry, a triangle is determined by means of two sides and an angle; or, which is the same, by its sides except one, and its angles except two. In like manner, in polygonometry a polygon may be determined when all its sides except one, and its angles except two, are given. A triangle also is determined by one side and two angles; that is, by its sides except two, and its angles except one. So likewise here any rectilinear figure is determinable when its sides except two, and its angles except one, are given. Again, a triangle is determinable when its three sides are given, that is, when all its sides are known, and its angles except three. So likewise in polygonometry, when all the sides of a polygon are given, and all its angles, except three, those three angles may be determined.

Note.—It is frequently necessary, in exhibiting the rules or formulæ of this science, to express the angles formed by two sides of the polygon, when those sides are not in contact in the diagram, by which is always to be understood the angle that they would form if produced till they meet; and this is indicated by a caret being put between two letters or pairs of letters denoting lines; thus, C B ^ F A denotes the inclination of the line C B to F A, or the angle that would be formed by the prolongment of those lines till they meet.

POLYGONOMETRY.

Theorem I.—In any polygon, any one side is equal to the sum of all the rectangles of each of the other sides, drawn into the cosine of the angle made by that side, and the side required to be found *Plate XI. Geometry, fig. 7.*

Let $A B C D E F$ be a polygon; then will

$$A F = \left\{ \begin{array}{l} A B \cdot \text{cof. } A + B C \cdot \text{cof. } C B^{\wedge} F A + C D \cdot \text{cof. } C D^{\wedge} A F \\ + D E \cdot \text{cof. } D E^{\wedge} A F + E F \cdot \text{cof. } E F^{\wedge} F A \end{array} \right.$$

For drawing lines from the several angles respectively parallel and perpendicular to $A F$, it will be

$$\begin{aligned} A b &= A B \cdot \text{cof. } B A F \\ b c &= B \beta = B C \cdot \text{cof. } C B \beta = B C \cdot \text{cof. } C B^{\wedge} A F \\ c d &= \delta D = C D \cdot \text{cof. } C D \delta = C D \cdot \text{cof. } C D^{\wedge} A F \\ d e &= \epsilon E = D E \cdot \text{cof. } D E \epsilon = D E \cdot \text{cof. } D E^{\wedge} A F \\ e F &= E F \cdot \text{cof. } E F e = E F \cdot \text{cof. } E F^{\wedge} A F \end{aligned}$$

$$\text{But } A F = b c + c d + d e + e F - A b$$

And $A b$, as expressed above, is in effect subtractive, because the cosine of the obtuse angle $B A F$ is negative, Consequently,

$$A F = \left\{ \begin{array}{l} A c + c d + d e + e F = \\ A B \cdot \text{cof. } B A F + B C \cdot \text{cof. } C B^{\wedge} A F + \&c. \end{array} \right.$$

which was to be demonstrated. And a like demonstration will apply to any other polygon. When the sides are reduced to three, this theorem becomes the same as the fundamental theorem for triangles.

Theorem II.—The perpendicular let fall from the highest point or summit of a polygon upon the opposite side or base, is equal to the sum of the products of the sides comprised between that summit and the base, into the sines of their respective inclinations to that base.

Thus, referring still to the same figure,

$$\begin{aligned} C c &= C B \cdot \text{fin. } C B^{\wedge} F A + B A \cdot \text{fin. } A, \text{ or} \\ C c &= \left\{ \begin{array}{l} C D \cdot \text{fin. } C D^{\wedge} A F + D E \cdot \text{fin. } D E^{\wedge} A F \\ + E F \cdot \text{fin. } F \end{array} \right. \end{aligned}$$

as is evident from an inspection of the figure.

In like manner,

$$\begin{aligned} D d &= D E \cdot \text{fin. } D E^{\wedge} A F + E F \cdot \text{fin. } F, \text{ or} \\ D d &= \left\{ \begin{array}{l} C B \cdot \text{fin. } C B^{\wedge} F A + B A \cdot \text{fin. } A \\ - C D \cdot \text{fin. } C D^{\wedge} A F \end{array} \right. \end{aligned}$$

Hence the sum of the products of each side, into the sine of the sum of the *exterior* angles (or into the sine of the sum of supplements of the interior angles) comprised between those sides and a determined side, is equal to zero; that is, in the preceding figure

$$\begin{aligned} &A B \cdot \text{fin. } A + B C \cdot \text{fin. } (A + B) + C D \cdot \text{fin. } (A + B + C) + \\ &D E \cdot \text{fin. } (A + B + C + D) + E F \cdot \text{fin. } (A + B + C + D + E) = 0 \end{aligned}$$

Hence, also, by substituting in this expression, for $\text{fin. } (A + B)$ $\text{fin. } (A + B + C)$, &c. their proper values; *viz.*

$$\begin{aligned} \text{fin. } (A + B) &= \text{fin. } A \cdot \text{cof. } B + \text{fin. } B \cdot \text{fin. } \text{cof. } A \\ \text{fin. } (A + B + C) &= \text{fin. } A \cdot \text{cof. } (B + C) + \text{fin. } (B + C) \cdot \text{cof. } A \\ \&c. & \qquad \qquad \&c. \qquad \qquad \&c. \end{aligned}$$

And recollecting also that $\tan. a = \frac{\text{fin. } a}{\text{cof. } a}$, we shall have

$$\tan. B A F = \frac{B C \cdot \text{fin. } B + C D \cdot \text{fin. } (B + C) + D E \cdot \text{fin. } (B + C + D) + \&c.}{A B + B C \cdot \text{cof. } B + C D \cdot \text{cof. } (B + C) + D E \cdot \text{cof. } (B + C + D) + \&c.}$$

which is frequently an useful formula when the number of sides exceed four.

When the number of sides is three, or when the figure becomes a triangle, we have

$$\begin{aligned} \tan. C A B &= \frac{B C \cdot \text{fin. } B}{A B + B C \cdot \text{cof. } B} \\ \tan. B C A &= \frac{A B \cdot \text{fin. } B}{B C + A B \cdot \text{cof. } B} \end{aligned}$$

Theorem III.—The square of any side of a polygon is equal to the square of the sum of all the other sides; *minus* twice the sum of the products of all the other sides multiplied two and two, by the cosines of the angles they include. *Fig. 8.*

$$a^2 = b^2 + c^2 + d^2 - 2 (b c \cdot \text{cof. } b^{\wedge} c + b d \cdot \text{cof. } b^{\wedge} d + c d \cdot \text{cof. } c^{\wedge} d)$$

And in like manner:

$$c^2 = a^2 + b^2 + d^2 - 2 (a b \cdot \text{cof. } a^{\wedge} b + a d \cdot \text{cof. } a^{\wedge} d + b d \cdot \text{cof. } b^{\wedge} d)$$

For the sake of brevity, let the sides be represented by the small letters which stand against them in the figure; then from *Theorem I.* we shall have the following equations, *viz.*

$$\begin{aligned} a &= b \cdot \text{cof. } a^{\wedge} b + c \cdot \text{cof. } a^{\wedge} c + d \cdot \text{cof. } a^{\wedge} d \\ b &= a \cdot \text{cof. } a^{\wedge} b + c \cdot \text{cof. } b^{\wedge} c + d \cdot \text{cof. } b^{\wedge} d \\ c &= a \cdot \text{cof. } a^{\wedge} c + b \cdot \text{cof. } b^{\wedge} c + d \cdot \text{cof. } c^{\wedge} d \\ d &= a \cdot \text{cof. } a^{\wedge} d + b \cdot \text{cof. } b^{\wedge} d + c \cdot \text{cof. } c^{\wedge} d \end{aligned}$$

Multiplying the first of these equations by a , and the second by b , the third by c , and the fourth by d , subtracting the three latter products from the first, and transposing b^2 , c^2 , d^2 , there will result

Or,

POLYGONOMETRY.

Or, since $b^{\wedge}c = C$, $b^{\wedge}d = C + D - 180$, $c^{\wedge}d = D$, we have

$$\begin{aligned} a^2 &= b^2 + c^2 + d^2 - 2 (bc \cdot \text{cof. } C - b^{\wedge}d \cdot \text{cof. } (C + D) + c^{\wedge}d \cdot \text{cof. } D) \\ c^2 &= a^2 + b^2 + d^2 - 2 (ab \cdot \text{cof. } B - b^{\wedge}d \cdot \text{cof. } (A + B) + a^{\wedge}d \cdot \text{cof. } A) \\ &\quad \text{\&c.} \quad \quad \quad \text{\&c.} \quad \quad \quad \text{\&c.} \end{aligned}$$

The same process applied to the pentagon $A B C D E$, will give

$$a^2 = b^2 + c^2 + d^2 + e^2 - 2 \left\{ \begin{array}{l} bc \cdot \text{cof. } C - bd \cdot \text{cof. } (C + D) \\ + be \cdot \text{cof. } (C + D + E) + cd \cdot \text{cof. } D \\ - ce \cdot \text{cof. } (D + E) + de \cdot \text{cof. } E \end{array} \right.$$

And a similar demonstration is obvious, applicable to a polygon of any number of sides; whence the truth of the proposition is manifest.

Theorem IV.—Twice the surface of any polygon is equal to the sum of the rectangles of its sides, except one taken two and two, by the sines of the sum of the exterior angles contained by those sides. *Fig. 9.*

For a trapezium, or polygon of four sides. Let the two sides, AB , DC , be produced till they meet at P ; then the trapezium $ABCD$ is manifestly equal to the difference between the triangles PAD and PBC . But twice the surface of the triangle PAD is $= AP \cdot PD \cdot \text{fin. } P = (AB + BP) \cdot (DC + CP) \cdot \text{fin. } P$; and twice the sur-

face of the triangle $PBC = BP \cdot PC \cdot \text{fin. } P$: therefore their difference, or twice the area of the trapezium $= (AB \cdot CD + AB \cdot CP + CD \cdot BP) \cdot \text{fin. } P$. Now in the triangle PBC ,

$$\text{fin. } P : \text{fin. } B :: BC : PC = \frac{BC \cdot \text{fin. } B}{\text{fin. } P}$$

$$\text{fin. } P : \text{fin. } C :: BC : PB = \frac{BC \cdot \text{fin. } C}{\text{fin. } P}$$

Substituting these values of PB , PC , for them in the above equation, and observing that $\text{fin. } P = \text{fin. } (PEC + PCB) = \text{fin. of the sum of exterior angles } B \text{ and } C$, there results,

$$\text{Twice the surface of } ABCD = \left\{ \begin{array}{l} AB \cdot BC \cdot \text{fin. } B \\ + AB \cdot DC \cdot \text{fin. } (B + C) \\ + BC \cdot DC \cdot \text{fin. } C \end{array} \right.$$

Since $AB \cdot BC \cdot \text{fin. } B =$ twice the area of the triangle ABC , it follows that twice the triangle ACD is equal to the remaining two terms, *viz.*

$$\text{Twice area } ACD = \left\{ \begin{array}{l} AB \cdot DC \cdot \text{fin. } (B + C) \\ + BC \cdot DC \cdot \text{fin. } C \end{array} \right.$$

For a pentagon, as $ABCDE$, see *fig. 10.* Its area is obviously equal to the sum of the areas of the trapezium $ABCD$, and of the triangle ADE .

Let the sides AB and DC , as before, meet when produced at P ; then from the above we have,

$$\text{Twice area } ABCD = \left\{ \begin{array}{l} AB \cdot BC \cdot \text{fin. } B \\ + AB \cdot DC \cdot \text{fin. } (B + C) \\ + BC \cdot DC \cdot \text{fin. } C \end{array} \right.$$

Also,

$$\text{Twice triangle } DAE = \left\{ \begin{array}{l} AP \cdot DE \cdot \text{fin. } (P + D), \text{ or fin. } (B + C + D) \\ + DP \cdot DE \cdot \text{fin. } D \end{array} \right.$$

Therefore,

$$\text{Twice area } ABCDE = \left\{ \begin{array}{l} AB \cdot BC \cdot \text{fin. } B \\ + AB \cdot DC \cdot \text{fin. } (B + C) \\ + AB \cdot DE \cdot \text{fin. } (B + C + D) \\ + BC \cdot DC \cdot \text{fin. } C \\ + BC \cdot DE \cdot \text{fin. } (C + D) \\ + DC \cdot DE \cdot \text{fin. } D \end{array} \right.$$

Taking away from this expression the first, second, and fourth terms, which together make double the trapezium $ABCD$, there will remain,

$$\text{Twice the area of } DAE = \left\{ \begin{array}{l} AB \cdot DE \cdot \text{fin. } (B + C + D) \\ + BC \cdot DE \cdot \text{fin. } (C + D) \\ + DC \cdot DE \cdot \text{fin. } D \end{array} \right.$$

For the hexagon $ABCDEF$, see *fig. 11.*

The double area will be found by supposing it divided into the pentagon $ABCDE$, and the triangle AEF . For by the preceding part of the proposition we have,

$$\begin{aligned} \text{Twice area of } ABCDE &= \left\{ \begin{array}{l} AB \cdot BC \cdot \text{fin. } B \\ + AB \cdot CD \cdot \text{fin. } (B + C) \\ + AB \cdot DE \cdot \text{fin. } (B + C + D) \\ + BC \cdot CD \cdot \text{fin. } C \\ + BC \cdot DE \cdot \text{fin. } (C + D) \\ + CD \cdot DE \cdot \text{fin. } D \end{array} \right. \\ \text{Twice area of } AEF &= \left\{ \begin{array}{l} AP \cdot EF \cdot \text{fin. } (B + C + D + E) \\ + DP \cdot EF \cdot \text{fin. } (D + E) \\ + DE \cdot EF \cdot \text{fin. } E \end{array} \right. \end{aligned}$$

Or

POLYGONOMETRY.

$$\text{Or twice area of AEF} = \begin{cases} AB \cdot EF \cdot \text{fin. } (B + C + D + E) \\ + DC \cdot EF \cdot \text{fin. } (D + E) \\ + DE \cdot EF \cdot \text{fin. } E \\ + BP \cdot EF \cdot \text{fin. } (B + C + D + E) \\ + CP \cdot EF \cdot \text{fin. } (D + E) \end{cases}$$

Now writing for BP, CP, their respective values, $\frac{BC \cdot \text{fin. } C}{\text{fin. } (B + C)}$, and $\frac{BC \cdot \text{fin. } B}{\text{fin. } (B + C)}$, the sum of the last two expressions in the double areas of AEF will become

$$BC \cdot EF \cdot \frac{\text{fin. } C \cdot \text{fin. } (B + C + D + E) + \text{fin. } B \cdot \text{fin. } (D + E)}{\text{fin. } (B + C)}$$

And this, by means of the analytical expression for five arcs, becomes

$$BC \cdot EF \cdot \text{fin. } (C + D + E).$$

Whence collecting and properly arranging the term as before, we shall obtain,

$$\text{Twice the area ABCDEF} = \begin{cases} AB \cdot BC \cdot \text{fin. } B \\ + AB \cdot CD \cdot \text{fin. } (B + C) \\ + AB \cdot DE \cdot \text{fin. } (B + C + D) \\ + AB \cdot EF \cdot \text{fin. } (B + C + D + E) \\ + BC \cdot CD \cdot \text{fin. } C \\ + BC \cdot DE \cdot \text{fin. } (C + D) \\ + BC \cdot EF \cdot \text{fin. } (C + D + E) \\ + CD \cdot DE \cdot \text{fin. } D \\ + CD \cdot EF \cdot \text{fin. } (D + E) \\ + DE \cdot EF \cdot \text{fin. } E \end{cases}$$

In a similar manner may the area of a heptagon be determined, by finding the sum of the area of the hexagon, and the adjacent triangle; and hence the area of the octagon, nonagon, or any other polygon, may be inferred; the law of continuation being sufficiently obvious from what is done

above, and the number of terms = $\frac{n-1}{1} \times \frac{n-2}{2}$, the number of sides of the polygon being n : for the number of terms is evidently the same as the number of ways in which $n-1$ quantities can be taken two and two, that is, by the nature of permutation = $\frac{n-1}{1} \times \frac{n-2}{2}$.

The above curious theorem was first investigated by Simon L'Huilier, and published by him in 1789. Its principal advantage over the common method for finding the area of irregular polygons is, that here there is no occasion to construct the figures, and of course the errors that may arise from such constructions are avoided.

In the application of this theorem to practical purposes, the above expressions become more simple by dividing the proposed polygon into two parts by a diagonal, and computing the area of each part separately.

Thus by dividing the trapezium ABCD (*fig. 8.*) into two triangles by the diagonal AC, we shall have,

$$\text{Twice area ABCD} = \begin{cases} AB \cdot BC \cdot \text{fin. } B \\ + CD \cdot AD \cdot \text{fin. } D \end{cases}$$

The pentagon ABCDE (*fig. 9.*) may be divided into a trapezium and triangle; whence,

$$\text{Twice area of ABCDE} = \begin{cases} AB \cdot BC \cdot \text{fin. } B \\ + AB \cdot DC \cdot \text{fin. } (B + C) \\ + BC \cdot DC \cdot \text{fin. } C \\ + DE \cdot AE \cdot \text{fin. } E \end{cases}$$

And in the same manner, by dividing the hexagon into two trapeziums, by a diagonal drawn from A to D, which is to be the line excepted in the theorem, we shall have,

$$\text{Twice area of ABCDEF} = \begin{cases} AB \cdot BC \cdot \text{fin. } B \\ + AB \cdot DC \cdot \text{fin. } (B + C) \\ + BC \cdot DC \cdot \text{fin. } C \\ + DE \cdot EF \cdot \text{fin. } E \\ + DE \cdot AF \cdot \text{fin. } (E + F) \\ + EF \cdot AF \cdot \text{fin. } F \end{cases}$$

For more on this subject, see L'Huilier's Treatise on Polygonometry, and chap. 6. vol. iii. of Dr. Hutton's Course of Mathematics.

POLYGONUM, in Botany, a name adopted from Dioscorides, whose πολυγωνον ἀρρην, or male polygonum, seems, without doubt, our *P. aviculare*, or Common Knot-grass. The numerous knots or joints of the stem and branches, readily explain the word; see also POLYGONATUM. Linn. Gen. 195. Schreb. 264. Willd. Sp. Pl. v. 2. 440. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 423. Prodr. Fl.

Græc. Sibth. v. 1. 264. Brown Prodr. Nov. Holl. v. 1. 419. Pursh 269. Ait. Hort. Kew. v. 2. 416. Juss. 82. Tourn. t. 290. Lamarck Illustr. t. 315. Gært. t. 119. (Bistorta; Tourn. t. 291. Perficaria; Tourn. t. 290. Gært. t. 119. Fagopyrum; Tourn. t. 290. Gært. t. 119. Helxine; Linn. Gen. ed. 1—5.)—Class and order, *Oxandria Trigynia*. Nat. Ord. *Holeraceæ*, Linn. *Polygonææ*. Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, turbinate, internally coloured, in five deep, ovate, obtuse, permanent segments.

POLYGONUM.

segments. *Cor.* none, unless the calyx be taken for such. *Stam.* Filaments generally eight, awl-shaped, very short; anthers roundish, incumbent. *Pist.* Germen superior, triangular; styles mostly three, thread-shaped, very short; stigmas simple. *Peric.* none, the calyx folding over the seed. *Seed* one, acute, with three, rarely only two, angles.

Obf. The stamens are in some species but seven, six, or five; the styles in some are only two, and these are often combined in their lower part. *P. frutescens* has three large segments to the calyx, with two smaller ones. Reichard is pleased to call the former *petals*; see his *Gen. Pl.* 200. Linnæus himself in *Syst. Veg.* terms the whole calyx a corolla, certainly contrary to all analogy, especially of the natural order where he properly places this genus; he is of course copied by Willdenow.

Eff. Ch. Calyx in five deep segments, coloured, petal-like, permanent. Seed one, superior, angular, covered by the calyx. Stamens and styles uncertain in number.

Thirty-one species of *Polygonum* are defined in the 14th edition of *Syst. Veg.* Willdenow has forty-three. Mr. Brown has twelve or thirteen new ones in his *Prodromus* of New Holland plants; and several additional American species are recorded by Michaux and Pursh. Twenty-three are mentioned in *Hort. Kew.* We shall, according to our usual custom, particularize the British species, which amount to ten, introducing along with them some of the most remarkable exotics.

The whole are disposed in five sections, chiefly named in allusion to the genera into which authors, antecedent to Linnæus, had divided his *Polygonum*.

SECT. 1. Atraphaxoides. Stem shrubby. Two species.

P. frutescens. Shrubby Polygonum. Linn. Sp. Pl. 516. Willd. n. 1. Ait. n. 1. (*P. fruticosum*, &c. n. 46; Gmel. Sib. v. 3. 60. t. 12. f. 2.)—Stem shrubby. Two outer segments of the calyx smallest, reflexed.—Native of Siberia; introduced into Kew garden by M. Richard, in 1770, flowering in July and August. The stem is shrubby, with smooth, whitish, leafy branches. Leaves alternate, about an inch long, lanceolate, somewhat spatulate, acute, entire, naked, smoothish, tapering at the base. Stipula membranous, torn, investing the branch within the insertion of each leaf, and reaching about half way to the next. Flowers numerous, in terminal clusters, with sheathing membranous bracteas; each flower on a capillary single-jointed stalk. Calyx small when in flower, white or reddish, with a broad green keel to the two smaller external segments: as the seed advances, these become reflexed, and somewhat enlarged; but the three inner, more petal-like divisions, are by degrees greatly dilated, and reticulated with strong veins; embracing the seed, as in *Rumex*. Some contend that Gmelin's n. 45. t. 12. f. 1, is but a spinescent variety.

SECT. 2. Bistortæ. Spike solitary. Two species.

P. Bistorta. Great Bistort; or Snakeweed. Linn. Sp. Pl. 516. Willd. n. 3. Ait. n. 2. Fl. Brit. n. 6. Curt. Lond. fasc. 1. t. 22. Engl. Bot. t. 509. Woodv. Med. Bot. t. 34. (Bistorta; Matth. Valgr. v. 2. 296. Camer. Epit. 683. B. major; Ger. Em. 399.)—Stem quite simple. Spike solitary. Leaves ovate, waved, running down into the footstalks.—Frequent in rather hilly pastures, in Germany, Switzerland, France, and the northern parts of England, flowering in June. The thick, woody, twisted root is perennial, and of an astringent quality. Stems about a foot and half high, each with one erect, cylindrical, thickish, obtuse spike, or dense cluster, of not inelegant rose-coloured flowers, destitute of scent. Stamens eight.

Styles three. The leaves are three or four inches long and above one broad, veiny, entire, glaucous beneath; the radical ones on long stalks, and most numerous.

P. viviparum. Alpine Bistort. Linn. Sp. Pl. 516. Willd. n. 4. Ait. n. 3. Fl. Brit. n. 7. Engl. Bot. t. 669. Fl. Dan. t. 13. (Bistorta minor; Camer. Epit. 684. Ger. Em. 399.)—Stem quite simple. Spike solitary. Leaves lanceolate, revolute.—Native of alpine pastures, in Lapland, Germany, Switzerland, and Britain. It grows in dry stony places, and is not uncommon about the sides and summits of the Scottish mountains, as well as in Westmoreland and the north of Yorkshire, flowering in June and July. This species is allied to the last, but seldom one third its size, with narrower, scarcely decurrent, leaves, whose revolute edges are, as it were, stiched with veins, and partly ferrated. The spike is more slender and elongated, its lower flowers viviparous, or rather their place is supplied by leafy buds. The seeds of the rest are rarely perfected. The number of stamens and styles is like that of the preceding.

SECT. 3. Perficariæ. Styles two, distinct or combined. Stamens generally fewer than eight. Fifteen species in Willdenow; nine new ones in Brown.

P. lapathifolium. Pale-flowered Perficaria. Linn. Sp. Pl. 517. Willd. n. 6. Ait. n. 5. Fl. Brit. n. 3. Engl. Bot. t. 1382. (*P. pensylvanicum*; Curt. Lond. t. 24, 25. Hydropiper; Ger. Em. 445.)—Stamens six. Styles two. Flower-stalks rough. Stipulas beardless. Seeds concave on each side.—Found on dunghills, and about rich moist places, in France and England, flowering in July and August. Not unfrequent in the neighbourhood of Paris and London. This is an annual, bushy, leafy herb, with swollen, jointed stems. Leaves alternate, stalked, lanceolate, entire; sometimes marked with a blackish spot, and occasionally hoary beneath. Stipulas lax, ribbed, almost always destitute of marginal bristles. Flower-stalks clothed with a glandular roughness, characteristic of the species. Flowers in dense copious spikes, mostly of a pale greenish-white; but sometimes red, as well as the stems. Mr. Curtis, whose observations on the various species of *Polygonum* have, more than those of any other botanist, served to place them in a clear light, erred like Hudson in taking this for the Linnæan *pensylvanicum*; which has likewise rough flower-stalks, but its stamens are eight, spikes lax, and leaves long and taper-pointed.

P. amphibium. Amphibious Perficaria. Linn. Sp. Pl. 517. Willd. n. 7. Ait. n. 6. Fl. Brit. n. 1. Curt. Lond. fasc. 4. t. 28. Engl. Bot. t. 436. Fl. Dan. t. 282. (Potamogeton angustifolium; Ger. Em. 821.)—Stamens five. Styles two, combined. Spike ovate.—Frequent in Europe, floating on the surface of still waters, which are ornamented with its beautiful crimson upright spikes in July and August. The roots are perennial and creeping. Stems throwing out copious radicles, by which they often creep over the mud about the borders of ponds, as well as float on the water. Stipulas entire. Leaves stalked, lanceolate, acute, finely ferrated, smooth, bright green, mostly floating.

P. Hydropiper. Biting Perficaria. Linn. Sp. Pl. 517. Willd. n. 9. Ait. n. 8. Fl. Brit. n. 4. Curt. Lond. fasc. 1. t. 26. Engl. Bot. t. 989. (Hydropiper; Fuchf. Hist. 842. t. 843.)—Stamens six. Styles two, combined at the bottom. Leaves lanceolate, waved. Spikes slender, drooping. Stem erect.—Common in ditches, and watery places, throughout Europe, flowering in August and September. This species is annual, and readily known by its pale unspotted leaves, and lax, slender, drooping spikes, of red

POLYGONUM.

red and white inconspicuous *flowers*. The *stamens*, usually six, very rarely vary to eight. *Styles* combined about half their length. Herb with a very hot acrid taste, owing to an essential oil, dispersed in glandular dots over the surface, and for the most part conspicuous on the *calyx*. Hence the name of *Hydropiper*, Water-pepper.

P. minus. Small Creeping Perficaria. Hudf. ed. 1. 148. Willd. n. 12. Ait. n. 10. Fl. Brit. n. 5. Curt. Lond. fasc. 1. t. 28. Engl. Bot. t. 1043. (Perficaria pusilla repens; Ger. Em. 446.)—Stamens six. Styles two, combined nearly to the top. Leaves linear lanceolate, flat. Spikes slender, almost erect. Stem creeping at the base.—Native of gravelly inundated spots, in various parts of Europe, flowering in autumn. Smaller and more creeping than the last, though likewise annual. Much ambiguity has formerly existed concerning this species, which Linnæus thought a variety of his *P. Perficaria*, and some others have referred to *Hydropiper*; but the want of glandular dots, and especially the close union of the *styles*, are sufficient to distinguish it, which marks were pointed out by Mr. Curtis. Sometimes there are three *stigmas*.

P. Perficaria. Spotted Perficaria. Linn. Sp. Pl. 518. Willd. n. 13. Ait. n. 11. Fl. Brit. n. 2. Curt. Lond. fasc. 1. t. 23. Engl. Bot. t. 756. Fl. Dan. t. 702. (Perficaria maculosa; Ger. Em. 445.)—Stamens six. Styles two, combined below. Spikes ovate-oblong, erect. Flower-stalks smooth. Stipulas fringed.—Extremely common in ditches, marshes, waste ground, and inundated fields, flowering principally in July and August. It is annual, but larger and more erect than the last, the *stem* scarcely creeping at the base. Each *leaf* is usually marked with a central, black, horse-shoe, or kidney-shaped, spot; the under side dotted with glands, and sometimes white and downy. The latter variety is Willdenow's *P. incanum*, n. 14, separated by him and some others, we presume improperly, from *Perficaria*. Its figure may be seen in Petiver's Herb. Brit. t. 3. f. 8; and another more slender, and more silvery, variety, at f. 9. The *spikes* of the species before us are short and rather thick, on smooth stalks. *Flowers* rose-coloured, with two, rarely three, *styles*, combined half way up.

P. orientale. Great Garden Perficaria. Linn. Sp. Pl. 519. Willd. n. 18. Ait. n. 12. Curt. Mag. t. 213. (Perficaria orientalis, nicotianæ folio, calyce florum purpureo; Tourn. Cor. 38.)—Stamens seven. Styles two, distinct. Leaves ovate, dependent. Stipulas hairy, salver-shaped. Stem erect, paniced. Spikes pendulous.—Native of the East. Tournefort obtained its seeds from the gardens of some convents in his journey, and it has ever since been a favourite and hardy annual in the European collections, and indeed in almost every cottage garden in England and France, sowing itself spontaneously, and blooming throughout the autumn. The *stem* is round, five or six feet high. *Leaves* large, downy, and flaccid. *Flower-stalks* paniced, hairy, laden with thick, obtuse, cylindrical, drooping *spikes*, of beautiful crimson, but inodorous, *flowers*. There is a white variety.

SECT. 4. Polygonæ. *Leaves undivided. Stamens eight.* Eleven species in Willdenow; two new ones in Brown.

P. maritimum. Sea Knot-grass. Linn. Sp. Pl. 519. Willd. n. 20. Sm. Prodr. Fl. Græc. Sibth. v. 1. 266. Fl. Græc. t. 363, unpublished. (*P. maritimum*; Camer. Epit. 691. Bauh. Hist. v. 3. 377, copied in Petiver's Herb. Brit. t. 10. f. 5.)—*Flowers* axillary. Styles three. Leaves elliptical. Ribs of the stipulas numerous, crowded. Stem shrubby, procumbent.—Native of the sandy sea-shores of the Mediterranean and Archipelago. *Stem* procumbent, a

foot long, much branched and somewhat woody, perennial. *Leaves* elliptical, stalked, glaucous, about an inch long. *Stipulas* long and membranous, with numerous close nerves. *Flowers* axillary, two or three together, flesh-coloured, or simple stalks. The whole plant is larger than the following, and essentially distinguished by the crowded ribs of its *stipulas*; to say nothing of its perennial woody habit, and broad glaucous *leaves*, whose edges are smooth, or very nearly so.

P. aviculare. Common Knot-grass. Linn. Sp. Pl. 519. Willd. n. 21. Ait. n. 13. Fl. Brit. n. 8. Engl. Bot. t. 1252. Curt. Lond. fasc. 1. t. 27. Mart. Ruft. t. 91. (*P. mas vulgare*; Ger. Em. 565.)—*Flowers* axillary. Styles three. Leaves elliptic-lanceolate, rough-edged. Ribs of the stipulas remote. Stem procumbent, herbaceous.—A common weed in every part of Europe, growing amongst rubbish, in towns, path-ways, &c. It is smaller than the last, though very variable in size, and of only annual duration. The crimson *flowers* are beautiful under a magnifier, and very copiously produced. One of Ray's very few errors consisted in mistaking a large maritime variety of this species, found on the coast of Cornwall, for the true *P. maritimum* above described.

P. equisetiforme. Horse-tail Knot-grass. Sibth. in Prodr. Fl. Græc. v. 1. 266. Fl. Græc. unpubl. t. 364.—*Flowers* axillary. Styles two, distinct.—Leaves oblong, revolute. Stipulas many-ribbed, in numerous capillary segments. Stem shrubby, ascending.—Found by Dr. Sibthorp, in hedges in Crete. Its shrubby *stem* agrees with *P. maritimum*, but its greater height and more erect mode of growth, as well as the narrower revolute *leaves*, distinguish it. The *styles* being only two afford a clear mark of difference, between *P. equisetiforme*, and both *maritimum* and *aviculare*. The *flowers* are variegated with green and white. *P. setosum*, Jacq. Obs. fasc. 3. 8. t. 57. Willd. n. 23, bears a considerable resemblance to our plant, but its *styles* are said to be three, and the *leaves* linear awl-shaped, which description by no means accords with *P. equisetiforme*.

P. divaricatum. Spreading White Knot-grass. Linn. Sp. Pl. 520. Willd. n. 26. Ait. n. 16. (*P. n. 42*; Gmel. Sib. v. 3. 57. t. 11. f. 1. Fagopyrum orientale, ramosum et multiflorum, perficariæ folio; Tourn. Cor. 39. Buxb. Cent. 2. 31. t. 31.) *Stem* much branched, smooth, spreading. Clusters lax. Leaves lanceolate, smooth. Stamens eight. Styles three.—Native of Siberia, as well as of Armenia, in the corn-fields of which last country Buxbaum says it is a troublesome weed. Miller seems to have introduced this plant into Chelsea garden, where it still abounds, making a very handsome appearance in June and July, with copious clusters of large white *flowers*. We have not seen it elsewhere, though it certainly merits general notice. The *root* is creeping, perennial, hardy, yellow. *Stems* three or four feet high, round, reedy, leafy, with abundance of wide-spreading smooth *branches*. *Leaves* clustered, lanceolate, acute, smooth, two or three inches long, on stalks of various lengths. *Clusters* lax, spreading. *Flowers* large, uniformly white.

Section 5. Helxine of Linnæus formerly. *Leaves dilated, and somewhat heart-shaped.* Thirteen species.

P. Fagopyrum. Common Buck-wheat. Linn. Sp. Pl. 522. Willd. n. 39. Ait. n. 21. Fl. Brit. n. 9. Mart. Ruft. t. 46. Engl. Bot. t. 1044. (Tragopyron; Ger. Em. 89.)—Leaves heart-arrow-shaped. Stem nearly upright, without prickles. Angles of the seeds even.—Native of the East, though now naturalized in England, Germany, &c., flowering in July and August. It is often cultivated for the sake of the seeds, an excellent food for pheasants, as

well as for domestic fowls. The *root* is annual, fibrous. *Herb* rather succulent, a foot or two high; with a zig-zag, round, branched, leafy *stem*, smooth, except a downy line along one side. *Leaves* acute, entire, smooth; the uppermost sessile. *Flowers* handsome, copious, red and white, in panicled *clusters*. Five of the eight *stamens* seem more perfect than the rest, and bear anthers whose lobes are separated by a short bar. *Styles* three, quite distinct. Edges of the *seed* even and straight, not lobed nor undulated as in some of the foreign species of this section.

P. Convolvulus. Climbing Buck-wheat. Black Bind-weed. Linn. Sp. Pl. 522. Willd. n. 40. Ait. n. 22. Fl. Brit. n. 10. Curt. Lond. fasc. 4. t. 29. Fl. Dan. t. 744. Engl. Bot. t. 941. (*Volubilis nigra*; Ger. Em. 863.)—Leaves heart-arrow-shaped. Stem twining, angular. Segments of the calyx bluntly keeled.—A frequent and troublesome weed in cornfields throughout Europe, flowering in June and July. The *root* is annual. The *stem* twines about corn and other plants, to the height of three feet or more, and is angular, roughish, somewhat branched. *Leaves* pale green, smooth, acute, entire, all stalked. *Clusters* axillary and terminal, interrupted with small leaves. *Flowers* drooping, variegated with green and white, often purplish. *Stamens* six or eight, uniform. *Styles* three, combined below; rarely only two. *Seeds* smaller than the last; their angles even, and sides concave. Small birds are fond of these seeds.

P. dumetorum. Bush Buck-wheat. Linn. Sp. Pl. 522. Willd. n. 41. Prodr. Fl. Græc. n. 411. Fl. Dan. t. 756.—Leaves heart-shaped, pointed. Stem twining, angular, smooth. Segments of the calyx winged at the keel.—Native of shady bushy places, chiefly in the south of Europe; unknown in England, even in our gardens. It is annual, larger than the preceding, with elongated leafy *clusters*. The *flowers* are readily distinguished by the dilated keels of the three large segments of the *calyx*, enclosing the triangular even-edged seed.

POLYGONUM, in *Gardening*, contains a plant of the herbaceous annual kind, of which the species cultivated is the oriental perficaria (*P. orientale*).

Of this there is a dwarf variety, and another with white flowers.

Method of Culture.—This plant is constantly raised from seeds, and is said to rise from scattered seeds better than when sown; but where they are sown, it should be in autumn, soon after they are ripe, as, when sown in the spring, they rarely succeed; or, if some plants come up, they seldom grow so strong. They may be removed in the spring into the borders of the plantation or flower-garden, giving them room. They are, however, commonly sown in the spring, with other annuals; thinning the seedlings, when they appear, so as to stand a foot apart. About the beginning of July, the side-shoots should be pruned off, to make them advance in height, and preserve them within compass; and when they are pruned up to five or six feet, they may be permitted to shoot out side branches. It delights in a rich moist soil. The seeds are sometimes sown on hot-beds, in March, in order to be more forward.

These plants are distinguished for their superior stature, and the brilliancy of their flowers: they frequently grow to the height of eight or ten feet, and rival the sun-flower.

POLYGRAM, in *Geometry*, a figure consisting of many lines.

POLYGRAPHY, POLYGRAPHIA, or *Polygraphice*, formed from *πολυ*, *multum*, and *γραφειν*, *scriptura*, *writing*, the art of writing in various unusual manners or cyphers; as also the art of decyphering the same.

The word is usually confounded with steganography, and cryptography.

The ancients seem to have been very little acquainted with this art; nor is there any mark of their having gone beyond the Lacedæmonian Scytala.

Trithemius, Porta, Vigenera, and father Niceron, have written on the subject of polygraphy, or *cyphers*; which see.

POLYGYNIA, in *Botany*, from *πολυς*, *many*, and *γυνή*, *a female*, the appellation of an order in several classes of the Linnæan system. The name expresses its character, which consists in a multitude of pistils. This order occurs in the 5th and 6th classes, as well as in the 12th and 13th; to the two latter of which it most naturally belongs, as the flowers of these classes have likewise numerous stamens.

POLYHEDRON, or POLYEDRON, *Πολυεδρον*, formed from *πολυ*, *much*, and *εδρα*, *seat*, in *Geometry*, a body comprehended under many rectilinear sides or planes.

If the sides of the polyhedron be regular polygons, all similar and equal, the polyhedron becomes a regular body, and may be inscribed in a sphere; that is, a sphere may be drawn round it, so that its surface shall touch all the solid angles of the body.

POLYHEDRON, *Gnomonic*, is a stone with several faces, on which are projected various kinds of dials. See DIAL.

Of this kind, that in the privy-garden, London, now gone to ruin, was anciently the finest in the world.

POLYHEDRON, or *Polyscope*, in *Optics*, is a glass, or lens, consisting of several plain surfaces, disposed into a convex form; popularly called a *multiplying-glass*.

The phenomena of the polyhedron are as follow: 1. If several rays, as E F, A B, C D, (*Plate XVII. Optics, fig. 12.*) fall parallel on the surface of a polyhedron, they will continue parallel after refraction.

If then the polyhedron be supposed regular, L H, H I, I M, will be as tangents, cutting the spherical convex lens in F, B, and D; consequently, rays falling on the points of contact, intersect the axis. Wherefore, since the rest are parallel to these, they will also mutually intersect each other in G.

Hence, if the eye be placed where parallel rays decussate, rays of the same object will be propagated to it still parallel from the several sides of the glass. Wherefore, since the crystalline humour, by its convexity, unites parallel rays, the rays will be united in as many different parts of the retina, *a, b, c*, as the glass has sides.

Consequently the eye, through a polyhedron, sees the object repeated as many times as there are sides. And hence, since rays coming from remote objects are parallel, a remote object is seen as often repeated through a polyhedron, as that has sides.

2. If rays A B, A C, A D (*fig. 13.*), proceeding from a radiant point A, fall on several sides of a regular polyhedron; after refraction they will decussate in G, and proceed on a little diverging.

Hence, if the eye be placed where the rays coming from the several planes decussate, the rays will be propagated to it from the several planes a little diverging: *i. e.* as if they proceeded from different points. But since the crystalline humour, by its convexity, collects rays from several points in the same point; the rays will be united in as many different points in the retina, *a b c*, as the glass has sides; consequently, the eye, being placed in the focus G, will see even a near object repeated as often through the polyhedron as that has sides.

Thus may the images of objects be multiplied in a camera obscura, by placing a polyhedron at its aperture, and

adding a convex lens at a due distance from it. And it makes a very pleasant appearance, if a prism be applied so that the coloured rays of the sun refracted from it be received on the polyhedron: for by this means they will be thrown on a paper or wall, near at hand, in lucid specks, much exceeding the brightness of any precious stone; and in the focus of the polyhedron where the rays decussate (for in this experiment they are received on the convex side) will be a star of surprising lustre.

If images be painted in water-colours in the areolæ, or little squares of a polyhedron, and the glass applied to the aperture of a camera obscura; the sun's rays, passing through it, will carry with them the images of it, and project them on the opposite wall.

This artifice bears a resemblance to that other, by which an image on paper is projected on the camera; viz. by wetting the paper with oil, and straining it tight in a frame; then applying it to the aperture of the camera obscura, so that the rays of a candle may pass through it upon the polyhedron.

To make an *Anamorphosis*, or *deformed Image*, which, through a Polyhedron, or Multiplying-glass, shall appear regular and beautiful.—At one end of a horizontal table erect another at right angles, on which a figure may be designed; and on the other erect another, to serve as a fulcrum, or support, moveable on the horizontal one. To the fulcrum apply a plano-convex polyhedron, consisting, e. gr. of twenty-four plain triangles; let the polyhedron be fitted in a draw-tube, of which that end towards the eye is to have only a very small aperture, and a little farther off than the focus. Remove the fulcrum from the other perpendicular table, till it be out of the distance of the focus; and that more, as the image is to be greater. Before the little aperture place a lamp; and trace the luminous areolæ projected from the sides of the polyhedron, with a black-lead pencil, on the vertical plane, or a paper applied on it.

In the several areolæ, design the several parts of an image, in such a manner as that, when joined together, they may make one whole, looking afresh every now and then through the tube to guide, correct, &c. the colours, and to see that the several parts match aptly together.

The intermediate space fill up with any figures or designs at pleasure, contriving it so, as that to the naked eye the whole may exhibit some appearance very different from that intended to appear through the polyhedron.

The eye, now looking through the little aperture of the tube, will see the several parts and members dispersed among the areolæ to exhibit one continued image, all the intermediate ones disappearing. See ANAMORPHOSIS.

POLYHEDROUS FIGURE, in *Geometry*, a solid, contained under, or consisting of many sides. See POLYHEDRON.

POLYHISTOR is used for a person of great and various erudition. See POLYMATHY.

POLYHYMNIA, in *Mythology*, one of the nine Muses, distinguished among authors and poets by holding some stringed instrument of music in her hands, and by marking out what she sings with her hand. See MUSES.

POLYMATHY, POLYMATHIA, Πολυμαθία, from πολυ, *multum*, and μαθησις, *disco, I learn*, the knowledge of many arts and sciences; or an acquaintance with a great number of different subjects.

Lipsius, Scaliger, Kircher, Petavius, Grotius, Salmasius, Leibnitz, &c. were famous for polymathy. Among the ancients, such as were eminent this way were called *polybistores*.

Polymathy is frequently little more than a confused

heap of useless erudition, occasionally detailed, either pertinently or impertinently, for parade. The genuine polymathy is an extensive erudition, or a knowledge of a great number of things, well digested, and applied to the purpose, and never but where they are necessary.

POLYMERIA, in *Botany*, from πολυ, *much*, and μερρις, *assistance*, a name well chosen by Mr. Brown, to express the superabundance of stigmas with which this genus is furnished, in comparison with *Convolvulus*, though its seeds are fewer.—Brown Prodr. Nov. Holl. v. 1. 488.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Campanaceæ*, Linn. *Convolvuli*, Juss.

Ess. Ch. Calyx in five deep segments. Corolla funnel-shaped, plaited. Stigmas from four to six, acute. Germs of two single-seeded cells. Capsule of one cell, with one or two seeds.

The genus consists of herbaceous, diffuse, or creeping plants, which have no milky juice. Their flower-stalks are axillary, each bearing a pair of bractæas. Five New Holland species are defined by the author above mentioned, and possibly others may be latent among the undescribed stores of collectors.

1. *P. calycina*. "Segments of the calyx unequal; the outer ones heart-shaped at their base. Seeds smooth."—Found by Mr. Brown in New Holland. There are two varieties: one with oblong, obtuse, and nearly smooth leaves; growing near Port Jackson, as well as within the tropic: the other with oblong-linear finely downy leaves, confined to the latter climate.

2. *P. pusilla*. "Segments of the calyx equal. Leaves heart-shaped, somewhat emarginate. Flowers solitary. Seeds rather villous."—Native of the tropical part of New Holland, as are all the following species. There are two varieties of *P. pusilla*; one in which the leaves are ovate and obtuse: while in the other they are somewhat hastate and linear.

3. *P. quadrivalvis*. "Segments of the calyx equal. Leaves heart-shaped, obtuse; smooth above; veins slightly downy beneath. Stalks single-flowered. Capsule with four valves, and two downy seeds."

4. *P. lanata*. "Segments of the calyx equal. Leaves heart-shaped, obtuse with a small point; woolly, like the seeds, on both sides. Stalks single-flowered."

5. *P. ambigua*. "Segments of the calyx equal. Leaves oblong-heart-shaped, obtuse with a small point; nearly smooth above; woolly beneath. Stalks with from one to three flowers."—By the name, as well as the characters, the distinction between this and the last appears doubtful.

POLYMNASTIC AIR, a name for flutes in the ancient Greek music, invented, according to some, by a woman of the name of Polymnestra, and according to others, by the son of Miles of Corinth.

POLYMNIA, in *Botany*, a genus which appears, by the 5th edition of Linnæus's *Genera Plantarum*, 396, to have been founded and named by Kalm; but of its etymology no account is there given: nor does this name occur in the *Philosophia Botanica*, published three years earlier. As the plant is of the tribe of sunflowers, possibly the author had in his mind πολυμνια, one of the Muses. The same word is, as professor Martyn remarks, an epithet of the sea, from πολυς and μινος, *abounding with moss or sea-weed*; but this idea does not apply to the subject before us.—Linn. Gen. 444. Schreb. 581. Willd. Sp. Pl. v. 3. 2335. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 5. 164. Pursh v. 2. 579. Juss. 187. Lamarek Illustr. t. 711. Gartn. t. 174. (*Tetragonotheca*; Linn. Gen. 438.)—Class and order,

order, *Syngenesia Polygamia-necessaria*. Nat. Ord. *Compositæ oppositifoliae*, Linn. *Corymbiferae*, Juss.

Gen. Ch. *Common Calyx* double; the *outer* largest, spreading, of four or five ovate leaves; *inner* of ten boat-shaped upright leaves. *Cor.* compound, radiant. *Florets* of the disk perfect, numerous, funnel-shaped, five-cleft; those of the radius five or ten, ligulate, with two or three teeth. *Stam.* in the florets of the disk. Filaments five; anthers united into a hollow cylinder, rather longer than the corolla. *Pist.* in the same florets, Germen minute; style thread-shaped, as long as the stamens; stigma obtuse: in those of the radius, Germen ovate, rather large; style thread-shaped, the length of the tube; stigmas two, acute. *Peric.* none, the calyx remaining unaltered. *Seeds* in the disk none; in the florets of the radius solitary, obovate, gibbous, somewhat angular at the inner side, naked. *Recept.* chaffy, convex, imbricated; the scales ovate, obtuse, concave, the length of the florets.

Eff. Ch. Receptacle chaffy. Seed-down none. Calyx double; the outer of four or five leaves; inner of ten concave leaves.

1. *P. canadensis*. Canadian Polymnia. Linn. Sp. Pl. 1303. Willd. n. 1. Ait. n. 1. (Polymnia; Linn. Am. Acad. v. 3. 15. t. 1. f. 5.)—Leaves toothed, pointed; the lower ones pinnatifid; the upper either three-lobed or undivided.—Found on shady mountains, from Canada to Virginia, flowering in June and July. *Pursh.* The root is perennial. *Herb* two to six feet high, downy and viscid, with a strong balsamic scent. *Branches* and *leaves* usually alternate; the latter not unlike those of a Sow-thistle. *Flowers* at the ends of the upper branches, few, or solitary, yellow, not ornamental.

2. *P. Uvedalia*. Broad-leaved Polymnia. Linn. Sp. Pl. 1303. Willd. n. 2. Ait. n. 2. (*P. maculata*; Cavan. Ic. v. 3. 14. t. 227.)—Leaves three-lobed, acute, deeply sinuated, running down into the footstalks.—Native of the mountains of Virginia and Carolina, as well as of Mexico, flowering from July to September. It has long been in our gardens, and occasionally occurs in the more curious collections. The *stem* is above the height of a man. *Leaves* opposite, not unlike those of a plane tree. *Flowers* yellow, two inches wide, with a large leafy external *calyx*.

3. *P. abyssinica*. Narrow-leaved Polymnia. Linn. Suppl. 383. Willd. n. 3. Ait. n. 3.—Leaves opposite, sessile, linear-lanceolate, somewhat toothed.—Brought from Abyssinia, as it is said, by James Bruce, esq. in 1775. It has flowered in the stove at Kew, in April and May; but being biennial, we know not that it is still preserved, nor does it appear to be any where figured. The *stem* is from two to six feet high, spotted, roughish, leafy, sparingly branched in the upper part. *Leaves* two or three inches long, and half an inch broad, acute, toothed in some parts, entire in others, clasping the stem with their dilated base. *Flowers* terminal, stalked. Outer *calyx* of five large heart-shaped leaves. *Corolla* yellow; the radiant florets large, dilated outwards. *Seeds* are said to be perfected in all the florets.

For other species, referred by Linnæus to this genus, see DIDELTA.

POLYMORPHOS, variously shaped, an epithet often given to the os sphenoides.

POLYMYTHY, ΠΟΛΥΜΥΘΙΑ, in *Poetry*, denotes a multiplicity of fables, in an epic or dramatic poem; in lieu of an unity or a single one.

Polymythia is a great fault. It consists in joining a number of distinct actions or fables into one complex body. Such a work Bossu compares to the Batrachomyomachia,

or one of the fables of Æsop: and such would be the idea of a Theſeid, an Heracleid, an Achilleid, or the like poems, which should comprehend all the actions of those heroes compared with the Iliad or Æneid. See FABLE.

POLYNEMUS, in *Ichthyology*, a genus of fishes of the order Abdominales, of which the generic character is; head compressed, covered with scales; snout very obtuse and prominent; gill-membrane from five to seven-rayed; pectoral fins with distinct appendages. The fishes of this genus are chiefly distinguished from those of the Trigla family, in having ventral fins placed on the abdomen, and in the appendages not being articulate. Four species are enumerated by Gmelin, which are as follow.

Species.

QUINQUARIUS. Appendages five, which are longer than the body. It is found in the American seas, as is the next.

VIRGINICUS. Seven appendages, with a tail entire. In this the gill-covers are serrate; the first ray of the first dorsal fin is very short; the tail is broad and very sharp.

PARADISEUS. Seven appendages; tail forked. This is also called the fish of Paradise, or mango fish. It grows to the length of about twelve or fifteen inches, and the thoracic filaments are very long, the outer ones often extending beyond the tail, and the others gradually shortening. It inhabits the Indian seas, and is reckoned the most delicate fish they have at Calcutta.

PLEBEIUS. Five appendages, the first extending beyond the tail, the others gradually shortening. This fish, which is called the Plebeian polyneme, resembles a mullet, except that its head is much blunted. It sometimes measures four feet in length. It is a native of the American and Indian seas, and is considered as excellent food.

POLYNESIA, derived from a Greek term signifying *many islands*, in *Geography*, an appellation by which De Brosses, more than half a century ago, distinguished the numerous isles in the Pacific ocean. (See AUSTRALASIA.) The division called Polynesia is by far the most extensive, and adjoins on the W. to a line drawn around the Asiatic isles; thence it ascends about lat. 18°. E. long. 128° in a N.E. direction, so as to include the isle called Rica de Plata, long. 161°, and thence curving S.E. and encompassing the northern Sandwich islands, where our great navigator fell, and the Marquesas, and extending to 120° W. from London. Any isles to the N.E. or E. of this line of demarcation may be regarded as belonging to North or South America. The southern boundary of the Asiatic isles may be considered as sufficiently ascertained by the wide channel between them and New Holland; while the N.W. extremity of Sumatra may present a meridian of separation on the W. between the Asiatic isles, eminently so styled, and those in the Indian ocean. The same western boundary may be assigned to Australasia. The southern limits of the last, and of Polynesia, alone remain; but as few or no islands have been discovered to the S. of New Zealand, the parallel of 50° S. lat. may be laxly assumed as the boundary of both. Polynesia will thus extend from 50° S. lat. to about 35° N. lat.; that is, 85°, or 5100 geographical miles; while the breadth taken from E. long. 170° to 130° W. upon the equator itself, will yield 60°, or 3600 geographical miles. For the dimensions of *Australasia*, see that article. The smallest division, that of the Asiatic isles, in what has been called the Oriental Archipelago, is of great extent from S. lat. 30° to N. lat. 22°, that is, 35° or 2100 geographical miles; while the length from E. long. 95° to 132°

yields 37 degrees not far from the equator, nearly corresponding with the breadth.

The chief subdivisions of Polynesia are as follow; viz. the Pelew isles, the Ladrones, the Carolines, the Sandwich isles, the Marquesas, the Society isles, and the Friendly isles; besides many other scattered in different directions, of small consequence, and not easily connected with any group. Pinkerton's Geog. vol. ii.

POLYNOMIAL, or *Multinomial Roots*, in *Mathematics*. See MULTINOMIAL, and ROOT.

To raise a polynomial to any given power, may be done by Sir Isaac Newton's binomial theorem. Among other methods of demonstrating this, we have one by signor Castillioni in the Philosophical Transactions, N^o 464.

POLYOPTRUM, formed from *πολυ*, *much*, *many*, and *οπτικαι*, *I see*, in *Optics*, a glass through which objects appear multiplied, but diminished.

The polyoptrum differs both in structure and phenomena from the common multiplying-glass, called *polyhedra*.

POLYOPTRUM, *Construction of the*.—In a glass plain on both sides, A B (*Plate XVII. Optics, fig. 14.*) and about three fingers thick, cut out spherical segments, scarce a fifth part of a digit in diameter.

If then the glass be removed from the eye, till you can take in all the cavities at one view, you will see the same object, as if through so many several concave glasses, as there are cavities, and all exceeding small.

Fit this as an object-glass in a tube A B C D, whose aperture, A B, is equal to the diameter of the glass, and the other, C D, is equal to that of an eye-glass, *e. gr.* about a finger's breadth. The length of the tube, A C, is to be accommodated to the object and eye-glass, by trial. In C D fit a convex eye-glass, or in lieu of it a meniscus, having the distance of its principal focus a little larger than the length of the tube; so that the point from which the rays diverge after refraction in the object-glass may be in the focus. If then the eye be applied near to the eye-glass, a single object may be seen repeated as often as there are cavities in the object-glass, but still diminished.

POLYOSTEON, a name given by authors to that part of the foot which consists of a great many bones.

POLYOZUS, in *Botany*, a genus of Loureiro's, named, in allusion to its numerous branches, from *πολυς*, *many*, and *κος*, *a knot*, or *branch of a tree*. Lour. Cochinch. 74.—Class and order, *Tetrandria Monogynia*. Nat. Ord.

Gen. Ch. *Cal.* Perianth tubular, four-toothed, short. *Cor.* of one petal; tube short; limb four-cleft, reflexed. *Stam.* Filaments four, reflexed, shorter than the corolla, inserted into the mouth of its tube; anthers oblong, erect. *Pist.* Germen roundish; style thread-shaped, longer than the corolla; stigma large, cylindrical, acute, emarginate. *Peric.* Berry formed out of the calyx, roundish, fleshy, of one cell. *Seeds* two, roundish.

Ess. Ch. Calyx four-toothed, becoming pulpy. Tube of the corolla short; limb in four segments. Berry fleshy, of one cell, with two seeds.

1. *P. bipinnata*. Cây Trâm ná of the Cochinchinese.—Leaves doubly pinnate. Clusters lateral.—Native of the woods of Cochinchina. A large tree, with abundant spreading branches. Leaves doubly pinnate, of numerous pairs of small, ovate, pointed, entire, shining leaflets. Clusters axillary, short, of many small greenish-yellow flowers, many of which are neuter, whose calyx and corolla are similar to the perfect ones. Berry middle-sized, brown, not eatable. The wood of this tree is white and heavy, not beautiful, but of great use in supporting bridges, as it suffers little either from wet or from worms.

2. *P. lanceolata*. Am fan cung of the Chinese.—Leaves lanceolate. Clusters terminal.—Native of the neighbourhood of Canton in China. A shrub, without spines, four feet high, with spreading branches. Leaves opposite, stalked, lanceolate, entire, smooth. Clusters terminal, compound. Flowers reddish. Calyx four-toothed, becoming a berry. Corolla funnel-shaped, its limb in four spreading segments, the length of the tube; the orifice filled with copious wool, and bearing the stamens. Stigma emarginate. Berry roundish, very small, of one cell, with two seeds. *Pavetta caffra*, Linn. Suppl. 121, agrees better with this genus than with *Pavetta*.

Such is the whole of Loureiro's account, except that he mentions *Roubamon* of Aublet, Guian. 93. t. 36, as scarcely differing from the above description. We are not able to refer this description to any plant with which we are acquainted, but there seems great reason to suspect that his two species do not really belong to one genus; of which he betrays a suspicion, by giving a particular account of the fructification of the second. Aublet's *Roubamon*, though described by Schreber as a genus, by the name of *Lasiostoma*, appears to be, as Jussieu makes it, a tetrandrous species of *Strychnos*.

POLYPARA, so termed by Loureiro, from *πολυς*, *many*, and *pario*, to bear or bring forth, an inadmissible hybrid word, referring to the great number of florets produced by one corolla. The genus and the name are superseded by the *Houttuynia* of Thunberg, which, according to the avowal of Loureiro himself, is the very same plant. See HOUTTUYNIA.

POLYPE, or POLYPUS, in *Zoology*, a small fresh-water insect, belonging to the genus of Hydra, in the class of Worms, and order of Zoophytes, in the Linnæan system, the *Hydra grisea*; which, when cut into a number of separate pieces, becomes in a day or two so many distinct and separate animals; each piece having the surprising property of producing a head and tail, and the other organs necessary for life and all the animal functions.

The first discovery of this animal was owing to M. Leeuwenhoek, who, in the year 1703, presented to the Royal Society of London a description of it, and an account of its uncommon way of producing its young; but the discovery of its amazing property of reproducing the several organs of its various pieces, was not made till the year 1740, by M. Trembley, at the Hague. See Martyn's Abr. Phil. Transf. vol. ix. p. 17, &c.

The production of its young is, indeed, different from the common course of nature in other animals: for the young one issues from the side of its parent, in form of a small pimple or protuberance, which, lengthening and enlarging every hour, becomes, in about two days, a perfect animal, and drops from off its parent, to shift for itself: but before it does this, it has often another growing from its side; and sometimes a third from it, even before the first is separated from its parent.

M. Trembley observes, that there is no distinguished place in the body of the polypus, by which the young are brought forth. He has seen some of them that have produced young ones from all the exterior parts of their bodies.

They breed quicker in hot than in cold weather; and what is very extraordinary is, that there never has yet been discovered among them any distinction of sex, or appearance of copulation; every individual of the whole species being prolific, and that as much if kept separate, as if suffered to live among others.

If the method of this little animal's producing its young be very amazing, its reproduction of the several parts, when

POLYPE.

cut off, is much more so. The discovery of this was perfectly accidental; for M. Trembley, who had often met with the creature in the water, and from its fixed residence in one place, and some other observations, not being able to determine whether it were an animal or a vegetable, made the trial by cutting it asunder, when, to his amazement, he found, that in a few days each of those pieces was become a perfect animal, the head part having shot forth a tail, and the tail a head.

A thousand other trials, by cutting the animal in different manners, first by M. Trembley, and afterwards, at his request, by Monf. Reaumur, and Bernard de Jussieu, at Paris, and Mr. Folkes, Mr. Baker, and the other naturalists in England, were the result of this; and all succeeded in the same manner by those who repeated them.

It is not easy to say what is the size of this creature; for it can contract or extend its body at pleasure from the length of an inch or more, and the thickness of a hog's bristle, to the shortness of a single line, with a proportionable increase of thickness. Its body is round and tubular, at one end of which is the head, surrounded with six, eight, ten, or more arms, with which it catches its prey; and at the other, the anus and tail, by which it fixes itself to any thing it pleases.

There have been many different species of it discovered, the most elegant of which, the *polype a panache*, or plumed polype, of M. Trembley, seems much to resemble the wheel-animal (so called from having the appearance of two wheels in its head), which Mr. Leeuwenhoek discovered living in a sheath or case, and affixed to the roots of duckweed.

All the species are found in clear and slowly running waters, adhering by the tail to sticks, stones, and water-plants, and live on small insects. They are easily kept alive a long time in glasses, often changing the water, keeping the glasses clean, and feeding them with a small red worm, common in the mud of the Thames, or with other small insects.

The creature has its name from the Greek *πολυ*, many, and *πυ*, a foot, signifying an animal with many feet; but a more apposite one might have easily been invented, since it has in reality no feet at all. What were originally taken for feet, are what have since been called its horns, and of late more properly its arms, their office being to catch its prey.

This animal is first of a worm-shaped figure, and of the same kind of tender substance with the horns of a common snail; it adheres by one end, like a sucker, to water-plants and other substances; the other end, which is the head, is surrounded by many arms or feeders, placed like rays round a centre; this centre is its mouth; and with these tender arms, which are capable of great extension, it seizes minute worms, and various kinds of water-insects, and brings them to its mouth; and often swallows bodies larger than itself; having a surprising property of extending its mouth wider, in proportion, than any other animal. After its food is digested in its stomach, it returns the remains of the animals upon which it feeds through its mouth again, having no other observable emunctory. In a few days there appear small knobs or papillæ on its sides: as these increase in length, little fibres are seen rising out of the circumference of their heads, as in the parent animal; which fibres they soon begin to use for the purpose of procuring nourishment, &c. When these are arrived at mature size, they send out other young ones on their sides in the same manner; so that the animal branches out into a numerous offspring, growing out

of one common parent, and united together and disposed in the manner represented in a figure. Each of these provides nourishment not only for itself, but for the whole society; an increase of the bulk of one polype by its feeding, tending to an increase in the rest. Thus a polype of the fresh-water kind becomes like a plant branched out, or composed of many bodies, each of which has this singular characteristic, that if one of them be cut in two in the middle, the separated part becomes a complete animal, and soon adhering to some fixed base, like the parent from which it was separated, produces a circle of arms; a mouth is formed in the centre; it increases in bulk, emits a numerous progeny, and is, in every respect, as perfect an animal as that from which it was severed.

The several strange properties recorded of this animal, though very surprising, are, however, none of them peculiar to it alone. The Surinam toad is well known to produce its young not in the ordinary way, but in cells upon its back. Mr. Sherwood has also discovered the small eels in four parts to be each, without exception, full of living young ones. And as to the most amazing of all its properties, the reproduction of its parts, we know the crab and lobster, if a leg be broken off, always produce a new one: and M. Bonet, M. Lyonet, Monf. de Reaumur, and Mr. Folkes, have all found on experiment, that several earth and water worms have the same property, some of them even when cut into thirty pieces. The *urtica marina*, or sea-nettle, has been also found to have the same: and the sea star-fish, of which the polype is truly a species, though it had long escaped the searches of the naturalists, was always well known by the fishermen to have it also. See REPRODUCTION.

POLYPE, Cluster, the name of a species of small insect of the polype kind, called by the French naturalists *polype en bouquet*.

There is found on several of the water-plants, and on other substances, as sticks, boards, and the like accidentally fallen into the water, a whitish substance, that at first sight appears to be only a sort of mouldiness; but if the bodies on which this is found be put into a vessel of clear water, and the matter examined with a magnifying glass, it is soon seen that this whitish substance is really a vast number of small animals, which are almost continually in motion. When this is brought before the microscope, the form and structure of the creatures are very evidently distinguished, and they are found to be minute roundish creatures, severally affixed to the end of a sort of stem or tail; and many of the stems are so interwoven and united together, that they form clusters, which have occasioned the name of a cluster-polype to be given to the animal, though in itself it is really and properly single from the beginning. There are several species of polype of this minute kind, that cluster themselves in this manner together; and according to these and other circumstances, the clusters are found larger or smaller, and more or less complex.

The smaller clusters should always be chosen for observation, as in the larger the bodies of the several animals that compose them are apt to hide and obscure one another; but the most beautiful and accurate of all observations is to be formed when they are single, as they are sometimes found; and this is the only opportunity of seeing distinctly in what manner the clusters are formed. One of these single animals is not in length above the two hundred and fortieth part of an inch, and is of a shape nearly resembling that of a bell: the anterior part of this generally appears open when it presents itself properly; and the posterior part is fixed to the stem or pedicle, by the other extremity

extremity of which the creature fastens itself to any solid body that it meets with. The body is of a brownish colour, except at the smaller end, which, as well as the tail, is whitish and transparent; and when the anterior part is open, there may always be perceived about its edges a very lively motion; and when the creature presents itself in a better manner, there may be seen on either side of the edges on the anterior part, somewhat resembling the wheels of a mill, continually moving with great velocity.

These creatures are able to contract their bodies, and often do it very suddenly, especially if any thing disturb the substance on which they are fixed: when they are thus contracted, the edges of their anterior parts are drawn just into their bodies: and when the fright is over, it is a very agreeable sight to behold these edges turning out again, and putting themselves in motion as before. If the edges of the anterior parts of the bodies of these animals be strictly observed while in motion, the water about them will be found to be full of extremely minute round bodies, which are brought together by means of that motion, and serve the creature for its food: these may be often seen going down into the cavities of the body of the polype, and that very suddenly, as if forcibly driven down; and when swallowed too voraciously, are often thrown up again. These observations are best made when a small cluster of the polypes are examined together.

If these polypes are kept some time in the rain-water, they, by degrees, lose their brown colour, and become white and transparent throughout, except that a few spots of a dusky colour remain in their bodies; but if, after this, they are removed into other water, of the same kind with the first, but newly taken out of the ditch, they in a little time recover their brown colour. When they become white, they plainly appear to be in a sickly condition, and cease to multiply; but when they have fresh water and recover their colour, they immediately begin to multiply again.

These creatures are not absolutely and immoveably fixed to the bodies on which they are placed, but they can at pleasure quit them and swim about: in this swimming state they are always found single and not in clusters; and they do not then appear in the same form as when they are fixed and open at the anterior ends. When they have swam about as long as they please, they either return to their clusters from which they separated themselves, or affix each singly to any thing they meet with: and this is a circumstance that merits to be carefully watched, because it is by means of this that we see in what manner the creature multiplies itself and the clusters are formed.

As soon as a single animal of this kind is fixed to a stick, a stone, or any other substance, it begins to lengthen its stem or tail, which, though very short while swimming, and when first fixed, very soon becomes of its pristine length while in the cluster; and after this the creature begins immediately to multiply by the most amazing means in the world, that is, by splitting itself to pieces lengthways. The first motion towards this operation is the drawing in the lips or edges; this is soon done, and the body then loses its bell-like shape, and becomes round; the motion which was before perceived at the edges ceases, and there is only a slight tremulation to be seen within the body; after which the anterior part of the body becomes flat or broad, and the whole body shortens in proportion; and soon after this the whole body gradually splits itself regularly into two, from the centre of the anterior part to the centre of the hinder end, where it joins the tail or pedicle, and there soon appear two round and perfect bodies joined to that pedicle

which before supported only one. The anterior parts of the two bodies soon begin to open, and gradually shew their edges, which perform the same motion the single one did before. The motion is at first very slow, but it grows quicker by degrees as they open; and when they are perfectly expanded, it is as quick as it was in the original single body; it is at this time that the two bodies may be esteemed quite perfect. They are at first indeed less than the original polype, from which they were formed, but they grow to the same size in a very little time: the whole operation of dividing itself, takes up the creature about an hour: but to form a true idea of the manner in which it is performed, there must be many observations made, and the creatures must be examined in all views and lights while about it.

The lips of these polypes, when closely examined, appear to be composed of four or five transparent bands, all of which have an undulatory motion. And when the newly divided polype is but slow in its motions, it is easy to discover that what afterwards appear to be like the wheels of a mill, are, in reality, only four or five oblong bodies, resembling a sort of figures which alternately bend down, and extend themselves every instant. These are fastened to the bands of the lips on each side of the mouth; and when they are put into swift motion in the time of the full growth and vigour of the animal, they are not to be distinguished as to form, nor can their motion be otherwise discovered than by its swiftness, which makes it resemble the quick turning of a wheel.

When the separation of the body of a single polype of this kind is complete, one sees two regular and perfect bodies adhering side by side to the same pedicle, but soon after each of the new-formed bodies begins to shew a pedicle of its own; these grow in a day's time to a moderate length, and unite at their bottoms to the end of what was the original single pedicle of the body while but one; they grow to this in the manner of the branches growing to the trunk of a tree.

Twenty-four hours after the separation of the original body into two, these two begin to separate themselves in the same manner, each into two again; and these, after a like time, again separate: each of these separated animals has its own tail formed in a like period of time with the first; and the consequence is, that the first separation producing two, the second gives four, the third eight, and so the sixth, sixty-four, the seventh, one hundred and twenty-eight, and so on; by which means a single animal, in a very few days, forms out of itself an immense cluster, each animal of which is perfect in itself and independent of all the rest, and can, when it pleases, swim away and form a new cluster. They will multiply as fast in glass jars, as in their native free state in the waters, and clusters of them, begun near one another, will often join in such a manner as to form one complex cluster of an inch diameter: from these several clusters there detach themselves single polypes from time to time, which go off, and fastening themselves to other bodies, become the authors of new progenies.

The original branch or stem of the first polype remains always in the centre of the cluster; but it is of no use, never afterwards having any body fixed to it.

There are, besides this species here described, four other known kinds of polypes, which divide themselves in the same manner by splitting into two lengthwise: those which come nearest to the first are slenderer, and their stems are more transparent. They are of a blueish colour, when many of them are seen together, and their stems or tails very aptly resemble spun glass. When this species is perfectly formed,

the motion of its lips is less distinct than in the other; but it may be discovered in the same manner while they are newly separated, and are but growing toward perfection, when it gradually becomes less and less distinct.

Another species of these polypes is smaller than the last, but more open at the mouth and deeper hollowed; and these are particularly distinguished from all the others, by having a motion in their stems and branches, which all the others want. The stems draw themselves up, and shorten all at once into the appearance of a spiral screw, and in a moment can dart themselves straight out to their full length again. All these multiply very speedily, but they have all enemies that destroy them in a very terrible manner, whole clusters making but single mouthfuls. The funnel-polypes are nearly allied to these creatures. Phil. Transf. N^o 474, vol. xliii. p. 169, &c. and vol. xlv. p. 627, &c.

POLYPE, *Funnel*, described by M. de Reaumur and M. Trembley under the appellation of *Tunnel-like polype*, a name given by naturalists to a small water-insect, in some respects approaching to the nature of the cluster-polype.

The funnel-polype nearly resembles a funnel, from which it has its name. It is long and hollow, and very wide at the anterior end. These little animals are of three species, a green, a blue, and a white one: they are all too minute for the observation of the naked eye, they must be viewed with great caution, and in several different directions and attitudes, before their true form can be discovered; and their anterior end, particularly when carefully observed, is of a much more compound structure than might at first be imagined; there may always be observed round the edges of this part a sensible motion, resembling that of an indented wheel, or rather that of a screw turned very nimbly about. These, though they approach to the shape of the cluster-polypes, and resemble them in their having this motion about the mouths, yet never have any tendency to form clusters, but are ever found loose and single. There is always a number of little round bodies, which seem to be animals of a very minute size, swimming about in the water in which these polypes live; and these are continually drawn into the mouths of the polypes, and serve them for food.

The manner of these creatures' propagating themselves is very amazing; they do it by dividing their own body into two; but this is not done longitudinally, as in the cluster-polypes, nor transversely, but diagonally from the edge of the head to the opposite edge of the tail; so that of the two thus formed out of one, the one has a head and no tail, the other a tail and no head; but these deficiencies are soon made up, and the head soon grows out of one, and the tail out of the other.

M. Trembley, in his account of this insect, calls that of the two which has the old head, the *superior* polype; that which has the old tail, the *inferior*. The first particulars observable in a funnel-polype that is going to divide, are the lips of the *inferior* polype, or those transparent edges, that are so very conspicuous in the creature when perfectly formed. These new lips first discover themselves upon the polype that is going to divide, from a little below the old lips to about two-thirds of the length of the polype, reckoning from the head; but these new lips are not disposed in a straight line, according to the length of the polype, but run sloping near half way round about. These lips are distinguished by their motion; but it is to be observed, that this motion is at first very slow, and requires an attentive eye and good glasses to discover it.

That portion of the body of the polype which is bounded by these new lips, then gathers up itself, and these lips in-

sensibly draw close together, and finally, they close themselves. By this means there is found a swelling at the side of the polype, which is found on close examination to be the head of the new polype, bounded by the lips before mentioned. Before this swelling is become very remarkable, it is easy to discover the true polypes that are forming themselves; and, after this, when the swelling is greatly increased, these two distinct animals will be found joined to one another only by a very small part of their bodies. The *superior* polype, in this case, no longer adheres to the *inferior* one but by its posterior extremity, which is still fixed on one side of the *inferior* one. The *superior* one then begins to make motions, which tend to the separating itself from its fellow; and these soon finish the work, and he becomes perfectly disengaged, and swims away whither he pleases, and soon fixes on some other place. The *inferior* polype remains fixed in the place where both were before, and becomes a perfect animal; and the *superior* one, after taking a tour in the water, sometimes returns to the old place, and fixes itself by the tail to the body of the inferior one. All these animals are extremely minute, and are not to be seen distinctly, much less are their operations observed without the help of glasses; and as there is no taking them out of the water to bring them before the microscope in the common way, without absolutely destroying them, M. Trembley, who has observed them with more accuracy than perhaps any other person ever did, has contrived to view them in a glass vessel, in their own water, by bringing them so near the sides of the glasses, that the microscope glasses are able to reach them properly from the outside. The substances on which they are fixed, are to be brought close to the edges of the vessel, by means of a set of quills framed properly together; and the microscope glasses to be supported on a moveable arm made for that purpose. Phil. Transf. N^o 474, vol. xliii. p. 180, &c. and vol. xlv. p. 627, &c.

POLYPE, *Marine*, is different in form from the fresh-water polype already described, but is nourished, increases, and may be propagated after the same manner: Mr. Ellis having often found, in his enquiries, that small pieces cut off from the living parent, in order to view the several parts more accurately, soon gave indications that they contained not only the principles of life, but likewise the faculty of increasing and multiplying into a numerous issue. It has been lately discovered and sufficiently proved by Peyssonnel, Ellis, Jussieu, Reaumur, Donati, &c. that many of those substances, which had formerly been considered by naturalists as marine vegetables or sea-plants, are in reality animal productions; and that they are formed by polypes of different shapes and sizes, for their habitation, defence, and propagation. To this class may be referred the corals, corallines, keratophyta, eschara, sponges, and alcyonium: nor is it improbable that the more compact bodies, known by the common appellations of star-stones, brain-stone, petrified fungi, and the like, brought from various parts of the East and West Indies, are of the same origin; to this purpose Mr. Ellis observes, that the ocean, in all the warmer latitudes near the shore, and wherever it is possible to observe, abounds so much with animal life, that no inanimate body can long remain unoccupied by some species. In those regions the ships' bottoms are soon covered with the habitations of thousands of animals: rocks, stones, and every thing lifeless, are covered with them instantly: and even the branches of living vegetables that hang into the water, are immediately loaded with the spawn of different animals, shell-fish of various kinds. And shell-fish themselves, when they become impotent and old, are the basis of new colonies of animals,

animals, from whose attacks they can no longer defend themselves. For a farther account of this system, see CORAL, and CORALLINES.

POLYPE, *Plumed*, or à *Pannache*, so called by M. Tremley, who noticed it in 1744, and denominated the "Bell-flower animal" by Mr. Arderon in 1743, a species of polype, which forms a kind of intermediate gradation between those creatures which hang in clusters and can detach themselves at pleasure, and others that are so intimately connected together that no one seems capable of moving or changing place without affecting the quiet and situation of all the rest. This species dwells in the same *general habitation* with others of its own species, from whence it cannot entirely separate itself; and yet, *therein* it appears perfectly at liberty to exert its own voluntary motions, and can either retire into the common receptacle, or push itself from thence and expand its curious members, without interfering with or disturbing its companions. These polypes dwell together, from the number of ten to fifteen, in a filmy kind of mucilaginous or gelatinous case; which, out of the water, has no determinate form, appearing like a little lump of slime, but when expanded in it resembles nearly the figure of a bell with the mouth upwards, and is usually about the length of half an inch, and a quarter of an inch in breadth or diameter. This case being very transparent, all the motions of its inhabitants may be discerned through it distinctly. It seems divided, internally, into several apartments, or rather to contain several smaller sacculi, each of which encloses one of these animals. The openings at the tops of these sacculi are just sufficient to admit the creature's head and a very small part of its body, to be thrust out beyond them, the rest remaining always in the case. The animal, however, can at pleasure draw itself entirely within the case, which is an asylum to secure it from its enemies, and an agreeable retirement in which to perform the functions of digestion, sleep, and other natural operations. It never fails to retire into this case, when any sudden motion of the water, or of the vessel in which it is placed, disturbs it; and also when it has seized with its arms any of the minute insects which serve it for food. The arms, to the number of forty, are set round the head, each being of the figure of long *f*, one of whose hooks is fastened to the head; and all together, when expanded, compose a figure somewhat of a horse-shoe shape, convex on the side next the body, but gradually opening and turning outwards so as to leave a considerable area within the outer extremities of the arms. When thus extended, by giving them a vibrating motion, the creature can produce a current in the water, which brings animalcules, or other minute bodies, with great velocity to its mouth, situated between the arms, where they are taken, if liked, or else, by a contrary current, which the creature can excite, they are carried away again: other minute animalcules, or substances lying withoutside the inclosure of the arms, being less subject to the force of the stream, are frequently seized by them, for so exquisite is their sense of feeling, that on being ever so slightly touched by any such small body, it is immediately caught and conveyed to the mouth. The food is conveyed immediately from the mouth, or opening between the arms, through a very narrow neck into a passage seeming to correspond with the œsophagus in land animals; down which it passes into the stomach, whence, after remaining for some time, it is voided upwards in small round pellets, through a gut, whose exit is near the neck, where it was first taken in. The body of this animal consists of three divisions, the uppermost containing the fore-mentioned intestines very visible after the creature has eaten,

and the other two seeming to be of no service besides that of giving the creature power of contraction and extension. The arms do not turn, like those of the common polype, capable of contracting themselves, but when the animal retires into its case, they are brought together in a curious and close order, so as to be easily drawn in. Their general figure, when expanded, is that of a cup, whose base and top are of an horse-shoe form; but they present sometimes a very different appearance, by separating into four parts, and ranging themselves in such a manner as to represent four separate plumes of feathers. Independently of the peculiar and separate motion of each of these creatures, the whole colony has together a power of altering the position, or even of removing from one place to another the bell, or common habitation of all. About ten or fifteen of these animals dwell together, forming, as it were, a little community, in one bell-like case; but when their number increases, the bell splits gradually, and two complete colonies are formed, independent of each other; one of which sometimes removes itself to another part of the vessel. It is conjectured, but not absolutely ascertained, that these single animals propagate by means of eggs. The bells, or colonies, of these animals are to be found adhering to the large leaves of duck-weed and other aquatic plants; and if water, with duck-weed in it, be suffered to remain quiet for three or four hours in glass vessels, exposed to a strong light, they will be found, on careful inspection, extending themselves out of their cases, spreading their plumes, and making an elegant appearance. These animals are extremely tender, and require no little care to preserve them. If they are daily supplied with fresh water, they will find sufficient food. Baker's Microscope, vol. ii. ch. 10.

POLYPE, *Ver.* See VER-Polype.

POLYPETALOUS FLOWERS, in *Botany*, are such as have their corolla formed of more than one piece, or petal. Such are the rose, lily, pea, and many others. (See COROLLA and PETALUM.) Some flowers, apparently monopetalous, by a partial or temporary cohesion of the parts in question, evince their truly polypetalous nature in fading, as may be seen in the natural order of *Proteaceæ*, and even in orange and lemon blossoms in some degree.

POLYPHEMA, so named by Loureiro, in fanciful allusion to the giant Polyphemus, because of the gigantic fruit, and the solitary stamen, as well as pistil, is no other than the Linnæan *Artocarpus*, or Bread-fruit, under which happier appellation this most distinct and important genus is now universally received. See ARTOCARPUS.

POLYPHEMUS, in *Mythology*, the most celebrated and the most terrible of the Cyclopes, who were deemed to be the sons of Neptune.

POLYPODES, a word used by some as the name for the millepedes.

POLYPODITES, a name given by the ancients to a wine impregnated with polypody, and sometimes for the juice of millepedes, expressed with wine.

POLYPODIUM, in *Botany*, *πολυποδιον* of Dioscorides, so called from *πολυς*, many, and *πους, ποδος*, a foot, on account of the appearance of its scaly root, creeping, by numerous radicles, superficially over the trunks of trees; a well-known genus of ferns, whose English name, Polypody, is but a slight alteration of the original.—Linn. Gen. 560. Schreb. 757. Mart. Mill. Dict. v. 3. Swartz Syn. Fil. 25. Sm. Fl. Brit. 1113. Ait. Hort. Kew. v. 5. 503. Pursh 658. Juss. 15. Tourn. t. 316. Lamarek Illustr. t. 866.—Class and order, *Cryptogamia Filices*. Nat. Ord. *Filices*.

POLYPODIUM.

Gen. Ch. *Capsules* annulated, numerously assembled in globular masses, scattered over the back of the frond like round dots. *Involucrum* entirely wanting.

Eff. Ch. Fructification in roundish scattered dots, without any involucrum.

This is, in Linnæus, the most extensive and most difficult genus, with respect to species, of the whole tribe of ferns; but its limits are much contracted by the establishment of Swartz's *Aspidium*. The latter is characterised by having a membranous involucrum over each dot, and is admitted in Fl. Brit. 1118, though the author of that work, and of the present article, had originally, in his Essay on Dorsiferous Ferns, not ventured on this separation; because of the great difficulty of ascertaining, in many exotic species, whether there be an involucrum or not. Dr. Swartz has, nevertheless, overleaped this obstacle, and may safely challenge the corrections of subsequent enquirers. He defines 102 species of *Polypodium*, and 91 of *Aspidium*; but his list of doubtful species amounts nearly to as many as those he has determined. Six of the former, and nine of the latter, are described in Fl. Brit.; but *P. fontanum*, n. 2, proves an *Aspidium*; and *P. arvenicum*, n. 3, constitutes Mr. Brown's new genus of *Woodfia*, Tr. of Linn. Soc. v. 11. 173. Two other species of *Aspidium* are added in Engl. Bot. *irriguum*, t. 2199, and *crisatum*, t. 2125, which, with *fontanum* just mentioned, t. 2024, make twelve British species, in all, of that genus, while those of *Polypodium* are reduced to four.

The genus under consideration is divided into five sections, according to the structure of the frond.

Section 1. *Frond simple*. Forty species, none British.

P. piloselloides. Mouse-ear Polypody. Sw. n. 1. Linn. Sp. Pl. 1542. Ait. n. 1. (Lingua cervina minima repens et hirsuta; Plum. Fil. 103. t. 118. Petiv. Fil. t. 10. f. 5.)—Fronds undivided, hairy; barren ones ovate; fertile lanceolate. Dots solitary. Shoots creeping.—Native of old trunks of trees, and mossy rocks, in the West Indies. The creeping, thread-shaped, hairy *shoots* are repeatedly branched, spreading widely, and throwing up scattered, simple, hairy *fronds*, on hairy *stalks*. Such of the *fronds* as are not destined to bear fructification are elliptical, obtuse, scarcely above an inch long; the rest are twice or thrice that length, lanceolate and acute. A row of about six large, hairy, orbicular masses of *capsules* stands on each side of the midrib.

This is one of a very curious tribe of Polypodys, remarkable for their widely creeping hairy *shoots*, and for a great diversity of form and proportion in the *fronds* of each species, as may be seen in Plumier's figures. Most of this section are natives of the East or West Indies, or of Japan.

Section 2. *Frond pinnatifid*. Twenty-eight species.

P. vulgare. Common Polypody. Sw. n. 57. Linn. Sp. Pl. 1544. Fl. Brit. n. 1. Curt. Lond. fasc. 1. t. 68. Engl. Bot. t. 1149. Bolt. Fil. 32. t. 18. Woodv. Suppl. t. 271.—Frond pinnatifid; its lobes oblong, obtuse, somewhat ferrated. Root scaly.—Common throughout Europe on walls, roofs, old trees, &c.; generally found in fructification, when full-grown. The thick *roots* are clothed with long, chaffy, rusty or golden scales. *Fronds* erect, a span high, including their stalks, rather glaucous beneath, with large golden copious dots of *capsules*. Tournefort strangely erred in denying the existence of a ring to these *capsules*. *P. cambricum* of Linnæus is a jagged, or doubly pinnatifid, barren, large variety.

P. Struthionis. Ostrich-plume Polypody. Sw. n. 64. Linn. Sp. Pl. 1545. (*P. crispum*, *struthionis pennam* re-

ferens; Plum. Fil. 64. t. 82. Petiv. Fil. t. 3. f. 8.)—Frond deeply pinnatifid; its lobes elongated, horizontal, parallel, linear, pointed, undulated.—Gathered by Plumier in a valley in the quarter of *Leogane*, in Hispaniola; nor do we find reason to believe that any other botanist has ever met with this singularly elegant and stately fern. We have not seen a specimen in any herbarium. Linnæus adopted it from Petiver, but has cited a wrong plant of Plumier, whose work he had not under his inspection while writing the Species Plantarum. The whole figure of the *frond* resembles an ostrich feather, except in being more flat altogether, though each segment is wavy. Plumier says he could find no dots of seeds on this species; but that its edges were bordered with an elegant little black cord. Surely this renders the genus doubtful at least, and is more indicative of *Pteris* than of *Polypodium*. We mention the plant here, not only for its singular beauty and rarity, but to point out this uncertainty, and to correct the above error of synonymy.

Section 3. *Frond pinnate*. Seventeen species.

P. crenatum. Crenate Polypody. Sw. n. 75. Ind. Occ. 1661. (Lingua cervina, rotundius crenata; Plum. Fil. 93. t. 111. Petiv. Fil. t. 6. f. 14. Felix latifolia, non ramosa, rotundius crenata; Plum. Amer. 7. t. 10.)—Frond pinnate; leaflets imperfectly opposite, somewhat stalked, elliptical, pointed, crenate. Dots accompanying the transverse veins.—Found by Plumier in Hispaniola, and by Swartz in the inland woods of Jamaica. A noble fern, whose *stalks* are erect, angular, one or two feet high. *Fronds* nearly as long, of a few very large *leaflets*, beset with a row of small dots of *capsules*, on each side of every transverse vein.

Section 4. *Frond bipinnatifid, or bipinnate*. Eleven species.

P. Phegopteris. Pale Mountain Polypody. Sw. n. 92. Linn. Sp. Pl. 1550. Fl. Brit. n. 4. Engl. Bot. t. 2224. Bolt. Fil. 36. t. 20.—Frond pinnate; leaflets lanceolate, pointed, pinnatifid, combined at the base; the lowermost pair deflexed.—Native of open stony mountainous places in the north of England. Linnæus says of beech woods in Europe and Virginia; but we have never met with it in or near any beech countries. The *root* is creeping. *Fronds* about a foot high, pale green, with long pale *stalks*. The drooping posture of the two lower *leaflets* constitutes the most striking character.

Section 5. *Frond more than twice compounded*. Six species.

P. Dryopteris. Tender Three-branched Polypody. Sw. n. 101. Linn. Sp. Pl. 1555. Fl. Brit. n. 5. Engl. Bot. t. 616. Bolt. Fil. 52. t. 28.—Frond ternate, doubly pinnate, spreading, drooping; segments obtuse, somewhat crenate. Root thread-shaped.—Found in shady places, about the sides of hills, in mountainous countries; as Wales and the north of England; also in Germany, &c. The *root* is black, creeping, very slender. *Stalk* smooth, nearly a foot high, slender, and delicate, bearing three elegantly drooping, tender, light green, compound *leaflets*; the middlemost rather the largest.

P. calcareum. Rigid Three-branched Polypody. Fl. Brit. n. 6. Sw. n. 102. Engl. Bot. t. 1525. (*P. Dryopteris*; Dickf. Dr. Pl. 16. Bolt. Fil. 53. t. 1. *Dryopteris Tragi*; Ger. Em. 1135.)—Frond ternate, doubly pinnate, erect, rather rigid; segments obtuse, somewhat crenate. Dots confluent.—Native of mountainous heaths, on a calcareous soil; abundant about Matlock bath, Derbyshire. It passed for a variety of the foregoing, till the publication of the Flora Britannica. If we remember right it was Mr. T. F. Forster who by culture first noticed its

different aspect. Indeed its upright, more rigid, habit; somewhat duller green; and paler, confluent masses of *capsules*, all indicate a specific difference. This species appears to be likewise a native of Germany.

POLYPODIUM, in the *Materia Medica*, the male polypody, or common male fern, is a native of Britain, and grows about the borders of woods near rivulets, and in stony rocky places.

The root has been greatly celebrated for its effects upon the tape-worm, or *Tænia lata*, of Linnæus; and this vermifuge power of fern-root seems to have been known to the ancients; and is since commended by different practical writers. Yet notwithstanding the virtues of this root are thus recorded, its use was very generally neglected till some years ago. Madame Noufer, a surgeon's widow in Switzerland, acquired great celebrity, by employing a secret remedy as a specific in the cure of the tape-worm. This secret was thought of such importance by some of the principal physicians in Paris, who were deputed to make a complete trial of its efficacy, that it was purchased by the French king, and afterwards published by his order. The method of cure has been stated as follows: after the patient has been prepared by an emollient clyster, and a supper of panada, with butter and salt, he is directed to take in the morning, while in bed, a dose of two or three drams of the powdered root of male fern. (The dose for infants is one dram.) The powder must be washed down with a draught of water, and two hours after a strong cathartic, composed of calomel and scammony, is to be given, proportioned to the strength of the patient. If this does not operate in due time, it is to be followed by a dose of purging salts, and if the worm be not expelled in a few hours, this process is to be repeated at proper intervals. Of the success of this, or a similar mode of treatment, in cases of *tænia*, there can be no doubt, as many proofs of it in this country afford sufficient testimony; but whether the fern root or the strong cathartic is the principal agent in the destruction of the worm, may admit of a question, and the latter opinion we believe is the more generally adopted by physicians. It appears, however, from some experiments, made in Germany, that the *tænia* has in several instances been expelled by the repeated exhibition of the root, without the assistance of any purgative.

The common polypody grows on old walls, stumps and roots of trees, and various shady places, fructifying from June till October. "The leaves," says Lewis, "have a weak ungrateful smell, and a nauseous sweet taste, leaving a kind of roughness and slight acrimony in the mouth. They give out their finell and taste, together with a yellow colour, both to water and rectified spirit: the spirituous tincture is sweeter than the watery; but in inspillation its sweetness is in great part destroyed, or covered by the other matter; the spirituous extract, as Cartheuser observes, being to the taste only subastringent and subacid, with very little sweetness, while the watery extract retains the full sweetness of the polypody."

The root of the polypodium quercinum, or those that grow on the oak, has been most esteemed for medicinal use, though no just reason can be assigned for this preference. By the ancients it was employed as a purgative, and thought to be peculiarly useful in expelling bile and pituitous humours; therefore much used in maniacal melancholical disorders; but to act as cathartic the root must be exhibited in its recent state, and in a large dose. Another character in which it has been recommended, and for which from its sensible qualities it seems to promise more advantage, is that of a demulcent or pectoral; thus joined with liquorice its

good effects have been experienced in coughs and asthmatic affections.

However, it is now rarely used in this country; nor have the French authors, Poissoner and Malouin, who have cited instances of its success in mania, been able to restore to it its ancient reputation in this calamitous disorder. Woodville's Med. Bot.

POLYPOGON, in *Botany*, from *πολυς*, many, and *παγων*, a beard, alluding to its unusual abundance of awns.—Desfont. Atlant. v. 1. 66. Schrad. Germ. v. 1. 192.—Class and order, *Triandria Digynia*. Nat. Ord. *Gramina*.

Gen. Ch. *Cal.* Glume single-flowered, oblong, of two nearly equal, straight, compressed, clasping, concave valves; their inner margin membranous, extended into an acute, deeply cloven point; their keel continued into a straight dorsal awn. *Cor.* of two ovate unequal valves, about half the size of the calyx; the outermost broadest, with a terminal straight awn; the inner awnless, notched at the summit; both smooth and naked at the base. Nectary of two oblong scales. *Stam.* Filaments three, capillary, the length of the corolla; anthers oblong, cloven at each end. *Pist.* Germen ovate, superior; styles two, short, divaricated; stigmas feathery. *Peric.* none, the calyx and unchanged corolla enfolding the seed. *Seed* solitary, ovate, clothed with the corolla, but not united to it.

Ess. Ch. Calyx single-flowered, of two, nearly equal, compressed, cloven, awned valves. Corolla of two valves, enclosed within the calyx; its outer one with a terminal awn. Seed invested with the unchanged corolla.

Obs. Schrader's more correct definition of the genus *Agrostis*, to which one or two tufts of hair at the base of the corolla are, it seems, essential, has induced us to accede to the establishment of the present genus; especially as habit is greatly in its favour, its character of the awned calyx strong and obvious, and its importance increased by an additional species unknown to Desfontaines or Schrader.

1. *P. monspeliensis*. Long-awned Beard-grass. Desfont. and Schrad. as above. (*Alopecurus monspeliensis* & *panicus*; Linn. Sp. Pl. 89, 90. *A. aristatus*; Hudf. 28. *Phleum crinitum*; Schreb. Gram. 151. t. 20. f. 3. Sm. Fl. Brit. 71. Fl. Græc. t. 62. *Agrostis triaristata*; Knapp. t. 23. *A. panicea*; Ait. Hort. Kew. ed. 1. v. 1. 94. ed. 2. v. 1. 148. Willd. Sp. Pl. v. 1. 363. Engl. Bot. t. 1704.)

—Awns thrice the length of the calyx. Root fibrous.—Native of moist, chiefly maritime, situations, in various parts of Europe, but rather rare in England. Dr. Sibthorp met with it in low ground about Athens. It is annual, flowering late in autumn. Root fibrous, small. Stems usually several, a foot or more in height, simple, ascending, leafy; some of them bent at the lower joints. *Herbage* pale, and rather glaucous. *Leaves* rough-edged, with long smooth sheaths. *Stipula* oblong, rough at the back. *Panicle* dense, erect, pale green, lobed and branched, of innumerable flowers, conspicuous for their long, tawny, shining, silky awns. The awn of the corolla is not longer than the valves of the calyx. We should have been glad if the authors we follow had retained *panicus* as the specific name. There are two varieties of this grass, made distinct species by Linnæus, but differing merely in luxuriance, owing to their growing in a more or less humid soil. The smaller is his *Alopecurus paniceus*.

2. *P. littoralis*. Short-awned Beard-grass. (*Agrostis littoralis*; Sm. Fl. Brit. 78. Engl. Bot. t. 1251. Dickf. H. Sicc. fasc. 16. 1. Knapp. t. 22. Ait. Hort. Kew. ed. 2. v. 1. 148.)—Awns about the length of the calyx. Root creeping.—This was first discovered in August 1777, in salt marshes on the north coast of Norfolk, by the Rev.

H. Bryant

H. Bryant and Mr. Rose; and has since been found in Essex and Kent; but in no other part of the world. Its affinity to the preceding species cannot be overlooked, but the *root* is perennial, creeping very extensively. *Stems* ascending, bent, and decumbent at their base, a little branched. *Leaves* roughish, slightly glaucous. *Panicle* purplish, much resembling the former in size and structure, but the awns of the *calyx* are scarcely so long as its valves, while that of the *corolla* exceeds its own valve in length, and extends rather beyond the *calyx*. Dr. Withering has actually figured and described, for the present species, a specimen of the preceding, sent him by some ignorant person from Wells, with a totally unfounded account of its first discoverer.

POLYPORUS, a name given by Micheli to the *Boletus* of Linnæus, expressive of the numerous pores which cover its under surface.

POLYPOSIA, a term used by the ancients to express a copious drinking of wine.

POLYPREMUM, in *Botany*, from *πολυς*, many, and *περιμνον*, a stalk, or shoot.—Linn. Gen. 56. Schreb. 74. Willd. Sp. Pl. v. 1. 623. Mart. Mill. Dict. v. 3. Pursh 99. Juss. 122. Lamarck Illustr. t. 71. Gærtn. t. 62.—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Scrophulariæ*, Juss.

Gen. Ch. *Cal.* Perianth interior, of four lanceolate, keeled, permanent leaves, internally coloured. *Cor.* of one petal, wheel-shaped; limb in four deep obovate segments, the length of the calyx. *Stam.* Filaments four, very short, in the bearded mouth of the corolla; anthers roundish. *Pist.* Germen superior, inversely heart-shaped; style short, permanent; stigma abrupt. *Peric.* Capsule ovate, compressed at the top, emarginate, of two cells and two valves, with a transverse partition. *Seeds* numerous, attached to an oblong ascending receptacle, connected below with the partition.

Ess. Ch. Calyx four-leaved. Corolla wheel-shaped, four-cleft, bearded at the mouth. Capsule superior, compressed, emarginate, of two cells. Seeds numerous.

1. *P. procumbens*. Linn. Sp. Pl. 161. Willd. n. 1. Figured in Petiv. Gazoph. t. 5. f. 6.—Native of dry pastures in North America, from Virginia to Georgia, flowering from May to August. The mouth of the *corolla* is bearded. *Pursh.* *Root* annual. *Stems* a foot long, spreading on the ground, very much branched and repeatedly forked, leafy, angular, with rough edges. *Leaves* opposite, sessile, linear-lanceolate, acute, rough-edged, about an inch long, resembling those of a *Galium*, their bases tapering, connected by a short membranous *stipula*. *Flowers* small, white, sessile, solitary in the forks of the stem, all together very numerous. The plant has the aspect of the pink tribe, to which Linnæus doubtfully referred it, principally on that account.

POLYPTOTON, Πολυπτωτον, in *Rhetoric*, a figure in which the same word is repeated in different cases, genders, or numbers, *i. e.* with different terminations.

Such is that of Cicero, pro Arch. "Sed pleni sunt omnes libri, plenæ sapientum voces, plena exemplorum vetustas."

So Virg. Æn. lib. iv. v. 28.

"Littora littoribus contraria, fluctibus undas
Imprecor, arma armis pugnent."

POLYPUS, the *Polype*, in *Zoology*. See **POLYPE**.

POLYPUS, in *Natural History*, a name given by some of the earlier writers to the thin shelled nautilus, or nautilus papyraceus. The body and arms of this creature somewhat

resemble those of the polype; it was supposed to be a species of polype enclosed in a shell, which it could quit occasionally, and go on shore to feed.

POLYPUS, in the language of *Surgery*, signifies a sarcomatous or fleshy excrescence, having a pedicle, and growing from the membrane, or lining, of various cavities of the human body. Thus, we meet with polypi of the nose, uterus, vagina, rectum, &c.

Polypi of the Nose and Throat.—These swellings have their origin in the substance of the pituitary, or mucous membrane, and may occur at any part of the whole extent of its surface; either at the entrance of the nostrils, in the fossæ nasales, in the irregularities of the ethmoid bone, or in the maxillary sinuses. Both children and grown-up persons are subject to nasal polypi, the cause of which is frequently very obscure, and even quite unknown. These swellings increase slowly, and the patients are not conscious of them until they have attained a certain size. The patient feels, at first, as if he had caught a cold, breathes with difficulty, loses, by degrees, the faculty of smelling, and perceives in one of his nostrils, seldom in both of them, a tumour, which is round, circumscribed, indolent, and of a greyish colour, inclining to red or brown; which is moveable, and causes more inconvenience in damp, than in dry weather. This swelling gradually enlarges, and at length either protrudes out of the nostril, or makes its way towards the nasal fossæ, and hangs down into the pharynx. It expands in every direction where there is most space, and least resistance to it, compressing the vomer, the ossa spongiosa, the nasal duct, and the orifice of the Eustachian tube. A polypus of the nose, or throat, whatever may be its magnitude, never has more than one root or pedicle, and the old opinion to the contrary is entirely unfounded.

The generality of surgical writers divide polypi of the nose into four kinds, according to the differences observable in the softness, hardness, and colour of these tumours. We have the *mucous*, or *vesicular* polypus; the *vascular* one, which is of a pale red colour; the *scirrhus* polypus; and that which is named *sarcomatous*. In the present place, we shall dismiss from consideration fungous diseases of the pituitary membrane, their nature having been explained in a former volume of this work. See **FUNGUS of the Antrum**.

The *mucous*, or *vesicular* polypus, so called from its resemblance to a round vesicle, is about as large as a grape stone, and of a greyish-ash colour. It is indolent, circumscribed, and never produces any serious inconvenience: it is scarcely ever single. Sometimes three or four distinct polypi of this kind are met with in the same nostril, and usually near its entrance. M. Lassus assures us, that he has never seen any situated in the posterior nasal fossæ. As the vesicular polypus is extremely soft, the slightest pressure breaks, or tears it. The extraction of it by means of forceps cannot be effected, except by small portions at a time, and the whole can be removed only by repeated introductions of the instrument. It is very apt to grow again, and its softness renders its complete extraction so difficult, that the practitioner is frequently under the necessity of cutting it away piecemeal, making use of a pair of dissecting forceps and scissars.

The *vascular* polypus is of a pale red, or sometimes of a brownish, or yellowish-brown colour, and it is the most common of all. It is soft, indolent, and moveable, with rather a broad base, and occasionally it fills the cavity of the nose completely, extending quite to the posterior nasal fossæ. It can be taken hold of with a pair of forceps, so as to admit of being entirely or partly extracted, which operation

tion is followed by a more or less considerable degree of hemorrhage.

The *scirrhus* polypus is as hard as cartilage, of which it also exhibits the colour. The strongest caustics, such as the liquid muriate of antimony, are said to be incapable of destroying it. The tumour is altogether insensible, and M. Lassus thinks the epithet *scirrhus* very applicable to it. The scirrhus polypi, which this gentleman has observed, filled the whole cavity of the nostril, to which they were likewise adherent. He considers them as incurable, since he has not succeeded in extirpating them either by excision, extraction, or caustics.

The *sarcomatous* polypus is red, fleshy, and of a dense fibrous texture: it is of considerable size, and of an oval oblong shape. As it usually hangs down behind the uvula and velum pendulum palati, which it pushes forward, it is sometimes called the polypus of the throat. It is implanted into the back part of the nasal fossæ, the ossa palati, the vomer, or the pterygoid fossa. Its attachment is seldom near the entrance of the nostril. It is furnished with numerous blood-vessels, bleeds profusely when an attempt is made to cut it out, is covered with a thin membrane, and its size never diminishes. When it descends into the pharynx, it obstructs deglutition and respiration, and renders the voice hoarse and thick.

A variety of plans has been suggested for the cure of polypi of the nose; excision, excision, extraction, setons, cauterization, and the ligature. The greater number of these methods, not attacking the root of the disease, not acting upon the insertion of the tumour, has fallen into disuse on account of their insufficiency. The method of excision, which was effected by means of astringent medicines, introduced into the nostril either in a dry or liquid form, has no action except upon such polypi as we have described under the name of *mucous*, or *vesicular*. The compression employed with the astringents, has also more effect than the medicinal applications themselves.

Excision, performed with a cutting instrument, is impracticable in a narrow tortuous space, like that of the nostrils. Extraction, by which is rather implied twisting the tumour off by means of forceps, is the only plan which is successfully adopted. The passage of a seton from the nostril into the mouth is prevented by the presence of the polypus itself, and if the introduction of this means were possible, the sound parts would be as much acted upon as the disease, and the swelling would be irritated, without being destroyed. As it is absolutely essential, in cauterization, that one precise point should be directly acted upon, without any injury being done to the healthy parts, this method is altogether hazardous, and very difficult of execution, especially when the actual cautery is that which is to be used. As for liquid caustics, they cannot be put upon the swelling, except when it is visible at the orifice of the nostril: it would be highly improper to attempt to apply them at random to any part of the tumour, which can neither be seen nor felt. Lastly, the ligature can only be applied to polypi of the throat. Such, therefore, as do not admit of being completely extracted, or twisted off, either at once, or at repeated times, are incurable, grow again, and, according to surgical writers, may even become cancerous, when irritated by violent means, on the inconsiderate application of caustic. Those indolent polypi, which ascend and descend in expiration and inspiration, which become larger in damp weather, and smaller in dry, which are attended with no head-ache, nor pain between the eye-brows, and round which a probe can be freely passed,

may and ought to be extracted. On the other hand, extensive adhesions, and the insertion of the tumour being deeply situated, may render the operation difficult, and, in the opinion of certain writers, ought to prohibit the attempt. The following is the manner of extracting a polypus from the nose. The patient should sit in an arm-chair in a good light, with his head supported on an assistant's breast. The practitioners then recommend him to snuff a little warm water up his nostril, and to blow his nose forcibly, in order to force the polypus as far out as possible. The proper forceps are then to be introduced, with which the tumour is to be taken hold of as deeply within the nose as the surgeon can manage to effect. The forceps are then to be slowly twisted round, and at the same time pulled outward, in proportion as the tumour yields and becomes elongated. Although a polypus has only one pedicle, it may have several appendices, and it sometimes happens, that merely one of these is extracted instead of the entire polypus.

It is possible, also, that there may be several distinct separate polypi in the nostril. In this case the surgeon is frequently obliged to introduce the forceps repeatedly, and to accomplish, by reiterated attempts, what he cannot do by one alone. When much bleeding arises, the surest and most ready mode of checking it generally consists in finishing the extraction of the whole of the swelling without delay. The patient may then be directed to snuff some cold water up his nose, or a mixture of vinegar and water may be injected up the nostril, and this aperture be plugged up with a dossil of lint. Should the blood run from the posterior openings of the nose into the back part of the throat, the accident may be obviated by passing from the nose into the throat a flexible bougie, or the stilet of a catheter, with a long ligature affixed to that end of it which is behind the uvula. The surgeon is to take hold of the extremity of the ligature, and then withdraw the bougie, or stilet, from the nostril. A large compress of lint is then to be fastened to the end of the ligature, which has been brought out of the mouth, and it is to be conveyed into the posterior nasal fossa by withdrawing the other end of the ligature from the nostril. In this manner an effectual degree of compression is made, and the hemorrhage is suppressed. In order to facilitate this operation, Bellocq, a French surgeon, invented a silver tube, which was a little bent, and included a flexible stilet, that could be pushed out into the back of the throat at the option of the practitioner: according to M. Lassus this instrument answers very well.

The ligature is the only means to be employed in the cure of polypi which present themselves towards the throat. Its use is attended with little pain, and it has the recommendations of not frightening the patient, and of constricting the root of the tumour, without any risk of hemorrhage. As it seldom happens that a patient is at the same time affected both with a polypus of the nose and one of the throat, the nostrils are unobstructed, and the surgeon therefore has it in his power to practise the method first suggested by M. Brasdor, member of the ancient French academy of surgery, and which several practitioners have subsequently endeavoured to simplify by some slight alterations. It may be executed as follows: the patient falling being seated in a good light, a long ligature is to be introduced through one of the nostrils down behind the uvula, for which purpose Bellocq's instrument, or a flexible bougie, is to be used. The ligature having been thus introduced, the instrument employed for passing it is to be withdrawn. Then the surgeon is to fasten to the end of the ligature in the mouth, the two extremities of a narrow silk ligature, which must

POLYPUS.

be about two feet in length, and doubled, so as to form a noose. The patient's head being now held back, the ligature, serving as a conductor to the silk noose, is to be gently drawn out of the nostril, and, in proportion as it is pulled out, the surgeon is, with his fingers, to get the silk noose as it passes behind the soft palate over the polypus. He is to continue to draw the noose out of the cavity of the nose, until he finds, from the resistance made, that the polypus is constricted as high up as possible at the place of its insertion. The two ends of the silk noose are next to be passed through a slightly curved silver tube, about six or seven inches long, which is to be introduced deeply into the nostril, and kept there the whole time of cure. A ring at the outer end of the cannula serves as a point, to which the ends of the silk ligature, after they have been sufficiently tightened, may be conveniently fastened. The silver tube is to be fastened to the patient's night cap with a ribband, and by tightening the silk twice a day, and twisting the cannula half round, the swelling becomes constricted, and falls off in the course of five or six days. Should the surgeon not succeed at first in conveying the noose over the polypus with his fingers, the noose must be drawn back towards the mouth, by means of a thread provided for the purpose, so that there may be no occasion for recommencing the operation. As it has sometimes happened, that the separation of a polypus of the throat, especially in the night time, has nearly suffocated the patient, M. Lassus is an advocate for passing a ligature through the tumour, with a long slightly curved needle, in order that the patient himself may be able to pull out the detached mass. The foregoing plan, if we can credit this last writer, was first devised by M. Dignet, principal surgeon of the Hospital S. L^ô. By him it was communicated to Default, who adopted it, and to whom it has since been erroneously ascribed. (*Journ. de Chirurgie, par Default, tom. iv. p. 283.*) The execution of this method is simple and easy, either when the operator faces the patient, or when the latter rests his head back upon the breast of the surgeon. As a polypus of the throat is not adherent to the uvula, nor soft palate, there is nothing to hinder the constriction from being made at the part where the tumour is inserted.

Polypi of the Uterus.—Polypi of the uterus were first described under the name of *môles pendantes*, or as extraneous substances. (*Fab. Hildan. cent. 2. obs. 52 et 55. Guillemeau, p. 267 de ses œuvres. Saviard, obs. 36. p. 168.*) Ruyfch was the first writer who gave a more clear account of the nature of these sarcomatous swellings, which, says he, being inserted by a pedicle, are formed in the uterus, just like polypi of the nose grow from the pituitary membrane. (*Observ. Anat. Chirurg. obs. 6 et 58.*)

It was, however, that intelligent practitioner, Levret, who subsequently illustrated this part of morbid anatomy by a large number of valuable observations. It appears from his remarks, and those made still more recently, that uterine polypi may be formed in three different situations: *viz.* 1. At some point of the inside of the uterus, and especially at the fundus of this organ. 2. In the kind of canal made by the elongation of the cervix uteri. 3. At the external or vaginal surface, or at the edges of the cervix uteri. See Levret's *Obs. sur la Cure radicale des Polypes de la Matrice et du Nez, Paris 1759, 8vo.*; et *Dissertation sur les Polypes de la Matrice, in Mém. de l'Acad. de Chir. tom. viii. 12mo.*

A polypus, growing in the cavity of the uterus, is at first soft, reddish, and of trivial size. It slowly distends the parietes of this viscus, and, after existing a certain time, acquires a round pyriform shape. It continues to increase,

and when it has attained a considerable size, it produces a slight swelling of the abdomen. By degrees, the cervix uteri becomes dilated, the os tincæ opens, and on the patient coughing, or making an exertion, the polypus slips out into the vagina, where its inferior part, which hardly sustains any compression, continues to enlarge, while its upper portion, which is surrounded by the cervix uteri, is rendered narrower by the constriction which acts upon it. Such a polypus is generally single, of a reddish colour, fleshy consistence, and fibrous and vascular texture. If left to itself, its own weight drags downward the fundus uteri, to which it is attached, and thus it often protrudes the vulva. Indeed, some polypi of the uterus of long standing have been known to become as large as a bullock's heart, and to weigh three or four pounds. In this state, the external round figure of the swelling may lead a careless practitioner to mistake the case for an inverted uterus; but it deserves particular notice, that a polypus, however great its size, is always quite incapable of reduction, and protrudes again immediately when the surgeon discontinues his efforts to get it up the vagina. Besides, it is invariably connected with a pedicle, remarkable for being much more slender than the rest of the swelling. The cervix uteri can be felt with the finger to be nearly in its natural situation, and it is equally obvious, that the tumour, which traverses it, has its origin from the fundus of this viscus.

These kinds of swellings produce different accidents, according to the place which they occupy. If the polypus be contained in the uterus, and remain there long, the inconvenience which it causes may be mistaken for the commencement of pregnancy. As the cervix uteri is not dilated, the existence of the tumour cannot be ascertained by a manual examination. The woman is troubled with colic, pains in the loins, hips, and above the pubes; she is subject to frequent bleedings, which become more and more considerable. When the polypus enters the cervix uteri, it renders this organ painful, the hemorrhage increases, and if a finger be passed sufficiently far up the vagina, a smooth slippery body may be felt protruding out of the dilated orifice. When the tumour has descended into the vagina, the patient is affected with difficulty of voiding her stools and urine, and the discharge of blood is almost incessant. When the polypus protrudes from the vagina, so as to appear in the form of a large swelling between the patient's thighs, its weight unavoidably drags downward the fundus uteri to which it is attached. This last viscus, as well as the vagina, undergoes a degree of prolapsus and inversion. Should the inversion not be considerable, the root of the polypus can be felt: should it be complete, two swellings present themselves; the lower one, formed by the polypus, being indolent and irreducible; the upper one, produced by the uterus in an inverted state, being capable of reduction and excessively painful. A polypus cannot be mistaken for pregnancy, a false conception, a prolapsus, or inversion of the uterus, or for any sort of hernial swelling in the vagina, if the practitioner will only bear in mind the symptoms peculiar to each of these cases, and not omit subjecting his patient to a careful manual examination.

There is yet another disease which may be mistaken for a polypus: it is a morbid elongation of the cervix uteri, an affection which is followed by an inversion of the vagina. In the natural state, the cervix uteri is not more than about an inch in length; but, in some women, it gradually becomes lengthened, so as to make a cylindrical body eight or nine inches long, without any perceptible alteration in the position of the uterus. An oblong, hard, sarcomatous, reddish swelling is the consequence, very much resembling the

the penis when tumefied, as it often is in severe cases of paraphimosis. (See PARAPHIMOSIS.) This tumour terminates in an oval gaping aperture, which, being in fact the os tincæ, gives issue to the menstrual discharge. If a probe be introduced into this opening, it passes along a space six or seven inches in length, before it reaches the fundus of the uterus, a circumstance proving that the disease consists altogether in an elongation of the neck of this organ, covered in part by the inverted vagina. Saviard has spoken of the disorder, under the title of "descente de matrice," as having occurred in a girl who was taken for an hermaphrodite. (Observ. 15. p. 70.) At a much later period, le Blanc, an eminent surgeon at Orleans, published several cases of this disease. (Opérations de Chirurgie, p. 412.) The affection admits of cure, even when it has attained the advanced state to which we have adverted. Such an elongation of the uterus has been mistaken for a polypus; a ligature has been rashly applied; and the patient has fallen a victim to this inexcusable error.

According to M. Levret, a polypus of large size, growing from the inside of the uterus, and partly or entirely protruding at the orifice of this organ, does not invariably render the woman who is thus afflicted incapable of conceiving; nor does it necessarily injure the growth of the fœtus, nor accelerate the period of parturition. (Mem de l'Acad. de Chir. tom. iii. p. 543.) Such cases, however, must be very uncommon, and, if they be admitted as unquestionable, it is at least certain that a large tumour, situated in the vagina, must render delivery laborious.

The observations of the latter writer also inform us, that a polypus, growing from the cervix uteri, is more frequently accompanied with a fluor albus, or an abundant serous discharge, than with an effusion of blood. From this he has inferred, that, in cases of fluor albus, a manual examination, for the purpose of detecting the cause, is as necessary as it is in instances of hemorrhage. However it may be, says M. Lassus, a woman with a polypus arising from the cervix uteri, feels about the rectum and perineum a sense of weight which hinders her from sitting down. When a finger is introduced into the vagina, a portion of the circumference of the cervix may be felt to be bent backwards in the manner delineated in plate 1, fig. 6 of Levret's *Traité des Polypes*. The finger cannot pass all round the root of the tumour, as it can when the polypus is inserted into the cavity of the uterus. A polypus, also, growing from the cervix uteri, if large, may bring on a prolapsus of this organ, but never can produce an inversion of it. *Pathologie Chirurgicale*, tom. i.

The symptoms are nearly the same when the polypus is attached to the edge of the external orifice of the uterus. This aperture is dilated: the portion of the cervix uteri, into which the tumour is implanted, is very much elongated; whilst that which faces the pedicle is in its natural state, and appears raised. The cervix uteri therefore is oblique; for a polypus always elongates the part with which it is connected. Hence, in consequence of its size and weight, it drags the uterus downward, and produces in a greater or lesser degree a prolapsus of this viscus. In M. Levret's work, plate 1, fig. 7, may be seen a representation of a polypus growing from the right edge of the orifice of the uterus, attended with obliquity of the cervix of this organ. The plates 15 and 16, of the third volume of the *Mémoires de l'Académie de Chirurgie*, also exhibit a polypus, which originated from the posterior lip of the cervix uteri, attained a large size without protruding at the vulva, and made its way backward betwixt the uterus and the rectum.

All these polypi are covered by a thickish membrane,

which is in fact the lining of the uterus, under which these swellings are said to be formed. Thus, when the pedicle is tied, it is the elongated thickened membrane of the uterus which is more or less firmly constricted. Hence the acute pain, the inflammation of that viscus, and the fatal symptoms which are apt to follow the operation of tying uterine polypi; evils which, if we are to believe Lassus, are generally ascribable to the ligature being at first too tightly applied. P. 545.

Polypi of the female parts of generation have been divided into two kinds; *viz.* uterine and vaginal. Lassus thinks this division has been made without good foundation. The swellings which are formed in the vagina, and have received the name of polypi, have not, according to this writer, any pedicle like those which grow from the inside of the uterus, or from its cervix. He states that they cannot be tied, but that they may be cut away. In his opinion, they are, for the most part, cancerous, or venereal excrescences; and some of them, he says, are swellings which are formed slowly between the vagina and rectum, and protrude into the former tube, which is afterwards more or less affected with prolapsus. These last tumours, which are hard, elastic, of middling size, protuberant in the vagina, and of the nature of steatoma, have been taken, in consequence of their colour and situation, for polypi, although they have nothing that can rightly be called a pedicle. Lassus thinks that Levret himself was thus deceived: the 27th observation in his memoir proves, when attentively perused, that the tumour which he calls a polypus, and with which a girl twelve years of age became afflicted, in consequence of a contusion of the parts of generation, was in reality formed in the cellular membrane of the vagina, which was inverted by the successive size of the swelling. The patient had the tumour till she was thirty-two years of age. (Mem. de l'Acad. de Chir. tom. iii. p. 572.) Levret applied a ligature with difficulty, and could tie only parts of the disease at a time; a circumstance which Lassus says is not surprising, as the nature of the tumour fitted it for excision.

Polypi, growing in the uterus, have sometimes been spontaneously expelled, nature of her own accord freeing herself from such excrescences after they have passed into the vagina. Then the cervix uteri strangulates the pedicle, so that the tumour perishes, and separates from the place where it first originated. It does not often happen, however, that nature thus accomplishes a cure; but art, in imitation of her, possesses the means of relieving such women as are afflicted with this disease.

They who have had children, and they who have not had any, are equally subject to the disorder, nor is the true cause of the complaint at all understood. There are also some cases, tending to prove that a polypus may be formed in the uterus of a young girl, and bring on symptoms resembling those which usually occur at the commencement of menstruation. *Deault, Journal de Chirurgie*, tom. iv. p. 276.

Two plans of destroying the pedicle of a polypus of the uterus, with a ligature as high as possible, so as to make the tumour slough, are daily adopted. The first is that proposed by Levret, which consists in putting over the polypus a noose formed of fine nealed silver wire, two or three feet long. The two ends of the wire are first to be introduced through two hollow silver cylinders, about eight inches in length, and soldered together throughout their whole extent. The noose and upper part of the instrument, from which the wire comes out, are to be conveyed along the posterior side of the vagina. The noose is to be put over the tumour, and the two ends of the wire, which hang out of the lower end of the instrument, are then to be tightened. The diameter

of the noose being lessened, in proportion as the extremities of the ligature are drawn out, the tumour is constricted, swells, and afterwards mortifies. The constriction may be augmented, by turning the instrument repeatedly round in one direction, after the wire has been fastened to the rings made for that purpose. The degree to which the instrument is to be twisted, ought to be regulated by the pain which the patient suffers, the surgeon being careful not to cause too great agony. Lastly, the instrument must be fastened with a bandage to one of the thighs, until the polypus is completely detached.

This method is easy of execution, and answers very well when the tumour is rather large and protrudes into the vagina; but as it is necessary that the introduction of the noose, which is to be put over the polypus, should precede the introduction of the instrument itself, the wire is apt to be stopped by the rugæ of the vagina, and to bend, and when the pedicle of the tumour reaches only a little way out of the os tincæ, the noose cannot be got round it.

A second plan has been devised, which consists in moving round the swelling two separate tubes, or solid long pieces of metal, so as to tie the pedicle of the tumour with a thread ligature, which either passes through the cannulæ, or through two little rings mounted on the long pieces of metal. This sort of ligature is said not to be so liable to break as silver wire. This mode of operating is that which has been practised by Herbiniaux, Default, Cullerier, and others. It is in the works of these writers that the professional reader will find a description of their respective instruments, which are also more easily comprehended when seen, than when only verbally explained.

The ligature, when applied with due tightness, extends its action a good way beyond the part which it embraces. The whole tumour is detached at the very place of its insertion, without any vestige of the disease being left. The ulceration of the uterus naturally existing after the detachment of the polypus spontaneously heals; and a thin discharge continues for a little while, which may readily be cured by suitable injections. LASSUS, *Pathologie Chirurgicale*, tom. i. chap. 78.

POLYPYRENEOUS FRUITS, in *Botany*, are such as contain several kernels or seeds.

They are thus called from the Greek *πολυ*, much, and *πυρον*, kernel or berry.

POLYSACTINODOS, in *Natural History*, a name given by Linkius, and some other authors, to those star-fish whose body is divided into more than five rays, that being the more usual and general number.

POLYSARCIA, in *Medicine*, from *πολυ*, much, and *σαρξ*, flesh, a term used by some writers to denote obesity.

Sauvages makes polyfarcia a genus in his classification, but includes under it only one species, polyfarcia *adiposa*. Nofol. Meth. class x. gen. 4. See **CORPULENCE**.

POLYSCHIDES FUCUS, a sea-plant, called in English *sea-banger*. It is one of the largest sea-plants we know, growing often to ten feet or more in length. Its root is not flat in the manner of most of the other sea-plants, but is composed of several little hooks, all which lay fast hold of the stone on which it grows: these, in some measure, resemble the tendrils of the vine, and are somewhat broad and flattened at the end, where they are fastened to the stone, though round elsewhere, and are about half an inch long. These hooks grow from a broad flattish part at the bottom of the stalk, which is often four or five inches in diameter, and is usually hollow, being composed only of two membranes considerably tough and firm, with a cavity between them; from the centre of this rises the stalk, which is often

twisted and undulated at the edges; from the top of this stalk grows the leaf, which is divided into eight or ten segments; each of which is often again divided into two. These segments are very long, and, as the plants float in the water, give it much of the appearance of a broad piece of leather cut into several thongs: these all terminate in sharp points, and their colour is a brownish-green. The nicest eye cannot distinguish the least nerve or fibre, either in the stalk or leaf of this plant; but on great numbers of these plants, that curious inquirer, M. Reaumur, found flowers of the same kind with those which he originally discovered on the common ferns: they are composed of slender filaments, not exceeding the twentieth part of an inch in length; and these were the more easy to be overlooked, as they are of the same colour with the leaves of the plant. Those plants on which M. Reaumur found these flowers were not, however, entirely covered with them; but they stood at about a twelfth of an inch distance from one another. It was in the month of July that M. Reaumur examined this plant, and at that time there were no seeds discoverable upon it; but doubtless at a proper season, and with proper care in the observer, they will hereafter be discovered as plainly in this as in many other of the sea-plants, usually supposed by authors to have wanted them. *Mem. Acad. Par.* 1712.

POLYSCOPE, a multiplying glass, *i. e.* a glass which represents one subject to the eye as if it were many; called also *polyhedron*.

POLYSPASTON, *πολυσπαστον*, from *πολυ*, and *σπασω*, *traho*, I draw, *q. d.* that may be drawn many ways, in *Mechanics*, a machine so denominated by Vitruvius, consisting of an assemblage of several pulleys, used for raising of heavy weights in a little time.

The multiplication of pulleys in the polyspaston is to very good purpose; it being demonstrated in mechanics, that the force required to sustain a weight by means of a polyspaston is to the weight itself as unity to the number of ropes, or of the pulleys, those ropes or pulleys being supposed parallel to each other. See **PULLEY**.

Hence the number of pulleys, and the power, being given, the weight that will be sustained thereby is easily found, *viz.* by multiplying the power by the weight.

E. gr. Suppose the power 50 pounds, and the number of pulleys 5, the weight they will balance is 250 pounds.

In like manner, the number of pulleys being given, together with the weight sustained, the power is found by dividing the weight by the number of pulleys: thus, if the weight be 900 pounds, and the number of pulleys 6, the power will be 150 pounds.

Dechales observes, that it is found by experience, that a moderate man, standing barely on the ground, will lift 150 pounds; whence the same man, by means of a polyspaston consisting of six pulleys, will be able to sustain 900 pounds.

The power of the pulleys will be still exceedingly increased by joining several polyspastons.

To find the number of pulleys a polyspaston is to consist of, to arise a given weight by a given power. Divide the weight by the power; the quotient is the number required.

Suppose, *e. gr.* the weight 600 pounds, and the power 150; the pulleys will be 4; whose diameters are to be all equal, supposing two of them upper, and two lower, moveable on the same common axes.

POLYSPASTUM, a powerful instrument for reducing dislocations.

POLYSPERMOUS PLANTS, in *Botany*, are such as bear more than one seed in each seed-vessel.

POLYSTICHUM, a genus of *Filices*, founded we believe

lieve by Roth, but not adopted by the leading writers on that family.

POLYSTYLE COLONNADE. See **COLONNADE.**

POLYSYLLABICAL ECHOES, those which repeat many syllables or words. See **ECHO.**

POLYSYLLABLE, from *πολυ*, *much*, and *συλλαβο*, *syllable*, in *Grammar*, a word consisting of more than three syllables.

Shuckford refers the origin of polysyllables in language to the confusion of Babel; observing, that the languages which most probably arose about this time do remarkably differ from the most ancient Hebrew, in words of a greater length than that of the original Hebrew words. The Chaldean, Syrian, Egyptian, and Arabian languages, he says, afford instances of this kind, as well as the more modern tongues. *Conn. of the Sacred and Profane Hist.* vol. i. p. 136, &c.

POLYSYNDETON, *πολυσυνδετον*, in *Rhetoric*, a figure consisting in the union of the several parts of a sentence by proper particles.

Such is, *Me præ ceteris & colit, & observat, & diligit.* In opposition to this stands *asyndeton*.

This figure adds a weight and gravity to an expression, and makes what is said to appear with an air of solemnity; and by retarding the course of the sentence, gives the mind an opportunity to consider and reflect upon every part distinctly. We often meet with this figure in Demosthenes, which very well suits the gravity of his style. Thus he encourages the Athenians to prosecute the war against king Philip of Macedon, from this consideration, that now "they had ships, and men, and money, and stores, and all other things, which might contribute to the strength of the city, in greater number and plenty than in former times." *Philipp.* iii.

POLYTHALAMIUM, in *Natural History*, a name by which some authors have called the tubuli marini concamerati, a sort of sea-shell found frequently fossil, with other shells, in Sweden, and brought over to us in the stones used for pavements, but not known in its recent state.

It is of the same general structure with the cornu ammonis, and thick nautilus, being composed of several cells or cavities, communicating with one another by means of a siphunculus or pipe; but it is usually straight, though sometimes its end is twisted exactly in the manner of the cornu ammonis.

POLYTHALAMIUS, a term invented by Breynius, to express a class of shells, the character of which is, that they are hollow shelly bodies, either straight or regularly twisted into a spiral form, always wide at the mouth, and growing narrower to the other extremity. They are divided within into several cells or chambers, which are called *thalami*, each separated from the other by a diaphragm, or partition of shelly matter. The upper or largest chamber contains the body of the animal; but all the others are perforated by a siphunculus, which gives them communication one with another, and which runs from the mouth to the very apex, growing slender all the way.

Of this class he distinguishes four genera, the orthoceros, lituus, ammonites, and nautilus. The two last of these, he observes, have been long well known to the world; the two first he gives as new, and of his own discovery.

Of the orthoceratitæ, which are stones cast in the shells of the orthoceros, there are at present distinguished nine kinds; these differ from one another principally in the position of the siphunculus, or in their external form; the cone which they describe running quicker or more gradually to a point;

or, finally, by the thalami or chambers being wider or narrower.

POLYTHEISM, from *πολυ*, *much*, and *θεος*, *deus*, the doctrine or belief of a plurality of gods. See **GOD**, **IDOLATRY**, and **JUPITER.**

It has been a subject of controversy among philosophers and divines, whether idolatry and polytheism, or the knowledge and worship of the *one* true God, constituted the first religion of mankind. Mr. Hume, in his "Dissertation on the Natural History of Religion," having endeavoured to shew, that the first men were not qualified to find out the existence and perfections of God, the sole creator of the universe, by reasoning from the works of nature, deduces from the position this conclusion, that theism was not the first religion of the human race. "If," says he, "we consider the improvements of human society from rude beginnings to a state of greater perfection, polytheism and idolatry were, and necessarily must have been, the first and most ancient religion of mankind;" and again, he pronounces it "impossible that theism could, from reasoning, have been the primary religion of the human race." To the same purpose, lord Bolingbroke observes, that "though the first men could doubt no more that there is some cause of the world, than that the world itself existed, yet in consequence of this great event, and of the surprise, ignorance, and inexperience of mankind, there must have been much doubt and uncertainty concerning the first cause.—The variety of phenomena which struck their senses would lead them to imagine a variety of causes." Dr. Leland (*ubi infra*) seems disposed to allow, that if men were left merely to themselves, without any other guide, they might be apt to imagine a multiplicity of causes and authors of the universe; and that the most conspicuous parts of it, which they might suppose to be distinct worlds, had different authors and architects. Hence this learned writer concludes, that the first men did not, probably, acquire the knowledge of God and religion by the mere force of their own reason; and therefore, that the Deity interposed, in an extraordinary manner, for their instruction. Consequently that, which in speculation is a most reasonable hypothesis, appears, from the account given by Moses, to have been true in fact; or that to supply the want of experience and observation on the part of the first parents of the human race, God was pleased, in his great goodness, to favour them with extraordinary notices and significations of his will and of their duty. It is also rational further to conclude, that they must have been led, both by a sense of duty and inclination, to communicate the knowledge which they thus received to their posterity. And the long lives of the first man and his immediate descendants, gave them a singular advantage for preserving and propagating by tradition the knowledge that was imparted to them at the commencement of their existence. It is easy to conceive, that it might, without much difficulty, be transmitted to Noah, the second father of mankind: for Methuselah was contemporary with Adam about 245 years, and with Noah 600 years; and as Noah himself was a man of eminent piety and virtue, and lived 600 years with those of the old world, he would, without doubt, take care to obtain a true information of the original principles of religion delivered to the first parents of mankind. Besides we may no less reasonably conclude, that God would make farther discoveries of himself and of his will to Noah, to be by him communicated to his descendants: and this may be justly regarded as a second promulgation of religion in its main principles to the whole human race. Accordingly we may reasonably suppose, that in those parts of the world which were first peopled after the flood, and which were
nearest

POLYTHEISM.

nearest the place where the first restorers of the human race chose to reside, what remained of acts or knowledge, after the universal shipwreck, was chiefly to be found. Thus also it might be expected, that the greatest vestiges of the ancient religion might be traced, as being nearest the fountain-head. And they that were afterwards scattered to distant parts would be apt sooner to lapse into ignorance and barbarism. The best remains of ancient history agree in this with the Mosaiical accounts; that in the eastern parts of the world, *i. e.* where Noah and his family first settled after the flood, societies and civil polities were first formed, cities built, and arts cultivated. The East was the source of knowledge, from whence it was communicated to the western parts of the world. There the most precious remains of ancient tradition were to be found. Thither the most celebrated Greek philosophers afterwards travelled in quest of science, or the knowledge of things divine and human: and thither the law-givers had recourse, in order to their being instructed in laws and civil polity. But without pursuing this digression, we may observe that religion, which first entered into the world by divine revelation, communicated by the Deity to the first parents of the human race, was delivered down by tradition to their descendants; though, in process of time, it became greatly obscured, and corrupted with impure mixtures. Thus theism, or the acknowledgment and worship of one God, although it was not the mere result of reasoning, was nevertheless the religion of the first ages; and polytheism and idolatry, so far from being the first and original religion of mankind, were the corruption of it. The farther we trace the removal of nations from the earliest ages, the more we find that they degenerated from the primitive religion. The nations which made the greatest figure in the most ancient times, were the Assyrians and Chaldeans, the Persians, Phœnicians, Arabians, and Egyptians; and there is great reason for thinking, that among all or most of these the worship of the one true God was preserved for some ages after the flood. To these might be added the ancient Chinese, the Indian Brachmans, and especially the ancient Persians, who seem to have been adorers of the true God in the earliest times. The Chaldeans and Assyrians seem to have been among the first corruptors of the true ancient religion. (Josh. xxiv. 3.) See IDOLATRY.

According to Mr. Kirwan (Transf. of R. Irish Acad. vol. xi.) the corruption of the primitive patriarchal religion arose from the cessation of the Schechinah, when mankind directed their worship to the sun, in which the deity had placed his Schechinah, and to the other heavenly bodies. This writer also asserts, upon authority no less insufficient, that the Hellenistic Greeks were the last of all civilized nations, which embraced polytheism and idolatry; and that the introduction of polytheism into Greece must be attributed solely to the Phœnicians.

The learned Cudworth observes (Intell. System. ch. iv. § 19.), that though the poets were the great depravers of the true primitive religion and theology among the Pagans, yet that they kept up the ancient tradition of one supreme Deity. Amidst the crowds of divinities which they mention, there is still in all their writings the notion of One Supreme, of whom they speak in the highest terms, and to whom they ascribe the highest divine attributes, and which are peculiar to the one true God. Several passages might be produced to this purpose from Homer and others of the Greek poets, who are followed in this particular by the Latins. See Plautus in the prologue to his Rudens, ver. 9. Virgil, *Æn.* l. x. v. 2 and 18. Horace, *Od.* xii. l. i. and l. iii. vol. iv. Cudworth (*ubi supra*) has collected other similar testimonies.

Among the illiterate and barbarous nations we also perceive traces of their acknowledgment of one supreme

Divinity. Nevertheless, this notion of a supreme Deity, which generally and for many ages prevailed, and which is so highly agreeable to reason, was at length, through the negligence and corruption of mankind, astonishingly perverted and depraved. It was covered and overwhelmed so as to be scarcely discernible under a monstrous load of superstitions and idolatries. The great number of divinities that were from time to time introduced, and the worship of which was established by public authority, turned off their attention and regards from the one true God, so that he was in a great measure neglected and overlooked, whilst they paid that worship to vain idols which was due to him alone.

The most ancient idolatry (see IDOLATRY), and that which was probably the first deviation from the worship of the one true God, seems to have been the worship of heaven and the heavenly bodies, the sun, moon, and stars. At first these were probably considered in a subordination to the Supreme, as the most glorious ministers of the Most High, and to whom the administration of things was chiefly committed; to whom therefore they paid a subordinate worship. But they afterwards regarded them as the principal deities, who had an universal dominion; and on whom mankind had their chief dependence. Thus was introduced a plurality of deities; and the knowledge and worship of the only true God was in a great measure neglected and lost. To this species of idolatry may be referred the worship of the whole compass of heaven or circumambient ether, to which divinity was ascribed, and which many of them esteemed to be the chief God; not considered merely as inanimate, but as animated with a soul, of which all the heavenly bodies are partakers.

This kind of idolatry, which the scripture calls the worship of the host of heaven, hath spread generally through the Pagan nations in Europe, Asia, Africa, and America, not only among the savage and illiterate, but the most learned and polite. Lord Herbert, in his book "De Religione Gentilium," apologizes for this idolatry, by saying, that they worshipped the stars to the honour of the supreme God.

Another species of idolatry, which began at an early period, and which very generally prevailed, was the worship of deified men or heroes. Here opens a new scene of polytheism, which produced an amazing multiplicity of gods, and continually increased.

The learned Cudworth maintains, that according to the more recondite and arcane theology of the Pagans, the three capitoline gods, Jupiter, Minerva, and Juno, as well as some others, may be understood to have been nothing else but several names and notions of one supreme Deity, according to its several attributes and manifestations.

We may here observe, that in consequence of blending the history of their heroes with their theology, the Pagan mythologist often ascribed very scandalous actions to their gods; and particularly to Jupiter, whom they regarded as the chief of them. Whilst they applied to their deities the most divine titles and attributes, they represented them with all the passions, and even vices of frail mortals: and hence they were led to speak of their deities in the most contemptuous manner. The primitive Christians looked upon the name of Jupiter as so contaminated and polluted, that they would rather endure the greatest torments, than make use of it to signify the one true God.

The most plausible apology, which is made for the Pagan polytheism, is, that the one true God was worshipped under different titles and characters: that those which are reckoned distinct deities and objects of worship, were really no more than different names or attributes of the one supreme Deity according to his various manifestations and effects. This is what the Stoics and some of the other

philosophers maintained. But these pretences of the philosophers made little impression upon the people, who had been always used to worship them as so many distinct personal divinities, and knew very well, that the public religion regarded them as such. In process of time, instead of adoring the one supreme God under his various names and attributes, these very names and attributes were now changed into so many different gods and goddesses, who were worshipped with different and sometimes with contrary rites; and they became an occasion of further polytheism and idolatry.

As the different names, so also the different symbols invented and made use of to denote the divinity, came also to be worshipped as gods; such as fire among the Chaldeans, the cow and bull among the Egyptians. And it is not improbable, that the other animal gods worshipped by the Egyptians, the sheep, goat, hawk, ibis, ichneumon, crocodile, cat, dog, &c. were at first designed as symbols and hieroglyphical characters of the supreme Deity, or some of his attributes; or, as the learned author of the "Divine Legation of Moses" supposes, they were marks of their elementary gods and heroes. But afterwards they worshipped and deified the symbols themselves, and thereby fell into the most stupid and gross idolatry, which exposed them to the ridicule of other Pagans. The same observation is applicable to the images which were erected to their deities, and which were supposed to have divine power residing in them. These very images became gods, and were worshipped as such, and had divine honours rendered to them: and this circumstance contributed very much to augment the multitude of their gods.

Their physiology also, as they managed it, was another fruitful source of polytheism. The first physiologers, being mostly poets, disguised the simple original tradition of the creation of the world by allegorical descriptions of the nature and origin of things. They turned natural objects and the parts of the universe into allegorical persons, and spoke of them as so many distinct divinities; and at the same time they mixed these physical fables and allegories with the disguised traditionary accounts of their ancient heroes. Thus the number of their gods and goddesses was strangely multiplied. Upon the same principles, divinity came to be ascribed to whatever was useful in human life. Hence it was that they called wine Bacchus, fire Vulcan, and corn Ceres, &c. Temples were also erected to mind, faith, virtue, health, concord, honour, victory, liberty; and because the force of these things was so great, that it could not be governed without a god, the thing itself obtained the name of god. Thus the qualities and affections of rational beings, and even the accidents which related to them, were personified, turned into deities, and became the objects of worship: and this honour was rendered not only to qualities and accidents that were good and useful, but to those that were bad and hurtful. At Rome a temple was erected to the fever, and an altar to evil fortune; and even lust and pleasure were consecrated, so that Voluptas, the goddess of pleasure, and Libentina, the goddess of lust, had temples erected to them. The Athenians, by the advice of Epimenides, erected a temple to contumely and impudence. Upon the whole, there was scarcely any thing in nature, which was not worshipped and deified by some or other of the Heathens. It cannot be denied, says Cudworth, that the Pagans did in some sense or other deify or theologize all the parts of the world, or things of nature. Accordingly they called every thing by the name of God, and God by the name of every thing. See MYTHOLOGY and THEOLOGY.

The learned bishop of Gloucester, in his "Divine Legation," has advanced an opinion with regard to the design and use of the Mysteries, which Dr. Leland has shewn to

be erroneous. The prelate maintains, that they were intended to detect the error of the vulgar polytheism, and to bring men to the acknowledgment and adoration of the one true God. Leland's Advantage and Necessity of Christian Revelation, vol. i. c. 8, 9. See MYSTERY.

Pagan philosophy, notwithstanding the high encomiums that have been passed upon it by its admirers, and even by some of those who have thus indirectly depreciated Christianity, was of little use for leading the people into a right knowledge of God and religion, and for reclaiming them from their idolatry and polytheism. For if the philosophers had been right in their own notions of religion, their influence on the people was very inconsiderable, because they wanted proper authority to enforce their instruction. Besides, they affected an obscurity in discoursing of the principles of their philosophy, especially when they treated of religion and divine things, which rendered them altogether unfit for instructing the people in religion. They not only disguised and concealed their principles from the vulgar, but they were themselves dark and uncertain in their judgment concerning matters of the greatest consequence. They also entertained very wrong notions concerning the Deity; and considering their errors and defects, they were not likely to succeed, even if they had really intended it, in reclaiming the multitude from idolatry and polytheism. The greatest and best of the Pagan philosophers generally expressed themselves in the polytheistic strain; and therefore, instead of leading the people to the one true God, they spoke of a plurality of gods, even in their most serious discourses. They ascribed those works to the gods, and directed those duties to be rendered to them, which properly belong to the Supreme. The censures therefore which Dr. Cudworth has passed upon the poets, may be justly applied to the most celebrated philosophers; *viz.* that they made the theology of the Pagans look aristocratically—by their speaking so much of the gods in general, and without distinction, and attributing the government of the world to them in common, as if it were managed and carried on by a common council and republic of gods, in which all things were determined by a majority of voices, and as if their Jupiter, or supreme god, were no more among them than a speaker of the house of lords or commons, or the chairman of a committee. The same learned author acknowledges, concerning the Stoics, that they often derogate from the honour of the supreme Deity, by attributing such things to the gods in common as the donors of them, which plainly belong to the supreme God. Moreover, the philosophers generally encouraged divination and the oracles. This was the case with regard to Socrates, Plato, and the Stoics; and they thus countenanced the popular idolatries and superstitions. Besides, it was an universal maxim among them, that it was the duty of every wise and good man to conform to the religion of his country; and not only did they worship the gods of their respective countries, according to the established rites, and exhort others to do so, but when they took upon themselves the character of legislators, and drew up plans of laws, and of the best forms of government, it was polytheism, and not the worship of the one true God, which was the religion they proposed to establish.

It must be owned that at the time when Maximus Tyrius, Plutarch, and Apuleius wrote, who all express themselves in a similar manner, the unity of god was far more generally known and acknowledged among the Pagan nations than before. But this was not owing to the reasoning of the philosophers, but to the light of Christianity, which then became generally diffused, and for which the Jewish revolution had prepared the way. It is needless to degrade the human intellect, or to depreciate the powers of reasoning,

in order to enhance the advantage which we derive in forming just conceptions of the perfections and providence of the Deity from divine revelation. This teaches us to reason correctly concerning the unity and attributes of God; and has done more towards preserving or recovering mankind from idolatry and polytheism, than all the efforts of the wise and learned in preceding ages of the world. How little availed the speculations of human learning and philosophy towards the accomplishment of these great objects! Do we not find in fact, that notwithstanding their instructions and illuminations, the popular idolatry and polytheism, and the many absurd and abominable rites of the Heathen superstition, still kept their ground. The philosophers never converted so much as a single village from idolatry. On the contrary, they patronized it by their maxims, and countenanced it by their practice. It is evident that whatever high opinion some have entertained of the Heathen learning and philosophy, they were unable to reform a corrupt and idolatrous world. These had been tried for many ages. "Philosophy," as Mr. Locke observes, "seems to have spent its strength, and done its utmost." And yet, after all, it was found ineffectual. Human reason, therefore, needed higher assistance. "Reason," says Leland, "may be, and has been, of great use, when under the conduct of divine revelation, and making use of the light which that affords; but when trusting to its own force, it has affected an independency, and endeavoured to strike out new paths; it has often made wild work in religion, and plunged men into atheism, scepticism, and infidelity on the one hand, or into idolatry, superstition, and numberless varieties of error on the other." If the philosophers could effect no reformation in religion, it was in vain to expect it from the priests, who were the great promoters of polytheism, and all the absurd rites of the Pagan superstition. Can it be imagined, that they would instruct the people to abandon that idolatry by which they maintained their own reputation and interest? Or, would the lawgivers and politicians, and great men of the state, attempt it? The public laws in every city and country established idolatry. Now, what other method could human wisdom devise to reform and recover mankind from their idolatry and polytheism to the right knowledge and worship of God, but the doctrines of their wise men and philosophers, the instructions of their priests, and the authority of the legislators and civil powers? But all these were found in fact and experience to be insufficient. At length Christianity triumphed over all opposition, and proved itself the "wisdom and power of God" for the destruction of polytheism and idolatry. Hence we learn, with an evidence that obviates every prejudice, and with an efficacy which overpowers all resistance, that there is one God, the object of universal worship, and one mediator between God and man, Christ Jesus. This clear and unequivocal dictate of revelation is confirmed by a variety of collateral arguments. The unity of God is deducible from his self-existence. There cannot be two or more beings existing by absolute necessity of nature; because all such beings, one excepted, may be supposed not to exist, without incurring a contradiction. It is only contingent existence that admits of diversity and multiplicity. Simplicity and unity are included in the idea of necessity. There are numberless beings who participate of perfection in an infinite variety of degrees; but there can be only *one* being, who is absolute perfection itself. There are numberless beings, who are powerful, wise, and benevolent; but there can be only *one* being, of whose nature, power, wisdom, and benevolence in necessary union, and forming one idea, are the essential attributes. It is not possible there should be two infinite beings, because they must either have several perfections or

the same; neither of which is consistent with the most obvious notion of God that he is a being of all possible perfection. The contemplation of the frame of nature leads us to ascribe its origin and contrivance, not only to design, but to unity of design. See Wilkins Nat. Rel. Locke's Fam. Lett. Price on Morals, Appendix. Clarke on the Attributes. Abernethy's Serm. vol. i. serm. v. Knight on the Attributes. Howe's works, vol. i.

POLYTHRIX, the *hair-stone*, a name given by some writers to those German agates which have received into their mass, while yet soft, either the branches of the conservæ, or other capillary water-plants, or else have thin streaks of a coarser matter frequent in them, and running in the form of hairs. See **AGATE**.

POLYTRICHUM, in *Botany*, from *πολυς*, *much*, and *τριξ*, *τριχος*, *hair*, an old name, alluding to the numerous brittle-like stalks which support the capsules.—Linn. Gen. 563. Schreb. 762. Dill. Musc. 419. Hedw. Fund. v. 2. 90. t. 7. f. 37. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 1372. Juss. 11. Lamarck Illustr. t. 874.—Class and order, *Cryptogamia Musci*. Nat. Ord. *Musci*.

Ess. Ch. Outer fringe of thirty-two or sixty-four short, flat, incurved teeth: inner a flat, transverse, orbicular, undivided membrane. Veil generally double: the outer hairy.

A genus of Mosses remarkable for their great stature, exceeding that of any others of this family, and clearly distinguished from all the rest by the structure of the fringe, even more certainly than by the rough, hairy, and usually double veil. Mr. Menzies, in Tr. of Linn. Soc. v. 4, has admirably illustrated the species of this genus, though he limits it according to the ideas of Linnæus, excluding certain species whose veil, though roughish, is simple, but whose fringe is precisely that of a *Polytrichum*, and unlike every thing else. These are *P. hercynicum*, Hedw. Crypt. v. 1. 40. t. 15. Engl. Bot. t. 1219, an Alpine species; and the common *P. undulatum*, Hedw. Crypt. v. 1. 43. t. 16, 17. Engl. Bot. t. 1220. (*Bryum undulatum*; Linn. Sp. Pl. 1582. Curt. Lond. fasc. 1. t. 70.)

Hedwig describes seventeen species of *Polytrichum*, in his Sp. Musc. 88—103. Sixteen are natives of Britain; some of them not known to Hedwig; as *P. rubellum*, Menz. Tr. of Linn. Soc. v. 4. 79. t. 7. f. 3. Engl. Bot. t. 1939; and *P. Dicksoni*, Turn. Musc. Hib. 90. t. 10. f. 2. Engl. Bot. t. 1605.

The following will serve to exemplify the genus.

P. commune. Common Hair-moss. Linn. Sp. Pl. 1573. Fl. Brit. n. 1. Engl. Bot. t. 1197. (*P. quadrangulare vulgare*, juccæ foliis ferratis; Dill. Musc. 420. t. 54. f. 1.)—Stem simple. Leaves linear-lanceolate, finely serrated. Capsule erect, quadrangular. Pedestal roundish.—Common in boggy or turfy groves and woods throughout Europe, bearing capsules with us in May and June. *Herb* perennial, forming large tufts of simple plants, matted together by the copious fibres of their very long unbranched creeping *roots*. *Leaves* of a fine dark shining green, spreading every way, copious, linear-lanceolate, acute, rigid, smooth, without a keel; their base membranous and sheathing. *Flowers* dioecious, terminal; the males pale, disk-like, surrounded by numerous short, dilated, membranous-edged leaves, and mostly proliferous from the centre. *Fruit-stalks* produced after the female flowers are faded, solitary, erect, firm, red, shining, two or three inches high; paler upwards; sheathed with several brown scales at the base. *Capsule* erect, short and thick, standing on a depressed, green, tumid base or pedestal. *Lid* depressed, yellowish, with a red crenate edge, and a short, straight, slender point. *Outer fringe* of sixty-four white-edged teeth, connected at their base. *Veil* double; the

outer of innumerable brown shaggy hairs; inner membranous, shorter, tubular, cloven at the bottom.

P. alpinum. Alpine Hair-moss. Linn. Sp. Pl. 1573. Fl. Brit. n. 7. Engl. Bot. t. 1905. (*P. alpinum* ramosum, capsulis e summitate, ellipticis; Dill. Musc. 427. t. 55. f. 4.)—Leaves lanceolate-awl-shaped, finely serrated. Capsule ovate, drooping. Pedicel turbinate. Stem branched.—Native of alpine tracts, on the mountains of Wales, Scotland, Switzerland, &c.; found by Dr. Swartz even on the lowland rocks of Sweden. The stems are three or four inches high, very slender below, copiously branched and level-topped above. Leaves brownish-green, recurved. Fruit-stalks yellowish, an inch and half high, slightly wavy. Capsule ovate, turgid, brown, soon drooping. Fringe of thirty-two teeth.

POLYTROPHOS, a name given by the Greeks to coarse bread, from its conveying much more nourishment to the body than the finer kind; which they called, by way of distinction, *oligotrophos*.

POLYZONOS, in *Natural History*, a name given by the ancients to a species of onyx, which had a dark or blackish ground, with a great number of zones.

POLZANO, in *Geography*, a town of Naples, in the province of Otranto; 5 miles S.E. of Tarento.

POLZEVERA, a part of the Bochetta or mountains north of Genoa, through which a magnificent road was made in 1778; the labour of which employed, for the space of three years, from 5 to 800 men, by the patriotic munificence of one noble family, the Cambiasi.

POLZEVERA, in *Mineralogy*, a species of compound stone, consisting of serpentine, mica, and calcareous spar, so called from the place in the mountains of Genoa where it is found.

POMA, in the *Writings of the Old Greek Physicians*, a word which has given the commentators a great deal of trouble rightly to explain.

Brassavolus says, that it means all sorts of shelly or crustaceous covering of fishes: but this is an absolute error; for even the medical authors do not extend its sense so far as that. The Greeks called all shells by the name *ostraca*, and this author attributing a different virtue to the whole shell of the purpura, sufficiently speaks this poma to have been but a part of it.

The Arabian writers were sensible of this, and rendered it by the words *adfor alhaib*, which signify fragments like nails. Serapio calls it *mucatha*, which signifies a morsel or piece of any thing cut from a solid body. The original sense in which the Greeks used the word poma, was to express the thing that closed the mouth of any vessel with a long and narrow neck. The Latins expressed this by the word *operculum*, and sometimes, as in Sulpicius Severus, by the word *umbo*.

The ancients also used the word poma to express the lid or covering of a well, or of any hole. Now the purpuræ buccina, and all those other shells which the Greeks have called *stromboide*, may in some sort be compared to narrow and deep vessels, and they have all of them a sort of poma; or, as the Latins have expressed it, an operculum, to stop the mouth of the shell, and prevent the ingress or egress of any thing at the creature's pleasure. This operculum, being what Aristotle has called *opicalimma*, is certainly also what Dioscorides means by the word poma; Aristotle has been very express in his description of it, and says that the tongue lies under it, and that all the stromboide shells gave it. The *onyx Indicus*, therefore, was only the poma, or operculum of an Indian stromboide shell, of the buccinum or purpura kind, and was of a sweet smell, and thence had the term *aromaticus*, or *odoratus*. The name *onyx* is easily accounted for, as the poma of every shell of this kind is flat and thin, and does not unaptly resemble the human nail.

POMACEÆ, in *Botany*, the 36th natural order among the Fragmenta of Linnæus, named from the apple, which belongs to it. The genera mentioned by the author are *Spiræa*, *Ribes*, *Sorbus*, *Cratægus*, *Mespilus*, *Pyrus*; to which are subjoined, in a second section, *Punica*, and in a third, *Chrysobalanus*, *Prunus* and *Amygdalus*.

POMADA, an exercise of vaulting the wooden horse, by laying one hand over the pommel of the saddle.

POMADERRIS, in *Botany*, so called by Labillardiere, from *παμα*, a covering, and *δερμις*, a skin, on account of a peculiar membranous covering to the capsule.—Labill. Nov. Holl. v. 1. 61. Ait. Hort Kew. v. 2. 23.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Rhamnif.* Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, turbinate; limb in five deep, ovate, acute, spreading, deciduous segments. Cor. Petals five, equal, obovate, concave, obtuse, spreading, smaller than the calyx, alternate with its segments. Stam. Filaments five, awl-shaped, ascending, opposite to the petals and of the same length; anthers heart-shaped, incumbent. Pist. Germen superior, roundish; style cylindrical, about as long as the stamens, three-cleft at the summit; stigmas capitate. Peric. Capsule ovate, separating into three almost membranous cells, each closed by a vertical lid on the inside. Seeds solitary, ovate, compressed.

Ess. Ch. Calyx turbinate, with five deciduous segments. Petals five, concave, opposite to the stamens. Capsule of three distinct cells, each closed by a lid.

1. *P. elliptica*. Oval-leaved Pomaderris. Labill. Nov. Holl. v. 1. 61. t. 86. Ait. n. 1.—Leaves oval, downy beneath. Heads of flowers somewhat umbellate, panicled.—Native of Van Diemen's land.—A greenhouse shrub at Kew, flowering most part of the summer. The stem is nine or ten feet high, branched, round. Leaves alternate, stalked, about three inches long and one broad; mostly entire. Flowers small, white.

2. *P. apetala*. Apetalous Pomaderris. Labill. Nov. Holl. v. 1. 62. t. 87. Ait. n. 2.—Leaves ovate-oblong, doubly serrated, downy beneath. Flowers racemose. Petals none.—Gathered by Mr. Brown on the west coast of New Holland. It flowers in our greenhouses in May.—The leaves are longer than the preceding, rusty beneath. Flowers numerous, greenish-white.

There are probably more species of this genus, some of them confounded with *Ceanothus*, from which, without fruit, they are scarcely to be distinguished.

POMARANCIO, NICOLO, in *Biography*. See CIR-CIGNANO.

POMARICO, in *Geography*, a town of Naples, in the province of Basilicata; 11 miles S.S.W. of Matera.

POMARTA, a town of Moldavia; 15 miles N.N.W. of Dorohoi.

POMATA, a town of Peru, in the diocese of La Paz; 20 miles S.E. of Xuli.

POMATIA, in *Natural History*, the name of a larger species of garden-fnail, so called from its feeding on apples and other fruit. It is originally a native of Italy, but is become of late years as familiar with us in England, as if a native with us. It is a noble remedy in consumptive decays; and a person of distinction in England having occasion to take great numbers, had several large parcels brought carefully alive from Italy, and turned loose in his garden, where they multiplied to such a degree, that the neighbouring woods and hedges soon became full of them, and they have since been propagated in many other places.

The pomatia is much larger than our common fnail, and of a paler colour: it is of a roundish figure, and has five spires or twists at the head: these are placed very close, and its mouth is large and almost circular, and has no duplica-
ture

ture or fold surrounding it, but is as thin as the rest of the shell.

POMATUM, or POMADO, a composition of apples, with lard and rose-water; used by way of unguent on many occasions, particularly for diseases of the skin, pimples, scurfs, &c. and to soften the hands, render the skin smooth, the complexion fresh, &c.

Pomatums are occasionally made with jessamins, oranges, jonquils, tuberoses, &c. *i. e.* they are perfumed with the odour of those flowers.

The best is said to be that prepared of kid's grease, pip-pins, an orange sliced, with a glass of rose water, and half a glass of white wine, boiled and strained, and at last sprinkled with oil of sweet almonds.

Dr. Quincy observes, that the apple is of no significance at all in the recipe; and that the common pomatum sold in the shops is only lard beat into a cream, with rose water, and scented with lemons, thyme, or the like.

The pomatum of the late London Dispensatory was formed by beating tried, or purified lard with rose-water, in the proportion of three ounces of the water to two pounds of the lard, till they were well mixed; then melting it over a gentle fire, and after it has stood for a little while, that the watery part may settle, pouring off the lard, and incessantly stirring and beating it about till it grows cold, so as to reduce it into a light yielding mass; and afterwards adding so much essence of lemons as will be sufficient to give a grateful smell. Some scent it with oil of rhodium; and previously digest the lard for ten days with common water, renewing the water every day, a process which does not appear to be of much use. The ointments may be tinged of a fine red colour, for lip-salves, by a proper addition of alkanet root. The faculty of Paris directs, for this purpose, twenty-four parts of the white pomatum, eight of ox's marrow, and eight of white wax, cut in small pieces, to be melted together by the heat of a water-bath; one part, *i. e.* one-fortieth of the whole mass, of powdered alkanet root to be added; the mixture stirred at times till it appears tinged of a deep red colour, and then strained through a linen cloth. Lewis.

POMAX, in *Botany*. See OPERCULARIA.

POMBAL, SEBASTIAN JOSEPH DE CARVALHO, *Marquis de*, in *Biography*, a celebrated Portuguese statesman, who is thought to have possessed more absolute power than any other minister ever did in Europe, was born in 1699, either at Lisbon or Coimbra. Little is known of his father: according to the report of some, he was merely a citizen, and of the humblest class; while others state that he was of noble extraction, and held the rank of captain in a regiment of horse. His mother was nearly related to one of the principal families in the kingdom, of the name of Mendoza. The subject of the present article was extremely well educated, and intended for the law, but the profession was ill-suited to his genius; he determined upon the army, and obtained a commission in the royal guards. He was at an early age possessed of an uncommon degree of bodily strength, accompanied with the most determined courage; but being under the dominion of his passions, he abandoned himself to pleasure, and displayed a revengeful disposition. He was, however, an agreeable companion, and ardent in every thing which he undertook. At this period the young Portuguese nobility were distinguished for the dissoluteness of their manners, and at the head of them was a brother of the king, whose boldest and most zealous supporter was Carvalho. While his conduct was applauded by his prince and other associates, it excited against him the displeasure of the sovereign, who shewed to him a marked coolness, at the same

time giving strict orders that he should be narrowly watched. Unable to endure the stigma attached to his name, he resigned his commission, and retired to Source, where he married a lady of distinction. He now felt an anxious desire to act a distinguished part on the theatre of the public, and obtained, through the interest of his uncle, a situation in the government. He was formally introduced at court, where he obtained the favour and protection of the queen. In 1739 he was appointed ambassador to the court of London, where he had a fine opportunity of displaying his diplomatic talents, and of improving himself in the other branches of knowledge necessary to a statesman. "His residence in England," says his biographer, "had undoubtedly a most decisive influence on his future administration. It was here that he became acquainted with the reciprocal interests of England and Portugal, and acquired a proper idea of the power and prosperity to which a nation may attain by industry. Here also he obtained a just notion of the mercantile system, and of the measures best calculated to support it; and these he afterwards endeavoured, with indefatigable zeal, and by the most despotic authority, to put in practice in his own country." In 1745 he was recalled to his own country, and being patronized by the queen, he was appointed by her to adjust a difference that had occurred between the pope and the empress Maria Theresa. For this purpose he went to Vienna, where he was received with every mark of distinction, and his wife dying, he paid his addresses to the young countess, Von Daun, a relation of the celebrated general of that name, and again entered the marriage state, but much against the will of the countess's family, who considered themselves disgraced by the alliance. After this, owing to the enmity of the king, he remained a considerable time unemployed, though he still retained the favour of the queen, and had likewise a warm friend in the sovereign's confessor. The king, John V., was almost entirely under the guidance of the priesthood. Though his confessor was a Franciscan, the Jesuits had acquired over him a most decisive influence; and those who wished to obtain any promotion were under the necessity of courting the patronage of this order. Carvalho, who aimed at the secretaryship of foreign affairs, left no means unemployed to secure their favour, and he acted his part so well, that he induced them to believe that they had gained a proselyte. By the death of the king, in July 1750, every obstacle was removed to his elevation at court. The queen-dowager, before the remains of the deceased king could be deposited in his grave, recommended him to her son Joseph I., who very soon appointed him secretary of state for foreign affairs, and admitted him completely into his confidence. He now assumed the character of the friend and advocate of the Jesuits, and was even, by his own wish, styled the *great Jesuit*. Joseph I. was a weak prince, who possessed neither talents nor strength of understanding. He found no enjoyment but in sensual gratification. Such was the monarch who nevertheless wished to become the reformer of his states, and who ventured to undertake the expulsion of the Jesuits, and the subversion of the power of the nobility. At the time, indeed, when Carvalho entered on his office as minister, a reform in the whole administration had become necessary. The picture drawn of the state at that period was gloomy in the extreme. "The government was without activity, and the offices of state were either unoccupied, or filled by the higher nobility and clergy; selfish and interested men, without talents, and incapable of discharging their duties with honour to themselves, or advantage to their country. The public revenues were in a state of the utmost derangement. The treasury was empty, and the sources from which it had been supplied

supplied were entirely exhausted. The whole trade of the kingdom was in the hands of the English, and the great body of the people possessed neither public spirit nor industry. The situation of the country, in regard to its foreign relations, was no less wretched and contemptible. Neither by land nor by sea, was it in a condition to provide for its internal safety." Such an aspect of things could not fail to excite the attention of an active and vigilant minister, and Carvalho soon found means of extending his activity beyond the boundaries of his own particular department, and his exertions inspired new life into those of his several colleagues. The principal object of his ministerial labours was to awaken a spirit of industry among the people, and to render the Portuguese trade more independent. In England he had formerly made himself acquainted with the principles of the mercantile system of that country, and endeavoured to introduce them into his own. The attempts which Carvalho made for the encouragement of national industry were attended with but a small degree of success, being counteracted by the natural indolence of the people, and other causes, which, he soon saw, time only, aided by a fortunate concurrence of circumstances, could remove. Some of his measures interfered with the interests of the Jesuits, and these ecclesiastics did all in their power to thwart his plans, and to decry, even in their pulpits, his reputation. But the minister was not to be deterred, and he made use of the harshest and most arbitrary measures to silence discontents, and awe the people to submission. These steps led to that formal and open war against the Jesuits with which this minister was occupied during the greater part of his administration. Without attempting to enter into a detail of these events, it may be observed, that they endeavoured to ruin him with the king, and in this they were powerfully supported by the nobility, who considered themselves excluded, chiefly by his means, from many high offices, and from all participation in the government. Carvalho's situation now became extremely critical, an host of foes being in arms against him. In the mean time an event took place which turned Carvalho's attention to objects of a different nature, and afforded him an opportunity of exhibiting his character in a very favourable point of view. On the melancholy and truly awful occasion of the earthquake at Lisbon, in 1755, he displayed the most humane and active attention to the wants of those who survived the catastrophe, and did every thing in his power to repair, as fast as possible, the misfortunes which had occurred. In this business he spared no personal efforts. Regardless of rest or refreshment, he sought no other lodging than his carriage; and in the course of forty-eight hours, his only nourishment was a little soup, which was served to him as he sat in his carriage. The services which he performed on this occasion procured for the minister universal respect: all his arbitrary acts were forgotten, and the king, who before was on ill terms with him, to convince the nation and world that the conduct of Carvalho met with his full approbation, raised him to the rank of a noble, under the title of count de Oeyras, after the name of an estate which he possessed, and treated him with the most marked respect and esteem. In the following year he was made prime minister of the country, and he now assumed a most unlimited power in every thing that related to the government. On this account great clamour was excited against him, and his measures were arraigned as arbitrary and severe. Some of these were, perhaps, rendered necessary by the licentiousness of the age; for when he authorized the officers of the police to execute on the spot the disturbers of the public peace, whom they might find in the night time in the streets, murder and robbery had become so common in the capital, that the inhabitants could

not stir from their houses in safety after the day closed in. None of his measures created so much discontent as the establishment of a company at Oporto for the exclusive sale of the Portuguese wine. The opposition which this excited he quelled by the most cruel laws, so that at length it was made a capital offence to speak or reason against the existing laws, or ordinance of the minister. His next attempt was to lower the reputation of the Jesuits in the eyes of the king, and the people at large, and he succeeded so completely, that this body of ecclesiastics began to be considered as the most wicked men, in whom no confidence could be reposed. The Jesuits were highly incensed at the proceeding, and boldly asserted, that every fact mentioned to their discredit was totally false, and that the papers circulated against them were unwarrantable and scandalous libels. In Paraguay, where their influence was very great, they caused them to be declared scandalous libels, and they exerted their influence so much in Spain, that they were publicly burnt by order of the government. At length the king of Portugal was persuaded by his minister, that his life was in constant jeopardy, and must remain so, unless the Jesuits were removed from the court. A regard to his own safety urged him, on the 16th of September, 1757, to order his own confessor, and all the rest of his brethren, about the hour of bed-time, to step into their carriages, which were waiting, and to retire to their colleges. Thus were they in a moment, and without the smallest preparation, banished from court, never more to return. The count de Oeyras, however, soon found that his triumph was not complete, and that nothing but the authority of the pope could destroy the attachment of the people in general to the Jesuits. He accordingly sent a memorial on the corruption of that body to pope Benedict XIV., who sent cardinal Saldanha, as apostolic visitor, to inquire into the truth of the circumstances alleged. By this investigation, it evidently appeared that the Jesuits, in order to enrich themselves, had not only deviated from their original destination, but disgraced the sacred character by embarking in commerce and trade: on this account they were interdicted from preaching or confessing in any part of the kingdom.

The count now attempted the improvement of agriculture, to accomplish which he did not hesitate to adopt the most violent and arbitrary measures. He caused the vine-stocks to be rooted up, that the owners of the vineyards might be compelled to cultivate corn in their stead; but the beneficial effects which this regulation was intended to produce were prevented by the clamour and opposition of his enemies. A similar fate attended many of his useful projects, which were ridiculed in order to render the minister contemptible. While he was employed in these and other pursuits of the same kind, the resentment of the Jesuits and nobility broke out in a sudden explosion, the object of which was the assassination of the king. This attempt was made in the night, between the 3d and 4th of September, 1758: it fortunately proved abortive, and the conspirators, being arrested, were tried and capitally punished. There was no doubt that the Jesuits were deeply implicated in this affair, and on that account the minister determined to put an entire end to the power of that body in Portugal. In the month of April 1759, he transmitted to the pope a letter from the king, in which it was stated, that if the Jesuits were any longer suffered to carry on their secret intrigues, the government would infallibly be overturned; and that therefore it was necessary to banish them completely from the kingdom. The pontiff strongly opposed the measure; but the count was determined to carry it into execution. On the 3d of September a decree was passed, by which the

Jesuits were declared rebels and traitors, and interdicted from remaining as a body in Portugal, or ever returning to it under any pretence whatever. At first they were determined to try their strength, and set the royal authority at defiance; but by the assistance of the military they were sent on board different transports, to the number of 1854, and conveyed to the states of the church. An offer was made to the younger brethren, that they should remain at liberty in Portugal, provided they would renounce all connection with their order; but they chose rather to share in the fate of their superiors, than comply with the terms of the minister.

During the war which broke out between Portugal and Spain, the count de Oeyras exerted himself very successfully in putting the Portuguese army and navy on a good footing, and obtained as commander-in-chief, the celebrated count de LIPPE. (See his article.) The minister now turned his attention to the encouragement of trade and commerce: he established schools of industry, in which the young were instructed in various useful arts. He also founded a school of commerce, where 200 pupils were admitted and taught the various branches of knowledge suited to their future destination; and he introduced a thorough reform in all the seminaries of the kingdom. A new institute was established for the education of the young nobility. He caused a number of schools to be opened for the children of citizens, and was particularly careful that they should be constantly supplied with able masters. A second attempt was made on the king's life in December 1768, by a disappointed mule-driver, who had served in the artillery, which circumstance led the king to pay a still greater attention to his minister, whom he regarded as his best protector. He presented him with several valuable estates, loaded him with pensions, and at length, in 1770, conferred on him the title of marquis de Pombal. During the remainder of this reign he kept the king entirely in his power; but upon the death of the monarch, in 1777, the marquis was dismissed from his office, but permitted to retain his titles and his income. He, however, soon found that he was become an object of suspicion; his papers were sealed up, and an intimation was sent to him, that he might retire to his estate in the country. This was not the chief source of his alarm, for the queen, who had always been inimical to him, ordered all those persons confined under the denomination of state prisoners, amounting to several thousands, to be set at liberty, and at the same time several of his favourites were deprived of their employments. Such was the downfall of a minister, who for twenty-six years had ruled Portugal with the most unlimited sway, and who, upon quitting his office, delivered into the hands of the queen a very large treasure, and a state, the inhabitants of which had been excited to a greater degree of industry, and where a foundation was laid for the establishment of good order, and for the preservation of security and peace. After his disgrace, the marquis de Pombal had the mortification to see the system which he had laboured with so much zeal to establish, completely overturned. He was, however, allowed to live quiet and retired in a village where he had hired a small mansion, and endeavoured, by his conduct and mode of life, to exhibit externally a spirit of resignation, which, probably, ill accorded with the genuine dictates of his heart. Towards the close of life, the marquis obtained permission to repair to the baths of Calvados for the benefit of his health, but the infirmities of age could not be alleviated by any assistance of that kind. He returned to his house, and died in the month of May 1782, in the 83d year of his age. It cannot be denied that his government was extremely beneficial to the

nation, but the arbitrary measures to which he perpetually had recourse cannot be justified, or even excused; nor will it be forgotten, that while he laboured for the public, he took care of his own interest. Gen. Biog.

POMBAL, in *Geography*, a town of Portugal, in Estramadura, containing about 3700 inhabitants; 21 miles S. of Coimbra.

POMBAS, a town of Portugal, in Estramadura; 12 miles S. of Abrantes.

POMBEDITA, JUBA, in *Ancient Geography*, a town of Asia, on the banks of the Euphrates, E.S.E. of Anetho.

POMBO, in *Geography*, a province of Africa, in the kingdom of Anziko, at the mouth of the Zaire.

POMBO Samba, a province of Congo, in the S. part of the kingdom.

POMBSDORF, a town of Silesia, in the principality of Neisse; 3 miles N.W. of Patzbau.

POME, among *Gardeners*. To *pome* is to grow or knit into a round head, somewhat like an apple.

Thus, they say, a cabbage begins to pome, &c. They sometimes use the term *to cabbage* in the same sense.

POMEGRANATE TREE, in *Botany*. See PUNICA.

POMEGRANATE, *Punica Granatum*, in the *Materia Medica*. The Greek writers, Theophrastus, Dioscorides, Hippocrates, and Galen, were well acquainted with the pomegranate; and we learn from Pliny, that its fruit was usually sold in the neighbourhood of Carthage. In England its cultivation is first dated in the time of Gerard, in 1596, but though its fruit seldom arrives at perfection in this climate, yet its large and beautiful scarlet flowers render it a desirable object of ornamental gardening. The rind of the fruit, and the flowers, including the calyces, are the parts directed for medicinal use in the Pharmacopœias. The fruit has been called cortex granati, malicorium, sidium, &c. Its smell is not remarkable, but to the taste it is bitterish and astringent. With water it yields near half its own weight of a very austere extract, but to rectified spirit it gives out very little; its astringent matter, like that of the fruit of the acacia tree, seeming to be indissoluble in spirituous menstrua. In this respect the astringency of the fruit differs from the latter, which are named "Balauftium," or "Balauftine" flowers: these are commonly taken from the double-flowered variety, and like the rind, have little or no smell, but a mild, bitterish, styptic taste. They are both powerful astringents; and with this effect have long been successfully employed in diseases, both internally and externally. Dr. Cullen observes, that the strong styptic taste of this bark, and the black colour it strikes with green vitriol, shew sufficiently its astringent power; and it is commonly supposed to be among the strongest of this kind. As at the same time it gives out such a large portion of its substance to water in infusion or decoction, it seems to be particularly fit for affording a liquid astringent; and Dr. Cullen frequently found it particularly useful in gargles, in diarrhœa, and in external applications. He has never found it to be more dangerous than others, as an internal astringent, and he doubts whether it has ever had the power of suppressing the catamenia. The dose, in substance, or in form of powder, either of the flowers or bark, is from half a dram to a dram; in infusion or decoction, to half an ounce. (Lewis and Woodville.) The red succulent pulp, contained in transparent cellular membranes of the rind, and included in nine cells, is pleasantly acid, resembling that of the orange, cooling and useful for quenching thirst, and gently loosening the belly. The ancients used the rind, as the moderns do sumach, in the preparation of leather. Conserves and syrups have sometimes been made used

of the kernels: but of the true conserve there is little fold, the preparation of it being difficult. That which ordinarily passes for it is only fugar melted down, to which the colour and sharp taste are given with cochineal, cream of tartar, and alum.

POMEGUE, in *Geography*, a small island in the Mediterranean, near the coast of France, at the entrance into the harbour of Marfeilles, defended by a tower, with a small garrison. N. lat. $43^{\circ} 16'$. E. long. $6^{\circ} 23'$.

POMEIS, in *Heraldry*, are green roundles; so called by the English heralds, who express different coloured roundles by distinct names.

The French, who content themselves to denote the different colour of the roundles, call the pomeis, *tourteaux vert*.

POMELSBRUNN, in *Geography*, a town of Germany, in the territory of Nuremberg; 5 miles E. of Herbruck.

POMERANIA, a country of Europe, bounded on the N. by the Baltic, on the E. by Pomerelia, on the S. by the duchy of Warsaw and the margraviate of Brandenburg, and on the W. by the duchy of Mecklenburg. The country is level, and has few hills; and the soil, though sandy in some parts, is in others so good, as to produce wheat, rye, barley, and oats, sufficient for the inhabitants, with a surplus for exportation. Its forests supply abundance of wood for fuel, for the construction of houses and ships, and also for the manufacture of tar and charcoal. Some parts yield turf for fuel; and those districts that do not answer the purpose of tillage, serve for grazing. The geese of Pomerania are famous for their size, and those that are dried, as well as the hams, sausages, and salmon, are reckoned the best in Germany. Situated on the Baltic, Pomerania is favourable for trade and navigation, though the coast, particularly about the Oder, is dangerous. The coasts of Hither Pomerania afford amber, but not in such quantities as those of Prussia. The whole duchy contains 68 towns; and most of the inhabitants, since the years 1534 and 1535, when the reformation took place, have professed Lutheranism, though in some parts there are Calvinists and Catholics. The ancient occupiers of this country were the Sævi and Vandals, comprehending the Goths, the Rugi, the Lemovi, and other nations. When these people quitted it, they were succeeded, about the middle of the sixth century, by the Slavi or Wendi. The first period in which the name of Pomerania occurs, is in a bull of pope Innocent, dated 1140, for the confirmation of the newly-erected bishopric of Pomerania. The appellation is said to be Slavonic, and to be compounded of the words "Po Mariski," on or near the sea, and in process of time it was extended to the country on the W. side of the Oder.

Pomerania is divided by the Oder into the Anterior or Hither Pomerania, and Hinder or Farther Pomerania; the former lying on the W., the latter on the E. side of that river. This duchy was founded by prince Suantibor in 1107, and he at his death divided his possessions among his four sons. When this family became extinct, the estates were taken possession of by Brandenburg and Poland; and in 1537, upon the death of the last duke, Boleslaus XIV., Sweden took possession of a part which had been previously gained by conquest. By the treaty of Westphalia, the Swedes were left in possession of Anterior Pomerania, with the principality of Rugen, the town of Stettin, the island of Wollin, the Oder, Frisch Haff, &c.; but after an unfortunate war, the principal part was ceded to Prussia, so that the Peene became the boundary of Swedish Pomerania. In 1807, the Swedes were deprived of the remaining part by the French. Before this event, two votes were given in

the college of princes, at the diet for Pomerania, one in the name of the king of Sweden, as duke of Anterior Pomerania, and the other in the name of the king of Prussia, as duke of Hinder Pomerania. Swedish Pomerania is said to contain about 103,000 inhabitants; its revenues scarcely exceed 140,000 rix-dollars, and are incumbered with a public debt. The governor of this country resides at Stralfund, the chief town, in which is a court of justice for military affairs: there is also a royal court of justice at Griefswald, which is the seat of an university founded in 1456; but the supreme tribunal is at Wismar. The isle of Rugen (which see) belongs to Swedish Pomerania, and has the title of principality. The chief town of Swedish Pomerania is Stralfund, surrounded on all sides with water, and maintaining a considerable trade. The population of Pomerania, according to Hoeck, is estimated at 472,957. It was surrendered to Denmark Jan. 15th 1814, in lieu of Norway, ceded to Sweden.

POMERANZA, LE, a town of Etruria; 5 miles S. of Volterra.

POMERELIA, a country bounded on the N. by the Baltic, on the E. by Prussia, on the S. by Poland, and on the W. by Pomerania, about 90 miles long and 50 broad. It was formerly a part of the duchy of Pomerania, and governed by its own princes. After some changes of masters, it fell under the dominion of Poland, and more lately became subject to Poland, and last of all was annexed to the dominions of Prussia. Its principal places were Dantzic and Stargard.

POMERIUM, in *Antiquity*. See **POMOERIUM**.

POMERIUS, JULIAN, in *Biography*, a philosophical and moral writer of the fifth century, was a native of Mauritania, who removed into France, where for some time he kept a rhetorical school at the city of Arles, and was afterwards ordained priest. He was author of many works, of which the titles of some only remain: in his treatise "De Anima," lib. viii., he maintained the gloomy notion of the materiality of the soul. Cave suspects that this was only an abridgment of a very curious work of Nemesius, "On the Nature of Man." Pomerius was also author of treatises "De contemptu Mundi ac Rerum Transitarum," and "De Virginibus Instituendis," which, as well as the preceding, are no longer extant. The only production of his still remaining, is entitled "De Vita contemplativa, five de futuræ Vitæ contemplatione, vel de actuali Conversatione," which was printed with the works of St. Prosper, and attributed to him when published in a separate form, at Cologne in 1487 and 1536, and at Paris in 1711. But the testimony of Gennadius and Isidore, which is confirmed by several ancient manuscripts, clearly proves that Pomerius was the author. Dupin has given an analysis of this work, which is said to abound in acute and just remarks, and very useful maxims, but it is not recommended by the excellence or perspicuity of its style. Dupin. Moheim's Eccl. Hist.

POMERO, in *Geography*, a town of Istria; 6 miles S.S.E. of Pola.

POMERSDORF, a town of Prussia, in Ermeland; 8 miles S. of Elbing.

POMERSFELDEN, a town of Bavaria, in the bishopric of Bamberg; 17 miles S.S.W. of Bamberg.

POMETIA, or *Suessa Pometia*, in *Ancient Geography*, a town of Italy, and capital of the Volsci. Strabo. It was taken by the Romans in one of the first years of the reign of Tarquin, and of its spoils he constructed the Capitol. Its site has been long since overwhelmed by the Pomptine marshes.

POMETIA, in *Botany*, Forst. Gen. 55, so named by Forster,

Forster, in honour of Pomet, the celebrated French writer on the *Materia Medica*. See EUPHORIA and SCYTHIA.

POMEY, FRANCIS, in *Biography*, a Jesuit, a native of Lyons, known as the author of the "Pantheon Mylticum," which was translated into English by Andrew Tooke, and given to the world as his own performance. This work, which has been known in all our best schools more than a century, was diligently revised, corrected, and greatly improved, a few years since. To this new edition, a beautiful set of out-line engravings from ancient statues has been added. Pomey, besides the Pantheon, wrote a French and Latin Dictionary, 4to.; "Flos Latinitatis;" "Libitina, or Funerals of the Ancients;" "Novus Rhetoricæ Candidatus." He died in 1673, at the age of 55.

POMFRET, JOHN, an English poet, born about the year 1667, at Luton, in Bedfordshire, was educated at Cambridge, and obtained the living of Maldon, in Bedfordshire. In 1703 he came to London for a larger living, but found bishop Compton strongly prejudiced against him, on account of four lines in his poem, entitled "The Choice," in which it was falsely said that he preferred a mistress to a wife, and before the prelate's scruples could be removed, the unfortunate candidate died, at the early age of 35. In another poem, entitled "Cruelty and Lust," he has introduced the character of the brutal Kirk with great effect and pathos. Dr. Johnson says no poem has been more frequently read than "The Choice."

POMFRET, in *Geography*, a township of America, in Windfor county, Vermont; containing 1473 inhabitants; 64 miles N.E. of Bennington.—Also, a post-town of Connecticut, in Windham county; 66 miles S.W. of Boston; containing a congregational church. Its houses are handsome, and the farms of the township are well cultivated. It was settled in 1686 by emigrants from Roxbury. The number of inhabitants is 1905.

POMIEDLUCK, a town of West Greenland. N. lat. $61^{\circ} 45'$. W. long. $47^{\circ} 30'$.

POMIGLION is a name given by seamen to the cascabel, or hindmost knob of a cannon. See GUN.

POMME', in *Geography*, a river of Louisiana, which runs into Mississippi, N. lat. $37^{\circ} 18'$. W. long. $90^{\circ} 15'$.

POMMÉ, or Pommété, in *Heraldry*. A cross pommé, or pommété, called also *trophe*, is a cross with a ball or knob, like an apple at each end.

POMMEL, or PUMMEL, in the *Manege*, a piece of brass, or other matter, at top, and in the middle, of the fiddle-bow, to which are fastened the holsters, stirrup-leathers, &c.

POMMEL is also a round ball of silver, steel, or the like, fixed at the end of the guard and grasp of a sword; to serve, in some measure, for a counterpoise.

Balzac observes, that there are still extant charters and privileges granted by Charlemagne, which were sealed with the pommel of his sword, which, ordinarily, he promises to defend with the same sword.

POMMERAYE, JOHN FRANCIS, in *Biography*, an able ecclesiastical historian, who flourished in the seventeenth century, was born at Rouen in the year 1617. At an early period he renounced all his employments in the order to which he had attached himself, that he might devote himself wholly to religious exercises and study. He died in 1687, aged 70, at the abbey of St. Germain des Prez near Paris. His principal works are, "The History of the Abbey of St. Owen at Rouen, and those of St. Amand and St. Catherine in the same City;" "The History of the Archbishops of Rouen," which is esteemed as the best of his works, and contains the celebrated remonstrance which Francis

de Harlay delivered to the king in 1658, on behalf of the three estates of Normandy; "Notes to the Collection of Councils and Synods of the Church of Rouen," which he edited in 1677 from the MSS. of father John-Anger Goden, and which work was afterwards superseded by the larger and more perfect collection of father Bessin; and the "History of the Cathedral of Rouen." Moreri.

POMMEREULLA, in *Botany*, so named by the younger Linnæus, in honour of Madame du Gage de Pommereull, (or rather Pommereuil, according to Palissot de Beauvois,) a French lady, reported to have bestowed great attention upon the natural family of grasses, to which this genus belongs.—Linn. Suppl. 12. Schreb. 42. Willd. Sp. Pl. v. 1. 314. Juss. 34. Palissot de Beau. Agrost. 91. t. 18. f. 6. Lamarck Illustr. t. 37.—Class and order, *Triandria Monogynia*. Nat. Ord. *Gramina*.

Gen. Ch. *Cal.* Glume turbinate, of two equal valves, containing three or four florets; each valve wedge-shaped, unequally four-cleft, with a linear base; and bearing at its back, between the smaller segments, a straight upright awn, exceeding its own length. *Cor.* Glume of two unequal valves; the outer similar to the calyx, and in like manner awned; inner very short, undivided, ovate, flat, awnless. *Stam.* Filaments three, very short; anthers linear, the length of the glumes. *Pist.* Germen superior, linear; style simple, capillary; stigmas two, bearded laterally. *Peric.* none, except the permanent corolla, investing the seed, but not united with it. *Seed* solitary, oblong, pelucid, very smooth, flat at the inner side, convex at the outer.

Eff. Ch. Calyx turbinate, of two equal four-cleft valves, each awned at the back, containing three or four flowers. Corolla of two unequal valves; the outermost awned.

1. *P. Cornucopia*. Linn. Suppl. 105. Roxb. Coromand. v. 2. 17. t. 131.—Sent from India by Koenig to Linnæus. Roxburgh says it grows under bushes, in dry uncultivated ground, on the coast of Coromandel. This is a small creeping grass, a few inches high. *Leaves* in two ranks, compressed, smooth. *Flowers* spiked, each resembling a little shuttlecock. Dr. Roxburgh's figure does not exactly answer to the description, nor to the appearance of our specimens.—We have not been able critically to examine this grass, for want of sufficient plenty of specimens in different states.

POMMETTE'. See POMMÉ.

POMNA, in *Geography*, a river of Hindoostan, which runs into the Mahany; 10 miles N. of Bahar.

POMOERIUM, among the Romans. Authors are not agreed as to particular circumstances relating to the pomœrium; some will have it to be a piece of ground without the walls; others a space within them; and others again think it was both within and without. But whichever of these is true, the pomœrium was a place esteemed sacred, and kept free from houses and every other kind of obstruction. Hist. Acad. Inscr. vol. ii. p. 91, seq.

POMONA ISLAND, or *Mainland*, in *Geography*, the largest of the Orkney islands which belong to Scotland, is situated in the northern ocean, between the coast of Caithness, and Shetland. The etymology of its distinctive appellation is much disputed; but is most properly to be referred to two Icelandic words that signify *Great Land*, in allusion to its size compared with the neighbouring islands. According to Barry it extends from east to west, its longest direction, not less than thirty English miles, and varies in breadth from sixteen miles on the west side, to five or six on the east side; and near the middle it is so narrow as to form a neck of

land, which comprehends little more than a mile across, dividing the island into two peninsulas. This isthmus is bounded on one shore by the beautiful and spacious bay of Scalpa, and on the other by the bay of Kirkwall. It is both extremely level and damp, and in other respects so formed, as to induce a reasonable conjecture that it was once covered by the ocean, and that the present Mainland was formerly two distinct islands.

Pomona is divided into nine parishes, *viz.* Evie-and-Rendal, Birfa-and-Harra, Sandwick, Stromness, Frith-and-Stennis, Kirkwall-and-St. Ola, St. Andrew's-and-Deerness, Holm-and-Paplay, and Orphir. These display much variety of appearance, soil, culture, and elevation. Two ridges of hills intersect a great portion of this island, and throughout a considerable extent run parallel to each other. The one runs from south to north, and forms the western boundary of the Mainland; and the other, rising towards its eastern extremity, stretches westward towards the parish of Holm into that of Orphir, (whence the direction is suddenly changed towards the north at nearly a right angle,) and extends through the parishes of Frith and Rendal. In both these ridges the acclivities are usually green, and when cultivated are fertile and productive. The summits are covered with various kinds of grass intermixed with heath, which at once affords pasturage for sheep, black cattle, and horses, and furnish a secure haunt for multitudes of moor-game. In the parish of St. Ola, around Kirkwall, the soil is mostly good, but the greater portion of it being either common or vested in the community of the borough, lies in a waste uncultivated state. The parish of Deerness-and-St. Andrew, consisting of an extensive tract of level ground, is better cultivated; as are likewise the united parishes of Holm and Paplay, which indeed constitute one of the most compact districts in the country. The soil here is a mixture of clay and sandy loam, and having for the most part a southern exposure, raises good crops of oats and bear. Flax also is grown in considerable quantities, and is manufactured into linen during the winter season. The parish of Orphir, on the west side of the bay of Scalpa, possesses more fertility of soil in its central parts, than perhaps any other in Orkney, but its extremities are dreary, bleak, and barren. Mackerel and herrings frequently visit the coast here in vast shoals, but from want of skill, industry, or capital, few of them are caught. Howton, a small harbour in this parish, is much noted in the history of Orkney, as the scene of some remarkable transactions of old, when Orphir contained the palace and chief residence of earl Paul, and other ancient counts of Orkney.

To the north-west of Orphir lie the united parishes of Frith and Stennis, which are chiefly remarkable for several monuments of antiquity. In a level tract between two ridges is a vast collection of sepulchral *tumuli*, or barrows, which are conjectured to contain the ashes of warriors, who may have fallen in battle on this spot. Neither history nor tradition, however, afford any clue to such an event. Not far from hence, and close to the loch of Stennis, is a circle of large stones, some of which are about fourteen feet high, and four broad. Several of them have fallen down, of others fragments remain, and of some only the holes in which they stood. The whole is surrounded by a circular ditch, twenty feet broad and twelve deep, and inclosing an area sixty fathoms in diameter. Near this circle are several scattered stones, also four tumuli of considerable magnitude ranged in pairs, and opposing each other on the east and west sides of the monument. A semicircle of stones is situated on the opposite side of the loch. These are of larger dimensions than the stones of the circle, and are environed by

a vallum instead of a ditch, exterior to which are likewise several stones, apparently fixed without any regular order. These monuments are usually ascribed to the Celtic Druids, like those of Stonehenge and Avebury, but the fact that no Celtic colony ever visited Orkney, completely invalidates this hypothesis, and leaves their origin veiled in the most profound obscurity, unless we conjecture that they were courts of justice, or temples formed in honour of Odin, the Scandinavian god of battle.

Northward from Stennis are the united parishes of Evie-and-Rendal and Birfa-and-Harra. Evie and Rendal, are only partially cultivated, but feed a large number of cattle. Fish of various kinds, and particularly cod, ling, haddocks, and skate, abound on the shores of Evie, which are also distinguished by several of those ancient monuments called Picts'-houses, and by numbers of scattered tumuli. Harra and Birfa were in very remote ages covered with a forest, though at present not a patch of wood remains. The proof of this is that trunks of trees, and horns and bones of red and fallow deer, are dug up in various parts of this district. Several beautiful lakes are dispersed through these parishes. The soil in Birfa is much diversified; but in Harra a deep clay is chiefly prevalent, intermixed with some wet and swampy ground. Marle is here abundant, but seldom used for the purposes of manure. Notwithstanding this, however, superior crops of bear and oats, and also of flax and hemp, are raised in this parish. Birfa is noted for a magnificent palace, (now in ruins,) which was erected by some of the ancient earls of Orkney, and was for many years the principal residence, and probably also the seat of government. It stands on a projecting point of land close to the sea side, and immediately fronting what is denominated the burgh of Birfa. This last is a small portion of high land, (now broken off from the Mainland by the force of the ocean,) which bears all the marks of having been a rock fortification in very remote times. On this islet are the remains of a chapel dedicated to St. Peter, and till lately a celebrated place of pilgrimage. Picts'-houses are frequent in Birfa, as are likewise single monumental stones. Two of these, known by the name of Stanevaudy, stand on a mound or barrow; and three of a smaller size are surrounded by a great number of tumuli, concerning which even tradition is totally silent. Marble and alabaster are said to have been discovered in this parish, also at Buquoy and Swanay.

The other two parishes in Pomona are Stromness and Sandwick, which occupy a peninsula on the west side of the island, formed by the Atlantic and the lochs of Stennis. They contain about thirty-one square miles, of which about a ninth part only is cultivated, and the remainder devoted to pasturage. Mineral springs are found in various parts of these parishes; and mines of lead and iron were opened and wrought for some time near Stromness, which is now the most populous town in Orkney, and is a place of some trade. Kirkwall is the only borough in the Mainland; but though the seat of the courts of justice for Orkney, it is more than rivalled in extent and in commercial enterprise by Stromness. See KIRKWALL and STROMNESS; see also ORKNEY *Islands* for some account of the history of Pomona, manners and customs of the people, &c. &c. History of the Orkney Islands by the Rev. Dr. Barry, second edit. with corrections and additions, by the Rev. James Headrick, 4to., 1808.

POMONA, in *Mythology*, an amiable nymph, for whose favour the deities of the fields were competitors. The name was originally appropriated to some person who had merited divine honours by the culture of fruit-trees, and especially of apple-trees. This nymph is represented as sitting on a

large basket full of fruit, holding a number of apples in her left hand, and in the right a nosegay of flowers. At Rome she had a temple and altars. Her priest was called *flamen Pomonalis*, and sacrifices were offered to her for the preservation of the fruits of the earth.

POMOZDINSKOI, in *Geography*, a town of Russia, on the Vitchehda.

POMPADOUR, a town of France, in the department of the Correze; seven miles S.W. of Uzerches.

POMPEI, GIROLAMO, in *Biography*, an Italian poet and a man of letters, was born of a noble family at Verona in 1731. He became an early proficient in classical literature, and attained an excellent style. At this period the marquis Maffei and other eminent literary characters were resident at Verona, in whose society the talents of Pompei received the most advantageous cultivation. He was first known as an author by "Canzoni Pastorali," in two vols. 8vo. Able critics spoke in the highest terms of these pieces, on account of their sweetness and elegance: it was thought by some good judges that they were never surpassed by any productions of the kind. He next translated some of the Idylls of Theocritus and Moschus, in which he exhibited a very happy selection of Italian words, corresponding with the Greek. The next object of his attention was dramatic poetry, in the higher departments of which the Italians were at that time very deficient, and he published in 1768 and 1770, his tragedies of "Hypermetra" and "Callirhoe," which were represented with great success in several cities of the Venetian state. He now employed several years on a translation of "Plutarch's Lives," which appeared in 1774 in four vols. 4to. This work gave him considerable reputation as a prose writer and scholar, and it ranks among the very best classical versions in the Italian language. In 1778 he published two volumes of "Nuove Canzoni Pastorali:" he also published poetical versions of the "Hero and Leander of Musæus;" of the "Hymns of Callimachus;" "A hundred Greek Epigrams;" and the "Epistles of Ovid." He was a member of some of the academies, and he served his native city in the capacities of secretary to the tribunal of public safety, and to the academy of painting. He died at Verona in 1790, at the age of 59, and his memory was honoured by various public testimonies, and by the erection of his bust in one of the squares of the city. He was highly respected and esteemed, as well for his morals as for his literary talents, and his fame was not limited to the confines of Italy. An edition of his works was published after his death in six vols. 8vo. Gen. Biog.

POMPEIA, in *Ancient Geography*. See POMPEII.

POMPEIA Trophœa, the *Trophies of Pompey*, a name given by Strabo, to the place called by other authors "Summum Pyrenæum," because these trophies were placed on the summit of the Pyrenées. They were situated in the eastern part of the Pyrenées, at the passage called "Col de Pertuis," and were erected to commemorate his victory over Sertorius, and to serve as a boundary between Gaul and Spain.

POMPEIANO, in *Geography*, a town of Italy, in the department of the Mela; 11 miles S.W. of Brescia.

POMPEII, in *Ancient Geography*, an ancient city of Naples, overwhelmed in the first century by the same disastrous catastrophe which destroyed *Herculaneum*. (See that article and PORTICI.) It is said to owe its name to the triumphant pomp in which Hercules led his captives along the coast after his conquest of Spain: it was probably situated on an arm of the sea, and served as a port for the inland towns; which inlet of the sea has been filled up by successive eruptions, besides that which destroyed the town. It is about 14 miles from Naples on the road to Nocera. From

Naples to "Torre del Greco," the high way is almost a street, so close are the villas, villages, and towns to each other. As the road was along the coast, and at the foot of Vesuvius, every break gives on one side a view of the bay, on the other of the mountain. Torre del Greco still presents in its shattered houses, half-buried churches, and streets almost choaked up with lava, a melancholy instance of the ravages of the last eruption. The depth of the destructive torrent is in some places 25 feet, so that the entrance into several houses is in the second story, and into one church, through the great window over the western door. Some edifices were entirely destroyed: others were surrounded, incruited, and filled with lava, and may perhaps give a very accurate idea of the state of Herculaneum at the time of its destruction. The town of Torre del Greco was supposed by Cluverius to occupy the site of Herculaneum, because the distances nearly corresponded, and inscriptions have been found that seem to corroborate this conjecture. In fact, making allowances for the extent of the ancient town, there is little more than three-fourths of a mile difference, so that its name and jurisdiction extended probably much farther. In the vicinity of this place are the ruins of ancient barracks, which were the quarters of a legion of Roman soldiers, and behind the barracks are two theatres, one small, and supposed to have been covered, the other large: both these edifices were lined with marble, beautifully paved, and in every respect highly finished. These theatres are exactly of the same form as the Teatro Olimpico of Palladio at Verona; having like it a narrow proscenium, and three entrances, one large and the other two less, to the stage from the scenery behind. These theatres, when discovered, were nearly entire, but though they have been stripped of all their decorations, they still retain all their great characteristic features. Behind the little theatre is a temple of Isis, occupying an angle formed by two streets. Some have supposed that oracles were issued from this temple, and have declaimed against the priestcraft that was practised here; but it does not appear that oracles were ever given at Pompeii, as this was a privilege reserved to the ancient and more renowned temples; besides, oracles had every where ceased before this edifice or temple, if it may be so called, was erected; and moreover, the entrances into it are too public, and the whole contrivance too gross to dupe the dullest peasant, much less the polished inhabitants of Pompeii. In this building there are niches where various statues of Venus, Priapus, &c. were found, which with the furniture, marble, and pictures, were transported to Portici. Behind this temple, on one side, is a court surrounded with a portico, supported by sixteen Doric pillars, and from a sort of pulpit on one side it may be inferred, that it was intended for some public assembly. Another court follows with a similar portico, and communicates with the grand portico of the theatre, supported by more than sixty stone pillars of the Doric order, but in proportion bordering upon Tuscan. Near this portico lie several fragments of columns of a much larger size, and of bolder proportion; which perhaps belonged to the temple of Neptune, and may have been thrown down and laid in their present situation by the earthquake which nearly destroyed this city a few years previous to the eruption that buried it finally. The damage occasioned by the first disaster was never probably repaired, and seems to account for the apparent want of architectural magnificence in a city, equal perhaps in size and population to Herculaneum, and complimented by Seneca with the addition of "Celebrem Campaniæ urbem." The most perfect and most curious object that has yet been discovered is a villa at a little distance from the town. It consists of three courts; in the first and largest is a pond,

and in the centre an *ædicula* or little temple: there are numerous apartments of every description paved in Mosaic, coloured and adorned with various paintings on the walls, all in a very beautiful style. The baths in this villa seem to have been objects of particular attention. Cicero's Pompeianum stood in the neighbourhood of this town, and possibly on this very spot. It was a favourite retreat much frequented by Cicero and his friends. The houses at Pompeii are on a small scale, generally of one, sometimes of two stories: the principal apartments are always behind, inclosing a court with a portico round it, and a marble cistern in the middle; two had glass windows, in the others shutters only were used; the pavements are all Mosaic, and the walls are stained with mild colours; the decorations are basso-relievos in stucco and paintings in medallions. Marble seems to have been common. Upon the whole Pompeii bears a strong resemblance to modern Italian towns, with this difference, that in point of general appearance the latter have the advantage. It should however be remembered, that Pompeii had already been damaged by an earthquake, as we learn from Tacitus (Ann. xv. 22.) "Motu terræ celebre campaniæ oppidum Pompeii corruit:" that the roofs and upper parts of the houses have been borne down by the weight of ashes and pumice stones upon them; and that, as not more than a quarter of the town has been hitherto explored, buildings of greater magnificence may still remain buried.

It is generally supposed, that the destruction of this city was sudden and unexpected; and it is even recorded that the people were surpris'd and overwhelmed at once by the volcanic storm while in the theatre. (Dio, lxxvi.) But to this opinion there are several objections. The number of skeletons discovered in Pompeii does not amount to sixty; and ten times this number would be inconsiderable when compared with the extent and population of the city. It may perhaps be doubted, whether Pompeii was ever fully restored and re-peopled after the earthquake of 63; but it was certainly in part repaired and inhabited by a very considerable body of citizens. As for the circumstance of the inhabitants, of either Herculaneum or Pompeii, being surpris'd while in the theatre, it is so palpably absurd, that it is difficult to conceive how the historian above-mentioned could relate it with so much gravity. The first agitation and threatening aspect of the mountain, must have banished all mirth and amusement from its borders, and filled every heart with awful expectation and terror. Such were the previous intimations, that must have alarmed the inhabitants of their danger, that the greater number of them had time to escape from Pompeii, and those whose skeletons remain were either decrepid slaves, or criminals in a state of confinement.

The excavations among the ruins of Pompeii continue to be prosecuted with much industry. An extent of about 500 feet of the town wall has been completely cleared. It is from eighteen to twenty feet high, twelve thick, and fortified at short distances with square towers. In the main street, passing in front of the temple of Isis, has been discovered the portico of the theatre. Near the same spot, ten feet below the level of the street, was found a human skeleton, and immediately beneath it a large collection of gold and silver medals, in the finest preservation, chiefly of the reign of Domitian. Under a superb portico in the quarter of the tombs a number of skeletons has been discovered, and among them those of a female and several children. Three finger-rings and several ear-rings were found among the bones. Among the vases discovered, there were two which were full of water, with a small quantity of ashes at the bottom. In one the water was limpid and odourless: in the other it was of a brownish tinge, and had the taste of

lye. For further particulars, see Eustace's Classical Tour through Italy, vol. i.

POMPEION, Πομπειον, in *Antiquity*, a stately edifice at Athens, in which were kept the sacred utensils made use of at festivals, and all things necessary for the solemn processions prepared. It stood at the entrance of the old city, which looked towards Phalerum, and was adorned with many statues of the Athenian heroes.

The word pompeion is derived from πομπειον, *cum pompa incedo*, and was likewise used for any utensils employed on these occasions.

POMPEIOPOLIS, or POLI, in *Ancient Geography*, a town of Asia, in Cilicia, which belonged to the Rhodians, and was situated between the mouth of the river Cydnus and that of Ladmus. Ptolemy. According to Tacitus and Dion Cassius it was situated on the coast, and had borne the name of Soli.—Also, a town of Asia, in the interior of Paphlagonia.—Also, a town of Mysia, which suffered much from an earthquake under the empire of Justinian.

POMPELO, or POMPEIOLIS, a town of Hither Spain, belonging to the Vascones. See PAMPELUNA.

POMPEY the GREAT, in *Biography*, an illustrious Roman, born in the year 107 B.C., was the son of Cn. Pompeius Strabo, an able commander, but extremely unpopular, on account of his severity and avarice. The subject of this article was distinguished for a fine expression of countenance, and a dignified grace of manner, and at a very early period he displayed talents fitted as well for the forum as the camp. He first served under his father, who commanded an army in the neighbourhood of Rome, against Cinna in the Marian civil wars. On this occasion he narrowly escaped assassination from Terentius, a young patrician, who had been engaged by Cinna to kill both the father and son. Pompey, being informed of the fact, retired in the night from his tent, and secured his father's life, by setting a guard round the pretorium. Soon after a mutiny broke out in the camp, and the soldiers were determined to abandon their detested general. His son, at this time not arrived to years of manhood, by his entreaties reconciled them once more to their general. In a very short time Pompeius Strabo was killed by lightning, and the party of Marius and Cinna became predominant, and filled Rome with slaughter. Young Pompey joined the party of Sylla, and after a series of sanguinary contests the Marian party in Italy was completely crushed, and Sylla became absolute master of Rome. It was fortunate for the reputation of Pompey, that while Sylla was exercising his cruelties in the capital, Pompey was employed in reducing Sicily. He succeeded in bringing the island to submission. Carbo, a distinguished Marian, having fled to the island of Corsica with several of his party, Pompey sent a squadron to invest the place, to which Carbo surrendered, in the hope that Pompey would recollect and readily repay the kindness he had done him, in saving his estate from forfeiture. But gratitude is not often found in persons raised so high as Pompey, and in the present instance the conqueror, unmoved by any principles of sympathy, or by the recollection of the former dignity of his enemy, (who had been thrice a consul,) received him with great harshness, and ordered him to be led to execution. If Carbo deserved his hard fate by his cruelties, Pompey lost some credit by his unfeeling rigour; he contrived, however, to win the affections of the Sicilians by his clemency. The Marian party had now revived in considerable force in Africa, and Pompey was sent over to quell the insurgents. In forty days, and with a comparatively small force, he regained all the territories of Africa which had forsaken the interest of Sylla.

Sylla. This rapid success astonished the Romans; and Sylla, who admired and dreaded the rising power of Pompey, recalled him to Rome. Pompey immediately obeyed, and the dictator, by saluting him with the appellation of GREAT, shewed to the world what vast expectations might be looked for from the maturer age of his victorious lieutenant. A mere title did not, however, satisfy the ambition of Pompey, he demanded a triumph, and when Sylla refused to grant it, he emphatically exclaimed, "that more people were ready to fall down before the rising than the setting sun." Sylla, struck with the observation, and not chusing to hazard a contest, gave up his opposition. Pompey, therefore, though as yet only a Roman knight, and not of the age requisite for entering the senate, enjoyed triumphal honours, but it was at a period in which the ancient discipline of Rome had been subverted to party violence. He now appeared not as a dependant, but as a rival of the dictator. Sylla soon after resigned the dictatorship, and Pompey, in a consular election, mortified him by a proof that his own interest with the people was superior to that of the late master of the commonwealth. Sylla repented the insult, by omitting his name alone among all his friends, as a legatee in his will; but Pompey had sufficient greatness of mind to overlook the slight, and to exert all his influence in obtaining a splendid public funeral for his remains. After the death of Sylla, Pompey supported himself against the remains of the Marian faction, which were headed by Lepidus. He defeated them, put an end to the war which the revolt of Sertorius in Spain had occasioned, and obtained a second triumph, though still a private citizen. He was soon after made consul, and in the exercise of that office, he restored the tribunitial power to its original dignity, and in forty days removed the pirates from the Mediterranean, where they had reigned for many years, and, by their continual plunder and audacity, almost destroyed the whole naval power of Rome. Pompey was now called to greater undertakings, and by the influence of his friends at Rome, and of the tribune Manilius, he was empowered to finish the war against two of the most powerful monarchs of Asia, *viz.* Mithridates, king of Pontus, and Tigranes, king of Armenia. His operations against the king of Pontus were bold and vigorous, and in a general engagement the Romans so completely vanquished the enemy, that the Asiatic monarch escaped with difficulty from the field of battle. After Pompey had settled the affairs of Asia, he made a progress through Greece, where he heard the recitations of the poets and rhetoricians, and shewed his respect to philosophy by a munificent present to the city of Athens. His victorious return to Italy excited great apprehensions in many, who feared a renewal of the scenes acted by Marius and Sylla, but he was aware of their anxiety, and quieted their minds by disbanding his army the instant of his landing at Brundisium, and proceeding with the train of a private person to Rome. He was now met by the whole body of citizens, who welcomed him with loud acclamations. His demand of a triumph was granted without hesitation, and Rome had never before witnessed so splendid a spectacle as his triumphal procession for two days afforded. Many captive kings, and persons of high rank, walked before his chariot; and the spoils of Asia, delivered to the public treasury, amounted to an immense sum. He displayed his humanity by liberating all his captives after the triumph, and sending them back to their own country, with the exception of Aristobulus and Tigranes. It was now his plan, under the appearance of a retired private citizen, to maintain the first place in the state, by means of his reputation and influence; but in this

design he found a strong opposition from various quarters. Crassus and Lucullus surpassed him in wealth; the zealous republicans regarded him with suspicion, and Cæsar was laying the foundation of his future greatness. Pompey was therefore obliged to descend to party manœuvres, and he gained over to his interest the infamous Clodius. Cæsar, now returning from his government in Spain, planned a reconciliation between Crassus and Pompey, and, at the same time, associating himself with them, he formed the first triumvirate. The object that Cæsar had in view was the consular dignity, which he obtained in the year B. C. 59, and by the marriage of Pompey to his daughter Julia, an apparently firm union was cemented between them.

"It is," says the biographer of Pompey, "painful to follow the steps of this great leader after he was converted into a party-chief, aiding measures which, as a good citizen, he could not approve, and acting a subaltern part in oppressing the liberty of his country, when he might have taken the first station as its defender. His ingratitude to his great encomiast Cicero, whom he suffered to be driven into exile by the fury of the tribune Clodius, stamps an indelible stain on his character, although a subsequent quarrel with Clodius induced him to be a promoter of Cicero's recall." He gave Cæsar all his interest in procuring the illegal appointment to the command in Gaul for five successive years, a subserviency which, in the end, proved fatal to himself. For the maintenance of their power, Crassus and Pompey stood candidates for the consulship a second time, which they obtained, but not without some acts of violence. At the expiration of the year, Crassus departed for his extensive government in the east, while Pompey, who had been nominated to the government of Spain, remained at Rome, endeavouring to ingratiate himself with the people, by opening the new theatre which he had built, and exhibiting games with unusual splendour. He did not, however, trust wholly to popular favour, but kept Rome in awe by an army levied on his own authority, and stationed at its gates. By the slaughter of Crassus, and the death of Julia in child-bed, only two chiefs were left to dispute the empire of the world, circumstances which soon dissolved their bond of union, and rendered them competitors rather than colleagues. Pompey, however, still retained a friendship for Cæsar, and gave him all the assistance he could, to supply the losses of his campaigns. The disturbances in the capital increasing, a party was desirous of nominating Pompey dictator; but Cato proposed, as a less obnoxious measure, that he should be elected sole consul, which unprecedented circumstance took place in the year 52 B. C. He now began to be fully sensible of the danger of Cæsar's superiority, and in order to improve his interest with the great families, he married Cornelia, widow of the younger Crassus, and daughter of Metellus Scipio, and he appointed her father his partner in the consulate. Pompey, by his influence, caused Cæsar's application for the prolongation of his command in Gaul to be rejected by the senate, and he filled the principal magistracies with the open enemies of that general. He also recalled the legions which he had lent Cæsar, and which were restored without any hesitation. Proposals were now made that they should both resign their commands, but Pompey's partisans remonstrated, that the legal term of Cæsar's was already expired, which was not the case with his. It was no longer attempted to be concealed, that they were both apprehensive of each other, and that neither was willing to sink into the condition of a private citizen. In the estimate of the comparative justice of the pretensions of each, Lucan, though by principle a Pompeian, has said, that Pompey could not bear an equal,

nor Cæsar a superior, (the former, indeed, had been accustomed to be the first man in Rome,) readily to admit the idea of a younger competitor. He had, however, the form of the constitution on his side; for the senate, while it superseded Cæsar in his province, allowed Pompey to retain his command. In real power the two rivals were very unequal. Pompey was never, in talents, a match for Cæsar, and now habituated to the indulgencies of a civic life, was become "magni nominis umbra," the mere shadow of a great name. Still he does not appear to have been sensible of any decline of his authority; and when Cicero, finding him deaf to proposals of accommodation, and nevertheless negligent in his preparations, asked him with what forces he intended to oppose Cæsar, he vauntingly replied, "When I stamp with my foot, an army will start out of the ground." Cæsar in the year 49 B.C. crossed the Alps, and encamped at Ravenna. A decree of the senate proclaimed him a public enemy, and Pompey was required to take upon himself the defence of the state. He began to prepare in earnest for war, but was behind hand with his rival. Cæsar passed the Rubicon, and advanced to Rome, and Pompey, finding himself unequal to oppose the force of his rival, fled. The result, however, was the famous battle of Pharsalia, which took place in the year 48 B.C. Pompey, who was compelled to engage, contrary to his judgment and inclination, did little worthy of his former fame, and as soon as he saw his army thrown into disorder, losing all that presence of mind for which he was formerly remarkable, he withdrew to his tent. There he remained silent, like one overpowered by calamity, till the approach of the victor's army urged him to a hasty flight; he proceeded to the sea-coast and embarked for Lesbos. In that island he had a most affecting interview with his faithful Cornelia, with whom, and a few friends, he sailed away to the coast of Asia. Touching at Cyprus, a consultation was entered upon respecting further proceedings, and it was resolved to withdraw to Egypt, where it was expected a friendly reception would be given them by Ptolemy, on account of the favours done to his father by Pompey. When, however, the approach of this Roman was made known to the Egyptian court, a council was held respecting the conduct proper to be observed on so important and delicate an occasion. It was at length resolved, as the safest course, that he should be enticed into their power, and then murdered. A barge was sent to bring him ashore; some appearances led him to suspect treachery, but it was too late to hesitate. Taking leave of his wife and son, he stepped into the barge, repeating a couplet of Sophocles, which says, that he who puts himself in a tyrant's power has lost his freedom. As soon as the boat touched the land a crowd ran to meet it; and as Pompey was rising to go on shore, one of the Romans stabbed him in the back, and a number of assassins joined in the bloody deed. He received their strokes without a groan or struggle. They cut off his head, and left his naked body exposed on the shore. His faithful freedman remained by it, till night coming on he was left alone, he then got together some planks from a wreck, and made a funeral pile. An old Roman soldier, who had served under Pompey in his youth, assisted him in performing the funeral rites. When Cæsar arrived in Egypt, the head of his rival was presented to him, but he turned away from the spectacle and burst into tears. To shew his detestation of the death, he put to death all those who had any hand in it, and causing the head to be interred with great solemnity, he erected over it a temple to Nemesis. Pompey perished in the fifty-ninth year of his age, leaving behind him a name among the most illustrious of antiquity. He left two sons, Cneius and Sextus, of

whom the first lost his life soon after the battle of Munda; the second, after having rendered himself formidable by sea to the triumvirs, was reduced to take refuge in Armenia, where he was killed. We shall close this article with the character of Pompey drawn by an able hand. "His private virtues were many; he was moderate in his pleasures, temperate and free from dissolute or ostentatious luxury in the highest fortune, kind-hearted, mild, and humane, when uninfluenced by party violence. His talents were great and various, if not of the highest class; and his mind was cultured by letters and philosophy. As a citizen he cannot rank among pure patriots, yet his ambition tended only to be the chief of a free state, not to be the subverter of its freedom. He wished to be, says Lucan, ruler of the senate, but of a senate of authority. He preferred arms to the toga, but in arms he was a lover of peace. In his ambitious pursuits he was occasionally guilty of violence and ingratitude; but this was a consequence of his commencing life under the auspices of party, from which baneful influence he never was freed. He finally rose to a station to which he was unequal, and forfeited in the last act of the eventful drama of his life, much of the reputation he had gained in the preceding acts." Plutarch. Univer. Hist.

POMPEY'S Pillar. See PILLAR.

POMPEY, in *Geography*, a post-town of America, in Onondago county, New York, incorporated in 1794, and containing 2332 inhabitants.

POMPHOLYX, in *Medicine*, a disease which is characterised by an eruption of *bullæ*, blebs, or large vesications on the skin, unaccompanied by fever, and without any inflammation surrounding them.

This is the sense in which Dr. Willan appropriated the appellation of *Pompholyx*, in his treatise on cutaneous diseases, with the view of avoiding the confusion of authors, who have classed, under the title of *Pemphigus*, all affections accompanied by *bullæ*, whether febrile or non-febrile, and have even included, under the same head, a supposed idiopathic and contagious disease. See PEMPHIGUS.

Foësius observes, in his glossary of the words used by Hippocrates, that the father of physic employed the word *πομφοι* to denote wheals, or those eminences which resemble the eruption produced by nettles; but that Galen explains the *pomphi*, as elevations of the cuticle, containing a fluid. The word *πομφολυξ*, however, signified a bubble of air, appearing upon the surface of water, to which these *bullæ* upon the skin bear a considerable resemblance.

Dr. Willan described three species of pompholyx, to which he gave the epithets *benignus*, *diutinus*, and *solitarius*. The *first* of these is characterised by the appearance of transparent *bullæ*, of the size of a pea, or sometimes as large as a hazel nut, which arise successively, and in three or four days break, discharge their contained lymph, and soon heal. They are seated chiefly in the face, neck, and extremities; and occur most commonly in boys in hot weather, in infants during the irritation of teething, and in young persons of irritable habit from eating acrid vegetable substances, or from swallowing a few grains of mercury. The *second*, Pompholyx diutinus, is a tedious and painful disorder, and is usually preceded for some weeks by languor and lassitude, head-ache, sickness, and pains in the limbs. At first numerous red pimply elevations on the cuticle appear, with a sensation of tingling, which are presently raised into transparent vesications, that become as large as a pea within twenty-four hours, and, if not broken, afterwards attain the size of a walnut. If they are rubbed off prematurely, the excoriated surface is sore and inflamed, and does not readily heal. The *bullæ* continue to rise in succession on different

different parts of the body, and even re-appear on the parts first affected, in some cases for several weeks, so that the whole number of bullæ is very great; and when the excoriations are thus multiplied, a slight febrile paroxysm occurs every night, and the patient suffers much from the irritation, and from want of sleep. Occasionally, indeed, the irritation is so severe, a certain degree of inflammation surrounding the diseased parts, that a constant febrile excitement is kept up, especially in elderly people.

The Pompholyx diutinus chiefly affects persons of debilitated constitution, and is commonly most severe in persons advanced in years. It is not always easy to trace the exciting causes of the disease; it seems to originate, indeed, under different conditions of the body, but often after the exhaustion of long fatigue and continued anxiety, with an imperfect nutriment; sometimes it appears to be brought on by intemperance; and not unfrequently it is connected with anasarca, or general dropsy, with scurvy, hæmorrhæa petechialis, and other states of the constitution, in which the powers of the cutaneous circulation are feeble. In some instances it has appeared under circumstances to which many forms of cutaneous eruption are ascribed, namely, after profuse sweating, during which cold liquors were copiously swallowed, and a sudden chilliness produced. In the fevers in which it has been observed to occur, the eruption has been obviously symptomatic, and not a characteristic of a peculiar febrile disease, like the idiopathic eruptive fevers, small-pox, measles, &c., with which it has been erroneously assimilated, under the appellation of Pemphigus; for it has not only occurred at various periods of the febrile attacks, and varied much in its duration; but it has accompanied fevers of every type, continued, remittent, and intermittent, and has even appeared among the symptoms of arthritic, catarrhal, and other secondary fevers.

If we refer to the descriptions, and to the details of individual cases, given under the appellation of Pemphigus by many writers, we shall find the preceding statement fully confirmed. It will also appear from the same authorities, that the pompholyx is never communicated by contagion, like the idiopathic exanthemata before alluded to; and that the fluid contained in the bullæ is, in fact, not ichorous, but a bland lymph, resembling that which is poured into the ventricles of the brain in hydrocephalus. This circumstance was demonstrated by one gentleman, not only by chemical analysis, but by the inoculation of his own person with the lymph, which produced no effect whatever. (See Mr. Gaitskell's case of Pemphigus, in the Memoirs of the Medical Society of London, vol. iv. art. 1.) There is another difference, too, between pompholyx and the idiopathic eruptive fevers; which is, that in several of the persons, whose cases are recorded, the disease occurred more than once.

There is some difference both in the appearance and in the method of cure of this form of pompholyx, as it affects the young and the old. It is always most troublesome and obstinate in aged people, in whom the transparent bullæ sometimes equal the size of a turkey's egg, while others of a smaller size are intermixed with them, which appear dark and livid. When broken, they leave a black excoriated surface, which sometimes ulcerates. In these cases the warm bath used every second day, was considered by Dr. Willan as the most active palliative of the symptoms, and as proving ultimately the most effectual remedy. Cases sometimes occur, however, even in people far advanced in age, in which there is a febrile disposition connected with the irritation of the eruption, which interdicts the use of the warm bath; in an old lady of eighty, in whom the bullæ were sur-

rounded by an exanthematous redness, the warm bath produced so violent an exacerbation of the fever, as to render its repetition no longer adviseable. Dr. Bateman observes, that the decoction of cinchona, with cordials and diuretics, has appeared to him to be of considerable advantage, in the pompholyx of old people, especially when the eruption was combined with anasarca, which is not uncommon in these debilitated habits. In young persons, the warm bath appears to be decidedly injurious, inasmuch as it seems to increase both the unpleasant tingling in the skin, and the number of the vesications. In such patients, indeed, the disease is seldom severe, and generally disappears in two or three weeks, especially under the use of cinchona with the mineral acids.

The *third* species, called Pompholyx solitarius by Dr. Willan, is so rare a form of the disease, that that experienced practitioner had only seen three cases of it in the course of his practice, and these occurred only in women. One large vesication arises usually in the night, after a sensation of tingling and prickling in the skin, and rapidly distends itself, so as to contain sometimes a tea-cup full of lymph; within forty-eight hours it breaks, discharging its fluid, and leaving a superficial ulceration. Near this another vesication appears in a day or two, and goes through the same course; and it is sometimes followed in like manner by two or three others in succession; so that the whole duration shall be eight or ten days. It is not easy to lay down any very decided plan of treatment for a disease which has been so little noticed; but Dr. Willan believed that cinchona internally, and linseed poultices externally, followed by light dressings to the sores, were employed with benefit in the cases which he treated. See Willan on Cutaneous Diseases, class iv. Bateman's Practical Synopsis of Cutan. Diseases, p. 138. See also the individual cases by Mr. Gaitskell, before quoted; by Mr. Upton in the Mem. of the Medical Society of London, vol. iii. appendix; by Mr. Christie, in the Lond. Med. Journal, vol. x. p. 385; by Dr. Stewart in the Edinburgh Med. Commentaries, vol. vi. art. 3; by Dr. Hall, in the Annals of Medicine, vol. iii. art. 9; by Mr. Ring, in the Lond. Med. Journ. vol. xi. p. 235; by Dr. Dickson, in the Trans. of the Royal Irish Academy for 1787; and by Bang, in the Acta Reg. Soc. Med. Hauniensis, vol. i. p. 8, &c.

POMPHOLYX, Πομφολυξ, literally denoting a *bubble arising on water*, in *Pharmacy*, a name anciently given to a sort of metalline flower; being a white, light, and friable substance, found adhering to the lid or cover of the crucibles or furnaces, in which zinc or its ore is melted with other metals.

It is esteemed detergent and desiccative, though only applied externally.

The early chemists called it *nil*, or *nihil album*, *luna philosophica*, *flores zinci*, and also *zincum calcinatum*, and it has been denominated sometimes *white tutty*, in regard of its resemblance to tutty in virtue. (See TUTTY.) In the modern London Pharmacopeia it is called *Oxide of ZINC*; which see.

POMPIDOUR, in *Geography*, a town of France, in the department of the Lozere; nine miles S. of Florac.

POMPIGNAC, a town of France, in the department of the Gironde; six miles E. of Bourdeaux.

POMPIGNAN, JEAN-JACQUES LE FRANC, *Marquis de*, in *Biography*, a man of letters, was born at Montauban in the year 1709. He was brought up to the law, and became advocate-general, and afterwards first president of the court of Aides at Montauban. At a very early period he displayed a talent for poetry, and in 1734 brought upon the stage his tragedy of Didon, in which he attempted an imitation of Racine. Being well acquainted with the learned

learned languages and modern ones, he continued to employ himself in original composition and translation, and in a residence at Paris formed extensive connections in the literary circles. In 1760 he was admitted into the French academy. At this time the Encyclopædists and their associates were become a numerous and powerful party, and they did not scruple to attack, without disguise, opinions that had been sanctioned by time and the prejudices of the world. Pompignan was avowedly enlisted in the opposite party; and in an academical harangue, which he was called on to make, he attacked with vigour and some degree of violence the principles which then assumed the name of philosophy. This decided hostility to the literati of the day, who had possession of the public mind, drew upon him a large portion of satire from Voltaire and others, in which not only his literary talents were ridiculed, but the imputation of hypocrisy, and the interested pursuit of court favour, were attempted to be fastened upon him. His contemporaries, however, who were not biassed with party prejudices, admit that he was a good writer, and that the whole tenor of his life gave abundant evidence of real and sincere piety. He retired from the contentions of the metropolis to his estate of Pompignan, where he died in 1784, esteemed by the public and regretted by his tenants, to whom he was a father and protector. His works were published collectively in six vols. 8vo. They consist of dramatic pieces, discourses, harangues, an imitation of Virgil's *Georgics*, and translations from *Æschylus* and *Lucian*. His style is pure and elegant, his sentiments are laudable, and his remarks judicious.

POMPIGNAN, JOHN-GEORGE LE FRANC DE, brother of the preceding, a prelate of high rank and distinguished merit, was born at Montauban in the year 1715. He was educated for the clerical profession, and was ordained priest at a proper age, and in 1744 he was presented to the valuable bishopric of Puy, in Languedoc. On the accession of Lewis XVI. he was translated to the archiepiscopal see of Vienne, in Dauphinè. In both these sees he discharged the duties of his episcopal functions with the greatest assiduity, and displayed unwearied zeal in his personal labours, as well as the productions of his pen. In 1789, he was one of the clerical deputies sent by the province of Dauphinè to the meeting of the states-general; and when it was deliberated in the chamber of the clergy, in what manner they should verify their powers, he was one of the members of that order, who voted that such verification should take place in the general assembly of the three orders. This point having been carried, the archbishop went at the head of the majority, and formed a junction with the deputies of the Commons. Soon afterwards he was a member of the royal council, and became minister of the department which had the superintendency of ecclesiastical benefices. At this period the pope addressed to him a letter, strongly conjuring him to resist, with all his influence and power, any encroachments on the rights of the church, and all innovations in the condition and appointments of the clergy. The stream was, however, too strong to be resisted by his efforts, and he sunk, probably through grief and disappointment, into the arms of death. He was a considerable author; his principal works are, "A Critical Essay on the present State of the Republic of Letters," 1743; "Pastoral Instructions of the Bishop of Puy, for the Benefit of the new Converts within his Diocese;" "Devotion not at enmity with Wit and Genius;" "Mandates prohibiting the Reading of the Works of Rousseau and the Abbe Raynal." His talents as a writer and preacher have been variously estimated: some have com-

pared him with Bossuet, to which he had no well-founded pretensions, nevertheless he always wrote with purity, and often with elegance. To an enlightened genius he united a candid liberal mind; and though he was zealous for the interests of religion, and spent his life in combating the new philosophy, he was not a bigot nor intolerant. "No minister," says his biographer, "was more exemplary and irreproachable in his manners, nor more exempt from worldly mindedness. No one was more devoted to the duties of his station, possessed more knowledge, or greater simplicity, or was better entitled to the veneration in which he was held by the Catholic clergy."

POMPILUS, in *Ichthyology*, the name of a sea-fish, in the Linnæan system a species of the coryphæna, remarkable for following the rudders of ships to vast distances. It has no scales; it has a very broad line from the gills to the tail, under which are a number of dotted transverse lines, reaching to the belly, above the line on the side; the back is spotted with different colours; the mouth is moderately large, but the teeth very small; its forehead, between the eyes, is of a gold colour, and it has four fins, two at the gills, and two on the belly; and beside these, one long one running all the length of the back, and another answering it from the anus to the tail; its tail is not forked.

POMPILUS is also used by some authors for the nautilus, as well of the papyraceous as the camerated kind.

POMPION, in *Botany*. See CUCURBITA.

POMPON, *Great and Little*, in *Geography*, two rivers of Hindoostan, which run into the Ganges; the former three miles below Putna, and the latter near Futwa.

POMPONA, a name given by the Spaniards in America to a sort of vanilla, the pods of which are shorter and thicker than those of the common kind, and of a stronger smell, though less agreeable. The pulpy matter also in these pods is more liquid than that in the common kind, and the seeds much larger, being as big as those of mustard. This is never brought to market alone; but the Indians who gather it, cunningly mix it among the right kind; but this should be taken care of by the buyer, since this kind is very prejudicial, occasioning violent head-aches in men, and in women vapours and disorders of the womb.

It is not yet certainly known whether this be the fruit of a different species of the vanilla plant, or whether it be only different from the common in age, or in the place of growth of the plant.

POMPONAZZI, PETER, in *Biography*, a celebrated Italian Peripatetic philosopher in the 15th and early part of the 16th century, was born at Mantua in the year 1462. He pursued his studies at the university of Padua, where he became a professor, and greatly distinguished himself. During the war in which the republic of Venice was engaged against the league of Cambray, the university being for a time dispersed, he retired to Bologna, where he occupied the philosophical chair till his death, which happened in 1625, when he was in the sixty-third year of his age. His remains were afterwards conveyed to Mantua, where they were interred, by the direction of cardinal Hercules Gonzaga, in a magnificent tomb, on which a statue in bronze was erected to his memory. He was addicted to superstition and fanaticism, and a zealous advocate for judicial astrology, as appears from his book "De Naturalium Effectuum admirandorum Causis, seu de Incantationibus." He had, however, an understanding capable of penetrating into the depths of the Peripatetic system, and his writings, though barbarous and inelegant in style, discover great acuteness and subtlety of thought. He, like many persons of considerable talents in the present day, publicly taught that

that the natural reasons asserted for the doctrine of the immortality of the soul, are not solid and satisfactory; that Aristotle did not believe it; and that the whole proof of a future existence depends upon revelation, on which ground he was firmly convinced of its truth. On this subject he published a treatise "De Immortalitate Animæ," and the doctrine became so popular, that pope Leo X. thought it necessary to issue a bull to suppress it; and the monks were so clamorous in denouncing it as an impious production, that the book was condemned to be publicly burnt at Venice, and it was with some difficulty that the author himself escaped the flames. He owed his life to the powerful influence of cardinal Bembo. Pomponazzi was author of some other works, particularly "De Fato, libero Arbitrio, Prædestinatione, et Providentia," and "De Incantationibus," which were not published till after his death. Moreri. Bayle.

POMPONESCO, in *Geography*, a town of Italy, on the Po; five miles S.E. of Sabionetta.

POMPONIO-LETO, GIULIO, in *Biography*, one of the Italian literati of the 15th century, was born about the year 1428, at Amendola, in Upper Calabria. He was the illegitimate son of a noble of very high rank, and his baptismal name has not been ascertained; but he assumed that of Pomponius from the love of antiquity, subjoining that of LÆTUS, which he sometimes changed into INFORTUNATUS. He was rather whimsical in his names, and occasionally called himself Julius Pomponius Sabinus. He went to Rome at an early age, where he was initiated into classical literature, and in 1457 he succeeded one of his masters, viz. Lorenzo Valla, in his school. At this period, the noble remains of antiquity in that city, and the memory of its past grandeur, so inflamed his imagination, that the study of its topography and relics became his ruling passion. There was not a corner in Rome, which possessed any vestiges of ancient times, with which he was not well acquainted. He was frequently seen wandering pensive and alone among these scenes; and so great was his enthusiasm, that when any object, that he had not contemplated before, struck his eye, he would stand in a kind of extacy, and weep with tenderness; and it is said, his fixed attitude, with his wild looks, and mean apparel, made him almost pass for a spectre haunting the ruined walls and caverns. Pomponio founded an academy in Rome devoted to classical literature and antiquarian researches. Each of the members assumed a Roman or Grecian name, and at their meetings they discussed questions of history and antiquity, and sometimes of philosophy. The freedom which they took in their conversations, was the cause of a terrible storm, that fell upon them in 1468, during the pontificate of Paul II. To a charge of impiety and heresy, was added that of a conspiracy against the pope, who caused all of them, who were within his reach, to be apprehended and put to the torture to force a confession. Leto, who was at that time in Venice, was brought in chains to Rome, and subjected to a rigorous examination. He was probably completely cleared from the suspicion of all guilt, as he was allowed again to open his school in Rome, which he continued for twenty-eight years longer. Such was his assiduity in his occupation, that he was accustomed every morning, at break of day, to go to his school, and there explain the Roman authors to a crowd of auditors, many of whom, on account of the smallness of the room, were obliged to stand in the street; so great was the ardour for literature in those days. He had furnished his house with marbles and other monuments of antiquity, some of which had

been presented to him by Lorenzo de Medici. He died in 1498, at the age of seventy. He was author of various works, principally relative to Roman history and antiquities. Of these the following are the principal, "A Compendium of the History of the Roman Empire from the Death of Gordian the Younger to the Exile of Justin III.;" "Treatises on the Magistracies, Priesthoods, and Laws of Rome;" "De Antiquitatibus Urbis Romæ;" and commentaries on various Latin authors. He made great collections of ancient inscriptions, but is charged with having offered some fictitious ones to the learned world. He was probably imposed upon himself, and therefore the imposition upon others was innocent.

POMPTINE MARSHES, *Pomptine Paludes*, in *Ancient Geography*, denote a district in the S.E. part of the Campagna di Roma, and derive their appellation from "Pometium," a considerable town of the Volsci. Although this city was so opulent as to enable Tarquin to build the Capitol with its plunder, yet it had totally disappeared before the time of Pliny. Homer, and after him Virgil, represent the abode of Circe as an island, and Pliny, alluding to Homer, quotes this opinion, and confirms it by the testimony of Theophrastus, who, in the year of Rome 440, gives this island a circumference of 80 stadia, or about 10 miles. It is not improbable that this vast plain, even now so little raised above the level of the sea, may, like the territory of Ravenna on the eastern coast, have once been covered by the waves. Whatever may have been its state in fabulous times, the same Pliny relates, on the authority of a more ancient Latin writer, that at an early period of the Roman republic, the tract of country afterwards included in the marshes contained 33 cities, all of which gradually disappeared before the ravages of war, or the still more destructive influence of the increasing fens. These fens are occasioned by the quantity of water carried into the plain by numberless streams that rise at the foot of the neighbouring mountains, and for want of sufficient declivity creep sluggishly over the level space, and sometimes stagnate in pools, or lose themselves in the sands. The principal of these streams are the Astura, the Nymfa, the Teppia, the Aqua Pazza, in the upper, and the Amasenus and Ufens in the lower marshes. The pools or lakes line the coast, and extend from the neighbourhood of the mouth of the Astura to the promontory of Circe. The flat and swampy tract spread from these lakes to the foot of the Volscian mountains, and covered an extent of eight miles in breadth and 30 in length, with mud and infection. The loss of so much fertile and valuable land, and the exhalations arising from such a vast tract of swamp, carried not unfrequently to the Capitol itself by the southerly winds, must have attracted the attention of a people, as active and industrious as the ancient Romans. Appius Claudius, about 300 years B.C., when employed in carrying his celebrated road across these marshes, made the first attempt to drain them; and his example was, at long intervals, followed by various consuls, emperors, and kings, down to the Gothic Theodosius inclusively. The wars that followed the death of this prince, the devastation of Italy, and the weak and unsettled state of the Roman government, withdrew the attention from cultivation, and left the waters of the "Paludes" to their actual operation. The popes, however, when their sovereignty was established, and their attention no longer distracted by the piratical visits of distant, or the inroads of neighbouring barbarians, turned their thoughts to the amelioration of the inundated territory; and we find, accordingly, that from Boniface VIII. down to the late pontiff Pius VI. no

fewer than 15 popes have attempted this grand undertaking. Most of these efforts were attended with partial, none with full success.

Of the methods employed by Appius, and afterwards by the consul Cethegus, we know little, though not the road only, but the traces of certain channels dug to draw the water from it, and mounds raised to protect it from sudden swells of water, are traditionally ascribed to the former. Julius Cæsar is said to have revolved in his mighty mind a design worthy of himself, of turning the course of the Tiber from Ostia, and carrying it through the Pomptine territory and marshes to the sea at Terracina. This grand project, which existed only in the mind of the Dictator, perished with him, and gave way to the more moderate but more practicable plan of Augustus, who endeavoured to carry off the superfluous waters by opening a canal all along the Via Appia from Forum Appii to the grove of Feronia. It was customary to embark on this canal at night time, as Strabo relates, and Horace practised, because the vapours that arise from these swamps are less noxious during the coolness of the night, than in the heat of the day. Many of the inconveniences of the marshes still continued to be felt, as appears from Horace's complaints, and the epithet applied by Lucan to the Via Appia :

“ Et qua Pomptinas via dividit *Udu* paludes.” L. iii.

However, the canal opened by Augustus still remains, and is called the “ Cavata.” The luxury and improvident policy of the immediate successors of Augustus, and the civil wars that raged under Galba, Otho, Vitellius, and Vespasian, diverted their attention from works of peace and improvement; so that the marshes had again increased, and the waters swelled, so as to render the Via Appia nearly impassable. (See Sil. Ital. lib. viii.) At length Nerva resumed the task, and his glorious successor, Trajan, carried it on during ten years, and with so much activity, that the whole extent of country from Treponti to Terracina was drained, and the Via Appia completely restored in the third consulate of that emperor. This event is commemorated in three inscriptions, one of which may be seen on a marble slab at the village of Treponti: another more explicit was found near the 42d mile-stone on the Via Appia, and the third exists on a stone in one of the angles of the wall of the cathedral at Terracina. During the convulsions of the following centuries the marshes were again overflowed, and again drained by Cecilius Decius, in the reign of Theodoric. The commencement of this work is announced in an epistle drawn up in the declamatory style of the times, and addressed by the Gothic prince to the senate. Its success is acknowledged in another to Decius, containing a grant of the lands drained by him free from taxes for ever.

Of the different popes who have revived this useful enterprise, Boniface II., Martin V., and Sixtus Quintus, carried it on with a vigour adequate to its importance, and a magnificence worthy of the ancient Romans. But the short reigns of these benevolent and enterprising sovereigns did not permit them to accomplish their grand designs; and their successors of less genius or less activity contented themselves with issuing briefs, and imposing obligations on the communities and proprietors to support and repair the drains. The glory of finally terminating this grand undertaking, so often attempted and so often frustrated, was reserved for the late Pontiff, Pius VI., who, immediately on his elevation to the papal throne, turned his attention to the Pomptine marshes. The level was taken with precision, the depth of the different canals and outlets founded, the degree of decli-

vity in the beds of the rivers ascertained, and at length the work began in the year 1778. It was carried on, with incredible ardour and vast expence, for the space of ten years, and at length crowned with complete success, and closed in the year 1788. The draining of the Pomptine marshes is one of the most useful, as well as most difficult works ever executed, and reflects more lustre on the reign of Pius VI. than the dome of the Vatican, all-glorious as it is, can confer on the memory of Sixtus Quintus. In order to secure the permanent benefit of this great work, it is necessary that the canals of communication should be kept open, and the beds of the streams cleared. It is reported, however, that since the last French invasion, these necessary precautions have been neglected, and that the waters begin to stagnate again.

Mr. Eustace informs us, that when he and his companions crossed the Pomptine marshes, fine crops of corn covered the country on their left, and seemed to wave to the very foot of the mountains; while on the right numerous herds of cattle and horses grazed in extensive and luxuriant pastures. In their worst state, these marshes, on the side towards the sea, are covered with extensive forests, that inclose and shade the lakes which border the coasts. These forests extend, with little interruption, from Ostia to the promontory of Circe, and consist of oak, ilex, bay, and numberless flowering shrubs. Eustace's Classical Tour through Italy, vol. i.

POMPTON, in *Geography*, a town of America, in Bergen county, New Jersey, situated on Ringwood, a branch of the Passaic river, about 23 miles N.W. of the city of New York; containing 2060 inhabitants.

POMPUS, a town of Peru, in the diocese of Lima; 90 miles N.E. of Lima.

POMUM, in *Gardening*, a term applied to those sorts of plants and trees which bear fruit of the apple kinds, or which is of a fleshy nature. See PYRUS.

POMUM, in *Botany and Vegetable Physiology*, an Apple, is a peculiar kind of fruit, consisting of a fleshy coat, like the DRUPA, see that article, but enclosing a capsule with several seeds, of which the common apple and pear are true examples. But in the Linnæan genus *Sorbus* are some species, the Mountain Ash for instance, whose capsule is of so membranous a texture, as to approach the nature of the cell of a *bacca*, or berry. Hence Gærtner considers the *pomum* as one sort of *bacca* only; and hence the writer of the present article has, in the *Flora Britannica*, reduced such species to PYRUS; as will be seen in its place.

POMUM *Adami*, in *Anatomy*, the prominence in the throat, caused by the thyroid cartilage: it is observed only in the male, and has been so called in reference to a notion, that the apple which Adam attempted to swallow stuck at that part. See LARYNX.

POMUNKY CREEK, in *Geography*, a river of Maryland, which runs into the Potomack, N. lat. 38° 38'. W. long. 77° 12'.

PONADA, a town of Hindoostan, in the circar of Joodpour; 22 miles W. of Meerta.

PONÆA, in *Botany*, so called by Schreber, in memory of John Pona, an apothecary of Verona, who published in Italian a celebrated account of a journey to mount Baldus, with wooden cuts. In this work many descriptions and figures of Cretan plants are also given, and the whole is translated by Clusius in his *Plantæ Exoticae*.—Schreb. Gen. 266. Willd. Sp. Pl. v. 2. 470. (Toulicia; Aubl. Guian. v. 1. 359. Juss. 248. Lamarck Illustr. t. 317.)—

Class and order, *Ostaudria Trigynia*. Nat. Ord. *Sapiudi*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five deep, roundish, concave, spreading segments. *Cor.* Petals four, lanceolate, acute, larger than the calyx, tipped with hairy glands, and attached to the annular receptacle of the flower. *Stam.* Filaments eight, capillary, inserted into the same receptacle, the alternate ones largest, as long as the petals, and opposite to them; anthers ovate. *Pist.* Germen oblong, triangular, somewhat stalked; styles three, short; stigmas acute. *Peric.* Capsule of three cells, each with a wing of two valves. *Seeds* solitary, ovate.

Ess. Ch. Calyx in five deep segments. Petals four. Capsule with three cells and three wings. Seeds solitary.

1. *P. saponarioides*. Willd. n. 1. (*Toulicia guianensis*; Aubl. Guian. v. 1. 359. t. 140.)—Found by Aublet, on the banks of the river Sinemari in Guiana, twenty-five leagues above its mouth. It bears flowers and fruit in November, and forms a lofty tree, about seven or eight inches in diameter, known to the natives by the name of *Toulici*, the origin of Aublet's barbarous appellation of the genus. The leaves are winged, of many pair of unequal-sized, entire, veiny, smooth leaflets, the largest of which measure eight inches in length. Flowers in dense spikes, collected into panicles at the extremities of the branches. The stalks are downy. Petals whitish, small, like the other parts of the flower.—Nothing is mentioned concerning the qualities or uses of the plant, except that the wood is white and soft.

PONAKELLY, in *Geography*, a town of Hindoostan, in Golconda; 15 miles S. of Byarem.

PONARON, a town of Hindoostan, in the Carnatic; 15 miles E.N.E. of Volconda.

PONAVERAM, a town of Hindoostan, in Coimbatore; 10 miles W. of Daraporum.

PONCE, PEDRO, in *Biography*, a Spanish Benedictine monk, who flourished at the close of the 16th century, is supposed to have been the first person who taught the dumb to speak, and it has been doubted whether the abbé l'Epee, Braidwood, and others, have even yet carried this art to greater perfection. Among his pupils was the family of the constable of Castille, consisting of two brothers and two sisters. One of them, Don Pedro, who lived only to be twenty years of age, spoke and wrote Latin as well as his mother tongue, and was at the time of his death making considerable progress in the Greek language. His own account of him is thus recorded: "Know sir," addressing himself to a friend, "that when I was a child, and knew nothing, even as a stone, I began first to write down the things which my master shewed me, and afterwards I wrote down all the Spanish words in a book which was made for that purpose. Afterwards, with God's assistance, I began to spell, and then to pronounce with all the force I could, though much saliva came from me. After this, I began to read history, and in ten years have read histories of all the world, and then I learnt Latin. All this was by the great mercy of God, without which no dumb person can proceed." Mr. Southey says, that "another of Ponce's pupils became a Benedictine monk, and was able to make confession, and explain his creed by word of mouth." Gen. Biog.

PONCELETIA, in *Botany*, a genus dedicated by Mr. Brown to the memory of the Abbé Poncelet, a French botanist, author of *Histoire Naturelle du Froment*, an octavo volume of 387 pages, with nine plates, published at Paris in 1779, in which the anatomy of wheat is very minutely detailed.—Brown Prodr. Nov. Holl. v. 1. 554.—Class and

order, *Pentandria Monogynia*. Nat. Ord. *Epacridea*, Brown.

Ess. Ch. Calyx leafy. Corolla bell-shaped, five-cleft, beardless. Stamens inserted into the receptacle. Anthers peltate below their middle, their partition bordered. Scales beneath the germen none. Receptacles of the seeds attached to the central column of the capsule.

1. *P. sprengelioides*. Br.—Native of the country near Port Jackson, New South Wales, in marshy places. A small upright slender shrub, whose branches become at length naked, but not annulated; the flowering ones brittle. Leaves with a tubular half sheathing base. Flowers terminal, solitary, erect. Calyx imbricated with smaller leaves. Anthers beardless and unconnected.

PONÇIN, in *Geography*, a town of France, in the department of the Ain, and chief place of a canton, in the district of Belley, seated on the Ain; seven miles N. of St. Rambert. The place contains 2511, and the canton 7956 inhabitants, on a territory of 90 kilometres, in 6 communes. N. lat. 46° 5'. E. long. 5° 25'.

PONCTUER, in *Fr. Music*, to point or phrase a melody, and mark the reposing places more or less strongly: or rather to divide the phrases in such a manner, as to be felt by the hearer.

POND, in *Geography*, a little lake, which neither receives nor emits its waters into any river.

POND, in *Rural Economy*, a reservoir, or receptacle for collecting and preserving water, for the use of cattle or other purposes, usually dug out of the ground.

The importance and necessity of water, in all pastures, is self-evident, as cattle cannot live without it; and the driving them far to it is known to be prejudicial to their health in hot weather, besides being attended with great trouble, and a considerable loss of time. This is so sensibly felt in many parts, that people are obliged to dig wells, even to such a depth, as frequently to require the assistance of a horse to draw up the water. The means of rendering it easily come at must, therefore, enhance the value of the land where it can be procured, and are of very essential consequence to the husbandman. Where the surface of the ground is sand or gravel, there seldom is occasion to dig deep for water; because such soils generally lie upon marle or some other rich earth, through which the water cannot descend. Beds of clay are most commonly thicker than those of sand or gravel; and chalk is often the thickest of all. But wherever water is wanting, the farmer should bore through the incumbent earth, if he intends to fit his land for pasture; and if he finds the expence of obtaining it too great, his best way will be to convert the ground so circumstanced into arable, or to plant it with timber-trees, suited to the nature of the soil and situation.

Various indications of the presence of water below the surface of lands have been suggested by the ancient writers on husbandry; such as the spontaneous growth of different aquatic plants, vapours near the surface, &c.; but the best mode of ascertaining it is by boring; and about the latter end of August, when the ground begins to be a little moist, is probably the most proper season for the purpose. But in whatever method water be found, the means of coming easily at it are the next consideration. If it be on a plain, there is no other way than digging a well. In doing this, the substance under the sand or light soil must be dug into, to form a reservoir of water for occasional wants; and this reservoir should be made deep and large in proportion to the quantity wanted. If there were no such reservoir, the water, after having risen a little above the impervious body underneath, would glide along its surface, as usual, and very little of

POND.

it could then be obtained, either by pumps, buckets, or any other way employed to raise it. If the well is made in a sloping ground, and the declivity is sufficient to give it an horizontal vent, it will be worth the husbandman's while to dig such a passage, and by means of pipes, or any other conveyance, to carry the water across the light soil, through which it would otherwise sink: the greatest quantity of water will be obtained in this manner, because there will then be a continual stream. If the soil is very deep, and its surface has inequalities, in which rain water runs in any quantity, this may be collected in ponds made in the lowest parts of such grounds.

But where a body of clay is found near the surface, it is worth the farmer's while to bore, that he may know at what depth a bed of sand or gravel may be met with; for he will be sure to find plenty of water in this last. If this be in a declivity, he need only cut an horizontal passage, and the water will flow so freely, as even to double the value of his land. Here, again, the farmer needs not ever be at a loss, because it cannot be very difficult to make a pond in a clayey soil, which is, of itself, retentive of water. But it may perhaps be advisable, even in this, to cover the bottom of the pond with a coat of gravel, in order to prevent its being poached by cattle, whose feet would otherwise be apt to sink deep into the clay. Some farmers judiciously pave the declivity by which the cattle enter into the pond, and this renders it much more lasting than it would otherwise be, and preserves the water clean.

In cases where ponds are made in a loose soil, much more care is necessary. The bottom and sides must be covered with a thick coat of the toughest clay, from a foot to two feet thick, well rammed down. Some have added hair and loam to the outer part of this covering, with a view of rendering it less liable to chap; but a thick coat of gravel is more necessary here, that the feet of the cattle may not pierce through the clay. Perhaps the expence of paving the whole inside of a pond might, in the end, be money well laid out.

There is the greatest difficulty in finding water in chalky soils; because these are not, in themselves, very retentive of it, and generally lie in such thick beds, that it is expensive to dig through them. However, it should be tried; and if sand or gravel be found underneath, water may be depended upon. Even here, ponds are easily made by digging into the chalk, and lining them with a coat of clay, as before directed. If there is a supply of proper manure, such as clay, or marle, this situation is well adapted to grain, which loves to stand dry; and as this kind of ground produces more forward crops than clayey or strong soils, it may be sowed early with corn, which will not, in that case, be so apt to be parched up as grass is, by the summer's drought. If a good soil can be made here a foot deep, it will yield plenty of various sorts of pasture, either roots or grasses, as the farmer shall judge most proper: or it may be planted with different kinds of timber trees.

There are different methods of constructing ponds, but the following has been proposed in the sixth volume of the *Annals of Agriculture* for the Yorkshire wold land, which is a dry tract of country, in order at all times, and in all situations, to supply water sufficient for the numerous flocks of sheep, and other cattle, kept upon it, and sufficiently good in quality for domestic purposes. About twelve or fifteen years ago, a man, by profession a well-sinker, first discovered the method of making these ponds; within this period the number of them has been so increased, that scarce a sheep-walk, or even field, is now without one; and the use of them is creeping into the neighbouring country,

in situations where otherwise water could not be had: so sudden and general an adoption is sufficient proof of their utility: before this period many sheep-walks were entirely destitute of water; it is, however, worthy of remark, that most of those sheep which have now a constant supply of water, are, by many intelligent persons, thought, from that circumstance only, to be considerably improved; whether, however, this opinion is well founded, the writer cannot, from his own experience, assert, not having had opportunity to make the necessary observations; but it does not admit of a doubt, that in very dry weather, much fewer sheep die than formerly: this, in several instances, was fully proved during the uncommon drought of a late summer, where the loss among sheep which had not this resource was very great, while that among others of the same kind, and in similar situations, which did not labour under the want, was very trifling; perhaps not greater than would have taken place in any other equal space of time. This plan is shewn in the *Plate* on the potatoe-harrow and set-scoops, in which the line A marks a circular hole dug in the ground, of the size required, upon which a layer of clay, B, sufficiently moistened, is to be carefully beaten and trod down into a compact and solid body, of about the thickness of a foot. Upon this, C is a layer of quick lime, finely and uniformly spread over the whole, of one inch or upwards in thickness. D is another layer of clay about one foot in thickness, which is to be trodden and rammed as the former; upon this are spread stones or coarse gravel, E, of such thickness as may prevent the pond receiving any injury from the treading of cattle, which would otherwise break through the body of the clay and lime, and by so doing let out the water; after this, according to the section, the pond will remain five feet deep, and forty-five feet diameter; the size they are usually made, F being the line of the water and of the ground. Brick-clay is by no means required for the ponds; any earth sufficiently tenacious to bear beating into a solid compact body, though not approaching to a pure clay, will answer the purpose very well.

It is usual, where there is an opportunity, to make the pond in a little valley, or at the bottom of a declivity, or near a high road, in which situation a stream of water may be brought into it after sudden showers or thaws; the object being to get it filled as soon as possible after it is made, that the sun and winds may not crack the clay. If it is not likely to be filled soon, some straw or litter must be spread over it; but in general, after it is once filled, the rains that fall in the course of the year will keep it full, no water being lost otherwise than by evaporation and the consumption of cattle. A pond of this size is usually made from 4*l.* to 6*l.*, exclusive of the time, and the expence of the carriage of the clay, when that is necessary: the first varies in price in different counties; the last will depend upon the distance. The whole excellence of the pond depends upon the lime; care must be taken to spread it regularly and uniformly over the surface of the lower bed of clay. It is well known, that ponds made with clay alone, however good its quality, and whatever care may be exerted in the execution, will frequently not hold water: these, with the above precautions, rarely fail. Never having seen a pond dug up, after it had been made some time, the writer cannot say by what means the lime prevents the loss of water. One of these two is probably the cause: either the lime sets like terrace into a body impervious to water; or, what he should rather think, the causticity of the lime prevents the worms, in dry weather, from penetrating through the clay in search of the water. Certain, however, it is, that with lime thus applied, ponds may be made in sand, however porous; or

POND.

on rocks, however open : in neither of which situations are they to be depended upon, when made with clay alone.

But on this mode of making ponds for the use of live stock, there are several circumstances of the process more fully detailed in the Rural Economy of Yorkshire, under the heads of, 1st, the run, or collecting surface; 2d, the reservoir; 3d, the liming; 4th, the claying; 5th, the covering; 6th, the time of making; and, 7th, the cost.

On the 1st, or the run, the author remarks that a bare firm surface, as a road, collects the greatest quantity of water; but that a grassy surface retains the rain-water which falls upon it, and which, in level situations, is conducted into the soil by worm-holes, and other inlets, with which grass land generally abounds, especially in summer, when a collection is of the greatest value. However, if the subsoil be retentive, ditches, especially of arable inclosures, will frequently afford a supply, even in summer; but in an upland situation, where the subsoil is generally absorbent, a road, or an artificial run, becomes necessary. But that in upland districts, as the wolds of Yorkshire, and the downs of Surrey and Kent, the surface is generally broken into hill and dale, and diversified by smaller vallies and inequalities. In situations of this kind artificial runs are most wanted, and may be most easily made. The writer has seen some faint attempts at making them, on the wolds of this district, by cutting a few grips, with a spade, above the reservoir; but they were too few, too short, and too seldom scowered, to answer, in any considerable degree, the intended purpose. They nevertheless shewed plainly enough the utility of channels for catching hasty showers, falling on grassy slopes, off which a considerable quantity of water will escape, provided there be channels at proper distances to receive it. But in order to reap the greatest benefit from an artificial run, and to make it with the greatest ease, it is advised to form the basin at some considerable distance from the head of a valley; from which, down to the reservoir, to open a main channel by two furrows of a plough turned outwards. From this main stem to plough lateral branches, with an easy descent towards it, along the sides of the slopes, by single furrows, turned down hill; by which means the ploughing will be rendered easy, the channels made free on the upper sides for the admission of water, and high on the lower sides for retaining it. And the plough would not be less expeditious in scowering than in making the channels; or, perhaps a more sledge-like implement would be still more effectual than the plough, in closing the fissures and worm-holes, which presently are formed in water-courses laid dry, and which, if left open, absorb an inconceivable quantity of water before they be saturated, especially if the current of water be retarded by grass, or other obstructions that may be formed in them.

In relation to the 2d, or the reservoir, the situation for them should depend principally upon the run. Near the side of a road is, in general, the most desirable situation, provided a sufficient descent can be had from the road to the reservoir. Roads leading along the sides of slopes can only afford a supply to the grounds on their lower sides. But in this country, when a road leads down the descent, it is generally furnished on both sides with ponds, some of them, perhaps, not having more than an hundred yards of run off a narrow roadway; yet, from that small quantity of surface, are sufficiently supplied with water. In the situation of a pond there is one thing requisite, which does not seem to be attended to, even by the most skilful in the art. This requisite is that of admitting a waste water place, on the upper side of the reservoir, to prevent the water, when the

pond is full, from running through it; by which means it becomes filled up unnecessarily. For the nature of foul water is such, that, whenever it changes from a current to a stagnant state, it deposits a considerable part of its foulness; so that the water that leaves a full reservoir is finer than that which enters it, the sediment, of course, being left behind in the reservoir: whereas, if the current into the pond were to cease when the pond is sufficiently filled, the sediment of the overplus water would be got rid of. The pond would receive, in this case, no other foulness than that which was given by the quantity of water requisite to fill it. The writer thinks that a small catch pool, between the run and the reservoir, would arrest much of the foulness of water collected from a road; and, in a situation which could admit of it, would be worth the trouble of forming. In many situations, the mud it might collect would amply repay the expence of forming it.

The form of the reservoir is universally that of a shallow basin, or, more strictly speaking, that of a flat cone inverted; the sides shelving straight from the brim to an angle or point in the centre. If the excavation be made sixty feet diameter, its greatest depth is about seven feet; if forty feet diameter, its greatest depth is about five, before the coats of clay, &c. be laid on. And a reservoir set out twenty-two yards diameter, by seven feet deep, will, when finished, measure about sixty feet by six, and will hold about two hundred and ten cubical yards, or near seven hundred hogsheds of water. Forty feet diameter, by four feet deep, when finished, contains sixty-two cubical yards, or two hundred hogsheds of sixty-three gallons, wine measure.

The first business in setting out a reservoir is to take the level of the site, and drive piles, as a guide in forming the banks, and in making the conducting channel and waste water place. If the situation be on a slope, the excavated mould is used in forming the bank on the lower side; if nearly level, the mould requires to be removed, or, if laid round the edge, the conducting channel to be raised. But if the clay or stone be excavated, it is laid separately aside, to save carriage. And if the lower side be raised with the excavated materials, they ought to be firmly worked together, or should lie a sufficient time to settle; otherwise the side, thus formed, is liable to settle after the reservoir is finished; by which means cracks are formed, and a miscarriage ensues. When the excavation has received the intended form, its sides are made firm and smooth, for the reception of the lime, or first coat.

In regard to the 3d, or liming, its use is merely that of preventing earth-worms from perforating the coat of clay. The proper quantity depends, in some measure, on the nature of the soil. A fat rich earth, among which worms always abound, requires more than a dead hungry mould, or a dry stony bottom; on which retentive pools are said to have been made, without lime. However, as no soil, perhaps, is entirely free from those enemies to ponds, it would be folly to risk a miscarriage in any situation; as the expence of liming makes but a small portion of the whole expence; and the only preparation of the lime is that of slaking it, and picking out the cores; no sifting or screening being in general used, though obviously useful, where it is usually laid on with a spade or shovel; but a sieve would perhaps be found, by the inexperienced, a better tool, and the extra labour no object; and the thickness of the coat laid on is about half an inch. Half a chaldron of lime is sufficient to complete a pond of forty feet diameter. The principal part of it is laid on beneath the clay; a few bushels only being reserved

reserved for scattering round the edges, to prevent the worms from getting into the clay. A still more secure, and, on the whole, a more eligible, method of liming has lately been thought of, and is now (June 1787) in practice, at Lockton, by the commissioners of inclosure, in making public drinking pools, for the use of the township. Instead of scattering the lime in powder, it is formed with sand into mortar; a regular coat of which is spread about an inch thick, not only beneath, and at the edges of the clay, but over the entire surface. This is an obvious improvement, which appears to human foresight to bring this method of forming pools near to perfection. The clay becomes cased on either side with a regular coat of cement, and is thereby secured, in perhaps the completest manner possible, from the attack of worms. The labour and expence, however, are by this method increased. A pond, nineteen feet diameter, took two chaldrons and a half of lime, and five small cart-loads of sand. Both the materials were sifted, and worked up in the usual way into mortar. Great caution is necessary in laying on the clay, in this case. And if the mortar does not lie some time to stiffen, the clay displaces it: if it get too dry before it be covered, it is liable to crack.

In respect to the 4th, or claying, it is in this operation the manual art and the labour principally centre. And upon the wolds, clay is sometimes fetched six or seven miles, and is seldom found at hand, in situations where artificial pools are most wanted: the carriage of the clay, therefore, generally becomes a heavy article of expence. But the choice of clay is thought to be less essential than the working of it. Good ponds are said to have been made with common loamy mould; but it is wrong to depend on any thing but a strong ductile clay, if it can be had within a moderate distance. And the thickness of the coat, now pretty generally laid on, is about five or six inches in the rough, beating it down to about three inches. In the infancy of the art, two coats of clay, of about that thickness, were laid on; but one coat has been found effectual, and much less expensive. However, it is probable it will not prove so durable. The method of beating will be difficult to describe, yet it most especially requires description. The drier the clay is worked, the less liable it will be to crack with drought, when finished. In a dry season, however, it is necessary to moisten it: for which purpose, the centre of the pit is sometimes finished first, to collect the water of showers; the carriage of water being in some cases expensive. In executing the work of laying on the clay, the workmen begin at the bottom of the pit, and work upward; laying patch after patch, or circle after circle, until the brim be reached; taking great care not to carry on sticks, straws, dirt, or any kind of foulness, among the clay, or with their feet; and being careful not to displace the lime, in throwing it on: to prevent which, the lime is not spread over the whole at once, but is scattered on, as it is wanted to be covered with the clay. And as soon as a plot of clay is laid on, and adjusted, it is beaten flat with a wooden "mell," or beetle, made at present of these dimensions: the head fourteen inches long, and three inches diameter; the handle four feet long, and suited in thickness to the hand of the workman. Beetles of different sizes have been in use, in different stages of the art; but none of them have been found to be so well adapted to the operation as that in use at present. The first operation is performed with the side of the beetle, to level the protuberances, and smooth the roughness, so as to make the whole into a regular sheet of an even thickness. And when

this is effected, it is struck forcibly with the end of the beetle, which is driven down nearly, but not quite, to the lime; leaving the surface full of somewhat honey-comb-like cells or dints. If the beetle be struck unguardedly quite through to the lime, a piece of clay, and a little lime, if required, is carefully placed in the breach, to prevent a defect in the part thus injured. And the whole being gone over, in this manner, with the end, the surface is again levelled down with the side of the tool; the workman passing backward.

The next beating is with the end, but not quite so deep as before; and the roughnesses being again levelled with the side, it is again worked over with the end, but still shallower than in the middle beating. The first strokes with the end of the beetle ought to close the bottom of the clay firmly with the lime, and the bed on which it is spread; the second ought to unite the middle of the clay with the bottom; and the last to close, without a pore, the upper part with the middle; and the last strokes, with the side of the beetle, ought to be sufficiently forcible to close entirely the dimples formed by the last given strokes with the end. When these several operations are thought insufficient, it is continued to be worked with the end and side of the beetle alternately, until not a flaw can be found; the entire coat of clay being manufactured into a lead-like sheet, firm enough to bear a man without an impression, and a horse without injury. And when two coats of clay were in use, the upper one was laid upon the rough surface of the last end-beating; by which means the two coats became, by the subsequent beatings, incorporated in one thick sheet: a substantial method this, of which the present appears to be rather a refinement, than an improvement.

In the 5th operation, or covering, the first coat is of common earth, to assist in keeping out the drought, and to make a bed for the stones; to prevent their asperities from piercing, and thereby injuring the sheet of clay. This coat may be three or four inches thick, according to the nature of the stones with which it is to be covered. If these be large and irregular, more earth is requisite than when the stones are small, smooth, or flat. The leanest, most infertile soil is fittest for this purpose. Worms and weeds are equally to be feared, and a rich soil is genial to both. In this point of view, two coats of clay are much preferable to a coat of clay and a coat of rich mould. The persons employed in this sort of business are not sufficiently aware of the mischievousness of weeds: indeed, some ponds will remain, for several years, in a manner free from them; but there are others, in which weeds, even docks, (near the edge,) have grown luxuriantly. It is probable that the tap-rooted weeds strike through the several coats; and whenever the roots decay, a perforation must be left. And mould taken from a dry found highland situation is, in all human probability, less liable to propagate aquatic weeds, than the earth of a low situation or bog. The following is an ingenious and simple method of keeping the weeds under, especially at the edges, where they are generally most abundant. Though all the sides of a drinking pool be open, cattle will go to particular places to drink; and in these places the weeds are trampled upon and killed: therefore, to check the rankest, the parts which are most free are covered with thorns, while those which are weedy are left open for the cattle to drink at.

The mould being rendered level and smooth, the stones are laid on: first covering the mould with the largest, laid with a flat side downward, to prevent their sinking down to the clay; and upon these laying smaller, until the coat be made

made five or six inches thick. Straw has been used between the clay and the stones; and that in the instance in which an improved method of liming was practised, a layer of thick fods was laid, grass-side downwards, upon the lime; and upon the fods, about six inches thick of loose stones.

Mr. Marshall, however, suggests that a pavement would be a more regular covering; and, if the stones were set in lime and sand, would not only prevent worms from getting into the mould, and upper side of the clay, when the pond happened to be dry; but would, in all probability, prevent weeds; and when the pond required to be cleaned from mud, would be a regular floor to work upon. And the only objection he has heard made to paving the bottoms of ponds is, that it would be a temptation to cattle to go into the water in hot weather; and by standing there, would not only foul the water, but in time tread up the pavement, and injure the clay; whereas sharp loose stones prevent their going farther than the edge. If the stones made use of in a pavement were sufficiently large, the latter part of the objection would fail; and whether cattle standing in a pool, in summer, be detrimental or beneficial may be a disputable point. But that whether or not the inside of the basin ought to be paved, the rim should certainly be a broad smooth causeway, with a gentle grassy slope from it; especially on the lower side, that the cattle may approach the water, without wading in dirt, to the injury of the bank; and without having sharp loose stones to walk and stand on while drinking. He thinks that a drinking pool, formed by a skilful artist, full to the brim, free from weeds, and smooth round the edge, is, in a green pasture ground, as agreeable an object as the eye can be entertained with.

In respect to the sixth, or the season of making them, the autumn is esteemed the best time, as has been seen above. Drought and frost are both enemies to new-made ponds. In autumn, drought has generally abated, and a sufficiency of rain water may be expected in this season, to fill them before frosts set in. A covering of straw over the stones is the usual guard against the extremities of seasons. And where a reservoir is formed in a slope, where the lower side requires to be raised with loose earth, it ought to remain a considerable time to settle before the coatings be put on; otherwise it is liable to settle afterwards, and crack the clay. He has seen an instance of miscarriage through this neglect. If there be much made earth requisite to be raised, the excavation ought to be formed twelve months before the claying is done.

But in speaking of the 7th, or expence, Mr. Marshall remarks, that though it is now twenty years since the discovery was made, the art is still partially hid under the veil of mystery; and is not yet become familiar to common farm labourers. In this neighbourhood, ponds still continue to be made by men from the wolds; all of them, in reality or pretence, pupils of the first inventors. And these men generally work by the gross; the price being in proportion to the diameter; but they seem to have no regular method of calculation. Ten pounds were formerly given, and may now be considered as a medium price, for twenty yards diameter; forming, claying, covering, and, generally, digging the clay, included; all carriage and extra labour being done by the employer. But in the early days of the art, and when two coats of clay were used, twenty pounds were given for ponds of this dimension. A circle twenty yards in diameter contains in its area 314 square yards. Therefore, each square yard of surface costs, at this price, seven-pence halfpenny. And that the solid contents of a cone, whose base is 60 feet diameter, and whose height is six feet, is 209.4 cubical yards; each of which costs, in the above instance, eleven-pence halfpenny. And five pounds have been given for a pond

twelve yards in diameter; which is ten-pence halfpenny each square yard of surface; and supposing it four feet deep, two shillings each cubical yard of water. And three guineas were given for forty feet diameter, and four feet deep, the excavation having been previously formed. This may be called four pounds for the gross; which is about seven-pence a square yard of surface; or fifteen-pence halfpenny each cubical yard of water. The men, in the last case, earned about three shillings and sixpence a day, without extraordinary exertion. In the first-mentioned instance, the same workmen did not (according to their own assertion) make more than two shillings and sixpence a day. But a large pond gives longer employment; and the business of pond-making being uncertain and inconstant, travelling workmen can afford to make a large pond at a cheaper rate than a small one. And the curve superficies or superficial contents of the sides, of a cone twenty yards in diameter at the base, and two yards high, is about 320 square yards. This, in making a pond of those dimensions, is the quantity of coating: for each yard of which near seven-pence halfpenny was given in the first instance, and less than seven-pence in the last. Sixpence each square yard of surface to be coated, may perhaps be taken as a fair medium price. At present, however, work of this sort is performed at a much higher price, as from ten-pence to a shilling, or more.

But to ascertain the quantity of coating to be done, it is advised to measure the exact circumference or rim of the pit, when finally formed and adjusted for claying; this dimension multiplied by half the length (or depth) of the side (measuring from the brink, down the slope, to the centre), is the quantity of surface to be clayed and coated. The digging would (under this mode of calculation) fall proportionably heavier on a large pond than on a small one, but this would be counterbalanced by the advantage above-mentioned.

The quantity of clay used, in the first instance, was about forty cart loads, fetched about three miles: in the last, about fifteen loads, fetched one mile. The quantity of lime in the former case, one chaldron; in the latter, half a chaldron.

On these principles it is plain, that the larger the pond, the less in proportion is the expence. A reservoir, to contain 200 cubical yards of water, requires little more than 300 square yards of coating; whereas one, to contain only 50 yards of water, would require 120 yards of coating; consequently, a cubical yard of the former would only cost (at nine-pence a yard for manual labour, materials, and carriage) eighteen-pence; while the same quantity of the latter would cost near two shillings and sixpence. This is, therefore, a point that should be attended to where this sort of work is to be performed.

The superiority of those ponds made in the manner above described, to those which have formerly been made by some other art, or which have been formed by nature or accident, may be mentioned. During the dry seasons which have prevailed of late years, it has been observed that newly made ponds retain a supply of water, when the waters of other stagnant drinking places are dried up. This can only be accounted for, perhaps, by their perfect retentiveness, and by their being free from weeds, which convert to their own nourishment, and throw off daily, by perspiration, a great quantity of water. Upon the wolds their excellence was most conspicuous:—while one man was driving his stock three or four miles to water, his neighbours, who had *made ponds* upon their farms, were free from this serious inconveniency. In many situations artificial ponds may, the writer thinks, repay the expence of making the first dry season. Driving stock to distant water in hot weather, and in a busy season,

POND.

is an expence, and a detriment to the stock so driven, which it would be difficult to estimate in many instances.

This important subject is concluded by remarking that on examining ponds in this neighbourhood, which have been made some years, the evil effect of covering with loose stones is evident. As for one, two, three, or more yards round the edges, according to the time they have been made, the use they have been liable to, and to the steepness of their sides,—the stones are entirely displaced, or trodden into the clay; which is, by this means, exposed to the feet of cattle, and to the open attack of drought and worms. For a while the clay, even thus exposed, preserves its retentiveness; but, in time, it is destroyed, and the most valuable part of the pond entirely lost. The writer adds, that this effect is so probable, so evident to be foreseen, that, on the first reflection, it seems astonishing so unsuitable a covering should be universally adopted. A beast, when it goes into a drinking pit, necessarily throws the chief part of its weight upon its forefeet; which, in the act of drinking most especially, are placed, as for the intention of forcing whatever they stand on down the slope, toward the bottom of the pit. Upon loose stones, laid on a steep surface, cattle cannot make a step, or move a foot without producing this effect in a greater or less degree, and by repetition and length of time, the entire coat (except some few stones which happen to be trodden into the clay) must, in the nature of things, be forced into the centre. But this absurd practice was first established upon the wolds, whose stone is of a perishable nature,—a species of chalk; which, on being exposed to air and water, and to the treading of cattle, unites into a cement, which, forming a regular casing, preserves the clay from injury for a considerable length of time. Loose chalk as a covering was, therefore, a good thought of the first inventors (indeed upon the wolds there was no alternative); and it is not to be wondered at, that their pupils, mostly day labourers, should imitate the practice in this country, by making use of loose stones for the purpose. But perishable or soft stones of any species, a strong rough gravel, or even sand, would, the writer believes, be better than loose hard unperishable stones. Though in this neighbourhood, where stones of various kinds abound, or in any country where stones of a proper size can be procured at a moderate expence, there appears to him to be no choice with respect to covering. A regular firm pavement, strong enough to bear stock without an impression, would last through ages; and although the expence, in the first instance, would be something more than that of loose stones, its durability would, in the end, doubly repay it. Even the wold ponds, which have been made fifteen or twenty years, are many of them beginning to fail, and will, in a few years more, require to be fresh coated; whereas, a pond properly paved would, in all human probability, remain perfect for at least a century. Where rough stones are used, they should be placed with the smooth side downwards upon the clay. And besides this, the pavement of stones has, the writer thinks, much less tendency to be disturbed by the pressure of the feet of the animals, from its being a sort of inverted dome, which acts as an arch against the materials underneath it.

The following hints have been suggested by Dr. Anderson in his "Recreations in Agriculture, &c." for collecting water in different cases for farm uses, in situations where it is not easily procured.

For this purpose he would beg leave to direct the attention to one never-failing source of water in this island, which, if duly husbanded, will certainly, he says, preclude the danger of want at any season, for almost any purpose, either

for man or beast, that can ever occur. He here refers to the rain that falls upon the roofs of houses, which amounts to a much greater quantity than most persons are aware of. It has been ascertained by repeated experiments, that in scarcely any part of this island does there fall less than twenty-eight inches deep in a year. At this rate there will fall upon every square foot of roof of any house above seventeen gallons and a half of water; or upwards of two hogsheds and a half on every square yard. At that rate, a house of thirty feet in length and twenty in width (which is not larger than an ordinary cottage), would collect one hundred and seventy-five hogsheds in a year, which would afford the expence of half a hogshed a day. There are few farms with their offices that have not roofs to ten times the extent of the above; so that were this water all preserved, they could expend at the rate of five hogsheds a day throughout the whole year, which would be sufficient for a very extensive stock of cattle. But when we consider that in almost every situation cattle can be easily supplied with water from other sources for the greatest part of the year, it will appear very plain, that if all this water were carefully preserved, no farm could ever be in want of water for cattle or other purposes. All that is wanted then is, to discover an easy manner of collecting and preserving that water till it shall be wanted; which he proceeds to shew is not a difficult matter. Few houses are now built, without having spouts placed along the eaves to collect the rain-water and convey it into a reservoir, usually a wooden cask, for the purpose of washing. But this reservoir is usually so small as soon to be filled, when the surplus runs over and is lost. Instead of that, let the whole of the water thus collected be led by pipes to one place, where it may be let into a well, dug in the ground to a proper depth for that purpose, and covered at top. It will there be screened from the sun, and prevented from evaporation, so as to be kept sweet and cool as long as necessary; and it is well known that no water is so pure and wholesome as rain-water. But to those who are peculiarly delicate it may occur, that some impurities may be washed off by the rain from the roof, which they would wish to get rid of. This may be easily and effectually done, by sinking another well at a moderate distance from the first, making a passage between the two near the bottom, to be filled up with small clean sand and gravel, through which the water must percolate before it reach the last well; in consequence of which it will be perfectly purified. The pump for supplying the family should be fixed in this last well, where it will of course find nothing but pure water.

But for the sake of cattle, if it be necessary, he advises that another reservoir be formed, also under ground near to the pump well, with which it may communicate by means of an opening at one side near the top of the well, through which the superfluous water will run off when it rises above that level. This may be made in the form of a trough, covered as far as may be found convenient, and open towards one end for the cattle to drink, without allowing them to set their feet in it.

In cases where the house is upon an eminence, it will be very easy to convey the water from this last reservoir, by means of a pipe under ground, to any convenient part of the fields or garden, where it may terminate in a box, to communicate with a trough for the cattle by means of a ballcock, which always allows water to flow into the trough as it is drawn off, and closes of itself when it is full, so as to keep it always full without ever running over. In this way abundance may at all times be had without any waste; and the pure element procured for the cattle, without any extravagance of expence. If pools are made in the
lower

POND.

lower places of the fields, the cattle may in these occasionally cool themselves: but if they have ready access to the troughs they never will drink there. But for fields which are at a distance from the house, where the surface of the ground is not a dead level, wells of this sort may be formed by collecting the water that flows over the surface of the ground, during rainy weather, and leading it into these wells. But these reservoirs should be always covered, and only have an open trough at one place to allow cattle to drink. He supposes that by these very simple contrivances many parts of the country that are now much distressed at times for want of water, may be effectually relieved, so as never to suffer any future inconvenience; and much expence in carting water to many villages might be entirely saved.

In the making of most other sorts of ponds, where the soil is of the more loose and porous kinds, it will be almost constantly necessary to have recourse to the same methods of management, only in particular cases it may not be requisite to make use of the limy material, which is rather expensive, and a good coat or lining of well wrought clay will answer every purpose perfectly well.

Wherever ponds or reservoirs of water are sufficiently high, they may be converted to the purposes of irrigation in many seasons with vast advantage to the farmer, without the use of machinery. Ponds are likewise beneficial for the purpose of breeding and preserving fish in many situations. See FISH-PONDS.

The management of the water of ponds is often very troublesome and inconvenient in the time of heavy rains or floods, from the want of proper means or contrivances for letting it off. The following is the sketch of a very easy, convenient, and effectual method of discharging the overabundant water from all sorts of ponds, basons, and reservoirs, without the necessity of attending to them at such seasons. It is the invention of Mr. Ley, a very ingenious clergyman in the county of Devon, in the agricultural report of which it is described. The plan of it is represented at *fig. 6.* in the *Plate on the Potatoe Harrow, &c.* in which A is the head of the pond; B, a beam of wood, suspended by an iron pin on the block W, so as to form a sort of lever, or balance, having attached to one end of it the box C, which is made so as to be rather leaky, and to the other the plug D, which, when the water of the feeding stream, or from rains, rises to the level of the surface of the pond F, is conveyed through the trunk or gutter, X Z, into the box C, by the weight of which the plug is drawn out, and the water carried off by the trunk E, at the bottom of the pond, as seen by the letter G. On account of the box, C, being so constructed as to let out the water very slowly, by the time the whole of the water has been discharged from the pond, bason, or reservoir, it will likewise have escaped from it, when, by the weight of the beam and plug, the empty box is raised, and the plug again placed in the trunk in its former situation.

It is evident that, from this ready method of getting quit of the water, no mischief can ever be sustained by its sudden rising and overflowing the banks of the ponds or other excavations, accidents which, under other circumstances, not unfrequently happen, to the great inconvenience and injury of those to whom they belong.

POND-Fisheries, in *Rural Economy*, are such as are formed in ponds, where the water is, for the most part, in somewhat a standing state. Ponds of this nature are occasionally met with in the county of Middlesex, as well as many others in different parts of the kingdom; but they are more attended to in Suffex, and the neighbouring counties, than any where else, in the view of producing fish for the purpose of sale.

There are ponds provided in various places in the above-named county for this use, and the raising of fish in them is an object of some consequence to the inhabitants. The ponds in the wolds are said to be innumerable; and numbers of them date their origin from that part of the county having once been the seat of an extensive iron manufactory, which has now deserted the country; and the mill-ponds now also raise large quantities of fish. A Mr. Fenn, of London, has long rented, and is the sole monopolizer of all the fish that are sold in this county. Carp is the chief stock; but tench and perch, eels and pike, are raised. A stream should always flow through the pond; and a marly soil is the best. Mr. Milward has drawn carp from his marle-pits 25lb. a brace, and two inches of fat upon them, but then he feeds with pease. When the waters are drawn off, and re-stocked, it is done with stores of a year old, which remain four years; the carp will then be twelve or thirteen inches long, and if the water be good, fourteen or fifteen. The usual season for drawing the water, is either the autumn or spring; the sale is regulated by measure, from the eye to the fork of the tail. At twelve inches, carp are worth 50s. and 3*l.* per hundred; at fifteen inches, 6*l.*; at eighteen inches, 8*l.* and 9*l.*; a hundred stores will stock an acre; or thirty five brace, ten or twelve inches long, are fully sufficient for a breeding pond. The first year the young fish will be three inches long; the second year seven; the third year eleven or twelve; and the fourth year fourteen or fifteen. This year they breed.

In stocking the ponds here, store fish of all the different sorts are made use of, both while very small, and when they are from two or three to eight or nine inches in length.

In Burton park, in this district, Mr. Biddulph has a fine reach of water, which yields carp, tench, perch, pike, &c. in great abundance, and from which vast quantities are occasionally taken and sold.

At Mitchel grove, sir John Shelley's pond, which contains one acre and thirty poles, and is fished once in three years, affords each time about 2*l.* 6*s.* 8*d.*, besides a sufficiency of young fish to stock two ponds.

Lord Egremont has several noble ponds for breeding, and others for fattening, one immediately under another, with streams running through them. They are fished every third year; and the best fish reserved for the stews; but none sold.

The tench remain for two fishings in his lordship's ponds, as they are a slow growing fish. At the last fishing of one of these ponds, three hundred store tench, and as many store carp, were put into it; the stores are worth 10*s.* 6*d.* a hundred. Male tench are good for nothing, and are thrown away; hen tench only are preserved. It is rather difficult to mark the distinction between the male and the female. Male perch are known by the appearance of milk upon squeezing; tench by the thick fin of the males. If the waters are good, about seventy two-years old store carp, and as many tench, are a fair allowance for one acre hereabouts.

In the Berkshire Report on Agriculture, it is stated that E. L. Loveden, esq. has two fine pieces of water, which apparently unite, covering thirty-three acres of land; and which produce plenty of pike, sometimes of very large sizes, as eighteen or twenty pounds weight each, eel, carp, tench, perch, trout, &c. Also about the parishes of Oakingham, Hurst, Lawrence, Waltham, and Ruscombe, there are many gentlemen who have natural or artificial fish ponds, which are let to tenants, and produce every third or fourth year a crop, if it may be so termed, of carp and tench. The occupiers stock them with yearlings about two inches

POND.

long, obtained chiefly from Yately, on the neighbouring confines of Hampshire. The breeders are about eight or nine pounds weight there; but in the Berkshire ponds they are never suffered to breed, but are sold off to the inns at Henley and other places, when the ponds are drawn, which is generally once in four years, and weigh, at that age, about three or four pounds each. The value of the land thus applied, cannot, it is supposed, average less than about twenty shillings the acre. S. Nicholls, esq. of Hinton-house, observes, on this subject, that "the ponds are regularly laid empty, and the fish with which they are stocked, which are uniformly carp and tench, are taken out every third or fourth year. The pond is afterwards allowed to lie fallow for the remainder of the summer season, and is again stocked early in the ensuing year with yearling fry of the same species. The ponds thereabouts, it is remarked, are all subject to an abundance of coarse, bony, insipid fish, denominated Prussian or German carp. As the species is carefully destroyed, it is wonderful, it is said, that they should increase with the rapidity and universality which they appear to do; the spawn must be plentiful, and singularly prolific. With respect to the profit, it is so variable, according to the varieties of situation, and exposure to the running of yards, as well as the aptitude to receive nutriment from animal or excrementitious matters, that no general estimate can possibly answer the question about it satisfactorily. Every acre of a pond, properly stocked and well situated, must, in the writer's apprehension, produce an annual increase of from eighty to one hundred pounds weight. If artificially fed, the increase will be greater, or less, if the pond is not so situated as to receive manure from the circumjacent lands. By retail, the fish here are generally sold at a shilling the pound; but under particular circumstances, they may sometimes be had as low as ten-pence.

It is noticed that Mr. Toomer of Newbury is famous for producing trout of a very large size in his stews. Not many years ago he had three fish of that species which weighed fifteen pounds each; two of them had been fattened by himself, the other was of that weight when taken out of the Kennet. At another time he had a trout which grew until it attained the weight of seventeen pounds, when it was given to the late lord Craven, who sent it as a present to his majesty.

The writer of the report mentioned above, dined, he says, in 1805, at Newbury, in a party who had, the day before, feasted on a trout weighing fifteen pounds and a quarter, and which had been fed in a stew for about eighteen months. It measured thirty-one inches in length, twenty and a quarter in circumference, and the length of the jaw was nine and an eighth inches. A trout of one pound and a half has, in the space of a year, grown in a stew to the weight of eight and a half. Instances indeed have been known of a trout growing a pound in the course of a week.

In this district, Mr. Loveden is likewise the contriver of a plan for a fish-house which cannot be robbed. It is built on a small point of land surrounded on three sides by a branch from the Thames, and has iron grates to the east and the west, to allow the water a free passage. Within the limits of the building, whose exterior appearance is that of a neat cottage, are three stews, about eight feet deep from the ground floor, and standing on an average three feet in water, which communicate with each other by holes bored through the wooden partitions. These stews are covered with trap doors, which, when locked, even the person who inhabits the cottage connected with them, could not open and get at the fish, without the certainty of detection. It is suggested that where noblemen and gentlemen of fortune are

desirous of having a regular supply of fish for their tables, and at the same time of providing a residence for a dependent, this kind of pond fish-house may be beneficially erected. See FISH, and FISH-PONDS.

POND Mud, in *Agriculture*, that sort of earthy vegetable material, which is collected from the depositions of stagnant waters, and becomes an useful manure when mellowed by exposure to the atmosphere, and blended with some sort of dung into a kind of compost. See MUD.

Mr. Young considers June as the proper season for emptying ponds and cleansing rivers, for the sake of the mud; for being early in the summer, there is afterwards an opportunity of turning the mud over, and thereby sweetening it, and laying it into the proper state for bringing on the land. This is a part of husbandry, he says, too much neglected by many farmers; but advantage should always be taken of it by a good husbandman, when he is lucky enough to succeed a great slover; for then he will probably find all the ponds, &c. full of rich mud.

He thinks it is improbable that pond mud, especially if there is a stream into the water, should ever fail of proving a good manure, when judiciously used. The method of managing it which has been found the most beneficial, is the following: as soon as the mud is dry and hard enough to spit, turn it over, and, in about three weeks or a month after, mix it with an equal quantity of chalk or marle: either bring the chalk to the mud, or carry the mud to the chalk. If lime is cheap and plentiful, it will be an excellent management to add about one-fourth the quantity of mud in lime. Let the whole be mixed well together and remain until September, when it should be turned over again, and spread upon pasture or meadow land in October. This is husbandry that will pay well in most cases.

It has been observed by the author of the Middlesex Report, that every pond that can be made by the damming of a stream, would collect large quantities of mud, always fit for immediate application on arable land, without any thing else being mixed with it, or on grass, after being mixed and turned up with dung. Of such great use, says he, are ponds, as collectors of mud, that some excellent farmers have a small one at the lowest corner of every close for the water to deposit the grosser parts of its rich sediment in.

In the county of Essex Corrected Report on Agriculture, Mr. Walford states three experiments which he made with mud upon an upland, laid down with grasses about eight years, the mud from a moat, the bottom of which is a white marly clay. In September 1790 he cast the moat, one end of which adjoins the farm-yard, and had received the draining from it eighteen or nineteen years; this part, he was advised, contrary to his own opinion of its being proper, to cart immediately upon the land, and spread it as soon as it was dry enough: he did so, and the effect was infinite injury to the succeeding crop of grass; it caked down so very firm, that the rain and frost, that season, with the assistance of a great deal of labour, did not pulverize it sufficiently for the grass to get through. The loss he sustained was very considerable, there being less hay than on any other part of the field. The following year he was very much inclined to have harrowed it with a heavy pair of harrows, and sow it again with seeds: he did not, yet he is convinced the crop would have been more productive if he had; for it was very light, and not equal to the crop before the mud was carried on.

The third year, being a wet season, it began to work, and produced him a tolerable burthen, but not sufficient to repay the loss of the two former; yet the benefit was very visible,

for the spot where it was laid might have been traced to great exactness.

The mud from the other parts of the moat was thrown upon the banks and left to drain; this he wished to have let remain there a year, to have stirred it over, and then carried it upon the pasture, but was again prevailed upon to carry on two parts out of three as soon as it was dry enough to cart; being told it would save a considerable expence, and be equally beneficial, in both of which he was disappointed: the extra expence of bush-harrowing, and beating the clods to pieces, was more than the stirring would have been; for, like the former, it caked down, and injured instead of benefiting the succeeding crop of grafs, but not in so great a degree, for he thought some advantage was derived from it the second year.

As the two methods above were quite contrary to his own ideas and opinion, he was determined with the mud that remained to adopt the following plan of his own, which probably may not be new in many other places, although it is in this. Instead of carting the mud when dry, he turned it over with a spade, except about one rod at the end, which, from some cause or other, was neglected till March; he then dug it and planted potatoes. The other part, from having had the winter's frost and rains, was very full of mould, and he imagined would do exceedingly well for carrots; it was sown with carrots; but whether from the dryness of the season, the badness of the seed, or the soil not being proper, the latter he believes, his crop was a very bad one; but the potatoes exceeded his expectations; had the whole been planted with them, the produce would have doubly paid him the expence of digging and planting; and the mud received great benefit, by being stirred over when they were taken up.

When the crops were cleared, he carted the mud upon the poorest part of the pasture, and was agreeably surpris'd to find it produced a very fine crop of grafs the June following, superior to many parts of the field that had been well manured at the same time. The luxuriance of the crop was so conspicuous, as to attract the attention of the neighbouring farmers.

Therefore, having met with such great success from the latter experiment, he shall in future empty his ponds between hay-time and harvest, let the mud lie till it is dry enough to dig, then stir it over, and in March dibble in potatoes; being convinced, if it is not the best method to adopt, it is a profitable one, where the mud is taken from a clay bottom.

At Halstead in the same county, Mr. Vaizey tried the mud from a pond which received no more than the wash of a small field, spreading it on the grafs land fresh, and it was decidedly beneficial; but on arable land he has not observed any benefit from it.

In the Oxford Corrected Agricultural Report, Mr. Hair-bottle, of Henley, is stated to have emptied the mud from a pond communicating with the Thames, and spread it for turnips, but that it did no good whatever.

In Lancashire and some other counties, they find the oozy mud taken from below the sand on the sea-coasts, to be a very useful and beneficial manure on the arable as well as the pasture lands. See MANURE.

POND Weed, in *Botany*. See POTAMOGETON.

POND Weed, *Water*. See PERSICARIA.

POND Weed, *Triple-headed*. See ZANNICHELLIA.

POND Weeds, in *Agriculture*, such weeds as are collected in ponds and rivers, and which are often used as manure. Some ponds and rivers are so full of weeds of this kind that they afford vast quantities of manure. It has been re-

marked that nothing is more surpris'ing than the great negligence which prevails, not only in Essex, but most other places, respecting the river *conserva*, which is very abundant in the streams thereabouts, as well as in most other parts of the kingdom. The Mallendine water, it is said, is full of it, in a thousand varieties; but this admirable manure is left to rot in its element; being noticed only by the millers, who, in order to keep it from clogging their mill-wheels, and to allow the water a free draught, cut it at some feet below the surface, with an instrument made of old scythe blades, loosely rivetted together at their ends, to any desired length: they sink this pliant instrument to a convenient depth, with the edge towards the part they are proceeding to, and dragging it with a swinging motion from side to side, as they walk on each side of the river, cut the weeds; which are then easily taken out by means of long rakes.

These weeds, when landed, are suffered to lie on the banks, where they rot in a very short time, and cause the grafs to grow very rank. From the experiments that have been made with these weeds as a manure, they appear to be particularly eligible, when laid on fresh, for light and warm lands; and as there are in this neighbourhood, as well as most others, many spots of that description, such as fine gravelly loams, lying upon chalk, which bear very fine barley, it is thought the owners of those soils are blind to their interests, when they overlook the opportunity that offers of collecting at least two thousand loads of water weeds, which could be annually drawn from the rivers between Stortford, Mallendine, and Elsingham alone!! These, with an immense quantity of slimy sediment, now forming heavy banks in many parts of those waters, and which might be taken out without any great exertion, it is supposed would tend to produce many a good bushel of corn!!

In almost every part of the country there is much too great a neglect of the collection of pond and river weeds for the purposes of manure. See MANURE and WEEDS.

POND Creek, in *Geography*, a river of Virginia, which runs into the Ohio, N. lat. $38^{\circ} 55'$. W. long. $81^{\circ} 55'$.

POND Creek, or Fern Creek, a river of Kentucky, which runs into the Rolling Fork, N. lat. $37^{\circ} 47'$. W. long. $86^{\circ} 16'$.

PONDA, a town of Hindoostan, in the country of Soonda; 13 miles S.E. of Goa. N. lat. $15^{\circ} 23'$. W. long. $73^{\circ} 56'$.

PONDERATE, in our *Ancient Customs*, a method of curing sick children, by weighing them at the tomb of some faint; counterpoising or balancing the scale with money, wheat-bread, or any other thing that parents were willing to offer to God, his faints, or the church.

But a sum of money was always to make part of the counterbalance. By this means the cure was effected. "Ad sepulchrum sancti, nummo se ponderabat."

PONDICHERY, in *Geography*, a town of Hindoostan, in the Carnatic, on the coast of Coromandel, at the mouth of the river Gingee. It was first settled by the French, who obtained a grant of it, in 1674, from a rajah of Gingee, who acknowledged the king of Narlinga as his superior. This grant was confirmed by Sevagee, who took possession of Gingee about the year 1677. In the year 1693 it was taken by the Dutch, who erected walls and bastions, and made every other addition which was necessary to render it one of the most complete fortresses in the Indies. In 1696 it was restored to the French for the sum of 5000*l.*, and then it became the chief residence of the French East India Company. Previous to the war

of 1756, Pondicherry was, perhaps, the finest city in India. It extended along the sea-coast about $1\frac{1}{4}$ mile, and was about $\frac{3}{4}$ of a mile in breadth; it was well built according to the fashion of the country; and had a citadel, then the best of its kind in India, but of too contracted dimensions. Although its situation within the torrid zone renders it very hot, its situation is not infalubrious. It has no rain, except for seven or eight days, towards the end of October. The native Indians, or Gentoos, who inhabit it, are mostly weavers or painters; and though their earnings are small, they are enabled to subsist; their chief food being rice boiled in water, or formed into a paste, which is baked upon the coals. The adjacent district is well cultivated, and produces abundance of rice, nor is there hardly a place in India, where fish, flesh, and fowl may be procured on more reasonable terms. Its want of a port is a great inconvenience; nor can ships approach the coast nearer than about half a league, and this they do with difficulty and danger. This fine city was first taken by the English in 1761, and was immediately razed to the ground, in retaliation of M. Lally's conduct towards the fortifications and buildings of Fort St. David in 1758. In the year 1763 it was restored to the French by the peace of Versailles, and orders were given for repairing the fortifications. In 1778 it was again taken by the English, and restored in 1783. In 1793 it was again taken by the British. It lies S. of Madras 100 road miles. N. lat. $11^{\circ} 56'$. E. long. $79^{\circ} 55' 40''$.

PONDICO, a small uninhabited island in the Grecian Archipelago; two miles N. of Negropont. N. lat. $39^{\circ} 10'$. E. long. $23^{\circ} 29'$.

PONDIL, a town of Hindoostan, in Bahar; 37 miles S.S.W. of Patna.

PONDIMARKA, a town of Hindoostan, in the circar of Cicacole; 20 miles S.W. of Visigapatam.

PONDONG, a small island in the East Indian sea, near the S.E. coast of Siao. N. lat. $2^{\circ} 40'$. E. long. $125^{\circ} 10'$.

PONDURO, a town of Peru, in the diocese of La Paz; 28 miles N. of Oruro.

PONDUS, WEIGHT. See WEIGHT.

PONDUS, in *Ancient Records*, denotes a duty paid to the king, according to the weight of merchandizes.

PONDUS Regis, the standard weight anciently appointed by the king; being that which we now call *troy weight*. See STANDARD and TROY WEIGHT.

Ad PONDUS Omnium. See AD.

PONDUS, *Temperamentum ad*. See TEMPERAMENTUM.

PONDY, in *Geography*, a small island in the East Indian sea, near the E. coast of Madura. S. lat. $6^{\circ} 57'$. E. long. $114^{\circ} 23'$.

PONE, in *Law*, a writ, whereby a cause depending in the county, or other inferior court, is removed to the common pleas, or sometimes to the king's bench.

PONE *per vadium, et salvos plegios*, is a writ, issuing out of the court of common pleas, commanding the sheriff to take surety or gage of one for his appearance at a day assigned. This is also called a writ of *attachment*.

PONENDIS in *Affisis*, a writ granted by the statute of Westmin. 2. cap. 38. which statute shews what persons sheriffs ought to impanel upon assises and juries, and what not.

PONENDUM in *Ballium*, a writ commanding that a prisoner be *bailed*, in cases bailable.

PONENDUM *sigillum ad exceptionem*, a writ by which justices are required to put their seals to *exceptions* exhibited by the defendant against the plaintiff's evidence, verdict, or

other proceedings before them, according to stat. Westmin. 2.

PONFERRADA, in *Geography*, a town of Spain, in the province of Leon; 23 miles of Astorga.

PONGA, in *Botany*, H. M. *Jaca minor sylvestris Malabarica*. D. *Commelin tatarisbe Brasiliensium Pison. similis*; a tall evergreen tree growing in Malabar, and bearing no observable flowers; the fruit adheres to the branches in the same manner as that of the jaca; and hence the Portuguese call the tree the wild jaca; the calyces are echinated, the first green, and afterward reddish, and contain multitudes of roundish, oblong, acuminate, and reddish seeds.

A cataplasm prepared of the green fruit of the tree bruised, being applied to tumours, promotes their suppuration. Of the bark and root, boiled in water, is prepared a fomentation for œdematous tumours of the legs; an endemic disease among the Indians, and called by the Portuguese *pædo St. Thomæ*, which preserves them from an inflammation. Raii H. P.

PONGALLAH, in *Geography*, a town of Hindoostan, in Palnaud, on the right bank of the Kistnah; 20 miles N.E. of Timerycotta.

PONGATIUM, in *Botany*, altered from the barbarous Pongati of the Hortus Malabaricus, Juss. 423. See SPHENOCLEA and RAPINIA.

PONG-HOU, or PISCADORES, in *Geography*, a cluster of small islands, or rocks, as M. de la Perouse calls them, in the channel of Formosa, about six leagues from the W. coast of that island. This navigator represents them as appearing in all kinds of shapes; and five of them, of a moderate height, formed like Sandy downs, without any trees upon them. These islands were known to the Dutch, when they were masters of Formosa, who are said to have fortified the port of Pong-hou; and it is known, that the Chinese maintain here a garrison of 5 or 600 Tartars, who are relieved annually. N. lat. $23^{\circ} 30'$.

PONGO, in *Zoology*, a name given in Purchas's Pilgrims and also by Buffon to the *orang-outang*; which see. See also SIMIA *Satyrus*.

PONI, in *Geography*, a river of Hindoostan, which runs into the Palia, five miles W. of Arcot.

PONIARD, formed from the French *poignard*, and that from *poignée, handful*, a little pointed dagger, very sharp-edged; borne in the hand, or at the girdle, or hid in the pocket.

The poniard was anciently in very great use; but is now in good measure set aside, except among assassins.

Sword and poniard were the ancient arms of duellists; and are said to continue still so among the Spaniards.

The practice of sword and poniard still makes a part of the exercise taught by the masters of defence.

PONIENUNAY, in *Geography*, a town of Samogitia; 28 miles E.S.E. of Birza.

PONIEWICZ, a town of Samogitia; 30 miles E.N.E. of Rosienne.

PONLAPILLY, a town of Hindoostan, in Golconda; 30 miles S.S.W. of Hydrabad.

PONO, a town on the S.W. coast of the island of Sumatra. S. lat. $4^{\circ} 21'$. E. long. $102^{\circ} 42'$.

PONOI, a town of Russia, in the government of Archangel, on the coast of the Frozen ocean; 144 miles N. of Archangel.—Also, a river of Russia, which runs into the Frozen ocean, near the town of its name. N. lat. $67^{\circ} 10'$. E. long. $40^{\circ} 44'$.

PONOMPING, a town of the kingdom of Cambodia; 20 miles S.E. of Cambodia.

PONORTZIC,

PONORTZIC, a town of Lithuania, in the palatinate of Troki; 20 miles N.W. of Troki.

PONPON. See EDISTO, in which article read PONPON.

PONS, a town of France, in the department of the Lower Charente, and chief place of a canton, in the district of Saintes. The place contains 4500, and the canton 15,350 inhabitants, on a territory of 250 kilometres, in 20 communes.—Also, a town of Spain, in Catalonia; 14 miles N. of Cervera.

PONS, *St.*, a town of France, and principal place of a district, in the department of the Herault. The town contains 4506, and the canton 8012 inhabitants, on a territory of 225 kilometres, in six communes.

PONS *Varolii*, in *Anatomy*, a part of the medulla oblongata. See BRAIN.

PONSAH, in *Geography*, a town of Hindoostan, in Bahar, at the union of the Coyle with the Soane; seven miles S. of Rotasgur. N. lat. $24^{\circ} 31'$. E. long. $84^{\circ} 1'$.

PONT, a river of England, in the county of Northumberland, which runs into the German ocean; seven miles N. of Tinemouth.

PONT *l'Abbé*, a town of France; in the department of Finisterre, and chief place of a canton, in the district of Quimper; nine miles S.S.W. of Quimper. The place contains 1895, and the canton 11,092 inhabitants, on a territory of $247\frac{1}{2}$ kilometres, in 11 communes.

PONT *d'Ain*, a town of France, in the department of the Ain, and chief place of a canton, in the district of Bourg, near the river Ain. The place contains 1089, and the canton 9099 inhabitants, on a territory of 205 kilometres, in 12 communes.

PONT *sur Allier*, a town of France, in the department of the Puy de Dôme, and chief place of a canton, in the district of Clermont. The place contains 3032, and the canton 10,110 inhabitants, on a territory of $87\frac{1}{2}$ kilometres, in six communes.

PONT *de l'Arche*, a town of France, in the department of the Eure, and chief place of a canton, in the district of Louviers; six miles N. of Louviers. The place contains 1462, and the canton 11,292 inhabitants, on a territory of 180 kilometres, in 20 communes.

PONT *Beauvoisin*, a town of France, in the department of Mont Blanc, and chief place of a canton, in the district of Chambéry. The place contains 1200, and the canton 6582 inhabitants, on a territory of $77\frac{1}{2}$ kilometres, in ten communes.—Also, a town of France, in the department of the Isere, and chief place of a canton, in the district of La Tour-du-Pin; separated by a small river from Savoy; 11 miles W. of Chambéry. The place contains 1482, and the canton 13,966 inhabitants, on a territory of $147\frac{1}{2}$ kilometres, in 15 communes.

PONT *de Camarez*, a town of France, in the department of the Aveyron, famous for its mineral waters; 18 miles S. of Millau.

PONT *de Cé*, a town of France, in the department of the Maine and Loire, and chief place of a canton, in the district of Angers; three miles from Angers. The place contains 3018, and the canton 18,393 inhabitants, on a territory of 180 kilometres, in 17 communes.

PONT *Chartrain*, a lake of West Florida, 60 miles in circumference, near New Orleans. N. lat. $30^{\circ} 13'$. W. long. 90° .—Also, an island in lake Superior, S.W. of Maurepas island.

PONT *Chateau*, a town of France, in the department of the Lower Loire, and chief place of a canton, in the district of Savenay; 13 miles W. of Blain. The place con-

tains 2572, and the canton 6964 inhabitants, on a territory of $142\frac{1}{2}$ kilometres, in five communes.

PONT *Croix*, a town of France, in the department of Finisterre, and chief place of a canton, in the district of Quimper; 15 miles W. of Quimper. The place contains 1355, and the canton 13,071 inhabitants, on a territory of $157\frac{1}{2}$ kilometres, in 11 communes. N. lat. $48^{\circ} 2'$. W. long. $4^{\circ} 27'$.

PONT *l'Evêque*, a town of France, and principal place of a district, in the department of the Calvados; 21 miles E. of Caen. The place contains 2500, and the canton 13,047 inhabitants, on a territory of $157\frac{1}{2}$ kilometres, in 27 communes. N. lat. $49^{\circ} 17'$. E. long. $0^{\circ} 16'$.

PONT *Gibaud*, a town of France, in the department of the Puy de Dôme, and chief place of a canton, in the district of Riom; 10 miles W.S.W. of Riom. The place contains 624, and the canton 8603 inhabitants, on a territory of $277\frac{1}{2}$ kilometres, in nine communes.

PONT-*a-Marcq*, a town of France, in the department of the North, and chief place of a canton, in the district of Lille. The place contains 406, and the canton 13,150 inhabitants, on a territory of $112\frac{1}{2}$ kilometres, in 15 communes.

PONT *de Montvert*, a town of France, in the department of the Lozere, and chief place of a canton, in the district of Florac; seven miles E. of Florac. The place contains 1938, and the canton 4602 inhabitants, on a territory of $222\frac{1}{2}$ kilometres, in six communes.

PONT-*e-Mousson*, a town of France, in the department of the Meurthe, and chief place of a canton, in the district of Nancy, situated on the Moselle, and divided by it into two parts. Charles IV. in 1354 made it imperial, and it had formerly an university, which in 1768 was removed to Nancy; 13 miles N.N.W. of Nancy. The town contains 6767, and the canton 14,384 inhabitants, on a territory of $157\frac{1}{2}$ kilometres, in 21 communes. N. lat. $48^{\circ} 54'$. E. long. $6^{\circ} 8'$.

PONT *de Remy*, a town of France, in the department of the Somme; six miles E.S.E. of Abbeville.

PONT-*en-Royans*, a town of France, in the department of the Isere, and chief place of a canton, in the district of Saint Marcellin; six miles S. of it. The place contains 1081, and the canton 7704 inhabitants, on a territory of 210 kilometres, in 13 communes.

PONT *Saint Esprit*, a town of France, in the department of the Gard, and chief place of a canton, in the district of Uzes, seated on the Rhone, and defended by a citadel. The place contains 4845, and the canton 11,278 inhabitants, on a territory of 240 kilometres, in 16 communes; 28 miles N.N.E. of Nîmes. N. lat. $44^{\circ} 16'$. E. long. $4^{\circ} 43'$.

PONT *Ste. Maxence*, a town of France, in the department of the Oise, with a bridge over the river Oise, and chief place of a canton, in the district of Senlis; six miles N. of Senlis. The place contains 2660, and the canton 9769 inhabitants, on a territory of 120 kilometres, in 17 communes.

PONT *St. Pierre*, a town of France, in the department of the Eure; six miles N.E. of Pont de l'Arche.

PONT *de Salars*, a town of France, in the department of the Aveyron, and chief place of a canton, in the district of Rhodes. The place contains 235, and the canton 6247 inhabitants, on a territory of 300 kilometres, in 14 communes.

PONT *sur Sambre*, a town of France, in the department of the North; seven miles E. of Le Quesnay.

PONT *St. Vincent*, a town of France, in the department of Meurthe; six miles S. of Nancy.

PONT-*Scorff-Lesbein*, a town of France, in the department of the Morbihan, and chief place of a canton, in the district of L'Orient; six miles N.W. of Hennebon. The place contains 1721, and the canton 12,909 inhabitants, on a territory of 197½ kilometres, in six communes.

PONT *sur Seine*, a town of France, in the department of the Aube; four miles N.E. of Nogent sur Seine.

PONT *de Sorques*, a town of France, in the department of the Mouths of the Rhone; six miles N. of Avignon.

PONT *Valain*, a town of France, in the department of the Sarthe, and chief place of a canton, in the district of La Flèche; 10 miles E.N.E. of La Flèche.

PONT *sur Vannes*, a town of France, in the department of the Yonne; six miles E.S.E. of Sens.

PONT *de Vaux*, a town of France, in the department of the Ain, and chief place of a canton, in the district of Bourg, near the union of the Rehouse with the Saone; 37 miles N. of Lyons. The place contains 2806, and the canton 12,881 inhabitants, on a territory of 142½ kilometres, in 11 communes. N. lat. 46° 26'. E. long. 5° 1'.

PONT *de Vesle* or *Vesle*, a town of France, in the department of the Ain, and chief place of a canton, in the district of Bourg; 15 miles W. of Bourg. The place contains 1426, and the canton 8474 inhabitants, on a territory of 140 kilometres, in 12 communes. N. lat. 46° 16'. E. long. 4° 58'.

PONT *le Voye*, a town of France, in the department of the Loire and Cher; nine miles S. of Blois.

PONT *sur Yonne*, a town of France, in the department of the Yonne, and chief place of a canton, in the district of Sens; six miles N.N.W. of Sens. The place contains 1442, and the canton 9419 inhabitants, on a territory of 202½ kilometres, in 23 communes.

PONTA, in *Biography*, a Bohemian performer on the chromatic French horn, whose taste and extraordinary execution were extremely applauded in London, particularly at the Pantheon, before that beautiful building was destroyed by fire.

PONTA-*Delgada*, in *Geography*, a sea-port town of St. Michael, one of the Azores, defended by a citadel, containing three parish churches, seven convents, and about 8000 inhabitants.

PONTA *do Sal*, a small town in the island of Madeira.

PONTAC, or PONTIAC, a town of France, in the department of the Lower Pyrenées, and chief place of a canton, in the district of Pau; 13 miles S.E. of Pau. The place contains 2400, and the canton 7780 inhabitants, on a territory of 117½ kilometres, in 12 communes.

PONTADURA, a small island in the Adriatic, with a town, S.W. of Pago. N. lat. 44° 33'.

PONTAFELLA, a town of Upper Carinthia; 16 miles S.W. of Villach.

PONTAGE, PONTAGIUM, a contribution towards the maintenance, repairing, and rebuilding of bridges. See BRIDGE.

This was anciently one of the three general national charges, from which no person of any degree whatever was exempted.

The three things called *trinoda necessitas*, whence Ingulphus tells us, *nulli possunt laxari*, were, the expedition to the wars, the building of castles, and the building and repairing of bridges. Mr. Selden, in his notes on Eadmerus, observes, that *ne quidem episcopi, abbates, & monachi, immunes erant*. And Matt. Paris adds, anno 1244, that in all grants of privileges to the monasteries, those three things

were always excepted, for the public good, and that the people might be better able to resist an enemy.

PONTAGE is also a due anciently belonging to the lord of the fee, for persons or merchandizes, that pass over rivers, bridges, &c. called in the later Latin *pontagium*, or *pontoniagium*, pontage.

PONTAGIA, a term used by Paracelsus, and his followers, to express a mixing saline substances with those which are bitter or styptic.

PONTAILLER *sur Saone*, in *Geography*, a town of France, in the department of the Côte-d'Or, and chief place of a canton, in the district of Auxonne. The place contains 1270, and the canton 10,631 inhabitants, on a territory of 202½ kilometres, in 20 communes.

PONTANO, GIOVANNI, in the Latin language Jovianus Pontanus, in *Biography*, one of the most distinguished Latinists of Italy, was born in 1426, at Cereto, in the diocese of Spoleto. He was educated at his native place, and at Perugia. For a time he quitted the pursuits of literature, and adopted a military life. He served under king Alphonso during the war with the Florentines, and in 1447 accompanied that prince to Naples, where he renewed his literary pursuits under Antonio Panormitano. After this he was entrusted by Ferdinand I. with the education of his son Alphonso, and procured for him a wealthy marriage. On the death of Panormita, Pontano succeeded him as secretary to Ferdinand, in which capacity he afterwards served two other kings, *viz.* Alfonso II. and Ferdinand II. He attended these princes in all their journeys and military campaigns, and was treated by them with great respect. In 1486 he was sent ambassador by Ferdinand I. to pope Innocent VIII. for the purpose of negotiating a peace; on which occasion he received singular tokens of the pontiff's esteem. He was much mortified at the disappointment of his high expectations of promotion through the influence of his pupil, prince Alfonso, and wrote a satirical dialogue, entitled "Asinus," in which he complained of royal ingratitude without reserve. He died in 1503, at the age of 77. His morals were infected with the licentiousness of the times; but he stands high as a promoter and encourager of literature. He augmented and firmly established the academy of Naples, which had been founded by Panormitano, and of which Pontano was, for a considerable time, at the head, and it is thought that he changed his name from John to Jovian, as an academician, and his example was followed by other members of that learned body. His reputation is chiefly founded on his character as a poet. He is reckoned among the first who revived the elegance, grace, and harmony of the best Latin poets. His compositions are numerous, and on various subjects, comprehending didactic pieces, eclogues, hymns, amorous verses, inscriptions, epigrams, &c. Of all his pieces, the most considerable is entitled "Urania," an astronomical work in five books, which is said to display great erudition. He wrote on the culture of oranges, on moral philosophy, and on various philological subjects. In the department of history, he wrote six books "On the Wars between Ferdinand I. of Naples, and John Duke of Anjou." His style is pure and elegant, but often obscure. The poems of Pontanus were printed in an octavo volume, by Aldus, in 1505 and 1533. All his works were published collectively in 4 vols. 8vo.

PONTANUS, JOHN ISAAC, an historian and writer on philosophy, was born, in 1571, at Helsingor, in Denmark, of parents from Haarlem, in Holland. He was brought up to the study of physic at Basil, where he took his degrees, but it does not appear that he practised it. He preferred general science to a particular branch of it, and became

became professor of philosophy and mathematics at Har-
derwick, and was nominated historiographer to the king of
Denmark, and the province of Gueldres. He died in the
year 1640. His principal works are, "Itinerarium Gallie
Narbonensis;" "Historia Urbis et Rerum Amsteloda-
mensium;" "Origines Rerum Franciscarum;" "Rerum
Danicarum Historia;" "Historia Geldrica." Moreri.

PONTANUS, JAMES, a learned Jesuit of Bohemia, was
born at Brugg in 1542. At the age of 21 he entered
the society of Jesuits, and was employed for a considerable
time as a teacher of the classics. He obtained a high re-
putation by several grammatical and philological publica-
tions. He died at Augsburg in 1626, at the age of 84.
His principal works are, "Institutiones Poeticæ;" "Com-
mentaries on Virgil and Ovid;" and translations of several
of the Byzantine historians, and of some Greek theological
writers.

PONTANUS, PETER, a grammarian of Bruges, who was
blind from three years of age, but who, by his talents and
indefatigable industry, acquired a great reputation as a
teacher of the belles lettres at Paris. He is author of
treatises on rhetoric and versification. The exact times
of his birth and death are not known; but he flourished
at the beginning of the 16th century.

PONTARION, in *Geography*, a town of France, in the
department of the Creuse, and chief place of a canton, in
the district of Bourgueuf. The place contains 289, and
the canton 6936 inhabitants, on a territory of 205 kilio-
metres, in 10 communes.

PONTARLIER, a town of France, and principal place
of a district, in the department of the Doubs, on the borders
of Switzerland, defended by a castle about half a mile from
the town. The place contains 3880, and the canton 12,116
inhabitants, on a territory of 337½ kilometres, in 26 com-
munes. N. lat. 46° 54'. E. long. 6° 25'.

PONTAUEMÉR, a town of France, and principal
place of a district, in the department of the Eure. The
place contains 5090, and the canton 13,631 inhabitants, on
a territory of 120 kilometres, in 18 communes. N. lat.
49° 21'. E. long. 0° 37'.

PONTAVEN, a town of France, in the department
of Finisterre, and chief place of a canton, in the district
of Quimperlé; 7 miles W. of Quimperlé. The place contains
760, and the canton 10,913 inhabitants, on a territory of
152½ kilometres, in five communes.

PONTAUMUR, a town of France, in the department
of the Puy-de-Dôme, and chief place of a canton, in the
district of Riom; 12 miles W.N.W. of Clermont. The
place contains 1160, and the canton 10,981 inhabitants,
on a territory of 355 kilometres, in 15 communes.

PONTDAROÏDE, a town of France, in the depart-
ment of Finisterre, and chief place of a canton, in the
district of St. Hippolyte. The place contains 440, and the
canton 5472 inhabitants, on a territory of 190 kilometres,
in 25 communes.

PONTE, GIACOMO DA, in *Biography*. See BASSAN.

PONTE, in *Geography*, a town of France, in the depart-
ment of the Dora, at the conflux of the Soana and
Orco; 19 miles N.N.W. of Turin.—ALFO, a town of
Portugal, in the province of Beira; 4 miles S. of Mon-
temor o Velho.

PONTE de Barca, a town of Portugal, in the province of
Entré Duero e Minho; 9 miles N. of Braga.

PONTE de Brenta, a town of Italy, in the Paduan; 5
miles N.N.E. of Padua.

PONTE-Centefimo, a town of Italy, in the duchy of Spoleto,
on the Topino; 5 miles S. of Nocera.

PONTE-Corvo, a town of Naples, in Lavora; 34 miles
N.W. of Capua.

PONTE-Decimo, a town of the Ligurian Republic; 8
miles N.N.W. of Genoa.

PONTE-Landelfo, a town of Naples, in Principato Ultra;
11 miles N. of Benevento.

PONTE-de-Lima, a town of Portugal, in the province of
Entre Duero e Minho, on the Lima, containing a colligate
church, three hospitals, two convents, and about 2000 in-
habitants; 12 miles N.E. of Braga. N. lat. 41° 44'.
W. long. 8° 15'.

PONTE-Molino, a town of Italy, in the Veronese; 24
miles S. of Verona.

PONTE-Nura, a town of Italy; 7 miles S.E. of Pia-
cenza.

PONTE de Olivença, a town of Spain, in Estramadura;
7 miles N.W. of Olivença.

PONTE de St. Mauro, a town of Goritz; 7 miles N. of
Goritz.

PONTE de St. Nicolo, a town of Italy, in the Paduan;
3 miles E.S.E. of Padua.

PONTE de Soro, a town of Portugal, in Estramadura; 15
miles S.S.E. of Abrantes.

PONTE Stura, a town of France, in the department of the
Marengo, at the conflux of the Stura and Po; 4 miles
W. of Casal.

PONTEAMASS, a town of Cambodia, near the
mouth of a river which runs into the gulf of Siam. N. lat.
10° 30'. E. long. 104°.

PONTEBA, or *Ponte Imperiale*, a town of the
duchy of Carinthia, separated by a small river from Pon-
teba Veneta.

PONTEBA Veneta, a town of Italy, in the county of Friuli,
belonging to Carinthia; 28 miles N.N.W. of Friuli.

PONTEDERIA, in *Botany*, so named by Linnæus,
after Julius Pontedera, professor of botany at Padua, who
published a quarto work called *Anthologia*, and wrote
against the sexes of plants. His last-mentioned treatise did
not see the light till its author was no more, when its whole
importance arose from the celebrity of the subject, and the
firm establishment of the doctrine it was designed to refute.
—Linn. Gen. 159. Schreb. 214. Willd. Sp. Pl. v. 2. 22.
Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 2. 206.
Juss. 55. Lamarek Illust. t. 225. (*Michelia*; Rel.
Houft. 8.)—Class and order, *Hexandria Monogynia*. Nat.
Ord. *Enfate*, Linn. *Narcissus quodammodo affinis*, Juss.

Gen. Ch. *Cal.* Common sheath oblong, bursting at
the side. *Cor.* of one petal, tubular, in two deep divisions;
the upper lip external, straight, in three deep equal seg-
ments; lower reflexed, in three deep equal segments.
Stam. Filaments six, inserted into the corolla, three
of them, which are longest and awl-shaped, into the
mouth, the rest into the base, of the tube; anthers
erect, oblong. *Pist.* Germen superior, oblong; style simple
declining; stigma swelling. *Peric.* Capsule fleshy, con-
ical, with a broad inflexed point, triangular, with three
furrows, and three cells. *Seeds* numerous, roundish.

Ess. Ch. Corolla of one petal, two-lipped, in six seg-
ments. Three of the stamens inserted towards the top of
the tube. Capsule superior, of three cells.

A handsome genus of aquatic, perennial, fibrous-
rooted, herbaceous plants. Linnæus has only three species
in his Sp. Pl., Willdenow has six. The two following are
known in our gardens.

P. cordata. Heart-leaved Pontederia. Linn. Sp. Pl.
412. Willd. n. 5. Trew Ehret 45. t. 83. Redout.
Liliac. t. 72. Curt. Mag. t. 1156.—Leaves heart-shaped.

Flowers

Flowers spiked.—Native of pools in Virginia, introduced by Peter Collinson, before the year 1751. It is hardy in ponds or water-troughs, flowering in July and August. The stem rises a foot or two above the water, bearing several alternate, heart-shaped, entire, smooth leaves, on long, spongy, sheathing stalks. Flowers numerous, of a brilliant full sky blue, composing a spike three or four inches in length.

P. dilatata. Dilated Pontederia. Buchanan in Symes's Voyage to Ava, 475, with a plate. Andr. Repof. t. 490. Ait. n. 2.—Leaves heart-shaped. Flowers in an umbel-shaped corymbus.—Native of the East Indies. Cultivated by Mr. William Anderson in 1806, in the stove of James Vere, esq., where it flowered in May. The leaves are more acute than in the foregoing, and the flowers much larger, disposed in a corymbose or umbellate tuft, overtopped by a leaf. This species is not included among those of Willdenow. The *hastata* of Linnæus, figured in Roxb. Coromand. v. 2. t. 111, is assuredly different.

PONTEE, in the *Glass Trade*, an iron instrument used to stick the glass at the bottom, for the more convenient fashioning the neck of it.

PONTEFRAC, or POMFRET, in *Geography*, is a borough, market-town, and parish, in the wapentake of Osgoldcross, West-Riding of Yorkshire, England. The town stands on the summit of an eminence, at the distance of 26 miles S.S.W. from York, and 178 miles N.N.W. from London. It is described to be of great antiquity; but the precise era of its origin is unknown. Leland and Drake ascribe its foundation to the Romans, and Camden and others to the Saxons. It was certainly a burgh in the time of Edward the Confessor, and at the Conquest a castle was built here by Ilbert de Lacy, to whom king William gave the manor soon after he had established himself on the English throne. Since that period, Pontefract and its castle have been the scenes of several events of great interest and importance in the general history of the kingdom. In the reign of Edward II., when its castle was the property of the rebellious Thomas, earl of Lancaster, it was besieged by the king, and surrendered to him at the first summons, the earl having previously marched northward. After the battle of Borough-bridge, in which Lancaster was taken prisoner, he was brought to Pontefract, and imprisoned in one of the towers of the castle till the day of his execution. On the same day many other noblemen and knights, his adherents, suffered here, and several also at York. King Richard II. was confined, and eventually murdered within the walls of this castle; and in the succeeding reign it was the prison and place of condemnation of Richard Scroope, archbishop of York, who was executed near Bishopthorpe on the 8th of June, A. D. 1405. In this castle, likewise, Anthony Woodville, earl Rivers, Richard lord Grey, sir Thomas Vaughan, and sir Richard Hawse, were put to death, without even the form of a trial, by command of Richard III. The next event of political moment which occurred here, was the surrender of the castle to Robert Aske, and the papal rebels, in the reign of Henry VIII.; from which time nothing again occurred till the period of the grand rebellion in the 17th century. At the commencement of that contest between the king and the parliament, the castle was garrisoned by a brave band of loyalists under colonel Lowther. It was first besieged, in 1644, by sir Thomax Fairfax, who used every effort to obtain possession of it, but without success, and was at length defeated under its walls by sir Marmaduke Langdale, who made a rapid march from Oxford for its relief. The second siege happened in the year following, when, after three months of

incessant cannonades, attacks, and forties, the garrison, being reduced nearly to a state of famine, surrendered the castle upon honourable terms. Sir William Fairfax was then appointed governor for the parliament; but as he found sufficient employment in pursuing the scattered forces of the king, he left the immediate command of it to colonel Coterel, as deputy governor. Towards the conclusion of the war, the garrison of this fortress having been reduced to about a hundred men, from an idea that the weakness of the royal party precluded the fear of an attack, a plan was formed by some of the king's friends to retake it. This plan was accordingly put into execution on the 6th of June 1648, and proved successful. The dispersed loyalists in the county now flocked to the castle, and in a short time it had a complete garrison for its defence. Cromwell besieged it in the month of October succeeding its seizure, and lay before it a month, when, finding it necessary to join the grand army under Fairfax, the command of the besieging army was confided to general Lambert. This able officer raised many new works, made regular approaches, and pushed the siege with all the vigour imaginable; but was, notwithstanding, unable to take it till the 25th of March 1649, when all hope of deliverance having vanished, and the garrison having dwindled away to few more than a hundred men, it was surrendered by capitulation; and about two months afterwards was unroofed and dismantled under the authority of an act of parliament. The castle, seated on an eminence, was formerly of great extent. It consisted of several towers, with intervening walls, and other buildings. The chief ballium was flanked by seven towers; called the round or keep tower; the red tower; the treasurer's, or pix tower; Swellington tower; queen's tower; king's tower; and conitable's tower: a chapel and a magazine were also included in the principal ballium; the latter is cut out of the solid rock, as is also a contiguous dungeon.

In tracing the etymology of Pontefract, topographers have entered into frivolous dissertations, without developing any useful information.

Camden says it was at first denominated Kirkby, and that it obtained the name of Pontefract from the destruction of an old bridge over a marshy place, near to which the town principally stood; and Leland observes, that "the ruins of such a bridge yet its scene scant half a mile east of old Pontefract, but I cannot justly say that this bridge stood full on Watheling-streete." That there was a bridge somewhere close to Pontefract, is corroborated by an inquisition taken in the reign of Edward II., from which it appears that one John Bubwith held the eighteenth part of a knight's fee "juxta veterem Pontem de Pontefract."

The first Norman possessor of Pontefract was Ilbert de Lacy, who received from the Conqueror the gift of upwards of a hundred manors. This nobleman had confirmation from William Rufus of all the customs belonging to his newly erected castle and honour of Pontefract; and, dying shortly after the accession of that monarch, left his vast estates to his son Robert, commonly called de Pontefract, from the circumstance of his having been a native of the town. He, imprudently joining with Robert, duke of Normandy, against Henry I., was banished from the kingdom, when his castle and estates were given to Henry Travers, and afterwards to Henry Delaval. Robert, however, seems to have been restored to his honours and property before the conclusion of Henry's reign. He was succeeded at his death by his eldest son Ilbert, who distinguished himself greatly in the war against the Scots, which terminated in the captivity of their king,

king, David. Ilbert having no children, his estates devolved to his brother Henry, the founder of the once magnificent abbey of Kirkstall, near Leeds. This great baron received from Henry II. the confirmation of his whole honour of Pontefract, with a charter for an annual fair. His successor, Robert de Lacy, was among the barons who attended the coronation of Richard I.; and as he died without issue, Pontefract and his other domains fell to his sister, by his mother's side, Awbrey de Lifours, who, having been likewise the inheritrix of her father's vast possessions, was one of the richest individuals in the kingdom. She married Richard Fitz-Eustace, constable of Chester, and baron of Halton; but her husband did not live to enjoy the estates of the Lacys. Neither did his successor, John, who accompanied king Richard I. to the Holy Land, where he died, leaving his honours and estates to his son Roger, who signalized himself by his courage and conduct at the memorable siege of Acre; and after his return to England assumed the name of Lacy, in consequence of his being put in possession of all the lands belonging to Pontefract, by agreement with his grandmother Awbrey. This Roger granted a charter to the burgesses of Pontefract, which was confirmed by Henry de Lacy, the last and greatest man of his line. He was the confidential friend of Edward I., and accompanied him in his campaigns both in France and Scotland. He obtained for Pontefract the privilege of a market, and died 5th Feb. 1310, when his estates devolved to Thomas earl of Lancaster, in right of his wife Alice, Henry's only daughter and heiress. From this period Pontefract followed the fate of the honour and duchy of Lancaster, and became vested in the crown by the accession of Henry VII.

Pontefract was first constituted a corporate borough by charter in the reign of Richard III. This deed has since been confirmed by different subsequent charters, and the town is now, in virtue of these, governed by a mayor, recorder, and twelve aldermen, all of whom are in the commission of the peace. When this borough began to send members to parliament does not appear; but it has now the privilege of being represented by two members. The elective franchise "is in persons having, within the said borough, a freehold of burgage tenure, paying a burgage rent." The number of voters is estimated at 330. The mayor is the returning officer. The market day here is Saturday; and there are, besides, several annual fairs.

The buildings of this town are chiefly disposed in three long streets, in the form of the letter Y. According to the parliamentary returns of 1811, the houses of Pontefract borough and township amount to 840, and the inhabitants to 3605 in number. Here were anciently two churches, one dedicated to All-Saints, and the other to St. Mary. The former is now a ruin, having been much damaged during the civil wars. From its present remains it has evidently been a large structure. It was built in the form of a cross, with a tower in the centre, which is still entire. St. Mary's, now called St. Giles's, is the parish church. It is of equal, or probably of greater antiquity than the church of All-Saints, but has been completely modernized by additions and repairs.

Pontefract formerly contained several religious establishments. Within the castle was a chantry chapel, or church of St. Thomas, founded in 1361, in memory of Thomas earl of Lancaster. No part of this chapel now exists, but its site may still be traced. Here was also a chapel dedicated to St. Clement. On the plot of ground called Monkhill, stood the priory of St. John, now entirely demolished. It was founded by Robert de Lacy in 1090, and filled with

Cluniac monks. The Dominican friars had a house here; as had likewise the Carmelite, or White friars, and the Augustine friars; but the buildings of all of them are destroyed. St. Nicholas hospital, founded about the time of the Conquest, is still in existence, having been rebuilt during the 17th century. Knolles, or Trinity hospital, is also standing, and constitutes a comfortable asylum for fifteen aged persons. Bead-house hospital supports sixteen poor people; Thwaites's hospital, four; Frank's hospital, two; Cowper's, or Butt's hospital, three; Perfect's hospital, six; and Watkinson's hospital, eight: Frank's hospital was built on the site of a lazaret, founded by Henry de Lacy.

The other charitable institutions in this town are the King's free grammar-school, which was erected and endowed by king Edward VI. for the education of fourteen boys; and a charity-school, in which a limited number of poor children are clothed and educated. The annual revenue of this school in land is 104*l.* 19*s.*; but this sum is much augmented by annual subscription. In the centre of Pontefract formerly stood a cross dedicated to St. Oswald, which was removed in 1734, when the present market-house was erected in its stead by Mrs. Elizabeth Dupier, in compliance with the directions of her husband. Near this building is the town-hall, a modern edifice, erected at the joint expence of the corporation, and of the county. The basement story is appropriated as a prison; and the upper one is occupied by a court-room and offices. In this hall are held the quarter-sessions for the wapentake of Osgoldcross, and also the mayor's court. Here is likewise transacted all the corporation business.

The chief public amusements of Pontefract are the theatre, and the races. The theatre is a neat building, erected a few years ago by subscription, and is open twice a-year. This town is celebrated for the number of gardens and nurseries in its vicinity, and is also particularly noted for the cultivation of liquorice. In one of the gardens here is a large ancient cave, the origin and purposes of which are unknown. The History of the Ancient Borough of Pontefract, &c. by B. Boothroyd, 8vo. 1807.

PONTELLA, a town of Portugal, in the province of Beira; 4 miles N.E. of Lamego.

PONTEQUE, or PONTIQUE, a cape with two small islands, on the W. coast of Mexico; 30 miles N.E. of cape Corrientes.

PONTES, in *Ancient Geography*, a Roman station of Great Britain, on the route from Londinum to Regnum, according to the Itinerary of Antonine.

PONTE-STAKE, in *Glass Making*, is the iron on which the under servants place the irons from the upper workmen, when they have knocked off the broken pieces of glass.

PONTE-VEDRA, or PONTEVEDRA, in *Geography*, a town of Spain, near the W. coast of Galicia; 25 miles N. of Tuy.

PONTEVICO, a town of Italy, in the department of the Mela: 18 miles S. of Brescia.

PONTEZUELO, a town of South America, in the government of Buenos Ayres; 132 miles N.W. of Buenos Ayres.—Also, a town of South America, in the province of Cordova; 150 miles N. of Cordova.

PONTHIEU, a small country of France, in Picardy, so called before the revolution, situated between the rivers Canche and Somme. Its capital was Abbeville.

PONTHIEVA, in *Botany*, received that appellation from Mr. R. Brown, in memory of the late Mr. Henry De Ponthieu, a French West Indian merchant, to whose communications the royal collection at Kew, and the her-

barium of fir Joseph Banks, are very greatly indebted.—Brown in Ait. Hort. Kew. v. 5. 199. Class and order, *Gynandria Monandria*. Nat. Ord. *Orchideæ*.

Eff. Ch. Anther united with the column, somewhat terminal, permanent. Corolla irregular. Lip posterior, inserted into the column along with the petals. Pollen farinaceous.

1. *P. glandulosa*. Glandular Ponthieva. (*Neottia glandulosa*; Sims in Curt. Mag. t. 842.)—Lip stalked, pointed. Petals half ovate.—Native of the West Indies. It flowers in our stoves from January to March. The leaves are radical, oval, recurved, wavy. Stem a foot high, downy, bearing a lax cluster of singular, but not ornamental, greenish-white flowers. Mr. Brown informs us he is possessed of one more species, as yet undescribed.

PONTI, in *Geography*, a town of Italy, in the Veronese; 2 miles S. of Peschiera.

PONTI, a town of France, in the department of the Marengo; 6 miles S.W. of Acqui.

PONTIA, PONZA, in *Ancient Geography*, an island near Sicily, at some distance to the W. of Campania. The Romans established here a colony. It was to this island that Tiberius banished Nero, the eldest son of Germanicus, and here he died of famine and wretchedness, A. D. 31.—Also, an island near the coast of Etruria, over-against Velia, according to Strabo and Pliny.—Also, an island situated on the coast of Africa, near that of Misinus. Ptolemy.

PONTIANA, in *Geography*, a river on the W. coast of Borneo, which runs into the sea, N. lat. $0^{\circ} 13'$.

PONTIANUS, pope, in *Biography*, a native of Rome, was elected to that see on the death of Urban, in the year 230. It was during his pontificate, that sentence of deposition and excommunication was passed upon the celebrated Origen, by Demetrius, bishop of Alexandria, which sentence was approved by Pontianus, who is supposed to have assembled the Roman clergy, for the purpose of having their sanction to that proceeding. Pontianus, in his turn, became the victim of persecution; for in the year 235, after the assassination of the emperor Alexander, by whom Christians had been favoured, his successor, at the instigation of the Pagan priests, exercised great oppression and cruelty against that people, and particularly against the bishops. Among others, Pontianus was persecuted by him, being banished from Rome to Sardinia, where he died, owing to the severe and cruel usage which he experienced, having filled the pontifical throne five years and a few months. Moreri. Bower.

PONTIBUS REPARANDIS, in *Law*, a writ, directed to the sheriff, commanding him to charge one or more persons to repair a bridge, to whom it belongs.

PONTICA GEMMA, in *Natural History*, a name given by the ancients to a stone of the agate kind, with a white ground and red and black spots, irregularly placed, and making a beautiful variegation in it. This seems to have been the same stone which some of the moderns have called the *small-pox* stone, from its spots resembling the eruptions in that disease. The ancients mention several kinds of it, as they were spotted with various colours.

PONTICA Vina, a term used to express acid, feculent, and tartarous wines.

PONTICCHIO, in *Geography*, a town of Naples, in the province of Capitanata; 4 miles W. of Dragonera.

PONTICUM MEL, a name given to a sort of poisonous honey.

PONTICUS MUS, in *Zoology*, the name of a creature described by the ancients, and supposed to be the same with our squirrel.

PONTICUSA, in *Geography*, a small island in the Grecian Archipelago; 2 miles S.W. of Stamfordia. N. lat. $36^{\circ} 33'$. E. long. 25° .

PONTIFEX, *Pontif*, *High-priest*, a person who has the superintendance and direction of divine worship; as the offering of sacrifices, and other religious solemnities.

The Romans had a college of pontifs, and over those a sovereign pontif, or *pontifex maximus*, instituted by Numa; whose function it was to prescribe those ceremonies with which each god was to be worshipped, compose the rituals, direct the Vestals, regulate the calendar, and settle the several games, and assist at them; and for a good while to perform the business of augury; till on some superstitious occasions he was prohibited intermeddling with it.

He consecrated the statues of the gods, before they were put up in the temple; conducted the dedications of the temples; offered sacrifices; blessed the figures of some of Jove's thunderbolts, to preserve the people from harms; and compiled their statutes.

The Jews, too, had their pontif, or high-priest; and among the Romanists, the pope is still styled the *sovereign* pontif.

Authors differ about the origin of the word pontifex. Some derive it from *posse facere*, that is, from the authority the pontifs had to sacrifice; others, as Varro, from *pons*, because they built the Sublician bridge, that they might go and offer sacrifice on the other side of the Tiber.

PONTIFICAL, PONTIFCALE, a book of the rites and ceremonies belonging to pontifs, bishops, popes, &c. See RITUAL, and CEREMONIALE.

PONTIFICAL Chapel. See MISERERE.

PONTIFICAL College, in *Roman Antiquity*, consisted of those who had the principal direction of the affairs of religion, who settled religious disputes, regulated the worship and ceremonies, and explained the mysteries of religion. This college, at the time of its first institution by Numa, was composed of four priests selected from the patricians, to whom were afterwards added four others from the plebeians. Sylla the dictator increased their number to fifteen, of whom eight were superior, and seven subordinate; and the chief among them assumed the title of "pontifex maximus."

PONTIFICALIA, the robes and ornaments in which a bishop performs divine service.

PONTIFICATE, PONTIFICATUS, the state or dignity of a pontif, or high-priest.

Cæsar reformed the calendar in the time of his pontificate.

PONTIFICATE is more peculiarly used in modern writers for the reign of a pope.

The concordat was passed in the pontificate of Leo X.

There was a pontificate that only lasted twenty-four hours.

PONTIGNY, in *Geography*, a town of France, in the department of the Yonne; 10 miles N.E. of Auxerre.

PONTIO, DON PIETRO, in *Biography*, an eminent Italian ecclesiastical composer. He published many learned compositions for the church at the latter end of the 16th century. He was likewise author of musical discourses; "Raggionamenti della Musica." This last work, which is in dialogue, was written by an eminent composer, of whose productions there are still excellent specimens subsisting. The author, however, though a practical musician, could not shun the pedantry of the times; but instead of going directly to work like a man of business, loses his time in calculating ratios, or transcribing them from Boethius, or other authors who had pillaged him already, bestowing upon the reader twenty pages of his small quarto tract upon speculative definitions, and arithmetical, geometrical,

and harmonical proportions; to which, if a practical musician understood them, he would never apply for help while he had the free use of his hands and ears. At length, having impressed his reader with a due sense of his profound science and erudition, the author, descending from the spheres, deigns to treat of the music of this nether world; and in his second *Ragionamento* gives precepts and examples for the use of all the concords and discords; in the third he goes through all the ecclesiastical tones; and in the fourth and last, all the moods and divisions of time; terminating his discourse with short instructions for composing masses, motets, psalms, madrigals, and *ricercari*. This term, which implied any work of fancy, and original invention, was succeeded by *fantasia*, as fantasia was by *sonata*. Adrian Willaert, and others of his time, composed *ricercari*, without words for the voice, which were a species of *solfeggi*. In the course of this little work, the author, though a composer himself, frequently refers to the productions of others. Among these, his favourites seem to have been Josquin, Giachetto, Morales, Adriano, Cipriano, Palestrina, and Vincenzo Ruffo. The theorists he cites are chiefly Franchinus, P. Aaron, Lanfranco, Fogliano, Zarlino, and Galilei. As a specimen of his own abilities in composition, we shall present the reader with a movement selected by the learned Padre Martini (*Saggio di Contrap. pt. i. p. 178.*), from the second book of his Magnificats. The subject of the composition is the Romish chant of the Magnificat in the eighth mode or tone, which is led off by the treble, accompanied by the counter-tenor and base in the counterpoint. At the fifth bar, the second tenor begins the chant, and at the seventh is answered by the first tenor in the 5th, at the distance of which interval these two parts continue in strict canon to the end.

PONTIS, LEWIS DE, a gentleman of Provence, born in the year 1583, was brought up to the military service. He entered the army under Henry IV., and served that king and his successor with great courage and fidelity. At length, disappointed in his expectations of promotion, he retired after fifty years' service, and devoted the remainder of his life to religious retirement. He died in 1670, at the age of 87. There are extant "Memoirs," under the name of De Pontis, printed at Paris in 2 vols. 12mo. Moreri.

PONTIUS, an ecclesiastical writer of the third century, was a native of Africa, and flourished about the year 250. He was appointed deacon to St. Cyprian, in the church of Carthage, and attended that father in his various fortunes, particularly during his last exile, and at his martyrdom. Pontius was the biographer of his friend, and wrote "The Life and Passion of Cyprian," which is generally prefixed to his works. Pontius is thought by some writers to have suffered martyrdom in the year 258.

PONTIUS, CONSTANTINE, a Spanish divine of great merit, and celebrated preacher in the 16th century, who was persecuted by the holy Inquisition for having imbibed the Protestant doctrine. He was a native of the town of St. Clement, in the diocese of Cuença, in New Castile, and appears to have received his academical education at the university of Valladolid. He became an excellent linguist, and acquired a high character for learning and eloquence. He had the degree of doctor of divinity conferred upon him, and obtained a canonry in the metropolitan church of Seville. He was also appointed to fill the theological chair at a lecture that was founded in that city, and displayed great erudition in his comments and explanations of various parts of the scriptures. He was so well skilled in all the beauties of his native language, and possessed such powers of elo-

quence, that he drew together an incredible number of auditors. So eager were the people to hear him, that crowds assembled for that purpose several hours before he entered the pulpit. He was appointed preacher to the emperor Charles V. and afterwards to his son Philip II., whom he attended into England, where he became a convert to the principles of the reformation. After his return to Spain, he resumed his employment of preacher at Seville, and by the style and manner of his discourses, subjected himself to the attacks of the priests and monks; who, at length, were not content with answering him in his own way, but made a seizure of his books, which he had endeavoured carefully to conceal, and among them one was found in his own hand-writing, containing a pointed condemnation of the leading points in the Popish creed. He now made no hesitation in avowing his principles, and declared his determination to maintain the truth of them. He urged his enemies to give themselves no sort of trouble in procuring witnesses against him, but to dispose of him as they pleased. He was speedily condemned and thrown into prison, where he was kept for two years, under sentence of condemnation to the flames. Before the day of the "Auto de Fe," on which it was to be carried into execution, he died of a dysentery, occasioned by the excessive heat of his place of confinement, and the want of proper food. His enemies reported that he had laid violent hands on himself, to escape the disgrace of a public execution. They were not satisfied with calumniating him: they burnt his remains and effigy, having first exposed them in a public procession. As an author, his works were "Commentaries" on the Proverbs, Ecclesiastes, the Song of Solomon, and Job; "A Summary of the Christian Doctrine;" "Sermons," and other smaller pieces. Moreri. Bayle.

PONTIVY, in *Geography*, a town of France, and principal place of a district, in the department of the Morbihan, seated on the river Blavet. The town contains 3090, and the canton 14,029 inhabitants, on a territory of 282½ kilometres, in 5 communes. It has a linen manufacture; 21 miles N.N.E. of Hennebon. N. lat. 48° 4'. W. long. 2° 53'.

PONTLEVIS, in the *Manege*, a disorderly resisting action of a horse, in disobedience to his rider; in which he rears up several times, and rises so upon his hind legs, that he is in danger of coming over. It is cured by clapping spurs smartly to him, as the fore-feet are returning to the ground.

PONTOGLIO, in *Geography*, a town of Italy, in the department of the Mela; 16 miles W. of Brescia.

PONTOISE, a town of France, and principal place of a district, in the department of the Seine and Oise, situated on a hill near the Oise, and defended by a castle. The place contains 5200, and the canton 14,716 inhabitants, on a territory of 140 kilometres, in 17 communes. N. lat. 9° 3'. E. long. 2° 11'.

PONTOON, in *Naval Language*, denotes a low flat vessel, resembling a lighter or barge of burthen, and furnished with cranes, capsterns, tackles, and other machinery, necessary for careening ships of all sizes. These are very common in the principal ports of the Mediterranean, but rarely used in the northern parts of Europe. Falconer.

PONTOON, or *Ponton*, in *War*, denotes a kind of flat-bottomed boat, whose carcass of wood is lined within and without with tin. The French pontoons, and those of most other powers, are covered on the outside with strong copper plates, without any inside lining; and these have the advantage of our's, because copper is much stronger than tin, and is not damaged by rust. Our pontoons are

twenty-one feet long, nearly five feet broad, and two feet one inch and a half deep within.

PONTOON-Bridge is made of pontoons slipped into the water, and placed about five or six feet asunder; each fastened with an anchor, when the river has a strong current, or to a strong rope, that passes across the river, and runs through the rings of the pontoons. Each boat has an anchor, cable, baulks, and chests. The baulks are about five or six inches square, and twenty-one feet long. The chests are boards joined together by wooden bars, about three feet broad, and twelve feet long. The baulks are laid across the pontoons at some distance from one another, and the chests upon them joined close. When several of these are thus connected, they form one firm, uniform bridge, by means of which a train of artillery, cavalry, infantry, &c. may pass over a river, arm of the sea, &c. If pontoons, &c. are wanting, bridges are formed of empty casks or barrels, that support baulks and planks.

Cæsar and Aulus Gellius both mention pontoons; but their's were no more than a kind of square flat vessels, proper for the carrying over of horse, &c. Our's, however, take their names from them: those authors call them *pontones*, of *ponto*.

PONTOON-Carriage is made with two wheels only, and two long side-pieces, whose fore ends are supported by a limber; and serves to carry the pontoons, boards, cross-timbers, anchors, and every thing else necessary for making a bridge.

PONTOPPIDAN, ERIC, in *Biography*, a Danish divine, was born in the isle of Funen, and being brought up to the church, he obtained various preferment, and was at length appointed to the bishopric of Drontheim, in Norway, where he died in 1678, at the age of 62. He published several learned works, particularly a grammar of the Danish language. His nephew, of the same name, became bishop of Bergen, and distinguished himself by a history of the Reformation in Denmark, and another of Norway, of which the last has been translated into the English language. He was author of many other works, the titles of which are given in the *General Biography*. This author was born at Aarhus; he received the early part of his education at the Frederician school, and having gone through his academical examination, became private tutor to the son of lieutenant-general Lützwow, in Norway. In 1726 he attended on a foreign tour another pupil, and was afterwards appointed preceptor to the young duke of Holstein. After filling various offices in the church he was promoted, in 1735, to be preacher to the Danish court; in 1738 he was appointed professor extraordinary of divinity, and in 1747 was raised to the bishopric of Bergen. In 1749 he obtained the degree of doctor of divinity, and in 1755 was made vice-chancellor of the university of Copenhagen. He died in 1764.

PONTORSON, in *Geography*, a town of France, in the department of the Channel, and chief place of a canton, in the district of Avranches, seated on the Coesnon, near the sea, with a tide-harbour; nine miles S.S.W. of Avranches. The place contains 1320, and the canton 8603 inhabitants, on a territory of 255 kilometres, in 16 communes. N. lat. 48° 33'. W. long. 1° 26'.

PONTREMOLI, a town of Etruria, on the Magra, well fortified and defended by a castle; 20 miles S.S.W. of Parma. N. lat. 44° 26'. E. long. 9° 50'.

PONTRIEUX, a town of France, in the department of the Northern Coasts, and chief place of a canton, in the district of Guingamp; seven miles N. of Guingamp. The place contains 1276, and the canton 10,229 inhabitants, on

a territory of 130 kilometres, in eight communes. N. lat. 48° 41'. W. long. 3° 4'.

PONT-VOLANT, FLYING-BRIDGE, a kind of bridge used in sieges. See **BRIDGE**.

PONTUS, in *Ancient Geography*, an extensive country of Asia Minor, which derived its name either from the neighbouring sea, called by the Latins Pontus Euxinus, or from an ancient king, who gave his name both to the country and the adjacent sea. The country of Pontus, appropriately so denominated, lay between the 41st and 43d degrees of N. lat., and was bounded on the N. by the Euxine sea, on the S. by Armenia Minor, on the E. by Colchis, and on the W. by the river Halys. Ptolemy divided this country into three parts, *viz.* Pontus Galaticus, Pontus Polemoniatus, and Pontus Cappadocius. The former derived its name from Galatia, to which it was added in the time of the Romans, and extended from the Halys to the river Thermodon. Its chief cities were Amisus, Eupatoria, Amasia, Themiscyra now Fanagoria, Cabira, and Comana, called Pontica. The second part of Pontus was called Polemoniatus from Polemon, king of this country, and extended from the Thermodon to the country of the Chalybes, or Pontus Cappadocius. Its most considerable cities were Næocesarea, Sebastia, Zela, called also Megalopolis, and Polemonium. This is supposed to have been the kingdom of the Amazons, who admitted among them no men, and yet were famous for warlike exploits. Pontus Cappadocius bordering on Cappadocia, whence its name, extended from Pontus Polemoniatus to Colchis, and had for its southern boundaries Armenia Minor and the upper stream of the Euphrates. Its chief cities were Cerasus, Tripoli, and Trapezus, or Trebisond, now called Trabofan.

The chief rivers of Pontus are the Halys, Iris now Calsmack, and the Thermodon. The air of this country was reckoned salubrious, and the soil in many places was fertile; the hills being mostly covered with olive or cherry-trees, and the plains, watered by small rivers, producing grain in abundance. Tradition reports, that the ancient inhabitants of this country were the descendants of Tubal, who in process of time became intermixed with Cappadocians, Paphlagonians, and other foreign nations, besides several colonies of Greeks. As for their arts and manufactures, the Chalybes, or inhabitants of Pontus Cappadocius, were celebrated by the ancients for their extraordinary skill in the working of iron and the making of steel armour, whence they derived their name. They were probably a commercial people, as they had many convenient harbours on the Euxine sea, and great quantities of timber, fit for the building of ships, and growing on the coast. Their language and religion were much the same with those of Cappadocia. Their chief deities were Ceres, Jupiter, and Neptune; to whom they offered burnt sacrifices, pouring on the fire honey, milk, oil, and wine. In honour of Neptune, they used to drive into the sea chariots drawn by four white horses, which they drowned.

This country was originally a part of Cappadocia, extending from mount Taurus to the Euxine sea, and was divided into several petty kingdoms, which, according to Diodorus Siculus, were first subdued by Ninus. The Medes and Persians became alternately masters of it; and the latter divided Cappadocia into satrapies, or governments; and bestowed that satrapy, which was afterwards named Pontus by the Macedonians, on one of the ancestors of Mithridates. This happened, it is said, in the reign of Darius, son of Hystaspes, who conferred this new kingdom on one Artabazes, of the royal family of Persia; so that Pontus, which to that time had been merely a province of Cappadocia,

docia, began to be governed by its own kings, and was a separate kingdom in the reign of Darius Hystaspes. However, in the reign of Ariobarzanes, the inhabitants, who had paid tribute to the Persians and were their vassals, shook off the Persian yoke, and their sovereign enlarged his small kingdom. In process of time the kings of Pontus became very considerable, having added to their dominions all Cappadocia, Paphlagonia, and great part of Bithynia to the W., and of Colchis to the S.; inasmuch that Mithridates VII. surnamed Eupator, was regarded as one of the most powerful princes that ever reigned in the East, having held it for forty years successively against the Romans, though their armies were commanded by the greatest generals ever produced by Rome, namely, Sylla, Lucullus, and Pompey. The first king of Pontus, that ever entered into an alliance with the Romans, was Mithridates VI., who sent them a considerable supply of ships in their third war with the Carthaginians, and proved a faithful ally to them in the war which they carried on against Aristonicus, who, upon the death of Attalus, laid claim to the kingdom of Pergamus. Mithridates VII. ascended the throne at eleven years of age, and his future greatness is said to have been prefigured by two comets, one of which appeared at his birth, and another in the first year of his reign. He began his reign with several inhuman and unnatural acts of cruelty; and marked the progress of it with characters of blood. He drove the Romans out of Asia; and over-ran all Phrygia, Mysia, Asia Proper, Caria, Lycia, Pamphylia, Paphlagonia, Bithynia, and other countries that had taken part with the Romans, as far as Ionia. All the free cities of Asia opened their gates at his approach; and as many Roman citizens were dispersed over Asia, he ordered them all to be massacred (B.C. 88); one moiety of their goods being forfeited to the king, and the other bestowed as a reward on the assassins. He also reduced several islands in the Archipelago. At length he sustained a signal defeat by Sylla, near Chæronea (B.C. 84.) In the following year a treaty of peace was concluded between them. After several sanguinary contests, Lucullus reduced Pontus into a Roman province; and was succeeded in the conduct of the war against Mithridates by Pompey. Upon the death of Mithridates, his son Pharnaces submitted himself and his kingdom to the Romans. Pompey bestowed the kingdom of Bosphorus on Pharnaces, and honoured him with the title of a friend and ally of the people of Rome; and in consequence of these measures, he got entire possession of Pontus, with its immense treasure, and reduced it to the form of a Roman province. After the return of Pompey to Rome, Pharnaces recovered great part of his hereditary dominions; but when Cæsar had defeated Pompey and his party, he directed his forces against Pharnaces, who sent ambassadors to him to treat of a peace. The conditions proposed by Cæsar were, that Pharnaces should retire immediately from Pontus, return all captives and hostages, whether they were Romans or their allies, and restore the effects of the Roman citizens and publicans which he had seized since he first took up arms. Pharnaces professed to accede to these conditions, but in the fulfilment of them he manifested a considerable degree of duplicity and delay, so that Cæsar was incensed, marched against him, and defeated him. In attempting to recover the kingdom of Bosphorus, which he lost in this contest, he fell in battle; and upon his death, the kingdom of Pontus was again reduced to the form of a Roman province, and so continued till the triumvirate of Marc Antony; who, after the battle of Philippi, conferred it upon Darius, the son of Pharnaces, for his service during the civil war. Darius was succeeded by Polemon, son of Zeno, a famous

orator of Laodicea. Upon his death, his son Polemon II. was, by the emperor Caligula, raised to the throne of Bosphorus and Pontus. But the emperor obliged him to exchange the kingdom of Bosphorus with part of Cilicia; and Nero, with his consent, reduced that part of Pontus which he enjoyed to the form of a province. Polemon dying without issue, the ancient kingdom of Pontus was divided into several parts, and added to the provinces of Bithynia, Galatia, and Cappadocia, only that part of it which was called Pontus Polemoniacus retaining the dignity of a distinct and separate province. The kingdom of Pontus continued to be a province of the empire till the time of David and Alexis Comneni, who, being driven from Constantinople by the French and Venetians, under the command of Baldwin, earl of Flanders, settled, the one at Heraclea, the other at Trebifond. The troubles that arose among the Latins, gave Alexis an opportunity of erecting here a new empire, which comprehended great part of Pontus, and was known by the name of the empire of Trebifond, which see. The Comneni held it above 250 years, till the time of Mahomet II., who carried David Comnenus, the last emperor of Trebifond, prisoner to Constantinople, with all his family, and subjected his empire to that of Constantinople, in which state of abject slavery, Trebifond and all Pontus have ever since continued.

PONTUS *Euxinus*. See *EUXINE Sea*.

PONTYPOOL, or PONT-Y-POOL, in *Geography*, a market-town in the parish of Trevethin, and in the upper division of the hundred of Abergavenny, Monmouthshire, England, is situated at the distance of $6\frac{3}{4}$ miles W. from Usk, and 146 miles W. by N. from London. This place is of modern origin, and owes its present importance entirely to the influence of trade. Its name is a corruption of Pont ap Howell, or Howel's Bridge. The houses here are chiefly ranged in two principal streets; but from the number of detached buildings, the town has a straggling appearance. Most of the inhabitants are engaged in the coal and iron works, carried on in the immediate vicinity. The iron ware, known by the name of *Pontypool ware*, is the chief manufacture of this town: it is called also Japan ware, because bearing a strong resemblance to Japanese lackered wood. The discovery of the art of japaning was accidentally made by a person named Thomas Allgood, who had fixed his residence at Pontypool in the reign of Charles II. He did not, however, live long enough to bring his discovery to perfection; but his son Edward, pursuing the same object with increasing spirit, effected such improvements in it as induced him to establish an extensive japan manufactory here, which is still carried on by one of his descendants. The iron-works of this place are indebted for their commencement to Capel Hanbury, esq., who purchased an estate at Pontypool in 1565. They did not, however, acquire much national importance till the beginning of the last century, when they were greatly extended and improved by major Hanbury, aided by the advice and exertions of Edward Allgood above-mentioned. The latter, on one occasion, made use of an artifice to obtain a secret in the wire manufacture, the fairness and propriety of which are at least questionable. Observing that the Woburn manufacturers understood the method of polishing that article in a very superior manner, and being refused a communication of the art, he repaired to Woburn, in the character of a beggar, and acting the part of a buffoon, gradually obtained access to the work-shops, and thus accomplished his object.

According to the parliamentary returns of 1811, the parish of Trevethin contains 469 houses, and 2423 inhabitants,

habitants, of whom two-thirds are resident in the town. The market-day is Saturday, and there are three annual fairs. The parish church, which is an ancient structure, with a square stone tower at one end, stands upon an eminence, at the distance of a mile from Pontypool. In this church are several monuments to the memory of different members of the Hanbury family, whose seat is situated between it and the town. The house is singularly placed on a perpendicular cliff above the Avon-Lwyd, which forms the western boundary of the grounds. It contains various family portraits, and also original portraits of the duke and duchess of Marlborough, Frederic II. of Prussia, and of Robert Dudley, earl of Leicester, the weak and haughty favourite of queen Elizabeth. Here are also two pictures, representing groups of boys, by Murillo, which were presents from the great sir Robert Walpole to Capel Hanbury, esq., father to the present possessor, who has assumed the name of Leigh, in consequence of the will of the late lord Leigh.

Three miles from Pontypool rises the immense mountain Mynydd-Maen, at the south-western extremity of which is another hill of an oval shape, called Twyn-Barlwn, or Tom-Balam. The summit of this mountain is occupied by an elliptical entrenchment, near which is a large circular tumulus, 30 feet in height, and environed by a deep fosse. According to tradition, this spot was anciently appropriated for holding the bardic meeting, called Eisteddfod. An Historical Tour in Monmouthshire, by William Coxe, A.M., F.R.S., F.S.A., rector of Bemerton, 4to. 1801.

PONZA, a small island in the Mediterranean, near the coast of Naples, at the entrance of the gulf of Gaeta; containing a town, harbour, and considerable salt-works, belonging to the duchy of Parma. N. lat. $40^{\circ} 58'$. E. long. $12^{\circ} 50'$.

PONZANO, a town of Italy, in the Trevisan; 3 miles N.N.W. of Treviso.

PONZIAC, a town of the Birman empire, on the Ava; 16 miles S. of Raynangong.

PONZONE, a town of France, in the department of the Tanaro; 10 miles S. of Acqui.

POOD, in *Commerce*, denotes a weight in Russia, equal to 40 of their pounds; and amounting to 36 English pounds avoirdupois; and 63 poods = 1 ton avoirdupois.

POODACOTTA, in *Geography*, a town of Hindoostan, in the Carnatic; 30 miles W.N.W. of Trichinopoly.

POODICHERAM, a town of Hindoostan, in Myfore; 24 miles W.S.W. of Periapatam.

POODOOR, a town of Hindoostan; 5 miles S. of Coimbatore.

POODUCAUD, a town of Hindoostan, in Cochin; 27 miles E. of Cranganore.

POOKAREEAH, a circa of Bengal, bounded on the east and north by Dacca, on the south by Caugmahry, and on the west by Barbazzoo; about 36 miles long, and from 10 to 20 broad.

POOL, a river of West Florida, which runs into the gulf of Mexico, N. lat. $30^{\circ} 20'$. W. long. $88^{\circ} 12'$ —Also, a town on the east coast of the island of Gilolo. N. lat. $0^{\circ} 2'$. E. long. $127^{\circ} 50'$.

POOL is properly a reservoir of water supplied with springs, and discharging the overplus by sluices, defenders, weirs, and other caufeways.

POOL-Fisheries, in *Rural Economy*, such as are formed in pools, or other waters which are in some measure stagnant. Mr. Marshall has remarked, that these are for the most part peculiar to the places of men of fortune, and the residences of country gentlemen. He knows but of one district, in

which fish-pools are viewed as an object of rural economy. On every side of the metropolis, something of this kind is, he thinks, to be observed; but it is only on the south side, in the adjoining parts of Surrey and Sussex, where the practice of fish-breeding may be said to be established. There, he says, fish-pools have been, and still are, formed, with the view of letting them to dealers in carp, and other pond fish; or of stocking them, and disposing of the produce; as an article of farm-stock, like that of other sorts, such as pigs, rabbits, poultry, or pigeons.

However, in a general view of the kingdom, fish-pools can scarcely, he supposes, be considered as an object worthy of consideration in the improvement of landed property. Yet there are situations, he conceives, in which they may be formed with profit; as in the dips and hollows of extremely bad ground, especially if waters, which are genial to any of the species of pond-fish, happen to pass through them, or can be profitably led to them. Even where the water which can be commanded is of an inferior quality, a profitable breeding pool may be formed, to stock ponds of a more fattening nature, or other uses. See POND-Fisheries.

POOL, *Mill*. See MILL.

POOL, *Whirl*. See WHIRL-*Pool*.

POOL-Snipe, in *Ornithology*, a name given in many parts of England to the red-shank. See SCOLOPAX *Calidris*.

POOLAMPATY, in *Geography*, a town of Hindoostan, in Baramaul; 6 miles N. of Darempoury.

POOLANGE, a small island in the East Indian sea, near the coast of Borneo. N. lat. $3^{\circ} 25'$. E. long. $117^{\circ} 6'$.

POOLAPPAUK, a town of Hindoostan, in the Carnatic; 20 miles S.W. of Madras.

POOLARON, or PULO RHUN, one of the Banda or Spice islands, in the East Indian sea, chiefly inhabited by fishermen. S. lat. $4^{\circ} 12'$. E. long. $130^{\circ} 22'$.

POOLBADA, a town of Hindoostan, in Orissa; 10 miles S.E. of Jaypour.

POOLBARRY, a town of Bengal; 18 miles S.E. of Dinagepour. — Also, a town of Bengal; 24 miles N.W. of Goragot.

POOLE, MATTHEW, in *Biography*, a very learned and eminent English non-conformist divine, was born at York in the year 1624. At the grammar-school he laid an excellent foundation in classical literature, and afterwards went to Emanuel college in the university of Cambridge, where he applied himself with great diligence to the different branches of academical learning, and more particularly to the study of the sacred scriptures. Here he took his degree of M.A., and embraced the Presbyterian faith. He was, however, ordained, and became, about the year 1648, rector of St. Michael le Querne in the city of London. In 1654 he undertook to defend the cause of orthodoxy against John Biddle, and published a piece entitled "The Blaphemer slain with the Sword of the Spirit, or a Plea for the Godhead of the Holy Ghost." On the enforcement of the act of uniformity in 1662, he was ejected from his rectory; upon which occasion he printed a small Latin treatise, entitled "Vox Clamantis in Deserto." He now devoted himself very closely to his studies, and employed his pen in the service of religion, without any regard to the particular differences in sentiment which existed among Protestants. With this view he formed the design of abridging the "Critici sacri," and other expositors of scripture. He met with much encouragement from the learned men of all parties, and was zealously supported by some of the greatest names in the church, among whom was the celebrated Tillotson.

lotson. When the work was in a state of sufficient forwardness to be sent to the press, his majesty granted Mr. Poole a patent for the privilege of printing it; and in 1669, the first two volumes were published in London, under the title of "Synopsis Criticorum aliorumque S. Scripturæ Interpretum," which were afterwards followed by three others. This work cost the author almost an infinity of labour, but it reflected great honour on his industry, erudition, and judgment, and proved a very valuable present to biblical scholars. But notwithstanding its acknowledged merits, it was, till within a few years, to be purchased on very low terms: it is, however, now regarded as a rare book, and seldom to be met with in the catalogues. While employed on the "Synopsis," Mr. Poole found leisure to testify his zeal against Popery, by the publication of some excellent pieces on the subject, which drew down upon him the hatred of the Papists. To this it was probably owing that his name was inserted in the list of persons who were to be assassinated, according to the deposition of Titus Oates, concerning the Popish plot. He entertained no apprehensions on this account, till he was beset in Clerkenwell, as he was returning from Mr. alderman Ashhurst's. He believed that he should that night have been murdered, had not a friend been with him, and determined to leave the country. He accordingly retired to Holland, where he died in 1679, at about the age of 56, not without suspicion of poison. Of Mr. Poole's extensive knowledge, solid learning, and critical skill, his Synopsis affords the most satisfactory evidence. He was author of several other works, besides those that have been mentioned above; and he left behind him in MS. "Annotations on the Bible," in English, which death prevented him from extending beyond the 58th chapter of Isaiah. This work was afterwards continued by other hands, and published in two vols. folio, and has been frequently reprinted.

POOLE, in *Geography*, a considerable sea-port and borough town, and a county of itself, is locally situated within the county of Dorset, England, at the distance of 27 miles E. by S. from Dorchester, and 105 miles S.W. by W. from London. It stands on a peninsula, which is connected with the main land by a narrow isthmus, and derives its name from a large bay, or pool, adjoining. This town is of great antiquity, and, according to Horsley, was the Magnus-Portus of Ptolemy; but Camden and other antiquaries support the opinion of Richard of Cirencester, who places that station at Porchester. Leland attributes the rise of Poole to "the Danes warres," which "fore rased Wareham." After the Conquest it became the property of the earls of Sarum, who granted to it various privileges, which were confirmed and extended by different monarchs. In the time of Edward III. it seems to have been a place of some consideration, as it is recorded to have furnished that king with four ships and 94 men, to assist at the siege of Calais. It is described as being well inhabited in the reign of Henry VI., and was doubtless much favoured by his successors, Edward IV. and Richard III.; but for its most considerable privileges it is indebted to queen Elizabeth. That sovereign constituted it a corporate and free borough by charter, and further directed it to be separated from the manor of Canford, and formed into a distinct county, with power to appoint its own sheriff, &c. in the same manner as the town and county of Southampton. In virtue of that deed, Poole is now governed by a mayor, recorder, four aldermen, a sheriff, two coroners, a senior and a water bailiff, and eighteen common council-men. The mayor is chosen from among the common council-men, and is, *ex officio*, a justice of the peace, escheator of the town, and admiral within the liberties. He

was likewise anciently mayor of the staple. The sheriff and the water bailiff are nominated from the common council. Poole sends two members to parliament, who are elected by the burgeses, whether resident or otherwise. The number of voters is ninety-six, and the sheriff is the returning officer. This town first enjoyed the privilege of national representation in the reign of Edward III.; but it intermitted exercising the same from the 42d year of that monarch till the 31st year of Henry VI.

Poole consists of four considerable streets, running nearly north-east and south-west, and a fifth one crossing these, parallel with the quay, at the eastern extremity of which stands a custom-house; this being the most considerable port in the county. The town dues for goods landed are claimed by the corporation, and the customs sometimes amount to upwards of 10,000*l.* in one year. In former times this place was fortified; but its fortifications were dismantled by Charles II., as a mark of ignominy for the townsmen having shewn peculiar enmity to the interests of his father. They are still, however, visible, as are likewise a ditch and vallum constructed in the year 1745. The principal public buildings in the town are a church, a market-house, a town-hall, a wool-house, and a town-house, erected in 1727, by a company of merchants. The church is an ancient fabric, divided into a body, two aisles, and a tower, and containing a monument in honour of the gallant Mr. Peter Jolliffe, who was rewarded by William III. with a gold medal and a commission, for having, with two assistants only, gallantly boarded and captured a French privateer. The market-house was rebuilt in 1761, at the joint expence of Joseph Gullston, esq. and lieutenant-colonel Calcraft. The town-hall, where the quarter-sessions for the town, and occasionally the assizes, are held, was erected in 1571. The wool-house, called also the king's-hall, or great cellar, is partly of ancient and partly of modern construction.

Poole, in the time of Leland, was only "a poor fisher village;" but it is now one of the largest and most flourishing towns in Dorsetshire. According to the parliamentary returns of 1811, it contained 1059 houses, and 4816 inhabitants. A market is held here twice a week on Monday and Thursday, and fairs on the 1st of May and 2d of November. Here are several meeting-houses for Presbyterians, Quakers, and Anabaptists; also several grammar and charity-schools, and a well-attended Sunday-school, established by W. Morton Pitt, esq. In this town was anciently a house of friars, dedicated to St. George, which was granted, in the reign of Edward VI., to John Churchill and William Samways.

Poole-bay communicates by a narrow entrance with the British Channel: its circumference, including all the windings of the shore, and the projections of the mud banks, is estimated to exceed 60 miles. In its bosom are several small islands. That portion of it which is distinguished by the appellation of Pool-harbour, extends about four miles in length from North Haven to Redcliffe-Attwell on the Purbeck shore. The depth of water here averages about 14 feet. The trade of this port is chiefly confined to Newfoundland, and a number of young seamen are trained up in this fishery. The exports are provisions, nets, cordage, sail-cloth, and wearing apparel, with a variety of commodities for plantation consumption. The returns are cod and salmon, which are afterwards sent to foreign markets, oil, seal-skins, furs, and cranberries. The exports and imports of grain are likewise considerable. The number of ships belonging to Poole is stated at about 250, of which 140 are employed in foreign commerce, and 40 in the oyster and herring fisheries. The court of admiralty here is held

at a place called Brome-hill, on the quay; and its records are extant from the time of Edward VI. The mayor is president, and there is a jury impanelled to judge of causes within the jurisdiction. Formerly this court was convened annually, but is now at pleasure. Beauties of England and Wales, vol. iv., by E. W. Brayley and John Britton, F.S.A.

POOLE, or *Welch Poole*. See *WELCH-Poole*.

POOLGOURY, a town of Hindoostan, in Madura; 21 miles W. of Coilpetta.

POOLOO, a town of Pegu, on an island in the mouth of the Ava; 26 miles E. of Perfain.

POOLPETTI, a town of the island of Ceylon; 30 miles S.S.E. of Candy.

POOLPOUR, a town of Hindoostan; 50 miles W.N.W. of Benares.

POOL'S ISLAND, a small island in the Chesapeake. N. lat. $39^{\circ} 22'$. W. long. $76^{\circ} 23'$.

POOLYLOPU, a town of Hindoostan, on the coast of Malabar; E.N.E. 4 geographical miles from Cadiapatam point. N. lat. $8^{\circ} 8'$. E. long. $77^{\circ} 20' 50''$.

POON, a town of Hindoostan, in the circar of Hindia, on the left bank of the Nerbudda; 30 miles W. of Hindia.

POONACAMADA, a town of Hindoostan, in the circar of Rajamundry; 40 miles W. of Rajamundry.

POONAH, a town of Hindoostan, in the country of Vifiapour, and capital of the western Mahratta empire; situated about 30 miles on the east of the Gauts, 100 road miles from Bombay, and about 75 from the nearest sea-coast. It is meanly built, and not large; and lies quite open and defenceless. Pooronder, a fortress on a mountain, about 18 miles to the E.S.E. of Poonah, is the place of refuge in case of invasion: there the archives of government are deposited, and there the principal officers usually reside. Whenever an invasion has happened, the Mahrattas never thought Poonah a place worthy of defence; and have accordingly destroyed it with their own hands. In 1803 Poonah was taken by the British. N. lat. $18^{\circ} 30'$. E. long. $73^{\circ} 55'$.

POONAH, a town of Bengal; 6 miles N.E. of Ramgur.

POONAKHA, a town of Bootan; 12 miles N.E. of Taffasudon. N. lat. $27^{\circ} 55'$. E. long. $89^{\circ} 46'$.

POONAMALEE, a town of Hindoostan, in the Carnatic; 10 miles S.W. of Madras.

POONDY, a town of Hindoostan, in the circar of Cicacole; 10 miles N.E. of Tickely.

POONKUR, a town of Hindoostan, in Coimbetore; 3 miles N.E. of Damicotta.—Also, a town of Bengal; 30 miles S.S.E. of Beyhar.

POONRAH, a town of Bengal; 60 miles N.W. of Midnapour.

POONUGGA, a town of Bootan; 28 miles S. of Taffasudon.

POOP, in *Sea Language*, denotes the hind part of a ship, or that wherein the helm is fixed; called also *stern*.

The French frequently call it *queue*, tail, because the rudder here applied serves the same purposes in a ship as the tail does to fishes. The poop is divided into three or four stories, which all together form the poop castle, or hind-castle, the outside of which is richly adorned with balconies, galleries, trophies, the arms of the prince, &c.

To have the wind in poop, in *Sea-phrases*, is to have it behind, or favourable.

POOP, *Puppis*, *Stern*, denotes more particularly the highest or uppermost part of a ship's hull a-stern.

POOP-Royal is a short deck or plat-form, placed over the

aftmost part of the poop in the largest of the French and Spanish men of war, and serving as a cabin for their masters and pilots. This is usually called the top-gallant poop by our shipwrights.

POOPING, in *Sea Language*, denotes the shock of a high and heavy sea upon the stern or quarter of a ship, when she scuds before the wind in a tempest. This circumstance is extremely dangerous to the vessel, which is thereby exposed to the risk of having her whole stern beat inwards, by which she would be immediately laid open to the entrance of the sea, and, of course, foundered, or torn to pieces.

POOPOOR, a white cosmetic used in Sumatra for rendering the skin fine, smooth, and soft. The mode of preparing it is as follows. The basis is fine rice, which is a long time steeped in water, then dried, reduced to a powder, and by wetting made into a paste. With this they mix ginger, and the leaf of a plant called "deelum" (patch leaf), which gives it its peculiar smell, and also, as is supposed, a cooling quality. They add likewise the flowers of the "jagong" (maize), "cayoo chendano" (sandal wood); and the seeds of a plant called there "capay antoo" (fairy cotton), which is the "abel mosc," or musk seeds. All these ingredients, after being well mixed together, are made up into little balls; and when they would apply the cosmetic, these are diluted with a drop of water, rubbed between the hands, and then on the face, neck, and shoulders. They have an apprehension, probably well founded, that a too abundant or frequent application will, by stopping the pores of the skin, bring on a fever. It is used, with good effect, to remove that troublesome complaint, so well known to Europeans in India by the name of the prickly heat; but it is not always safe for strangers thus to check the operations of nature, in a warm climate. The Sumatran girls, as well as our English maidens, entertain a favourable opinion of the virtues of morning dew, as a beautifier; and believe, that by rubbing it to the roots of the hair, it will strengthen and thicken it. With this view they take pains to catch it before sun-rise, in vessels, as it falls. Marsden's Sumatra, p. 219.

POOPOOROO, in *Geography*, a small island in the East Indian sea, near the north-east coast of Borneo. N. lat. $6^{\circ} 18'$. E. long. $117^{\circ} 54'$.

POOR, PAUPER. A poor person, in a legal sense, is one who is a burden to and charge upon a parish.

It has been maintained by several authors of reputation, that the legal provision made for the poor by the last parliament of queen Elizabeth, was rendered necessary by the dissolution of the monasteries in the reign of her father. Before this event took place, it has been said that the wants of the indigent were relieved by the charity of the monks; and Dugdale remarks, that while the convents stood, there was no act for the relief of the poor, so amply were they provided for by these houses; whereas in the next age, there were no less than eleven bills brought into the house of commons for the purpose. That the monasteries afforded relief to the poor is a position maintained also by Smith and Blackstone; and the latter attributes to the dissolution of these the numerous statutes made in the reign of Henry VIII. and his children, for providing for the poor and impotent. This account of the origin of the poor laws has not, however, passed without contradiction. Mr. Alcock, who in 1752 published observations on the defects of the poor laws, has strongly objected to it. If the abbies maintained the poor, says this writer, how came the poor not to have been equally destitute in other Protestant countries, on the secularization of them? And how came the

the poor laws not to have passed here in England immediately on the dissolution or secularization, when the poor, we must suppose, were most to seek for a maintenance, and no new resources were yet opened? How did they subsist in the latter part of the reign of Henry VIII., through the whole reign of Edward VI., during the reigns of queen Mary and of queen Elizabeth, till about a year before the death of the latter, that is, near 70 years in the whole? The same train of argument is pursued by Mr. Daines Barrington, in his Observations on the more ancient Statutes. Mr. P. Andrews, in his Continuation of Henry's History of Great Britain, has remarked, in support of the same opinion, that the first act, which immediately affected the poor, was passed by Henry VIII., some years before the dissolution of religious houses; which remark, he adds, confutes at once the favourite system of those who date the commencement of the poor's rates from the destruction of monasteries. It is, however, observed by an ingenious anonymous writer (*ubi infra*), that statutes for the regulation of beggars are of much older date in England than the reign of Henry VIII.; nor does the act 22 Hen. VIII. c. 12, on which Mr. Andrews builds his whole conclusion, contain any provision for a compulsory poor's rate; and it by no means follows, that though in the preamble to that act complaint is made of the increase of beggars and vagabonds, that when monasteries were afterwards suppressed, these beggars were not reduced to greater misery. Besides, it is not correct to say, that from the 27th and 31st of Henry VIII., when the monasteries were dissolved, to the 43d of Elizabeth, when the present system of poor's rates was established, no laws were made for the relief and maintenance of the poor. From the 22d of Henry VIII. to the 43d of Elizabeth, hardly a parliament met, in which some laws that regarded the poor were not enacted. On the other hand, it must be admitted, that no mode of administering relief to the indigent is more likely to increase the evil which it is meant to alleviate than the charity of convents. Such charity augments the number of the indigent; and therefore, says our author, the suppression of monasteries cannot have been the cause of that enormous addition to the poor, which took place in England during the 16th century, notwithstanding the general improvement of the kingdom at that period, and the manifest increase of wealth and comfort among the higher and middling classes of society. It appears likewise, from an account of the regulations concerning mendicity in Spain, from the earliest times to the reign of Charles III., by Sempere y Guerinós, in the first volume of his "*Biblioteca Economico-politica*," and from the similarity of the English poor laws with those of Spain at the same time, that the popular opinion, which ascribes to the dissolution of convents the origin of our poor laws, is unfounded. In other Catholic countries, where no monasteries were suppressed, regulations for the poor became necessary about the same period. Hence it has been inferred, that the increase of the poor, which led to the English poor rates, was not owing to the dissolution of monasteries in England, but to some cause of more general operation, which extended its influence to other countries of Europe, that did not embrace the Protestant faith, nor suppress the religious institutions of their ancestors. This cause, the ingenious writer, whose remarks we are citing, inclines to think was the discovery of America, and consequent depreciation of the precious metals. This depreciation of money has the same effect on the circumstances of the labourer as a bad harvest. Commodities rise in price; and if the change in the value of money is progressive for a number of years, he suffers the same hardships as from a

succession of bad seasons, which every year become worse. While money continues to sink, the labourer, though occasionally relieved by an advance of wages, feels himself exposed, in a few years, to a recurrence of the same difficulties. In a little while he will be reduced to indigence; and from indigence to beggary the transition is short; and he who cannot maintain himself by his own labour, will seek for support in the benevolence of others. By a train of such reasoning it appears, that the natural effect of a gradual depreciation of money, when not counteracted by an extraordinary, steady, and progressive demand for labour, is to impair the comfort, and reduce the condition of the labouring part of the community, and to drive many of them to habits of idleness and beggary. That this was the case in England during the 16th century, that the number of the poor was continually increasing, that the country was overrun with idlers and vagrants, we have the authority of the poor laws to prove, and the concurrent testimony of all contemporary authors to corroborate. The writer, now cited, proceeds to shew, that from the discovery of America to the end of the 16th century, there was a gradual rise of prices in England, not accompanied by a corresponding rise in the price of labour. *Edinburgh Review*, N^o 43.

Formerly, the maintenance of the poor was chiefly an ecclesiastical concern; and a fourth part of the tithes in every parish was set apart for that purpose. The minister, under the bishop, had the principal direction in the disposal of it, assisted by the churchwardens and other principal inhabitants: hence naturally sprung the parochial settlement. Afterwards, when the tithes of many parishes were appropriated to the monasteries, these societies were the principal resource of the poor, who were farther relieved by voluntary contributions. But though the relief of the poor was in a great degree an ecclesiastical concern, it is not true, as some have imagined, that the common law of England made no provision for the poor. The "*Mirror*" (c. 1. § 3.) shews the contrary; but it does not appear how it was done. (1 Bur. 450.) Judge Blackstone observes, that till the statute 27 Hen. VIII. cap. 25, he finds no compulsory method for providing for the poor; their relief depending upon the humanity of their neighbours. But upon the total dissolution of the monasteries, the inconvenience of thus encouraging the poor in habits of indolence and beggary, who had been accustomed to partake of the alms daily distributed at the gates of religious houses, was gradually felt throughout the kingdom; and abundance of statutes were made in the reign of Henry VIII., Edw. VI., and Elizabeth, for this purpose. These poor were principally of two sorts: sick and impotent, and therefore unable to work; idle and sturdy, and therefore able, but not willing, to engage in any honest employment. To provide, in some measure, for both of these, in and about the metropolis, Edward VI. founded three royal hospitals: Christ's and St. Thomas's, for the relief of the impotent through infancy or sickness; and Bridewell, for the punishment and employment of the vigorous and idle; but these were found to be insufficient for the care of the poor through the kingdom at large. At length, by stat. 43 Eliz. cap. 2, overseers of the poor were appointed in every parish. See *OVERSEERS*.

The two great objects of the statute of Elizabeth seem to have been, 1st, to relieve the impotent poor, and them only; 2d, to find employment for such as are able to work: and this principally by providing stocks of raw materials to be wrought up at their separate towns, instead of accumulating all the poor in one common workhouse; a practice which puts the sober and diligent upon a level (in point of their earnings) with those who are dissolute and idle, de-

POOR.

presses the laudable emulation of domestic industry and neatness, and destroys all endearing family connections, the only felicity of the indigent. Whereas, if none were relieved but those who are incapable of getting their livings, and that in proportion to their incapacity; if no children were removed from their parents, but such as are brought up in rags and idleness; and if every poor man and his family were regularly furnished with employment, and allowed the whole profits of their labour:—a spirit of busy cheerfulness would soon diffuse itself through every cottage; work would become easy and habitual, when absolutely necessary for daily subsistence; and the peasant would go through his task without a murmur, if assured that he and his children, (when incapable of work through infancy, age, or infirmity,) would then, and then only, be entitled to support from his opulent neighbours. This appears to have been the plan of the statute of queen Elizabeth; and as far as this was the case, it was wise and laudable. The only, or at least the principal, defect of it seems to have been confining the management of the poor to small parochial districts; which are frequently incapable of furnishing proper work, or providing an able director. However, the labouring poor were then at liberty, under certain limitations to be hereafter mentioned, to seek employment wherever it was to be had; none being obliged to reside in the places of their settlement, but such as were unable or unwilling to work.

POOR-Rate. It is curious to trace in succession the several gradations by which the compulsory maintenance of the poor became established in this kingdom. By a statute made in the 12 Rich. II. c. 7, the poor were restrained from wandering abroad, and were required to abide in the towns where they were born, or in other places within the hundred; within which districts they were allowed to beg. By the 22 Hen. VIII. c. 12, the justices were to distribute themselves into several divisions, within which divisions respectively they might license persons to beg. By the 27 Hen. VIII. c. 25, the several hundreds, towns corporate, parishes, or hamlets, were required to sustain the poor with such charitable voluntary alms, as that none of them might of necessity be compelled to go openly in begging, on pain that every person making default should forfeit 20s. a month. And the churchwardens or other substantial inhabitants were to make collections for them with boxes on Sundays, and otherwise by their discretions. And the minister was to take all opportunities to exhort and stir up the people to be liberal and bountiful. By the 1 Edw. VI. c. 3, houses were to be provided for them by the devotion of good people, and materials to set them on work; and the minister, after the gospel every Sunday, was specially to exhort the parishioners to a liberal contribution. By the 5 & 6 Edw. VI. c. 2, the collectors of the poor on a certain Sunday in every year, immediately after divine service, were to take down in writing what every person was willing to give weekly for the ensuing year; and if any should be obstinate, and refuse to give, the minister was gently to exhort him; if he still refused, the minister was to certify such refusal to the bishop of the diocese, and the bishop was to send for him to induce and persuade him by charitable ways and means, and so according to his discretion to take order for the reformation thereof. By the 5 Eliz. c. 3, if he stood out against the bishop's exhortation, the bishop was to certify the same to the justices in sessions, and bind him over to appear there; and the justices at the said sessions were again gently to move and persuade him; and, finally, if he would not be persuaded, then they were to assess him what they thought reasonable towards the relief of the poor, and in case of refusal, were to commit him till paid.

By the 14 Eliz. c. 5, power was given to the justices to lay a general assessment; and this hath continued ever since. For by 43 Eliz. c. 2, the churchwardens and overseers of the poor of every parish, or the greater part of them, (with the consent of two or more justices, one of whom is of the quorum, dwelling in or near the parish,) are empowered to raise weekly, or otherwise, by taxation of every inhabitant, parson, vicar, and other, and of every occupier of lands, houses, &c. materials for employing the poor, and competent sums for their relief. Notice shall be given in church of every such rate the next Sunday after it is allowed, which may be inspected by every inhabitant, paying 1s., and copies of it granted on demand, 6d. being paid for every twenty-four names; and a churchwarden or overseer refusing, shall forfeit 20l. to the party aggrieved. The rate is to be levied by distress on those who refuse to pay it; and appeals against it are allowed. 17 Geo. II. c. 2. c. 38. 41 Geo. III. c. 23. See **RATE**.

If the justices find, that the inhabitants of any parish are not able to levy among themselves sufficient sums for the purposes specified in the act, they may assess any other parish within the hundred; and if the hundred be unable to grant necessary relief, they may rate and assess any parish within the county. 43 Eliz. c. 2.

Concerning the obligation of parents and children, see **PARENT** and **CHILD**.

In order to compel husbands and parents to maintain their own families, the law hath provided, that all persons running away out of their parishes, and leaving their families upon the parish, shall be deemed and suffer as incorrigible rogues. (1 Jac. cap. 4.) And if a person merely threatens to run away and leave his wife and children upon the parish, he shall, upon conviction, before one justice by confession, or oath of one witness, be committed to the house of correction, for any time not exceeding one month. 17 Geo. II. cap. 5.

If persons, who have some estates, run away and leave their children chargeable to the parish, it shall be lawful for the churchwardens or overseers, where any such wife, child, or children shall be so left, on application to, and by warrant or order of two justices, to take and seize so much of the goods and chattels, and receive so much of the annual rents and profits of the lands and tenements of such husband, father, or mother, as two such justices shall order and direct, towards the discharge of the parish or place where such wife, child, or children are left, for the bringing up and providing for such wife, child, or children; which warrant or order being confirmed at the next quarter sessions, it shall be lawful for the justices there to make an order for the churchwardens or overseers to dispose of such goods or chattels by sale or otherwise, or so much of them for the purposes aforesaid, as the court shall think fit, and to receive the rents and profits, or so much of them as shall be ordered by the said sessions, of his or her lands and tenements for the purposes aforesaid. 5 Geo. III. c. 8.

And whereas several persons, by their wilful default and neglect, permit their wives and children to become chargeable to their parish: it is enacted, that if it shall be made appear to two justices, that any such person doth not use proper means to get employment, or if he be able to work, by his neglect of work, or by spending his money in ale-houses or places of bad repute, or in any other improper manner, and do not apply a proper portion of the money he earns towards the maintenance of his wife and family, by which they or any of them become chargeable to their parish, he shall be deemed an idle and disorderly person, and punished accordingly. 32 G. 3. c. 45.

POOR.

For the farther maintenance of the poor, there are many fines and forfeitures payable to their use: as for swearing, drunkenness, destroying the game, &c. And also parts of wastes, woods, and pastures, may be inclosed for the growth and preservation of timber and underwood for their relief. See *WORK-house*.

POOR, Settlement and Removal of the. The first rudiments of parish settlements seem to be the statutes 12 Ric. II. c. 7. and 19 Hen. VIII. c. 12. which direct the poor to abide in the cities or towns where they were born, or such wherein they had dwelt for three years, a term afterwards (*viz.* by 39 Eliz. c. 4.) confined, in the case of vagabonds, to one year only. But after the Restoration, by 13 & 14 Car. II. c. 12. a legal settlement was declared to be gained by birth; or by inhabitancy, apprenticeship, or service for forty days; within which period all intruders were made removable from any parish by two justices of the peace, unless they settled in a tenement of the yearly value of 10*l.* The frands, naturally consequent upon this provision, which gave a settlement by so short a residence, produced the statute 1 Jac. II. c. 17. which directed notice in writing to be delivered to the parish officers, before a settlement could be gained by such residence. Subsequent provisions allowed other circumstances of notoriety to be equal to such notice given; and those circumstances have from time to time been altered, enlarged, or restrained, whenever the experience of new inconveniencies, arising daily from new regulations, suggested the necessity of a remedy. And the doctrine of certificates was invented, by way of counterpoise, to restrain a man and his family from acquiring a new settlement by any length of residence whatever, unless in two particular excepted cases; which makes parishes very cautious of giving such certificates, and of course confines the poor at home, where frequently no adequate employment can be had. The law of settlements may be, therefore, now reduced to the following general heads; or a settlement in a parish may be acquired, 1. *By birth*; for wherever a child is first known to be, that is always *prima facie* the place of settlement, until some other can be shewn. This is also always the place of settlement of a bastard child; for a bastard having, in the eye of the law, no father, cannot be referred to his settlement, as other children may. However, this rule admits of several exceptions which render the mother's settlement that of the child; as in the case of a bastard born in a place by collusion; after the order of removal is made out; in removing; after the removal, and before the appeal; in a state of vagrancy; in a house of correction or prison; and in a house of industry or lying-in hospital. A bastard born under a certificate is settled where born; unless the certificate undertakes to provide for the woman and her child, she being then pregnant of a bastard, in which case the child is settled in the certificated parish. But with regard to legitimate children, though the place of birth be *prima facie* the settlement, yet it is not exclusively so; for there are, 2. Settlements by *parentage*, being the settlement of one's father or mother: all children being really settled in the parish where their parents are settled, until they get a new settlement for themselves. A new settlement may be acquired several ways; as, 3. *By marriage*: for a woman, marrying a man that is settled in another parish, changes her own; the law not permitting the separation of husband and wife. But if a man has no settlement, her's is suspended during his life, if he remains in England, and is able to maintain her; but in his absence, or after his death, or during (perhaps) his inability, she may be removed to her old settlement. The other methods of acquiring settlements in any parish are all reducible to this one, of *forty days' resi-*

dence therein; but this forty days' residence (which is construed to be lodging or lying there) must not be by fraud, or stealth, or in any clandestine manner, but accompanied with one or other of the following concomitant circumstances. The next method, therefore, of gaining a settlement is, 4. *By forty days' residence and notice*. For if a stranger comes into a parish, and delivers notice in writing of his place of abode, and number of his family, to one of the churchwardens or overseers (which must be read in the church and registered), and resides there unmolested for forty days after such notice, he is legally settled thereby. (13 & 14 Car. II. cap. 12. 1 Jac. II. cap. 17. 3 & 4 W. & M. cap. 11.) But there are also other circumstances equivalent to such notice: therefore, 5. *Renting* for a year a tenement of the yearly value of 10*l.* and residing forty days in the parish, gains a settlement without notice. (13 & 14 Car. II. c. 12.) 6. Being charged to and paying the public taxes and levies of the parish, excepting those for scavengers, highways, house, and windows. (9 Geo. I. c. 7. 21 Geo. II. c. 10. 18 Geo. III. c. 26.) And, 7. Executing, when legally appointed, any public parochial office on a man's own account for a whole year in the parish, as churchwarden, &c. are both of them equivalent to notice, and gain a settlement, if connected with a residence of forty days. (3 & 4 W. & M. c. 11.) But no settlement shall be gained by any person being charged with and paying his share of the public taxes or levies, in respect of any tenement under the yearly value of 10*l.* (35 Geo. III. c. 101.) By the same act no settlement can be gained by delivery of notice. 8. Being *hired* for a year, when unmarried and childless, and *servng* a year in the same service; and 9. Being bound an *apprentice* for seven years, give the servant and apprentice a settlement without notice, in that place in which they serve the last forty days. (3 & 4 W. & M. c. 11. 8 & 9 W. III. c. 10. 31 Geo. II. c. 11.) By 12 Ann. st. 1. c. 18, a person who serves as a hired servant with one who came and resided in a parish by means or licence of a certificate, without afterwards gaining a legal settlement in such parish, shall not gain a settlement, by reason of such hiring or service: and by 33 Geo. III. c. 54, no person who is servant or a certificated member of a benefit society shall gain a settlement by hiring and service. 10. Lastly, the having an *estate* of one's own, and residing thereon forty days, however small the value may be, in case it be acquired by act of law, or of a third person, as by descent, gift, devise, &c. is a sufficient settlement; but if a man acquire it by his own act, as by purchase (in its popular sense, in consideration of money paid), then, unless the consideration advanced *bona fide* be 30*l.* it is no settlement for any longer time than the person shall inhabit thereon. 9 Geo. I. c. 7.

All persons, not so settled, may be removed to their own parishes on complaint of the overseers, by two justices of the peace, if they shall adjudge them likely to become chargeable to the parish into which they have intruded; unless they are in a way of getting a legal settlement, as by having hired a house of 10*l. per. annum*, or living in an annual service; for then they are not removeable. And in all other cases, if the parish to which they belong will grant them a certificate, acknowledging them to be their parishioners, they cannot be removed, because likely to become chargeable, but only when they become actually chargeable. But such certificated persons can gain no settlement by any of the means above-mentioned, unless by renting a tenement of 10*l. per annum*, or by serving an annual office in the parish, being legally placed therein; neither can an apprentice or servant to such certificated person gain a settlement by such their service. (8 & 9 W. III.

c. 30. 12 Ann. ft. 1. c. 18. 3 Geo. II. c. 29.) If such persons as are removeable shall refuse to go, or shall not remain in that parish where they ought to be settled, but shall return of their own accord to the parish from which they were removed, the justice may send them to the house of correction, there to be punished as vagabonds. (13 & 14 Car. II. c. 12) And by the 17 Geo. II. c. 5. all persons who shall unlawfully return to such parish or place from whence they have been legally removed by order of two justices, without bringing a certificate from the parish or place whereunto they belong, shall be deemed idle and disorderly persons; and any one justice may commit them (being thereof convicted before him, by his own view, or by their own confession, or by the oath of one credible witness) to the house of correction, there to be kept to hard labour for any time not exceeding one month. And if the churchwardens and overseers of the parish to which he shall be removed, refuse to receive such person, and to provide work for him, as other inhabitants of the parish; any justice of that division shall bind any such officer in whom there shall be default to the assizes or sessions, there to be indicted for his contempt in that behalf. (13 & 14 Car. II. c. 12.) And by the 3 W. c. 11. if any person be removed by virtue of this act, from one county, riding, city, town corporate, or liberty, to another, by warrant of two justices; the churchwardens or overseers of the poor of the parish or town to which the said person shall be so removed, are required to receive the said person: and if he or they shall refuse so to do, such person so offending shall (on proof thereof by the oath of two witnesses before one justice of the place to which the person shall be removed) forfeit for each offence 5*l.* to the use of the poor of the parish or town from which such person was removed, to be levied by distress, by warrant to the constable of the parish or town where such offender dwells; and for want of sufficient distress, the said justice shall commit the offender to the common gaol for forty days. By 35 Geo. III. c. 101. so much of the said act of 13 & 14 Car. II. c. 12. as enables justices to remove persons that are likely to become chargeable, is repealed. And it is enacted, that after the 22d of June 1795, no poor person shall be removed from the parish or place where he shall be inhabiting, to the place of his last legal settlement, until he shall have become actually chargeable to the parish, township, or place in which he shall then inhabit, in which case two justices may remove such person, in the same manner, and subject to the same appeal, and with the same powers, as might have been done before the passing of this act, with respect to persons likely to become chargeable. Provided always, that every person who shall have been convicted of larceny, or any other felony, or by the laws now in being deemed a rogue, vagabond, idle or disorderly person; or who shall appear to two justices where such person shall reside, upon the oath of one witness, to be a person of evil fame, or a reputed thief, such person not being able to give a satisfactory account of himself, or of his way of living; shall be considered as a person actually chargeable within the meaning of this act to the parish where he shall reside, and may be removed to his place of settlement by order of the said justice. Provided also, that every unmarried woman with child shall be deemed and taken to be a person actually chargeable to the place where she shall inhabit, and may be removed as such to the place of her settlement. This act supercedes the necessity of granting certificates.

These are the general heads of the laws relating to the poor, which by the resolutions of the courts of justice thereon, within a century past, are branched into a great

variety. And yet notwithstanding the pains that have been taken about them, they still remain very imperfect, and inadequate to the purposes for which they are designed.

When the shires, the hundreds, and the tithings, were kept in the same admirable order in which they were disposed by the great Alfred, there were no persons idle, consequently none but the impotent that needed relief; and the statute 43 Eliz. seems entirely founded on the same principle. But when this excellent scheme was neglected and departed from, we cannot but observe with concern, what miserable shifts and lame expedients have from time to time been adopted, in order to patch up the flaws occasioned by this neglect. There is not a more necessary or more certain maxim in the frame and constitution of society, than that every individual must contribute his share, in order to the well-being of the community; and hereby they must be very deficient in sound policy, who suffer one-half of a parish to continue idle, dissolute, and unemployed; and at length are amazed to find, that the industry of the other half is not able to maintain the whole. Blackst. Comm. book. i. For a variety of cases and arguments relating to the settlement, removal, &c. of the poor, see Burn's Justice, art. *Poor*.

The author of the Present State of Husbandry in Great Britain, considers the poor laws and poor rates scarcely less oppressive to the farmer, or injurious to the interests of agriculture in England, than the tythes.

In speaking of them, he says, those most impolitic of all impolitic laws, were unquestionably established on principles and from motives that do honour to the feelings of the legislative body of the time in which they were enacted. They were considered, not only by those who framed and supported them, but by all sensible and intelligent people, as the wisest and most philanthropic of human institutions. They had for their chief object the comfortable subsistence of those who, feeble through age or misfortune, were rendered incapable of exerting themselves in such a manner as to procure from their labour a sufficient supply of the necessaries of life; and that by means the most rational, namely, by compelling those who possessed none, or but a small share, of "the milk of human kindness," to contribute in an equal proportion with those who, from liberal and benevolent dispositions, would have continued to do so without legal compulsion. It was expected, that the enacting of these laws would have had the effect of introducing a spirit of industry among the lower ranks; which, while it tended to render the operation of the poor laws in a very small degree burthensome to the wealthy part of the community, would also have greatly promoted the prosperity of the nation. But how blind, says he, is human foresight, and how imperfect all human institutions! These laws, from the establishment of which so many happy effects were expected to result, have tended to consequences of the most alarming nature; consequences which, if effectual measures are not speedily taken to avert them, may and probably will end in universal ruin. That something is necessary to be done in respect to these laws, the late rapid increase of the rates sufficiently shews. It is further remarked by the above writer, that it is stated in Kames's Sketches of the History of Man, "that in Dr. Davenant's time the poor's rates were about 700,000*l.* annually. In 1764 they amounted to 2,000,000*l.* In 1773 they amounted to 3,000,000*l.*, equal to six shillings in the pound land-tax." So that if they have increased in an equal ratio since the year 1773, which will not be denied, they cannot, he says, in 1796, be less than 5,000,000*l.*, equal, by the above calculation, to ten shillings in the pound land-tax. That this is the case there can be little doubt, though

the sum would seem to be a great deal more than would maintain all the poor of the kingdom under proper management. The increase, however, has been still greater since the last of these periods.

But it is added, that notwithstanding the enormous assessments to which they give rise, they are by no means attended with the advantages which were expected. In place of tending to improve the morals or increase the industry of the poor, they have had, he says, quite a contrary effect. It was but a short time after the enactment of these laws that the public were, he observes, insulted with the famous song of

“ Hang sorrow, cast away care,
The parish is bound to maintain us.”

And how much this sentiment seems to be impressed on the minds of the generality of that description of people for whose benefit these laws were framed, is well known to all who live under their influence. They require not to be reminded how necessary it is become to endeavour, by every possible means, to curb that spirit of licentiousness which so generally reigns within the walls of a parish workhouse; whence shame, honesty, and pride seem to be for ever banished. And Mr. Middleton, in his able Survey of the County of Middlesex, after observing that agriculture occasions very few poor, — on the contrary, it provides them almost constant labour, — remarks, that it is only the blind, the extreme old, the very young children and idiots, which become chargeable in a parish purely agricultural. He thinks that a labourer in agriculture is more likely to support his family without assistance from the parish, at twelve shillings a week, than is a journeyman in any large manufactory, though his earnings should be a guinea, or a guinea and a half. But, says he, large manufactories, like crowded workhouses, destroy every virtuous principle. Such situations are the very sinks of vice; the old and the young, the healthy, and those afflicted with loathsome diseases, the necessitous and the abandoned, are all mixed in one house, or perhaps in one room. Here the young, the unfortunate, and persons of weak, yet honest minds, every minute have their ears assailed with infamous oaths, and descriptions of every species of vice, deception, and theft. The scene is in the highest degree horrid, and infinitely surpasses any powers of description. It is added, that the idea of supporting a large family at a less expence *per* head than a small one, has led us into sad extremes. The supporters of such a system neglected to estimate the effect of that general contamination of morals, which always takes place in situations crowded with paupers of every description; as well as the impossibility of preventing frauds and of effecting the most prudent management, in large workhouses, or houses of industry, such, in short, as in the end to have the effect of more than doubling the expence; and which is calculated to be perpetually increasing, in something like the proportion of compound interest. In support of this, he further remarks, that the difference in favour of small or thinly inhabited parishes, when put in comparison with such as are large and populous, as to the expence and orderly behaviour of their poor, is astonishingly great. Hence the latter should divide and subdivide their poor, in order to put them on the advantageous terms of the former. And he justly thinks, that all the really necessitous, and who only want a part of their support, should be assisted in their own houses, where five shillings will frequently go as far as twenty would do in the workhouse. He adds, that the Rev. John Howlett, speaking of the means used for lowering the poor-rates in his parish of Dunmow, in the county of Essex, attributes it to two causes: first, a determination in

the parish officers to spare their money to the utmost; and, secondly, by admitting as few as possible into the workhouse, where experience had taught them, that the maintenance of the poor is much more expensive than out of it. The consequence was a very large decrease in the rates. This is a strong fact, which deserves the particular attention of the farmer and land proprietor of every district.

Mr. Middleton thinks, that for distressed objects who of necessity must have the whole of their support from the parish, there should be a sufficient number of small cottages built, in lieu of a workhouse, not all close together, but perhaps in pairs, or at least so much apart, as to admit of each cottage having a piece of ground for the production of potatoes, turnips, &c.; if widely dispersed over several parts of the same parish, so much the better; they should be made to hold two persons, and one or two children, or in lieu of the children, one or two of those paupers who should be found the most infirm. They should be obliged to assist each other, and to do something towards their own support. Alms-houses are, he says, a case in point, where poor persons live, on an average, for half the expence that supports others in a workhouse, which incontrovertibly shews the more cheap and superior comforts which cottages afford over workhouses, and likewise the wisdom of erecting them in lieu of workhouses for the reception of the poor. Many instances of this sort are to be found.

He contends, that they who are able to work, but who are idle and incorrigible, should be let out to persons who are in the habit of employing and supporting such characters; or they might be committed to the house of correction. And in many cases paupers might, he thinks, be employed in scraping the turnpike roads and highways. The overseers should undertake the work by contract, which would be a benefit to the parish, and a convenience to the public.

And it is strongly stated, that lodging and diet in the workhouses, in every instance, are superior to what the industrious labourer can provide for his family. It is obvious, he says, that this must have an influence over their minds, and become most injurious to the interests of society. It holds out encouragement to prefer the workhouse to labour; and, by filling the poor-houses with improper inhabitants, it reduces the amount of industry. In this county, in those parishes with which he is acquainted, the annual expence of each pauper is about fifteen guineas; a stout healthy labourer in husbandry, with a wife and three children, earns only thirty for the support of five persons; and that the earnings of the inhabitants of workhouses, on an average of the whole of the county, do not amount to eight shillings *per* head *per annum*; which taken from the former sum, leave fifteen pounds seven shillings, or near six shillings a week, as the expence of supporting each pauper. This is a profuse expenditure of parish money, as two-thirds of the whole number of persons would support themselves out of the house, on being allowed only two shillings a-week each. If it be true, he says, that two-thirds of the number can be supported for two shillings a-week in their own houses, the whole might, in that case, be maintained for half the expence incurred under the present system. Nor ought they in any case to be allowed so much as one-fifth of the earnings of a labourer, otherwise their situation is made as good or better than his. This is a point that ought to be well considered by the managers of parishes, where the workhouse system prevails.

He concludes by well observing, that every institution which tends to make the poor depend on any other support than their own industry, does them great disservice, and it is highly

highly injurious to society, by diminishing the quantity of labour which annually produces consumable goods, the only wealth of a nation.

It is only necessary here to consider these laws as they affect agriculture. And it is contended by Mr. Donaldson, that from no alteration having been made in regard to the species of property assessable in virtue thereof, although they might have been considered equitable at the time they were enacted, they have, in consequence of the alteration of circumstances that has gradually taken place, become almost intolerably oppressive on the landed interest; while the merchant, the manufacturer, and the monied man, are either entirely exempted, or but in a very small degree affected. In short, poor's rates, according to the present establishment, are, he supposes, the most partial tax that ever was levied in this or in any other country. He well remarks, that in the days of queen Elizabeth, when poor's rates were first established, the commerce and manufactures of England were in their infancy, and three *per cents.* India bonds, exchequer bills, scrip, omnium, &c. were unknown. That being the case, permanent property only, as the rents of lands and houses, could fall under the view of the then legislators as subject to assessment. Hence the reason why these laws, which, as formerly observed, may be supposed to have been arranged on equitable principles, according to the state of matters at the time, have now become an engine of oppression against two descriptions of people,—the proprietors of land and farmers. That this is the case, is obvious, he thinks, on the most cursory view of the subject. The poor's rates, for instance, in the parish of Kettering, in the county of Northampton, were last year (1795) at fifteen shillings in the pound of rack rent. And he has been informed, that, in the city of Norwich, the poor's rates were the same year at twenty-four shillings in the pound; that is, while the tenant paid twenty pounds to his landlord, he was obliged to pay twenty-four pounds towards the maintenance of the poor. The cause of so high an assessment was, as may easily be supposed, owing to the failure of the manufactures in consequence of the war.

Suppose, therefore, that a proprietor in the former parish was entitled to receive 1000*l.* of rent from his tenants, they would at the same time have to pay to the overseers of

£.	s.	d.
750	0	0

Suppose, further, that a merchant, manufacturer, or stock-holder, residing in the same parish, had a clear annual revenue of 1750*l.* arising from the profits of trade, or the interest of money in the funds, he would probably possess houses at an established rent of 60*l.* a-year: in which case his assessment for the maintenance of the poor would amount to

45	0	0
Difference	705	0 0

From this, he thinks, it appears, that the land-owner possessing an estate of the value of 1000*l.* a-year, pays upwards of 700*l.* towards the support of the poor beyond what could be legally demanded from the merchant, the manufacturer, or the stock-holder, under similar circumstances, in regard to the extent of funds. Were the land-holders the only persons that suffer by this partial, and consequently oppressive tax, it would not be generally regretted; as it is well known, he says, that it is to their supineness in not applying to the legislature for an alteration of the existing poor's laws, that the evil has arrived at such a height, and that such heavy

assessments are rendered necessary: but the farmers, unfortunately, are also sufferers, and owing to the concurrence of several causes, frequently to a very considerable extent. In the instance mentioned of the parish of Kettering, the poor's rates, previous to the commencement of the war, did not, he says, exceed 5*s.* in the pound; so that from that period, and during its continuance, a tenant paying 100*l.* a-year rent to his landlord, has to pay 50*l.* of additional poor's rates, and that, whether he possesses his farm under lease or at the will of his landlord. If the farm be held under lease for a term of years, the tenant can have no recourse to the landlord, who generally stipulates that he shall pay all parish-taxes. If, on the other hand, it be held from year to year, the tenant is, from that circumstance, so dependent on the proprietor, that he dare not make the least objection against paying the additional assessment, from an apprehension of being turned out of his farm, and thereby deprived of the means of providing for his family. The proprietors, therefore, pay only the ordinary poor's rates, the tenants being subjected in payment of such as are rendered necessary in consequence of the nation being at any time engaged in war, or that a stagnation of paper credit, or any other circumstance occurs whereby the manufacturers are interrupted. While, says he, the manufacturers can promote their own interest by employing the labouring class of the people, they do so; but when they perceive they can no longer benefit themselves, they send them to their different parishes, to be maintained at the farmer's expence till the return of peace, or other favourable circumstances occur, to create a new demand for manufacturing labourers. He further states, that Mr. Marshall, in the first volume of his Rural Economy of the West of England, mentions, as an evidence of the mischief which manufacturers are capable of entailing on agriculture, that a woollen manufacture was some time ago set on foot at Modbury, and carried on with spirit and with success to the individuals who prosecuted it: but their end being answered, the manufacture ceased, and all the vice and debility which it had drawn together were left a load upon the parish. The consequence of which is, the occupiers of land within the township of Modbury are now paying five shillings in the pound to the poor, while those of the surrounding parishes do not pay two shillings. Numerous instances of this sort might be mentioned to prove, that while the manufacturers pocket all the profit that can be derived from employing these people in prosperous times, they consign them to the farmer's charge the moment the wages which they choose to give are inadequate to their maintenance, or when they, the manufacturers, cannot profit by continuing them in their service.

On this subject, it is further observed, there is another circumstance that requires to be mentioned as productive of many evil consequences, namely, that which regards the gaining a settlement in a parish. It is well known how much superior the situation of all ranks of people in this country is to that of those in some parts of the continent of Europe; particularly in Russia, where the peasantry may, he says, be considered as appendages of the soil, being doomed to cultivate a particular tract of land, whoever becomes the proprietor. It is, he says, with regret that he mentions, that a species of slavery exists in England nearly of the same nature with that. Can, says he, that country be called free where the great body of the people are bound to reside in the particular spots where they were born? Yet this is certainly the case in England. The peasantry of the present day are bound by laws, enacted long before they were born, to confine themselves to their own parish; and if perchance they emigrate to a strange

county, although perhaps only to the adjoining parish, they are not only prevented from exercising the rights of citizens; but when there is the least prospect of their becoming burdensome to the inhabitants, they are hunted home like a parcel of strayed cattle or sheep that had overleaped the inclosures in which they were confined. Why not, he asks, permit the poor to seek a livelihood wherever work offers, or inclination leads them? In place of being subjected to be taken up as vagrants, if found out of their own parish, a parish in which they cannot find employment; would it not be for the interest of the community were they permitted to go where they could render essential service to the public, and where they have a certainty of supporting themselves and their families, without being reduced to the necessity of making a mortifying application to an unfeeling parish officer? Were such an alteration to take place, both the rich and the poor would, he thinks, experience the benefit. But while the laws of parish settlements remain on their present footing, let Englishmen, while they boast of the liberty they enjoy, reflect on these, and they will find that they accord not with genuine liberty: that wherever such laws are in force, rational liberty must be considered as in shackles.

It is strongly contended, that while this order of things remains, while the manufacturers shall continue in a great measure exempted from contributing towards the expence of maintaining those people who have become old and infirm in their service; while the farmers are subjected to such heavy exactions on every interruption to which the manufactures of the country are liable, agriculture must remain in a languid state, and the spirit of the farmer continue depressed.

The same writer then takes a view of the method of management in respect to the poor in Scotland, in order to shew, in how small a degree the expence of their maintenance affects the agriculture of that country. It is stated, that the sum necessary to maintain the poor in any particular parish in Scotland, especially in the country, amounts only to a few pounds in the year; which may be accounted for by stating the simple manner in which they live; oat-meal cooked in various ways, and potatoes, being their principal food. When reduced, by unforeseen accidents, or old age, to have recourse to the parish for relief, they are satisfied with a very small sum, two or three shillings in a month; asking in charity, what their neighbours in the same class in England demand as a matter of right. Indeed, says he, few but such as are destitute of relations able to support them make the application; it being considered disgraceful, both to themselves and their relations, to have their names entered on what is called the *poor's roll*. And, he adds, that the money necessary for the support of the poor is, for the most part, made up of voluntary contributions from the more wealthy inhabitants, which take place every Lord's day, before or after divine service. But, that there is also an old Scotch act of parliament still in force, by which the proprietors and tenants are liable to be assessed equally in such additional sum as may be judged necessary to support the poor of each parish: but this act is very seldom put in force, except in large towns, or in those parishes in the neighbourhood of the mountainous parts of the country, where the greatest number of poor people reside. He observes, that the slavish law of parish settlement is unknown in Scotland; the labouring poor, like the rich, are at liberty to settle where they can dispose of their time, or their talents to the best advantage. Should a poor family, after having received supply from the funds of the parish in which they reside, remove to another, that parish in which they formerly resided, in some cases,

supply their necessities for two or three years after their removal; at the expiration of which period, they become entitled to receive a share of the funds of that parish in which they are resident. But although this regulation has, it is believed, the sanction of the law, there are, he says, very few instances where it becomes necessary to enforce it. It is therefore contended, that the maintenance of the poor in Scotland cannot be said to be oppressive to any class or description of the inhabitants. It is, however, remarked, that a disposition to encourage the introduction of poor's laws, appears to evince itself in many parts of that kingdom. A pound rate is, he says, already established in Berwickshire; 3*d.* or 4*d.* on the acre of improved land is payable by the farmers; and in many country parishes in other districts, yearly assessments are made. Should the negligence of the proprietors to the situation of the poor, be the means of rendering the establishment of additional poor's laws necessary, their conduct must be considered by every thinking person as reprehensible to the highest degree. The existing laws are fully sufficient for the purpose of securing the means of subsistence to the industrious poor, by their being at liberty to continue to reside in the place where they had spent the active part of their life: after they are able no longer to procure themselves the necessaries of life by the labour of their hands, the manufacturers are compelled to contribute more liberally to their relief than if, under the authority of laws of settlement, the manufacturers, or mercantile, or monied people, residing in towns, had it in their power to order them, in the decline of life, when their period of labour is for ever past and gone, to the parishes in the country in which they were born. The writer strongly addresses the proprietors of Scotland ever to consider the situation of England, in consequence of establishing impolitic poor's laws as a warning to them against any innovation of that nature. And that, while they study that the poor in Scotland shall pass the remainder of their days without ever having to apprehend the fear of want; that they never make such an establishment as can tend, in any degree, to render morality and industry empty names.

The writer of the Scots Farmer has introduced some very strong remarks on the mischievous tendency of the present poor's laws. In speaking of the mode of levying taxes for the support of the poor, and the method in which they are maintained, he says he is for doing good to the poor, but he differs in opinion about the means. He thinks the best way of doing good to the poor is, not making them easy in poverty, but leading or driving them out of it. In his youth he travelled much, and he observed in different countries, that the more public provisions were made for the poor, the less they provided for themselves, and, of course, became poorer; and, on the contrary, the less was done for them, the more they did for themselves, and became richer. There is no country in the world, he says, where so many provisions are established for them; so many hospitals to receive them when they are sick and lame, founded and maintained by voluntary charities; so many alms-houses for the aged of both sexes, together with a solemn general law made by the rich to subject their estates to a heavy tax for the support of the poor, as in England. Under all these obligations, he asks, are our poor modest, humble, and thankful? and do they use their best endeavours to maintain themselves and lighten our shoulders of this burden? On the contrary, he affirms, that there is no country in the world in which the poor are more idle, dissolute, drunken, and insolent. In addressing himself to the public, he says, the day you
passed

passed that act, you took away from before their eyes the greatest of all inducements to industry,—frugality and sobriety—by giving them a dependence on somewhat else than a careful accumulation during youth and health, for support in age and sickness. In short, says he, you offered a premium for the encouragement of idleness, and you should not now wonder that it has had its effect in the increase of poverty. Repeal that law, and you will soon see a change in their manners. Saint Monday and faint Tuesday will soon cease to be holidays. Six days shalt thou labour, though one of the old commandments, long treated as out of date, will again be looked upon as a respectable precept. Industry will increase, and with it plenty, among the lower people. Their circumstances will mend, and more will be done for their happiness, by inuring them to provide for themselves, than could be done by dividing all your estates among them.

These remarks deserve the fullest consideration of the landed proprietors and farmers of this country, and it is sufficiently obvious, from the rapid increase of such rates, that material alterations must soon necessarily take place in regard to the objects of taxation, as well as in respect to the modes in which the money levied is expended. At present it is conceived that a system of peculation is established, in too many instances, among those whose province it is to expend the money so levied for the purposes to which the law directs it should be applied. The shameful expence of litigations between parishes, respecting the settlement of individual paupers, and the extravagant charge often incurred in transporting them from one parish to another, according to the present system, is often so great, as to add very considerably to the sum total necessary to be levied on the industrious and opulent inhabitants. There is likewise much other mismanagement both in the system of work-houses, as fully shewn above, and in that of the regulations in respect to the expenditure of the money, which should be attended to in making such alterations as from the change of circumstances now become necessary in supporting the poor.

It is stated in a very forcible manner, in the Cheshire Corrected Agricultural Report, that, from the great increase which has, of late years, taken place in the number of the poor throughout the kingdom, there certainly seems too much reason to believe, that the measures which the system of the poor laws involves, are, to say the least of them, incompetent to the ends they have in view; and that there exists a necessity for adopting, and pursuing with vigour, others which are more efficient and salutary. Whatever may be the advantages derived from the existing laws, the positive evils which they produce are but too apparent. They have a direct tendency to annihilate the spirit of honest independence amongst the lower classes of the community; to take from them the strongest stimulus to industry; and by affording a refuge to the idle, the profligate, and the abandoned, to contribute greatly to the extension of every species of vice and immorality. That some provision must be made in every community for the aged and infirm among the lower classes, is, it is said, a position concerning which no doubts can possibly be entertained. This provision the poor laws in England certainly do make; but by a mode of operation, according to the opinion of many intelligent individuals, defective in so many respects, as to render an alteration of the system a measure sincerely to be desired by every person who wishes well to the interests of his country.

These useful remarks are further enforced by the insertion of the following communication from J. T. Stanley,

esq., a most active and intelligent magistrate of the same county, whose situation has afforded him every opportunity of making observations on the subject.

“The poor rates,” says he, “will in a short time alter the whole character of the English nation: they promote an enmity between the land occupiers and the poor, which makes every township a scene of warfare. The poor, and particularly the wicked and idle, demand dwellings, cloathing, fire, and a weekly pension as their right; and by insolent importunity obtain them. The industrious honest labourer cannot be said to have one advantage in point of comfort over the man who lives in the alehouse, and suffers his children to run wild over the commons. The overseer must relieve all who have wants; and the magistrate, should he hesitate, must order him to do so. The facility of being maintained destroys every stimulant to exertion; and honestly having no advantage, the rogue laughs at the honest man. Debauchery, drunkenness, petty thefts, and perjury, are increasing with rapid strides; and the expence of prosecutions leaves the common people in the secure enjoyment of their licentiousness. The wicked, from their numbers, are absolutely become powerful; no magistrate can now attempt to put in force any of the old laws respecting small offences. The pillory, the stocks, and all means of inflicting moderate punishment, are laid aside; and imprisonment in the public gaols alone is resorted to, which always adds to the depravity of the offender.

“If there was an earnest desire in the legislature to remedy the evil, many modes might be pointed out; but no half measures would do any good. The evil is of great magnitude, and every day renders its cure more difficult; because the number of those who would suffer by a vigorous law affecting the idle, is increasing. Whatever the law is, it should be imperious; and the overseers should be allowed no choice in the distribution of their charities. They should be compelled to find work for the idle, and not suffered to give them money. For the maimed and the sick there should be public hospitals. There should be punishment for the depraved: and magistrates and constables should be armed with a power that could reach petty offences. No woman ought to have a right to call on the public for the maintenance of an illegitimate child, without suffering some punishment for her misconduct. More should be left to private charity than is at present. Indeed, who now will give money to relieve distress, which, if charity does not, the law must relieve? Charity now only goes in aid of the poor rate; and whoever maintains a poor labourer or sick widow, exempts his neighbour from a portion of their tax.”

It has been suggested from another quarter, that it would tend much to allay the public clamour of the increasing expence of the poor, and would promote the ends of private justice, if the poor rates were universally assessed according to the real value of the land or property, to be taken without prejudice or partiality by sworn parochial commissioners, every seven years; as we know that estates are frequently doubled in rent, while the nominal assessed rate remains the same. And also, if the same sort of rate was equally applied to other kinds of property which at present pay nothing towards this very heavy and increasing expence.

In short, the writer of the Berkshire Report on Agriculture is sure, that if half the trouble and expence were incurred to prevent poverty which are taken to relieve it, the lower orders would be infinitely more comfortable, than experience and observation convince us they are. “Labour,”

says

says he, "according to doctor Adam Smith, is the fund which originally supplies a nation with all the necessaries and conveniences of life which it consumes." If this position, which appears incontrovertible, he adds, applies to a period antecedent to civilization, it must be admitted, that when social and civil order was established, the triple union of *land, flock, and labour*, formed the basis of every valuable possession. It is in vain that the proprietor of land boasts of the extent of his domains, if no one will till the soil; or that the merchant or manufacturer commands stock, without hands to render it productive. The importance of labour is thus established without further argument; and though in every well regulated society, they who possess hereditary or acquired property will always be secured in their rights, and in consequence of those rights will be entitled to the enjoyments they confer, it must be allowed, that they who labour with a proper degree of diligence, ought likewise to acquire the necessaries of life by their own industry; and not be rendered dependent on others, or become a tax on the bounty of their employers. Since the poor laws, however, were established, however humane and judicious in their first institution, by affording a certain provision for infancy and age, we find pauperism has been continually increasing, and that with growing wealth, the labouring poor have become more and more numerous and depressed. The law of settlement, the restrictions on the amount of wages, and, above all, the inadequacy of wages in agriculture to support a family, have created and kept up that enormous mass of ills, which is equally distressing and disgraceful. In consequence of this, the labouring poor too frequently lose the pride of independence, as is evident from the state of Scotland, the best guardian of every moral virtue; and finding it in vain to struggle with their fate, become careless and improvident, clamorous and dissatisfied. They are more ready to demand their legal rights from the parish to which they belong, than to perform their proper duties; and thus give a colour to the injurious imputations which are cast upon their conduct and principles. The characters of men are influenced by circumstances, and are formed by habits; and the only effectual means, in his opinion, of ameliorating the condition of the labouring poor, and of giving them honourable feelings and impressions, is to assist and direct their endeavours in the path of independence.

The first step, it is conceived, is to render their cottages comfortable, and to give them an interest, if possible, in this kind of property, which is dear to every mind not wholly lost to sensibility and reflection. Nothing would more tend to make men good labourers, good husbands, good fathers, and good subjects, than a property in their homes, or an assurance that they would not be dispossessed, except by their own misconduct, with such a portion of land for a garden, &c. as would employ their leisure hours, without drawing them off from their regular engagements. It is wonderful how much may be produced from a small spot of ground, well managed, both for the use of families and for sale, as is evinced by numerous instances.

And next to the comforts of a residence, to which he would wish the poor to be attached by interest as well as choice, it seems necessary to teach them the value of property, and to point out the way by which it may be acquired. The duty that survives hope will seldom be performed with energy or effect. While the wages of a labouring man are perhaps only nine shillings a week, except when he works by the great, if he has a family too young to assist his endeavours, it is wholly impossible that he can support himself and them; and, therefore, instead of being more

frugal and economical, he becomes indifferent about expence; instead of seeking resources in industry, he tries to bury reflection in the dissipation of the ale-house; and weary of struggling with fortune, sinks into a parish pauper, and loses the dignity of a man. It must, however, be admitted, that with a large family, no fair and reasonable wages will enable a labourer to acquire even the bread necessary to support life; and therefore, in addition to his daily or weekly pay, it will be requisite to give him an interest in some fund, on which he can draw without shame, and without the humiliating sense of obligation. For this purpose, parochial friendly societies should be established, to which every servant and labourer should be obliged to contribute, without regard to sex, on arriving at an age when they can provide for themselves; and to continue subscribing till the age of sixty, even if they should be drawing largely from the fund, to which they are contributing only in a small degree.

Further, and in order to render this adequate to the demands arising from ill health, or an increase of family, and other incidentals, the proprietors of land and houses should be invited to join the society, and the occupiers of both assessed in fair proportions, according to the necessary expence; while those not chargeable to church and poor, should in no case be obliged to pay more than their regular subscription. It would likewise be a judicious regulation, to allow pecuniary premiums, or honorary distinctions, to such labouring people as brought up children to the age of fourteen, respectively, without claiming any aid from the fund, except during illness, or when they were thrown out of employment; and when a man had laboured with a fair character till he was sixty years of age, he ought to receive, from the same source, a small annuity for life, as a reward for his past services; but not sufficient to keep him idle, if still able to work. In this case, it is supposed, parish rates for purposes unconnected with the poor would alone be required, and poor rates would lose their name. He does not, he says, presume to enter into the details of the plan he has proposed, to effectuate the object of doing away poor rates, as he is aware that legislative provisions would be necessary, and that the system must receive more attention to perfect it than he can bestow; but should it only be adopted to a limited degree, as far as establishing a friendly society, according to the common acceptation, in every parish, or in every two or three adjoining parishes, where the population is small, he is deeply impressed with the benefit that would result from it; particularly if the proprietors and occupiers of land were to become honorary members, and to countenance the society by attending their meetings, and assisting to regulate their affairs. Double the ordinary subscription, and disclaiming any demands on the fund, would be sufficient to constitute an honorary member; and the sum thus applied would be more than saved to parishes during the illness of the poor, or their incapacity to work. But it is not to a saving only that he confines his views; it is a principle of independence he wishes to establish, of more value in its consequences than any immediate diminution of expence.

It is observed, that there are various regulations of a subordinate nature, which might be grafted on the present system, and which would all, more or less, tend to promote the independence and comfort of the poor. Premiums might be proposed for such persons as had reared families of three or more children to maturity, without parochial relief; and an annuity on the approach of age, for an industrious and regular life, would at once be a stimulus and reward. He would likewise recommend, that labourers in agriculture

should be paid any part of their wages that was agreeable to themselves, in flour, barley, or other grain, at the lowest market price, and in any quantity required. This would at once check improvidence, and promote comfort. There might also, it is suggested, be regulations made for providing them with milk, beer, and other necessaries, and above all for proper education and instruction.

POOR, or *Power*, in *Ichthyology*, a name given by the people of Cornwall to a species of bearded gadus. This is the gadus minutus of Linnæus, and is the only species of cod-fish with three dorsal fins that is found in the Mediterranean sea. It is taken in great quantities near Marseilles, and esteemed good, but incapable of being salted or dried. Its length is little more than six inches. See **GADUS**.

POOR man's pepper, in *Botany*. See **DITTANDER**.

POORALEE, in *Geography*, the ancient *Arabijs*, a river of Persia, in the district of Lus, which rises in the mountains near Bayla, the capital of Lus, and running in a S.E. direction, falls into the bay of Sonmany. Bayla, built on its N.E. bank, contains 1500 houses, and 6000 inhabitants, of whom 400 are Hindoos.

POOR-BUNDER, a town of Hindoostan, on the coast of Guzerat; 56 miles N.W. of Puttan Sumnaut.

POOR-KNIGHTS, a cluster of islands in the South Pacific ocean, near the N.E. coast of New Zealand. S. lat. $35^{\circ} 30'$. E. long. $174^{\circ} 42'$.

POOROONDER. See **POONAH**.

POORUP, a town of Hindoostan, in Oude; 30 miles N.E. of Bareilly.

POORVAH, a town of Hindoostan, in Oude; 20 miles S. of Lucknow.

POOSHAU LAKE, a lake of America, in the county of Hancock, and province of Maine, which communicates by a river with Penobscot bay.

POOSPANSCUM, in *Natural History*, the name of a peculiar species of fossil in the East Indies. It is of the nature of the blende, or mock-lead, with us; but it is not formed into so large flakes, but more resembles the steel-grained lead ores. It is found in the beds of rivers, and when calcined, it is used with the juices of certain herbs, for ulcers and other cutaneous disorders. Before calcination it is also used by the women to make their hair of a fine glossy black colour, which it performs very neatly.

POOSTOLE, in *Geography*, a small circar of Bengal, bounded on the N. and W. by Dinagepour, on the E. by the Moosheda, and on the S. by Bettooriah.

POOTEWATOMIES, Indians of America. N. lat. 42° . W. long. 81° .

POOTGAUT, a town of Hindoostan, in the circar of Sumbul; 10 miles N.W. of Sumbul.

POOTI, a river on the E. coast of Sumatra, which runs into the sea of Java, S. lat. $4^{\circ} 38'$. E. long. $105^{\circ} 45'$.

POOTLAPASSA, a town of Hindoostan, in Tellin-gana; six miles E. of Warangole.

POO-TOO, or **POU-TEOU**, a small island in the cluster of those denominated Chusan islands in the Chinese sea, a little to the E. of Tcheouchan. It is represented as a perfect paradise. It was chosen, without doubt, on account of its natural beauties, and afterwards embellished by a set of religious men, who, in number about 3000, possess the whole of it, living there in a state of celibacy. This small island contains 400 temples, to each of which are annexed dwelling-houses and gardens, for the accommodation of those monks. This large monastery, as it may be called, is richly endowed, and its fame is spread throughout the empire. Staunton's Emb. vol. i.

POOTOOPOOT'OOA, one of the small Friendly islands; 18 miles N. of Annamooka.

POOTYA, a town of Bengal; 10 miles W.S.W. of Nattore.

POOUSOOMSUCK, a river of Vermont, which runs into the Connecticut, in the township of Barnet, N. lat. $44^{\circ} 18'$. W. long. $71^{\circ} 58'$. On this river, which is settled 20 miles upwards, are some of the best townships in the state; the river is noted for the quantity and quality of its salmon.

POPA MADRE, a town of South America, in the province of Carthagea; 50 miles E. of Carthagea. N. lat. $10^{\circ} 3'$. W. long. $74^{\circ} 32'$.

POPACATEPEC. See **ORIZAVA**.

POPACHTON, a town of New York; 38 miles W.S.W. of Esopus.

POPÆ, among the Romans, were such persons as attended the sacrifices, whose business it was to provide victims, and to kill them after they had knocked them down. They were half naked, their shoulders, arms, and upper parts of their bodies being uncovered as far as their navels, and the rest covered to the mid-leg with a linen apron, or the skins of the sacrifices; and they wore crowns of laurel upon their heads. See **SACRIFICE**.

POPAYAN, in *Geography*, one of the provinces of the viceroyalty of New Granada; bordering northward on the province of Carthagea; extending southward to the river Mayo and to Ipiales, where it borders on the jurisdiction of the town of Miguel de Ibarra, and terminating towards the N.E. with the province of Antioquia, the best of its provinces, and contiguous to that of Santa Fé. Its western boundary was formerly the South-sea; but it has in later times been so contracted by the new government of Choco, that the territory of Barbacoas is the only part of it which reaches to the sea; eastward it spreads itself to the sources of the river Coqueta, which are also thought to be those of the rivers Orinoco and Negro. Its extent is not precisely ascertained; but it is probably conjectured, that from E. to W. it is about 80 leagues, and at least as much from N. to S., if not more, some asserting that its length is 110 leagues. It contains many towns and villages, and is divided into several departments, over each of which the principal governor nominates a deputy for the administration of justice. Those which form the government of Popayan, according to Don Juan and De Ulloa, are the following, *viz.* Santiago di Cali, Santa Fé de Antioquia, Las Quatro Ciudades, Timana, Guadalajara de Baga, S. Sebastian de la Plata, Almaguer, Caloto, San Juan de Pasto, El Raposo, and Barbacoas. Of the above-mentioned departments, those towards the N. and E. of the city of Popayan, as Santa Fé de Antioquia, Las Quatro Ciudades, Timana, and S. Sebastian de la Plata, belong to the audience and province of Santa Fé; the others lying near to Quito belong to its province; and those of San Juan de Pasto and Barbacoas are within its diocese. The departments of Cali and Baga, lying between the governments of Popayan and Choco, thrive, as being the channel of the commerce which is carried on continually betwixt those two governments; whereas, it is otherwise with that of Almaguer, from the smallness of its jurisdiction, and its inconsiderable traffick. That of Caloto, the extent of which is greater and its soil fertile, is of course richer; it abounds with the products of the earth, and the country is every where interspersed with farms. The department of El Raposo resembles the two first; that of Pasto is large, but less wealthy; Barbacoas is small, and being scantily supplied within itself, is indebted for provisions of various kinds to other provinces. The temperature of Popayan

popayan is the same with that of Quito, and varies in different places, according to their situation; some parts, and particularly Popayan the capital, enjoy a continual spring. The soil also varies, producing, however, grains and fruits in abundance; and the farms breed great numbers of horned cattle and sheep. The jurisdiction of Popayan is more subject to tempests of thunder and lightning than even Quito, where they are very frequent. This frequency of tempests and earthquakes is supposed to be owing to its great number of mines, in which it exceeds all the other departments within the province of Quito. Caloto is said to be the most subject to such tempests. In the vallies of Neyba, and others within the jurisdiction of Popayan, is a poisonous insect, resembling in shape a spider, and called coya or coyba, of a fiery red colour, the venom of which is extremely malignant. Among the plants of Popayan, in the jurisdiction of Timana, grows the cuca or coca, which is more highly valued by the Indians than the most precious metals or gems. The Indians use it for chewing, after mixing it with a kind of chalk or whitish earth, called mambi. This herb is so nutritious and invigorating, that they labour whole days without any other sustenance. This coca is exactly the same with the betel of the East Indies. In Pasto, one of the most southern districts of Popayan, are trees which yield a resin, called mopamopa; of which is made a varnish of exquisite beauty, which will bear boiling water and even acids. It is used for varnishing the cabinets, tables, &c. made by the Indians, which are carried to Quito, where they are highly valued.

Popayan is one of the best trading countries within the province of Quito, as all the vast variety of Spanish goods from Carthageua are consigned thither and forwarded to Quito; and great numbers of traders go their rounds through the several jurisdictions, to the great conveniency of the towns and villages, which thus supply themselves. Besides this transitory commerce, it has another reciprocal with Quito, to which it exports horned cattle and mules, and receives in return cloths and bays. Its active commerce consists in dried beef, salted pork, roll-tobacco, hog's-lard, rum, cotton, pita, ribbons, and other small wares, which are brought to Choco, and there exchanged for gold; sugar and snuff are imported from Santa Fé and sent to Quito; and the returns to Santa Fé are home-made cloths and bays. Here is also another traffic, which consists in bartering silver for gold; for, there being an abundance of the latter, and a scarcity of the former, silver is brought to exchange for gold; of which great profit is made by converting it into doubloons: the like is also practised at Choco and Barbacoas, which are in the same case as to metals.

Popayan being the centre of all these several kinds of commerce, the most wealthy persons of the whole jurisdiction are here, and five or six of its inhabitants are reckoned to be masters of above 100,000 dollars; twenty to be worth between 40 and 80,000; besides many of smaller, yet handsome, fortunes: and this exclusive of their farms and mines, with which this country abounds.

POPAYAN, the most ancient city in that part of South America where it is situated, and capital of the province or jurisdiction above-described, was founded, in 1537, by Sebastian de Belalcazar, after he had finished the conquest of the whole country now containing the government of Popayan. This city, so denominated in July 1538, is seated on a large plain, commanding on the N. side an uninterrupted prospect of the country. It lies on the E. side of a mountain of a moderate height, called M, from its resemblance to that letter, which being covered with a variety of trees, affords an agreeable view; the west side is also diversified with small eminences. On a spacious plain, near the top of this moun-

tain, is a convent of bare-footed Carmelites; and from it issues a river, which, running through the city, carries away all its soil. This river is called Del Molina, and over it are two bridges, one of stone and the other of wood. About a league to the N. of Popayan flows the river Cauca, which is large and deep, with a rapid current, and subject to dangerous inundations in the months of June, July, and August, the season when the torrents of the mountains of Cuanaacas, where it has its source, are most prevalent, so that the passage of it is extremely dangerous, as many travellers, exposing themselves to the intenseness of the cold, amidst thick snows and violent winds, have fatally experienced. The streets of Popayan are broad, straight, and level, the town being built in a square form; and the houses, which are constructed of unburnt bricks, are many of them handsome, with a story, distinguishing them from those with only a ground floor.

The inhabitants of Popayan and Quito differ very sensibly in their casts; for as at Quito, and the other towns and villages of its jurisdiction, the most numerous class of people is that of the casts which sprung from the intermarriages of Spaniards and Indians; so at Popayan, Carthageua, and other parts where negroes abound, the lower class consists of casts, resulting from the marriages of the whites and negroes; but very few Indian casts. This is owing to the great multitude of negro slaves, kept as labourers at the plantations in the country, the mines, and to do the servile offices in the city; so that the number of Indians here are very few, compared with the other parts of the province. This government has, however, many large villages of them; and it is only in the capital, and other Spanish towns, that they are so greatly out-numbered by the negroes. De Ulloa reckons their number at between 20 and 25,000, including several descendants of noble families in Spain, and supposed to be increasing; but late authors estimate them at only 8000. Popayan is an ancient bishopric, suffragan of the archbishop of Bogota. The church was erected into a cathedral in 1547, and it is the only parochial church in the city. Here are also convents of Dominicans, Franciscans, and Augustines, with a college of Jesuits: all of which have churches. The number of religious in these convents is small. The two nunneries, that of the Incarnation, and that of the order of Santa Teresa, are occupied by a greater number of persons. Popayan is the residence of the governor, who is the chief magistrate of the city, and within the limits of whose government, all matters, civil, military, and political, are under his direction. The annual coinage at Popayan amounts to 1,000,000 dollars; and that of Santa Fé to 1,200,000. N. lat. 2° 27' 30". W. long. 76° 16' 15".

POPE, ALEXANDER, in *Biography*, a very distinguished English poet, was born in London in 1688. His parents were both of the Roman Catholic religion. Soon after the revolution, and his son's birth, the father, who was attached to the exiled king, retired from business to a village in Windsor forest, where he purchased a small house, and a few acres of land, and not choosing to vest his money in government securities, or to trust it in private hands, lived frugally upon the capital. Young Pope was from infancy of a very delicate constitution and a feeble frame of body, and his early disposition, by its gentleness and docility, seemed conformable to his corporeal habit. He was taught the very elements of learning at home, and when he was about eight years of age he was placed under the care of a Romish priest, in Hampshire, where he learnt the rudiments of the Latin and Greek languages. At this period he became acquainted with and read Ogilby's translation of Homer, and Sandy's translation of Ovid's *Metamorphoses*, and

from the perusal of these specimens of English poetry, he may be said to have become a poet himself. At a school in which he was afterwards, in the neighbourhood of London, he had an opportunity of occasionally visiting the theatre, which led him to frame a kind of play from Ogilby's Homer, intermixed with verses of his own, and procured it to be acted by his school-fellows. When he was about twelve years of age, his first poem, "An Ode to Solitude," was written, which, says his biographer, "is nothing remarkable for that age: it shews a correct ear for versification, and a power of neat expression, but affords no indication of fancy or strong feeling." From this time he seems to have been the director of his own studies, as poetry appears to have been adopted by him from his earliest years as a profession, for his poetical reading was at all times accompanied with attempts at imitation or translation. In the latter he soon excelled: "if the translation of the 'Thebais,' and of 'Sappho to Phaon,' made at the age of fourteen, were not much improved in their publication, it may be affirmed that he rose at once almost to perfection in this walk; the latter piece, especially, has never been surpassed." His manners and conversation were probably as much above his years as his productions were; for before he was sixteen he attracted the notice of sir William Trumbull, with whom an intimacy was formed. He now composed his "Pastorals," which gained him many admirers, among whom was Walsh, who was considered as the best English critic of his time. He also formed an intimacy with Mr. Cromwell, a pedant and a beau, whose example produced unfavourable impressions on the youthful poet, who fell into a strain of ironical compliment towards the female sex, mixed with coarseness and indelicacy, so that it has been said, "if the simple, natural, ardent character be supposed congenial to the poet, no one of the tribe set out with a more unpoetical character than Pope;" and it is added, which is uncreditable to a young man, that "he does not appear to have cultivated friendship with any of his own age or condition, and in all his early connexions of this kind, some purpose of obtaining credit and distinction may be traced." His pastorals were printed in 1709, in a volume of Tonson's Miscellanies, and obtained general admiration on account of the melodious sweetness of the versification, and the polished lustre of the diction: they, however, were thought to be deficient in original observation, and to have an artificial cast of sentiment. He was at the same time exercising his talents in compositions of a higher order. He had written his "Ode for St. Cecilia's Day," and in this year he wrote his "Essay on Criticism," which was justly esteemed a master-piece in its kind, and shewed not only the peculiar turn of his talents, but that those talents, young as he was, were ripened nearly to perfection. He was not then more than twenty years of age, and yet the maturity of his judgment, the knowledge of the world, and the penetration into human nature displayed in that piece, were such as would have done honour to the greatest abilities and experience. It cannot, however, be denied, that it has some of the inaccuracies of a juvenile author, and in other respects it has been held rather too high as critical authority. In this piece he made an attack upon the critic John Dennis, who slighted his pastorals, and an open war was carried on between them. Another enemy whom he acquired in consequence of his pastorals was AMBROSE PHILLIPS, (see his article,) and the result was a lasting animosity between them. In 1711 he wrote his "Elegy on an unfortunate Woman," one of his most finished compositions. The story of the lady is enveloped in mystery, and some have supposed that it refers to a person who had inspired him with a real passion; though others have doubted

whether he ever felt the force of a passion, which in him must have been an unfortunate one, since his deformed figure forbade him to expect a return. The elegy is reckoned a very fine piece, considered as poetical eloquence employed on an interesting topic, but at the same time it has too much art and ornament for the expression of genuine feeling. In the following year (1712), he published his "Rape of the Lock," a mock heroic, that outstript all competition, and conferred upon him the chief title he possesses to the merit of invention. The essay on criticism excelled in the didactic way, for which he was peculiarly formed; a clear head, strong sense, and a sound judgment, being his characteristic qualities; but it is the creative power of the imagination that constitutes the poet properly so called, and therefore it is in the "Rape of the Lock" that Pope principally appears one, there being more of the *vis imaginandi* displayed in this poem than in all his other works together. Its ground-work is a trifling incident in fashionable life, and its object appears to be a playful satire on female frivolity, a topic to which he often recurs, amidst all his compliments to the sex. This he pursues with admirable vivacity and polished wit, but the poetry of the work is chiefly conspicuous in his machinery of the sylphs, wrought with unrivalled skill and beauty. About the same time he published the "Temple of Fame," written two years before, and altered from Chaucer. In 1713, Mr. Pope published his "Windsor Forest," the first part of which was written at the age of sixteen, and bears the stamp of juvenility. The concluding part is of a much higher strain, and serves as a scale of the poet's intermediate advancement in the art. In the same year he circulated proposals for publishing a translation of the Iliad by subscription, and almost instantly received such assurances of encouragement, as removed all doubt of an ample remuneration for his labour. He proceeded in his work with diligence, and published the first volume in quarto, containing four books, in the year 1715. Immediately after the appearance of this volume, a rival translation was published under the name of Tickell, to which Addison, who had quarrelled with Pope, seemed to give the preference, and Pope was persuaded that it was his own. This is not, at present, believed to be the case, for Tickell was well able to have written it, and was indeed a better poet than Addison. Pope was extremely exasperated, and wrote some lines of keen and polished satire upon him, which were published and admired. The rival version never went farther than a single book, and sunk before that of Pope. The produce of the subscriptions, which was between seven and eight thousand pounds, enabled him to take that house at Twickenham, which he rendered so famous by his residence and decorations, and he removed thither with his father and mother. The former died in about two years, leaving but a slender subsistence to his family. He had left off business with a fortune of 20,000*l.*, but being a Papist, he could not lay out his money on real securities, and as he adhered to the cause of the exiled James, he made it a point of conscience not to lend it to the existing government, so that, as we have seen, he lived upon the principal, which rapidly diminished his stock. Pope's mother survived her husband many years, comforted and consoled by the truly filial attentions of her son.

It was about this period that he wrote his "Epistle from Eloisa to Abelard," chiefly extracted from the extant letters of those distinguished persons. He has, however, heightened the descriptions, and added warmth to the passions, so as to render it the most impressive of all poems of which love is the subject, but it treads too closely upon the borders of licentiousness to be excused. In 1717, Mr. Pope republished his poems already written, in one volume quarto, to which

he prefixed a very elegant preface, and in 1720 he completed the publication of his Iliad. This stands at the head of metrical translations of the same class, that is, of the splendid and ornamental, formed upon the model of cultivated poetry in the same language, rather than upon the style and character of the original. It made a great addition to the writer's poetical fame, and produced a swarm of critics and depreciators of the work, whose voices were speedily lost in the general applause. In 1721 he published a volume of select poems of his deceased friend Parnell, with a dedication in verse to the earl of Oxford, now a retired statesman, under the frowns of a triumphant party. Pope was always attached to the Tory party, but he had an independent spirit with respect to the great, and entertained enlarged ideas of the nature of government, the authority of which he had generally viewed through the medium of opposition.

In 1721 he engaged, merely for a pecuniary consideration, in a task for which he was not qualified, *viz.* in the editorship of Shakspeare's works, splendidly published by Tonson. His deficiencies as a critical editor were so obvious, that they exposed him to the censure of Theobald, and from that time he not only waged perpetual warfare with Theobald, but became an enemy to editors, collators, commentators, and verbal critics, and tried to persuade the world that he miscarried in this undertaking only by having a mind too great for such minute employment. He next undertook, on the same motives, the love of emolument, the translation of the *Odyssey*, with the assistance of Broome and Fenton. The work was finished in 1725, and brought him a considerable sum. He translated twelve books, which were done in no ways inferior to the *Iliad*. The other twelve, notwithstanding his corrections, alterations, and amendments, were of inferior quality, and he was paid accordingly.

He became acquainted, soon after his removal to Twickenham, with lady Mary Wortley Montague, and ventured to address her in the style of lover, which she thought she might indulge from one of his personal disqualifications, without danger of scandal. He was admitted to correspond with her during her residence abroad, but after her return they became the bitterest foes.

After the publication of the *Odyssey*, Pope appeared almost solely as a satirist and moralist, and in 1727 he joined Swift in a publication of miscellanies, chiefly of a humorous kind, in which he inserted a treatise of the Bathos, or the art of sinking, the ironical precepts of which were illustrated by examples, and in which a classification was given of bad poets. Several of these plainly pointed out living writers, who retaliated by virulent abuse of the author.

He published his *Dunciad* in the year 1728, the object of which was to overwhelm, with indelible ridicule, all his antagonists, together with some other authors, whom spleen or party led him to rank among the dunces, although they had given him no personal offence. "There is not," says one of his biographers, in the *History of Literature*, "scarcely another instance of an eminent writer thus devoting the maturity of his powers to so futile a piece of vengeance, for he himself represents his enemies as such a contemptible set of wretches, that, if left alone, must infallibly sink into speedy oblivion, and in fact several of them are now only known by the place which they occupy in the poem. The diction and versification of the *Dunciad* are in his most finished manner, and shew the pains bestowed upon the work, but its imagery is often extremely gross and offensive." He was first encouraged to personal satire by his friend bishop Atterbury, and he felt that it was so well suited to his disposition, as to bring it into most of his subsequent productions. In one of these, an Epistle on Taste, printed in 1731, he was supposed to have

held up to ridicule the duke of Chandos, who had shewn to the poet many civilities, which excited against him the public indignation; and though he employed every art of equivocation to refute the opinion, he could not effectually clear himself from the charge of ingratitude. By the suggestion of lord Bolingbroke, he planned and wrote the "Essay on Man," which must ever rank high in the first class of ethical poems. In it the author had a fine opportunity of shewing his extraordinary power of managing argumentation in verse, and of compressing his thoughts into clauses of the most energetic brevity, as well as expanding them into passages fraught with every poetic ornament. This piece was attended or followed by his "Imitations of Horace," which had all a satirical cast, and were accompanied by a "Prologue and Epilogue to the Satires," and by his "Moral Epistles or Essays" on the characters of men and women, and on the use of riches. He is reckoned a good imitator of Boileau as a satirist, but more coarse in his language, and at the same time more spirited and poetical.

Mr. Pope was now to appear in a new character, *viz.* that of a letter writer. Some juvenile letters of his to Mr. Cromwell had been surreptitiously published in 1727, and some years afterwards, Curl the bookseller published another collection of letters between Pope and several friends, which had been put secretly into his hands. Though Pope affected so much anger on the occasion, as to procure Curl to be summoned before the house of lords for a breach of privilege, there being some letters from noblemen among the number, yet there were pretty strong proofs that he himself had contrived the plot, in order to obtain a decent excuse for giving an edition in his own name, which he did in a quarto volume by subscription: and the collection was thought to make a valuable addition to English literature. As Pope lost his old friends Gay, Atterbury, and others, he acquired new ones, ready to pay him the respect to which his high reputation seemed to lay claim. Of these, some composed the court of the prince of Wales, then in avowed opposition to his father's ministers, and he was ready to join them in their political warfare. He was flattered by the prince, who dined at his house. Thus stimulated, he wrote his two last satires, denominated from the year in which they were written, "Seventeen hundred and thirty-eight." In the year 1742, Pope added a fourth book to the *Dunciad*, intended to ridicule useless and frivolous studies. In the following year the whole poem came out together, intended as a specimen of a more correct edition of his works. He had made some progress in the design, but did not live to complete it. He had through life been subject to nervous complaints, and at this period an oppressive asthma began to indicate the decline of his weak frame. When the last scene was manifestly approaching, Hooke the historian, one of his friends, and a convert to popery, asked him whether he would not have a priest to administer the last sacrament. Pope replied, that though he did not think it essential, it was very right, and the ceremony was performed. He died soon after, *viz.* on the 30th of May, 1744, at the age of 56, and was interred at Twickenham, where a monument was erected to his memory by bishop Warburton, to whom he had bequeathed the property of all such of his works, already printed, as he had written or should write commentaries upon, and which had not been otherwise disposed of or alienated; with this condition, that they were to be published in future without alterations. In discharge of this trust, that gentleman gave a complete edition of all Mr. Pope's works, in 9 vols. 8vo.

Various characters have been drawn of this poet. Lord Orrery says, "If we may judge of him by his works, his chief aim was to be esteemed a man of virtue. His letters

letters are written in that style; his last volumes are all of the moral kind; he has avoided trifles, and consequently escaped a rock which has proved very injurious to Swift's reputation. He has given his imagination full scope, and yet has preserved a perpetual guard upon his conduct. The constitution of his body might really incline him to habits of caution and reserve. The treatment which he met with afterwards, from an innumerable tribe of adversaries, confirmed this habit, and made him slow in pronouncing his judgment upon persons and things. His manners were delicate, easy, and engaging; and he treated his friends with a politeness that charmed, and a generosity that was much to his honour. Every guest was made happy within his doors, pleasure dwelt under his roof, and elegance presided at his table." Dr. Johnson's account is very different: "His parsimony," he says, "appeared in petty matters, such as writing his compositions on the backs of letters, or in a niggardly reception of his friends, and a scantiness of entertainment. He was full of his fortune, and frequently ridiculed poverty; he seems to have been of an opinion not at all uncommon in the world, that to want money is to want every thing. He was proud of his connection with the great, and boasted that he obtained their notice by no means or servility. He was capable of generous and elevated sentiments, and had a dignified regard to his independence. Implacable in his dislikes, he was firm in his attachments; and Bolingbroke testified of him, that he had never known a man, who had so tender a heart for his particular friends, or more general friendship for mankind. As a poet, admitting that he was deficient in invention, his claim to pre-eminence in other qualities will scarcely be disputed; and it will be generally admitted, that no English writer has carried farther, correctness of versification, strength and splendour of diction, and the truly poetical quality of vivifying and adorning every subject that he touched." Johnson's Lives of the Poets. Warton's Essay on the Writings and Genius of Pope.

POPE, *Papa*, i. e. *universal father*, the bishop of Rome; being the head or patriarch of the Roman Catholic church. Father le Coite, in his Annals, observes, from St. Jerom, St. Cyprian, St. Gregory, St. Augustine, and Sidonius Apollinaris, that the title pope was anciently given to all bishops. Accordingly we find, that in the eighth general council, held at Constantinople in the year 869, which was composed of three hundred bishops, all the patriarchs were there called popes.

Bishops were also addressed under the term *holiness* and *beatitude*; and their churches were called *apostolical sees*.

He adds, that it was only in the eleventh century, that Gregory VII. first appointed, in a synod held at Rome, that the title pope should be restrained to the bishop of Rome, as a particular distinction and prerogative.

It is one of the maxims of Gregory, contained in a famous piece, entitled "*Dictatus Papæ*," that there is no name in the world but his, i. e. as some understand it, he alone is to be styled pope; and F. Paul observes, that the name of pope, formerly common to all bishops, was appropriated by Gregory VII. to the Roman pontiff.

In the council in the Lateran, held under Innocent III. the pope was declared *ordinary of ordinaries*.

The power of the pope has advanced by slow degrees to that plenitude in which it has been exercised in later times. It appears, that towards the end of the third century, the bishop of Rome, in common with those of Antioch and Alexandria, had a kind of pre-eminence over all others, because they were considered as rulers of primitive and apostolic churches. However, this pre-eminence implied no

superior power and authority, infringing on the rights and liberties of other bishops, but merely a power of convening councils, of presiding in them, of collecting voices, and such other things as were essential to the order of those assemblies; a power similar to that which Cyprian, bishop of Carthage, possessed in the African churches. About the close of the fourth century, the bishop of Rome surpassed all his brethren in the magnificence and splendour of the church over which he presided; in the riches of his revenue and possessions; in the number and variety of his ministers; in his credit with the people; and in his sumptuous and splendid manner of living. Nevertheless it is certain, that at this time the bishops of that city had not acquired the pre-eminence of power and jurisdiction in the church, which they afterwards enjoyed. Differences in religion were ultimately decided, and ecclesiastical laws were enacted, either by the emperor or by councils; nor does it appear, that any of the bishops acknowledged that they derived their authority from the permission and appointment of the bishop of Rome, or that they were created bishops by the favour of the apostolic see. But in this century we may trace, in the imprudence of the emperors, the dexterity of the Roman prelates themselves, and the inconsiderate zeal and precipitate judgment of certain bishops, several of those steps by which they afterwards ascended to the summit of ecclesiastical power and despotism. The law of Valentinian, in 372, which empowered the bishop of Rome to examine and judge other bishops, that religious disputes might not be decided by profane and secular judges, approved and confirmed in a council at Rome in 378, proved very favourable to the ambition and advancement of the Roman pontiff; and his votaries have likewise laid great stress on the fourth canon of the council held at Sardis, in 347, which prohibited the election of a successor to a bishop deposed by neighbouring prelates, before the bishop of Rome had examined the cause, and pronounced sentence: but the authority of this council has been generally considered as extremely dubious, and its decrees have been regarded by many as altogether fictitious and spurious. In the fifth century a variety of circumstances united in augmenting the power and authority of the bishop of Rome; though he had not, as yet, assumed the dignity of supreme law-giver and judge of the whole Christian church. The bishops of Alexandria and Antioch, unable to make head against the lordly prelate of Constantinople, fled often to the Roman pontiff for succour; and the inferior order of bishops used the same method, when their rights were invaded by those prelates. The protection afforded them by the Roman pontiff was the means of extending his dominion in the East, and of imperceptibly establishing his supremacy. In the West its increase was owing to other causes; the declining power, and the supine indolence of the emperors, left the authority of the bishop who presided in their imperial city almost without controul. The incursions, moreover, and triumphs of the barbarians, contributed to its advancement; for the kings, who penetrated into the empire, when they perceived the subjection of the multitude to the bishops, and the dependence of the bishops upon the Roman pontiff, resolved to reconcile this ghostly ruler to their interests, by loading him with various kinds of honours and benefits. However, the Africans could not be prevailed upon, by threats and promises, to submit the decision of their controversies, and the determination of their causes, to the Roman tribunal. Although the Roman pontiffs artfully availed themselves of every circumstance that could contribute to their obtaining universal dominion, yet it is certain, that towards the close of the sixth century, the emperors, and the nations in general, were far from being disposed

disposed to bear with patience the yoke of servitude, which the see of Rome was arrogantly imposing upon the Christian church. The Gothic princes set bounds to the power of the bishop of Rome in Italy, permitted none to be raised to the pontificate without their approbation, and reserved to themselves the right of judging concerning the legality of every new election. They enacted spiritual laws, called the religious orders before their tribunals, and summoned councils by their regal authority.

In the beginning of the seventh century, or about the year 606, Boniface III., as Baronius relates, engaged the emperor Phocas to take from the bishop of Constantinople the title of œcumenical or universal bishop, and to confer it upon the Roman pontiffs; and thus, as it is said, introduced the papal supremacy. But the ambitious views of the bishops of Rome were still vigorously opposed, not only by several emperors and princes, but also by whole nations; and the civil magistrate retained his influence in religious matters, and the Roman pontiffs were obliged to acknowledge their subordination to the regal authority. No event seems to have been more favourable to their ambitious views than the part they took in the eighth century, in promoting the advancement of the traitor Pepin to the throne of Childeric III. in anointing and crowning him as king of France. This proved an abundant source of opulence and credit to the church, and to its aspiring ministers; for Pepin, having obtained two victories over Aistulphus, king of the Lombards, in 754 and 755, compelled him to deliver up to the see of Rome the exarchate of Ravenna, Pentapolis, and all the cities, castles, and territories, which he had seized in the Roman dukedom. And thus the bishop of Rome was raised to the rank of a temporal prince. The grant of Pepin was afterwards confirmed by his son Charlemagne, who also ceded to the Roman pontiffs several cities and provinces in Italy, which were not contained in his father's grant; reserving to himself the supreme dominion. It is said that a pretended grant of Constantine the Great was made use of both by Adrian I. and Leo III. in order to persuade Charlemagne to this donation. At this time the power of the pope was subordinate to that of the emperors, and confined within very narrow limits. The right of election was vested in the emperor, and his approbation was necessary to the consecration of the bishops of Rome. However, their authority and affluence greatly increased from the time of Lewis the Meek, and more especially from the accession of Charles the Bald to the imperial throne. Their power was augmented in a very considerable degree by the divisions and troubles that arose in the empire towards the close of the ninth century: the emperors were divested of their ecclesiastical authority, the power of the bishops was greatly diminished, and even the authority of both provincial and general councils began to decline. The Roman pontiffs availed themselves of various circumstances that occurred at this time to promote an opinion that the bishop of Rome was constituted by Jesus Christ supreme legislator and judge of the church universal; and that, therefore, the bishops derived all their authority from the Roman pontiff, and that the councils could not determine any thing without his permission and consent. They had also recourse to forged memorials, acts of councils, and epistles, in order to establish their claims to supremacy. The most notorious forgeries of this kind were the decretal epistles, compiled by an obscure writer, but ascribed, in order to give them credit, to Isidore, bishop of Seville. In the tenth century, a novel doctrine was propagated by some mercenary and interested prelates, who publicly maintained that the Roman pontiffs were not only bishops of Rome, but of the whole world; and that

their authority, though divine in its origin, was conveyed to them by St. Peter, the prince of the apostles. The cruades (see *CROISADES*) of the eleventh century very much contributed to the augmentation of the influence and authority of the Roman pontiffs; so that towards the close of this century they seem to have attained the zenith of their dominion. From the time of Leo IX. the popes employed every method, which the most artful ambition could suggest, to render their dominion both despotic and universal. They not only aspired to the character of supreme legislators in the church, to an unlimited jurisdiction over all synods and councils, whether general or provincial, to the sole distribution of all ecclesiastical honours and benefices, as divinely authorized and appointed for that purpose, but they carried their insolent pretensions so far as to give themselves out for lords of the universe, arbiters of the fate of kingdoms and empires, and supreme rulers over the kings and princes of the earth. Gregory VII. seems to have exceeded all his predecessors in the lust of dominion, as well as in the success which attended his endeavours to obtain it. He considered the Roman pontiff, under the character of Christ's viceregent, as the king of kings, and the whole universe as his rightful domain. Accordingly, with an arrogance hardly to be paralleled, he claimed tribute from France, Saxony, Spain, England, the most powerful of the German princes, Hungary, Denmark, Poland, &c. soliciting them to do homage to the Roman see, to make a solemn grant of their kingdoms and territories to the prince of the apostles, and to hold them under the jurisdiction of his vicar at Rome, as fiefs of the apostolic see. If the success of this pontiff had been answerable to the extent of his insolent views, all the kingdoms of Europe would have been this day tributary to the Roman see, and its princes the soldiers or vassals of St. Peter, in the person of his pretended vicar upon earth. Many of his attempts, however, were crowned with a favourable issue, and from the time of his pontificate, the face of Europe underwent a considerable change, and the prerogatives of the emperors, and other sovereign princes, were necessarily diminished. In Italy his success was the most remarkable; for he prevailed upon Matilda, the daughter of Boniface, duke of Tuscany, to settle all her possessions in Italy and elsewhere upon the church of Rome; and though the Roman pontiffs have not been able to preserve the whole inheritance, thus granted to them, they long remained in the possession of a considerable part of it. See *ECCLESIASTICAL State*.

The monstrous power of erecting new kingdoms, which had been claimed by the pontiffs from the time of Gregory VII., was not only assumed, but exercised also by Alexander III. in a remarkable instance; for in the year 1179 he conferred the title of king, with the ensigns of royalty, upon Alphonso I. duke of Portugal, who, under the pontificate of Lucius II., had rendered his province tributary to the Roman see. In the thirteenth century the same ambitious spirit governed the councils and proceedings of succeeding pontiffs; and they were industrious in inculcating the maxim, that the bishop of Rome is the supreme lord of the universe, and that neither princes nor bishops, civil governors nor ecclesiastical rulers, have any lawful power in church or state, that is not derived from them. In consequence of this arrogant pretension, they not only claimed the right of disposing of ecclesiastical benefices, but of conferring civil dominion, and of dethroning kings and emperors, according to their good pleasure. They also assumed to themselves the power of disposing of the various offices of the church, and of creating and deposing bishops, abbots, and canons, according to their fancy.

Instances

Instances of these practices occur in the pontificates of Innocent III., Honorius III., Gregory IX., and of several of their successors. And Boniface VIII. maintained, in the most express and inapparent terms, that the universal church was under the dominion of the pontiffs, and that princes and lay patrons, councils and chapters, had no more power in spiritual things than what they derived from Christ's vicar upon earth. Under Innocent III. and Nicholas IV. the possessions and revenues of the Roman see received very considerable augmentation, partly by the events of war, and partly by the munificence of kings and emperors; and arrived at that high degree of grandeur and opulence, which it maintained almost to our times. The former of these pontiffs followed the steps of Gregory VII., and not only usurped the despotic government of the church, but claimed also the empire of the world, and thought of nothing less than subjecting the kings and princes of the earth to his lordly sceptre. In Asia and Europe he disposed of crowns and sceptres with the most wanton ambition. The Roman pontiffs derived great advantages in the exercise of their dominion from the attachment and zeal of the several orders of Mendicants. In the fourteenth century the papal authority diminished by reason of the continued residence of the popes in France: and in the fifteenth century, by the schism which happened in the papacy, the dawnings of the reformation, and a variety of other concurring causes. In the councils of Constance, held in 1414, and of Basle, opened in 1431, the power of the Roman pontiffs was declared to be inferior and subordinate to that of general councils, and the papal impositions, called expectatives, reservations, and provisions, were entirely annulled. The revival of learning, and the progress of the reformation in the succeeding century, contributed very much to the abridgment of the papal authority; not only by withdrawing several provinces from the yoke of papal tyranny, but by producing a change in the sentiments of many kings and princes, and sovereign states, who adhered to the religion of Rome, with respect to the claims and pretensions of its bishop. Besides, it is necessary to observe, that the authority of the pope is circumscribed by various limits in the different countries where his spiritual jurisdiction is acknowledged; and that in all his decisions relating to the government of the church, he previously consults the cardinals who form his privy council; and in matters relating to religious doctrine, he is obliged to ask the advice of eminent divines; and that matters of different degrees of moment are referred to the conduct of certain colleges, called *congregations*. It is well known, that when the authority of the pope declined in Europe, he sought to extend the limits of his spiritual dominion to other parts of the globe, and for this purpose deputed missionaries to gain proselytes. And a new order was formed, that became afterwards so famous, under the appellation of *Jesuits*, in order to preserve those parts of the papal dominions that remained yet entire, and to augment them by new accessions. The fate of this fraternity is well known; and many circumstances seem to concur in different countries, hitherto devoted to the see of Rome, that are likely to reduce within very narrow limits the spiritual jurisdiction and secular dominion of the pope. For a brief account of the rise, establishment, and decline of the church of Rome, see the article *CHURCH*.

The pope is chosen by the cardinals out of their own body.

In the first ages of the church, the people and the priests, and sometimes only the priests, elected the pope, according to the plurality of voices. The emperors afterwards claimed

the right of confirming the election. In the eighth century, pope Adrian I. in a council of bishops assembled at Rome, conferred upon Charlemagne and his successors the right of election; and they reserved to themselves the privilege of approving the person that was elected by the priests and people; nor was the consecration of the elected pontiff valid, unless performed in the presence of the emperor's ambassadors. The election, however, after undergoing many revolutions as to the form of it, is now referred to the cardinals in conclave.

The see of the pope is at Rome, whence he issues out his orders, called *briefs* and *bulls*, throughout the Catholic world.

The person of the pope, says Mr. Eustace, in the second volume of his "Classical Tour," may be considered in two very different capacities, as temporal sovereign of the Roman territory, and as chief pastor of the Catholic church. In order, says our candid Catholic author, to give the Protestant reader a clear and precise idea of the rights which every Catholic considers as inherent in the Roman see, or, as he adds, to speak more correctly, in the successor of St. Peter, it will be necessary to observe, that the pope is bishop of Rome, metropolitan and primate of Italy, of Sicily, and of Macedonia, &c., and patriarch of the West: that in each of these capacities he enjoys the same privileges and the same authority as are enjoyed by other bishops, metropolitans, primates, and patriarchs, in their respective dioceses and districts; that his authority, like theirs, is confined within certain limits marked out by ancient custom, and by the canons; and that, like theirs also, it may be modified or suspended by the church at large. "I shall only add," says our author, "that as patriarch of the West, the pope enjoys a pre-eminence elevated enough to satisfy the wishes of the most ambitious prelate, as by it he ranks before all western ecclesiastics, and takes place and precedence on all occasions." But, as Mr. E. proceeds, "the Roman pontiff claims honours still more distinguished, and as successor of St. Peter is acknowledged by the Catholic church to sit as its first pastor by divine institution." According to a canon of the general council of Florence, cited by our author, "the pope enjoys, by the institution of Christ, the primacy of honour and jurisdiction over the whole Christian church, and to refuse it to him would be deemed an act of rebellion. But no authority has yet determined, and it seems indeed difficult to fix the precise rights and prerogatives which are conferred by this primacy, or flow immediately from it, so that to oppose their exercise or to deny their existence would be either schism or heresy. Suffice it to say, that the greater part of the powers exercised by the popes, and especially those acts which have been considered as the most offensive in themselves as well as galling to other bishops, are allowed to be of human institution. In fact, the object of the canon above-mentioned, as also of the article corresponding with it in the creed of Pius IV., seems to have been solely to ascertain the existence of a *divinely* appointed superior in the Catholic church, leaving in the interim the mode of exercising his prerogative to the canons and discipline of the same church, to be enlarged or restrained as its exigencies may require. But though no temporal advantages are originally, or by its institution, annexed to it, yet it is evident that such an elevated dignity must naturally inspire reverence, and consequently acquire weight and consideration. Influence, at least in a certain degree, must accompany such consideration, and give the spiritual pastor no small degree of worldly importance."—"But besides the consideration inseparable from the office itself, another source

source of temporal greatness may be found in the extensive possessions of land, and in the great riches in plate, of the Roman church itself. These riches were considerable even under the Pagan emperors, and during the persecutions, as we may presume from various passages in ancient authors, and they were not a little increased by the liberal donations of the Christian princes, and particularly of Constantine the Great." After all the invasions and spoliations which the Roman church has experienced, "it still retained extensive possessions, not in Italy only, but in Sicily, and other more distant provinces." From the period in which Gregory the Great distributed the wealth of the church for the relief of innumerable objects of distress, and by his talents, as a statesman, rescued Rome and Italy from the intrigues of the imperial court, from the weakness and wickedness of the exarchs, and from the fury of the Longobardi, then a recent and most savage horde of invaders;—"from this period," says our author, "though the Greek emperors were the nominal, yet the popes became the real and effective sovereigns of Rome, and attached to it, as they generally were, by birth, and always by residence, duty, and interest, they promoted its welfare with unabating, and oftentimes, successful efforts. Upon the merits of these services, therefore, and the voluntary submission of an admiring and grateful flock, rests the original and best claim which the Roman pontiffs possess to the temporal sovereignty. But though this sovereignty was enjoyed, many years elapsed before it was avowed on the side of the pontiff, or admitted on that of the emperor, and many more ages before it was fully and finally established on a solid and unshaken basis."—"From the tenth century," says our author, "the popes began to degenerate from the piety of their predecessors, and to sacrifice their spiritual character to their temporal interests; Rome became the theatre of insurrection, warfare, and intrigue; and continued so, with various intervals of tranquillity, occasioned by the intervening reigns of milder pastors, till the sixteenth century, when they resumed the virtues of their early predecessors, and by them regained the veneration and affection of their flocks. Since that period the pope has reigned pastor and prince, an object at once of the reverence and of the allegiance of the Roman people, seldom alarmed by foreign invasion, or insulted by domestic insurrection; devoted to the duties of his profession, the patron of the arts, the common father of Christendom, and the example and oracle of the Catholic hierarchy."—"But though the pope is both bishop and prince, yet his titles, dress, equipage, and the whole ceremonial of his court, are adapted to the first of these characters. He is styled Holiness, the Holy Father, and sometimes, in history, the Sovereign Pontiff; but the former appellations, as more appropriate to his duties and functions, are exclusively used in his own court. His robes are the same with those of a bishop in pontificals, (excepting the stole and the colour, which is white and not purple.) His vestments, when he officiates in church, as well as his mitre, do not differ from those of other prelates. The tiara seems originally to have been an ordinary mitre, such as is still worn by the Greek patriarchs. The three circlets, which have raised it into a triple crown, were added at different periods, and, it is said, for different mystic reasons. The first, or lowest, seems to have been originally a mere border, gradually enriched with gold and diamonds. The second was the invention of Boniface VIII. about the year 1300; and to complete the mysterious decoration, the third was superadded about the middle of the 14th century. The use of the tiara is confined to certain extraordinary occasions, as in most great ceremonies the pope used the common episcopal mitre."—

"Whenever he appears in public, or is approached even in private, his person is encircled with reverence and with majesty. In public, a large silver cross, raised on high, is carried before him, as a sacred banner; the church bells ring as he passes, and all kneel in his sight. When he officiates at the patriarchal Basilicæ he is carried from his apartments in a chair of state, though in the chancel his throne is merely an ancient episcopal chair, raised only a few steps above the seats of the cardinals or clergy."—"When he is approached in private, he has, in his anti-chamber, a prelate in full robes, always in waiting, and when the bell rings, the door of the pontifical apartment opens, and the pope is seen in a chair of state with a little table before him. The person presented kneels once at the threshold, again in the middle of the room, and lastly, at the foot of the pontiff, who, according to circumstances, orders him to kiss the cross embroidered on his shoes, or presents his hand to raise him. The pontiff then converses with him a short time, and dismisses him with some slight present of beads or medals, as a memorial. The ceremony of genuflexion is again repeated, and the doors close." Our author observes, in order to obviate some objections that will naturally occur to the minds of Protestants, that "in all the ceremonial of the Roman church and court, the only parts liable to misrepresentation or censure, are certain additions of later times, when, in religious pomps and court pageants, in dress and in style, all was inflated and cumbersome. The rule of reform is easy and obvious; to prune off the excrescences of barbarous ages, and to restore the majestic forms of antiquity." The offices which the pontiff is required to perform occupy a very considerable part of his time; so that "a morning of business and application closes with a solitary meal; and a walk in the gardens of the Quirinal or the Vatican, a visit to a church or an hospital, are his only exercises." It is observed, that the pope never dines in company, so that to him a repast is no recreation; it is consequently short and frugal.

"To speak of the prerogative of the pontiff as a sovereign," says our author, "is scarcely necessary; as it is known to be uncontroled by any legal or constitutional authority; a despotism which, though mildly exercised, is diametrically opposite both to the interests of the people and to the personal happiness of the prince himself. The mischiefs that result from hence to the former are obvious, while the latter, if alive to sentiments of religion and of moral obligation, as the modern sovereigns of Rome must unquestionably be, cannot but tremble under the weight of a responsibility so awful thus confined to his own bosom. To share it with the best and wisest members of the state is safe, and would at the same time be so glorious, that we should be tempted to wonder that the experiment had never been tried, if every pope in history did not prove how sweet despotism is to the vitiated palate of sovereigns. But if any monarch had either an opportunity or an inducement to realize the generous plan formed by Servius Tullius, of giving liberty and a constitution to his people, the popes, we should imagine, could have wanted neither."

The prime ministers of the Roman pontiff are the cardinals, who constitute a college, and whose principal and most honourable privilege is that of electing the pope. The number of titles, or churches, says our author, which gave a title to this dignity, is 72 (others have reckoned 70). (See CARDINAL and COLLEGE.) The grand assembly of the cardinals is called the *consistory* (which see), where the pontiff presides in person. This assembly is not precisely a council, as it seldom discusses, but witnesses the ratification of measures, previously weighed and adopted in the cabinet of the pontiff. But the chief prerogative of a cardinal is exercised in the *conclave*

(which see), so called because the members of the sacred college are there confined within the precincts of the great halls of the Vatican palace, where they remain immured till they agree in the election of a pope. For the general mode of electing the pope, we shall refer to the article CONCLAVE, and merely mention in this place two or three ceremonies that are practised during the process, and at the conclusion of the election. The first we shall mention is the custom of putting the tickets containing the votes of the cardinals in the patena (or communion plate), and then into the chalice. To this ceremony our author objects, because the application to this purpose of the vase, devoted in a peculiar manner to the most awful institutions of religion, seems to pass beyond disrespect, and almost to border on profanation. The next ceremony is that called the adoration of the pope, which takes place almost immediately after his election, when he is placed in a chair on the altar of the Sixtine chapel, and there receives the homage of the cardinals: this ceremony is repeated again on the high altar of St. Peter's. (See ADORATION.) Our author vindicates the ceremony of adoration paid to the pope, and his being placed on a throne, because he is both pontiff and prince; but he objects to the altar's being made his footstool. Another ceremony which we shall mention is the following. "As the new pontiff advances towards the high altar of St. Peter's, the master of the ceremonies kneeling before him, sets fire to a small quantity of tow placed on the top of a gilt staff, and as it blazes and vanishes in smoke, thus addresses the pope, 'Sancte Pater! sic transit gloria Mundi!' This ceremony is repeated thrice."—"When the late pope was torn from his capital by the orders of the French directory, and dragged prisoner into France, the cardinals were banished, or departed with circumstances of peculiar cruelty, and the cardinal *Chiaromonte* of course shared in common with his brethren the hardships and dangers of this persecution. On the death of Pius VI. the cardinals assembled in conclave at Venice, and in a short time unanimously proclaimed cardinal *Chiaromonte* pope. The election took place in the month of March 1800. The French were obliged to evacuate Rome about the same period, and the pope embarked for Ancona, and made his public entry into Rome in the following April." Pius VII. is of a noble family, whose name is *Chiaromonte*, and became early in life a Benedictine monk of the abbey of St. Giorgio at Venice. "To relieve the sufferings of his people," says our author, "and to restore the finances of the country, was his first object, and to attain it he began by establishing a system of the strictest economy in his own household and around his own person. He next suppressed all immunities or exemptions, and subjected the nobility and the clergy to the same or to greater burthens than the lower orders." Notwithstanding several useful regulations that were adopted, the general amount of the taxes is considerably increased. "Other salutary arrangements are, it is said, in contemplation, and the good intentions, the sense, and the virtuous feelings of Pius VII., encourage the hope, that his reign, if he be not thwarted in his designs, will be the commencement of an era of reform and of prosperity."—"At the present crisis," says Mr. Eustace, "when the temporal possessions of the Roman church are at the mercy of the strongest, a spirit of conciliation is perhaps the best calculated to preserve their integrity; and even in the spiritual concerns of the apostolic see, the interest of religion may doubtless be best consulted by such concessions and changes in discipline as the reason or even the prejudices of the age may seem to demand. In both these respects, and particularly in the latter, the lenient and judicious pontiff is likely to employ his authority in a manner highly conducive to public utility." But the Roman court was, for a long time,

alarmed by the power of the French government. The exercise of this hostile power, however, terminated with the late glorious revolution in France, when Buonaparte abandoned the throne, and Louis XVIII. was restored, and the pope resumed his authority.

The income of the pope has varied at different periods. Several years ago, when in full possession of the territory of the Roman court, both in Italy and in France, it was not calculated at more than six hundred thousand pounds. This income arose principally, as our author asserts, in opposition to a very general opinion, from internal taxation, and a very small part of it was derived from Catholic countries. This part may be comprized under the two heads of annats and of dispensations; and these, when united, did not produce in France, the richest and most extensive of Catholic countries previous to the revolution, more than fifteen thousand pounds *per annum*. In Spain the annats had been abolished, or rather bought off; and in Germany, as it is apprehended, suppressed. Dispensations, that is, licences to take orders, to hold livings, to contract marriages, and to do various acts, in cases and circumstances contrary to the prescriptions of the common canon law, produced merely sufficient to pay the expences of the courts through which they necessarily passed, and added little to the papal revenue. As for the concourse of pilgrims, which was supposed to be so very productive a source of income, it brought nothing to Rome but the filth and the beggary of Catholic Europe, and entailed an expence for their support in the hospitals, where they were received and maintained. "The revolutionary invasion of Italy, and the consequent dismemberment of part of the Roman territory, lessened the papal income, not only by diminishing the number of persons who contributed to it, but by impoverishing all the inhabitants of the Roman state, and by depriving even the industrious of the means of paying the taxes. In truth, the greatest distress still prevails at Rome, and the government, it is said, can scarce collect the sums essential to its very existence."

In estimating the expenditure of the Roman court, we shall restrict ourselves to the causes of disbursement which are peculiar to the pontifical treasury. In order to support the missionaries that have been sent to various parts of the globe, there are several establishments at Rome, and one in particular, which from its object is called the "Collegium de propaganda fide." To prepare persons for the undertaking of missionaries, and to establish seminaries for their education, has been an object of primary importance, and has called forth annual sums, which have formed a considerable part of papal expenditure. In this article may be added the support of several hospitals, asylums, schools, and colleges founded by various popes for objects in their times pressing, and still maintained by the apostolical treasury. Moreover, the same treasury has to keep all the public edifices in repair, especially those immense palaces, which, though of little use as residences, are the receptacles of all the wonders of ancient and modern art; to protect the remains of ancient magnificence from further dilapidation; to support the drainage of the Pomptine marshes; and, in fine, to continue the embellishment and amelioration of the capital and of its territory. When to these burthens we add the pensions which the pope is accustomed to settle on bishops when unusually poor and distressed, and the numberless claims upon his charity from every part of Europe, we shall not be surprised either at the expenditure of an income not very considerable, or at the difficulties under which the papal treasury laboured towards the end of the late pontiff's reign.

Our author, in accounting for his having omitted the "infallibility" of the pope, asserted to be his most glorious prerogative, and for the supposed maintenance of which Catholics

Catholics have so long suffered the derision and contempt of their antagonists, observes, "that there is no such article in the Catholic creed; for according to it, infallibility is ascribed not to any individual or even to any national church, but to the whole body of the church extended over the universe. That several theologians, particularly Italian and Spanish, have exaggerated the powers and privileges of the pope, is admitted; and it is well known, that among these, some or rather several carried their opinion of pontifical prerogative so high, as to maintain that the pontiff, when deciding "ex cathedra," or officially, and in capacity of first pastor and teacher of the church, with all the forms and circumstances that ought to accompany such decisions, such as freedom, deliberation, consultation, &c. was by the special protection of providence secured from error. The Roman court favoured a doctrine so conformable to its general feelings, and of course encouraged its propagation, but never pretended to enforce it as an article of Catholic faith, or ventured to attach any marks of censure to the contrary opinion. This latter opinion, the ancient and unadulterated doctrine of the Catholic church, prevailed over Germany, the Austrian empire, Poland, the Low Countries, and England; and in France was supported by the whole authority of the Gallican church, and by the unanimous declaration of all the universities. So rigorously indeed was their hostility to papal infallibility enforced, that no theologian was admitted to degrees, unless he supported in a public act the four famous resolutions of the Gallican church against the exaggerated doctrines of some Italian divines relative to the powers of the Roman see. These resolutions declare, that the pope, though superior to each bishop individually, is yet inferior to the body of bishops assembled in council; that his decisions are liable to error, and can only command our assent when confirmed by the authority of the church at large; that his power is purely spiritual, and extends neither directly nor indirectly to the temporalities or prerogatives of kings and princes; and, in fine, that his authority is not absolute or despotic, but confined within the bounds prescribed by the canons and the customs of the church. This doctrine was taught in all the theological schools, that is, in all the universities and seminaries in France, as well as in all the abbeys; and was publicly maintained by the English Benedictine college at Douay.

The conclusion to be drawn from these observations is, first, that no Catholic divine, however attached to papal prerogative, ever conceived an idea so absurd as that of ascribing infallibility to the *person* of the pontiff; and, secondly, that those theologians who ascribed infallibility to papal decisions when clothed with certain forms, gave it as *their* opinion only, but never presumed to enforce it as the doctrine of the Catholic church. "Therefore," says our author, "to taunt Catholics with papal infallibility as an article of their faith, or to urge it as a proof of their necessary and inevitable subserviency to the determinations of the Roman court, argues either a great want of candour, or a great want of information."

For an account of the character and general conduct of the popes before and after the time of Gregory the Great, which our author has laboured to vindicate, and on which, indeed, he has pronounced an elaborate eulogy, we refer to Eustace's "Classical Tour," vol. ii. Appendix.

We have enlarged on this article, because we wish to give Catholics, and especially so able and so liberal a writer as Mr. Eustace, an opportunity of advocating their own cause; and also to remove prejudices, which have a tendency to obstruct and delay the extension of religious freedom. Nevertheless, we disclaim the opinion of all those who maintain the *divine right* of the Roman pontiffs, nor can we join in

sentiment with a late eloquent writer (Chateaubriand), cited by our author, and incline with him, "to discover something sublime in the establishment of a common father in the very centre of Christendom, within the precincts of the eternal city once the seat of empire, now the metropolis of Christianity; to annex to that venerable name sovereignty and princely power; and to entrust him with the high commission of advising and rebuking monarchs, of repressing the ardour and intemperance of rival nations, of raising the pacific cross between the swords of warring sovereigns, and checking alike the fury of the barbarian, and the vengeance of the despot." *One is our master, even Christ*; and it is from the diffusion and prevalence of the genuine spirit of his religion, and not from the interference of worldly power in his kingdom, that we augur the peace and prosperity of the Christian world, and the permanence as well as diffusion of the Christian faith.

We shall here subjoin a brief account of the causes that contributed to the introduction and establishment of the papal power in our own country, and also to its decline and termination.

The ancient British church, whensoever or by whomsoever planted, was a stranger to the bishop of Rome, and his pretended authority. But when the Saxons invaded the country, they compelled the professors of Christianity to withdraw to the remotest corners of our island, and their own conversion was afterwards effected by Augustin the monk, and other missionaries from the court of Rome. This naturally introduced some few of the papal corruptions in point of faith and doctrine; but we read of no civil authority claimed by the pope in these kingdoms, till the era of the Norman conquest; when the reigning pontiff, having favoured duke William in his projected invasion, by blessing his host and consecrating his banners, laid hold of that opportunity for the purpose of establishing his spiritual encroachments; being permitted to do this by the policy of the conqueror, in order more effectually to humble the Saxon clergy, and aggrandize his Norman prelates: prelates who, being bred abroad in the doctrine and practice of slavery, had contracted a reverence and regard for it, and took a pleasure in rivetting the chains of a free-born people. For the purpose of more effectually enslaving the consciences and minds of the people, the Romish clergy themselves paid the most implicit obedience to their own superiors or prelates; and they, in their turns, were as blindly devoted to the will of the sovereign pontiff, whose decisions they held to be infallible, and his authority co-extensive with the Christian world. Hence his legates *à latere* were introduced into every kingdom of Europe; his bulls and decretal epistles became the rule both of faith and discipline; his judgment was the final resort in all cases of doubt or difficulty; his decrees were enforced by anathemas and spiritual censures; he dethroned even kings that were refractory, and denied to whole kingdoms (when undutiful) the exercise of Christian ordinances, and the benefit of the gospel of God. Something was still wanting besides this spiritual authority, which only operated on conscientious minds, to establish dominion; and the court of Rome was fully apprized that power could not be maintained nor exercised for any long time, and to any great extent, without property, and therefore to the acquisition of this its attention was very sedulously directed. Doctrines and practices were enjoined that were likely to secure pecuniary advantages. The doctrine of purgatory was of this kind, for it was accompanied with the purchase of masses to redeem the souls of the deceased. New-fangled offences were created, and indulgences were sold to the wealthy, for liberty to sin with-

out danger. The canon law took cognizance of crimes, enjoined penance *pro salute animæ*, and commuted that penance for money. Non-residence and pluralities among the clergy, and marriages among the laity related within the seventh degree, were strictly prohibited by canon; but dispensations were seldom denied to those who could afford to buy them. In short, all the wealth of Christendom was gradually drained, by a thousand channels, into the coffers of the holy see.

The establishment of the feudal system in most of the governments of Europe, by which the lands of all private proprietors were declared to be holden of the prince, gave a hint to the court of Rome for usurping a similar authority over all the preferments of the church; which began first in Italy, and gradually spread itself into England. The pope became a feudal lord; and all ordinary patrons were to hold their right of patronage under this universal superior. Estates held by feudal tenure, being originally gratuitous donations, were at that time denominated "beneficia;" and the care of the souls of a parish thence came to be denominated a "benefice." Lay fees were conferred by investiture or delivery of corporal possession; and spiritual benefices, which at first were universally donative, now received in like manner a spiritual investiture, by institution from the bishop, and induction under his authority. As lands escheated to the lord, in defect of a legal tenant, so benefices lapsed to the bishop upon non-presentation by the patron, in the nature of a spiritual escheat. The annual tenths collected for the clergy were equivalent to the feudal render, or rent reserved upon a grant; the oath of canonical obedience was copied from the oath of fealty required from the vassal by his superior; and the "primer seisin" of our military tenures, by which the first profits of an heir's estate were cruelly extorted by his lord, gave birth to as cruel an exaction of first-fruits from the beneficial clergy. And the occasional aids and talliages, levied by the prince on his vassals, gave occasion to the pope to levy, by the means of his legates *à latere*, peter-pence and other taxations. At length the holy father went a step beyond any example of either emperor or feudal lord. He reserved to himself, by his own apostolical authority, the presentation to all benefices which became vacant while the incumbent was attending the court of Rome upon any occasion, or on his journey thither, or back again; and moreover such also as became vacant by his promotion to a bishopric or abbey: "etiam si ad illa personæ consueverint et debuerint per electionem aut quemvis alium modum assumi." And this last, the canonists declared, was no detriment at all to the patron, being only like the change of a life in a feudal estate by the lord. Dispensations to avoid these vacancies begat the doctrine of *commendams*: and papal *provisions* were the previous nomination to such benefices, by a kind of anticipation, before they became actually void; though afterwards indiscriminately applied to any right of patronage exerted or usurped by the pope. In consequence of which the best livings were filled by Italian and other foreign clergy, equally unskilled in and averse to the laws and constitution of England. The very nomination to bishoprics, that ancient prerogative of the crown, was wrested from king Henry I., and afterwards from his successor king John; and seemingly indeed conferred on the chapters belonging to each see: but by means of the frequent appeals to Rome, through the intricacy of the laws which regulated canonical elections, was eventually vested in the pope. And, to sum up this head with a transaction most unparalleled and astonishing in its kind, pope Innocent III. had at length the effrontery to demand, and king John had the meanness to consent to, a resignation of

his crown to the pope, whereby England was to become forever St. Peter's patrimony; and the dastardly monarch re-accepted his sceptre from the hands of the papal legate, to hold as the vassal of the holy see, at the annual rent of a thousand marks.

Moreover, not content with the ample provision of tithes, which the law of the land had given to the parochial clergy, the court of Rome endeavoured to grasp at the lands and inheritances of the kingdom, and (had not the legislature withstood them) would by this time have probably been masters of every foot of ground in the kingdom. To this end they introduced the monks of the Benedictine and other rules, men of four and austere religion, separated from the world and its concerns by a vow of perpetual celibacy, yet fascinating the minds of the people by pretences to extraordinary sanctity, while all their aim was to aggrandize the power and extend the influence of their grand superior the pope. And as, in those times of civil tumult, great rapines and violence were daily committed by overgrown lords and their adherents, they were taught to believe, that founding a monastery a little before their deaths would atone for a life of incontinence, disorder, and bloodshed. Hence innumerable abbeys and religious houses were built within a century after the conquest, and endowed, not only with the tithes of parishes which were ravished from the secular clergy, but also with lands, manors, lordships, and extensive baronies. And the doctrine inculcated was, that whatever was so given to, or purchased by, the monks and friars, was consecrated to God himself; and that to alienate or take it away was no less than the sin of sacrilege.

Many other contrivances were set on foot by the court of Rome for effecting an entire exemption of its clergy from any intercourse with the civil magistrate: such as the separation of the ecclesiastical court from the temporal; the appointment of its judges by merely spiritual authority, without any interposition from the crown; the exclusive jurisdiction it claimed over all ecclesiastical persons and causes; and the *privilegium clericale*, or benefit of clergy, which delivered all clerks from any trial or punishment except before their own tribunal. Nevertheless, though this plan of pontifical power was so deeply laid, and so indefatigably pursued by the unwearied politics of the court of Rome through a long succession of ages; notwithstanding it was polished and improved by the united endeavours of a body of men, who engrossed all the learning of Europe for centuries together; notwithstanding it was firmly and resolutely executed by persons the best calculated for establishing tyranny and despotism, being fired with a bigotted enthusiasm, (which prevailed not only among the weak and simple, but even among those of the best natural and acquired endowments), unconnected with their fellow-subjects, and totally indifferent what might befall that posterity to which they bore no endearing relation:—yet it vanished into nothing, when the eyes of the people were a little enlightened, and they set themselves with vigour to oppose it. So vain and ridiculous is the attempt to live in society, without acknowledging the obligations which it lays us under; and to affect an entire independence of that civil state, which protects us in all our rights, and gives us every other liberty, that only excepted of despising the laws of the community.

In order to encounter the growing evil of the papal usurpations in England, the legislature were led to frame the statutes of *præmunire*. King Edward I. a wise and magnanimous prince, set himself in earnest to shake off this servile yoke. He would not suffer his bishops to attend a general council, till they had sworn not to receive the papal benedic-

benediction. He made light of all papal bulls and processes: attacking Scotland in defiance of one; and seizing the temporalities of his clergy, who under pretence of another refused to pay a tax imposed by parliament. He strengthened the statutes of mortmain; thereby closing the great gulf, in which all the lands of the kingdom were in danger of being swallowed. And, one of his subjects having obtained a bull of excommunication against another, he ordered him to be executed as a traitor, according to the ancient law. And in the thirty-fifth year of his reign was made the first statute against papal provisions, being, according to sir Edward Coke, the foundation of all the subsequent statutes of *præmunire*; which we rank as an offence immediately against the king, because every encouragement of the papal power is a diminution of the authority of the crown.

In the weak reign of Edward II. the pope again endeavoured to encroach, but the parliament manfully withstood him; and it was one of the principal articles charged against that unhappy prince, that he had given allowance to the bulls of the see of Rome. But Edward III. was of a temper extremely different; and, to remedy these inconveniences first by gentle means, he and his nobility wrote an expostulation to the pope: but receiving a menacing and contemptuous answer, withal acquainting him, that the emperor, (who a few years before at the diet of Nuremberg, A. D. 1323, had established a law against provisions,) and also the king of France had lately submitted to the holy see; the king replied, that if both the emperor and the French king should take the pope's part, he was ready to give battle to them both, in defence of the liberties of the crown. Hereupon more sharp and penal laws were devised against provisors, which enact severally, that the court of Rome shall not present or collate to any bishopric or living in England; and that whoever disturbs any patron in the presentation to a living by virtue of a papal provision, such provisor shall pay fine and ransom to the king at his will, and be imprisoned till he renounces such provision: and the same punishment is inflicted on such as cite the king, or any of his subjects, to answer in the court of Rome. And when the holy see resented these proceedings, and pope Urban V. attempted to revive the vassalage and annual rent to which king John had subjected his kingdom, it was unanimously agreed by all the estates of the realm in parliament assembled, (40 Edw. III.) that king John's donation was null and void, being without the concurrence of parliament, and contrary to his coronation oath: and all the temporal nobility and commons engaged, that if the pope should endeavour by process or otherwise to maintain these usurpations, they would resist and withstand him with all their power.

In the reign of Richard II. it was found necessary to sharpen and strengthen these laws, and therefore it was enacted by statutes 3 Ric. II. c. 3. and 7 Ric. II. c. 12. first, that no alien should be capable of letting his benefice to farm; in order to compel such, as had crept in, at least to reside on their preferments: and, afterwards, that no alien should be capable to be presented to any ecclesiastical preferment, under the penalty of the statutes of provisors. By the statute 12 Ric. II. c. 15. all liegemen of the king, accepting of a living by any foreign provision, are put out of the king's protection, and the benefice made void. To which the statute 13 Ric. II. st. 2. c. 2. adds banishment and forfeiture of lands and goods: and by c. 3. of the same statute, any person bringing over any citation or excommunication from beyond sea, on account of the execution of the foregoing statutes of provisors, shall be imprisoned, forfeit his goods and lands, and moreover suffer pain of life

and member. (See PRÆMUNIRE and PROVISOIRS.) At length, by the reformation in religion under Henry VIII. and his children, the usurped power of the pope was forever routed and destroyed, all his connections with this island were cut off, the crown restored to its supremacy over spiritual men and causes, and the patronage of bishoprics once more indisputably vested in the king. Blackst. Comment. vol. iv. See REFORMATION.

History mentions a pope's, Joan. The reality hereof has been opposed and defended by many learned men. The tradition might possibly take its rise from the weakness of pope John VIII. in restoring Photius to his communion, and owning him as true patriarch; for he hence got the appellation of woman; as that prince called *king Mary* did, by leaving himself to be governed by queen Mary his wife.

M. Spanheim, professor of theology at Leyden, has written very amply on the subject; and shews it to be a question *de facto*, scarcely determinable at this time of day.

POPE, in *Ornithology*, a name by which the people in many parts of England call the *anas arctica clusii*. See PUFFIN.

POPEDOM, or PAPACY, in *Ecclesiastical History*, denotes the office and jurisdiction of the pope.

POPELNESS, in *Geography*, a cape on the N. coast of the island of Yell. N. lat. 61° 6'. W. long. 1° 14'.

POPENREUF, a town of Germany, in the territory of Nuremberg; three miles N.W. of Nuremberg.

POPERINGHE, a town of France, in the department of the Lys, and chief place of a canton, in the district of Ypres; six miles W. of Ypres. The place contains 7967, and the canton 10,485 inhabitants, on a territory of 65 kilometres, in 3 communes.

POPERY, in *Ecclesiastical History*, comprehends the religious doctrines and practices, said to be adopted and maintained by the church of Rome. The following summary, extracted chiefly from the decrees of the council of Trent, continued under Paul III., Julius III., and Pius IV., from the year 1545 to 1563, by successive sessions, and the creed of pope Pius IV. subjoined to it, and bearing date November 1564, may not be unacceptable to the reader. One of the fundamental tenets, strenuously maintained by popish writers, is the infallibility of the church of Rome; though they are not agreed, whether this privilege belongs to the pope, or a general council, or to both united; but they pretend that an infallible living judge is absolutely necessary to determine controversies, and to secure peace in the Christian church. However, Protestants allege, that the claim of infallibility in any church is not justified by the authority of scripture; much less does it pertain to the church of Rome; and that it is inconsistent with the nature of religion, and the personal obligations of its professors; and that it has proved ineffectual to the end for which it is supposed to be granted, since popes and councils have disagreed in matters of importance, and they have been incapable, with the advantage of this pretended infallibility, of maintaining union and peace. For the manner in which this claim is understood, and maintained by modern Catholics, see POPE and PAPIST.

Another essential article of the popish creed is the supremacy of the pope, or his sovereign power over the universal church. On this subject it is maintained, that every Christian, under pain of damnation, is bound to be subject to the pope; that no appeals may be made from him; and that he alone is the supreme judge of all persons, in all ecclesiastical causes, but that he himself can be judged by no man. To this purpose they assert, that the church of Rome

is the Catholic church; the mother and mistress of all churches; that the pope is the vicar of Christ, successor of St. Peter, and the supreme pastor over all the world. And they likewise assert his dominion over temporal princes; pretending that he may over-rule what they command; excommunicate and depose them, if they contradict his commands; and absolve their subjects from allegiance, and exempt the clergy from their jurisdiction.

This exorbitant power hath been challenged by the pope for many successive ages, and in several instances actually exercised. Thus Gregory VII. excommunicated the emperor Henry IV. and gave away his kingdoms to Rudolphus, duke of Sweden. Gregory IX. excommunicated the emperor Frederick II. and absolved his subjects from their oath of allegiance. Pope Paul III. excommunicated and deposed Henry VIII. king of England, and commanded all his subjects, under a curse, to withdraw their obedience from him. Pope Pius V. and Gregory XIII. damned and deposed queen Elizabeth, and absolved her subjects from their allegiance. And this practice has been warranted by the decree of the third Lateran council under pope Alexander III., and by the fourth Lateran council under pope Innocent III., though it is contrary to the express language of scripture, to the doctrine and conduct of the apostles and primitive fathers, and to the confessions and practice of the ancient bishops of Rome, and altogether inconsistent with the rights of government and the welfare of society. For the sentiments of modern Catholics with regard to this article, we refer to the article PAPIST.

Farther, the doctrine of the seven sacraments is a peculiar and distinguishing doctrine of the church of Rome: these are baptism, confirmation, the eucharist, penance, extreme unction, orders, and matrimony. The council of Trent (sess. 7. can. 1.) pronounces an anathema on those who say, that the sacraments are more or fewer than seven, or that any one of the above number is not truly and properly a sacrament. And yet it does not appear that they amounted to this number before the twelfth century, when Hugo de St. Victore and Peter Lombard, about the year 1144, taught, that there were seven sacraments. The council of Florence, held in 1438, was the first council that determined this number. These sacraments confer grace, according to the decree of the council of Trent (sess. 7. can. 8.) *ex opere operato*, or by the mere administration of them: three of them, *viz.* baptism, confirmation, and orders, are said (can. 9.) to impress an indelible character, so that they cannot be repeated without sacrilege; and the efficacy of every sacrament depends on the intention of the priest by whom it is administered (can. 11.) Pope Pius expressly enjoins, that all these sacraments should be administered according to the received and approved rites of the Catholic church. With regard to the eucharist in particular, we may here observe, that the church of Rome holds the doctrine of *transubstantiation*; the necessity of paying divine worship to the consecrated bread, or *host*; the propitiatory sacrifice of the mass, according to their ideas of which Christ is truly and properly put to death as a sacrifice, as often as the priest says mass; and *solitary mass*, in which the priest alone, who consecrates, communicates; and allows *communion* only in one kind, *viz.* the bread, to the laity. Sess. 14. See PAPIST.

The doctrine of *merit* is another distinguishing tenet of popery; with regard to which the council of Trent has expressly decreed (sess. 6. can. 32.), that the good works of justified persons are truly meritorious; deserving not only an increase of grace, but eternal life, and an increase of glory; and it has anathematized all who deny this doctrine.

Of the same kind is the doctrine of satisfactions; which supposes that penitents may truly satisfy, by the afflictions they endure under the dispensations of Providence or by voluntary penances to which they submit, for the temporal penalties of sin, to which they are subject, even after the remission of their eternal punishment. Sess. 6. can. 30. and sess. 14. can. 8 & 9. See PAPIST.

In this connection we may mention the popish distinction of venial and mortal sins: the greatest evils arising from the former are the temporary pains of purgatory; but no man, it is said, can obtain the pardon of the latter without confession to a priest, and performing the penances which he imposes.

The council of Trent (sess. 14. can. 1.) has expressly decreed, that every one is accursed, who shall affirm, that *penance* is not truly and properly a sacrament instituted by Christ in the universal church, for reconciling those Christians to the divine majesty, who have fallen into sin after baptism: and this sacrament, it is declared, consists of two parts, the matter and the form: the matter is the act of the penitent, including contrition, confession, and satisfaction; the form of it is the act of absolution on the part of the priest. Accordingly it is enjoined, that it is the duty of every man, who hath fallen after baptism, to confess his sins, once a year at least, to a priest; that this confession is to be secret; for public confession is neither commanded nor expedient; and that it must be exact and particular, including every kind and act of sin, with all the circumstances attending it. When the penitent has so done, the priest pronounces an absolution, which is not conditional or declarative only, but absolute and judicial. This secret, or auricular confession, was first decreed and established in the fourth council of Lateran, under Innocent III. in 1215 (cap. 21). And the decree of this council was afterwards confirmed and enlarged in the council of Florence, and in that of Trent, which ordains, that confession was instituted by Christ; that by the law of God it is necessary to salvation; and that it has been always practised in the Christian church. As for the penances imposed on the penitent, by way of satisfaction, they have been commonly the repetition of certain forms of devotion, as pater-nosters, or ave-marias, the payment of stipulated sums, pilgrimages, fasts, or various species of corporal discipline. But the most formidable penance in the estimation of many, who have belonged to the Romish communion, has been the temporary pains of purgatory. But under all the penalties which are inflicted or threatened in the Romish church, it has provided relief by its indulgences, and prayers or masses for the dead; performed professedly for relieving and rescuing the souls that are detained in purgatory. Sess. 25. See PAPIST.

Another article that has been long authoritatively enjoined and observed by the church of Rome, is the celibacy of her clergy. This was first enjoined at Rome by Gregory VII. about the year 1074, and established in England by Anselm, archbishop of Canterbury, about the year 1105; though his predecessor Lanfranc had imposed it upon the prebendaries and clergy that lived in towns. And though the council of Trent was repeatedly petitioned by several princes and states to abolish this restraint, the obligation of celibacy was rather established than relaxed by this council; for they decreed, that marriage contracted after a vow of continence is neither lawful nor valid; and thus deprived the church of the possibility of ever restoring marriage to the clergy. For if marriage, after a vow, be in itself unlawful, the greatest authority upon earth cannot dispense with it, nor permit marriage to the clergy, who have al-

ready vowed continence. Sess. 24. can. 9. (See CELEBATE, and PAPIST.) To the doctrines and practices above recited may be farther added the worship of images: to justify which, the papists often leave the second commandment out of their catechisms (see DECALOGUE); the invocation of saints and angels, with respect to which the council of Trent decreed, that all bishops and pastors, who have the cure of souls, do diligently instruct their flocks, that it is good and profitable humbly to pray unto the saints, and to have recourse to their prayers, help, and aid; for which practice no scripture command or example, nor any testimony within the first three hundred years after Christ, can be pleaded: the worship of sacred relics, by which they understand not only the bodies and parts of the bodies of the saints, but any of those things that appertained to them, and which they touched; and the celebration of divine service in an unknown tongue, to which purpose the council of Trent hath denounced an anathema on any one who shall say, that mass ought to be celebrated only in the vulgar tongue. (Sess. 25. and sess. 22. can. 9.) Though the council of Lateran under Innocent III. in 1215 (can. 9.) had expressly decreed, that, because in many parts, within the same city and diocese, there are many people of different manners and rites mixed together, but of one faith, the bishops of such cities or dioceses should provide fit men for celebrating divine offices, according to the diversity of tongues and rites, and for administering the sacraments. See PAPIST.

We shall only add, that the church of Rome maintains, that unwritten traditions ought to be added to the holy scriptures, in order to supply their defect, and regarded as of equal authority; that the books of the Apocrypha are canonical scripture; that the Vulgate edition of the bible is to be deemed as authentic; and that the scriptures are to be received and interpreted according to that sense, which the holy mother church, to whom it belongs, to judge of the true sense, hath held, and doth hold, and according to the unanimous consent of the fathers. Sess. 4. See INDEX.

Such are the principal and distinguishing doctrines of popery, most of which have received the sanction of the council of Trent; and that of the creed of pope Pius IV. which is received, professed, and sworn to by every one, who enters into holy orders in the church of Rome; and at the close of this creed we are told, that the faith contained in it is so absolutely and indispensably necessary, that no man can be saved without it. Hardouin's Concil. tom. x. p. 1—211.

Many of the doctrines of popery were relaxed, and very favourably interpreted by M. de Meaux, bishop of Condom, in his exposition of the Doctrine of the Catholic Church, first printed in the year 1671; but this edition, which was charged with perverting, in endeavouring to palliate the doctrine of the church, was censured by the doctors of the Sorbonne, and actually suppressed: nor does it appear, that they ever testified their approbation, in the usual form, of subsequent and altered editions. See the examination of this work by archbishop Wake, in the Pre-servative against Popery, vol. iii. p. 3—112.

For the articles of faith and discipline avowedly maintained by modern Catholics, and particularly by those of our own country, we refer to the title PAPIST; observing, that no tenets ought to be charged on any body of Christians, which they do not expressly acknowledge and avow, and much less any, which they solemnly renounce and disavow.

POPIGAN, in *Geography*, a river of Russia, which rises in N. lat. 68° 40'. E. long. 101° 14', and runs into the Chatanga at Popiganskoi.

POPIGANSKOI, an ostrog of Russia, in the government of Tobolsk, on the Chatanga. N. lat. 72°. E. long. 100° 14'.

POPILIUS, in *Biography*, a name common to many eminent Romans, of whom the most celebrated is Lænas, a Roman ambassador to Antiochus, king of Syria. He was commissioned to order the monarch to abstain from hostilities against Ptolemy, king of Egypt, who was the ally of Rome. Popilius put many questions to the monarch, who wished to evade any direct answers; but Popilius, with a stick in his hand, made a circle in the sand on which Antiochus stood, and bade him, in the name of the Roman senate and people, not to go beyond it before he had given decisive answers. This boldness had the desired effect: Antiochus withdrew his garrisons from Egypt, and no longer thought of making war upon Ptolemy.

POPLAR, in *Botany*. See POPULUS.

POPLAR Tree, in *Agriculture*, a well-known sort of tree of the willow kind, of which there are several species, that are proper to introduce as ornamental and timber trees, as may be seen under the head POPULUS, in *Gardening*.

To marshy grounds no trees are better adapted than poplars, especially the first three or four sorts, noticed in that place, all of which thrive remarkably in moist situations. And as forest or timber trees, the white, black, tremulous, and Lombardy poplars, are proper to be employed. Marshy lands are capable of being improved to much advantage by coppices of these trees, to cut every four, five, or six years, for poles and other small purposes; being planted in rows a yard asunder, and in seven years they will be fit to cut for many small uses, and the stools shooting up again strong, afford a cutting every four or five years afterwards. And some of the sorts may also be planted occasionally to form hedges in moist or other situations, more particularly the Lombardy poplar, as this sort is peculiar in branching out numerously from the bottom upwards, and may be planted hedge fashion along the sides, or top of outward watery ditches, in large plants, so as at once to form a hedge; they may be topped to five, six, or seven feet in height.

Some think, that when these trees are to be propagated by cuttings, it is best to do it in February, cutting off large truncheons of eight or ten feet long; which, being thrust down a foot deep in the ground, will take root very quickly, and, if the soil be moist, will grow to a considerable size in a few years.

The black poplar is not so easily raised from these large truncheons, but should be planted in cuttings of about a foot and a half long, planting them a foot deep in the ground. This will grow on almost any soil, but does much better on a moist one than on any other. They are the fittest of all trees for raising a shade quickly, as they will grow fourteen feet in height sometimes in one season, and in four or five years will be large trees.

A considerable advantage may be obtained by planting these trees upon moist boggy soils, where few other sorts will thrive; and many places of this nature there are in this country, which do not, at present, bring in any money to their owners; whereas if they were planted with these trees, they would in a very few years more than purchase the ground, and clear off all expence: but there are many persons, who think nothing except corn worth cultivating:

tivating: or, if they plant timber, it must be oak, ash, or elm; and if their land be not proper for either of these, it is deemed of little worth; whereas if the nature of the soil was examined, and proper sorts of plants adapted to it, there might be a very great advantage made of several large tracts of land, which at this time lie neglected.

The wood of these trees, especially of the white, is very good to lay for floors, where it will last many years; and, for its exceeding whiteness, is by many persons preferred to oak; but being of a soft contexture, is very subject to take the impression of nails, &c. which renders it less proper for this purpose: it is also very proper for wainscoting of rooms, being less subject to swell or shrink than most other sorts of woods; but for turnery ware, there is no wood equal to this for its exceeding whiteness, so that trays, bowls, and many other utensils, are made of it; and the bellows-makers prefer it for their use; as do also the shoemakers, not only for heels, but also for the soles of shoes: it is also very good to make light carts: the poles are very proper to support vines, hops, &c. and the loppings will afford good fuel, which in many countries is much wanted. They also answer very well for hurdle-wood.

There are several species or varieties capable of being cultivated with advantage, as has been seen; as the white poplar, the trembling poplar or aspen, the black poplar, the Lombardy poplar, the common Tacamahaca poplar, the heart-leaved Tacamahaca poplar, the smooth poplar, the Canadian poplar, and the Carolina poplar; but the three or four first are the sorts most commonly made use of for the purposes of agriculture.

All the sorts are capable of being readily increased by cuttings, layers, and suckers. But the planting of the cuttings is the most expeditious mode, as they grow freely without any trouble; when made either from the young year old shoots, a foot and a half in length, and planted a foot in depth; or large truncheons of two, three, or more years growth, from about a yard to five or six feet long, planted in moist places as we have mentioned above; though these large cuttings or truncheons are not proper for general plantations only in some particular parts, as in a marshy or watery situation, where shade, shelter, &c., may be required as soon as possible, in which they may be planted finally to remain, putting them in to the depth of one or two feet. But in order to raise plants for regular plantations or for handsome standards, it is the best method to raise them principally from young cuttings of one year's growth, or two at most. These young cuttings should be made about fifteen or eighteen inches long, and planted out in nursery rows two feet asunder, placing each cutting two parts or half way in the ground, and about a foot distant in the lines, they readily take root, and make good shoots the following summer, care being taken to trim off the straggling laterals in order to encourage the leading shoots to grow straight and rise more expeditiously in height: after having had from two to four or five years' growth in this situation, they may be finally removed for the purposes for which they are wanted at the proper season. The layers may be laid down in autumn, choosing the lower young shoots, that are conveniently situated, laying them by flat laying. They will be well rooted, and fit to remove by the autumn following into nursery-rows, to have two or three years' growth. And suckers, which some of the sorts send up in abundance from the roots, as the fifth sort, may be taken off after the fall of the leaf, and be planted in nursery-rows, as directed for the cuttings, where they form good plants in two or three years. See **POPULUS**.

The Lombardy poplar is said to be esteemed the most profitable tree that can be planted, in several parts of the west of England; particularly in Shropshire, where it is erroneously called the Italian poplar. When introduced sparingly, and in particular circumstances and situations, as near buildings, or backed by other trees, it is, Mr. Loudon thinks, highly ornamental. When opposed to the sky, it has commonly a meagre effect. The peculiarity of its shape may be varied at pleasure, by placing scandent plants or creepers near it, which may climb up among its branches, and hang round it in irregular masses. In many places a number of these trees may be seen varied in this way with an excellent effect. The Carolina, the Canadian, and the hoary poplars, are trees of very agreeable forms. In a tolerably good soil, they grow with great rapidity; frequently upwards of six feet in a season, and seldom less than three or four feet, until they become twelve or fourteen years of age. In forming a residence, they may in most cases be used, he supposes, with great advantage; as they will not only shelter the other sorts of trees, but give the whole estate or park a wooded appearance within a year or two after planting. The hoary poplar, in this respect, is particularly to be recommended. Its effects may be seen to advantage in some small places in Scotland, though it has not been long known there. Those of the Canadian and Carolina poplars are likewise visible in some other places in England. And they have been taken advantage of in some other situations and instances of ornamenting residences.

POPLAR Galls. The black poplar is famous among naturalists for producing a sort of galls, or protuberances of various shapes and sizes, on its leaves and branches, which have been usually mistaken for the lodgments of worms hatched from the eggs of an ichneumon fly; but they are in reality produced from the operations of a viviparous insect, called the *pucceron*, for the bringing up of its offspring.

These galls are of the bladder kind, being usually skinned over, and more or less hollow within, not woody, as those of the oak, &c. They proceed from different parts of the plant, some from the pedicles of the leaves, and many from the young shoots; they are very various in figure, some being roundish, others oblong, others crooked, and contorted in various directions, and some of them are in the figure of horns, like those of the turpentine-tree, and of the same origin.

POPLAR, in *Geography*, a hamlet of Stepney. See **STEPNEY**.

POPLAR Creek, a river of America, in the state of Tennessee, which runs into the Clinches, N. lat. 36° 2'. W. long. 84° 10'.—Also, a river of Maryland, which runs into the Patomack, N. lat. 38° 16'. W. long. 76° 42'.

POPLAR Island, an island in Chesapeake bay, about 10 miles in circumference. N. lat. 38° 45'. W. long. 76° 28'.

POPLAR Spring, a town in the N.W. part of Ann Arundel county, in the state of Maryland; 27 miles W. of Baltimore. The whole county of Ann Arundel contains 26,668 inhabitants.

POPLES, in *Anatomy*, the ham, or space at the back of the leg, behind and above the knee. This space is defined by the tendons of two of the flexors of the knee; viz. the biceps and semitendinosus, which are called respectively the outer and inner hamstrings.

POPPLICANI, **POPULICANI**, or *Publicani*, a name given in the West to the Manichees; or rather to a particular branch of them, called in the East Paulicians.

POPLIFUGIA, in *Antiquity*. See **FUGALIA**.

POPLIN, in *Geography*, a township of America, in New Hampshire,

Hampshire, Rockingham county, 12 miles W. of Exeter; incorporated in 1764, and containing 462 inhabitants.

POPLIN, a town of Prussia, in Pomerelia; 12 miles S.W. of Marienburg.

POPLITEAL, in *Anatomy*, (from *poples*, the ham,) an epithet applied to some parts situated in the ham, as the artery, vein, and nerve of the lower limb.

POPLITEAL *Aneurysm*, in *Surgery*. See ANEURYSM.

POPLITEUS, in *Anatomy*, (poplito-tibien,) a small muscle situated deeply in the upper and back part of the leg, and extending from the tuberosity of the external condyle of the femur to the back of the tibia. Its form is nearly triangular, so that we may describe in it two surfaces, two edges, a basis, and an apex.

The posterior surface is covered by the gastrocnemius, the plantaris, the popliteal vessels, and posterior tibial nerve. The anterior surface is attached to the back of the tibia, from the upper extremity as far as the oblique line, which traverses the bone from side to side. This surface also covers the upper end of the tibialis posticus, and the peroneo-tibial articulation. The lower edge is the longest, and slants from above downwards, and from without inwards. Its upper part is connected to the upper extremity of the fibula and the soleus muscle by a thin membrane: in the rest of its extent, it is attached to the oblique line of the tibia. The upper edge slants from above downwards and inwards: at the outside it is connected to the capsule of the knee; at the inside, to the back of the upper extremity of the tibia. The apex of the muscle, turned upwards and outwards, is fixed to a depression in the outer surface of the external condyle of the femur, below the attachment of the external lateral ligament of the knee. The basis is attached to about the upper fourth part of the inner edge of the tibia.

The popliteus is tendinous and fleshy: its tendon, attached to the femur, is flattened, and more than an inch in length. The back of this tendon is covered by the external lateral ligament of the knee and the tendon of the biceps. Its anterior surface is contiguous to the external condyle, to the convex edge of the external femilunar cartilage, which is slightly excavated to receive it, and to the back of the knee joint. The edges are closely united to the capsule of the joint. This part of the tendon in short forms a part of the internal surface of the knee. The back of the muscle is covered in nearly its whole extent by an aponeurosis, chiefly produced by the tendon of the femimembranosus. The fleshy fibres rise from the tendon first mentioned, and terminate in this aponeurosis, and in the surface of the tibia. The upper ones are the shortest and nearly transverse: they become longer and more oblique as we go lower.

It bends the knee joint, either by moving the leg on the thigh, or *vice versa*; when the knee is bent, it draws the inner edge of the tibia backwards, and thus rotates that bone on its axis, so as to turn the front of the foot inwards.

POPO, in *Geography*, a town of Peru, in the jurisdiction of Oruro, situated near a mountain celebrated for its mines; 16 miles N.E. of Paria.

POPO, or *Papa*, a kingdom of Africa, on the Slave coast, about 24 miles in extent; the soil of which is flat and sandy, without hills or trees.

POPO, *Grand*, a town of Africa, on the Slave coast, situated near the sea, in a fertile soil, at the mouth of a river which comes from the country of Ardra. N. lat. 6° 22'. E. long. 1° 5'.

POPO, *Little*, a town of Africa, on the sea-coast, not far from Grand Popo. N. lat. 6° 18'. E. long. 0° 40'.

POPOCATAPEC, a town of Mexico Proper; 36 miles S.E. of Mexico.

POPOLI, a town of Naples, in Abruzzo Citra; seven miles N.N.W. of Sulmona. N. lat. 42° 10'. E. long. 13° 45'.

POPORNICA, a town of European Turkey, in Moldavia; 36 miles N.E. of Stephanowzc.

POPORTZIE, a town of Lithuania; 12 miles N.W. of Troki.

POPOVITZ, a town of Bosnia; 10 miles N. of Bosnaferai.

POPPE, a town of Prussia, in Oberland; 17 miles E. of Ortelsburg.—Also, a town of Austria; eight miles S. of Bohmisch Waidhoven.

POPENDORF, a town of the duchy of Stiria; 10 miles N.N.E. of Rackesburg.

POPSETS, pieces of fir-baulk or other timber, fixed perpendicularly under the ship's bottom, upon the bildgeways, at the foremost and aftermost parts of the ship, to support her in launching.

POPSETS, the two upright pieces of elm or harder wood, cut with a screw at their lower ends, having holes in their head or upper end to admit levers. See SCREW.

POPPINA, in *Geography*, a town of European Turkey, in Bulgaria; 17 miles S.W. of Dristra.

POPPL, a term sometimes applied to the weed cockle. It is very injurious among grain.

POPPOSORI, in *Geography*, a town of Naples, in the province of Otranto; three miles S.W. of Oris.

POPPY, in *Botany* and *Gardening*. See PAPAVER.

POPPY, in the *Materia Medica*. (See OPIUM.) The seeds of the *white poppy*, or *papaver somniferum*, possess, according to some authors, a narcotic power; but for this opinion, says Dr. Woodville, there is no foundation: they consist of a simple farinaceous matter united with a bland oil, and in many countries are eaten as food. As a medicine they have been usually given in the form of emulsion, in catarrhs, stranguries, &c. The heads or capsules of the poppies, which are directed for use in the pharmacopeias, like the stalks and leaves, have an unpleasent smell, resembling that of opium, and an acrid bitterish taste. Both the smell and taste reside in a milky juice, which more especially abounds in the cortical part of the capsules, and in its concrete state constitutes the officinal opium. These capsules are powerfully narcotic or anodyne; boiled in water, they impart to the menstruum their narcotic juice, together with the other juices which they have in common with vegetable matters in general. The liquor, strongly pressed out, suffered to settle, clarified with whites of eggs, and evaporated to a due consistence, yields an extract, which is about one-fifth or one-sixth of the weight of the heads. This possesses the virtues of opium, but requires to be given in double its dose to answer the same intention, which it is said to perform without occasioning a nausea and giddiness, the usual effects of opium. See the sequel to this article. White poppy heads are also used externally in fomentations, either alone, or more frequently added to the "decoctum pro fomento." The officinal preparations of the poppy capsules are as follow.

Decoctum papaveris, decoction of poppy, which the London Pharmacopeia directs to be prepared by boiling four ounces of the capsules bruised in four pints of water for a quarter of an hour, and then straining. In making this decoction the seeds should not be rejected, as they contain a considerable quantity of bland oil; which, added to the mucilage and narcotic principle of the capsules, increases the emollient qua-

lity of the decoction. This is a very useful fomentation in painful swellings, and in the excoriations produced by the thin acrid discharge of ulcers, and those common to infants.

Extractum papaveris of the Lond. Pharm. and *Extractum papaveris somniferi* of the Edinb. Ph., extract of poppies, is prepared by macerating a pound of the capsules bruised in a gallon of boiling water for twenty-four hours; then boiling down to four pints, straining the hot liquor, and evaporating it to a proper consistence. This, as we have already observed, possesses nearly the same properties as opium, but in a much weaker degree; and as it is less apt to occasion the nausea, headache, and delirium, occasionally produced by opium, it is to be preferred for procuring sleep in diseases that much affect the head. The dose is from grs. ij to ℥j, given in the form of pills. This extract was first recommended by Mr. Arnot. Edinb. Med. Ess. and Obs. vol. v. art. 11.

Syrupus papaveris, syrup of poppy, is prepared, according to the directions of the London Pharm., by macerating four ounces of the dried capsules of the poppy, bruised and freed from the seeds, in two gallons and a half of boiling water for twelve hours; then boiling it down in a water bath to one gallon, and strongly expressing it; boiling the liquor again down to two pints, and straining it while it is hot; setting it aside for twelve hours that the feces may subside; then boiling down the clear liquor to one pint, and adding two pounds of refined sugar, in the manner ordered for making syrup.

The *Syrupus papaveris somniferi*, syrup of white poppy, of Edinb. Ph., is prepared by macerating two pounds of the sliced capsules of the white poppy, dried and freed from the seeds, in thirty pounds of boiling water for twelve hours; then boiling until a third part only of the liquor remains, and having expressed strongly, straining the decoction; boiling the strained liquor to one-half, and again straining it: and lastly, having added four pounds of refined sugar, boiling it for a short time so as to form a syrup.

The *Syrupus papaveris albi*, syrup of white poppy, of the Dub. Ph., is directed to be prepared in the following manner: Take of the capsules of the white poppy, gathered before they are ripe, dried and freed from their seeds, a pound; boiling water three pints. Slice and bruise the capsules; then pour over them the water, and macerate for twelve hours; express the liquor and evaporate it by a gentle heat to a pint; strain through a linen cloth, and set it aside six hours that the feces may subside; finally add sugar to the liquor that it may make a syrup.

The syrup may be conveniently prepared from the extract of the Edinb. Ph. by dissolving one dram in two pounds and a half of simple syrup. This syrup ferments more readily than most other syrups, and loses its narcotic power when it becomes acefcent. One fluid-ounce of it contains about one grain of extract. Syrup of poppy is an useful anodyne for allaying the violence of the cough in catarrh, for easing pain and procuring sleep in the diseases of children. The dose is from fʒj to fʒj, according to the age of the patient.

The capsules of the red or corn poppy, *papaver Rhæas* or *erraticum*, common in corn-fields, like those of the *somniferum*, contain a milky juice of a narcotic quality, but the quantity is very inconsiderable, and has not been applied to any medical purpose; but an extract prepared from them has been successfully employed as a sedative.

It has been the general opinion of authors, that the narcotic quality of the red poppy lay in its flowers; but Mr. Boulduc, in his course of experiments for the finding out an European plant which should yield us a juice of the nature

of the opium of the East, without its bad effects, found that the virtue of this plant, which is very great, lay much more in the heads than the flowers; and from four ounces of these heads, while fresh and green, he obtained five drams of a solid extract, of the nature of opium, two, three, or four grains of which were a full dose, and which possessed the virtues of opium, and might be given with great success and safety in obstinate coughs and other such cases. Hist. Acad. Par. 1712.

Fouquet of Montpellier prefers this extract to opium. See Murray, App. Med. vol. ii. p. 213.

The flowers of the red poppy have somewhat of the smell of opium, and a mucilaginous taste, accompanied with a slight degree of bitterness. The officinal preparation is a syrup, called *syrupus Rhæados* in the London Pharm. This syrup of the red poppy is prepared in the following manner: Take of the recent petals of the red poppy, a pound; boiling water a pint and two fluid-ounces; refined sugar, one pound and a half. To the water, heated in a water bath, add gradually the petals of the red poppy, stirring them occasionally; then, having removed the vessel, macerate for twelve hours; press out the liquor, and set it aside that the impurities may subside; lastly, add the sugar as in making syrup. The *syrupus papaveris erratici*, or syrup of the red poppy, of the Dub. Pharm., is prepared as follows: Take of the first petals of the red poppy, a pound; boiling water, twenty fluid-ounces; add the flowers gradually to the boiling water; then having removed the vessel from the fire, macerate in a lower heat for twelve hours; express the liquor, and set it aside that the feces may subside; finally, let the sugar be added, so as to make a syrup. By pursuing exactly either of the above processes, the petals yield their fine rich colour, for which the syrup has been principally, and as some say only, valued. However, this syrup has been thought useful by some as an anodyne and pectorant, and is, therefore, prescribed in coughs and catarrhal affections. Woodville, Med. Bot. Thomson's Lond. Dispensatory.

POPPY, in Agriculture. The common red poppy, or *papaver erraticum*, is one of the most troublesome and mischievous weeds the farmers are plagued with among their corn, and it is the most difficult to thoroughly destroy of almost any other. Its seeds will lie a long time in land unploughed, without ever shooting: but they will be sure to grow with the first crop of corn. Mr. Tull gives an instance of the seeds of this plant being buried four and twenty years in a field of saintfoin, and at the end of that time, the land being ploughed for wheat, they all grew up among the corn, though they had laid dormant so long before.

POPPY, Horned. See CHELIDONIUM *Majus*.

The yellow horned poppy, called by authors *papaver corniculatum luteum*, is one of those vegetable poisons of our own growth, which may be very mischievous by their not being generally known or suspected to be so. We have an account of the strange effects of this plant in the Philosophical Transactions, in an instance of a family in Cornwall, who eat of a pye made of the roots of this instead of those of eryngo, or sea-holly, which it is the custom of the poorer people there to make into a coarse sort of pye for their food. See Phil. Trans. N^o 242.

POPPY, Prickly. See ARGEMONE.

POPPY, Spatling, a species of the cucubalus, or berry-bearing chick-weed. This stands in the catalogue of medicinal plants under the title of *behen album*. See BEN.

POPPY-Seeds. The poppy-seed is of a more delicious taste than sweet almonds; it is oily and farinaceous. Dr. Allston says, he has eaten large quantities of the black as well as the

white seed, and never found it somniferous or noxious. See Med. Ess. Edinb. vol. v. art. 12.

If emulsions of poppy-seeds have been found serviceable in coughs, catarrhs, heat of urine, and other like disorders, their virtue is to be ascribed not to an anodyne, but an emollient quality.

These seeds are used in food in some places, as is their expressed oil, which is as wholesome as olive-oil. Vide Matthiol. p. 476. Geoffr. Mat. Med. vol. ii. p. 713.

The qualities and uses of this oil, with regard to painting, are much the same as those of nut-oil; only when it is perfectly good, it is more clear and limpid, and will dry better than the best oil of that kind.

POPPY, *Syrup of*. See MECONIUM, and POPPY, *supra*.

POPPY *Water*. See WATER.

POPRA, in *Geography*. See JUNKSEILON.

POPRA, a river which rises in Hungary, and runs into the Vistula, about 20 miles below Cracow.

POPULAGO, in *Botany*, Tournefort's name for the *CALTHA* of Linnæus; see that article.

POPULAR, POPULARIS, something that relates to common people.

The Roman nobility was distinguished into two factions; the *optimates*, who adhered strenuously to the ministry, the senate, &c. in opposition to the people; and the *populares*, who favoured the rights and pretensions of the people, in opposition to the noblesse.

POPULAR *Action*. See ACTION.

POPULAR *Diseases*, are such as become common, and run through the body of the people; called also *endemic* and *epidemic* diseases.

Hippocrates has written expressly "De Morbis Popularibus."

POPULAR *Errors*, are such as people imbibe from one another, by custom, education, and tradition, without having considered the reason or foundation of them.

POPULARIA, among the Romans, were steps or places where the people sat and beheld the games and horse-races.

POPULATION, in *Political Economy*. The state of a country, with respect to the number of its inhabitants, is of great importance in the science of political economy. The increase or diminution of the members of a state has at all periods been thought an object deserving the attention of governments, though very different theories have been formed on the subject. Some ancient nations adopted regulations to prevent any considerable augmentation of the number of its citizens; but in modern times it has generally been thought the part of a wise policy to encourage population as essential to the strength and prosperity of a state. Positive regulations against an increase of population are always nugatory: it is, without contradiction, limited in every country by the means of subsistence; and if ever it actually passes this barrier, it must in a very short time be restored to its former level. So long as there is a facility of subsistence, the people will be encouraged to early marriages, and to the augmentation of the national stock of inhabitants. On this subject, Dr. Adam Smith, in explaining the causes which proportion the reward of labour to the extent of the funds for its support, observes, "It is in this manner that the demand for men, like that of any other commodity, necessarily regulates the production of men; quickens it when it goes on too slowly, and stops it when it advances too fast. It is this demand which regulates and determines the state of population in all the different countries of the world,—in North America, in Europe, and in China; which renders it rapidly progressive in the first, slow

and gradual in the second, and altogether stationary in the last." This passage is said to have given rise to the celebrated work of Mr. Malthus, to which we shall shortly have occasion to refer, and the idea contained in it is illustrated and confirmed by a multitude of indisputable facts collected from almost every country on the globe. In the American states the inhabitants, particularly those engaged in agriculture, congratulate themselves upon the increase of their families, as upon a fresh accession of wealth; for the labour of their children, even in an early stage, soon redeems, and will quickly repay, with ample interest, the expence and trouble of rearing them. In such countries the wages of the labourer are high, for the number of labourers bears no proportion to the demand. Whereas, in many European countries, a large family too frequently entails upon the parents poverty and wretchedness.

In contemplating this interesting subject, it will be discovered that the rate of population is by no means the same in all countries:—there is, for instance, a striking difference in its progress, not only in North America, to which we have just alluded, compared with Europe and Asia in general, but a similar difference is exhibited in the different states of Europe, at the same period of time; and in the same state at different periods. As men cannot live without food, it will be readily admitted that these variations in the rate of population must have been universally preceded and accompanied by variations in the means of maintaining labourers, on which, indeed, the demand mentioned by Dr. Smith must depend. Where these funds are rapidly increasing, as in North America, the demand for an increasing number of labourers renders it easy to provide an ample subsistence for each, and the population of the country is observed to make rapid advances. Where these funds increase only at a moderate rate, as in most parts of Europe, there the demand for labourers is moderate, because the command of the labourer over the means of subsistence is consequently much diminished, and the population proceeds very slowly, varying in each country according to the variation in the funds for its support. Where these funds are stationary, as probably in China, Spain, Italy, &c., the demand for labour being stationary, the command of the labourer over the means of subsistence is comparatively scanty, and the population is diminishing rather than increasing.

It is no less certain, that the actual increase of the funds for the maintenance of labour does not depend simply upon the physical capacity of a country to produce food and other necessaries, but upon the degree of industry, intelligence and activity, with which these powers are at any particular period called forth. Thus we have seen or heard of countries possessing every requisite for producing the necessaries and conveniences of life in abundance, sunk in a state of ignorance and indolence from the vices of their governments, or the unfortunate constitution of their society, and continuing on for ages, with scarcely any increase in the means of subsistence, till some fortunate event introduces a better order of things; and then the industry of the nation being roused, and allowed to exert itself with more freedom, more ample funds for the maintenance of labour are immediately provided, and population is seen to make a sudden start forwards, at a rate wholly different from that at which it had before proceeded. An instance of this kind has been produced with regard to Russia, the population of which, though early inhabited, was so extremely low before the beginning of the last century, and has proceeded with such rapidity since the reigns of Peter the Great and Catharine II. It has also been noticed in the review of

the history of nations, that the waste of people occasioned by the great plagues, famines, and other devastations, to which the human race has been occasionally subject, has been repaired in a much shorter time than it would have been, if the population, after these devastations, had only proceeded at the same rate as before. From which circumstance it is obvious, that after the void thus occasioned, it must have increased much faster than usual; and the greater abundance of the funds for the maintenance of labour, which would be left to the survivors, indicates the usual conjunction of a rapid increase of the funds for its maintenance. A fact in proof of this is, that just after the pestilence in the reign of Edward III., a day's labour would purchase a bushel of wheat, while immediately before, it would scarcely have obtained a peck as a fair equivalent. Again, wherever any new channels of industry, and new sources of wealth are opened, so as to provide the means of supporting an additional number of labourers there, almost immediately a stimulus is given to population; and it proceeds, for a short time, with a vigour and celerity proportionate to the greatness and duration of the funds on which it alone can subsist.

It is certain that the greater the number of persons any country contains, the greater are the means it possesses of carrying on agriculture, manufactures, and commerce, and likewise of defending itself against any hostile attempts of other states: a high degree of population has therefore been generally considered as conducive to national prosperity and security, and almost every writer on political economy has assumed an increasing population as one of the principal objects which the internal regulations of a country should be calculated to promote. Mr. Malthus, in his "Essay on the Principle of Population," has taken a different view of the subject. He has endeavoured to shew that population invariably increases where the means of subsistence increase, unless prevented by some very powerful and obvious checks. He goes farther, and lays it down almost as an axiom, that there is a constant tendency in all animated life to increase beyond the nourishment prepared for it, and he traces to this source a very considerable portion of the vice and misery, and of that unequal distribution of the bounties of nature, which it has been the object of the philanthropist in all ages to correct. To place the subject in a different point of view, we may endeavour to ascertain what would be the natural increase of population, if left to itself with perfect freedom; and what might be expected to be the rate of increase in the productions of the earth under the most favourable circumstances of human industry. Hitherto, in no state has the population been left to exert itself with perfect freedom. In some of the northern states of America, in which the means of subsistence have been more ample, and the checks to early marriages fewer, than in any of the modern states of Europe, the population has been found to double itself for several successive periods every twenty-five years. In the back settlements this was effected in fifteen years. Sir William Petty supposed it possible that population might be doubled in ten years. Mr. Malthus takes the slowest of these rates of increase, and assumes, that population, when unchecked, goes on doubling itself every twenty-five years, or it increases in a *geometrical* ratio. The rate according to which the productions of the earth may be supposed to increase, is not so easily determined; but when acre has been added to acre, till all the fertile land is occupied, the yearly increase of food must depend upon the melioration of the land already in cultivation, and Mr. Malthus shews most satisfactorily, that, on this supposition, the means of subsistence, under circumstances the most favourable

to human industry, could not possibly be made to increase faster than in an *arithmetical* ratio. He then points out the necessary effects of these two different rates of increase, and observes, that taking the whole earth, by which means emigration is put out of the question, and supposing the present population equal to a thousand millions, the human species would increase as the numbers 1, 2, 4, 8, 16, 32, 64, 128, 256, and subsistence as 1, 2, 3, 4, 5, 6, 7, 8, 9. Hence, in two centuries, the population would be to the means of subsistence as 256 to 9; in three centuries, as 4096 to 13; and in two thousand years the difference would be almost incalculable. Upon this supposition, no limits whatever are placed to the produce of the earth, it may increase for ever, and be greater than any assignable quantity; but the power of population being in every period so much superior, the increase of the human species can only be kept down to the level of the means of subsistence by the constant operation of some powerful check.

From what has been said above, it appears, 1. That man, like all other animals, multiplies in proportion to the means of subsistence which are placed within his reach. 2. That there is a power of increase in the human race, much greater than is generally exercised, always ready to exert itself as soon as it finds an opening, and appearing continually in sudden starts of population, whenever the funds for the maintenance of labour have experienced an increase, in whatever way this may have been occasioned. 3. That this power of increase is so great, and, in its nature, necessarily so different from any increase which can result from adding together different portions of a limited quantity of land, or gradually improving the cultivation of the whole, that the funds for the maintenance of labour cannot, under any system the most favourable to human industry, be made permanently to keep pace with such an increase of population as has been observed to take place for short periods in particular countries; and consequently, as man cannot live without food, that the superior power of population cannot be kept on a level with the funds which are to support it, without the almost constant operation of considerable checks of one kind or other. These checks, according to Mr. Malthus, are all resolvable into moral restraint, vice, and misery.

Dr. Adam Smith, in speaking of the dependence of man, like other animals, on the means of subsistence, and of the impossibility of his increasing beyond them, observes, "But, in civilized society, it is only among the inferior ranks of people, that the scantiness of subsistence can set limits to the farther multiplication of the species; and it can do so in no other way, than by destroying a great part of the children which their fruitful marriages produce." As the poverty and misery which would destroy a considerable portion of children must necessarily be severely felt, not only by the beings thus suffering, but by their parents and survivors, it must be acknowledged, that such premature mortality is a very stern leveller, but fortunately this is not the only method used to effect the purpose. There are other ways by which population may proportion itself to the means of subsistence. Mr. Malthus shews very satisfactorily, that the effects of the difficulty of providing for a family do not appear only in a premature mortality, but also in the delay of engaging in a connection that is likely to be attended with such a consequence, which he ranks under moral restraint. This view of the subject not only accords better with our ideas of a being who possesses reason, but is confirmed by what is taking place in all the countries with which we are acquainted, where it is found, that when the funds for the maintenance of labour become comparatively

POPULATION.

comparatively scanty, the marriages generally become later and less frequent.

It hence appears, that the checks to population may be divided into two general classes, *viz.* those which operate in *preventing the birth* of a population which cannot be supported, and those which *destroy it* after it has been brought into existence; or, as they are denominated by Mr. Malthus, the *preventive* checks, and the *positive* checks. The determination to defer or decline matrimony from a consideration of the inconveniences to which a large portion of the community would subject themselves by pursuing the dictates of nature, Mr. Malthus denominates the *preventive* check: and whatever contributes to shorten the natural duration of human life, as extreme poverty, bad nursing of children, excesses of all kinds, the whole train of common diseases and epidemics, wars, pestilence, plague, and famine, are the *positive* checks to population.

The necessary and constant effect of some checks to population being fully established, and these checks being divisible into the classes above-mentioned, we cannot for a moment hesitate in determining which of them we should wish to see put in operation. It has been noticed, in most countries, that in years of scarcity and dearth, the marriages are fewer than usual; and if, under all the great variations to which the increase of the means of subsistence is necessarily exposed from a variety of causes, the population were proportioned to the actual means of subsistence, more by the prudence of the labouring classes in delaying marriage, than by the misery which produces premature mortality among their children, it cannot be doubted that the happiness of mankind would be decidedly improved. It is equally certain, that under a given increase of the funds for the maintenance of labour, it is impossible to give to each labourer a larger share of these funds, or materially to improve his condition, without some increase of the preventive check; and that all efforts to improve the condition of the poor, which, at the same time, have no tendency to produce a more favourable proportion between the means of subsistence and the population which is to consume them, can only be partial or temporary, and must ultimately defeat their own object. Hence it follows, that in order to improve the condition of the lower classes of society, to make them suffer less under any diminution of the funds for the maintenance of labour, and enjoy more under any actual state of these funds, every attempt should be made to discourage helpless and improvident habits, and to raise them as much as possible to a sense of the dignity of their nature. The causes which chiefly tend to foster helpless, indolent, and improvident habits among the lower classes, are despotism and ignorance, and whatever increases their dependence, and weakens the motives to personal exertion. Whereas the causes which principally tend to promote habits of industry and prudence, are good government, and good education, and whatever has a tendency to increase their independence and respectability. Wherever the registers of a country indicate great mortality, and the general prevalence of the check arising from disease and death over the check arising from prudential habits; there we find the people debased by oppression, and sunk in ignorance and insolence. On the other hand, wherever the registers of a country indicate a small mortality, and the prevalence of the check from prudential habits above that from premature mortality; there we as constantly find security of property established: some degree of intelligence and knowledge, with a certain taste for cleanliness and comforts.

The differences observable in different nations, in the pressure of the evils resulting from the tendency of the human race to increase faster than the means of subsistence, lead to the inference, that those which are in the best state are still susceptible of great improvement; and that the worst may at least be made equal to the best. "This," says a good writer on the subject, "is surely sufficient both to animate and direct our exertions in the cause of human happiness; and the direction which our efforts will receive, from thus turning our attention to the laws that relate to the increase and decrease of mankind, and seeing their effects exemplified in the state of the different nations around us, will not be into any new and suspicious path, but into the plain, beaten track of morality. It will be our duty to exert ourselves to procure the establishment of just and equal laws, which protect and give respectability to the lowest subject, and secure to each member of the community the fruits of his industry; to extend the benefits of education as widely as possible: and, in general, to discourage indolence, improvidence, and a blind indulgence of appetite, without regard to consequences; and to encourage industry, prudence, and the subjection of the passions to the dictates of reason. The only change, if change it can be called, which the study of the laws of population can make in our duties, is, that it will lead us to apply, more steadily than we have hitherto done, the great rules of morality to the case of marriage, and the direction of our charity; but the rules themselves, and the foundations on which they rest, of course remain exactly where they were before."

Mr. Malthus thinks the effect of our poor laws, is to encourage marriage between persons who have no prospect of providing for the presumptive issue of marriage. Thus, he adds, these laws create mouths, but are perfectly incompetent to provide food for them: instead of raising the real price of labour, by increasing the demand for labourers, they tend to overstock the market, to reduce the demand, and diminish the value. They raise the price of provisions by increasing the consumption, and by supplying the parochial pensioners with the means of obtaining them. In consequence of this, the class of industrious labourers who are above soliciting assistance are frequently sunk in the scale of misery, much lower than others who have thrown off all sense of shame, and all honest feelings of independence. Mr. Malthus shews, that in a moral point of view the effects of the poor laws are equally injurious to the best interests of society: he is not, however, for an immediate and abrupt abolition of them: he suggests what will answer the end, *viz.* a gradual abolition of them, by proposing, that no child born from any marriage taking place after the expiration of a year from the date of the law, and no illegitimate child born two years from the same date, should be entitled to parish assistance. This, he thinks, would operate as a fair notice, which no man could mistake, and without pressing hard upon any individual, would at once throw off the rising generation from that wretched dependence upon the government and the wealthy, the consequences of which are almost incalculable.

Although the good intentions of Mr. Malthus are clearly evident in every page of his work, we are not prepared to follow him in all his theories; in endeavouring to avoid one extreme, he has probably fallen into its opposite. The system of Providence, with respect to the increase of the population, does not seem to us liable to such objections as must present themselves to every reflecting person on the careful perusal of the Essay on Population. Besides, admitting

mitting that the parish funds were shut up from the poor—that public benevolence were restrained by a fixed and undeviating law; no act of the legislature could blunt the feelings of individuals—private benevolence would undoubtedly be extended in proportion as public charity was withdrawn.

According to Mr. Malthus's system, the most effectual mode of improving the condition of the poor, is to explain to them clearly and explicitly the true cause of their poverty; to make them feel, that a redundant population is the real source of all their evils; and that they themselves, by early and improvident marriages, are the causes of the calamities which they bewail: to shew them, that the withholding of the supplies of labour is the only possible way of raising its price; and that they themselves, being the possessors of this commodity, have alone the power to do it. This mode of diminishing the evils of poverty would not be found so simple and easy as Mr. Malthus imagines. Political economy is a subject not easily understood but by persons accustomed to patient thought and moral investigation. Those in the lower ranks of society must be better instructed, before they can possibly apprehend and appreciate the maxims Mr. M. would inculcate. Before, therefore, they can be expected to understand the nature and causes of poverty, they must be better educated in all other topics; but education is the *effect* of a meliorated condition in life, and not the cause. Another very forcible objection is, that the system of reform would not benefit the present race of individuals: the advantages proposed are to be felt by posterity, or, at the most, by the rising generation; and other things remaining the same, is it to be expected that the mass of the people would readily sacrifice personal and present pleasures for the sake of promoting general and future good?

Mr. Malthus lays it down as a fundamental maxim, that in any efforts which we may make to improve the condition of the lower classes of society, we must not, on any account, do any thing which tends directly to encourage marriage: he adds, that "the precise reason why I think that more children ought not to be born than the country can support, is, that the greatest possible number of those that are born may be supported. We cannot, in the nature of things, assist the poor, in any way, without enabling them to rear up to manhood a greater number of their children. But this is of all other things the most desirable, both with regard to individuals and the public. Every loss of a child from the consequences of poverty, must evidently be preceded and accompanied by great misery to individuals; and with respect to the public, every child that dies under ten years of age, is a loss to the nation of all that has been expended in its subsistence till that period. Consequently, in every point of view, a decrease of mortality, at all ages, is what we ought to aim at. We cannot, however, effect this object, without first crowding the population, in some degree, by making more children grow up to manhood; but we shall do no harm, in this respect, if, at the same time, we can impress these children with the idea that to possess the same advantages as their parents, they must defer marriage till they have a fair prospect of being able to maintain a family. If we cannot do this, all our former efforts will have been thrown away. It is not in the nature of things, that any permanent and general improvement in the condition of the poor can be effected without an increase in the preventive check; and unless that take place, either with or without our efforts, every thing that is done for the poor must be temporary and partial; a diminution

of mortality, at present, will be balanced by an increase of mortality in future; and the improvement of their condition in one place, will proportionally depress it in another. This is a truth so important, and so little understood, that it can scarcely be too often insisted upon. The generality of charitable people, and of the encouragers of marriage, are not in the smallest degree aware of the real effects of what they do." The practice of mankind, on the subject of marriage, our author admits, has been much superior to their theories, and however frequent the exhortations may have been to enforce the duty of early unions, each individual has practically found it convenient, not to say necessary, to consider the means of supporting a family before he ventured to take so important a step. The desire of bettering our condition, and the fear of making it worse, have been constantly directing people into the right road, in spite of all declamations which tended to lead them aside. Owing to this powerful spring of health in every state, the prudential check to marriage has increased in Europe, and upon the increasing operation of this principle, much of the future melioration of the state of society probably depends.

Such is the substance of Mr. Malthus's work. He maintains, that his theory and conclusions are not only undeniable, but rest on facts that are obvious to every observer. They are, however, rejected by a large class of respectable and well-meaning people, because they say, that the acknowledgment of a law of increase in the human race, greater than any possible increase of the means of subsistence, is an impeachment of the power, or the benevolence of the Deity. "The religious mind," says one of his opponents, "revolts at the apparent want of intelligence and contrivance in the author of the creation, in infusing a principle into the nature of man, which it required the utmost exertion of human prudence and ingenuity to counteract." To which it has been replied, that we are not permitted to reject truths, of which our senses and experience give us the firmest assurance, because they do not accord with our preconceived notions respecting the attributes of the Deity. All our evidence for the prevailing benevolence of the works of creation—all our evidence of the power of the Creator—is derived from these sources. This evidence we must not and cannot refuse to hear, and it is an after concern, to reconcile the undeniable state of the fact to the attributes which we assign to the divinity. Besides, this world is unquestionably a state of discipline and preparation for another; and it may be affirmed, that in the whole compass of the laws of nature, not one can be pointed out, which, in so peculiar and marked a manner, accords with this view of the state of man on earth. The purpose of the earthquake, the hurricane, the drought, or the famine, by which thousands, and sometimes almost millions of the human race are at once overwhelmed, or left the victims to lingering want, is certainly inscrutable. Events of this kind are, however, of obvious and acknowledged recurrence, and on this principle we should find little or no difficulty in believing, that a law of nature exists peculiarly calculated to rouse the faculties, and direct the exertions of the human race, which, by its varying pressure, and the difficulties to which it gives rise, exercises and enlarges the powers of the mind, and calls into action all the great moral virtues which dignify and adorn human nature, as necessary to human happiness; which, above all, is constantly inculcating the necessity of the subjection of the passions to the dictates of reason and religion, and which, even if vice and misery were well nigh banished from the earth by the efforts of virtue, would occasion the necessity

POPULATION.

necessity of constant watchfulness and attention to maintain and secure the happiness which has been obtained.

It has been urged, that checks to population will occasion a dearth of soldiers for the army, and of hands to our manufactures; but the power of a country, as well in war as in commerce, must depend upon that part of its population which is active and efficient, not upon the helpless and inefficient. If, for instance, it has been found by experience, that one country which has 100,000 births in a year, does not rear so many to manhood as another country which has only 80,000, the latter is unquestionably the stronger of the two. If, in addition to the question of numerical force, we take into consideration the state of misery and depression in the first country, which must have occasioned the premature mortality, we cannot doubt that the second would be indefinitely superior in industry and energy, as well as in the happiness of its inhabitants. "Not only would a country where the checks to population arise from the prudential habits of the lower class, rather than from premature mortality, possess a greater military and manufacturing population, with the same means of subsistence, but from the very circumstance of the country's containing this larger proportion of persons in the active periods of life, the means of subsistence would stand a much fairer chance of being increased with rapidity. This is, in fact, confirmed by experience; England, Scotland, Switzerland, and Norway, where the premature checks to population are observed to prevail with the greatest force, increase faster in the funds for the maintenance of labour, and, of course, in the population supported by them, than most of the countries of Europe that have a larger proportion of births."

The progress of the population of the world, and its present total amount, cannot be ascertained with much precision, as there are no sufficient grounds on which such a computation can be formed. Sir W. Petty, in 1682, stated the population of the world at only 320 millions. Other writers have estimated it much higher; some, indeed, have gone so far as to suppose there were at least 1000 millions

of inhabitants on the earth: and the late Mr. J. J. Grellier says, a strong presumption that the inhabitants of the earth at present (1801) exceed considerably a thousand millions, arises from the circumstance, that, in almost every country where the people have been numbered, or sufficient data obtained for computing their number, it has been found considerably greater than it had been previously supposed. In Great Britain, for instance, the most correct estimates previously to 1801, did not make the population exceed seven or eight millions, whereas by the enumeration in that year it appeared to amount to nearly eleven millions, and, as will be seen hereafter, in 1811, to more than twelve millions and a half. The population of France was estimated by M. Sufmilch at sixteen millions, others supposed it to be eighteen, twenty; and twenty-four millions; but at the commencement of the revolution in 1789, it appeared, from the returns of the births and burials, to contain thirty millions of inhabitants. Spain, which with Portugal had been estimated at only six millions, or at most eight millions, was found in 1787, by actual enumeration, to contain alone ten millions and a half. Russia, about 1765, was supposed to contain only fifteen millions of inhabitants; but according to the calculation given by Mr. Coxe, grounded upon the result of a poll-tax, they amounted to 26,766,360; and including the provinces not subject to the poll-tax, the calculation for the year 1796, amounted to thirty-six millions of inhabitants. It is true a great part of this empire is in Asia, still the author to whom we have alluded, has no hesitation in concluding, that the population of Europe, usually taken at one hundred millions, is considerably greater than this. Mr. Grellier stated the number, as he believed, below the truth, in 1801, at 130,000,000. In 1812, the numbers were given according to the following statement; but in both cases the results can be only approximations to the truth.

The following table, containing the number of inhabitants in each European country, and also the population of its chief cities, will afford a comparative view of the present population of the European states, and of their respective capitals.

POPULATION.

The population of Great Britain was very long a subject of great uncertainty, both with respect to the actual number of inhabitants, and their increase or diminution; it became the subject of frequent controversy among writers on the internal policy and strength of the country, till it was at length, in a measure, set at rest by an act of parliament, passed on the 31st of December 1800, which directed a general enumeration of houses and families, and persons, to be made on the tenth of the following March, and in Scotland, on account of the coldness of the climate, as soon as possible after that day. The result was as follows.

Summary of the Enumeration for 1801.

	No. of Inhabited Houses.	By how many Families inhabited.	Uninhabited Houses.
England	1,472,870	1,787,520	53,965
Wales	108,053	118,303	3,511
Scotland	294,553	364,079	9,537
Totals	1,875,476	2,269,902	67,013

	No. of Males.	No. of Females.	Total.
England	3,987,935	4,343,499	8,331,434
Wales	257,178	284,368	541,546
Scotland	734,581	864,487	1,599,068
Army including militia	198,351	—	198,351
Navy and marines	126,279	—	126,279
Seamen in regt. ship-ping	144,558	—	144,558
Convicts on board the hulks	1,410	—	1,410
Totals	5,450,292	5,492,354	10,942,646

The islands of Guernsey, Jersey, Alderney, and Sark; the Scilly islands, and the Isle of Man, were not included in this enumeration: the total population of these islands has been usually reckoned at about 80,000. The number of houses in Ireland has been nearly ascertained by the collection of a hearth money tax, from whence it has been computed, that the population of that island exceeds four millions of persons; therefore, with a moderate allowance for those places from which no returns were received, and for some omissions in others, the total population of the united kingdom of Great Britain and Ireland, amounted, in 1801, to more than fifteen millions. At the commencement of the preceding century, Dr. Davenant published an account of the number of houses in England and Wales, taken in the year 1690, and a comparison of them shews an increase

from 1690 to 1801 of 261,708 houses, which makes an increase of the population equal to nearly a million and a half of people. There must, however, have been a greater increase than this, as the number of soldiers and seamen in 1801, certainly exceeded by much those employed in 1690. The circumstance that caused considerable disagreement in the estimates, which, previously to the enumeration, had been formed on this subject, was the want of sufficient accounts to determine the proportion of persons to a house. Dr. Davenant and Dr. Brakenbridge reckoned six persons to a house, whereas Mr. G. King allowed but little more than $4\frac{1}{2}$ in London, and $4\frac{3}{10}$ in the other cities and market towns, and four in the villages. Dr. Price asserted, that six persons to a house for London, and five to a house for all England, was no doubt too large an allowance, but it was found in 1801, that in England and Wales the proportion was $5\frac{3}{5}$ persons to a house, and in Scotland $5\frac{2}{5}$. The proportion of inhabitants to a house differs very considerably in some counties of England: the principal cause of this difference is the large towns, and particularly the sea-ports which some of them contain, as in such places the inhabitants live more crowded together than in moderate sized inland towns; thus in the enumeration of 1801, the following results were given.

Inhabitants.	Towns.	No. of Persons in a House.
864,845	London	$7\frac{1}{4}$
84,020	Manchester	$6\frac{3}{4}$
77,653	Liverpool	$6\frac{3}{4}$
63,645	Bristol	6
43,194	Plymouth	$9\frac{1}{4}$
32,200	Bath	$7\frac{1}{2}$
32,166	Portsmouth	6
29,516	Hull	$6\frac{1}{4}$
28,366	Newcastle	9

A remarkable difference will be seen between those and the following, which are manufacturing towns; the trade of which had, for several years, previously to the census, been in a declining state.

Inhabitants.	Towns.	No. of Persons in a House.
73,670	Birmingham	5
53,162	Leeds	$4\frac{3}{4}$
36,832	Norwich	$4\frac{1}{2}$
31,314	Sheffield	$4\frac{3}{4}$
28,861	Nottingham	$5\frac{3}{4}$

In these the population is unquestionably much below the usual standard; but a few years of peace will probably restore the inhabitants which they had lost, and reduce, in some degree, the population of the principal out-ports. The following table, taken from Thomson's Journal, will, it is presumed, be deemed an important addition to the present article.

This gives us rather more than $4\frac{1}{2}$ persons to each family.

An attempt was made to ascertain the population of France in the tenth year of the republic; but the account was not deemed very accurate. The whole population of the 102 departments, into which France was then divided, was stated at 33,104,343 persons, on an extent of about 185,600 square miles. The account included thirteen departments incorporated with the north of France, four departments in the south, and some smaller acquisitions, comprehending 23,790 square miles, containing 5,114,419 inhabitants.

According to tables published in 1811, in the Almanac of the French Board of Longitude, the population of the French empire, as it was then denominated, amounted to 43,937,144 persons. Of this number it was supposed that 28 millions spoke the French language; 6,453,000 the Italian; 4,063,000 the Dutch or Flemish; 967,000 the Breton; and 108,000 the Basque.

The population of the states connected with the system of France, in which number were included the kingdoms of Italy, Switzerland, Spain, the Confederation of the Rhine, &c. was estimated at more than 38 millions.

In the returns to parliament in 1811, we have an account of the population of the principal towns in Great Britain. We shall set down all those which contain 20,000 inhabitants, and upwards. Of these there are 17 in England, and five in Scotland: whereas in France, according to a census taken in the same year, there were 49 such towns; as will be seen below:

ENGLAND.

* This and several others now (April 1814) are no part of the kingdom of France.

Malthus on Population. Monthly Magazine. Imperial Review, vol. i. Edinburgh Review, vol. xvi. Thomson's Journal, vol. i.

POPULEUM, or POPULNEUM, in *Pharmacy*, an unguent prepared of the buds of black poplar, violet leaves, navel-wort, and lard, bruised and macerated; to which are added bramble-tops, leaves of black poppies, mandragora, henbane, nightshade, lettuce, and burdock, boiled in rose-water, and strained. It was formerly much used as a cooler in burns, scalds, all sorts of inflammations, and also to allay arthritic pains, but it is now almost entirely disregarded.

POPULICANI. See POPLICANI.

POPULO, in *Geography*, a town of New Navarre; 200 miles S. of Casa Grande.

POPULONIUM, or POPULONIA, in *Ancient Geography*, a town of Italy, upon a promontory of the same name, founded by a colony, conducted from Volterra to this place by king Propertius.

POPULUS, in *Botany*, the Poplar tree, an old Latin name, concerning whose derivation we find nothing conclusive. Possibly the verb *παλλω*, or *πιπαλλω*, may have been its basis.—Linn. Gen. 526. Schreb. 693. Willd. Sp. Pl. v. 4. 802. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 1079. Ait. Hort. Kew. v. 5. 394. Pursh 618. Juss. 409. Tourn. t. 365. Lamarck Illustr. t. 819. Gærtn. t. 90.—Class and

order, *Dioecia Polyandria*. Nat. Ord. *Amentaceæ*, Linn. Juss.

Gen. Ch. Male, *Cal.* Common catkin oblong, loosely imbricated, cylindrical, composed of oblong, single-flowered, flat scales, torn at the margin. *Cor.* Petals none. Nectary of one leaf, turbinate and tubular at the base, terminating upwards in an ovate oblique border. *Stam.* Filaments eight, rarely 16 or 20, short; anthers short, quadrangular, large.

Female, on a separate plant, *Cal.* and *Cor.* as in the male. *Pist.* Germen ovate, pointed, superior; style scarcely any; stigma in four, rarely eight, oblong segments. *Peric.* Capsule ovate, of two cells and two valves, which are at length reflexed. *Seeds* numerous, ovate, winged with capillary down.

Ess. Ch. Male, Calyx the scales of a catkin; torn. Nectary turbinate, oblique, entire. Stamens eight or more.

Female, Calyx and Corolla like the male. Stigmas four or eight. Capsule superior, with two cells and two valves. Seeds winged with down.

Of this important genus five species only are given by Linnæus in his *Species Plantarum*; Willdenow has thirteen. Four are natives of Britain. All Willdenow's species are mentioned in the new edition of Hort. Kew. as cultivated in Britain; and indeed were adopted by him from the former edition of that work, in which the exotic ones were first determined. They are all lofty trees, of quick growth and ample shade; their wood, though not of prime value for hardness or solidity, is valuable for many purposes. The parts of fructification afford clearer specific distinctions in our English Poplars, than any given previous to the publication of *Fl. Brit.*, but the exotic ones have not, as yet, been sufficiently examined in this particular.

P. alba. Great White Poplar, or Abele tree. Linn. Sp. Pl. 1463. Willd. n. 1. Ait. n. 1. Engl. Bot. t. 1618. Matth. Valgr. v. 1. 123. Camer. Epit. 65.—Leaves roundish, somewhat heart-shaped, lobed, and toothed; downy and very white beneath. Female catkins ovate. Stigmas four.—Native of rather moist woods and hedges, or mountainous thickets, in most parts of Europe, flowering in March. The leaves are fully expanded in May or June. *Root* creeping, throwing up copious young plants. *Tree* large, with a smooth bark, and horizontal branches. *Leaves* alternate, on longish downy stalks; their upper side dark-green, smooth and veiny; the under snow-white with dense soft cottony down. On young luxuriant branches the *leaves* are most deeply lobed, and almost palmate. *Stipulas* on such branches linear-lanceolate, toothed. *Male catkins* long, hairy. *Anthers* violet, eight, twelve, or twenty to each flower. *Female catkins* ovate, but an inch in length, with rather smaller scales. *Stigmas* four, linear, all equally spreading, pale yellowish-green. The wood is white, soft, but tough and close-grained.

P. canescens. Common White, or Grey, Poplar. Fl. Brit. n. 2. Engl. Bot. t. 1619. Willd. n. 2. Ait. n. 2.—Leaves roundish, deeply waved, toothed; grey and downy beneath. Female catkins cylindrical. Stigmas eight.—Native of wet ground in England, France, and Germany; sometimes also found on open elevated spots, where the soil is loamy. This is a taller and more handsome tree than the foregoing, with a beautiful fatty bark. The wood is firmer, being of slower growth, and makes good floors, having the valuable property of not catching fire like deal. The *leaves* are much less white, and less deeply cut or lobed than the *alba*: and the longer female *catkins*, with eight *stigmas* to each flower, afford a decisive specific character.

P. tremula.

P. tremula. Aspen, or Trembling Poplar. Linn. Sp. Pl. 1464. Willd. n. 4. Ait. n. 4. Engl. Bot. t. 1909. (*P. Lybica*; Ger. Em. 1487. Matth. Valgr. v. 1. 125. Camer. Epit. 67.)—Leaves nearly orbicular, toothed, smooth on both sides. Footstalks compressed. Young branches hairy. Stigmas four, auricled at the base.—Native of rather moist woods, as well as of various other situations, throughout Europe, flowering in March. The young suckers are hairy, but no part of the tree is hoary. The long compressed footstalks cause the leaves to tremble with every breath of wind. Catkins two inches long, very hairy. Stamens eight. Stigmas four, erect, crimson, with a pair of reflexed auricles at the base.—The wood is white, soft, light, of a fine grain. Beavers are said by Linnæus to be very fond of the bark.

P. nigra. Black Poplar. Linn. Sp. Pl. 1464. Willd. n. 7. Ait. n. 7. Engl. Bot. t. 1910. Ger. Em. 1486. Matth. Valgr. v. 1. 124.—Leaves deltoid, pointed, serrated, smooth on both sides. Catkins cylindrical, lax. Stigmas four. Common in low woods about the rivers of Europe, flowering in March, but it will, like the rest, grow on a dry gravelly soil. This species throws up no suckers. The tree is large and spreading, with a tough close-grained wood. Footstalks but half the length of the smooth deep-green serrated leaves. Catkins long, lax, and hairy. Stamens usually eight; Leers says sixteen. Stigmas four, awl-shaped, without any appendage.

Such are our native species.

P. dilatata, Willd. n. 8. Ait. n. 8, is the Lombardy, or Po, Poplar, so commonly cultivated, and now so abundant in England, though the first plant was brought from Italy, by lord Rochford, in his travelling carriage, hardly fifty years ago. The leaves of this are very near the *nigra*, but the upright growth of the tree, at least till it attains a considerable height and age, gives it a very different aspect. The fructification requires examination. There is of course but one sex in England, but this, if we recollect right, is fortunately the female, where a specific difference is most to be expected.

P. monilifera, Willd. n. 9. Ait. n. 9. Canadian, or Berry-bearing, Poplar, is a very hardy tree in this country, valuable for planting in exposed situations on a poor sandy soil; but the down of the seeds is a great nuisance near houses, as it sticks to clothes and furniture in a most troublesome manner. Hence the male trees should be selected for planting.

P. balsamifera, Linn. Sp. Pl. 1464, Tacamahac tree, figured in Pallas's Fl. Ross. v. 1. t. 41, is planted in gardens, chiefly for the balsamic fragrance of its buds and young leaves.

POPULUS, in Gardening, contains plants of the hardy deciduous kind, of which the species cultivated are, the white poplar (*P. alba*); the trembling poplar tree, or aspen (*P. tremula*); the black poplar tree (*P. nigra*); the Lombardy or Po poplar tree (*P. dilatata*); the common Tacamahaca poplar tree (*P. balsamifera*); the heart-leaved Tacamahaca poplar tree (*P. candicans*); the smooth poplar tree (*P. lævigata*); the Canadian poplar tree (*P. monilifera*); the Athenian poplar tree (*P. græca*); the various-leaved poplar tree (*P. heterophylla*); and the Carolina poplar tree *P. angulata*.

Of the first sort there are two varieties; the common white poplar, and the great white poplar, or Abele. In the first, the leaves are rounder, and not much above half the size of those of the latter; and the shoots of the latter are paler, the catkins are larger, and the down of the seeds whiter and longer.

In the latter the leaves are large, and divided into three, four, or five lobes, which are indented on their edges; they are of a very dark colour on their upper side, and very white and downy on their under, standing upon footstalks, which are about an inch long: the young branches have a purple bark, and are covered with a white down, but the bark of the stem and older branches is grey. In the beginning of April the male flowers or catkins appear, which are cylindrical, scaly, and three inches long, and about a week after come out the female flowers on catkins, which have no stamina like those of the male. Soon after these come out, the male catkins fall off, and in five or six weeks after, the female flowers will have ripe seeds inclosed in a hairy covering, when the catkins will drop, and the seeds be wafted by the winds to a great distance. According to Mortimer, the best sort comes from Holland and Flanders. Hence in some places it is called Dutch beech.

The fourth sort has been esteemed by some as no more than a variety; and indeed it can scarcely be considered as a distinct species. It has been stated in Mr. Young's Annals, that the Italian poplar is fit to cut for building uses in twelve years, and that at eight years' growth they are forty feet high. For rafters, small beams, studs, boards, &c. it is very durable.

The peculiar use of it in this country has hitherto been for ornamental plantations, and covering unsightly buildings. To the latter purpose its upright close conical mode of growing, with its feathering very readily down to the very ground, particularly adapts it. The conic form of it, as a deciduous tree, is peculiar. Among evergreens we find the same character in the cypress; and both trees in many situations have a good effect. One beauty the Italian poplar possesses which is almost peculiar to it; and that is the waving line it forms when agitated by wind. Most trees in this circumstance are partially agitated; one side is at rest, while the other is in motion; but the Italian poplar waves in one simple sweep from the top to the bottom, like an ostrich-feather on a lady's head. All the branches coincide in the motion; and the least blast makes an impression upon it, when other trees are at rest. Although this tree sometimes has a good effect, when standing single, it generally has a better when two or three are planted in a clump.

Of the fifth sort there are varieties, with much wider leaves; the Daurian, with a longer ovate leaf, more like this sort; and an Altaic variety, with a lanceolate leaf. In Siberia the trunk is straightish, not tall, covered with an ash-coloured bark; the wood reddish, closer, and a little harder than in the common poplars. The branchlets in the Altaic tree are more slender, and rod-like; in the Daurian thick, short, knobbed, and wrinkled, with a yellow skin sometimes of a very deep colour; the leaves in the rod-like variety ovate-acuminate, in the Altaic commonly lanceolate; in the common Daurian ovate and thicker, so as to be in a manner coriaceous; in both very sharp, serrate, quite smooth, shining as if varnished, deep green above, pale underneath; aments terminating, thick, the female ones ripening in June; containing ovate thick rugged capsules, subcylindric with the receptacle, scarcely peduncled.

Method of Culture.—All the sorts are readily increased by cuttings, layers, and suckers.

The planting of the cuttings is the most expeditious mode of raising all these trees, as they grow freely without any trouble, when made either from the young year-old shoots, a foot and a half in length, and planted a foot in depth, or large truncheons of two, three, or more years growth, from about a yard to five or six feet long, planted in moist places: though

PORCELAIN.

which is the whitest, and whose stains are the greenest, being always chosen for this purpose. The manner of preparing the oil is thus: the petunses, being washed, undergo the same preparations as for making the squares; excepting that the matter of the second urn is not put in moulds, but the finest part of it taken to compose the oil. To a hundred pounds of this matter they cast a mineral stone, called *shekau*, or *kekao*, resembling our alum; this stone is first heated red-hot, and thus reduced in a mortar into an impalpable powder; and serves to give the oil a consistence; which, however, is still to be kept liquid.

The oil of lime makes the fourth ingredient; the preparation of which is much more tedious and circumstantial. They first dissolve large pieces of quick-lime, and reduce it to a powder, by sprinkling water on it; on this powder they lay a couch of dry fern, and on the fern another of the flaked lime, and thus alternately, till they have got a moderate pile; which done, they set fire to the fern; the whole being consumed, they divide the ashes that remain on new couches of dry fern; setting them on fire as before. And this they repeat five or six times successively, or even more; the oil being still the better, as the ashes are oftener burnt.

In the annals of Feou-learn it is said, that instead of fern they anciently used the wood of a kind of medlar-tree; and that it was this gave the ancient porcelains that admirable hue, which the moderns cannot come up to for want of that wood. But this is become scarce in the country, and is no longer used. It is certain, however, the quality of the fern and lime contribute very much to the goodness of the oil.

A quantity of these ashes of fern and lime is now thrown into an urn full of water; and to a hundred pounds of ashes is added a pound of *shekau*, which dissolves therein. The rest being performed after the same manner as in preparing the earth of the petunses, the sediment found at the bottom of the second urn, and which is to be kept liquid, is what they call the *oil of lime*; which the Chinese esteem as the soul of the former oil, and which gives the porcelain all its lustre.

This oil is easily sophisticated by adding water to increase the quantity; adding, at the same time, proportionably of the same *shekau* to maintain the consistence. Ten measures of oil of petunse usually go to one of lime. To have the mixture just, the two oils should be equally thick.

PORCELAIN Vessels, forming of. The first thing is to purify the petunse and kaolin; which, for the first, is done after the manner already described in preparing the squares. For the second, as its softness makes it dissolve easily, it is sufficient, without breaking it, to plunge it in an urn full of water in an open basket. The dregs that remain are perfectly useless, and are emptied out of the work-house when a quantity is got together.

The work-houses are properly vast yards walled round, with sheds and other conveniences for the workmen to work under; as well as other buildings for them to live in. It is almost inconceivable what number of persons are employed in these works; there being scarce a piece of porcelain but passes through above twenty hands, before it comes to the painter's work-house; and above sixty before it be brought to perfection.

To make a just mixture of petunse and kaolin, regard must be had to the fineness of the porcelain to be made; for the finer porcelains, they use equal quantities; four parts of kaolin to six of petunse, for moderate ones; and never less than one of kaolin to three of petunse, for the coarsest.

The hardest part of the work is the kneading and tewing the two earths together; which is done in a kind of large basons, or pits, well paved, and cemented, in which the work-

men trample continually with their feet, relieving one another, till the mass be well mixed, grow hard, and become of the consistence required to be used by the potter.

The earth, when taken out of the basons, is kneaded a second time, but piece-meal, and with the hands, on large slates for the purpose; and on this preparation, in effect, it is, that the perfection of the work depends; the least heterogeneous body remaining in the matter, or the least vacuity that may be found in it, being enough to spoil the whole. The smallest grain of sand, nay, sometimes a single hair, shall make the porcelain crack, splinter, run, or warp.

The porcelain is fashioned or formed either with the wheel, like our earthen ware, or in moulds. See POTTERY.

Smooth pieces, as cups, urns, dishes, &c. are made with the wheel. The rest, *i. e.* such as are in relievo, as figures of men, animals, &c. are formed in moulds, but finished with the chissel.

The large pieces are made at two operations; one half of the piece is raised on the wheel by three or four workmen, who hold it till it have acquired its figure; which done, they apply it to the other half, which has been formed in the same manner; uniting the two with porcelain earth, made liquid by adding water to it, and polishing the juncture with a kind of iron spatula.

After the same manner it is that they join the several pieces of porcelain formed in moulds, or by the hand; and after the same manner they add handles, &c. to the cups, and other works formed with the wheel.

The moulds are made after the manner of those of our sculptors; *viz.* of divers pieces, which severally give their respective figure to the several parts of the model to be represented; and which are afterwards united to form a mould for an entire figure. The earth they are made of is yellow and fat, dug out of its proper quarries, of which there is abundance about King-te-tching. It is kneaded like potters' earth, and when sufficiently mellow, fine, and moderately dry, beating it stoutly, they form it into moulds, according to the works required, either by hand, or on the wheel. These moulds are sold very dear, but they last a long time.

All the works made in moulds are finished by the hand, with several instruments proper to dig, smooth, polish, and to touch up the strokes that escape the mould; so that it is rather a work of sculpture than of pottery. There are some works on which relievos are added, ready made, as dragons, flowers, &c. others that have impressions in creux; which last are engraven with a kind of puncheons. In the general, all porcelain works are to be sheltered from the cold, their natural humidity making them liable to break when they dry unequally.

To conceive the number of hands each piece of porcelain passes through before it is perfect, we shall close this article with what F. d'Entrecolles instances of a common tea-cup, before it be fit for the painter. The cup begins with the potter, who has the management of the wheel, where it acquires its form, height, and diameter. This operator has only three farthings sterling for a plate furnished with twenty-six cups; accordingly, they go out of his hands exceedingly imperfect, especially towards the feet, which are only unformed lumps of earth, to be afterwards cut with a chissel, when the cup is dry. When it comes from the wheel, the cup is received by a second workman, who fits it to its base. A third takes it immediately from him, and applies it on a mould, to bring it to its true form. This mould is on a kind of lathe. A fourth workman polishes the cup with a chissel, especially about the edges; and brings it to the thinness necessary to make it transparent; in doing which, he moistens it

PORCELAIN.

it from time to time, lest its dryness should make it break. When of its proper thickness, another workman turns it gently on a mould, to smooth its inside; taking great care that it be done equably, lest any cavity be formed, or it warp. Other workmen add some ornaments in relieve; others, impressions in creux; others, only handles; as the quality of the cup requires. At last, they round and hollow the foot on the inside with the chissel; which is the function of a particular artist, who does nothing else.

This multiplicity of workmen is so far from retarding the work, that it is found, by experience, to go on the faster for it; as well as to be the better done; each workman, by a continual attention to the same thing, becoming very dexterous at it; besides saving the time of changing instruments, &c.

PORCELAIN, Painting of. The Chinese painters, especially those that meddle with human figures, our author observes, are all bad workmen; he adds, that the defect is scarcely any where so sensible as in the whapey, or porcelain painters, among whom, setting aside flowers and landscapes, which are sometimes tolerable, the greatest masters are not to be compared to ordinary apprentices among the Europeans, for the beauty and justness of design. But it is otherwise with the colours these whapey use; which are so exceedingly lively and brilliant, that there are but little hopes our workmen should ever come to vie with them.

The painting work is distributed among a great number of workmen, in the same laboratory: to one it belongs to form the coloured circle about the edges of the porcelain; another traces out flowers, which another paints: this is for waters and mountains alone; that for birds and other animals; and a third for human figures.

There are porcelains made of all colours: both with regard to the grounds, and to the representations upon them. As to the colour of landscapes, &c. some are simple; such are all blues, which are those most usually seen in Europe; others are mixed up of several tints; and others, again, are heightened with gold.

The Chinese, for a great many ages, used only white porcelain. The first colour they employed was blue, and after that they came into the use of all the rest. Their ancient blues were prepared by themselves from a kind of lapis lazuli; but we now supply them with the smalt so much cheaper, that it is no longer worth their while to make it themselves. They used to prepare this only by giving a gentle calcination to the stone, and then beating it to powder, and grinding it to the utmost fineness in mortars of unglazed porcelain ware, with pestles of the same.

The fine deep blue of the old porcelain ware of China is much valued by the curious; and it is much lamented, that the same colour is not used at this time. The art seems at present to be lost; but perhaps it might be recovered by trials.

It is certain that the Chinese have cobalt among them, and very probably they used a blue colour prepared from this, before they had any commerce with us: notwithstanding all the conjectures about their materials for colouring, this seems the most probable substance; and there is a way of preparing a colour from this, much superior to that now in use, which we call smalt.

Cobalt is a mineral containing arsenic, and a blue vitriifiable earth. The common way of preparing smalt is, by roasting this cobalt in a reverberatory fire. This disposes it to vitrify, and drives off the arsenic it contains in fumes, which, collected at the top, form true flowers of arsenic. It is very certain, however, from experiments, that if this arsenic could be preserved in the cobalt, the smalt would be

of a much finer colour; for there are some kinds of cobalt which yield smalt without previous roasting; and as the arsenic is in a great measure contained in these, the smalts are much finer coloured.

Arsenic added to smalt, while in fusion, greatly exalts its colour also; and there is a way of procuring smalt from cobalt without fire, only by dissolving it in an acid, and precipitating that solution with oil of tartar. The smalt thus precipitated to the bottom, is of a much finer colour than any prepared by fire; but it is much more expensive, and prepared in less quantity. It is very possible that the Chinese might have the art of making this kind of smalt before they knew us, and that to this was owing the fine blue of their porcelain ware: but when we trafficked with them, and they purchased smalt so much cheaper of us than they could make it themselves, they naturally discontinued the manufacture of their own finer kind, without considering how greatly inferior the colour was which the other yielded. If this be the case, it will be easy to revive this art, and the adding the true old china blue to our European manufactures, in imitation of porcelain, may give them a value which they have not at present.

The red, which the Chinese use, is made of our green vitriol, or common copperas, which they call *tfa-fan*. They put about a pound of this into a crucible; and lute on this another crucible inverted: this last has a hole cut in the top, which they keep covered or open at pleasure. They set this crucible in a furnace of bricks, so contrived, as to throw all the flame upon the lower vessel, in the way of our chemists' reverberatory furnaces. They make a large fire of charcoal all round it, and observe the hole at the top; for so long as there ascend thick black fumes through that, the matter is not sufficiently calcined. They watch the going off of this fume, and when there appears in the place of it a fine and thin cloud, they take away the crucible, the matter being then sufficiently burnt. They try this, however, by taking a little out, and examining the colour; if it is not sufficiently red, they let it remain longer in the fire. When they find that it is of a good colour; they take away the fire, and leave the vessels to cool; this done, they find a cake of red matter at the bottom of the crucible, and a quantity of a finer powder about its sides. They keep these separate, the latter being the purest, the finest, and the brightest colour.

One pound of copperas affords about four ounces of this colour, and this is the red which they manage in different shades, and vary so much. See *Blown RED*.

The Chinese have also a white colour, which they use in their figures painted on the china: the ware itself is naturally white, and the varnish, or oil of stone, is a great addition to its whiteness all over. But they have yet a way of making a much brighter and finer white than these, as may be seen in most of the fine china-ware, where there is any white in the figures. This white is made in the following manner: they collect on the shores of their rivers a sort of flint or agate, which is of a whitish hue, without veins, and tolerably transparent. It approaches very much to the nature of crystal, and probably crystal may be found to supply its place with us. They calcine this stone to a white powder, and to every ounce of this, when ground in their porcelain mortars to an impalpable fineness, they add two ounces of ceruss in fine powder: this they mix with the varnish, and lay on in the common way of other colours. This white mixture serves not only for the colouring white, but it is the basis of several other of those beautiful colours which we see on the china-ware, and which our manufacturers have been often perplexed what to make of. Their green colour

PORCELAIN.

is made of copper rusted with acid ; and their fine deep violet colour is made of this green, by adding to it a due proportion of this white. It is not to be supposed that this effect is produced according to the common laws of mixing colours among our painters, for then the white and green would only make a paler green. But copper being a metal that as well gives a fine blue as a fine green, according to the nature of the substances it is mixed with, the white in this case alters the very nature of the green, and converts it into that fine and deep violet blue, which we may draw from copper by means of any of the volatile alkalies, such as spirit of sal ammoniac, spirit of hartshorn, spirit of urine, or any the like liquor. The workmen know how to bring this blue to any degree, by putting in different proportions of the two colours. There is not any admixture of them, that will not produce a blue of some kind ; but always the more of the green colour is used, the deeper the blue will be, and the less the paler. The yellow is made of an admixture of several drachms of this white, and three drachms of copperas, or more if they desire the colour to be deeper.

Most of these colours are mixed with gum water, for application ; with a little salt-petre, sometimes cerufs, or copperas, but more usually copperas alone, being first dissolved in the water. Indeed for porcelain, that are to be quite red, the colour is usually applied with oil ; *i. e.* with the common oil of the porcelain, or another made of the white flints.

These colours are laid upon the vessels when they have been once baked, but they do not appear till the second baking is over in their proper shades or tinges, and sometimes scarcely at all.

The black china called *umiam*, is much esteemed in the East, and particularly when it is ornamented with gold ; this colour looking better with that ornament than any other. The black is always laid on when the porcelain is first dried, and is prepared by mixing three ounces of the fine deep blue, with seven ounces of that fine varnish which they call *oil of stones*. This admixture gives a fine deep black ; but the proportion is varied, as the colour is designed to be more or less deep. When the colour is thoroughly dry, the vessels are baked, and when this is done, the gold is laid on, and the whole is baked again in a particular furnace made for this purpose.

The gold on this ware is never laid on alone, but managed in the following manner: they grind it in water to a fine powder, and leave it to dry in the shade ; they then mix with every ten grains of gold one grain of cerufs, and incorporating the whole with gum-water, they lay it on in the manner of other colours. See *GILDING of China-ware*.

If they would have the black degenerate into blue, they need only add less of the blue, and a little of the cerufs and agate white before described. They have two peculiar ways of applying the red, besides the common one, both which require a nice workman, and make the ware come very dear. They call one of these oils *red*, and the other *blown red*, which is very rare and of great price.

There is likewise a kind of marbled porcelain, called by the Chinese, who are very fond of it, *tsou tchi*.

It is generally plain white, sometimes blue, and has exactly the appearance of a piece of china which had been first broken, and then had all the pieces cemented in their places again, and covered with the original varnish. The manner of preparing it is easy, and might be imitated with us. Instead of the common varnish of the china-ware, which is made of what they call oil of stone and oil of fern mixed together, they cover this with a simple thing made

only of a sort of coarse agates calcined to a white powder, and separated from the grosser parts by means of water, after long grinding in mortars. When the powder has been thus prepared, it is left moist, or in form of a sort of cream, with the last water that is suffered to remain in it, and this is used as the varnish. Our crystal would serve fully as well as these coarse agates, and the method of preparation is perfectly easy.

The occasion of the singular appearance of this sort of porcelain is, that the varnish never spreads evenly, but runs into ridges and veins. These often run naturally into a sort of mosaic work, which can scarcely be taken for the effect of chance. If the marbled china be desired blue, they first give it a general coat of this colour, by dipping the vessel into a blue varnish ; and when this is thoroughly dry, they add another coat of this agate-oil. See *PARTY-China*.

There are several other kinds of porcelain ; but they are such as are rather for curiosity than use : the prettiest are the magic porcelains, whose colours only appear when filled with water, or some other clear liquor. These are made double ; the outside is white, and all laid out in compartments ; the inside is a solid cup of coloured porcelain ; though the cup is sometimes of glass, which has a better effect than porcelain.

The Chinese called this sort of china-ware *kiatsem*, that is to say, the concealed blue china.

The art is now in a great measure lost ; but there may be some guess made as to the manner in which it might be done at this time. The vessels which are to be made in this manner must be very thin : the colour must be laid on in the form of fish, or other animals or figures, on the inside, after the vessel has been once baked. After this colour has had time to dry, the inside of the vessel must have a second coat of the same earth, or stone-ware, of which the vessel is made ; and over this a varnish of the common kind. The consequence of this will be, that the figures of the fish, in a very strong colour, will be buried between two coats of the ware, which together form a complete vessel. The outside is then to be ground down almost to the figures, and when they begin to appear, a new coat of the varnish must be laid over this. The figures will then be obscure, and scarcely, if at all, perceivable ; but on filling the vessel with water, the transparency of the sides will be taken off, and the liquor will make a sort of foil behind, which will throw out the figures of the fish. This might be done in any ware tolerably clear and transparent. The porcelain of China would succeed better with it ; but the pains and nicety required are too great, and all the attempts lately made by them have miscarried.

The Chinese make a great variety of figures on the surfaces of the vases of white china-ware, and there is one kind of this greatly in esteem among them, in which there are flowers and other figures ; yet the surface is quite smooth, and the substance extremely thin. The manner of making it is this ; they first form the vessel of the finest materials, as thin as they can ; then, when they have polished it, inside and out, at the wheel, they put into it a stamp of its own shape, but cut with all these figures : they press this down so firmly on the yet moist vessel, that the impression is received in a very perfect manner ; and if the shape of the vessel be at all hurt, they take it into the wheel again to restore it. They then finish it with the knife and scissars ; and when they have made it as perfect as can be, they cover it with the fine white varnish within and without. This fills up all the cavities of the impression, and gives a perfectly smooth and even surface ; yet the thickness of this varnish

PORCELAIN.

in the traces of the figures gives it a different white, and the whole figures are as finely and accurately seen, as if painted on the outside. This is an artifice that might easily be brought to bear among us, and several of our finer wares would make a pretty figure with it.

There are many things practised by the Chinese in their colouring and forming the several kinds of porcelain, which may be well brought into use among us, and give a new value to our own wares, even though we should never arrive at their art of making the thing itself. One kind of colouring easily introduced among us, would be what they call *hoan ton hoan*. This produces vessels of great beauty and price, and is done in this manner. The matter of which the vessels are made, for this purpose, need not be fine; they usually take any of the common vessels baked, without having been varnished, and consequently simply white, and without lustre. When these are intended to be of one simple colour, they need only be plunged into a liquid varnish of oil, as the workmen there call it, coloured with such ingredients as will strike the most lively tinges; but if it is to be coloured in compartments, as is usually the custom with this sort of china, it is to be done by the pencil. The usual way is to paint these in pannels, one green, another blue, and so on, and they make a very agreeable appearance. There requires no more to this, than the laying on the colours tolerably thick with a large pencil; but if the pictures of animals and plants are to be given, they are to be done with the most permanent colours, and the vessel being again well baked, becomes very beautiful.

The Chinese, who are deceivers in every thing, find the way of cheating very much in regard to this sort of china-ware. They paint the flowers of plants, and some parts of the birds, &c. in very bright colours, after the vessel has been baked. Vermilion is a fine colour, which they often add on this occasion; but they cannot use this before the baking, because it would be destroyed by the fire. These colours which are laid on afterwards cannot last, but soon rub off in the wiping, or using the things; the others last for ever; for they are laid on with the greatest heat of all, the vessels being put into the same furnaces to lay on these, as the other things are baked in for the first time.

Salt-petre, and powder of flints, are generally the things added to the colours thus laid on, to make them penetrate, and run properly. Thus, for the fine deep violet colour, which makes the greatest figure of all others on this ware, they mix together equal quantities of the fine azure, the powder of flints and salt-petre, all first powdered separately till perfectly fine; this is tempered with water, and then laid on with a pencil, and though it looks rough at first, it comes out of the furnace of as beautiful a glossy hue as any thing can be conceived. The yellow is made by mixing together three ounces of cerufs, and three ounces of powdered flints, and adding three, four, or more drachms of the red copperas, till the whole is of the proper degree of colour.

The white is composed only of powder of flints and cerufs, with a small admixture of the salt-petre, or it will succeed tolerably well without. These are all the particulars necessary to be observed for the making a sort of porcelain of great beauty, in which the nature of the ware itself is not concerned; so that it seems easy to imitate it with any of our own wares. *Obs. sur les Coûtumes de l'Asie*, p. 320, &c.

The several kinds of porcelains above-mentioned, being quite painted, with their several colours, and all the colours dry, are to be polished, to prepare them to receive the oil or varnish; which is done with a pencil of very fine feathers,

moistened with water, and passed lightly over, to take off even the smallest inequalities.

The oiling or varnishing is the last preparation of the porcelain, before it be carried to the oven: this is applied more or less thick, and seldomer or oftener repeated, according to the quality of the work. For thin fine porcelain, they give two very thin couches: to others one; but that one equivalent to the other two. There is much art in applying the varnish, both that it be done equally, and not in too great quantity. The couches on the inside are given by asperision, *i. e.* by casting in as much varnish as is necessary: those on the outside by immersion, or by plunging the pieces in a vessel of oil.

It must be observed, that the foot is not yet formed, but continues in a mere mass, till the work has been varnished: it is at length finished on the wheel, and when hollowed, a little circle is painted in it, and sometimes a Chinese character. This painting being dry, the foot is varnished, and the work now carried to the oven to be baked.

The varnish they lay on is so thick, that it often hides the colours, till the baking afterwards brings them out again: this is the case with the fine deep blues; we see none on the best china; it is all hid under the coat of white, and the vessel appears plain, till it has passed through the fire again; but then the colour appears deeper than when at first laid on. See *HOACHE*.

The china varnishes have been always famous; the manner of making which is said to be as follows: Take crude varnish, sixty ounces; common water, the same quantity: mix them well together till the water disappears; afterwards put this into a wooden vessel five or six palms long, and two or three broad; mix them together with a wooden spatula, for a whole day in the summer's sun, for two days if in the winter, and afterwards keep it in an earthen vessel, covered with a bladder. The water will not separate again: this is called the sun varnish.

The oil of wood, called by the Portuguese *azeile de pao*, is made in the following manner: Take twenty ounces of that oil, which they call oil of wood; and ten drachms of the oil of the fruit; boil these a little together, and the oil will look yellow; then let it cool, and add to it five drachms of quick-lime powdered. To make the first grounds, called *camiseca*, take swine's blood and quick-lime powdered, of each an equal quantity; spread this mixture upon the wood, and when it is dry, smooth it with pumice-stones.

To make the black varnish: Take the varnish prepared in the sun, sixty ounces; stone black alum (supposed to be a sort of copperas) dissolved in a little water, three drachms; and seventy drachms of lamp oil, called by the Portuguese *azeile de Candea*. These things are all to be mixed together in a wooden vessel, putting the lamp oil in at twice, and stirring the whole together with a wooden spatula.

The pitch-coloured varnish is made in the following manner: Take oil of wood, crude, forty drachms, called *da pao*; of the lamp oil, called *da Candea*, crude, forty drachms; mix them together in the sun in a wooden vessel, in the same manner as the common varnish and water are ordered to be mixed in the first process.

To make the red varnish: Take ten drachms of cinnabar, twenty drachms of prepared varnish, and a little lamp-oil; mix them all together.

To make a yellow varnish: Take of the yellow colour ten drachms, prepared varnish thirty drachms, a little lamp-oil; mix all together.

To make the varnish of a musk colour: Take of the red varnish ten drachms, and of the black varnish four drachms; mix them well together. *Phil. Transf. N^o 261. p. 524.*

PORCELAIN.

These are the accounts sent to the great duke of Tuscany by the Jesuits in China. Dr. William Sherard communicated them to the Royal Society; and to render the accounts useful to the world, he presented them with the several substances mentioned; these are deposited in the museum of the society, and may serve as instructions to all who are curious in this art.

The Chinese have of late years discovered a new kind of varnish for their ware: they call this *tsékinyeou*, that is to say, the brownish gold varnish; it is of the colour of the brown images, or of what we call coffee colour. The novelty of this has made it much esteemed: it is made in the manner of all their other varnishes, by dissolving the finer part of an earthy substance in water.

The substance which they make it of is a common yellow earth: this they dissolve in water, and letting the coarse parts settle, they pour off the yet thick liquor, and what afterwards subsides from this is the pure and fine part, which they keep in form of a soft paste, or thick cream. They use this only to the thinnest and most delicate porcelain ware.

The manner of using it is this: they mix a quantity of this fine sediment with so much water as renders it thin and liquid, like the common varnish: this and the common kind are to be used together, so that care must be taken that they are nicely of the same degree of thickness: this the workmen try by dipping a petunse or brick of their earth into both, and seeing which comes out most covered; that which lies on the thickest is to be diluted with more water, or the other to be heightened with more of the earth, to bring them to the same standard. They are both judged to be sufficiently liquid when they enter the pores of the petunse. They then mix some of the oil of fern ashes and lime along with the brown varnish, and add as much of this mixture to the common varnish as they find upon trial will give such a colour as is required. The common proportion for the brown colour most esteemed at present, is two pints of the brown varnish to eight pints of the common; and to four pints of this mixture they add one pint of the varnish, or oil of fern. It might puzzle a stranger to their terms, to understand what these people meant by oil; but it is a word with them in use for any thing liquid; and they call all their varnishes so, though made of the powders of earths and stones mixed with water. They apply this varnish to the vessels by dipping them into it, and so completely covering them inside and out before they put them into the oven; and the baking gives a great brightness to the colour. This is the nicest part of the whole manufacture of the porcelain, and other wares of that kind.

The varnishes used by the Chinese are two; the one they call *oil of STONES*, the other *oil of FERN*; which see. They mix these together, and with great caution and delicacy apply them to the vessels all over equally, with a steady hand and a fine pencil.

PORCELAIN, Baking or Nealing of. There are two kinds of ovens used in baking porcelain; large ones, for works that are only used to come to the fire once, which is the common way; and small ones, for such as require a double baking.

The large ones are two Chinese fathoms deep, and almost four wide. They are formed of a mixture of three earths; one of which, yellow and common, makes the basis; the two others are scarcer, and dug out of deep mines, in which people can only work in winter. One of them, called *loutou*, is a very strong stiff earth; the other, *youtou*, oily.

The sides and roof of the ovens are so thick, that one

may lay the hand on them, when the fire is at its height, without danger of burning. At the top of the dome, which is in form of a tunnel, is a large aperture, to give vent to the flames and smoke, which mount up incessantly, as soon as fire is once set to the oven: beside the principal aperture, there are four or five small ones around; which, by being opened and shut, serve to augment or diminish the heat; like the holes in the chemists' furnaces, called *registers*. The hearth, which takes up the whole breadth of the oven, is placed in front, precisely against the opening of the door, and is two or three feet deep, and two broad; people passing over it on a plank, to go into the furnace to range the porcelain. As soon as the fire is lighted, the door is walled up, only leaving an aperture for the conveyance of wood. Lastly, the bottom of the oven is covered with sand, in which part of the first porcelain cases are buried. The oven itself is usually placed at the extremity of a long, narrow vestibule, which serves in lieu of bellows; the cold air and wind being thus driven directly in the face of each oven.

Each piece of porcelain of any note, is disposed in the furnace, in its peculiar separate case, or coffin. Indeed, as to tea-dishes, &c. the same case serves for several. The cases are all of the same matter with the oven; they have no lids, but serve each other mutually; the bottom of a second case fitting into the aperture of the first; and thus successively to the top of each column. Each coffin, which is usually of a cylindrical form, that the fire may communicate itself more equably to the porcelains inclosed, has, at bottom, a little lay of very fine sand, covered over with dust of kaolin, that the sand may not stick to the work; and care is taken, that the porcelain may not touch the sides of the case. In the larger cases, which hold the small pieces, they leave the middle vacant, in regard porcelains placed there would want the necessary heat. Each of these little pieces is mounted on a little mass of earth, of the thickness of two crowns, covered with powder of kaolin.

F. d'Entrecolles observes, that the porcelains are put in cases to prevent any diminution of lustre from the too violent effect of a naked fire; adding, that it is owing to those thick veils, that the beauty, or, as he calls it, the complexion of the porcelains, is not tanned by the heat of the fire.

As fast as the cases are filled, a workman ranges them in the cavity of the furnace; forming them into piles, or columns, of which those in the middle are, at least, seven feet high: the two cases at the bottom of each column are left empty, because being partly sunk in the sand, the fire has the less effect on them; and, for the same reason, the uppermost one is left empty. In this manner is the whole cavity of the oven filled with columns, excepting that part precisely under the grand aperture. In ranging the cases, they observe always to place the finest piles of porcelain in the centre, the coarsest at the bottom, and those that are high-coloured, and consist of as much petunse as kaolin, and in which the worst oil is used, at the mouth.

These piles are all placed very near one another, and are bound together at top, at bottom, and in the middle, by pieces of earth, in such manner as that the flame may have a free passage among them, and insinuate equally on all sides; in which a great part of the workman's art lies, and on which the perfection of the porcelain much depends. Another thing to be observed is, that an oven must never be set altogether with new coffins; but half one, half the other: the old ones at the bottoms and tops of the pile, and the new ones in the middle. Indeed it were better to have them all burnt in an oven apart, before they come to be

PORCELAIN.

be used for porcelain, as was anciently done. The cases, our author observes, are brought ready prepared from a large village on the river, a league distant from King-te-tching. Before they are burnt, they are yellow; and afterwards of a dark red.

When the oven is filled, they wall up the door, only leaving a small aperture for the throwing in of little pieces of wood, a foot long, but very slender, to keep up the fire: it is then heated by degrees for the space of a day and night; after which, two men, who relieve one another, continue to throw in wood without any intermission. To know when the porcelain is baked enough, they open one of the lesser holes of the oven, and with a pair of tongs take off the lid of one of the piles. If the fire appears very brisk and clear, and the piles equally inflamed, and especially if the colours of the porcelain, that is uncovered, dart forth a noble lustre, the coction is sufficient; they discontinue the fire, and wall up what remained of the door of the furnace.

If the oven be only filled with small porcelain, they take them out twelve or fifteen hours after the fire is extinct: if it be filled with larger, they defer opening it for two or three days. In this the modern practice differs from the ancient; in which the door was not opened till after ten days for the large pieces, and five for the small ones. One thing very surprising, and almost inconceivable, F. d'Entrecolles observes, is, that there are never found any ashes on the hearth of the oven, what quantity of wood soever is consumed. He adds another thing, which with him passes for equally strange, that the workmen employed about the furnaces, slake their thirst by continually drinking hot tea, with salt dissolved in it.

The Chinese make another kind of porcelain, which they paint and bake twice; and for this second baking they have a kind of little ovens on purpose. These ovens, when very small, are made of iron; or otherwise of a kind of bricks an inch thick, a foot high, and half a foot broad, made of the same earth with the porcelain cases. The biggest of these ovens do not exceed five feet in height, and three in diameter; and being made much in form of bee-hives, the bricks are arched a little, to form the curvity the better. The hearth is of earth half a foot high, formed of two or three ranges of bricks; and on this massive is the oven built. Around the oven, at the distance of about half a foot, is raised a shell of common bricks, joined to the oven itself by a kind of arc-boutant of earth, which serves to strengthen it. They usually build four or five of these ovens at equal distances from each other. At the bottom of the shell are holes to give air to the fire when lighted: at top is an aperture, which they cover up with a piece of the baked earth, when the porcelains are laid in the oven.

The porcelains here are not inclosed in coffins, as in the common ovens; the oven itself serving that purpose, and being so exactly closed, that they receive no other impression of the fire, but that of the heat of the charcoal disposed in the hearth, at the bottom of the oven, as well as at top of the vault, and in the interval between the oven and the shell, or brick-wall.

To prepare the porcelains for a second baking, they must have had their varnish in the common manner, and have passed the great oven: in this state they are painted with various colours, after which, without giving them any new varnish, they are ranged in piles in the little oven; setting the little ones over the larger, in form of pyramids.

The Chinese are very artful in their disposition of these, arranging them in the most compact manner, and putting

the little ones within the great ones; but great care is also necessary, that the vessels do not touch one another in the parts where they are painted, for the consequence of that would be the spoiling of both vessels, as the colours would run together. The bottom of one vessel may generally be placed on the bottom of another, though both are painted, because the rims are not painted, and they keep the painted parts from touching one another. High and narrow vessels, such as chocolate-cups, and the like, are very troublesome on this occasion. The method the Chinese workmen take with them, is this: they place a range of them, so as to cover the whole bottom of the furnace, and they cover this with a thin bed of broken china-ware, over which they place another row of the cups, and so on to the top, where they lay on no covering; they never bake any thing else with these cups, when they are of this kind of twice-baked porcelain.

This second baking is sometimes intended to preserve the lustre of the colours the better, and at the same time to give them a kind of relieve; but more usually its design is to hide defective places, by covering them over with colours; but the artifice is easily found out, by passing the hand over them.

When the workman judges his porcelains enough baked, he takes off the piece that covers the aperture; takes out the charcoal; and, when the oven is cold, the porcelain is so too.

How beautiful soever the modern porcelain may be, the taste for antiquity, which reigns in China, as well as in Europe, gives the ancient porcelain a value far above that of the modern.

It must be owned, the ancient seems finer as to the matter, more perfect as to the baking, and of a more pleasant cast, both as to the white of the ground, and the other colours; yet it is certain, the most able and discerning may be deceived in it; and there are workmen who make it their business to counterfeit the ancient porcelain, called *kutong*, in the modern.

The matter of the false *kutong* is a soft and yellowish earth, found near King-te-tching. There is nothing particular in the first part of the process, except that they are made thicker, and that they are varnished with an oil drawn from the yellow-stone, mixed with the common oil, which gives them a kind of sea-green hue. When taken out of the oven they throw it into a fatty broth, made of capons, &c., in which they boil it a second time; they then bury it in the filthiest sink they can find, for a month or six weeks, or more, according as they would give it the greater appearance of antiquity. Besides their thickness, and their colour, these false antiques resemble the true ones in this, that they do not resound when struck, nor even give the least buzz when held to the ear.

Notwithstanding the vast quantity of porcelains made in almost all the provinces of the empire of China, they still continue very dear, though not near so dear as anciently. The Chinese annals tell us of times, in which a single urn cost ninety or a hundred crowns on the spot. What chiefly occasions the extraordinary price of this commodity, especially in Europe, is, beside the great profits of the merchant in Europe, and their factors in China, that it rarely happens an oven succeeds throughout; that it is frequently quite spoiled, so that upon opening it, in lieu of fine porcelains, is found a hard unformed mass, into which both the porcelains, and their coffins, are converted, either by excess of heat, or some ill qualities in the matter.

Another reason of the dearness of porcelain is, that the ingredients it is made of, and the wood with which it

PORCELAIN.

is burnt, grow more and more scarce. One may add a third reason for the excessive price of porcelains to the Europeans; and it is this: that most of those sent to Europe are formed on new models, frequently very capricious, and difficult to succeed in; which yet for the smallest defects are turned on the manufacturer's hands; and he, not being able to dispose of them to the Chinese, because not to their taste, nor to their use, is forced to charge the porcelain he delivers the higher, to pay himself for those refused.

The art of making porcelain is one of those in which Europe has been excelled by oriental nations. However, earthen-wares have been made, for several years past, in different parts of Europe, so like the oriental, that they have acquired the name of porcelain. The first European porcelains are said to have been made in Saxony and in France; and afterwards in England, Germany, and Italy; all of which differed from those of Japan and China, but each possessing its peculiar character. The first person, who seems to have made this manufacture the object of scientific attention, was M. Reaumur; and he communicated his researches in two Memoirs to the Academy of Sciences, in 1727 and 1729. Having broken pieces of the Japanese, Saxon, and French porcelains, he examined the difference of their grains or internal structure. The grain of the Japanese porcelain appeared to him to be fine, close, compact, moderately smooth, and somewhat shining. The grain of the Saxon porcelain was found to be still more compact, not granulous, smooth, and shining like enamel. And the porcelain of St. Cloud had a grain much less close and fine than that of Japan, shining little or not at all, and resembling the grain of sugar. In order to determine their difference still farther, he exposed them to a violent heat; and found that the Japanese porcelain was unaltered by the fire, and all the European porcelains were melted. This essential difference suggested to him the most just and regular idea, that has yet been formed of the porcelain or china-ware, *viz.* that it is a half vitrified substance or manufacture, in a middle state between the common baked earthen-ware of our vulgar manufactures, and true glass. This is the essential and distinctive character of porcelain; and it is only by considering it in this light, that we are to hope to arrive at the perfect art of imitating it in Europe.

The determining the due degree of heat for the baking the china-ware, and the finding out the proper time it should remain in that heat, are two very essential points in the manufacture of this elegant ware. Perhaps our English attempts to imitate it would be brought nearer the perfection we are aiming at, by a just regard to these particulars, than by many other less material articles, about which we seem more solicitous.

This attempt is to be made on these principles in two different manners: the one by finding some appropriated matter on which fire acts with more than ordinary strength, in the time of its passing from the common baked state of earthen-ware into that of glass. The other is to compose a paste of two substances reduced to powder: the one of which shall be of force to resist a very violent fire, so as not to become vitrified in it; and the other, a matter very easily vitrifiable.

In the first case, the matter is to be taken out of the fire at the time when it is imperfectly vitrified; and in the other, the compound mass is to remain in the furnace till the one substance, which is the more easily vitrifiable, is truly vitrified; and being then taken out, the whole will be what porcelain is, a substance in part vitrified, but not wholly so.

The first method is that by which the European porcelain

has generally been made; and though that of St. Cloud, and some other places, has been very beautiful, yet it is always easy to distinguish even the finest of it from the china-ware, and the nature of the two substances appears evidently different; these owing all their beauty to their near approach to vitrification, are made to endure a long and violent fire, and are taken from it at a time when a very little longer continuance would have made them perfect glass: on the contrary, the china-ware being made of a paste, part of which is made of a substance in itself scarcely possible to be vitrified, bears the fire in a yet much more intense degree than ours, and is in no danger of running wholly into glass from it.

The two substances used by the Chinese are well known by the names of *petunse* and *kaolin*; and on examining these, it appears very evident that we have in Europe the very same substances, or at least substances of the very same nature, and capable of being wrought into a porcelain equally beautiful and fine. *Mém. Acad. Scienc. Par. 1739.* See *KAOLIN* and *PETUNSE*.

These are the two different semi-vitrifications, on one or other of which all the European manufactures have hitherto been founded; and it is easy from the knowledge of these principles to determine, on breaking a piece of the china of any of our manufacturers, by which of the two processes it is made. If it is made by seizing the half-vitrified mass of a substance, which would soon after have been wholly vitrified, then the putting it in a crucible, into an equal degree of fire, will soon turn it wholly into glass. This is the case of most of our European porcelain; but if it be made of two ingredients, the one of which is not vitrifiable, or at least not by such fires, then the matter will melt, but will not vitrify. This is the case with the Chinese porcelain, which if kept in fusion a long time, yet when cold is china-ware still; so that this is evidently made of two such different ingredients.

Besides these methods, there is yet another, of late invention, which makes a very beautiful china; and which, if it does not afford vessels equal to those of china, yet will afford them nearly approaching to those, and at a considerably smaller price. This method consists in reducing glass to china. See *GLASS-Porcelain*.

Macquer, the author of the *Chemical Dictionary*, observes, that M. Reaumur has erroneously confounded the Saxon porcelain with the other fusible porcelains in Europe. For though it contains, as every porcelain does, particularly that of China and Japan, a fusible substance, which has been completely fused in the operation of baking, and to which it owes its density and internal lustre; yet it contains also a large quantity of a substance absolutely infusible, from which it receives its admirable whiteness; its firmness and solidity, during the baking, supplying the place of the oriental kaolin, and contracting its dimensions in a considerable degree, while it incorporates with the fusible substance. He has actually found, that this porcelain cannot be fused, unless by a fire capable also of melting the best Japanese porcelain. And he observes, that it is superior to the oriental in the smoothness, lustre, and less granulous appearance of its internal surface. The manufacture of Saxony has been long established; and that at Meissen, a few miles from Dresden, has produced porcelains painted and enamelled in such perfection, that they have been reckoned more beautiful, and sold at a higher price than even those of China.

The invention is said to have been owing to an alchemist called Botticher, who, being confined in the castle of Königstein by the king of Poland, on a suspicion of being
master

PORCELAIN.

master of the philosopher's stone, had leisure sufficient, not indeed to make gold, but to invent a ware, which, by the excellence and value of it, considerably enriches the country. He died in 1719, but it seems that he only invented the white sort; the art of making brown and blue porcelain not having been discovered till the year 1722.

Porcelain is also made at Vienna, Frankenthal, and lately in the neighbourhood of Berlin; all which are made of the same kind of materials with those of Saxony. In Italy there are also manufactures of porcelain, at Naples, and Florence. In France they have had manufactures of this kind for many years: porcelain was made at St. Cloud, and in the suburb of St. Antoine at Paris, before M. de Reaumur's publication; but though beautiful, it was of the vitreous and fusible kind. Since that time, considerable manufactures of it have been established at Chantilly, Villeroy, and Orleans, the porcelains of which have a distinguished merit; but those produced in the king's manufactory at Seve are said to do greatest honour to France, on account of their shining, white, beautiful glazing, and coloured grounds.

M. Guettard, who has published an account of his discoveries in the Memoirs of the Academy of Sciences for the year 1765, seems to have been one of the first who, since M. Reaumur, found in France a kaolin and petunse of the same nature as the Chinese: the former is a white argillaceous earth filled with mica; the latter a hard quartzose stone. The count de Lauraguais has also so far succeeded in his attempts in this way, that some pieces, presented by him in 1766 to the Academy of Sciences, were declared to resemble the porcelain of China and Japan in solidity, grain, and infusibility, more than any other that had been made in that country, though it wants the whiteness and lustre observable in the ancient Japanese porcelain.

In the first attempt to make porcelain in France and in this country, it possessed very inferior qualities to that made in China and at Dresden: it was much more fusible, and had an open fracture. In consequence of these defects, it has been distinguished from genuine porcelain by the name of soft and tender porcelain.

It is painful to confess that we have not as yet produced any thing superior to the latter in this country. The French, till the discoveries of Reaumur and others, did not make the real porcelain.

Porcelain appears to have been first brought into Europe by the Portuguese, but at what period it is difficult to say; but doubtless long before any attempts were made by the Europeans to manufacture it.

The first attempt was, as we have already observed, by baron de Botticher, a German chemist. In making some crucibles, he found they assumed by heat the character of porcelain. This gave rise to the manufactory, which is still carried on at Dresden; and it is curious to have to remark, that their materials, from the first, proved to be similar to those employed in China.

The success of this manufactory soon produced other attempts in France and this country. It was known that the Chinese employed two substances for the body of the porcelain: one called kaolin, having the ductile properties of clay; and the other named petunse, which was a white stone, and did not produce a paste in itself.

A French missionary in China, of the name of d'Entrecolles, sent over to France specimens of the kaolin and petunse, with such instructions as he could collect. It seems that very little was gained by this. They did not at first succeed in finding similar materials in France; and if they had, the account given them by d'Entrecolles was

so defective, that it rather misled them than otherwise. Very little progress was made by the French, till the celebrated Reaumur, as we have already mentioned, investigated the subject. His first object was to examine the fracture of the different porcelains. He found the fracture of Chinese porcelain to be very compact, but slightly granular; the Dresden more compact, and resembling enamel; that of St. Cloud, which was the best attempt after the Dresden, had an open granular fracture, more resembling sugar. His next object was to ascertain their relative degrees of fusibility. He found the Chinese to withstand the greatest heat without fusion, while the others yielded to the ordinary heat of furnaces. He concluded from his experiments, that it was essential to have two substances for the formation of porcelain. The one should constitute the body or skeleton of the substance, by being infusible with the greatest heat of the furnace employed; the other substance should, at the greatest heat required, become fused, and enveloping the infusible parts, constitute the semi-transparency so conspicuous in porcelain. The first of these properties he found to exist in the kaolin, and the second in the petunse of the Chinese.

It was not, however, till after the researches of Macquer and Montigny, that the French porcelain became fit to compare with that of Dresden and the Chinese. They put the manufactory at Seve in possession of the means of employing substances similar to kaolin and petunse, with as much success as the Chinese.

If, agreeably to the principle laid down by Reaumur, porcelain is constituted of two substances, one of which is infusible, and acts as a prop or skeleton, while the other, which is fusible, cements and binds the infusible parts together; it will be easy to conceive, that a great variety of this species of earthen-ware may be formed with substances possessing different degrees of fusibility. The best and true porcelain, however, appears to be formed when the fusible part of the porcelain requires the greatest heat for that purpose. This is the petunse of the Chinese, and is similar, if not the same, with the feldspar which is found in Cornwall, and employed in most of the manufactures here. The other substance to which the porcelain mass owes its ductility, is called porcelain clay, and by some porcelain earth. This is nearly the same with the kaolin of the Chinese. Sometimes the substance known by the name of soap rock, and also called steatite, is employed with the kaolin, or porcelain clay. This is said to give firmness to the infusible part of the porcelain. A substance similar to this last is in some cases used by the Chinese. The body of the best porcelain should, therefore, be formed of certain proportions of porcelain clay with the feldspar. The less of the latter, the more difficult it will be to bring about the semi-transparency by heat. But if the feldspar were in great proportion, the vessels so formed would shrink in the fire, before the diaphanous property was produced. If vessels were made solely of the porcelain clay, without any feldspar, they would possess great whiteness and firmness, but not the least transparency. Hence this clay answers very well for crucibles or other vessels required to resist great degrees of heat. Porcelain made of the best proportions of these two substances, we have before observed, is called hard porcelain. In some parts of France, and in this country, the porcelain is made of these substances in part, but other materials are employed to give the required transparency at a lower temperature. This has received the name of soft porcelain. The receipts for making soft porcelain are very numerous; scarcely two manufacturers using the same, although each keeps his own a profound secret, and thinks it the best.

PORCELAIN.

They all use more or less of porcelain clay and feldspar. The former is often called Cornwall clay, the latter Cornwall stone. This they employ in different proportions with bone ashes. The latter constitute the infusible part, while the feldspar, which is used in greater proportion, serves to give the transparency. Some use gypsum in their composition, to give it an opal appearance. All these porcelains are so fusible, that they are obliged to be glazed with a substance containing oxyd of lead, which must ever be considered as objectionable in the manufacture of vessels used in domestic life. The true porcelain is glazed with feldspar, which can only be effected when the fabric will bear a heat sufficient to make the coating of feldspar flow thinly over the surface.

It may be proper here to state some facts respecting the porcelain clay and the feldspar, which may be a means of improving upon the materials which nature furnishes.

The Cornwall stone is a species of granite in a state of decomposition, and principally consists of feldspar. The porcelain clay is found in situations where this decomposition is constantly going on, and the clay is separated by the action of water, which washes these parts miscible with that fluid into pits made, in succession, for the purpose. In order to give some idea of the similarity between feldspar and porcelain clay, we will give the following analysis by Vauquelin.

Before it was suspected that the alkalies entered into the composition of minerals, the analysis of these two substances afforded nearly the same substances, offering very little in their proportions. In the analysis of feldspar, however, a great loss was always observed, which could not be accounted for, but which is now found to be potash. This satisfactorily explains the fact of porcelain clay, from which the alkali has been separated by the decomposition of the feldspar, being infusible with the greatest heat of furnaces; while the feldspar itself, which contains potash, melts at little more than a red heat. These facts will, no doubt, give some valuable hints to the scientific manufacturers of porcelain.

It may seem to the reader a little strange, why the soft porcelain, which is a vague and artificial composition, should be made at all, and why the simplest proportions of the clay and Cornwall stone should not be universally employed. In answer to this we may state, that in none of the manufacturing arts in which fire is an important agent, has there been less skill displayed, or less improvement made, than in the potter's kiln, which from its construction is limited to a very low degree of heat, and has besides many other defects, which must ever be an obstacle to the manufacture of porcelain. On this subject we shall give some observations in another place. We shall now proceed to

go through the different manipulations for many vessels of porcelain, which will be the same whatever may be the nature of the materials.

Previously to the different materials being mixed which are to constitute the mass from which the vessels are to be formed, they are first ground between two surfaces of chert or porphyry: the first of these is a hard siliceous stone, found in Derbyshire, and other places. The passive part of this machine consists of these stones, which occupy the bottom of a cylinder, about twelve or eighteen inches in depth, and from six to ten feet in diameter. In the middle of the cylinder works an upright shaft, with arms at right angles, on which are placed the active stones, so that by the rotation of the latter upon the passive stones, the substance, such as flint or feldspar, is ground. As much water is always present as keeps the substance grinding to the consistency of pulp.

After the substances have been ground in this way to a certain fineness, which also effects their intimate mixture, the pulp is passed through a sieve of fine silk. The operation is called *lawning*. This renders the pulp very fine, and prepares it for evaporation.

The evaporation of the water is performed in a vessel made of fire-brick; its surface is great, and the depth not more than twelve to eighteen inches. The breadth is about six feet. The fire is at one end, and the flame runs under the whole length, to the chimney at the other end. The heat is given very slowly to the pulp, till the mass will admit of being cut out with a spade in square masses. These masses are a little too soft for working, and require another operation, called *wedging* or *flapping*. This consists in separating each of these squares with the hand, and flapping them violently together on different sides to those immediately separated. This is repeated till the mass becomes perfectly uniform. In mixing water with clay or any other dry substance which requires to be thoroughly penetrated by that fluid, it is found that considerable time is necessary to do it effectually for this purpose. It is common, after the first wedging, to allow the mass to remain undisturbed for some time. This allows every part of the substance to be saturated with water, and the mass requires that degree of uniformity and tenacity, by which it is worked with greater facility. Previously to being worked it undergoes another wedging, by which it acquires the proper consistency for working into utensils of different kinds.

This branch of the art is divided into three departments, namely, throwing, pressing, and casting.

Throwing is performed upon a machine called the potter's lathe. This consists of an upright shaft, about the height of a common table, on the top of which is fixed a circular piece of wood, of a breadth sufficient for the widest vessel to stand upon. The bottom of the shaft runs in a step, and the upper part in a socket a little below the circular board, so that the shaft and the board turn together. The shaft is turned by a pulley, placed upon it by a band, which passes from it to a wheel about ten times the diameter at some distance. This latter, being turned by a handle, gives motion to the lathe. The masses to be thrown are first weighed out. The thrower places the mass on the face of the circular board, which is in motion, and shapes it by his hand and fingers previously wet, aided by the circular motion, to the desired form. He then cuts it off at the base by means of a piece of fine brass wire, with a handle at each end. The vessels thus roughly formed are placed in a situation, where they dry gradually to a certain extent. During the drying of the vessels, there is one point in which the clay possesses a greater tenacity and hardness than at any other

PORCELAIN.

other period. This is called the green state. At this period they are taken to another lathe, which, to distinguish it from the throwing lathe, is called a turning lathe. The vessel is here slightly attached to a wooden chock by wetting, and then turned into its proper shape with a very sharp tool, which gives it great smoothness at the same time. After this it is slightly burnished with a smooth steel surface. Such vessels as require to have other parts attached to them, such as handles, spouts, &c. undergo this operation when they come from the turning, this being the proper state of dryness for that purpose. The handles are first made of the proper size and shape in moulds of plaster: they are then stuck to the vessels, by means of a pulpy mass of the same material, of the consistency of thick cream. In this state it is called slip. The surface where the union is formed is then smoothed with a wet sponge. The vessels are now taken to the stove to be thoroughly dried.

When they are perfectly dry they are examined, to see if any parts be still rough; indeed, some places cannot be made perfect in the green state. The perfect finish is given by rubbing the rough parts with a small bundle of hemp.

The throwing and turning can be employed only for such utensils as are of a circular form. When the form is otherwise, recourse is had to moulds. The moulds are made of plaster, and sometimes, for delicate work, of sulphur. The clay is first made into a flat piece of the thickness of the vessel: it is then gently pressed into one-half of the mould, a similar piece being pressed into the other half. The two halves are now united together, and the plaster moulds removed. The vessels now undergo repairs, and are set to dry, to the same degree at which the thrown articles are turned. The vessels are now all finished as to their form and the different appendages, which are put to them by means of the slip. These are now fully dried, and finished by rubbing with hemp.

The casting operation consists in pouring the clay, in the state of pulp or slip, into plaster moulds, which are kept in a certain state of dryness. These moulds are made in two halves, and fit together in the same way with those used for casting metals: the pulp is poured in till the cavity is quite full, and suffered to remain for a certain time, which is more or less according to the intended thickness of the vessel: that part of the pulp which is contiguous with the plate soon loses its excess of water, which is absorbed, leaving the clay in that part so stiff, that when the unchanged pulp is poured back, a portion remains, which, when removed from the mould, constitutes a vessel, the exterior of which has the exact form of the mould; the thickness of the clay being more or less, according to the time the pulp remains in the mould.

The articles formed in this way are dried to the green state, similar to those above-mentioned, at which period the parts to be united are put together with slip.

It is in this way that the greater parts of those elegant figures and ornamental works are formed, and sold in a state of white biscuit. These are made in the greatest perfection at the Derby porcelain works. The imitation of flowers and foliage is exquisitely managed. Each of the leaves and petals being made in a separate mould, renders this kind of work very expensive.

All the various kinds of work made by the different processes, after being finished, so far as regards their shape, are placed on a stove to keep them in a hot state for burning, till there is a sufficient quantity to fill the kiln.

The next process is that of burning or firing, which consists in giving the porcelain a very considerably red or almost white heat, by which it acquires its hardness, and

possesses at the same time great whiteness, and is semi-transparent. In this state it appears like very white sugar, and it is called biscuit.

The potter's kiln, which that used for porcelain strictly resembles, is built in the form of an erect cone, with an opening at the top for the escape of smoke. A certain part within the cone is built with fire-bricks, within which the vessels containing the porcelain are piled one upon another. These vessels for defending the ware from the immediate action of the fire, are called *saggars*, which in all probability is a word corrupted from *safeguards*. They are cylindrical vessels from twelve to eighteen inches in diameter, from six to twelve inches deep, and from one inch to one and a quarter thick. These dimensions, however, vary with the size of the articles to be burnt.

The bottoms of the saggars are slightly covered with a fine white sand, which does not change by the fire. The particles act like so many little spheres, allowing the porcelain to touch the saggars' bottom only in a few points.

When the ware is put into the saggars, they are to be piled up in the kiln, each superior saggars serving as a lid to the one beneath it. These piles are by the workmen called *bungs*. Before one saggars is laid upon another, a ring of soft clay is laid upon the edge of the lower one; so that the upper one, being placed upon it, secures the ware in the same from any dust or smoke. The rings of clay so placed between the saggars, are called *wads*. The uppermost saggars is, lastly, covered by a lid, or an empty additional saggars.

The piles in the kiln being completed, the next thing is to apply the fire. This is made with wood on the continent, and probably in China; but in this country the kilns are fired with pit-coal, that producing the most flame being preferred for this purpose.

The fire-places are generally several in number, more or less, according to the size of the kiln. They are made at the bottom of the cone, on the outside, and the flame penetrates the kiln through a horizontal flue, and then ascends perpendicularly, surrounding the piles of the saggars, till it makes its exit at the opening in the top of the cone. The want of a sufficient quantity of oxygen in the body of the kiln does not afford a perfect combustion of the smoke. This not only limits the heat which is so essential, but is the cause of immense volumes of unburnt matter escaping from the chimney, to the annoyance of the surrounding country. (See the kiln described under POTTERY.) The fire is kept up from twenty-four to forty-eight hours, when the kiln is suffered to cool before the saggars are disturbed.

The porcelain is now taken from the saggars, and cleared from any particles of sand which may have adhered to it. In this state it is called biscuit. All the common earthen-ware and the soft porcelain are so porous in the state of biscuit, as to be permeable to water, and, in consequence, would be useless, without the surface being covered with glaze, in order to fill up the pores.

The glazes used for soft porcelain, and the common earthen-ware, are mixtures of some earthy substance, such as flint or clay, or both combined, with some vitrifiable metallic oxyd, in order to give it the necessary fusibility. The oxyd of lead is generally employed for this purpose, with sometimes the addition of oxyd of tin or arsenic, in order to give the glaze a certain degree of opacity. In the hard porcelain, such as that of China and Dresden, the glaze does not contain lead or other metallic oxyd, except we call potash the oxyd of a metal. The porcelain being formed of such proportions of the porcelain clay and the feldspar, as to bear a great degree of heat, a glaze may be employed, much

less fusible than those employed for the soft porcelain. The glaze of such porcelain is, therefore, the felspar alone. We have before stated, that the felspar owes its fusibility to a certain portion of potash which it contains: it might hence be inferred, that the common fusible glaze could be formed by combining potash or soda with earthy substances, in greater proportions, and thus obviate the use of oxyd of lead entirely, which, from its poisonous qualities, is very objectionable. Such an expedient has often, and is still resorted to, by the manufacturers of earthen-ware; but it is found, that when a glaze contains more than a certain proportion of alkali, it does not undergo the changes of expansion agreeably with the body on which it is laid, and is apt, in consequence, to crack. It is not uncommon to see some of the very common species of earthen-ware appear covered with cracks on the surface. Whenever this happens, the body soon becomes penetrated by grease, or any other substance applied to the vessels so glazed. The oxyd of lead, in a certain proportion, forms a more permanent glaze, and is less liable to the above objection; but we find that acids, particularly vinegar, dissolve the lead in such glaze, and has, in many instances, been productive of bad consequences. The glazing used for the soft porcelain in general contains lead, and differs very little from that used for common white earthen-ware, which is generally called white enamel. Since the substance known by this name enters into the composition of the porcelain glaze, and also into the flux used as a vehicle for the colours, we will give the process for forming white enamel, as recommended by Chaptal in his *Chemistry applied to the Arts*. Take equal parts of lead and tin, and expose them on a melted slate till they are completely oxydated. Let the powder so formed be ground with water, and well washed from any impurities, which will be known by the water being clear. This fine powder being dried, is kept free from dust. This being done, take the whitest flints, and fuse them with salt of tartar, or carbonat of potash; the latter being in such proportion to the flint, that the compound may be soluble in water. If to the solution of flint so formed, muriatic acid be added till flint ceases to be precipitated, the precipitate may be considered as pure flux. This being well washed and dried, is kept for use. Of the first preparation of tin and lead, take 100 parts; of the prepared flint, 100 parts; to these add 200 parts of carbonat of potash: fuse the whole in a clean white crucible, and pour it on a clean slate: when cold, reduce it to a fine powder, and keep it for use.

This preparation is intended for the nicest purposes. For the common earthen-ware less pains would be taken in preparing the flint and the oxyds of lead and tin. In future this preparation will be called white enamel. If the porcelain to be glazed will not bear a great heat, the white enamel may be used alone as glazing. The three following are recommended by count Milly in his work on porcelain. First, very white quartz, 8; white enamel, 15; and calcined gypsum, 9. The second is, 17 of quartz; 16 of white enamel; and 7 of gypsum. The third is, 11 of quartz; 18 of enamel; and 12 of gypsum.

These possess different degrees of fusibility, according to the lead they contain. The very hard porcelain, such as that of Dresden or China, is glazed with felspar alone: for this purpose, the felspar is reduced to a fine powder, similar to that constituting the glazé already mentioned.

Having now pointed out the material for glazing, we will shew the manner of laying it upon the biscuit, in which state we left it when taken from the kiln, and cleared from any small particles adhering to it. The material for glazing is to be mixed with water till it is about the con-

sistence of fresh cream. The powder should be extremely fine, that it may remain in suspension. The mixture, besides this, should be agitated all the time of glazing, in order to keep the fluid of an uniform thickness. The biscuit is dipped into the glaze. On taking it out, the piece of porcelain is to be turned hastily into different positions, in order that the covering may be uniform. The biscuit, from its porosity, absorbs the water from the solid part, leaving a coating which is of sufficient hardness to remain permanent till it is exposed to the fire. Those articles which are coloured in any part with cobalt, and sometimes the black or brown colours, require to be painted with the colouring matter before they are dipped in the glaze. In these instances the colours are seen to the greatest advantage through the glazing.

The next process is the firing. To fuse the glaze for this purpose, the coated ware is placed in clean faggars, such as those used in the first firing. That part of the porcelain which is to rest upon the bottom of the faggar has the glazing rubbed off. If this were not the case, the glaze would fasten it to the bottom of the faggar. The faggars are now to be piled up in the same kiln, and in the same manner as employed in the first firing, but the temperature not so high: it should be, however, just sufficient to give perfect fusion to the glaze. The heat employed for the felspar glaze, in the manufacture of hard porcelain, is much greater than for the glaze of the soft kind, although the relative degrees of the biscuiting and glazing heat may be nearly the same in each kind. In this state the porcelain has attained all its useful qualities, the painting and gilding requiring an additional process. Before we speak of the method of laying on the colour, we shall give some account of the preparation of the colouring materials, and the proper flux by which the colour is united to the body. The different colours are produced by metallic oxyds: these bodies are, in general, capable of assuming a vitreous form with different degrees of facility. The oxyd requires to be accompanied by a certain vehicle, called a flux, which has the effect of rendering the whole more fusible than the first or proper glazing already described. Some manufacturers exclude lead from their flux used with the colour, as being injurious to the colour; others employ it constantly. Certain it is, however, that in its tendency to promote the fusion of the under glaze, the colour becomes diluted, particularly when too much heat is employed.

The flux which contains lead may be formed by adding a little borax to the white enamel already described, fusing the mixture, and reducing it, when cold, to powder.

The flux given by Chaptal for this purpose consists of glass in powder, free from lead, 20 parts; calcined borax 11 parts; and purified nitre 22.

The flux, whatever may be its composition, is to be ground with some metallic oxyd into fine powder. It is then mixed with oil of lavender, or, what is cheaper and better, old oil of turpentine. The latter is merely to give that consistency to the whole, which will make it, in the best state, to be laid on the work with a camel's hair pencil.

As the preparation of the metallic oxyds to be used as colouring matter, require great nicety in their preparation, we will give some account of the best means of their preparation, before we proceed to state the different processes of painting porcelain.

Colour produced by Gold—The oxyd of gold has been considered a valuable substance in producing the carmine, rose, and purple tints. The most common preparation is the purple powder of Cassius: it is prepared by dissolving the gold

PORCELAIN.

gold in aqua regia, formed of equal parts of nitric and muriatic acids. Next dissolve tin in the same menstruum, keeping the vessel in which the solution is formed as cool as possible. The solutions of each should be perfectly clear. First dilute the solution of gold with three or four times its bulk of water; then add the solution of tin by a very little at a time: a purple precipitate will fall down. Continue to add small portions of the solution of tin till no more purple precipitate is produced. It must be observed, that the solution of tin should be kept close stopped from the air, between the intervals of using it; as the presence of oxygen would soon render it unfit for forming the purple powder. This powder is well washed by pouring hot water upon it, and drawing off the clear liquor from time to time. It is then to be dried and kept for use. The yellow oxyd of gold is sometimes used for painting. It is obtained by precipitating it from its solution by an alkali, or by lime water. The precipitate is to be washed and dried in the same way as the last, and kept for use.

When either of these substances is used, they are to be intimately ground with the flux above-mentioned, in quantity proportionate to the intensity of the colour required. The mixture is then used by some manufacturers in that state for painting. Others fuse the mixture into a glass, and again reduce it to powder. In either state it is mixed with oil of turpentine till the mixture assumes a proper state for the pencil. The figures are painted upon the glazed porcelain, the volatile part evaporates, leaving the colouring matter with a small remain of resinous. In this state the goods are ready for a third firing, to fix and bring out the colour by the fusion of the vitreous colouring matter. When the fusibility of flux is greater than common, and the heat moderate, the purple colour is produced; the rose colour requiring less flux and more heat.

The purple colour is also produced by the addition of a little more lead to the flux than is used for carmine and rose colour.

The carmine colour is also produced by means of oxyd of gold, produced by the slow decomposition of fulminating gold, and a small portion of leaf silver, or muriat of silver. The preparations of gold are chiefly confined to the manufacture of what is called tender or soft porcelain, for producing carmine, purple, and rose colours. When employed for the hard porcelain, such as that of Dresden and the French, the colours are very apt to change, from the great heat employed to bake them, and in consequence they have almost entirely ceased to be used in those manufactories.

Iron Colours.—Iron is capable of producing a variety of colours on porcelain, but it is the most celebrated for producing red and rose colour. For the latter colours it is used in the state of pure oxyd, which should be of the same colour before and after baking. It is commonly prepared for the common pottery by calcining green vitriol at a red heat, in which state it is called *colcothar* and *crocus martis*.

For the delicate colours of porcelain, it is common to prepare it with nitric acid. For this purpose, dissolve the purest iron in strong nitric acid. This acid oxydates the iron to its maximum. Let the solution be diluted, and stand till it is perfectly clear; then add a solution of carbonat of potash, till the whole of the oxyd of iron is precipitated. Wash the precipitate well with hot water. Drive off the last washing by heat, and raise the heat almost to redness: this will drive off the carbonic acid. This oxyd will now be of a fine red colour, and is fit for use. A certain portion is now mixed, and intimately ground with the flux, which is then laid on with the oil of turpentine, similar to the gold colour.

This colour is employed with great success in painting

hard porcelain for the rose and red colours, and is much preferred to gold. On the contrary, the iron colour does not answer so well for the soft porcelain, as it becomes very faint by baking, and sometimes almost disappears when the heat is great. It may appear a paradox that the iron should answer for hard porcelain, which is baked at a much greater heat than the soft; while it should totally fail with the soft, if the heat be much increased above its common heat. This fact is explained, by attributing the faintness of the colour to the softness of the under-glaze of the soft porcelain, which absorbs the colouring matter; while the hard and less fusible glaze of the hard porcelain, which is mostly feldspar, has no such effect upon the colour. The oxyd of lead, which is generally present in the flux, may also have a tendency to lessen the intensity of the colour of the iron.

Oxyd of lead, as a colour, is generally used in the state of minium (red oxyd of lead) and litharge. It is reduced to a very fine powder, and washed very clean. It is often used with oxyd of tin and flint, and sometimes potash. Its general effect, when in sufficient quantity, is to produce a yellow colour. The lead, being in small quantity, and mixed with a certain portion of oxyd of manganese, has no colour. The oxyd of lead alone fuses into a transparent glass of a beautiful yellow colour.

Oxyd of antimony is employed to give a yellow colour to porcelain. The oxyd is prepared by dissolving antimony in the state of regulus in muriatic acid, with heat, and to the clear solution add water, till no more precipitation takes place. Separate the white powder, and add to it a solution of carbonat of potash to take up the remaining acid. The white powder, well washed with hot water, and dried, will be the pure oxyd of antimony. This oxyd may be fused into a yellowish vitreous mass. If it be exposed to heat for some time, it absorbs more oxygen from the atmosphere, and becomes volatile. This oxyd, with its proper flux, which may be similar to that used for the other oxyds, produces a yellow colour. It is generally used with lead, and sometimes also tin for this colour.

Oxyd of cobalt is almost the only substance used for giving a blue colour. Its being used with so much certainty, as well as its superb colour, renders it of great importance in manufactures of porcelain and pottery. To prepare oxyd of cobalt, let the arsenical ore of pyrites be treated with nitric acid. Most of the sulphur is separated in its pure form, but some becomes converted into sulphuric acid. The latter, with the arsenic acid, formed at the expense of the nitric acid, is to be separated by the nitrat of lead, adding the latter so long as any precipitate is formed, but not more. If an excess has been added, the lead may be separated by sulphuric acid. If copper be present, separate it by a bar of iron. Precipitate the oxyd of cobalt, held in solution by carbonat of potash. If the precipitate be digested in liquid ammonia, the oxyd of cobalt and nickel, if any, will dissolve, while the others will remain. Drive off the ammonia, and add a solution of pure potash: the pure oxyd of cobalt will dissolve, leaving the nickel behind. The pure oxyd may be separated by adding an acid. This last process is to be pursued only when it is required to get the oxyd in a state of purity. The common process is to roast the ore above-mentioned, by which the arsenic and sulphur are expelled. The residuum consists of the oxyd, contaminated with a little iron, nickel, and copper, and with flux. In this state it is sold under the name of *zaffer*. This mass admits of fusion into a blue vitreous mass, which is called *smalt*. In the two latter states it is used in the colouring of common pottery. We have already observed that oxyd of cobalt, when used for the blue colour, is in general

PORCELAIN.

laid on before the glazing. This is more particularly the case when the deep blue ground in porcelain is to be formed. The greater the heat, the more intense and fine this colour becomes. Hence the blue is much better upon hard than soft porcelain. When great heat is given to it, the oxyd becomes, in some measure, volatile, since the white ground in its vicinity becomes a little tinged with its colour. The oxyd of copper has hitherto been employed for producing a green colour. There are two oxyds of this metal, one the brown or protoxyd, the other the black, containing a maximum of oxygen. The former produces a reddish-brown, the latter the green colour. The brown oxyd is generally obtained from the surface of copper by the action of heat. The brown scales which are detached from the surface are made into a fine powder. The black oxyd is best obtained by first precipitating the oxyd from a nitric solution of copper by lime water. Let the precipitate be dissolved in ammonia; then draw off the ammonia by distillation, and the black oxyd will be left in the residuum.

The brown oxyd, being melted with its flux, produces a reddish-brown glass. This, being pounded, may be used with other colours for producing the different tints of red and brown. The black oxyd, treated in the same way, produces a green colour. The oxyd of nickel has been tried in painting on enamel and porcelain, and is said to produce a green colour. The oxyd is obtained from the ore by the same method given for obtaining oxyd of cobalt. The ammoniacal solution spoken of in that process, generally contains both those metals. The residuum which the solution of potash leaves, is oxyd of nickel.

The oxyd of chrome has been tried in the manufactory at Seve by Brougniart. With the chromate of lead he produced a blue of considerable beauty. This substance is found in nature, and might be employed to advantage.

The oxyds of tin and arsenic do not produce any colours, but have the property of producing opacity when united with transparent vitreous bodies. The former, it may be remembered, is in the composition of the white enamel before-mentioned, to which it owes its milky and opal appearance. Arsenic has the same property to a certain extent. The latter, however, may be united with glass, without diminishing its transparency. The mass, when fused, becomes transparent; but when it is exposed at a red heat to the air for some time, it assumes an opaque and opal appearance. Arsenic is very seldom used in enamels, the oxyd of tin answering the same purpose: this circumstance, and also the danger in preparing arsenic, are sufficient reasons for laying it aside. With these metallic oxyds, separately or combined, all the varieties of tints which can be produced in the common methods of painting are obtained.

These may be divided into blue, purple, violet, red, rose colour, carmine, brown, orange, and yellow.

The blue is produced to the greatest advantage by the oxyd of cobalt. Its flux for soft porcelains is potash, flux, and lead; that for hard porcelain being felspar alone. The flux recommended by Chaptal, already given, would answer for the soft porcelain. In some instances it might be proper to use lead instead of borax. When lead is used, the coloured coating is less liable to crack and peel off. When borax or potash is used in sufficient quantity, the lead may be omitted.

The purple is produced on soft porcelain by the purple powder of Cassius, the flux containing a greater proportion of lead, in the absence of which the colour would incline to red. Oxyd of manganese, which is found plentifully in nature, and used for bleaching, produces a purple colour, but it is seldom used for that purpose. The

purple tint may also be produced by the mixture of red oxyd of iron with cobalt. These may also give the different states of indigo and violet.

The reds are produced in soft porcelain by a compound of one part of the purple powder of Cassius, and five or six of the flux with borax. This red, with particular management, may be varied from a carmine to the rose colour. These colours may be much modified by the use of a little leaf silver, or muriate of silver ground up with the flux. The reds of hard porcelain are produced with good effect from the red oxyd of iron. If this oxyd be mixed with an oxyd of the same metal having less oxygen, a great variety of tints may be produced from orange and carmine to purple. Indeed it may be possible to produce every possible colour with iron in different degrees of oxydation. Manganese may be employed with iron to afford a variety of tints.

Browns are produced in soft porcelain by the brown oxyd of copper, with manganese and the brown oxyd of iron. By varying the proportions of these, different shades of brown are obtained.

Orange and yellow are produced by the oxyds of lead and antimony, and different proportions of red oxyd of iron give various tints of orange. The antimony and lead produce yellows of different degrees of intensity, according to the quantity employed. Great care is required in the management of the heat; if the heat be too great, the oxygen leaves the lead and forms black spots.

In all instances the colour is to be mixed with the flux, and sometimes fused with it, and afterwards reduced to powder. This is more especially the case when oxyd of copper is employed. The powder is ground with oil of turpentine rather in a viscid state: with this substance the articles are painted. After painting they require to be baked or fired, for the purpose of fusing the matter laid on. This is not only necessary to fix it, but in most instances the colour does not appear till it becomes fused with its flux. The baking is performed in furnaces, called enamel kilns. The enameller, who has the same work to perform, uses a muffle. But in baking porcelain the furnace employed is generally made of cast iron. It consists of a cubical vessel provided with a lid: four sides are surrounded by a loose wall of brick, perforated with holes. The space between the two vessels is about four or five inches: this cavity is filled with charcoal. The outer casing is deeper than the inner, that the top may be covered with charcoal. The holes in the outer casing are to admit air for the combustion of the charcoal.

The ware is piled up in the enamel kiln on iron grates, resting on earthen props of different lengths, forming alternate strata with the grates, and the lid placed upon it. The charcoal is now set on fire at the top, and kept up till the colour is brought out. For the purpose of ascertaining when the proper effect is produced, there is an opening from the side by a tube which passes from the outer casing to the inner vessel. Small specimens are passed through this tube, having the different colours painted upon them. The tube is stopped with a plug. These specimens are withdrawn from time to time with a pair of small tongs, in order to know when the fire is to be removed. The whole is now left to cool before the porcelain is taken out.

It will be obvious, that when one colour requires to be laid upon another, this is performed by a second operation. It frequently happens that a piece of porcelain has to go into the enamel kiln four or five times, when a great variety of colours is contained in the painting.

Besides the painting, porcelain is frequently ornamented by gilding. This is performed in a manner very similar to the painting. The precipitate of gold from its solution is ground up with the oil of turpentine, and a very small quantity of the flux. The parts intended to be gilt are covered with this, similar to the painting, and are fired in the same way. The oxyd of gold, in this case, is not defended by the flux, and the oxygen flies off, leaving the gold in its metallic form, firmly fixed to the porcelain. The gold, although metallic, is dead in its appearance, and requires to be burnished. This is another department in the manufacture of porcelain. The burnishers are of hardened steel polished, and the blood stone, and are used in the same way as in burnishing gold and silver vessels. The common kinds of porcelain are painted by means of copper-plate prints. This, however, is more practised in the manufactories of the common earthen-ware. See POTTERY.

PORCELAIN Earth, or Clay, (Kaolin,) in *Mineralogy*, is referred by Kirwan to the second tribe of argillaceous earths.

Colour, white, greyish-white, or reddish, or yellowish-white.

Lustre, o. Transparency, o.

Friable and dusty, often compact.

Adheres very slightly to the tongue.

Feels soft but not greasy.

Hardness seldom exceeds 4; but lately some much harder has been found in Siberia Maquart 430. Sp. gr. (which is best taken when hardened by fire) varies with the proportion of its ingredients between 2.23 and 2.4. That of Limoges, which is worked without any mixture, has its spec. gr. 2.341. Brisson 273.

In water it immediately falls into powder. Those of Japan, and St. Iriez in France, are perfectly white; those of Saxony, reddish or yellowish; those of China, and Cornwall, are mixed with particles of talc and mica.

In general porcelain earth is infusible in our furnaces, as Cronstedt remarked; but, in manufacturing this earth, some fusible ingredient is commonly added; however, nature sometimes furnishes these ingredients with the earth, and to this compound we cannot refuse the name of porcelain earth. According to Mr. Hassenfratz, to whom mineralogy, in all its branches, and the arts connected with it, are much indebted, the porcelain earth of Limoges above mentioned contains, when dried, 0.62 filix, 0.19 argill, 0.12 magnesia, and 0.07 barofelenite. Mr. Wedgwood, in the porcelain clay of Cornwall, found on the contrary 60 per ct. argill, and only 20 of filix; this clay is therefore infusible. When dried by a summer heat, or that of a room moderately warm, it loses about $\frac{1}{10}$ of its weight; in the heat of boiling water as-much more; in that of melted lead, and thence to a strong red heat, in which copper melts $\frac{1}{10}$, in all $\frac{1}{10}$; after that no more. The matter thus lost is common and fixed air, but no inflammable air. Hence it appears to differ from the first tribe, or native argill, only in containing filix. It has been suggested, that porcelain clays derive their most estimable properties from a mixture of magnesia. Mr. Nicholson, in his Journal, vol. xii, mentions a porcelain earth, which appeared, upon analysis, to consist only of carbonate of magnesia and filix. Magnesia is said to be of use in porcelain, by diminishing the degree of contraction to which it is liable.

PORCELAIN-Shell, Porcellana, or Concha Venerea, in *Conchology*, the name of a genus of shell-fish, the characters of which are these: they are of the univalve kind, and have for their mouth a long and narrow slit, dentated on each side, and of a conglobated, oblong, gibbose, or umbonated form.

These shells are classed in the Linnæan system under the genus of *Cypræa*; which see.

This genus of shells originally had the name of *porcellana* and *concha venerea* from the resemblance of its mouth to the pudendum muliebre, called by some of the Roman writers, *porculus* and *porcellus*, and always alluded to under the word Venus. We have of late so far misunderstood the name, as to suppose it derived of the word *porcelain*, from an imagination, that the Chinese porcelain ware was made of it. Gefner has fallen into the opinion, and Aldrovand seems to have been mistaken in regard to its other name, *concha venerea*, supposing it so called because of its beauty, and therefore sacred to Venus. Rondeletius calls it the *remora Mutiani*; and the murex of the same author. Aldrovand. de Test. i. 3. p. 352. Gefner, Rondelet. de Test. i. 2. p. 102.

These shells are current in several parts of Asia, Africa, and America, as money; and they have been prescribed, pulverized, in medicine. See *CONCHA Veneris*, and *COWRY*.

The name *concha venerea* may be apt to create confusion, because there is another shell of a very different kind, a bivalve, called *concha veneris*. This genus is therefore much better distinguished by the name *porcellana*. There is a prodigious difference among the species of this genus: some are heavy, others very light; some have the mouth placed in a longitudinal, others in a transverse direction. The gibbous porcelain is a very remarkable species, as is also the egg-porcelain, which has two buttons at the extremities; and the egg-porcelain called the *navel* is not less remarkable than these: this has, instead of a button, a long beak at each end.

The mouth of the porcelain must be narrow and oblong; this is the great characteristic, and is usually dentated either on both sides or on one.

The species of porcelain are so numerous, that it may be proper, in the enumeration of them, to arrange them under some regular heads.

Some porcelains are conglobated, and thick; of these the cabinets of the curious afford us sixteen species.

Some, again, are thick and of a pyriform figure; of these we have twenty-one; and others are gibbous, of which we have five species. Hist. Nat. Eclairc. p. 308. See *CONCHOLOGY*.

PORCELIA, in *Botany*, Prodr. Fl. Peruv. 84. Pursh 383, is the same genus with *ORCHIDOCARPUM*; see that article. Mr. Pursh gives the following characters.

Calyx of three leaves. Petals six; the innermost largest. Stigmas sessile, obtuse. Berries several; often by abortion nearly solitary, ovate-kidney-shaped. Seeds several, tunicated, attached to the inner future.

Four species, all shrubs or small trees, are natives of North America, flowering in spring.

PORCELLANA, a species of the *Voluta*; which see. —Also, a species of the *Patella*; which see.

PORCELLANITE, in *Mineralogy*. See *JASPER*.

PORCELLIO, PIETRO, in *Biography*, a writer of poetry and history in the 15th century, was a native of Naples, of the family of Pandoni. In after life he resided chiefly at Rome, where he taught a Latin school. In 1434 he was thrown into prison by order of pope Eugenius IV. Probably he had taken a part in the tumults which drove that pontiff from Rome. When he was released, he passed some time in exile. He then became secretary to Alfonso, king of Naples, by whose order he joined the Venetian army engaged against Francesco Sforza for the avowed purpose of becoming the historiographer of that war. He was, after this, employed in other official situations, but was never able to rise to any degree of affluence.

fluence. The time of his death is not known, but it is supposed to have taken place during the pontificate of Paul II. He was regarded as one of the most eminent Latin poets of his time. His style in prose is better than in verse. Some of his Latin poems have been printed in collections, and his history of the war, of which he was a witness, was published by Muratori.

PORCELLIONES, in the *Materia Medica*, a name given by some to the millepedes.

PORCELLO, in the *Glass Trade*, the instrument with which the workman, after having made the opening for the bowl of a drinking glass or other such vessel with his passage, widens and renders it more capacious at pleasure.

PORCELLUS CASSOVIENSIS, in *Medicine*, the name of a disease to which the people of Hungary and Poland are very subject.

It is a hard tumour of the belly, attended with a wind and violent pains. It is truly an infarction of the spleen, and is to be cured by aperitives. Philof. Tranfact. N^o 243.

PORCELLUS *Fruentarius*, in *Zoology*. See *MUS Cricetus*.

PORCELLUS *Indicus*, a name given by authors to the animal called with us the guinea pig. See *CAVIA Cobaya*.

PORC-EPIC. See *HYSTRIX Cristata*.

PORCH; ATRIUM, a kind of vestibule, supported by columns, much used at the entrance of the ancient temples, halls, churches, &c.

In the ancient architecture, a porch was a vestibule, or a disposition of insulated columns, usually crowned with a pediment, forming a covert place before the principal door of a temple, or court of justice. Such is that before the door of St. Paul's, Covent-garden, the work of Inigo Jones.

When it had four columns in front, it was called a *tetrapstyle*; when six, *hexastyle*; when eight, *octostyle*; when ten, *decastyle*, &c. Vitruvius calls it *pronas*; Pollux, *περοδομος*, *prodomos*: when finer than ordinary, the ancients call it, *alio*, *propyleum*.

PORCHERON, DAVID-PLACIDE, in *Biography*, a learned Benedictine monk, born at Chateaux-roux, in Berri, in the year 1652, was librarian of the abbey of St. Germain-des-Près. He is celebrated for his profound erudition in the languages, history, geography, and genealogical and medallic researches. He died at the age of 42. He had a considerable share in a new edition of the works of St. Hilary, and other works edited by his fraternity; and he published an edition of the "Anonymous Geographer of Ravenna," with learned and curious notes: and an improved edition of "Maximes pour l'Education d'un jeune Seigneur," to which he subjoined a translation of the "Instructions of the Emperor Bazil, the Macedonian, to his son Leo," with the "Lives of both Emperors."

PORCHOV, in *Geography*, a town of Russia, in the government of Pskov; 60 miles E. of Pskov. N. lat. 57° 40'. E. long. 30° 14'.

PORCIA, in *Biography*, one of the most celebrated females of antiquity, was daughter of Cato of Utica. She was married to Bibulus, by whom she had two children. Becoming a widow, she was united in a second marriage to Marcus Brutus, who was her cousin. The events of the times called forth all the principles of fortitude which she had imbibed from her father and husband. When the latter engaged in a conspiracy against Cæsar, the agitation of mind under which he laboured could not be concealed from his wife, who did not venture to urge him to let her share in the secret, till she had given decisive proof of the strength of her mind. She accordingly gave herself a deep wound in her thigh, and then, when loss of blood and pain had confined her to the bed, she represented to him

that the daughter of Cato and *his* wife might hope to be considered as something more than a mere female companion: aware, however, of the weakness of her sex, she did not claim a participation in his secret anxieties, till she had made trial of her fortitude. She then shewed him her wound; upon which Brutus, having offered up a prayer that he might approve himself worthy of such a wife, informed her of the conspiracy. In her breast the secret was secure, yet when the important day arrived, she was unable to conceal the agitation of her mind, but sent messenger after messenger to bring her word what Brutus was doing, and at length fainted away, so that a report reached her husband that she was dead. After the death of Brutus, Porcia declared a resolution not to survive him, but being closely watched by her friends to prevent her from executing her purposes, she snatched burning embers from the fire, and thrusting them into her mouth was suffocated. This was the current account, but Plutarch, who speaks on good authority, says, that the neglect of her friends was the cause of her refusing to live. Plutarch. Univer. Hist.

PORCIA, in *Geography*, a town of Italy, in Friuli; 16 miles N.N.W. of Concordia.

PORCINA, a town of Naples, in the province of Capitanata; 8 miles N.E. of St. Severo.

PORCINE DEER, in *Zoology*. See *CERVUS Porcinus*.

PORCO, in *Geography*, a jurisdiction of La Plata, in South America, enclosing the district of Potosi, beginning at the west side of the town of Potosi, and at the distance of about 25 leagues from the city of Plata, and extending about 20 leagues farther. The coldness of its situation occasions a scarcity of grain and fruits, but it abounds in fine cattle, and particularly in sheep and vicunas. In this situation is the mountain of Porco, which gives it its name, and from the mines of which the Incas extracted all the silver for their ornaments and expenditure; and accordingly it was the first mine wrought by the Spaniards after the conquest. The capital of the above jurisdiction is of the same name. S. lat. 19° 40'. W. long. 67° 56'.

PORCO, in *Ichthyology*, a name by which some authors have called the fish more usually known by the name of *capripræus*, supposed to be the porcus of Pliny. See *GOAT-fish*.

PORCOS, in *Geography*, a small island in the Atlantic, near the coast of Brasil. S. lat. 23° 30'.

PORCUNA, a town of Spain, in the province of Jaen; 8 miles S.S.W. of Andujar.

PORCUPINE, in *Zoology*. See *HYSTRIX*.

PORCUPINE-FISH, in *Ichthyology*. See *DIODON Hystrix*.

PORCUPINE RIVER, in *Geography*, a river of America, which runs into lake Superior, N. lat. 46° 14'. W. long. 87° 36'.

PORCUS ACULEATUS, in *Zoology*. See *ERINACEUS Malaccensis*, and also *HYSTRIX Macroura*.

PORCUS of Pliny, &c. &c. See *SUS*.

PORCUS *Marinus*. See *DELPHINUS Delphis*.

PORCUS, in *Ichthyology*, a species of *Scorpena*; which see.

PORCUS *Fluviatilis*, a name given by the old Latin authors to the fish we at this time call the *cernua* and *aurata*, and in English the *ruffe*. See *PERCA Cernua*.

PORCZOW, in *Geography*, a town of Lithuania, in the palatinate of Novogrodek; 60 miles W.S.W. of Novogrodek.

PORDEN, a town of Prussia, in Ermeland; 11 miles S. of Allenstein.

PORDENACK POINT, a cape on the S.W. coast of England; two miles S. from the Land's End.

PORDENONE, IL, in *Biography*, the cognomen of a painter

painter of great merit, whose real name was Giovanni Antonio Licino, and who afterwards adopted that of Regillo. He was born at Pordenone, in Friuli, in 1484. It is not certain that he frequented the school of Giorgione, but he resembles him more in grandeur of mind, vigour of conception, and manner, than any of his scholars, Titian excepted, whom he frequently rivalled with no light degree of success. His works in oil are of a very superior brilliancy and richness, but his great excellence was in fresco. The most considerable picture which Rome possessed of him is that with the portraits of his family in the palace Borgheze; but his most splendid work in oil is the altar piece of Santa Maria del Orto, at Venice, which represents a St. Lorenzo, surrounded by other saints, among whom a St. John Baptist surprises no less by correctness of forms, than a St. Augustin by a boldness of fore-shortening, which makes his arm start from the canvas.

The frescoes of Pordenone are spread over the towns and castles of Friuli: some are found at Mantua, Genoa, and Venice; but the best preserved ones are at Piacenza and Cremona. In these he is not always equal, but all bear marks of innate vigour and bold conception: of a mind as eager to form as to resolve difficulties in variety of expression, singularity of perspective, novelty of fore-shortening, and magic resources of chiaro-scuro. Highly valued and ennobled by the emperor Charles V., Pordenone was called to Mantua by Ercole II., where he soon after died at the age of 56; not without suspicion of being poisoned. He had an imitator in Bernardino Licinio, who from the name may be supposed to have been related to him; and Sandrart mentions in high strains of praise Giulio Licinio da Pordenone as his nephew and scholar; who, according to that author, quitted Venice, and left frescoes of extraordinary beauty at Augsbourgh. Fufeli.

PORDENONE, in *Geography*, a town of Italy, in Friuli, on the Noncello; 26 miles W.S.W. of Udina. N. lat. 45° 50'. E. long. 12° 39'.

PORDOSELENA, in *Ancient Geography*, an island situated between the isle of Lesbos and the continent of Myfia; called Porofolene by Strabo and Pliny.

PORE, formed from *προς*, aperture, or *duē*, a little interstice between the particles of matter which constitute bodies either empty, or filled with some insensible medium.

Condensation and rarefaction are only performed by closing and opening the pores.

The transparency of bodies is usually supposed to arise from their pores being directly opposite to one another.

The matter of insensible perspiration is conveyed through the pores of the cutis.

Sir Isaac Newton shews, that bodies are much more rare and porous than is commonly believed: water, *e. gr.* is nineteen times lighter, and consequently rarer, than gold; and gold itself is so rare, as very readily, and without the least opposition, to transmit magnetic effluvia, and easily to admit quicksilver into its pores, and to let even water pass through it: for a concave sphere of gold hath, when filled with water, and foldered up, upon pressing with a great force, let the water squeeze through it, and stand all over its outside, in multitudes of small drops like dew, without bursting or cracking the gold. See COMPRESSION.

Whence it may be concluded, that gold has more pores than solid parts; and by consequence, that water hath above forty times more pores than parts.

The magnet transmits its virtues, without any diminution or alteration, through all cold bodies that are not magnetic; as gold, silver, brass, glass, water, &c. See MAGNETISM.

The rays of light, let them be either bodies actually coming to us from the sun, or only motions or impressions upon the medium, move in right lines, and are hardly ever, unless by great chance, reflected back again in the same line, after their impingence upon objects; and yet we see, that light is transmitted to the greatest distances through pellucid bodies, and that in right lines.

Now how bodies should have pores sufficient for these effects, may be difficult to conceive, but not impossible: for Sir Isaac shews, that the colours of all bodies arise from their particles being of such a determinate size, or magnitude. Wherefore, if we conceive those particles to be so disposed, as that there is as much porosity as there is of matter; and, in like manner, those particles to be composed of others much less, and that have as much interspersed vacuity, or space, as their quantity of matter amounts to; and so on, till we come to solid particles without pores: then, if in any body there be, for instance, three of these sizes of particles, and that the last be of the solid, or least sort; that body will have seven times as much vacuity as solid matter; if four such degrees, and the last be least, and solid, that body will have fifteen times as much porosity as solidity; if five such degrees, it will have thirty-one times as much space as solidity; and if six degrees, then it will have sixty-three times as much vacuity as solid matter.

And perhaps, in the wonderful conformation and fabric of natural bodies, there may be other proportions of space to matter, which are to us wholly unknown; whence it is possible there may be yet farther great quantities of interspersed vacuity.

PORES, in *Anatomy*, are certain permeable spaces, between the parts of the skin; by which we sweat, or perspire, &c.

The pores are most remarkable in the hands and feet. By viewing the palm of the hand with a moderate glass, after washing it well, we perceive innumerable little ridges, of equal size and distance, running parallel to each other, especially on the tips and joints of the fingers, &c. where they are regularly disposed into spherical triangles, and ellipses.

On these ridges stand the pores, in even rows, big enough to be seen by a good eye without a glass; but with one, every pore looks like a little fountain; and the sweat may be seen to stand in it, clear as rock water; and as often as it is wiped off, it springs up again.

The pores are placed on the ridges, not in the furrows between them; that they might be less liable to be stopped by compression: for the same reason, the pores of the hands and feet are larger than the rest; those parts being more used and pressed than the rest; and hence, again, there are no ridges on other parts.

These pores serve as a convenient outlet for the more noxious parts of the blood, which, by the continual use of the hands and feet, are plentifully brought into them: whence, in hypochondriac and hysteric people, there is a continual burning in the palms and soles. See INTEGUMENTS and SKIN.

In the stoppage or constriction of the pores of the skin, that disease which we popularly call a *cold*, is commonly supposed to consist; though Dr. Keill maintains a quite contrary opinion in a dissertation at the end of his "*Medicina Statica Britannica*."

In the Philosophical Transactions we have an instance of a student near Leyden much addicted to astronomy, who spending many nights in star-gazing, had, by the nocturnal wet and cold, so obstructed the pores of his skin, that little or nothing exhaled from his body: as appeared hence, that the shirt he had worn five or six weeks was then as white as if

if it had only been worn one day. In the mean while, a water was collected under the skin, of which he was afterwards cured.

PORE, *Biliary*. See BILIARI Pori, and PORI *Biliary*.

POREY, CHARLES, in *Biography*, a distinguished professor of rhetoric, was born in 1675, at Vendées, near Caen. He was early entered into the society of Jesuits, and became a teacher of the languages in the province, by which he gained a high reputation. Being summoned to Paris for his theological studies in 1708, he was soon nominated to the chair of rhetoric in the college of Louis le Grand. He accepted the post with regret, because it took him off from the great object which he had in view; viz. of consecrating his life to missions among infidels. As a teacher, it is said no one ever fulfilled the duties with more zeal, industry, and success; he had the talent of making himself beloved by his pupils, and of guiding them by gentleness, and the force of his own example. He so entirely devoted himself to the business of his professorship, that he lived almost as a solitary in the midst of Paris. His labours were continued thirty-three years, during which he formed many pupils that did honour to the instructions of their master, and he died in general esteem in 1741, at the age of sixty-six. His writings are numerous, chiefly in the Latin language, his style being formed rather upon that of Seneca than of Cicero. His principal works are two "Collections of Harangues," published in 1735 and 1747; also six Latin tragedies and five Latin comedies. He was also author of several fugitive pieces in prose and verse. He had a brother, Charles Gabriel, who died in 1770, at the age of 85, a considerable writer, but known principally for a work entitled "Nouvelles Littéraires de Caen," in 3 vols. 8vo., being a collection of pieces in prose and verse, written by the academicians of that city, and also for "Forty-four Dissertations on different Subjects," read before the academy of Caen, of which he was a member more than thirty years.

POREITCH, in *Geography*, a town of Russia, in the government of Smolensk; 28 miles N.W. of Smolensk. N. lat. 55° 5'. E. long. 26° 40'.

PORELLA, in *Botany*, from a number of pores in the supposed seed-vessel, Dill. Musc. 459. t. 68, adopted by Linnæus and others as a distinct genus of *Musci*, is proved by Mr. Dickson, Tr. of Linn. Soc. v. 3. 238. t. 20, to be a *Jungermannia*, whose sheath had been accidentally perforated in various directions, and mistaken for a capsule. This accurate observer therefore calls the plant *Jungermannia Porella*. It comes from Pennsylvania, and belongs to that tribe of the genus which has two-ranked auricled leaves, an inflated sheath, and very short fruit-stalk. Loureiro nevertheless has a *Porella*, Cochinch. 683, to which he gives the specific name of *imbricata*, with the following characters,

Gen. Ch. Anther (rather, as we presume, Capsule) of many cells, perforated, without operculum or veil.

Sp. Ch. Leaves lanceolate, imbricated in five rows.—Native of moist places in Cochinchina. Stem erect, branched, three inches high. Leaves linear inclining to lanceolate, curved, undulated, whitish. Anther (Capsule?) ovate, porous, naked, sessile, of many cells. We do not pretend to determine the genus of this plant, which, if really distinct, should retain the old name of *Porella*, while it replaces that now abolished genus. It seems to belong to the same order as *Lycopodium*, and possibly may be a species of that genus, not accurately understood.

PORENTROY, in *Geography*. See PORRENTROY.

PORFILIGON, a word used by some of the chemical

writers to express the *squamæ martis*, or the scales of iron which fly off in the smith's hammering of it.

PORI, in *Geography*, a small island near the north coast of Sardinia. N. lat. 41° 12'. E. long. 9° 35'.—Also, a small island in the Mediterranean; 20 miles S.S.E. of Cerrigo.

PORI *Biliary*, in *Anatomy*, the small branches of the biliary ducts in the liver. See LIVER.

PORIME, PORIMA, in *Geometry*, a theorem or proposition, so easily demonstrated, that it is almost self-evident.

The word is formed from the Greek ποριμος, *pervious*, a thing easy to penetrate or conceive, and which opens the way to something more difficult.

Such, e. gr. is this; that a chord is wholly within the circle.

Porime stands opposed to *aporime*, which denotes a proposition so difficult, as to be almost impossible to be demonstrated: such as the quadrature of the circle is now, and as the squaring of any assigned portion of Hippocrates's lunes formerly was.

The porime coincides nearly with the lemma, or assumption.

PORISM, a proposition partaking both of the nature of a problem and a theorem, but is strictly neither the one nor the other, but of an intermediate kind between the two.

Euclid wrote three books of porisms, which are, however, lost; and nothing remains of them, in the works of any of the ancient geometricians, besides what Pappus has preserved in a very obscure and imperfect state, in his Mathematical Collections, in the introduction to his seventh book. He there states the following definitions of a theorem, a problem, and a porism: "Differentias autem horum trium, melius interlexisse veteres manifestum est ex definitionibus. Dixerunt enim *theorema* esse quo aliquid proponitur demonstrandum. *Problema* quo proponitur aliquid construendum. *Porism* vero esse quo aliquid proponitur investigatum." Pappus also mentions another definition of a porism, given by those mathematicians which were accounted modern in his time, but which he censures as incomplete; viz. "quod deficit hypothesi a theoremate locali;" which clearly implies that a porism had an immediate reference to a *locus*; though it is not less clear that Pappus considered loci as only one class of porisms, and that in fact there are many porisms that have no connection whatever with loci.

It has, however, been justly observed, that while this definition was censured by Pappus as not sufficiently general, because it includes a number of porisms unconnected with loci, the one he has given, as more characteristic of porisms, is as much too general, because though it does correspond to the nature of these propositions, it is deficient in discrimination, and of itself neither conveys any precise idea of Euclid's porisms, nor gives assistance in the investigation of any individual proposition. It appears, therefore, that between the time of Euclid and Pappus the correct idea of porisms had been lost, and consequently it became a very difficult task for the moderns to recover this intricate part of the ancient geometry; and it is, therefore, not astonishing that many who have attempted this task have completely failed, while the success of others is sometimes very doubtful.

Albert Girard, a geometer of eminence in the early part of the 17th century, was the first who announced the restoration of the porisms of Euclid in his Trigonometry, published in 1629; and also in his addition of Stevinus in 1634, he states his having restored the porisms of Euclid, but in such general terms, that no precise opinion can thence be formed of his notions on the subject: and indeed it seems to be the opinion

opinion of Simson, that Girard had deceived himself with regard to the nature of the porisms of the ancients. Bullialdus is the next author who mentions them, in one of his *Exercitationes Geometricæ* (1657); but in it he refers to Fermat as the inventor, who had communicated the discovery in letters to some of his friends at Paris. Fermat, therefore, may be considered as the first among the moderns who made any near approach to the discovery of the ancient porisms. He supposed even that he had made such progress, as to ensure a complete restoration of Euclid's work; but the five propositions he has given as a specimen of his invention, though undoubtedly porisms, are no part of Euclid's treatise, which, with other circumstances connected with them, have made it a question whether or not this celebrated author had acquired a correct idea of these propositions, though he had certainly made an important step towards it.

Passing over the attempts of some other mathematicians, we come immediately to Dr. Simson, who is certainly the first whose endeavours were crowned with complete success. This celebrated geometrician had at an early part of his life considered this subject, and after many fruitless endeavours, had laid it by for a considerable time; but afterwards upon reconsidering it, he fell upon a complete and satisfactory illustration of these propositions. His first paper on this subject was published in the *Philosophical Transactions*, vol. xxxii.; besides which, he left at his death a considerable treatise on porisms, which was published in his "*Opera Reliqua*," in 1776. Simson there defines a porism as follows: "Porisma est propositio in qua proponitur demonstrare rem aliquam, vel plures datas esse, cui, vel quibus, ut et cuilibet ex rebus innumeris, non equidem datis, sed quæ ad ea quæ sunt eandem habent relationem, convenire ostendendum est affectionem quandam communem in propositione descriptam;" which Mr. Lawson has rendered into English thus: "A porism is a proposition, in which it is proposed to demonstrate that some one thing, or more things, are given, to which, as also to each of innumerable other things, not indeed given, but which have the same relation to those that are given, it is to be shewn that there belongs some common affection described in the proposition." This, which is intended to be a literal translation of the above, is subject to some obscurity; in order to obviate which, Playfair, without regarding the exact literal translation, has rendered it as follows: "A porism is a proposition, in which it is proposed to demonstrate that one or more things are given, between which and every one of innumerable other things, not given, but assumed according to a given law, a certain relation, described in the proposition, is to be shewn to take place." The professor, however, does not himself adopt this definition, but, after a learned and very ingenious chain of argument, draws this conclusion, that "a *porism* is a proposition, affirming the possibility of finding such conditions, as will render a certain problem indeterminate, or capable of innumerable solutions." This definition is given by Playfair in vol. iii. of the *Edinburgh Transactions*, in a paper highly interesting to mathematicians, both on account of its reference to the subject of this article, and the many curious and important observations which it contains on the geometry of the ancients in general. He here, after enumerating the various attempts that have been made by modern mathematicians to restore some of the lost works of the ancients, and particularly Dr. Simson's successful illustration of Euclid's porisms, observes: "The subject of porisms is not, however, exhausted, nor is it yet placed in so clear a light as to need no farther illustration. It still remains to inquire into the probable origin of these propositions; that is to say, into the

steps by which the ancient geometers appear to have been led to the discovery of them.

"It remains also to point out the relation in which they stand to other geometrical truths; to consider the species of analysis, whether geometrical or algebraical, that belongs to them; and, if possible, the reason why they have escaped so long the notice of modern mathematicians. It is to these points that the following observations are chiefly directed."

He then proceeds to describe the steps which appear to have led the ancient geometers to the discovery of porisms; supplying, as he observes, the want of express testimony by probable reasonings.

It cannot be doubted, says our author, that it has been the solution of problems, which, in all states of the mathematical sciences, has led to the discovery of most geometrical truths. The first mathematical inquiries in particular must have occurred in the form of questions, where something was given, and something required to be done; and by the reasonings necessary to answer these questions, or to discover the relation between the things that were given and those required to be found, many truths were suggested, which came afterwards to be the subject of separate demonstrations. The number of these was the greater, because the ancient geometers always undertook the solution of problems with the most scrupulous and minute attention, which scarcely suffer any of the collateral truths to escape their observation. We know, from the examples they have left us, that they never considered a problem as resolved, till they had distinguished all its varieties, and evolved separately every different case that could occur, carefully remarking every change that might arise in the construction, from any change that was supposed to take place amongst the magnitudes which were given.

Now as this cautious manner of proceeding was not less calculated to avoid error, than lay hold of every truth that was connected with the main object of inquiry, these geometers soon observed that there were many problems, which, in certain circumstances, would admit of no solution whatever; and that the general construction by which they were resolved would fail, in consequence of a particular relation being supposed among the quantities which were given.

Such problems were then said to become impossible; and it was readily perceived that this always happened, when one of the conditions prescribed was inconsistent with the rest, so that the supposition of their being united in the same subject involved a contradiction. Thus, when it was required to divide a given line, so that the rectangle under its segments should be equal to a given space, it was evident that if this space was greater than the square of half the given line, the thing required could not possibly be done; the two conditions, the one defining the magnitude of the line, and the other that of the rectangle under its segments, being then inconsistent with one another. Hence an infinity of beautiful propositions concerning the maxima and minima of quantities, or the limits of the possible relations, which quantities may stand in to one another.

Such cases as these would occur even in the solution of the simplest problems; but when geometers proceeded to the analysis of those that were more complicated, they must have remarked their constructions would sometimes fail, for a reason directly contrary to that which has now been assigned. Instances would be found where the lines, that by their intersection were to determine the theory sought, instead of intersecting one another, as they did in general, or of not meeting at all, as in the above-mentioned case of im-

possibility, would coincide with one another entirely, and leave the question of consequence unresolved.

But though this circumstance must have created considerable embarrassment to the geometers who first observed it, as being perhaps the only instance in which the language of their own science had yet appeared to them ambiguous or obscure, it would not probably be long before they discovered the true interpretation to be put upon it. After a little reflection, they would conclude, that since, in the general problem, the magnitude required was determined by the intersection of the two lines above mentioned, that is, by the points common to them both; so, in the case of their coincidence, as all their points were in common, every one of these points must afford a solution; which solution, therefore, must be infinite in number; and also, though infinite in number, they must all be related to each other, and to the things given, by certain laws, which the position of the two coinciding lines must necessarily determine.

On enquiring farther into the peculiarity in the state of the data which had produced this unexpected result, it might likewise be remarked, that the whole proceeded from one of the conditions of the problem involving another, or necessarily including it; so that they both together make in fact but one, and did not leave a sufficient number of independent conditions to confine the problem to a single solution, or to any determinate number of solutions. And it was not difficult afterwards to perceive, that these cases of the problem formed very curious propositions, of an intermediate nature between problems and theorems, and that they admitted of a separate enunciation peculiarly elegant and concise; and to such propositions thus enunciated the ancient geometers gave the name of porisms.

In order to illustrate this deduction, our author proposes several problems, one of which we shall transcribe, in order to shew the method of investigation.

A triangle ABC (*fig. 12. Plate XI. Geometry,*) being given, and also a point D , to draw through D a straight line DG , such that perpendiculars being drawn to it from the three angles of the triangle, *viz.* AE , BG , CF , the sum of the two perpendiculars on the same side of DG shall be equal to the remaining perpendicular; or that AE and BG together, may be equal to CF .

Suppose it done, bisect AB in H , join CH , and draw HK perpendicular to DG .

Because AB is bisected in H , the two perpendiculars, AE and BG , are together double HK , and as they are also equal to CF , by hypothesis CF must be double of HK ; and CL of LH . Now GH is given in position, and magnitude; therefore the point L is given; and the point D being also given, the line DL is given in position; which was to be found. The construction is obvious. Bisect AB in H , join CH , and take HL equal to one-third of CH ; the straight line which joins the points D and L is the line required.

Now it is evident, that while the triangle ABC remains the same, wherever the point D may be, the point L will also remain the same. The point D may, therefore, coincide with L ; and when this happens, the position of the line to be drawn is left undetermined; that is to say, any line whatever drawn through L will satisfy the conditions of the problem. Here, therefore, we have another indefinite case of a problem, and of consequence another porism, which may be thus enunciated. "A triangle being given in position, a point in it may be found, such that any straight line whatever being drawn through that point, the perpendicular drawn to this straight line from the two angles of the triangle, which are on one side of it, will be together equal

to the perpendicular that is drawn from the same line from the angle on the other side of it."

This porism may be made more general; for if, instead of the angles of a triangle, we suppose ever so many points to be given in a plane, a point may be found such, that any straight line being drawn through it, the sum of all the perpendiculars that fall on that line from the given points on one side of it, is equal to the sum of the perpendiculars that fall on it from all the points on the other side of it. Or, still more generally, any number of points being given not in the same plane, a point may be found, through which if any plane be supposed to pass, the sum of all the perpendiculars which fall on that plane from the points on the one side of it, is equal to the sum of all the perpendiculars that fall on the same plane from the points on the other side of it. It is unnecessary to observe, that the point to be found in these propositions is no other than the centre of gravity of the given points; and that, therefore, we have here an example of a porism very well known to the ancient geometers, though not distinguished by them from other theorems.

Our author then proceeds to a farther illustration by other examples and remarks, from which he ultimately arrives at the conclusion, which furnishes him with the definition given above, *viz.* a porism is a proposition, affirming the possibility of finding such conditions as will render a certain problem indeterminate, or capable of innumerable solutions.

To this definition, he observes, the different characters that Pappus has given will apply without difficulty. The propositions described in it, like those which he mentions, are, strictly speaking, neither theorems nor problems, but of an intermediate nature between both; for they neither simply enunciate a truth to be demonstrated, nor propose a question to be solved; but are affirmations of a truth, in which the determination of an unknown quantity is involved. In as far, therefore, as they assert, that a certain problem may become indeterminate, they are of the nature of theorems; and in as far as they seek to discover the conditions by which that is brought about, they are of the nature of problems.

In this definition also, and the instance from which it is deduced, we may trace that imperfect description of porisms which Pappus ascribes to the latter geometers, but which he censures as deficient, *viz.* "Porisma est quod deficit hypothesei a theoremate locali." Now to understand this, it must be observed, that if we take the converse of one of the propositions called *loci*, and make the construction of the figure a part of the hypothesis, we have what was called by the ancients a *local theorem*. And again, if in enunciating this theorem, that part of the hypothesis which contains the construction be suppressed, the proposition thence arising will be a *porism*; for it will enunciate a truth, and will also require, to the full understanding and investigation of that truth, that something should be found, *viz.* the circumstance in the construction supposed omitted.

Thus, when we say, if from two given points E and D , (*fig. 13.*) two lines, EF and FD , are inflected to a third point F , so as to be to one another in a given ratio, the point F is in the circumference of a circle given in position; we have a locus.

But when it is said conversely; if a circle ABC , of which the centre is O , is given in position, as also a point E ; and if D be taken in the line EO , so that the rectangles EO , OD , be equal to the square of AO , the radius of the circle; and if from E and D the right lines EF and DF be inflected to any point whatever in the circumference ABC ; the ratio of EF to DF will be a given ratio, and

and the same with that of $E A$ to $A D$; we have a local theorem.

And, lastly, when it is said, if a circle $A B C$ be given in position, and also a point E , a point D may be found, such, that if the two lines $E F$ and $F D$ be inflected from E and D to any point whatever, F , in the circumference, these lines shall have a given ratio to one another; the proposition becomes a porism. Here it is evident, that the local theorem is changed into a porism, by leaving out what relates to the determination of the point D , and of the given ratio. But though all propositions formed in this way, from the conversion of *loci* be porisms, yet all porisms are not formed from the conversion of loci; and, therefore, the definition which defines all porisms as being so convertible is not sufficiently comprehensive. Fermat's idea of porisms was founded wholly on this definition, and therefore could not fail to be imperfect.

Hence it follows, that the definition of porisms given above agrees with Pappus's idea of these propositions, as far at least as can be collected from the imperfect fragments which contain his general description of them; and it agrees also with that of Dr. Simson, as stated in the former part of this article, *viz.* "Porisma est propositio in qua proponitur demonstrare rem aliquam, vel plures datas esse, cui, vel quibus, ut et cuilibet ex rebus innumeris non equidem datis, sed quæ ad ea quæ data sunt eandem habent relationem, convenire ostendendum est affectionem quandam communem in propositione descriptam."

It is here that there is a considerable degree of obscurity in this definition; notwithstanding which it is certain, that every proposition to which it applies must contain a *problematical* part, *viz.* "in qua proponitur demonstrare rem aliquam, vel plures datas esse;" and also a *theoretical* part, which contains the property or communis affectio, affirmed of certain things that have been previously described.

It is also evident, that the subject of every such proposition, is the relation between magnitudes of three different kinds; determinate magnitudes, which are to be found, and indeterminate magnitudes, which, though unlimited in number, are connected with the others by some common property, which are exactly the conditions contained in the definitions that have been given above.

In an enquiry into the origin of porisms, the etymology ought not to be forgotten. The question indeed is not about the derivation of the word *πορισμα*, for on that head there is no doubt, but about the reason why this term was applied to the class of propositions above described. Two opinions may be formed on this subject, and both of them with considerable probability. One of the significations of *πορίζω*, is to *acquire* or *obtain*, and hence *πορισμα* the thing *obtained* or *gained*.

Accordingly Scapula says, "Est vox a geometris desumpta qui theoremata, aliquid ex demonstrativo syllogismo necessario sequens inferentes illud quasi lucrari dicuntur, quod non ex professio quidem theorematis, hujus instituta sit demonstratio, sed tamen ex demonstratis recte sequatur." In this sense Euclid uses the word in his Elements of Geometry, where he calls the corollaries of his propositions, *porismata*. This circumstance creates a presumption, that when the word was applied to a particular class of propositions, it was meant, in both cases, to convey nearly the same idea, as it is not at all probable, that so correct a writer as Euclid, and so scrupulous as he was in his use of words, should use the same word to convey two ideas, which are so perfectly different. May we not, therefore, conjecture that these propositions got the name of porisms entirely with a reference to their origin.

According to the idea explained above, they would generally occur to mathematicians, when engaged in the solution of the most difficult problems, and would arise from those particular cases, where one of the conditions of the data involved in it some one of the rest. Thus a particular kind of theorem would be obtained, following as a corollary from the solution of the problem: and to this theorem the term *πορισμα* might be very properly applied, since, in the words of Scapula above-mentioned, "non ex professio theorematis hujus instituta sit demonstratio, sed tamen ex demonstratis recte sequatur."

But though this interpretation agree so well with the supposed origin of porisms, it is not free from difficulty. The verb *πορίζω* has another signification, *to find out*, *to discover*, *to devise*, and is used in this sense by Pappus, when he says, that the propositions called porisms afford great delights, *τοις δυναμοις οραν και ποριζμα*, to those who are able to understand and investigate. Hence comes *πορισμος*, the act of *finding out* or *discovering*; and from *πορισμος*, in this sense, the same author evidently considers *πορισμα* as being derived. His words are; *Εφασαν δε (οι αρχαιαι) πορισμα ενωπιον προτεινομενον εις πορισμον αυτη προτεινομενου*, *the ancients said a porism is something proposed for the finding or discovering of the very thing proposed*. It seems singular, however, that porisms should have taken their name from a circumstance common to them with so many other geometrical truths; and if this was really the case, it must have been on account of the enigmatical form of their enunciations, which required, that in the analysis of these propositions a sort of double discovery should be made, not only of the truth, but also of the meaning of the very thing that was proposed. They may, therefore, have been called *porismata*, or investigations, by way of eminence.

We might next proceed to consider the particular porisms which Dr. Simson has restored, and to shew that every one of them is the indeterminate case of some problem. But of this it is so easy for any one, who has attended to the preceding remarks, to satisfy himself by barely examining the enunciations of those propositions, that the detail into which it would lead seems to be unnecessary. We shall, therefore, go on to make some observations on that kind of analysis which is particularly adapted to the investigation of porisms.

If the idea we have given of these propositions be just, it follows, that they are always to be discovered by considering the cases in which the construction of a problem fails in consequence of the lines, which by their intersection, or the points which by their position were to determine the magnitude required, happening to coincide with one another. A porism, therefore, may be deduced from the problem it belongs to, in the same manner that the propositions concerning the maxima and minima are deduced from the problems of which they form the limitations; and such, no doubt, is the most obvious and most natural analysis of which this class of propositions will admit.

It is not, however, the only one that they will admit of, and there are good reasons for wishing to be provided with another, by means of which a porism that is any how suspected to exist may be found out, independently of the general solution of the problem to which it belongs. Of these reasons one is, that the porism may perhaps admit of being investigated, more easily than the general problem admits of being resolved; and another is, that the former, in almost every case, helps to discover the simplest and most elegant solution that can be given of the latter.

It is desirable to have a method of investigating porisms, which does not require that we should previously have re-

PORISM.

solved the problems they are connected with, and which may always serve to determine whether to any given problem there be attached a porism or not. Dr. Simson's analysis may be considered as answering to this description; for as that geometer did not regard these propositions at all in the light that is done here, nor in relation to their origin, an independent analysis of this kind was the only one that could occur to him; and he has accordingly given one which is extremely ingenious, and by no means easy to be invented, but which he uses with great skilfulness and dexterity throughout the whole of his Restoration.

It is not easy to ascertain whether this be the precise method used by the ancients. Dr. Simson had here nothing to direct him but his genius, and has the full merit of the first inventor. It seems probable, however, that there is at least a great affinity between the methods, since the *lemmata* given by Pappus as necessary to Euclid's demonstrations, are subservient also to those of our modern geometer.

It is, as we have seen, a general principle, that a problem is converted into a porism, when one or when two of the conditions of it necessarily involve in them some one of the rest: suppose, then, that two of the conditions are exactly in that state which determines the third; then while they remain fixed or given, should that third one be supposed to vary, or differ ever so little, from the state required by the other two, a contradiction will ensue. Therefore if, in the hypothesis of a problem, the conditions be so related to one another as to render it indeterminate, a porism is produced; but if, of the conditions thus related to one another, some one be supposed to vary, while the others continue the same, an absurdity follows, and the problem becomes impossible. *Wherever, therefore, any problem admits both of an indeterminate and an impossible case, it is certain that these cases are nearly related to one another, and that some of the conditions by which they are produced are common to both.*

It is supposed above, that two of the conditions of a problem involve in them a third, and wherever that happens, the conclusion which has been deduced will invariably take place. But a porism may sometimes be so simple, as to arise from mere coincidence of *one* condition of a problem with another, though in no case whatever any inconsistency whatever can take place between them. Thus, in the second of the foregoing propositions, the coincidence of the point given in the problem with another point, *viz.* the centre of gravity of the given triangle, renders the problem indeterminate; but as there is no relation of distance, or position, between these points that may not exist, so the problem has no impossible case belonging to it.

There are, however, comparatively but few porisms so simple in their origin as this, or that arise from problems, in which conditions are so little complicated; for it usually happens, that a problem which can become indefinite, may also become impossible; and if so, the connection between these cases, which has been already explained, never fails to take place.

Another species of impossibility may frequently arise, from the porismatic case of a problem, which will very much affect the application of geometry to astronomy, or any of the sciences of experiment or observation. For when a problem is to be resolved by help of data, furnished by experiment or observation, the first thing to be considered is, whether the data so obtained be sufficient for determining the thing sought; and in this a very erroneous judgment may be formed, if we rest satisfied with a general view of the subject. For though the problem may in general be resolved from the data that we are provided with, yet these data may be so related to one another in the case

before us, that the problem will become indeterminate, and instead of one solution will admit of an infinite number.

Suppose, for instance, that it were required to determine the position of a point, F, from knowing that it was situated in the circumference of a given circle ABC, and also from knowing the ratio of its distances from two given points E and D; it is certain that in general these data would be sufficient for determining the point F. But, nevertheless, if E and D should be so situated that they were in the same straight line with the centre of the given circle, and if the rectangle under their distances from the centre were also equal to the square of the radius of the circle, then the position of F could not be determined.

This particular instance may not indeed occur in any of the practical applications of geometry; but there is one of the same kind which has actually occurred in astronomy, and as the history of it is not a little singular, affording besides an excellent illustration of the nature of porisms, the detail of it will not be uninteresting to the reader. Sir Isaac Newton having demonstrated that the trajectory of a comet is a parabola, reduced the actual determination of the orbit of any particular comet to the solution of a geometrical problem, depending on the properties of the parabola; but of such considerable difficulty, that it was necessary to take the assistance of a more elementary problem, in order to find, at least nearly, the distance of the comet from the earth at the times when it was observed. The expedient for this purpose, suggested by Newton himself, was to consider a small part of the comet's path as rectilinear, and described with a uniform motion, so that four observations of the comet being made at moderate intervals of time from one another, four lines would be determined, *viz.* the four lines joining the earth and comet at the time of observation; across which, if a straight line were drawn so as to cut them in three parts, in the same ratio with the intervals of time above-mentioned, the line so drawn would nearly represent the comet's path, and by its intersection with the given lines, would determine, at least nearly, the distance of the comet from the earth at the times of observation.

The geometrical problem here employed, of drawing a line to be divided by four other lines given in position into parts having a given ratio to one another, had been already resolved by Dr. Wallis and Sir Christopher Wren, and to their solution Sir Isaac Newton added three others of his own, in different parts of his works; yet no one of these geometers observed that peculiarity in the problem which rendered it applicable to astronomy. This was first done by M. Boscovich, but not till after many trials, when, on its application to the motion of comets, it had never led to any satisfactory result. The errors it produced in some instances were so considerable, that Zanotii, seeking to determine by it the orbit of the comet of 1739, found that his construction threw the comet on the side of the sun, opposite to that on which he had actually observed it. This gave occasion to Boscovich, some years afterwards, to examine the different cases of the problem, and to remark, that in one of them it became indeterminate, and by a curious coincidence, this happened in the only case which could be supposed applicable to the astronomical problem above-mentioned. In other words, he found that in the state of the data, which must there always take place, innumerable lines might be drawn that would be all cut in the same ratio, by the four lines given in position. This he demonstrated in a dissertation published at Rome in 1749; and since that time in his *Opuscula*. A demonstration of it, by the same author, is also inserted at the end of Castillon's Commentary on Arithmetica

metica Universalis, where it is deduced from a construction of the general problem, given by Thomas Simpson, at the end of his Elements of Geometry. The proposition in Boscovich's words is this; "Problema quo quaeritur recta linea quae quatuor rectas positione datas ita secet, ut tria ejus segmenta sint invicem in ratione data, evadit aliquando indeterminatum, ita ut per quodvis punctum cujusvis ex iis quatuor rectis duci possit recta linea, quae ei conditioni faciat satis."

This proposition, our author observes, thus enunciated, is a porism, and that there is no doubt it was discovered by Boscovich in the same manner as we have supposed porisms to have been first discovered by the geometers of antiquity.

But a question nearly connected with the origin of porisms still remains to be solved, namely; from what cause has it arisen, that propositions which are in themselves so important, and that actually occupied so large a part of the ancient geometry, have been so little remarked in the modern? It cannot indeed be said, that propositions of this kind are wholly unknown to the moderns before the restitution of what Euclid had written concerning them. For before Boscovich's proposition, of which so much has been already said, the theorem which asserts, that in every system of points there is a centre of gravity, has been shewn above to be a porism, and we shall see hereafter, that many of the theorems in the higher geometry belong to the same class of propositions. We may add that some of the elementary propositions in geometry want only the proper form of enunciation to be perfect porisms. It is therefore not strictly true, that none of the class of propositions called porisms have been known to the moderns; but it is certain, that they have not met from them with the attention they met with from the ancients, and that they have not been distinguished as a separate class of propositions. The cause of this difference is undoubtedly to be sought for in a comparison of the methods employed for the solution of geometrical problems in ancient and modern times.

In the solution of problems, the geometers of antiquity proceeded with the utmost caution, and were careful to remark every particular case, that is to say, every change in the construction, which any change in the state of the data could produce. The different conditions from which the solutions were derived, were supposed to vary one by one, while the others remained the same, and all their possible combinations being thus enunciated, a separate solution was given wherever any considerable change was observed to have taken place. This was so much the case, that the *scitio rationis*, a geometrical proposition of no great difficulty, and one of which the solution would be dispatched, according to the methods of the modern geometry, in a single page, was made by Apollonius the subject of a treatise, consisting of two books. The first book has seven general divisions, and seventy-three cases, each of which cases is separately considered. Nothing, it is evident, that was any way connected with the problem, could escape a geometer who proceeded with such minuteness of investigation. The same scrupulous exactness may be remarked in all the other mathematical researches of the ancients; and the reason doubtless is, that the geometers of those ages, however expert they were in the use of their analysis, had not sufficient experience in its power, to trust to the more general applications of it. That principle which we call the *law of continuity*, and which connects the whole system of mathematical truths by a chain of insensible gradations, was scarcely known to them, and has been unfolded to us, only by a more extensive knowledge of the mathematical sciences, and by that most perfect mode of expressing the relations

of quantity, which forms the language of algebra; and it is this principle alone that has taught us, that though in the solution of a problem, it may be impossible to conduct the investigation, without assuming the data in a *particular* state, yet the result may be perfectly *general*, and will accommodate itself to every case with such a wonderful universality, as is scarcely credible to the most experienced mathematician, and such as often forces him to stop in the midst of his calculus, and look back with a mixture of diffidence and admiration on the unforeseen harmony of his conclusions. All this was unknown to the ancients, and therefore they had no resource, but to apply their analysis separately to each particular case, with that extreme caution which has just been described; and in so doing they were likely to remark many peculiarities, which more extensive views, and more expeditious methods of investigation, might perhaps have led them to overlook.

To rest satisfied, indeed, with too general results, and not to descend sufficiently into particular details, may be considered as a vice that naturally arises out of the excellence of the modern analysis. The effect which this has had, in concealing from us the class of propositions we are now considering, cannot be better illustrated than by the example of the porism discovered by Boscovich, in the manner related above. Though the problem from which that porism is derived was resolved by several mathematicians of the first eminence, among whom also was sir Isaac Newton, yet the porism, which, as it happens, is the most important case of it, was not observed by any of them. This is the more remarkable, that sir Isaac Newton takes notice of the two most simple cases, in which the problem evidently admits of innumerable solutions, *viz.* when the lines given in position are either all parallel, or all meeting in a point, and these two hypotheses he therefore expressly excepts. Yet he did not remark, that there are other circumstances, which may render the solution of the problem indeterminate as well as these; so that the porismatic case considered above escaped his observation; and if it escaped the observation of one who was accustomed to penetrate so far into matters infinitely more obscure, it was because he satisfied himself with a general construction, without pursuing it into its particular cases. Had the solution been conducted after the manner of Euclid or Apollonius, the porism in question must infallibly have been discovered. Edinburgh Phil. Transf. vol. iii. See also a paper on the same subject by H. Brougham, esq. Phil. Transactions for 1798, or New Abridgment, vol. xviii. p. 345—355.

PORISTIC METHOD, in *Mathematics*, is that which determines when, by what means, and how many different ways, a problem may be solved.

PORLAIT, or **PORLOYD**, in *Geography*, a river of North Wales, in the county of Caernarvon.

PORLARKSHOFEN, a bay on the S. coast of Iceland. N. lat. 64°. W. long. 17°.

PORLEZZO, a town of Italy, in the department of the Lario; 14 miles N. of Como.

PORLOCK, or **PORTLOCK**, a small sea-port, market town, and parish, in the hundred of Carhampton, and county of Somerset, England, is situated on the southern shore of the Bristol channel, at the distance of 167 miles W. by S. from London. The town was anciently a place of considerable note. In the time of the Saxon dynasty it was a royal vill, and was invested with many important privileges. It had then, and for many years posterior to the conquest, an extensive chace annexed to it, and also a free weekly market. Tradition even affirms, that it was a large and populous city, possessing all the splendour and magnificence

science of a royal metropolis; but this is a mere vulgar tale, and utterly undeserving of credit. That it was far more important, and better inhabited than any other sea-port town in the vicinity, however, is extremely probable, as extensive foundations of houses have been discovered here within the last century. Leland speaks of it as "a meatly good rode for shippes," but at present it is little frequented.

Porlock makes some figure in history during the Danish wars. In the year 918, a party of these marauders landed here under the conduct of earls Ohtor and Roald; but being soon discovered, they were attacked with such impetuosity by the inhabitants, that the greater part of them was cut off, and the remainder forced to re-embark with the utmost precipitation. In 1052, Harold, earl of Essex, who had been banished with his father, the earl of Kent, also landed at this place with a body of troops from Ireland, and met with the same firm resistance from the inhabitants as had been experienced by the Danes. The event of the contest, however, was different; for Harold not only obtained possession of the town, but advanced many miles into the country, spreading death and desolation every where around him. At length the approach of the royal forces compelled him to retrace his steps; but before re-embarking, he set fire to the town of Porlock and the adjacent woods, which were in consequence completely consumed.

At present Porlock consists only of two mean straggling streets, situated close to the church; which is an ancient structure in the English style of architecture, and contains several old tombs. Formerly a market was held here weekly, on Thursday, but there are now only three markets during the year, one at Michaelmas, which is the great market, and two in the spring, all for cattle. In the middle of the town stands an ancient market cross.

According to the parliamentary returns of 1811, Porlock parish comprises a population of 633 persons, inhabiting 140 houses. The scenery in this neighbourhood is highly picturesque and romantic. Steep and lofty hills, covered with wood, and intersected by deep vales, environ the town on every side except towards the sea, where the rocks rise with the boldest irregularity in many places, to the perpendicular height of three hundred feet. The whole of these rocks display numerous metallic veins and crystals of different kinds. In a wood, about a mile and a half from the town, are still seen the remains of an entrenchment, supposed to have been formed by Harold. Swords and other warlike instruments have been frequently dug up within the area. The History and Antiquities of the County of Somerset, by the Rev. John Collinson, F.S.A. 3 vols. 4to. 1791.

PORNASCE, a town of the Ligurian republic; 13 miles W.N.W. of Albenga.

PORNIC, a town of France, in the department of the Lower Loire, and chief place of a canton, in the district of Painbœuf, chiefly inhabited by fishermen; 11 miles S. of Painbœuf. The place contains 806, and the canton 6335 inhabitants, on a territory of 150 kilometres, in six communes.

PORO, a town of European Turkey, in Albania, near the river Vojussa; 12 miles N.E. of Valona.—Also, an island in the gulf of Engia, near the coast of Greece, anciently called "Calanrea;" 22 miles W. of Cape Colonna. N. lat. $37^{\circ} 31'$. E. long. $23^{\circ} 42'$.—Also, a small island among the Philippines, near the W. coast of Leyta. N. lat. $10^{\circ} 35'$. E. long. $124^{\circ} 20'$.

PORO Hotun, a town of Chinese Tartary; 108 miles N.E. of Peking. N. lat. $41^{\circ} 22'$. E. long. $117^{\circ} 14'$.

POROCELE, in *Surgery*, a hard tumour of the testicle.

POROG, in *Geography*, a town of Russia, in the government of Archangel; 20 miles S.E. of Oneg.—Also, a town of Austrian Poland, in Galicia; 28 miles S.S.W. of Halicz.

POROMASHIR. See PARAMOUSIR.

POROMPHALON, in *Surgery*, a hard tumour of the navel.

POROPHYLLUM, in *Botany*, so called from the pellucid dots, or pores, in the leaves. See CACALIA.

POROS, in *Geography*, an island in the Grecian archipelago, about 12 miles in circumference, near the E. coast of Greece, opposite to a bay called the "gulf of Poros." N. lat. $37^{\circ} 37'$. E. long. $23^{\circ} 30'$.

POROSLO, or BOROSLO, a town of Hungary, on the W. side of the Theyffe, in which is a magazine for salt; 18 miles S.E. of Erlau.

POROSTEMA, in *Botany*, from *πορος*, a pore, and *σημα*, a flamen, alluding to the origin of the stamens from the pores of the nectary.—Schreb. Gen. 517. Mart. Mill. Dict. v. 3. (Nectandra; Rolander MSS. Ocotea; Aubl. Guian. 780. Juss. 80.)—Class and order, *Polyadelphia Polyandria*. Nat. Ord. *Lauri*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, coloured, permanent, in six deep ovate obtuse segments; the three inner ones smallest. *Cor.* Petals none. Nectary of nine oblong abrupt scales, of which six are external, inserted into the base of the segments of the calyx, and lying upon them; and three internal, inserted into the receptacle, opposite to the others; each scale marked with four pores, the outer ones on the inside, the inner ones on the outside. There are also six roundish fleshy glands, inserted into the base of the calyx, between the two rows of scales. *Stam.* Filaments 36, each springing from a pore of the scales; anthers roundish, peltate, compressed. *Pist.* Germen ovate, angular, immersed in the receptacle; style short; stigma obtuse, concave. *Peric.* Capsule roundish, invested with the calyx, of from four to six cells. *Seeds* numerous, minute.

Eff. Ch. Calyx in six unequal segments. Petals none. Nectary of nine scales, each bearing four stamens. Capsule of several cells. *Seeds* numerous.

1. *P. guianensis*. (*Ocotea guianensis*; Aubl. t. 310.)—Native of most of the Guiana forests, flowering in April, and bearing fruit in June. The natives call this tree Ajouhou-ha. Its trunk is thirty feet high; the branches spreading. *Leaves* alternate, nearly sessile, lanceolate, pointed, entire, four or five inches long; smooth above; white and beautifully silky beneath. They are very remarkable for a plait or line, situated on each side of the nerve; but these are very differently placed, one being transverse near the base, and very short; the other longitudinal, not meeting with the nerve, though very long. The latter line has, in the dried plant, every appearance of having been caused by the hard pressure of some other leaf, which is however a deception. The specific name ought to have alluded to these very peculiar marks in the foliage. The flowers are small, fragrant, in axillary panicles. The leaves are employed as a cataplasm to ripen tumours or buboes.

POROSZOW, in *Geography*, a town of Lithuania, in the palatinate of Novogrodek; 10 miles S. of Wolkomyisk.

POROTICKS, in the *Materia Medica*, a term used by the ancients for such medicines as would consume calluses.

POROZ, in *Geography*, a river of Russia, in the government of Viatka, which runs into the Kama, near Kai.

PORPESE, in *Ichthyology*. See DELPHINUS *Phœnæna*.

To the brief account that has been given of the porpesse, under

under the article DELPHINUS, we shall give some farther particulars. This fish has no gills, nor any aperture in the place of them; but in the middle of the upper part of its head, before the brain, it has a pipe or spiracle, in form of a half moon, through which fishes of this sort draw in their breath, and spout out the water; this pipe terminates outwardly in one hole, but it is within divided into two parts by a bony septum, so as to represent two nostrils; but at its lower end it again becomes one hole, and opens into the mouth by a common orifice furnished with a very strong sphincter muscle, by means of which it may be shut and opened at pleasure; above this sphincter, the sides of the pipes are lined with a glandulous flesh, from which, when pressed, a glutinous liquor is forced out of certain little holes in it into the inside of the pipe; above the nostrils is a strong valve or membrane, which serves to stop the pipe at pleasure, and prevent any water from getting into it, but when the fish requires it within; within the fistula are six blind holes, having no outlet, four tending towards the snout, two placed above the valve, which stops the nostrils, and two beneath it; and two tending towards the brain, having a long and narrow cavity, which seems intended for the use of smelling, though, on opening the brain, no such olfactory nerves, or processus mamillares, as other animals are furnished with for this purpose, are to be found. The great contrivance of nature in the horizontal position of the tail in these fishes is, that it may supply the place of the hinder pair of belly-fins in other fish, those of the cetaceous kind having none such. These fins in other fish serve to balance the body, and keep it under water, and answer also in many respects to the hinder legs of a quadruped; and hence we see, that those fish which have long bodies, and have not this hinder pair of fins, nor the horizontal tail, cannot suspend themselves quietly in the water, but are forced to keep grovelling at the bottom. This is the case of eels, and all other fish of that kind: the use of respiration being as necessary to the porpessæ as to quadrupeds, and its wanting this pair of hinder fins, to poise or elevate itself with, nature has abundantly provided against the mischiefs that would attend that defect, by giving it this transverse tail, by a sudden jerk of which it can in a moment throw itself up to the surface from the deep water. The whale, and all the cetaceous fishes requiring the use of respiration, have also this manner of raising their unwieldy bodies allotted them by nature, instead of the hinder pair of fins, which must have been inconveniently large to be capable of this office. Its lungs and heart are like those of quadrupeds. The porpessæ has no gall-bladder, and thence authors have concluded that it has no gall; but this is too hasty a conclusion; for there is a duct which arises in the liver, and has a great many branches, and which, tending downwards, joins itself to the pancreatic duct; and these two, so united together, form a canal, or common duct, about four or five lines long, before they discharge their contents into the duodenum; from whence it appears that the porpessæ has always a discharge of bile into the duodenum, though it is thin and diluted, and such as, in other animals, is usually called *hepatic bile*. The brain is large, and resembles that of man; and probably it has been an observation of this that has given occasion to the opinion of this animal having so great a share of will and understanding, that has given rise to the story of Herodotus, that Arion was carried to shore on the back of one; and that of Pliny the elder, of one of these fish so fond of a certain boy, that he used to carry him daily from Baiæ to Puteoli, across the sea to school, and wait to carry him back again at a certain time. Pliny the younger gives us also a story of this kind in his epistles.

The blood of the porpessæ is as warm to the touch as that of quadrupeds, and the blubber, or fat, which lies in great quantity under the skin, covering the muscular flesh of the back and sides, is to keep up the natural heat, and prevent the cold of the sea water from chilling the circulating fluid. This blubber yields a great quantity of excellent oil.

The food of the fish seems to bespeak its living at the bottom of the water; for the common matter found in its stomach is the remains of fish that live in or on the bottom. The young porpessæ are generally found to feed on the ammodytæ, or sand-eels, and sea-worms.

We have from Dr. Lister an account of the tooth of this creature, after death, giving an envenomed wound. The accident happened to the doctor himself, and he relates it in *Phil. Trans.* N^o 233. *Abridg.* vol. ii. p. 842.

PORPHYRA, in *Botany*, so named from the purple colour of the flower.—*Lourec. Cochinch.* 69.—Class and order, *Tetrandria Monogynia*. *Nat. Ord.*

Gen. Ch. *Cal.* Perianth inferior, abrupt, permanent. *Cor.* of one petal, bell-shaped; tube longer than the calyx; limb in four deep rounded segments. *Stam.* Filaments four, twice the length of the corolla, inserted into its base; anthers ovate, erect. *Pist.* Germen roundish; style thread-shaped, equal to the stamens; stigma roundish, abrupt. *Peric.* Berry globose, of one cell. *Seeds* three, convex at the outside, angular at the inside.

Ess. Ch. *Calyx* inferior, abrupt. *Corolla* bell-shaped, in four deep segments. *Berry* with three seeds.

1. *P. dichotoma*. Tû hōa uôn of the Chinese.—Native of hills about Canton, in China. A *shrub* three feet high, erect, with many weak, straight branches. *Leaves* opposite, nearly sessile, lanceolate, serrated, dotted. *Clusters* axillary, forked. *Flowers* purple. *Berries* very small, copious, violet-coloured, globose, fleshy.—We know nothing of this genus, which seems nearly related to *Callicarpa*, but from the author quoted.

PORPHYREUM, or PORPHYREON, in *Ancient Geography*, a town of Phœnicia, between Berytus and Sidon. *Steph. Byz.* says, that it derived its name from its situation on the coast, near which was found the fish that afforded the purple dye.

PORPHYRIANA ARBOR. See ARBOR.

PORPHYRIANS, in *Ecclesiastical History*, an opprobrious name given to the Arians, by an edict of Constantine, at the council of Nice, in 325. *Cap.* 36. *apud Hard. Concil. tom. i.* p. 446.

That prince, publishing an edict against Arius and his writings, declares, that as Arius had imitated Porphyry in composing books against religion, he deserves to be noted with his infamy; and that, as Porphyry is become the reproach of posterity, and his writings suppressed, so he wills, that Arius and his followers be called *Porphyrians*, &c.

PORPHYRIO, in *Ornithology*, the name of a bird figured and described by all the natural historians from one another, but which, it seems, none of them ever saw; and there is some room to doubt whether there be in nature any such bird. According to the accounts we have of it, it appears to be one of the gallinula or moor-hen kind, and is all over of a fine deep blue, only the middle of the tail is at the extremity of a greyish-white; its legs and feet are of a fine shining purple. There have been some fabulous things related of it, as having five toes on each foot, and the like; but if there be any such creature, it seems to be a moor-hen of these remarkable colours. In the Linnæan system this is a species of *Fulica*. The name is also given to other species, for which see *FULICA*.

PORPHYRIO *Refescens* is also a name given by Briffon to a variety of the *RALLUS Crax*; which see.

PORPHYROGENITUS, in *Antiquity*, an appellation given to the children of the Eastern emperors; implying as much as *born in purple*.

Cedrenus will have the word to signify, *born in the purple palace*, or the *palace of porphyry*, a palace so called in Constantinople, in which the empresses used to lie in. Others derive the appellation hence, that the imperial children, as soon as born, were wrapped in purple; others from this, that the chamber, in which they were born, was hung with purple hangings.

This term is sometimes found on the medals of the lower empire, struck at Constantinople.

PORPHYRY, in *Biography*, one of the most learned and celebrated preceptors of the Plotinian school, and an inveterate enemy to the Christian faith, was descended from an honourable family of Tyre, in Phœnicia, in the year 233. His original name was Meleck, which, in Syriac, signifies king, and hence he was sometimes called King. Afterwards Longinus changed his name into Porphyry, signifying in Greek purple, which was usually worn by kings and princes. He was introduced at an early age to the study of literature and philosophy under the Christian Origen, whose school he probably attended at Cæsarea, in Palestine: afterwards he went to Athens, where he became a pupil of Longinus, and improved his taste in literature. He was at Rome in the year 253, but did not then make a long stay there, but came thither again when he was about thirty years of age, and put himself under the instruction of Plotinus, who in a short time regarded him as one of the brightest ornaments of his school, and frequently employed him in combating the objections of his opponents, and in explaining to his younger pupils the more difficult parts of his writings. He even confided to him the care of methodizing and correcting his works. At the age of thirty-six he formed a resolution of putting an end to his life, in order that, according to the Platonic doctrine, he might release his soul from her wretched prison the body. Plotinus prevented the execution of his design. He was in Sicily when Plotinus died in Campania, and appeared in the character of an open and implacable adversary to the Christian religion. It has been said, that he was originally a believer in Christianity, but there is no proof of the fact, though he probably gained some acquaintance with the scriptures while he was a child, and pupil of Origen. The treatises of Porphyry against Christianity were supposed to have been written in Sicily: they are now lost, and are said to have been partially destroyed, through orders issued by the emperor Constantine. Many of them were extant in the fifth century, and were known to Jerome, who made large extracts from them. From Sicily Porphyry returned to Rome, where he taught the doctrines of Plotinus, and acquired great celebrity for learning and eloquence. He pretended to be divinely inspired, and relates, that when he was in the sixty-eighth year of his age, he was in a sacred extacy, in which he saw the supreme intelligence, the God who is superior to all gods, without an image. He married a widow, not he said for the sake of having children by her himself, but that he might have an opportunity of educating those which she had borne to a former husband. He died at Rome about the year 303. "He was," says Enfield, "a writer of deep erudition, and had his judgment and integrity been equal to his learning, he would have deserved a distinguished place among the ancients. But neither the splendour of his diction, nor the variety of his reading, can

atone for the credulity, or dishonesty, which filled the narrative parts of works with so many extravagant tales, or interest the judicious reader in the abstruse subtleties and mystical flight of his philosophical writings." His works were very numerous, of which a long catalogue has been given by Suidas, Fabricius, and others. The fragments that remain of them may be found in Lardner, to whom we refer our readers, and also to Enfield's Hist. Phil.

Porphyry was author of several works upon music, some of which are still preserved, particularly his "Commentaries on Ptolemy's Harmonics," which is published in the third volume of Dr. Wallis's mathematical works, with Ptolemy and Bryennius, which, with the seven Greek writers on music, published by Meibomius in 1652, include all the Greek treatises on the subject of music that are come down to us.

PORPHYRY, in *Mineralogy*, derived from *πορφυρο*, purple, in reference to its colour, is a denomination that distinguishes a large class of primitive rocks, composed of one substance in the form of grains or crystals, imbedded in another consisting most commonly of a compact paste, as its basis. The base is clay-stone, horn-stone, compact felspar, pitch-stone, pearl-stone, or obsidian; the implanted grains or crystals are of quartz or felspar. Of porphyry there appear to be two formations; the most ancient consists principally of horn-stone and felspar porphyry, and the most recent are of clay, pitch-stone, pearl-stone, and obsidian porphyry. The porphyritic formation is not very distinctly separated from the other rock formations which accompany it, nor is its rank among the primitive mountains, with regard to antiquity, very clearly ascertained. The mountains of porphyry are not stratified, and never enclose beds of other substances. Its texture is commonly compact, but it occasionally occurs in schistone. It is not very rich in mineral veins; the clay porphyry is the most rich. The mines of Schweitz, in Hungary, which are of this description, are found in this species of rock. Some writers have reckoned five species of rocks belonging to the proper porphyritic formation, which are as follow: viz. 1. *Horn-stone porphyry*, the base of which, being horn-stone, is generally red or green, with a conchoidal or splintery fracture; and inclosing crystals of quartz and felspar. This is also distinguished, says Kirwan, by its hardness, slight transparency, and want of lustre; it is fusible without difficulty. Sometimes the felspar is decayed, and sometimes also the horn-stone, whilst the quartz and hornblende remain entire: the whole thus acquires the appearance of indurated volcanic ashes, though the quartz might prove the contrary: if the felspar alone be decayed, the horn-stone will appear porous, and may be taken for lava. Its transitions are into granite and sand-stone. 2. *Felspar porphyry*, the base of which is commonly red compact felspar, inclosing crystals of felspar and quartz. (See FELSPAR.) 3. *Sienitic porphyry*, which differs from the preceding in containing crystals of hornblende in addition to the other ingredients. 4. *Pitch-stone porphyry*, the base of which is pitch-stone, either red, green, brown, grey, black, or yellow, of various shades, having generally many colours at once in the same specimen. According to Kirwan, this porphyry has the following characters; lustre greasy, 2.1: transparency, 2.1: fracture, imperfectly conchoidal: hardness, 8, 9, 10: the felspar often blue: the fracture of some is slaty, and colour yellowish-grey; lustre, scarcely 1; transparency, 1; hardness, scarcely 9; specific gravity, 2.452. 5. *Clay porphyry*, the base of which is indurated clay, passing into horn-stone; generally of a reddish colour, and containing crystals of quartz and felspar. The colour of this

PORPHYRY.

this porphyry, belonging to Kirwan's Argillaceous porphyries, is generally some shade of grey, or greenish-grey, or brown, or blackish or reddish-brown, or isabella yellow. Lustre and transparency, 0; fracture, earthy; hardness, from 5 to 7; sometimes adhering to the tongue. The metalliferous stone of Born, or graustein of the Germans, celebrated in Hungary, is of this species; its colour being some shade of green, inclining to black, rarely reddish, and consisting of indurated clay, in which are found hornblende, felspar, mica, and quartz. This porphyry is much subject to decay; the felspar either moulders, or loses its lustre; and also the hornblende; and the whole has been thus mistaken for volcanic traafs. The reddish porphyry of the Hartz, whose specific gravity is so low as 2.405, is probably of this species. Also the porphyry of the Pottchapel, described by Mr. Weifs; which consists of quartz, felspar, and mica, held together by a grey clay, and there called a white sand-stone. The isabella yellow clay porphyry of Leske is remarkable: it has the earthy aspect of a marle. Its lustre and transparency, 0; fracture, earthy; hardness, 9; specific gravity, 2.563; melting at 148° into a greyish glazed porcelain: the felspar in this stone is ochre-yellow, and easily distinguished while the stone is undecayed, but it is very subject to moulder.

Mr. Kirwan refers the porphyry to the class of aggregated stones, and says, that any stone, which, in a siliceous or argillaceous ground, or basis, contains scattered specks, grains, or dots of felspar, visible to the naked eye, is at present denominated a porphyry: but with felspar it generally contains quartz, hornblende, and mica, which imbedded, or inhering, stones are generally of a different colour from the ground, in which, as in a cement, they are stuck and crystallized. Of late, he adds, this name has been given to stones which do not visibly contain felspar. He distinguishes four sorts of porphyry, viz. the *siliceous*, *argillaceous*, *muritic*, and *calcareous*, most of which may be compact, or shistose, or slaty. The specific gravity of porphyries varies with the nature and proportion of their bases. Under the head of *siliceous* porphyries, Kirwan enumerates those, which have either jasper, horn-stone, pitch-stone, obsidian, siliceous shistus, shistose horn-stone, or felspar itself for their basis. The existence of jasper porphyry has been questioned. Of the horn-stone and pitch-stone porphyries we have already given an account. The obsidian porphyry is black or greyish-black; its lustre glossy, 3.2; transparency, 0 or 1; fracture, perfectly conchoidal; hardness, 10. The horn porphyry, or porphyry schiefer of Werner, has siliceous shistus, or horn-slate for its basis: it frequently contains hornblende and quartz much more apparently than felspar; its ground is generally blueish, or greenish, and the felspar white, and often very minute; lustre, 1; transparency, 0 or 1; fracture uneven, coarse, or fine splintery; sometimes tending to the conchoidal, frequently slaty in the gross; hardness, 9.10. It is often decomposed, or disintegrated; its grain is often as fine and close as that of horn-stone, but in that case does not give fire so smartly as the horn-stone of fine grain. It passes into argillite and trap. The basis of the horn porphyry, according to Leske, seems to be a kind of mean between siliceous shistus and argillite: its colour blueish-grey, with some reddish and whitish specks; fracture, thin slaty; hardness, 10; and surface shews a whitish-brown crust from decomposition. The petunse porphyry has felspar for its base; its colour is generally yellowish-brown, or reddish-brown, or brownish-red, or reddish-grey, or flesh-coloured, or yellowish-red: lustre, 0; transparency, 0, or scarcely 1; fracture unequal, or earthy, or fine splintery, or presenting small

folia or lamellæ, exhibits often distinct concretions; hardness, 10.

The *argillaceous* porphyries may have indurated clay, hornblende, trap, wacken, mullen, kragg, or argillite, for their basis. Those with indurated clay for their basis we have already mentioned. The hornblende porphyry, or ophtes of Briffon, denominates masses of sienite, in which the hornblende abounded. (See above.) The colour of the basis is black, or greyish-black, or dark-green, or yellowish-green; the fracture striated, or foliated; specific gravity, when the proportion of hornblende is considerable, 2.972. The trap porphyry has its colour greyish, or blueish-black, or blackish, or reddish-brown, or greenish-grey; lustre and transparency, 0; fracture, earthy, or fine splintery; hardness, from 7 to 9; specific gravity, exceeding 2.7. Sometimes abounding so much in quartz and felspar as to have its hardness 10. (See TRAP.) *Wacken* porphyry is greenish, blackish, reddish, or yellowish-grey, or greyish-black, or liver-brown; lustre and transparency, 0; hardness from 6 to 9; fracture even, earthy, seldom uneven; feeling somewhat sandy. *Mullen* porphyry is blueish-grey, light or dark; lustre and transparency, 0; fracture uneven, and fine splintery; hardness, from 7 to 9; specific gravity, from 2.6 to 2.728. *Kragg* porphyry is greyish-red, or dark-purplish red; lustre and transparency, 0; exceedingly porous; fracture uneven and earthy; hardness, from 5 to 7; feels rough and harsh; gives a yellowish-grey, or reddish streak; often verges to sand-stone. *Argillitic* porphyry is distinguishable from the preceding not merely by its slaty fracture, but also generally by its lustre, and often by its slight transparency. *Novaculite* porphyry is greenish-grey, or greyish-yellow; lustre, 0; transparency, 1, 1.5; fracture fine splintery, earthy, or slightly conchoidal; but in the gross, often slaty; hardness from 7 to 8, rarely 9; feels somewhat greasy.

The *Muritic* porphyries have either potstone or serpentine for their base. Potstone porphyry is greenish, reddish, or yellowish-grey, or speckled with red, or leek green: lustre, 2.1; transparency, 1.0; fracture, undulatingly foliated; the folia very thin; its hardness, from 4 to 6; sp. gr. exceeds 2.7. The serpentine porphyry is dark or olive-green, or greenish-grey, or brownish-red, or greyish-blue, or yellowish, and yellowish-green: lustre, 0; transparency, 1.0; fracture fine splintery, often passing to the uneven; hardness, from 6 to 7; sp. gr. not exceeding 2.7; feels rather soft; found near Florence.

When porphyry is overloaded with felspar, it is difficult to say whether it be a granite or a porphyry, which hath a granitel for its base. To this sort we may annex porphyries, the ground of which makes the smallest part, such as that described by Herman, 2 Chy. An. 1790, 21, which he calls a "porphyrite." It consists of small sparks of felspar, grains of quartz, splinters of hornblende, and fragments of shorl, cemented together by a scarcely discernible jaspidean cement: lustre, 0; fracture fine splintery; hardness, 9; transparency, 0; colour greyish, black, or red, or white. To the species of sand-stone porphyry we may refer the yellowish-grey argillaceous sand-stone, which contains large grains of felspar and quartz; this readily moulders by exposure to the air. Derivative stones are also frequently the ground of porphyries, of which sort is the "earthy horn-stone porphyry." Colour, dark reddish-brown; lustre, 0; transparency, scarcely 1; fracture, fine splintery; fragments, nearly 3; hardness, 9; sp. gr. 2.617. The felspar is scattered, small, and white. Kirwan's El. of Mineral. vol. i.

Porphyry, on account of its hardness, has furnished the

apothecaries and colourmen with stones on which to grind or levigate their powders, and the same quality renders it applicable to other similar purposes. As it is also capable of the most beautiful polish, the porphyry, and the red and black in particular, has been much employed in architectural ornaments; so that temples and public buildings, as well as private houses, have been decorated with it. For this purpose it has been used of different hues and variegations of colour. In a church at Rome there are two exquisitely fine columns of black porphyry, mentioned by Ficoroni. There are also three famous pillars, or obelisks, of porphyry in Egypt; one near Cairo, and the other two at Alexandria. The French call them "Aguglias," the English "Cleopatra's Needles;" which see. Porphyry of different shades of colour is found in Arabia Petræa, in Egypt, in Germany, in Sweden, in France, in Minorca, in many parts of England and Ireland, and in other countries. M. Dorthes has described more than twenty varieties of porphyry thrown up in pebbles by the Mediterranean upon the French coasts, whither they are brought by the Rhone; and many have been found on the British shores, and in some parts of Devonshire far from the sea.

The art of cutting porphyry, practised among the ancients, seems lost. In effect, it is hard to conceive what kind of tools they must have used for the fashioning of these huge columns, and other porphyry works found in some of the antique buildings in Rome.

One of the most considerable pieces, now remaining entire, is a tomb of Constantia, daughter of the emperor Constantine, in the church of St. Agnes without the walls; ordinarily called *the tomb of Bacchus*, because of several boys represented in it, playing among the vine-leaves. Add to this Apollo's, and the busts of twelve emperors, all in porphyry, in the palace of the Thuilleries.

Some of the ancient pieces appear to have been wrought with the chissel, others with the saw, others with wheels, and others ground down by degrees with emery. Yet the modern tools will scarcely touch porphyry: it should seem, therefore, and Dr. Lister (Phil. Trans. N^o 203, or Lowth Abr. vol. ii. p. 560.) adopts this opinion, that the ancients had the secret of tempering steel better than we; not, as some incline to think, that they had the art of softening the porphyry; though it is probable that time and air have contributed to increase its hardness.

Mr. Addison tells us, he saw a workman at Rome employed in the cutting of porphyry; but his advances were exceedingly slow, and almost insensible.

The method which the Italian sculptors use to work the pieces of old porphyry columns still remaining (for the porphyry quarries are long since lost), is with a brass saw without any teeth. With this, together with emery and water, they rub and wear the stone with infinite patience.

Yet have many excellent persons endeavoured to retrieve the ancient art, particularly Leon Baptista Alberti; who, searching for the necessary materials for temper, says, he found goat's blood the best of any; yet even this availed but little; for, in working with chissels thus tempered, sparks of fire came much more plentifully than pieces of the stone. By these means, the sculptors were able to make a flat or oval form; but could never attain to any thing like a figure.

It is true, in 1555, Cosmo de Medicis is said to have distilled a water from certain herbs, with which his sculptor, Francesco Tadda, gave his tools such an admirable hardness and temper, as that he performed some fine works with them; particularly our Saviour's head in demi-relievo, and Cosmo's head, and his duchess's. Even the very hair and beard, how difficult soever, are here well conducted;

and there is nothing of the kind better in all the works of the ancients: but the secret seems to have died with him.

The French have lately found another method of cutting porphyry, viz. with an iron saw without teeth, and *grez*, a kind of free-stone pulverized, and water. The authors of this invention pretend they could form the whole contour of a column by it, had they matter to work on.

Others have proposed a method of hardening tools, so as to make them proper to cut porphyry, by steeping them in the juice of the plant called bear's breech, or brankursine. Birch's Hist. R. S. vol. i. p. 238. vol. ii. p. 73, &c.

Mr. Boyle tells us, that he caused porphyry to be cut by means of emery, steel saws, and water. He observes, that in his time, the workmen in England were ignorant of the manner of working upon porphyry, and that none of them would undertake to cut or polish it. See Works, abr. vol. i. p. 111.

M. Da Costa conjectures, that the method used by the ancients in cutting and engraving porphyry was very simple, and performed without the aid of any scientific means that are now lost. He supposes that, by unwearied diligence, and with numbers of common tools at great expence, they rudely hewed or broke the stone into the intended figure, and by continued application reduced those rude figures into more regular designs; and that they completed the work by polishing it with great labour, by the aid of particular hard sands found in the country of Egypt. And he supposes, not without reason, that, in the porphyry quarries, there were layers of grit, or loose disunited particles, analogous to the porphyry which they carefully sought for, and used for this work. Nat. Hist. of Fossils, p. 285.

PORPHYRY-Shell, in *Conchology*, a name given by authors to a species of sea-shell of the purpura kind, with a short clavicle and beak.

PORPITA, in *Natural History*, a species of *Medusa*; which see.—Also, a species of *Madrepersa*; which see.

PORPITES, the *Hair Button-stone*, a name given by authors to a small species of fossil coral; which is usually of a rounded figure considerably flattened, and striated from the centre every way to the circumference. These are of different sizes, and of different colours, as greyish, whitish, brownish, or blueish, and are usually found immersed in stone.

PORPOISE, CAPE, in *Geography*, a cape on the coast of York county, in the state of Maine; 5 miles S.W. of Wood island.

PORPORA, NICOLA, in *Biography*, began to contribute to the lustre of the Neapolitan school about the same time as Leo. Porpora had great merit of various kinds; but in composition his style was feeble, compared with that of Leo and Handel, his two most powerful rivals in point of force. He had likewise rivals in grace and elegance, in Vinci, Haffe, and Pergolesi. Yet in other respects he had talents peculiar to himself: he was the best singing-master in Europe, and formed the greatest singers of his time. He was fortunate, indeed, in the voices he had to cultivate, particularly that of Farinelli. Porpora was more a man of judgment than genius. Of his opera of Arianna, the first which was performed in England, as little of the music was printed, and a MS. score is not to be found, we are unable to speak of its merits, but by analogy. His other operas and cantatas which we have seen, are written in a good taste; the melodies of the airs is natural and graceful; and the recitatives, particularly of his cantatas, are still regarded in Italy as models of perfection for narrative music. In his airs he rather polished and refined the passages of other composers than invented new; and in his accompaniment there

there is nothing very picturesque or ingenious. His first opera of *Ariadne and Theseus*, which Rolli pretended to have written expressly *per la nobiltà Britannica* in 1734, was performed at Vienna in 1717, and at Venice in 1727. The operas which Porpora composed for Naples, Rome, and Venice, before and after his arrival in England, amount to more than fifty. In 1736, during his residence in London, he published six *Sinfonie da Camera*, or trios, for two violins and a base, which he dedicated to the late prince of Wales; but these, like almost all the instrumental music of *vocal composers*, except that of Handel and the late John Christian Bach, are fanciful, and no more fit for one instrument than another. Indeed, Vinci, Haffé, Pergolesi, Marcello, and Porpora, the great luminaries of vocal compositions, seem never to have had any good thoughts to bestow on music merely instrumental. Perhaps the superiority of vocal expression requires fewer notes in a song than a sonata; in which the facility of executing many passages that are unfit for the voice, tempts a composer to hazard every thing that is new. Thus the simplicity and paucity of notes, which constitute grace, elegance, and expression in vocal music, render instrumental meagre and insipid.

Porpora was long the principal master of the *Incurabili Conservatori* at Venice, for which he composed several masses and motets, that are held in great estimation by the curious. He retired, however, late in life, to Naples, the place of his nativity, where, in 1767, he died in great indigence, at the advanced age of 82. Corri, who had studied under him five years, was his disciple at the time of his decease; and he says, that though his friends paid him a considerable sum, not only for his instruction, but board, Porpora kept so miserable a table, that he was frequently driven out of the house, by hunger, to seek a dinner elsewhere.

PORPORINO, ANTONIO UBERTO, in 1772 was the principal singer for male parts in the opera at Berlin. His voice was a *contralto*. He had been more than twenty years in the service of his Prussian majesty, and was extremely admired for his taste and expression, particularly in singing adagios.

PORPUS POINT, in *Geography*, a cape in the straits of Magellan. S. lat. $53^{\circ} 8'$. W. long. $71^{\circ} 17'$.

PORQUEIRA, a town of Portugal, in Estramadura; 6 miles S.W. of Leyria.

PORQUERIZA, a town of Spain, in Catalonia; 13 miles E. of Cervera.

PORQUEROLLES, a small island of France, the principal of those called "Hieres," about 10 miles long, and $2\frac{1}{2}$ wide; defended by an old castle, and a small fort. N. lat. $47^{\circ} 30'$. E. long. $6^{\circ} 17'$.

PORRACEOUS, formed from *porrum*, *leek*, in *Medicine*, a term applied to the bile, fæces, &c. when their colour is green, approaching that of a leek.

PORRENTROI, or PORENTRUY, in *Geography*, a town of France, and principal place of a district, in the department of the Upper Rhine, lately belonging to the diocese of Bâle, and residence of the bishop, populous and well-built, and situated in a fertile district. The inhabitants are chiefly Protestants; 21 miles S.W. of Bâle. The place contains 2032, and the canton 12,191 inhabitants, on a territory of $272\frac{1}{2}$ kilometres, in 31 communes. N. lat. $47^{\circ} 30'$. E. long. $7^{\circ} 1'$.

PORRETANI, in *Ecclesiastical History*, a religious sect, the followers of Gilbert de la Porree, bishop of Poitiers, condemned by Eugenius III. in the council of Rheims, held

in 1147, for admitting a physical distinction between God and his attributes; or, as Marsham says, for having written too curiously on the subject of the Trinity: as to his real sentiments, we are not well acquainted with them.

However, he gave occasion for those suspicions, by maintaining that this proposition, "Deus est bonitas," is not true, unless reduced to this, "Deus est bonus." And there are some passages noted by St. Bernard, who wrote warmly against him, in which he seems to admit a real distinction between the nature of God and his attributes. The Porretani are set in opposition to the Nominals.

PORRIGO, in *Medicine*, an obstinate contagious disease, generally of a pustular character, principally, though not exclusively, affecting the scalp, and most commonly observed in children. According to the different appearances which it assumes, it is variously denominated in popular language, the *scalled head*, *honey-comb scab*, the *ringworm* of the scalp, &c.

It is not easy to give a definition of this disease, which shall be applicable to all its varieties of form; whence not only the popular voice, but the nomenclature of the learned has multiplied its appellations, and subdivided it into a number of distinct diseases, which have been scarcely acknowledged to belong to the same family. Celsus seems to have included most of its varieties under the denomination of *porrigo*, and his authority is not to be questioned: nevertheless he also treats of the species of ulcer or pustule, which is called *favus*, or *κηρίον*, the smaller species of which, he says, is peculiar to the head, and produces foramina about the roots of the hair; and likewise of those forms of baldness, which are called *alopecia* and *ophiasis*, the former of which is usually seen in children. Most of the modern writers, however, limit the signification of *porrigo* to a furfureous or scurfy affection of the scalp, considering it as synonymous with the *pityriasis* of the Greeks; and they have adopted a generic term, (borrowed probably from the Arabians,) under which they include several of the varieties of this contagious disease, namely, *tinea*, or *tinea capitis*. (See Sauvages, *Nosol. Method. class. x. gen. 29*, where this term is used in the same generic sense in which we here employ the term *porrigo*.) Some of those writers, however, who have described these affections under the various appellations of *crusta lactea*, *achores*, *scabies capitis*, *alopecia*, *pityriasis*, *favi*, *tinea*, &c. have nevertheless pointed out the identity of the nature and causes of these eruptions in general. (See especially the treatise of the able and learned Sennertus, "De Morbis Infantum," p. ii. cap. 4; and also his general work, entitled "Practicé," lib. v. p. iii. § 2. cap. 4; also Heister, *Chirurg. p. i. lib. v. cap. 10*; and Plenck, "Doctrina de Morbis Cutaneis.") Dr. Willan adopted the term *porrigo*, in the same sense with the more ordinary term *tinea*, in consequence of the classical authority of Celsus for its employment in that sense. See Bateman's *Practical Synopsis of Cutan. Diseases*, according to the arrangement of Dr. Willan, p. 158.

Different writers have divided the disease into various species. Sauvages has described no less than nine species; Dr. Willan, as we learn from Dr. Bateman's *Synopsis*, included all the forms under six species; Alibert has mentioned only five; and Plenck, in addition to the *crusta lactea* and *tinea*, has delineated four species of *scabies capitis*. Similar divisions were made by the Arabian writers, and Haly Abbas especially described six species, which have been nearly the prototypes of those of all the writers just named, who have borrowed even his specific appellation. These species are distinguished by the different magnitude of the pustules, or by the absence of pustules, and by the

formation of crusts and scabs, or of branny scales, in which they terminate.

From the time of the Greek physicians, the pustules which constitute the different species of this disease have been denominated ἀχῆρες, *achores*, and κηεις, *favi*, which are considered as differing from each other only in magnitude; the latter being larger than the former. The term *favus*, honey-comb, has been applied to the ulceration which follows this larger pustule, and therefore to the pustule itself, in consequence of the number of large foramina which are produced by the pustules, and from which a thick viscid discharge takes place, which has been compared also to honey. Thus Paul of Ægina says, "Of the affections which take place in the scalp, the *achor* is one, which erodes the surface with very small foramina, from which a glutinous humour is discharged: the *cerion* or *favus* is of the same kind, but produces larger foramina, and emits a honey-like discharge, like the favi or combs of bees." (De Re Medica, lib. iii. cap. 3.) The other Greek writers express the same opinion in nearly the same terms, which it is unnecessary, therefore, to repeat. (See Alex. Trall. lib. i. cap. 8, and 9. Aëtius, tetrab. ii. serm. ii. cap. 68.) The discharge emitted by these pustules, whether large or small, is contagious in its qualities, and communicates the same disease to the heads of those to whom it is conveyed by clothes, or by actual inoculation by contact.

Species 1.—The *milk-crust*, or *crusta lactea* of authors, has been ranked as the first species of this disease by Sauvages, in which he has been followed by Dr. Willan; the former denominating it *tinea lactea*; the latter, *porrigo larvalis*. Plenck calls it *rabies capitis larvata*. We are not quite satisfied, however, of the propriety of arranging this *milk-crust* in general with the true porriginous affections; especially since it appears only in early infancy, and independently of any contagious influence, and is usually, if not always, incapable of affecting others by contagion. Its characters, on the whole, more nearly resemble those of impetigo, in the classification of Dr. Willan, to which perhaps it ought to be referred. The face, as the epithets *larvalis* and *larvata* (which signify *masked*) indicate, is the seat of this unsightly eruption, which appears in the form of extensive patches of a thin, yellowish, greenish, brownish, and sometimes of a dirty-white scab or crust. Generally one large patch extends along the whole forehead, from the eye-brows to the roots of the hair of the scalp; and each cheek is covered with another of considerable extent, and of a circular form. Sometimes the chin is likewise affected; and occasionally, indeed, the whole face is enveloped in a continuous crust, forming an entire mask, through which the eyes, eye-lids, and nose, alone present themselves free from the disease. These scabs, like all similar incrustations, are the result of the concretion of the viscid purulent matter, which is discharged from the small pustules, or *achores*, with which the disease commences. This discharge varies materially at different times, in the course of the progress of the disease. Sometimes it nearly ceases, and the crust remains dry, or even falls off, leaving a red and irritable surface; and sometimes it is so copious, and flows with a constant oozing from small pores, that no concretion takes place, and the cuticle is in a state of constant excoriation. These conditions commonly alternate with each other, at intervals, during the continuance of the complaint. In some instances, the eruption is confined to the face; but in general the ears are affected, especially round the back part of them, and the scalp becomes partially incrustated with patches of the scabs. The eruption is, under all its changes, accompanied by a considerable degree of itching and irrita-

tion, which excites a constant disposition to rubbing and scratching the face, by which the crusts are partially torn off, and the surface is excoriated, and made to bleed; and thus the irritable condition of the diseased part is augmented. By this continued irritation, the constitution becomes at length affected, in consequence of the loss of sleep, and of the derangement of the digestive organs, so that the little patient is sometimes emaciated, an habitual feverishness prevails, the absorbent glands, both parotid and mesenteric, become enlarged and indurated, and a fatal marasmus ensues.

In the majority of cases, however, the disease is compatible with tolerable good health; and after continuing, with various fluctuations, for many weeks, and sometimes many months, it usually terminates favourably, without leaving any scar, pit, or other deformity, notwithstanding the extent or continuance of the disease, as Sauvages long ago remarked. It has received its denomination of *milk-crust*, from its ordinary occurrence during the time of lactation; and it often ceases immediately after the child is weaned. Sometimes it appears to be relieved by the protrusion of the teeth. An observation has been made by Dr. Strack, in a treatise written expressly upon this disease, which we have not had any opportunity of verifying, namely, that the urine of the patient assumes the same odour as the urine of cats, previous to a favourable change in the symptoms. See Strack, Diss. de Crusta Lactea Infantum, et ejusdem specifico Remedio.

For the cure of this disease, most writers recommend a change of nurse, or actual weaning, ascribing it, as its name imports, to the influence of the milk. The former, however, is not always practicable, nor is either plan always successful. Indeed the disease will commonly continue a considerable time under any measures that may be resorted to. The inflammatory disposition of the surface, and consequently the discharge and incrustation which result from it, may, however, be often alleviated, and its termination expedited, by a repetition of certain alterative medicines, of which mercury especially makes a part. Small doses of the hydrargyrus cum sulphure, or old æthiops mineral, combined with a little dried soda, or nitre, administered twice a day, appear to be very beneficial in some individuals; in others more active medicines are required, comprising the submuriate of mercury, so as to act more freely on the bowels; especially where there is a torpor of the canal, or a disposition to marasmus, with enlargement of the mesenteric glands, tumid abdomen, and a constant febrile condition.

As to external applications, they must be varied according to the condition of the eruption. While the surface is inflamed, excoriated, and humid with the discharge, every application of a stimulating nature should be avoided, such as the use of soap in washing, and of acrid liniments and ointments; gentle washing, with some mild tepid fluid, such as milk and water, or simple water, or light decoctions of the farinaceous seeds, barley water, gruel, &c. with soft linen, and without much friction, will be beneficial; and, under the same circumstances, simple lard, or a mild saturnine or zinc ointment, or some other softening and drying unguent, should be applied twice a day. When the inflammatory condition has declined, and the discharge has nearly subsided, some gently stimulant ointment, especially of the mercurial class, should be employed; such as a diluted citrine ointment, in the proportion of one-fourth of the latter, or the ointment of the white precipitate of mercury, diluted one half; which may be strengthened, as the surface becomes less irritable, and the crusts cease to form. The "remedium specificum"

PORRIGO.

specificum" alluded to by Dr. Strack, is the common viola tricolor, a decoction of which he recommends to be made in milk, in the proportion of a handful of the fresh, or half a drachm of the dried leaves, to half a pint, and to be taken night and morning. He affirms that this medicine invariably cures the disease in the third week, although it seems to augment the eruption during the first fortnight. The only other testimony that we have seen, relative to the virtues of this specific, is that of professor Selle, who affirms, in contradiction to Strack, that the medicine is either actually prejudicial in this eruption, or altogether inert. See his *Medicina Clinica*, i. 185.

Species 2.—This species has been distinguished from the time of the Arabians by the same appellation by the best writers; namely, by the epithet *favosa*, indicating that the eruption consists of the larger variety of pustules, the *favi*, or honey-comb eruption. It is the *Tinea favosa* of Haly Abbas, of Astruc, and Sauvages; the *Scabies capitis favosa* of Plenck; the *Porrigo favosa* of Willan; and the *Teigne favuse* of Alibert. Under this species, however, we may include also the *Tinea humida*, and the *Tinea fcosa*, of Sauvages, and perhaps the *Teigne muqueuse*, or *Tinea muciflua*, and *Teigne granulée* of Alibert. (Sur les Maladies de la Peau, spec. 5. et 2.) The *Tinea volatica* of Sauvages appears also to be the same species of the disease, so named because it occurs on different parts of the body, as well as on the head.

Whatever may be the ultimate form which this species of the disease assumes, it always commences with the large *favi*, or soft, whitish pustules, which arise separately from each other, not acquiring much elevation above the surface of the skin, nor being preceded by much inflammation. They do not commonly exceed the diameter of a pea, and are somewhat flattened, and not very regularly circular; and, as Sauvages remarks, they are readily ruptured by slight pressure of the finger, or even spontaneously, pouring out a thick, viscid, pultaceous, yellowish-white matter, which dries into a greenish scab. The head is the most common seat of these pustules, which most frequently appear first above and behind the ears, or about the angles of the mouth. As they increase in number, they become confluent in irregular patches, sometimes extending over the whole scalp, and matting together the hair in masses of the scabs. In this condition, from the difficulty of using a comb, and from the peculiar tendency of the disease, great numbers of lice are often generated, which greatly aggravate the disorder by the irritation which they produce, and greatly increase the itching and smarting which belong to the disease, and therefore add much to the distress of the patient. This accumulated irritation, indeed, sometimes entirely deprives children of their rest, destroys the digestive powers, and induces emaciation, hectic fever, and at length complete marasmus. In children of scrofulous habit, under this extreme irritation, the eyes become inflamed, and the eyelids are ulcerated, discharging a thick glutinous pus, by which they are generally glued together in the night; the upper lip becomes tumid, the glands of the neck and lower jaw take on the scrofulous inflammation, and those of the mesentery are affected in a similar manner. In children of this constitution, indeed, the disease sometimes assumes an acute febrile form, the eruption being preceded by the usual rigors, heat, and disturbed functions, which characterize common fever, and continue after the eruption appears. In one instance, we have seen this acute form of the disease spread rapidly, by its contagion, through the children of a family. In other children, of a more decided scrofulous diathesis, the whole scalp sometimes becomes ulcerated, discharging copiously,

from numerous distinct superficial cavities, which are extremely red and tender, as well as the intervening portions of the scalp, a mucous or viscid fluid, nearly colourless; in which cases, the glandular system is almost invariably affected to a considerable extent, and the constitution suffers severely.

Although the head is the ordinary seat of these *favous* eruptions, yet they are not exclusively confined to the scalp and face, but occasionally occur upon the extremities, and even upon the trunk, although they are seldom seen on these parts without attacking the head also. Neither are children the only subjects of their attack, although the most frequent; for occasionally adults receive the contagion, and suffer considerably from the eruption; and occasionally it appears to originate under particular circumstances of the constitution. Adults, however, are not so liable to be affected by the disease; since it frequently happens that mothers and nurses receive the contagion, in those parts which come frequently in contact with the diseased parts of their children, as in the face, about the mouth, from kissing them, or on the mammæ from suckling, or on the arm in which they are held, where a single pustule or cluster of pustules forms, and gradually disappears, without any remedy.

Except in cases of exquisite scrofulous constitution, the varieties of *porrigo favosa* are more manageable by medicine than the foregoing species, and those of which we shall immediately treat. More dependence is to be placed on the constitutional, than on the local management of the disease, though the latter is of considerable importance. As the digestive organs are commonly deranged, and the functions of the bowels imperfectly performed, and there is some tendency to mesenteric congestion, the more active alteratives, containing small doses of calomel, with soda, and the testaceous powders, should be resorted to; or, if the bowels are very irritable, the grey oxyd, or the hydrargyrus cum creta may be substituted. In children who exhibit a squalid complexion, and other obvious marks of a cachectic condition, some tonic may be combined with alterative doses of a laxative; such as light infusions of calumbo, or cascarrilla, with rhubarb or a neutral salt; or the precipitated iron united with soda and rhubarb. At the same time all the attention that can be paid to the diet and regimen of the little patients, will be requisite to assist the operation of medicine; the exercise should be regular and frequent; the clothing warm; and the diet of a nutritious, but light and unstimulating quality. Milk, puddings, well-dressed vegetables, and a moderate portion of plain animal food, should constitute the food; and wine, fruits, especially unripe acid fruits, and crude vegetables, should be discarded. Sea-bathing, if the patient yet retain a considerable portion of vigour, is also to be recommended.

The external applications must be appropriated to the peculiar state of the disease. An ancient precept, which is to be found in the treatises of the Greek writers on this subject, cannot be too strictly attended to; namely, that in the inflammatory, excoriated, and discharging state of the scalp, the tender surface is not to be irritated by any stimulant, but softened and soothed by tepid and emollient applications; as by warm fomentations, or by poultices, or by the application of cream, or some simple ointment. The popular applications, such as a cabbage-leaf, oiled silk, and other rigid coverings, are sometimes productive of great aggravation of the disease, exciting a highly inflammatory state of the surface, and even considerable symptomatic fever, followed by ulceration and a copious purulent discharge. (See Bateman's Synopsis, p. 178.) When the inflammation and discharge have been reduced by these emollient means, the zinc ointment, or saturnine and mercurial ointments, mixed and diluted

PORRIGO.

luted as already mentioned, will contribute to restore the surface to its healthy condition.

Species 3.—This is of a scaly, or *furfuraceous* character, and has been distinguished by all writers on the subject. The term *porrigo*, indeed, has been limited to this species by many authors, and by all the translators of the Greeks, who seem to have confounded this contagious branny eruption, with the non-contagious *dandriff*, under the appellation of $\pi\iota\tau\upsilon\delta\iota\sigma\iota\varsigma$, or *porrigo*, which they deem synonymous. Whence this species of the disease has been called *tinea porriginosa* (meaning *furfuraceous*) by Astruc and Sauvages: it is the *tinea furfuracea* of Sennertus, the *porrigo furfuracea* of Plenck, the *porrigo furfurans* of Willan, and the *teigne furfuracée* of Alibert. The intelligent Plenck properly pointed out the distinction, which has been subsequently repeated by Dr. Willan, between the mere scurfy pityriasis, and the contagious scurfy porrigo; for although he applies the term *porrigo* to both, yet he adds the epithet *vera* to the contagious disease; and calls the other *porrigo farinosa*, seu *spuria*. *Doctrina de Morbis Cutan.* class vii.

This is the least common form of the contagious porrigo, and different authors disagree as to the subjects whom it attacks; some asserting, that it occurs chiefly in adult persons, and especially in women; while others maintain, that it is seldom seen in adults, but most commonly appears in children above seven years of age. M. Alibert, who asserts the latter, is, however, not the most able authority. (See Bateman's Synopsis, and Alibert, before quoted.) Although the character of this eruption, when fully formed, is determined by the branny exfoliations which appear among the hair, yet the origin of these exfoliations is probably to be ascribed to the matter discharged from the *achores*, or minute pustules, which form in the scalp in the beginning of the disease. Afterwards, however, the pustules are not generally discernible; but when the scurf is removed by combing, the surface of the scalp appears of a rose-red hue, and smooth and shining in its texture, the hair in general being thin, and falling off in an irregular manner. At times there is a discharge of a viscid nature, which encourages the propagation of pediculi; and the itching, which is at all times considerable, is then much increased; sometimes the little pores, from which the discharge issues, pass into superficial ulcerations, but in general the surface is dry. This eruption is confined exclusively to the scalp, except that it occasionally extends a little way on to the forehead from the roots of the hair. It is not always easy to distinguish this eruption from the other scaly affections of the scalp; for the lepra, psoriasis, and pityriasis, especially the first and last, are frequently seated in the same part. These three diseases, however, are not communicable by contagion, they appear in larger and stronger scales, they do not interfere with the growth of the hair, they are not alternately dry and humid, for they never form any pustules, or occasion any discharge, unless the surface is broken by violence, and they are often accompanied by other patches of the same nature on other parts of the body.

The *furfuraceous* tinea is often very obstinate, like the rest of the species, under every mode of treatment; the principles of cure, however, are similar to those already laid down. It seems agreed by all writers, that constant shaving is peculiarly necessary in this form of the disease, with a view to facilitate the application of remedies to the diseased surface, and the frequent clearance of that surface of its branny exfoliations by tepid ablutions. From ancient times a variety of stimulant applications have been recommended to be made to the diseased scalp, such as liniments of frankincense, with oil or vinegar, or wine, oil of rue, decoctions

of fænugreek, beet-root, &c. (see Aëtius, before quoted, and Oribasius, Synopf. lib. viii. cap. 25.): and applications of a similar nature have been resorted to in modern times such as ointments of tar, sulphur, and the various mercurial compounds, especially the citrine ointment, and that of the red precipitate, and also ointments of hellebore, stavesacre, and other acrid vegetable substances. It is only in the dry and uninfamed state of the surface, however, that these stimulant substances can be applied with advantage; for, as in the preceding species of the disease, the nature of the applications must be varied, with the varying condition of the malady, and the stimulants especially must be superseded by applications of an opposite quality, when the surface becomes inflamed, moist, and irritable. The mildest ointments, as common cerate, light saturnine liniments, or the zinc ointments, should be resorted to under these circumstances, and soap, even of the least acrid kind, should be avoided in washing.

Species 4.—This form of the disease is popularly termed a *ringworm*, in common with many other eruptive complaints, on account of the circular figure of the patches in which it appears upon the scalp. Dr. Willan gave it the appropriate epithet of *scutulata*, (from *scutulum*, a little shield,) in allusion to the same figure; but other authors have included this species under the other forms already described, not conceiving that the mere mode of distribution was sufficient to constitute a distinct specific character. And, in truth, this might be arranged with propriety with either of the preceding species, since it puts on a considerable variety of form; in general originating in the smaller pustules, or *achores*, but not unfrequently exhibiting a branny exfoliation, and sometimes large pustules, or *favi*, and even dry and thick crusts, within the area of its patches. In general, the surface of the patches is smooth, sometimes red, and sometimes of a pallid or white hue, and almost always shining, and free from any cuticular lines, as if the cuticle were on the stretch; and this surface is interspersed with the small pustules, or the minute scabs that form upon them, or sometimes only with elevated points or papulæ, some of which desquamate, while in others small globules of pus form, converting them into *achores*. The hair, if it does not entirely fall off from the diseased patch, becomes extremely thin, a few straggling hairs only remaining; and about the roots of these the pustules are more apt to form. Until the diseased surface is beginning to resume its healthy condition, the hairs do not grow again, or if any new ones appear, they are of a thinner and more delicate texture, and commonly of a lighter colour than natural. So that the re-growth of thick and natural hair is the best criterion of the removal of the disease.

The patches of this species of porrigo vary greatly in size and number in different instances. Sometimes three or four small patches appear on different parts of the head, and these occasionally extend, and become confluent, so as to affect the greater part of the scalp, and sometimes only one large patch occurs, on the crown, or on one side over the ear, and will remain stationary for months, in spite of every application for its relief; but with considerable variations in respect to the inflammation and number of pustules, and to the discharge, incrustation, or exfoliations from the surface.

This disease appears to have become more prevalent of late than formerly in this country, so that it has been supposed to be a new complaint, or to have been imported from our colonies in warmer climates, where cutaneous diseases are said to be extremely prevalent. The disease, however, has been described by medical writers in all ages and countries; and as it is principally propagated by contagion, from actual contact with the matter of the pustules, and as we see it most commonly among children at school, it is probable that

its more frequent occurrence is to be ascribed to the multiplication of boarding schools, in which the contagion is more readily propagated than in private families or in day schools, where there is less opportunity of actual contact, or of using the combs, towels, hats, &c. of the diseased.

There is scarcely any limit to the catalogue of medicines, which have been recommended from ancient times for the cure of this among other forms of the disease; and, in our own times, every one is in possession of a nostrum, which is confidently pronounced a remedy for the malady. Nevertheless it is extremely difficult of cure, and has been known to continue, not only for many months, but for years, in spite of every mode of treatment that could be devised. The general character of the applications which have been employed, is that of active stimulants and irritants; such as tar, sulphur, mustard, turpentine, essential oils, and spirits; mercurial ointments, especially those of nitrico-oxyd, or red precipitate, the citrine ointment, that of the white precipitate, and the oxymuriate of mercury; other metallic salts, such as the sulphate of zinc, copper, and iron, the nitrate of silver, &c. in ointments and lotions; strong vinegar, borax, muriate of ammonia, and the mineral acids, both in lotions and unguents; and various acrid vegetable powders, such as hellebore, stavesacre, cocculus indicus, &c. It is probable that all these applications, separately and in various combinations, have been successful in removing the disease in different instances: but that they all very frequently fail, is also too well known. Their success or failure is not always to be anticipated from the appearances of the disease; so that under the same apparent circumstances, the same remedy will be sometimes active, and sometimes inert. This general principle, however, appears to be applicable; that if the eruption be in a highly inflammatory state, the milder and less irritating substances should be employed; and if it be torpid, and free from much irritation or discharge, the stronger stimulants may then be resorted to.

Several practitioners have adopted various means of destroying the morbid surface, which, upon being renewed, has not unfrequently become free from the disease, the new skin having assumed a healthy action. Thus, after blistering, a healthy surface has returned: but in many cases a blister produces only a temporary change, and the disease recurs upon the new skin. But as it is merely the cuticle which is removed by a blister, and the disease appears to be commonly seated deeper, in the true skin; so the simple vesication may not reach the root of the malady. When one blister has failed, however, a repetition of the application has sometimes proved successful. The morbid skin may be destroyed more effectually by corrosive or caustic applications; and these are perhaps still more successful than the more superficial vesications. Some have used the strong mineral acids, lightly brushing over the diseased patch, and then wiping off the fluid; and others have used the caustic potash, or the nitrate of silver; even after these applications, however, the disease is apt to return upon the new surface which succeeds.

As this contagious ringworm of the scalp is commonly the result of the application of infectious matter to the skin of the cranium, so it is usually a merely local affection, with which the constitution does not sympathize, and therefore the health is not at all disordered: hence local remedies alone are generally requisite. If, however, the constitution suffers from the irritation of the local disease, or if this becomes highly inflammatory, approaching in its nature to the second species above described, then a similar course of alterations will be necessary to that recommended for the cure of the first and second species, and the general health must be attended to by a proper regulation of regimen.

Species 5.—The patches of baldness which have been described by Celsus, under the generic term *area*, and by the Greeks and their translators under the appellations of *alopecia* and *ophiasis*, were included under this genus, *porrigo*, by Dr. Willan, with the epithet *decalvans*. As, however, no pustules are ever visible in these patches, nor are there any crusts, or even scales, nor is the surface excoriated, nor is there any kind of discharge, it might be questioned, whether this affection is properly associated with the pustular and contagious porrigo. It is said, however, that in schools and families, where the disease appears in several individuals successively, from the influence of the contagion, this form of the disease sometimes occurs among the rest, as the product of the same infection. But this occurrence is rare; and it is certain that these bald patches, which exhibit only a smooth, white, polished surface, free from any remnant of hair, occasionally appear, even in adults, where no suspicion of contagion existed; whence the majority of medical writers have deemed the *alopecia* a distinct disease.

Celsus recommends repeated shaving of the scalp for the cure of this affection, after which the bald parts were to be rubbed with the sulphate of iron (*atramentum futorium*). The disease is certainly often allied, in obstinacy at least, to the species before described, and seems to be the most advantageously treated by the application of some of the more active stimulants before enumerated, especially by the terebinthinate substances and essential oils, mixed with alcohol.

Species 6.—This species of the porrigo, which has been denominated from the time of the Arabians downwards with some allusion to the seeds of lupines, appears to be but a modification of the second, or *favous* species. Haly Abbas gave it the epithet of *lupinosa*, and described it as “*ficca, et colore alba, lupino similis, à quâ quasi cortices et squamæ fluunt.*” After him, Astruc and Sauvages called it *tinea lupina*; Plenck denominated it *scabies capitis lupina*, and also *porrigo lupina*; and Willan, *porrigo lupinosa*. It seems to differ from the second species merely in the dry, small, and nearly circular crusts, which it forms in consequence of the occurrence of the pustules in small clusters, and which may be compared, both from their shape and greenish hue, to the seeds of lupines.

The treatment required is very similar to that recommended for the second and third species, with the necessary addition of some means of removing the hard and dry crusts, in order to facilitate the application of remedial substances to the diseased surface. Copious ablution with warm water and soap will often effect this purpose, aided by the ointments, which also tend to correct the morbid surface, especially the mercurial preparations before mentioned; but sometimes it is necessary to have recourse to more caustic substances, as the pure alkalies diluted with water. Professor Selle considers those alkaline lotions as the most effectual means of removing these hard and durable scabs. “*Imprimis salia lixiviva ad crustam tam firmam atque alias insolubilem emolliendam sunt apta.*” See his *Medicina Clinica*, 187. See also Sennert. *Opera*, lib. v. part i. cap. 32. Haly Abbas, *Theorica*, lib. viii. cap. 18. Heister, *Chirurgia*, part i. lib. v. cap. 10. Underwood, on the Diseases of Children, vol. ii.; and Bateman's *Practical Synopsis of Cutaneous Diseases*.

PORROGONG, in *Geography*, a town of Bootan; 17 miles S. of Tassafudon.

PORROS, in *Surgery*, any fleshy or hard swelling; a scirrhus.

PORRUM, in *Botany*, an ancient Latin name. See ALLIUM.

PORSAN-

PORSANGER, or **POSANGUER**, in *Geography*, a town of Norwegian Lapland, situated on a bay of the North sea; 104 miles W. of Wardhuys. N. lat. 70° 50'.

PORSELON, or **PORSELONE**, a rich and commercial town of Siam, situated on a large river, which runs into the gulf of Siam, surrounded with fourteen bastions. N. lat. 17° 48'. E. long. 99° 46'.

PORSICA, in *Ancient Geography*, a town of Asia, in Mesopotamia, situated on the E. bank of the Euphrates, S.E. of Samofata.

PORSILE, **GIUSEPPE**, of Naples, in *Biography*, the son of Carlo Porfile, who composed the opera of "Nerone" for that city in 1686, appears to have been in the service of the emperor at Vienna in 1720. Apostolo Zeno speaks of his *bella musica* to "Spartaco," an opera written by the Abate Pasquini for the imperial court in 1726; between which period and 1735, he composed several dramas for the different theatres of Italy. His favour at Vienna, however, appears to have been durable, as he was employed there, in 1733, to set the oratorio of "Giuseppe Riconosciuto," by Metastasio, which Hasse publicly declared to be the finest music he had ever heard. We have never met with any of his productions; but his style is said, by others, to have been natural, and full of force and expression.

PORSON, **RICHARD**, a very celebrated Greek scholar, was born at East-Ruſton, in Norfolk, on Christmas-day, 1759. His father, Mr. Huggin Porson, who was in humble life, and the parish-clerk of East-Ruſton, laid the basis of his son's acquirements. He had taught him all the rules of common arithmetic, without the aid of book or slate, before he was nine years of age. His memory thus incessantly exercised, he acquired a talent of close and intense thinking, and such a power of arranging every operation that occupied his mind, as in time to render the most difficult problems easy of solution. He likewise learnt reading and writing at the same time. The father drew the form of the letter on a board, or on sand, and Richard was shewn how to imitate the impression. As soon, therefore, as he could speak, he could trace all the letters of the alphabet, and soon learnt the power of each. At nine years of age, he and his brother Thomas were sent to the village school, kept by Mr. Summers. This worthy man professed to teach nothing beyond English, writing, and arithmetic, with the first rudiments of the Latin language; but he did all that he professed, and under him Richard Porson acquired the talent of writing a most beautiful hand. He continued under this gentleman three years, during which, he every evening repeated to his father the lessons and the tasks of the day. He and his brother were now transferred to the care of the reverend Mr. Hewitt, who instructed them in classical learning. Richard soon became the topic of general conversation in the district, and before he had completed his fourteenth year, he had engaged the notice of all the gentlemen in the neighbourhood. He was, through the influence of Mr. Norris, sent to Eton in 1774, where he displayed such a superiority of intellect, such facility in the acquirement of his various lessons, and such a talent of being able to bring forward to his purpose all that he had ever read, that the upper boys took him into their society, and frequently imposed upon him their own exercises. He was looked up to as the almost never-failing resource in every difficulty; and in their frolics as well as tasks, Porson was their constant adviser and support. After the death of Mr. Norris he was supported at Eton by the liberality and kindness of some friends, who were unwilling that such talents as he possessed should be lost to the world for want of due culture. He was entered of Trinity college about the close of the year

1777; and in every branch of college study to which he applied himself, his course was so rapid, as to astonish every competent observer. By accident, he was first led to read mathematics, in which he might have surpassed the most of his contemporaries; but the prospect of a scholarship, which did not become vacant for a long time, induced him to devote his attention to the study of the classics. In this department of learning he soon acquired undisputed pre-eminence. He obtained the medal, and was elected fellow in 1781. In 1783 he took his degree of master of arts. In 1788 he determined to surrender his fellowship, though he had even then nothing to depend upon, but acquirements that are difficult to be brought to market, and are often, in a pecuniary point of view, very unprofitable to the owner. In 1791 his fellowship ceased, and he was thrown upon the world without a profession, his feelings wounded by mortifications which he had received, and with a constitution little qualified to encounter the bustle of the world. He was soon after this elected Greek professor at Cambridge, by an unanimous vote of the seven electors. The salary attached to this office was 40*l.* a-year only, still it was his earnest wish to have made the duties of it active and efficient; and he resolved, if he met with encouragement, to give an annual course of lectures in the college. For these lectures he had made preparations, in which he intended to elucidate the languages in general, to have shewn their relations, their differences, their near and remote connections, their changes, their structure, their principles of etymology, and their causes of corruption. The office, however, was regarded as a mere sinecure, and so those, in whose gift it was, intended it to remain, as they would not allow Mr. Porson rooms for the purpose of rendering it really efficient.

Three years after this he married: this lady unfortunately died in 1797, and from that time the health of the professor himself began to decline. An almost incessant spasmodic asthma, which was probably much increased by irregularity in his modes of life, interrupted him in every study to which he applied himself. Perhaps his sedentary habits were unfavourable to his course of general health, for few men had accustomed themselves to so much patient and continued toil. On the establishment of the London Institution, he was elected the principal librarian, an office which he did not hold very long, being seized, early in the month of September 1808, with an intermitting fever, which was followed on the 19th day of the same month by an apoplectic seizure, from which he partially recovered, but only to endure a second attack on the following day. He languished a few days, and then died in the 49th year of his age.

Such is the brief narrative of the life of this learned man. We shall now turn particularly to his literary labours, by which he has left an unfading reputation. These were commenced while he was an under-graduate, in 1785, by the republication of Xenophon's *Anabasis*, originally edited by the learned Hutchinson. He added many original notes, chiefly relating to MSS., of which Hutchinson was either ignorant, or had passed by in neglect. In 1790, a new edition of the work entitled "*Emendationes in Suidam et Hesychium et alios Lexicographos Græcos*," was published at the Clarendon press. To this the professor subjoined some critical notes, which were claimed only by the addition of the initials of the learned Grecian. In the course of the same year, Mr. Porson distinguished himself by his celebrated controversial work, which was the first that extended his reputation beyond the boundaries of the universities, and spread his fame through the whole of Europe. The work to which we allude was entitled letters to Mr. Archdeacon Travis, in answer to his defence of the three heavenly witnesses,

nesses, 1 John, v. 7. This, which was the first regular avowed publication, received the applause of Mr. Gibbon, who rejoiced to behold one of his own most imperative antagonists humbled to the dust, "by the most acute and accurate piece of criticism which has appeared since the days of Bentley." And the historian adds, that the "author's strictures are founded in argument, enriched with learning, and enlivened with wit, and his adversary neither deserves nor finds quarter at his hands." The writer in the Monthly Review, vol. v. of the New Series, says, Mr. Porson "has gone to the bottom of the subject; has furnished a critical repast for the biblical scholar; and has exhibited a cloud of witnesses against the three heavenly witnesses. He proves that the reading which he defends is the reading of all the Greek MSS., above an hundred and ten: of near thirty of the oldest Latin, of the two Syriac versions, of the Coptic, Arabic, Æthiopic, and Slavonic."

In 1793 he published a beautiful edition of Heyne's Virgil, to which he prefixed a short preface, disclaiming any other merit than that of a few conjectural criticisms. Mr. Porson has with great labour corrected Pauw's edition of Æschylus throughout, of which, very unaccountably, a surreptitious impression found its way to the press. In 1795 a beautiful edition of the seven tragedies was published by Foulis; and Schultz printed another in Germany, and added to it Mr. Porson's new readings, to which he prefixed a short introduction, replete with respect for the learning and talents of the English professor.

In 1797 appeared the Hecuba of Euripides, in one volume 8vo., with notes and a learned vindication. This was intended, in part, to try what success he was likely to meet with, if he published the other plays in the same way: two more accordingly made their appearance in succession: and he left, at his death, the Orestes ready for the press. As a proof of his great patience, we may add, that he had undertaken to make out, and copy, the almost obliterated manuscript of the Lexicon of Photius, which he had borrowed from the library of Trinity college. This he had with vast difficulty completed, when the beautiful copy that had cost him ten months of incessant toil, was burnt in the house of Mr. Perry, at Merton. The original, being an unique, and entrusted to him by his college, he carried with him wherever he went, and he was fortunately absent from Merton when the fire happened. Unruffled by the loss, he sat down without a murmur, and made a second copy in as beautiful a style as the first. "The principal qualities," says one of his biographers, "in this great man's mind, were his extraordinary acuteness of discernment, and solidity of judgment; and these, added to his intense application and stupendous memory, made him what the world, perhaps, never saw before, a complete critic, in the most honourable and extended sense of that appellation. His reading was immense: he was an excellent French scholar, but in his native language, in the Latin, and in the Greek, he was most familiarly and profoundly versed. He had, indeed, applied the knowledge which he had gained of the origin and structure of language in general, to all these dialects, if we may so express ourselves of the universal language; and had not his eminence in classical literature, by its uncommon lustre, obscured other attainments, he would doubtless have been considered as one of the first English scholars. In Greek, however, we have no hesitation in pronouncing him the very first, not merely of his own age, but of every other. In him were conspicuous boundless extent of reading, a most exact and well ordered memory; unwearied patience in unravelling the sense of an author, and exploring the perplexities of a MS.; perspicacity in discovering the corruptions of a text, and

acuteness, almost intuitive, in restoring the true reading. All this was tempered with a judgment which preserved him invariably from the rocks against which even the greatest of his critical predecessors have at some time or other split; we mean precipitation in determining that to be unsound, which after all had no defect; and rashness in applying remedies which only served to increase the disease. His character was manly and independent: he both cultivated and inculcated a love of freedom, and was, at all times, a strenuous supporter of the civil and religious liberties of his country."

On his death, his college claimed the body, in order to be deposited in the chapel of Trinity, near the ashes of Bentley, whom he so much resembled. It was accordingly removed, on the third of October, from London to Cambridge, where it was received, with every mark of respect, by the bishop of Bristol, the master of the college, the vice master, fellows, &c. Monthly Mag. vol. xxvi. Gent. Mag. for 1808. Monthly Review.

PORT, HAVEN, or *Harbour*, a commodious place situate on the sea-coast, or at the mouth of a river, with depth of water sufficient for ships of burden, and convenient bottom for anchorage; where vessels lie by to load or unload; screened from the wind, and safe from any enterprize of enemies; either by the disposition of the place, or by means of a mole, or dike, or the like; with a chain and light-house.

Ports are either *natural* or *artificial*.

PORTS, *Natural*, are those which Providence seems to have formed for the communication of commerce: or, where the natural figure of the land forming them, is such as contributes to the safety of the shipping therein, by sheltering the vessels from the fury of the sea; and this happens in various ways; such as a shoal lying off the harbour's entrance, which breaks the waves, and thereby keeps the water still within; or by the points of land, forming the harbour's mouth, stretching themselves so far into the sea, and coming so near to one another, that the surges are broke at their entrance; or by a narrow inlet that runs into the land for a considerable way, and where the shores near the entrance, receiving the shock of the waves, render the upper ports smooth enough to anchor in; of which kind are navigable rivers: or by a large deep bay, in which islands, or other obstructions, contribute to render a port secure for the riding of ships at anchor, &c.

The properties of a good harbour are, a sufficient depth of water for large ships to enter at any time, whether the tide be in or out; good offing, and an easy access out of all danger from the winds, and good anchoring ground; free entrance, without rock or sand-bank; the entrance not too wide, to be easily barred and defended upon occasion, and yet of sufficient extent to admit the entrance or departure of large ships without difficulty; not subject to overflow, and where ships may lie close to the quays; where the vessels are sheltered from all winds by the high mountains surrounding the harbour, and from whence there is an extended view of the sea; that the shipping therein be out of all danger, either from being set on fire, bombarded, or cannonaded from sea by the ships of an enemy; that it be furnished with a good light-house, and have variety of proper rings, ports, moorings, &c. in order to remove or secure the vessels contained therein; and lastly, that it have plenty of wood, and other materials for firing, besides hemp, iron, mariners, &c.

PORTS, *Artificial*, are those formed with piers, moles, or projectures into the sea; and when the moles or piers can be brought so close as to be shut up by sluices or gates, the harbour is then called a *basin*; but the inner part of a har-

bour, where the ships ride in still water, is usually called *the basin*.

All artificial ports of this kind are easily fortified by building on the moles or piers either batteries, redoubts, or forts, which command the entrance into the harbour. But the method of fortifying harbours, and also roads, in general depends on a variety of circumstances peculiar to each. See *MARINE FORTIFICATION*, *FORT*, and *BOOM*.

The English coasts are exceedingly thin of ports. France has the advantage of all other countries in the number and excellence of ports; that of Brest is the finest natural port in the world, as that of Dunkirk was lately the strongest artificial one.

The statutes 1 Eliz. cap. 11. and 13 & 14 Car. II. cap. 11. § 14. enable the crown by commission to ascertain the limits of ports and havens, and to assign proper wharfs and quays in each port, for the exclusive landing and lading of merchandize.

PORTS, Bar, Ports de barre, are such as can only be entered with the tide; as that of Goa.

PORTS, Close, are those within the body of a city; as those of Rhodes, of Venice, Amsterdam, Rochelle, Bayonne, and St. Jean de Luz.

PORT, Free, in *Commerce*, a port open and free for merchants of all nations to load and unload their vessels in, without paying any duties or customs.

Such are the ports of Genoa and Leghorn.

PORT, Free, is also used for a total exemption and franchise which any set of merchants enjoy, for goods imported into a state, or those of the growth of the country exported.

Such was the privilege the English enjoyed for several years after their discovery of the port of Archangel; and which was taken from them on account of the regicide in 1648.

PORTS, Cinque. See *CINQUE Ports*.

PORT is also sometimes used for the burden of a ship.

The capacity of a vessel is estimated in tons; each of which may contain about two thousand pounds weight of sea-water. When we say, a vessel is of the port or burden of a thousand tons, it is not meant, as some imagine, that it bears so many casks full of merchandize; but that the sea-water, which would be contained in the space which the capacity of the vessel possesses in the sea, weighs a thousand tons, which, at the rate of two thousand pounds each, is as much as to say, it bears a burden of two millions weight.

For the method of estimating this, see *BURDEN*.

PORT is also used for the palace of the grand signior, or emperor of the Turks.

PORT is also used for a strong wine brought from Oporto, or Port-a-Port in Portugal; whence its name. See *WINE*.

PORT of the Voice, in *Music*, the faculty and habit of making the shakes, passages, and diminutions, in which the beauty of a song, or piece of music, consists; and which the Italians comprehend under the terms *trilli*, *gruppi*, *straf-cini*.

PORT, among *Sailors*, denotes the larboard or left side of the ship; and is used, no doubt, to prevent any mistakes happening from the similarity of sounds in the words starboard and larboard, particularly when they relate to the helm, where a misapprehension might be attended with very dangerous consequences. Thus,

To port a helm, is to put the helm on the left side of the ship, that the ship may go to the right, or starboard.

The ship heels to port, denotes that she inclines or stoops to the larboard side.

Top the yard to port, is the order to make the larboard extremity of a yard higher than the other.

PORTS of a Ship. See *PORT-HOLES*.

PORT Abineau, in *Geography*, a harbour on the N. side of lake Erie.

PORT Allan, a harbour on the S. coast of Scotland, and W. side of Wigton bay. N. lat. $54^{\circ} 50'$. W. long. $4^{\circ} 24'$.

PORT Almeyda, a harbour on the coast of Africa, in the Indian sea. S. lat. $13^{\circ} 25'$.

PORT Althorp, a harbour on the N.W. coast of King George Third's Archipelago, between point Lucan and point Lavinia. N. lat. $58^{\circ} 11'$. Long. of the entrance $223^{\circ} 55' E$.

PORT Amherst, a harbour on the S. coast of Nova Scotia. N. lat. $43^{\circ} 32'$. W. long. $65^{\circ} 20'$.

PORT Angel, a harbour on the W. coast of Mexico, in midway between St. Pedro and Compostella, with a broad open bay, and good anchorage. N. lat. $13^{\circ} 32'$. W. long. $97^{\circ} 4'$.

PORT Anna Maria, a bay or harbour on the S. coast of Sir Henry Martin's island, in the Pacific ocean; easy of access and egress, with 24 fathoms of water at its entrance, in depth gradually decreasing to seven fathoms, within a quarter of a mile of its shore, with a fine sandy bottom; well guarded by the surrounding lands against the winds and sea in all directions, supplied by a stream of fine water; seven miles W. of port Marko.

PORT Antonio, a harbour on the N.E. coast of Jamaica. N. lat. $18^{\circ} 5'$. W. long. $76^{\circ} 5'$.

PORT Bainbridge, an inlet of the North Pacific ocean, extending about 20 miles northward into the W. coast of North America; its entrance is in N. lat. $59^{\circ} 55'$. E. long. $212^{\circ} 14'$.

PORT Banks, a harbour on the W. coast of North America, so called by Capt. Dixon. The land to the N. rises to a great height, and is covered with snow; eastward it is lower, and pines grow well. The prospect is pleasing and romantic. N. lat. $56^{\circ} 35'$. W. long. 135° .

PORT Baxwell, a harbour on the W. coast of North America. N. lat. $59^{\circ} 40'$. W. long. $149^{\circ} 40'$.

PORT Blanc, a harbour on the coast of Egypt, in the Red sea; 25 miles S.S.E. of Cossair.

PORT Bourbon, a sea-port on the S. coast of the island of Mauritius.

PORT Cabanos, a harbour on the N. coast of Cuba, E. of Florida bay.

PORT Camden, an inlet or branch from Prince Frederick's sound, extending about 20 miles south. N. lat. $56^{\circ} 55'$. Long. from the entrance $226^{\circ} 15' E$.

PORT Canan, a harbour on the S. coast of Scotland, and E. side of Glenluce bay. N. lat. $54^{\circ} 67'$. W. long. $4^{\circ} 30'$.

PORT Chalmers, a harbour on the W. coast of Montague island, in Prince William's sound. N. lat. $60^{\circ} 16'$. E. long. $213^{\circ} 22'$.

PORT Charles, a harbour on the E. coast of New Zealand, on the N. part of a peninsula, which bounds the river Thames eastward; six miles E. of cape Colville.

PORT Chatham, a bay or harbour on the E. coast of Greater Andaman island. N. lat. $11^{\circ} 41'$. E. long. $92^{\circ} 51'$.—Also, a harbour on the W. coast of North America, behind the island which forms cape Elizabeth, at the E. end of the entrance into Cook's inlet, and from that cape extends to a point in a direction N. 45, E. $5\frac{1}{2}$ miles; and from thence it terminates in an excellent harbour about two miles

long from N. to S., affording convenient and secure anchorage. N. lat. $59^{\circ} 14'$. E. long. $209^{\circ} 4'$.

PORT *Chaudiere*, a harbour on the S. coast of Hispaniola; 50 miles W. of St. Domingo.

PORT *Clarke*, a harbour on the W. side of Christian's sound, on the coast of Terra del Fuego; four miles N.N.E. of York Minster.

PORT *Conclusion*, a harbour on the E. coast of the southern extremity of King George Third's Archipelago, called so by Capt. Vancouver, on account of its being the last harbour which he examined on the coast of America. N. lat. $56^{\circ} 15'$. E. long. $225^{\circ} 37'$.

PORT *Cornwallis*, a harbour and settlement belonging to the English on the E. coast of the island of Andaman. The settlement was founded, in 1791, on an island called "Chatham," about two miles long, and half a mile broad; the southern extremity being separated from the larger Andaman island by a narrow channel, fordable at low water. N. lat. $13^{\circ} 20'$. E. long. $93^{\circ} 10'$.

PORT *de Conquel*, a harbour of France, on the peninsula of Quiberon. N. lat. $47^{\circ} 30'$. W. long. 3° .

PORT *Cox*, a bay on the W. coast of America; 60 miles S.E. of Nootka found.

PORT *Daniel*, a harbour in Chaleur bay. N. lat. $48^{\circ} 10'$. W. long. 65° .

PORT *Dauphin*, a bay on the E. coast of the island of Cape Breton. N. lat. $46^{\circ} 20'$. W. long. $60^{\circ} 25'$.

PORT *Desire*. See DESIRE.

PORT *Dick*, a harbour on the W. coast of North America. N. lat. $59^{\circ} 13'$. E. long. $209^{\circ} 45'$.

PORT *Discovery*, a harbour on the W. coast of North America, in the gulf of Georgia, E. of New Dungeness, so called from the ship of Vancouver denominated Discovery, which anchored here in May 1792. The entrance of the port is in N. lat. $48^{\circ} 7'$. E. long. $237^{\circ} 29'$.

PORT *Egmont*. See EGMONT.

PORT *d'Envaux*, a town of France, in the department of the Lower Charente; six miles N. of Saintes. N. lat. $49^{\circ} 51'$. W. long. $0^{\circ} 35'$.

PORT *d'Espagne*, a small sea-port in the island of Trinidad.

PORT *Effington*, a harbour of the North Pacific ocean, on the coast of New Cornwall, with a depth of water from seven to nine fathoms. N. lat. $54^{\circ} 14'$. E. long. $230^{\circ} 12'$.

PORT *Etches*, a bay or harbour on the S.W. of Hinchinbrook island, and the entrance of Prince William's sound, where the Russians have a factory; guarded by an armed galliot placed on the shore. N. lat. $60^{\circ} 21'$. E. long. $213^{\circ} 56'$.

PORT *Famine*. See FAMINE.

PORT *Fidalgo*, an inlet on the west coast of North America, extending about 20 miles from the north-east part of Prince William's sound, so called by captain Vancouver in honour of signior Fidalgo, a Spanish officer, who examined the neighbouring coast in the year 1790. N. lat. $60^{\circ} 49'$. Long. of entrance $213^{\circ} 57'$ E.

PORT *Float*, a bay and village of Scotland, in the county of Wigton; 7 miles S. of Stranrawer.

PORT *Français*, a harbour on the coast of Brasil. S. lat. 7° .

PORT *de Français*. See FRANÇAIS.

PORT *Fuego*, a sea-port on the west coast of the island of Luçon. N. lat. $14^{\circ} 14'$. E. long. $120^{\circ} 30'$.

PORT *Galeres*, a port on the south coast of the island of Samos. N. lat. $37^{\circ} 44'$. W. long. $26^{\circ} 54'$.

PORT *Gallant*, a harbour in the straits of Magellan, on

the coast of Patagonia, within Fortescue bay. See *Cape Gallant*.

PORT *Gardner*, a harbour on the east coast of Whidby's island, in the gulf of Georgia. N. lat. $48^{\circ} 2'$. E. long. $237^{\circ} 47'$.

PORT *Glasgow*. See GLASGOW.

PORT *Gore*, a bay of the North Pacific ocean, on the west coast of North America. N. lat. $59^{\circ} 10'$. W. long. $150^{\circ} 20'$.

PORT *Hannah*, a bay on the west coast of North America; 40 miles S.E. of Nootka found.

PORT *Hawkebury*, a bay on the west coast of North America, at the north entrance of the straits into Juan de Fuca. N. lat. $48^{\circ} 35'$. W. long. $124^{\circ} 40'$.

PORT *Holland*, a harbour on the coast of Patagonia, in the straits of Magellan, with good anchorage. N. lat. $53^{\circ} 57'$. W. long. $72^{\circ} 34'$.

PORT *Hood*, a bay on the west coast of Cape Breton. N. lat. 46° . W. long. $61^{\circ} 16'$.

PORT *Houghton*, a harbour on the west coast of North America, between point Hobart and point Walpole. It is bounded by lofty mountains, and from their base extends a small border of low land, forming the shores of the harbour.

PORT *Hubert*, a bay on the south coast of Nova Scotia. N. lat. $34^{\circ} 53'$. W. long. $64^{\circ} 55'$.

PORT *Jackson*. See JACKSON and *New Holland*. See also *BOTANY Bay*.

PORT *Ingraham*, a harbour on one of the Queen Charlotte's islands, in the North Pacific ocean, said to be a good port in which to winter. N. lat. $53^{\circ} 37'$. W. long. $133^{\circ} 18'$.

PORT *Inbambane*, a harbour on the coast of Africa, in the Indian sea. S. lat. $23^{\circ} 10'$.

PORT *John*, a good harbour on the west coast of King's island, in the North Pacific ocean. N. lat. $52^{\circ} 7'$. E. long. $232^{\circ} 10'$.

PORT *Joli*, a town of Canada, on the right bank of the St. Lawrence. N. lat. $47^{\circ} 15'$. W. long. $70^{\circ} 10'$.

PORT *Isaac*, a haven of England, on the north-west coast of the county of Cornwall. N. lat. $50^{\circ} 37'$. W. long. $4^{\circ} 16'$.

PORT *Kisfit*, a harbour in the Red sea, on the coast of Nubia, near the mouth of the Farat.

PORT *Lethen*, a sea-port on the east coast of Scotland, in the county of Kincardine; 6 miles S. of Aberdeen. N. lat. $57^{\circ} 1'$. W. long. $2^{\circ} 5'$.

PORT *Loquez*, a bay on the east coast of Madagascar. S. lat. $13^{\circ} 25'$. E. long. $50^{\circ} 20'$.

PORT *Louis*, a sea-port town on the west coast of the island of Guadaloupe. N. lat. $16^{\circ} 38'$. W. long. $61^{\circ} 33'$.

PORT *Louis*, a sea-port and principal town of the island of Mauritius, in which the governor and council reside. It is situated on the west side of the island, in a valley surrounded with high mountains, and contains above 500 houses, built of wood, and consisting of one story with garrets; though by the scarcity of wood, and the difficulty of procuring it from a distance, stone is now introduced. The town is irregular in the arrangement of its houses, but the quays are very commodious both for loading and unloading vessels. Water is conveyed to the town from a river at the distance of about a league, by a canal to the foot of a mountain, where is a large reservoir that supplies those who bring barrels in their boats to fetch it. Towards the middle of the town there is a large space, surrounded by a high stone wall, within which are the buildings assigned to the slaves of the company, as well as public stables, &c.

At the extremity of the valley, in which the town is situated, there is a space of ground, called the "Field of Mars," in which the military perform their exercise: here are also a rope-walk, and a promenade for the inhabitants. The port is not large; its entrance is narrow, and defended by two opposite batteries. About two or three miles to the west of the town is a considerable river, called "Le Grand Riviere," from which the town and harbour are supplied with water, and at the mouth of it is a powder-mill. On the summit of a high mountain is a guard-house, from whence a flag is hoisted, whenever a vessel is discovered in the offing. There is also another at a higher elevation, which serves as a signal to the inhabitants of the country, and by means of which intelligence is speedily communicated through the whole island. At the entrance of the harbour is an island, called "Isle des Tonnières," on which are several redoubts and batteries, well furnished with heavy artillery for defending the town. S. lat. $20^{\circ} 10'$. E. long. $57^{\circ} 32'$.

PORT *Louis*, or *Blavet*, a town of France, in the department of the Morbihan, at the mouth of the Blavet, situated at the extremity of a peninsula, defended by a citadel, surrounded by the sea and rocks. The road is spacious, and the harbour secure. It is guarded by other fortifications besides the citadel, and its commerce is considerable; 3 miles S. of L'Orient. N. lat. $47^{\circ} 43'$. W. long. $3^{\circ} 16'$.

PORT *Mahon*, a sea-port town of the island of Minorca, of which it is the present capital. It owes its name and foundation to Mago, erroneously called Magan and Mahon, the Carthaginian general. This town is situated on rocks, on the left bank of the port, on entering from the sea, which it commands; and this elevated situation affords it the benefit of a pure and healthy air. The houses have in general no other foundation than the rocks, which are undermined, or rendered hollow by the water, and which in course of time will render their situation dangerous. In general they are constructed with taste; many of them are terminated in the Italian style by a terrace, and almost all of them have a cistern. The parish church and three convents are tolerably well built, though without any exterior ornament. The hospital is large enough to accommodate 60 invalids; and there are some private schools for both sexes. The streets are narrow, rough, uneven, and badly paved with flints. Mahon was formerly surrounded with walls, supposed to have been erected by the Moors; but of these there is nothing left but one of the gates. The place of arms is square, large, and handsome; having on one side a barrack, capable of containing 1200 soldiers; and the other three sides are surrounded with houses. The alameda is an alley of trees, and this is the only promenade. The port has been long celebrated; and it is reckoned one of the finest, safest, and most convenient in the Mediterranean: a large fleet of ships of the line can enter and lie at anchor in it very conveniently. Hence has arisen the proverb: June, July, August, and port Mahon, are the best ports in the Mediterranean. At the entrance there are some shoals, but within the ships are sheltered from all winds. It is near $1\frac{1}{2}$ league in extent, and contains four islands: viz. the King's isle, where is a neat hospital built by the English; the isle of Quarantine; the isle of Lazaret; and the isle Redonda, which is a circular mass of rocks. Stocks for ship-building are established on the right bank of the port. The Cabo Mola, or promontory, situated on the east, at the entrance into the mouth of the port, is very high, and joins the island by a narrow mass of sand. At a short distance from Cape Mola stands the signal-tower, to correspond with mount Toro, which is connected with other points. The

signals are conveyed during the night by fires, and in the day-time by flags. Fort St. Philip was famous in the maritime wars of the last century. This fortress occupied a space of about a league in circumference; but the whole was blown up and destroyed, by order of the Spanish government, in 1805. There is nothing left in the centre but some small edifices. N. lat. $39^{\circ} 52'$. E. long. $4^{\circ} 52'$.

PORT *Mahesbury*, a bay or harbour on the west coast of an island in the North Pacific ocean, and southern part of Chatham strait. N. lat. $56^{\circ} 17'$. Long. of the entr. $225^{\circ} 59' E$.

PORT *Mangarin*, a harbour on the south coast of the island of Mindoro. N. lat. $12^{\circ} 25'$. E. long. $121^{\circ} 12'$.

PORT *Margot*, a town of Hispaniola; 14 miles E.S.E. of Port Paix.

PORT *Maria*, a bay on the north coast of Jamaica.

PORT *Mariel*, a harbour on the north coast of Cuba.

PORT *Marquis*, a harbour on the west coast of Mexico; 3 miles E. of Acapulco.

PORT *Mary*, a bay on the west coast of King George Third's Archipelago. N. lat. $57^{\circ} 11'$. E. long. $224^{\circ} 29'$.

PORT *Mathanon*, a harbour on the south-east coast of the island of Cuba, between Cape Mayzi and Cape Cruz.

PORT *Maurice*, a bay on the south-east coast of Terra del Fuego, south-west of Cape St. Diego. N. lat. $54^{\circ} 44'$. W. long. $66^{\circ} 15'$.

PORT *Morant*, a bay on the south coast of the island of Jamaica, near the east end of the island. N. lat. $17^{\circ} 54'$. W. long. $76^{\circ} 2'$.

PORT *Mulgrave*. See ADMIRALTY Bay.

PORT *Nevile*, a bay in Johnstone's straits, on the coast of North America. N. lat. $50^{\circ} 31'$. E. long. $234'$.

PORT *Nockie*, a harbour of Scotland, on the coast of Bamffshire. N. lat. $57^{\circ} 40'$. W. long. $2^{\circ} 47'$.

PORT *Oliver*, or *Port Yero*, a sea-port on the south-east coast of the island of Metelin. See MITYLENE.

PORT *Orchard*, a bay or harbour within ADMIRALTY Inlet; which see. N. lat. $47^{\circ} 39'$. E. long. $237^{\circ} 36'$.

PORT *Paix*, a town of the island of Hispaniola, on the north shore, with a good harbour, and in the midst of the most healthy territory in the island. N. lat. $19^{\circ} 55'$. W. long. $73^{\circ} 12'$.

PORT *Palliser*, a harbour on the north-east coast of Kerguelen's land, in the Southern Indian ocean. S. lat. $49^{\circ} 3'$. E. long. $69^{\circ} 37'$.

PORT *Pasquet*, a harbour on the south-west side of the island of Majorca.

PORT *Penn*, a town of America, in the state of Delaware, on the Delaware river; 30 miles below Philadelphia.

PORT *Plate*, a harbour on the N. coast of Hispaniola. N. lat. $19^{\circ} 45'$. W. long. $71^{\circ} 25'$.

PORT *Praslin*, a bay on the N. coast of New Georgia, on the land of Arfacides, discovered by M. Surville in 1769. S. lat. $7^{\circ} 25'$. Long. of the entr. $154^{\circ} 50' E$.

PORT *au Prince*, a sea-port, with a jurisdiction of the same name, at the head of the great bay or bight of Leogane, on the W. coast of Hispaniola, or St. Domingo. This town, in time of peace, has been the seat of the French government, and a place of considerable trade. The adjacent country produces cotton, indigo, sugar, and coffee. In 1770 a great part of the town was destroyed by an earthquake; in 1791 it was very much damaged by fire; and in 1794 it was taken by the English. Its situation is low and marshy, and of course insalubrious. The hills that surround it, and that command the town and harbour, and the intervening valleys are very fertile. To the E. lies the fruitful plain of Cul de Sac, 30 or 40 miles long, and

9 broad, containing about 150 sugar plantations, most of which may be watered by canals. Port au Prince is seven leagues E. by N. from the town of Leogane. N. lat. $18^{\circ} 35'$. W. long. $73^{\circ} 10'$.

PORT *du Prince*, a town on the northern coast of the island of Cuba, with a good harbour, situated in a large meadow, where the Spaniards feed numerous herds of cattle.

PORT *Protection*, a harbour on the W. coast of North America, at the N.W. extremity of the Prince of Wales's Archipelago, so called by Capt. Vancouver, on account of its affording him an asylum after a violent storm, Sept. 8, 1793. The shores are in many places steep and rocky, and are covered with impenetrable forests of pine and other trees, which afforded several streams of fresh water. N. lat. $56^{\circ} 20'$. E. long. of the entrance $226^{\circ} 35'$.

PORT *Raphiti*, or *Raffii*, a harbour of the Ægean sea, on the N.E. coast of Attica, anciently the port of "Prasiæ." It is described as a most safe, commodious, and delightful harbour; almost surrounded with vallies, which terminate in mountains; the intervening slopes being covered with pine-trees and verdure. The bay is divided by a sharp point of land, and near its mouth are two islands, or rocks; on the summit of one of which, whose base is about a mile in circumference, is a large colossal statue in a fitting posture, with the arms and legs broken off, supposed to have been about twelve feet high before it was mutilated. On the other island is another figure, representing a female. These statues are supposed to represent Apollo and Diana, and were probably placed as guides to seamen by day, or with lights at night. N. lat. $37^{\circ} 52'$. E. long. $24^{\circ} 1'$.

PORT *Razoir*, a harbour on the S.W. coast of Nova Scotia.

PORT *Resolution*, a harbour on the N. side of the most easterly point of the island of Tanna, in the Pacific ocean. Although it is only a small creek, it is very convenient for taking in both wood and water. S. lat. $19^{\circ} 32'$. E. long. $169^{\circ} 35'$.

PORT *Rosemary*, a bay on the S.E. of Nova Scotia, in which the town of Shelburn is built. N. lat. $43^{\circ} 40'$. W. long. $65^{\circ} 13'$.

PORT *Royal Island*, an island in Port Royal entrance, near the coast of South Carolina, separated from the main land on the W. by Broad river; about twelve miles long, and one wide. The principal town is Beaufort. It has an excellent harbour, sufficient to contain the largest fleet in the world. N. lat. $32^{\circ} 12'$.

PORT *Royal*, or *Porto Escondendo*, a small island and harbour in the bay of Campeachy, near the coast of Yucatan. N. lat. $18^{\circ} 22'$. W. long. $92^{\circ} 36'$.

PORT *Royal*, a sea-port of the county of Surry, in the island of Jamaica, situated on the S. side of the island, on a narrow neck of land; in which a thousand sail of ships could anchor with the greatest convenience and safety. Port Royal was once of the greatest wealth and importance in the West Indies; but it is now reduced by repeated calamities to three streets, a few lanes, and about 200 houses. It contains, however, the royal navy-yard, for hewing down and refitting the king's ships; the navy-hospital, and barracks for a regiment of soldiers. The fortifications are kept in excellent repair; 20 miles S.W. of Kingston. N. lat. $17^{\circ} 50'$. W. long. 77° .

PORT *Royal*, a post-town of America, in Virginia, on the S. bank of Rappahannock river, in Caroline county. It is laid out on a regular plan, and contains about 200 brick houses, of handsome appearance, with three churches, for Episcopalians, Presbyterians, and Methodists; 22 miles

S.E. of Fredericksburg. N. lat. $38^{\circ} 13'$. W. long. $77^{\circ} 34'$. —Also, a town and harbour in the island of Martinico, one of the chief places in the island. N. lat. $14^{\circ} 38'$. W. long. $61^{\circ} 9'$.

PORT *Royal*, or *Annapolis*. See ANNAPOLIS.

PORT *Royal Harbour*, a port on the S. coast of the island of Ruatan.

PORT *St. Antonio*, a harbour on the S. coast of the island of Stalimenc.

PORT *St. Felice*, a harbour on the W. coast of Madagascar. S. lat. $22^{\circ} 15'$.

PORT *St. James*, a bay on the W. coast of Madagascar. S. lat. $21^{\circ} 55'$. E. long. $47^{\circ} 4'$.

PORT *St. Juan*, a bay or harbour on the N.W. coast of the island of Quadra and Vancouver, at the entrance of the strait of Juan de Fuca. N. lat. $48^{\circ} 32'$. E. long. $235^{\circ} 52'$.

PORT *St. John*, a small town in the province of Nicaragua, in New Spain, at the mouth of a river on the North Pacific ocean; the harbour is safe and capacious, and is the sea-port of the city of Leon, 30 miles S.E. of it. N. lat. $12^{\circ} 10'$. W. long. $87^{\circ} 38'$.

PORT *St. Julian*, a harbour of the Atlantic, on the E. coast of Patagonia, discovered by Magellan, in April 1520. S. lat. $49^{\circ} 10'$. W. long. $68^{\circ} 44'$.

PORT *Sainte-Marie*, a town of France, in the department of the Lot and Garonne, and chief place of a canton, in the district of Agen, on the Garonne; 10 miles W. of Agen. The place contains 2805, and the canton 12,643 inhabitants, on a territory of $147\frac{1}{2}$ kilometres, in 17 communes.

PORT *St. Mary*, a port on the N.W. coast of the island of Paros. N. lat. $37^{\circ} 8'$. E. long. $25^{\circ} 18'$.

PORT *St. Pere*, a town of France, in the department of the Lower Loire; nine miles S.W. of Nantes.

PORT *Salut*, a sea-port on the S. coast of the island of Hispaniola; 16 miles S.W. of Les Cayes.

PORT *Sandwich*, a harbour of the island of Mallicollo, in the South Pacific ocean. S. lat. $16^{\circ} 25'$. E. long. $167^{\circ} 57'$.

PORT *sur-Saone*, a town of France, in the department of the Upper Saone, and chief place of a canton, in the district of Vesoul; six miles N.W. of Vesoul. The place contains 1914, and the canton 9078 inhabitants, on a territory of 180 kilometres, in 18 communes.

PORT *Sepsila*, a harbour on the N. coast of the island Patino, about a mile E. of La Scala.

PORT *Serivan*, a harbour on the coast of the isthmus of Darien, with a rocky dangerous entrance, but safe within, with good anchorage in a sandy bottom.

PORT *Seaton*, a sea-port of Scotland, on the Frith of Forth; eight miles E. of Edinburgh. N. lat. $55^{\circ} 58'$. W. long. $2^{\circ} 55'$.

PORT *Seitan*, a port on the N. coast of the island of Samos. N. lat. $37^{\circ} 49'$. E. long. $26^{\circ} 40'$.

PORT *Selanguin*, a harbour on the W. coast of the island of Luçon. N. lat. $14^{\circ} 50'$. E. long. $120^{\circ} 10'$.

PORT *Shimene*, a harbour on the N. coast of the island of St. John, in the gulf of St. Laurence.

PORT *Skerry bay*, a harbour on the N. coast of Scotland. N. lat. $58^{\circ} 31'$. W. long. $3^{\circ} 47'$.

PORT *Snettisham*, a harbour on the W. coast of North America, in Stephens's Passage, between point Styleman, and point Hanmer.

PORT *Solidad*, a port on one of the Falkland islands, with a fortress erected by M. Bougainville, and called by him "St. Louis."

PORT *Stephens*, a bay on the E. coast of New Holland. S. lat.

S. lat. $32^{\circ} 40'$. W. long. $207^{\circ} 51'$.—Also, a harbour on the S. coast of Pitt's Archipelago, in the North Pacific ocean. N. lat. $33^{\circ} 28'$. E. long. $230^{\circ} 21'$.

PORT *Stewart*, a harbour on the W. coast of North America, surveyed by Mr. Stewart, one of Vancouver's mates. N. lat. $55^{\circ} 38'$. E. long. $228^{\circ} 4'$.

PORT *Subec*, a harbour on the W. coast of Luçon. N. lat. $14^{\circ} 50'$. E. long. $120^{\circ} 20'$.

PORT *Susan*, a harbour on the W. coast of North America, in the gulf of Georgia, E. of Whidby's island. N. lat. $48^{\circ} 5'$. E. long. $237^{\circ} 55'$.

PORT *Taytay*, a harbour on the E. coast of the island of Paraguay. N. lat. $10^{\circ} 35'$. E. long. $119^{\circ} 35'$.

PORT *Thouloufe*, a harbour on the S. coast of the island of Cape Breton.

PORT *Tibori*, a sea-port town on the S.W. coast of the island of Negropont. N. lat. $38^{\circ} 17'$. E. long. $27^{\circ} 10'$.

PORT *Tobacco*, a post-town of America, in Maryland, and capital of Charles county, situated a little above the confluence of two small streams, which form the creek of its name, that empties through the N. bank of the Potowmac, at Thomas's Point, about four miles below the town. It contains about 80 houses, and a large episcopal church; and also a warehouse for the inspection of tobacco. Near it are the celebrated cold waters of Mount Misery; it is 52 miles S.W. of Annapolis.

PORT *Towan*, a small bay on the N.W. coast of Cornwall; 12 miles N.W. of St. Ives.

PORT *Townshend*, a harbour in the gulf of Georgia, on the W. coast of North America, discovered by Vancouver in 1792. N. lat. $48^{\circ} 3'$. E. long. $237^{\circ} 31'$.

PORT *de la Trinidad*, a bay of the North Pacific ocean, on the W. coast of North America.

PORT *Ucab*, a harbour on the W. coast of North America. N. lat. $52^{\circ} 25'$.

PORT *Velas*, or *Velasco*, a harbour on the coast of California. N. lat. $28^{\circ} 13'$.

PORT *Vendre*, a town of France, in the department of the Eastern Pyrenées, with a small harbour on the Mediterranean, defended by two forts; deriving its name from a temple consecrated to the goddess Venus; 17 miles E. of Ceret. N. lat. $42^{\circ} 31'$. E. long. $3^{\circ} 12'$.

PORT *Vinegora*, or *Round Port*, a bay on the N. coast of the island of Madagascar. S. lat. $13^{\circ} 30'$. E. long. $53^{\circ} 44'$.

PORT *Wells*, a harbour or inlet on the N.W. part of Prince William's sound, on the W. coast of North America, from N. to S. about 10 miles in length, and 3 in its medial breadth. N. lat. $60^{\circ} 59'$. E. long. of the entr. $202^{\circ} 30'$.

PORT *Yarrook*, a harbour of Scotland, on the W. side of Wigton bay. N. lat. $54^{\circ} 49'$. W. long. $4^{\circ} 24'$.

PORTA, in *Anatomy*. See PORTARUM *Vena*, and LIVER.

PORTA, SIMON, in *Biography*, a celebrated Peripatetic philosopher in the sixteenth century, was born at Naples in the year 1496. He studied under Pomponazzi at Pisa, (see his article,) whose sentiments he adopted on the subject of the immortality of the soul. He became a lecturer in different Italian cities, and was nominated professor of philosophy at Pisa in the year 1546, where he explained the writings of Aristotle to crowded auditories, with profound learning and great applause. In 1552 he returned to his native city, where he died in 1554, at the age of 58. He was author of various works in moral philosophy, which were collected and published at Florence a short time before his death. The titles of these are given in the General Biography, to which our readers are referred.

PORTA, GIAMBATISTA, a Neapolitan gentleman, born about the year 1540. At a very early age he applied himself to the study of nature, and so great was his zeal for the advancement of knowledge, that he assembled a kind of academy in his house named *de' Secreti*, to which no one was admitted who had not made some useful discovery in philosophy or medicine. He likewise travelled for improvement, and became acquainted with the famous Fra. Paolo, from whom he acquired much valuable information. At Rome he was admitted into the academy de' Lincei. He travelled throughout Italy, into France and Spain, visiting all the libraries and learned men, and conversing with artists on matters relative to their several professions. His publications widely extended his fame, and Peiresc, when he visited Naples, about the end of the sixteenth century, held frequent conversations with Porta, and his brother, also a man of learning, and examined with attention the various curiosities of their museum. He was accused of unlawful superstitions, and was obliged to appear in person at the court of Rome to answer the accusation. He died at Naples in 1615, much regretted as one of the most acute geniuses of the age; his various talents were, however, joined with no inconsiderable portion of credulity and extravagance. His earliest work was entitled "*Magia Naturalis*," first printed in four books in 1538, which he afterwards augmented to twenty books. It has been frequently printed and translated into various languages. His work entitled "*Phytognomica*," in 1588, is an elaborate attempt to detect the qualities of plants by their resemblances to animals and their parts. One of his most fanciful works is entitled "*De Humana Physiognomia*," in which he professes to teach the art of discovering all the propensities of the human mind from the countenance, and of correcting them by suitable remedies. To this he added a "*Physiognomia Cœlestia*," treating upon the influence of the planets and constellations upon the manners and constitution, on which he supposes the bodily temperament to exert a greater effect. His work "*De Æris Transmutationibus*," gives an account of all that was then known of meteorological phenomena. His mathematical works obtained for him a still higher reputation than his other pieces; the principal of these were "*Elementa Curvilinea*," and "*De Refractione Optices*." In optics he was a great improver, if he does not merit the higher rank of a discoverer. The theory of light is much indebted to his labours; he was probably the first who fully satisfied himself that vision is performed by the intromission of something into the eye, and not by the visual rays proceeding from it. He invented the *camera obscura*, and applied it to the action of the human eye, though he suspected that the crystalline lens, and not the retina, was the seat of vision. He attributes to refraction the colours of the rainbow, but does not suppose it to be refraction in single drops, but of the whole mass of the falling rain. He wrote a curious work "*De occultis literarum notis*," in which he gives a great number of modes of secret writing. He is said to have composed comedies and tragedies, but those attributed to him have not yielded any addition to his fame. Priestley's Optics. Gen. Biog.

PORTA, BACCIO DELLA, called *Fra. Bartolommeo di San Marco*. (See BACCIO.) In addition to what is there inserted, we shall give M. Fuseli's judicious characteristic of this great artist, whose real surname has unfortunately escaped from the records of history. The appellation of Baccio is merely a vulgar diminutive of Bartolommeo, and that of della Porta was attached to him in consequence of his having his abode near one of the gates of Florence. When he afterwards took the sacerdotal habit of the Dominican

minican convent of St. Marco, he obtained that cognomen by which he is best, and indeed universally known, Fra. Bartolommeo di St. Marco; and sometimes is simply called by authors 'Il Frate.' "He studied under Cosimo Roselli, but soon grew enamoured of the grand chiaro-scuro of Lionardo da Vinci, and strove to emulate it. His progress was rapid, and he became the instructor of Raphael in colour, who gave him lessons in perspective. In imitation of him, Baccio aimed at uniting gracefulness with grandeur of form. The composition of his sacred subjects, and he painted little else, is the usual one of his time; which adhered to Raphael himself, and was not dismissed by the Florentine school before the epoch of Pontormo: but he disguised its formality by the introduction of architecture and majestic scenery. To repel the invidious charge of incapacity for large proportions, he produced the sublime figure of St. Marc, which alone fills an ample pannel, and is now among the spoils of the Louvre. His St. Sebastian, for skill in the naked, and energy of colour, obtained every suffrage of artists and of critics, but unfortunately became such a favourite with the female visitants of the chapel, that the monks thought proper, first to remove the picture to a more private place, and afterwards to sell and send it to France. In drapery he may be considered as an inventor; no artist of his school formed it with equal breadth or dignity, or so natural and expressive of the limits; and if he were the constructor, he was certainly not the slave of the layman." One work of his, of prodigious grandeur and beauty, is unnoticed by our author, viz. the Assumption of the Virgin, at Lucca. Its situation being retired, this picture is little known to travellers, though it is one of the most sublime productions of the pencil. Mr. West, the president of the Royal Academy, has in his possession a considerable part of the Studies mentioned by Vasari as having been left to his scholar, a nun of St. Catherine at Florence; and among them several drawings for this picture and its various parts. They are accompanied by about 200 drawings of figures, draperies, and limbs; studied from nature with great care and taste, and exhibit the industry and uncommon zeal with which he laid the basis of his justly acquired fame.

PORTA, COSTANZO, of Cremona, a disciple of Willaert, and fellow-student with Zarlino. He was at first maestro di cappella at Padua, next at Osimo, in the March of Ancona; then at Ravenna; and lastly, at Loretto; where he died in 1601. He was author of eighteen different works for the church, full of elaborate and curious compositions, which have been always sought and admired by masters, and collectors of learned music. This author seems not only to have vanquished all the difficult contrivances for which John Okenheim, Jusquin del Prato, and Adrian Willaert, from whose school he sprung, were celebrated, but considerably augmented their number: for, as orators, lawyers, and commentators have the art of twisting and subverting words to any meaning that favours their cause or hypothesis, so Costanzo Porta had equal power over any series of musical notes in a canon or fugue; which he could not only work in *recte et retro*, but invert, augment, diminish, divide, or subdivide, at his pleasure. In this faculty he very much resembled our Tallis, his contemporary. He began to flourish towards the latter end of the reign of Henry VIII. as did Tallis. According to Draudius, his five-part motets were published at Venice in 1546; and between that period and 1599, the rest of his works were published, either by himself or scholars, of whom he had a great number; particularly Lodovico Balbo, who flourished about 1578, and Giacomo Antonio Piccioli, 1588, both voluminous composers,

in their master's artificial and elaborate style, and consequently great canonists.

A composition by Costanzo Porta, in seven parts, is inserted in Burney's General History of Music, vol. iii. p. 227, taken from the author's fifty-two motets, in four, five, six, seven, and eight vocal parts, printed in 1588, while he was maestro di cappella of the holy church of Loretto; it consists of four parts in canon, two *per moto ritto*, and two *per moto contrario*, while the other three are in free fugue. Though long, it is so curious, and constructed with so much art, that it is exhibited as an example of that scientific species of writing, by which alone the abilities of a contrapuntist were measured in the sixteenth century, when there were no musical dramas, or full pieces for instruments, and but few single songs, or solos of any kind, to exercise genius and invention. Masses and motets for the church, and madrigals for the chamber, in three, four, five, six, and more parts, comprised almost all the music that was then composed.

PORTA, GIOVANNI, of Venice, first appeared as an opera composer in that city in 1716. His favour in his native place must have been very considerable; as we find in the catalogue of musical dramas performed in Venice in the beginning of the last century, twelve composed by Porta.

PORTA *Augusta*, in *Ancient Geography*, a town of Spain, in the country of the Vaccæi, between Viminatum and Antraca. Ptolemy.

PORTA, *La*, in *Geography*, a town of the island of Corfica, and capital of a district; 22 miles 'S.S.W. of Bastia. N. lat. 42° 18'. E. long. 9° 30'.

PORTA *Canonne*, a town of Naples, in the province of Capitanata; 8 miles S. of Termola.

PORTA *Maria*, lies in the N.E. part of the island of Jamaica, S.E. from Gallina point.

PORTA *Port*, lies on the N.W. side of the island of Newfoundland, having its S. entrance 10 or 12 leagues from Cape St. George.

PORTABLE, something easy of carriage.

PORTABLE *Barometer*. See BAROMETER.

PORTACRA, KARA-SOU, in *Ancient Geography*, a town in the interior of the Tauric Chersonesus, placed by Ptolemy 50' W. of Cimmericum.

PORTADOWN, in *Geography*, a post-town of the county of Armagh, Ireland, situated on the river Bann, over which it has a stone bridge, and noted for extensive business in the linen manufacture. It is 65½ miles N. by W. from Dublin.

PORTÆ AMANICÆ, in *Ancient Geography*, a defile of mount Amanus, at the eastern extremity of the Mediterranean sea, which, according to Ptolemy, separated between Cilicia and Syria. Here was the passage from the gulf of Issus into Cilicia, and the scene of two famous battles, one near Issus between Darius and Alexander, in which the latter was victorious, and another between Septimius Severus and Pescennius Niger, in which the latter was vanquished.

PORTÆ, or *Pyle ad Helos*, a defile of Arcadia, upon the route from Megalopolis to the canton of Menale. On the left of this defile was a wood consecrated to Bonus Deus, and at a small distance was the tomb of Aristodemus, who had usurped the sovereign power at Megalopolis, and who possessed many excellent qualities under the denomination of a tyrant. Minerva, the inventress, had also a temple near this place. On the right was a place consecrated to Boreas, to whom the Megalopolitans offered sacrifices as a god. At no great distance were also the burying-place of Amphiar-

raus, and a temple of Ceres of Helos, accessible only to females.

PORTAFERRY, in *Geography*, a post-town of the county of Down, Ireland, situated in the barony of Ardes, which is in a great measure separated by Strangford lough from the rest of the county. Portaferry is on one side of the channel by which this extensive lough is connected with the sea, and there is a ferry from it to the town of Strangford on the other side, from which it derived its name. It is 80 miles N.N.E. from Dublin, and six E. from Downpatrick.

PORTAGE, in *Commerce*, denotes money paid for the wages of sailors, while in port.

PORTAGE, in *Geography*, a county in the state of Ohio, containing, in 1810, 9 towns and 2995 inhabitants.

PORTAGE River, a river of America, which runs into lake Erie, N. lat. $41^{\circ} 55'$. W. long. $82^{\circ} 42'$.

PORTAGE, Le Grand, leads from the N.E. end of lake Superior, in Upper Canada, to a chain of smaller lakes, on the communication to the north-western trading ports.

PORTAGE Point, on the E. coast of New Brunswick, and in the S.W. part of the gulf of St. Lawrence, forms the N. limit of Miramichi bay, as Point Ecoumenac does the S.

PORTAIGUILLE, in *Surgery*, the handle of a tentaculum.

PORTAIL, in *Architecture*, the face or frontispiece of a church, viewed on the side in which is the great door.

Portail is also used for the great door, or gate itself of a palace, castle, &c.

PORTAL, a term used for a little square corner of a room, cut off from the rest of the room by the wainscot; frequent in the ancient buildings, but now disused.

The word seems a diminutive of the French *porte*, door, gate, it being through this that they entered into the room.

PORTAL is sometimes also used for a little gate, *portella*; where there are two gates of a different size. See **GATE**.

PORTAL is sometimes also used for a kind of arch of joiner's work before a door.

PORTAL di St. Luis, in *Geography*, a town of Brasil, in the government of Goyas, on the river Tocantin. S. lat. $13^{\circ} 30'$.

PORTALEGRE, a town of Portugal, in Alentejo, the see of a bishop; containing, besides the cathedral, four parish churches, five convents, an hospital, and about 5600 inhabitants; fortified with walls and towers; 84 miles E. of Lisbon. N. lat. $39^{\circ} 8'$. W. long. $7^{\circ} 11'$.

PORTALOON. See **PUTELAM**.

PORTAMENTS, in *Italian Music*, signifies the conduct of the voice, which is said to be good, when it is neither nasal nor guttural.

PORTARLINGTON, in *Geography*, a post-town of the Queen and King's county, Ireland, being partly in each, but chiefly in the Queen's county. It is situated on the river Barrow, by which it is divided. It is a large town, and an agreeable residence, from the number of genteel families which live there. It was formerly a settlement of French Protestant refugees, the descendants of many of whom are still living there, and is remarkable for a great number of schools for children of both sexes, which are principally employed in the preparative education of very young children. At the union it was chosen as one of the boroughs to be represented, and accordingly sends one member. It is 37 miles W.S.W. from Dublin.

PORTARUM VENA, in *Anatomy*, a large vein, produced by the union of the veins of the stomach, intestines,

spleen, and pancreas, and ramified in the liver. See **LIVER**.

PORTASCAWET, or *Port Skezewet*, in *Geography*, a small sea-port of England, in the county of Monmouth, on a small river, which runs into the Severn; anciently, before the building of Chepstow, the only port in the country; 4 miles S.W. of Chepstow.

PORTATE, in *Heraldry*. A *cross portate* is a cross which does not stand upright, as crosses generally do, but lies athwart the escutcheon, in bend, as if it were carried on a man's shoulder. See **CROSS**.

Colombiere tells us, it is by some called *porté*, that is, *carried*, because, when our Saviour went to suffer death, he was obliged to carry his cross, which is always thus represented sloping, and inclined after this manner.

PORTCHESTER, or **PORTCHESTER-STREET**, in *Geography*, a parish and village in the hundred of Portfdown, in the vicinity of Portsmouth, and county of Southampton, England, is a place noted for its ancient castle, and military barracks. The former appears to be partly of Roman construction, with additions and alterations by the Saxons, Normans, and English. It is seated on a neck of land, in the middle of Portsmouth harbour, or bay, and consists of a series of walls and towers, which occupy an area of about five acres of land. The walls are nearly twelve feet thick, and eighteen feet in height, and have in many places a passage round them covered with a parapet: it has eighteen towers of various shapes and magnitudes, including those of the keep, and is defended on the north, west, and south sides by a ditch varying in breadth, and fifteen feet in depth: on the east are two ditches which extend to the water, and have probably been filled by the influx of the tide. The entrance on the west side is thirty feet deep and fourteen wide, under a square tower: on the inside, over the gate, are two projecting figures, somewhat resembling Egyptian sphynxes. In the east wall, nearly opposite this gate, is another of like dimensions: there are likewise two sally-ports.

The keep, observes Grose, encompasses a parallelogram of sixty-five feet by one hundred and fifteen. It has four towers, three of them standing on the outside wall: one of these, which is much larger than the rest, forms the N.W. angle of the square; the fourth tower stands at the S.E. corner of this building. Here are many rooms, several very large, and some arched with stone: among them is one which appears to have been a chapel; the entrance is through a gate on the south side, only eight feet wide. Several of these towers, as well as parts of the walls, are now in ruins.

The round towers are placed at the north-east, south-east, and south-west angles; the north-west angle is now taken up by the great square tower of the keep: some of these towers are twenty and others nineteen feet in diameter; and in general they project about eighteen feet and a half from the wall. In some of them are still visible regular rows of Roman brick, dividing the rows of stone-work; and particularly in one on the south side, in which are three rows very distinct: in the wall itself on this side they may also be traced, and indeed in many other parts. The extent of the outward walls, exclusive of the projecting parts of the round corner towers, is about 620 feet on the north and south sides; and 610 on the east and west sides. In the keep, which forms the north-west angle of the castle, traces of the architecture of the Saxon and Norman periods, and even of later ages, to the time of queen Elizabeth, are plainly to be seen. The great tower is lofty, and contains two vaults or dungeons at bottom, with the remains of three double apartments above them, in so many several stories:

its walls are nearly eight feet thick; and its external dimensions on the north and south fifty-seven feet; and on the east and west fifty-eight feet.

The most curious part of the inner or *Norman* court, as it may be called, is its fortified entrance, which opens from the outer area on the east, where is a large Norman tower, which is now much dilapidated, built on the Roman work; and formerly secured by a portcullis, and double-folding doors strongly barricadoed. The west, or opposite entrance, is also by a strong Norman tower, about 35 feet wide and 30 deep, having a passage through the centre about eight feet in width; this also is in ruins.

The *Sacellum of the Prætorium* of the Romans is supposed by Mr. King to have been on the spot now occupied as the site of the parish church, which is an edifice of great antiquity, dedicated to St. Mary, standing within the outer court. Though part of it has been rebuilt and other parts repaired at various periods, it still displays many specimens of Saxon architecture, particularly in the west front. Its original form was that of a cross, with a low tower rising from the intersection; but the south transept has been taken down. All the doors and windows of the ancient part have semi-circular arches; and those of the west end are decorated with double zig-zag ornaments. Here it was that Henry I. founded the priory of Black canons, afterwards removed to Southwick. Within the church is a monument to the memory of sir Thomas Cornwallis, knt. groom porter to queen Elizabeth and James I., who died in November 1618. Here is a curious and ancient font. Parts of the castle were recently fitted up for, and occupied by, prisoners of war; but it is hoped that it may never again be required for that purpose.

It has been asserted by some writers, that the Roman general Vespasian landed here on his first arrival in Britain; but this has been contradicted by others on better testimony. That it must have been in his possession is, however, extremely probable, as the conquest of the Isle of Wight could hardly have been otherwise effected. That several of the Saxon invaders landed here is more certain, and particularly Porta, with his sons Bieda and Megla, by whose aid Cerdic was enabled to establish the kingdom of the West Saxons. At what period it was deserted of inhabitants is unknown; though presumed to be on the rise of Portsmouth, after the sea had in some degree retired from the upper parts of the harbour. This place is generally admitted to have been the *Portus-Magnus* of the Romans, and the *Caer-peris* of the Britons. For a more ample account of the castle and village, the reader is referred to King's *Munimenta Antiqua*, vol. ii., and to the *Beauties of England and Wales*, vol. vi., by J. Britton and E. W. Brayley.

PORT-CRAION, a pencil-case, an instrument serving to enclose a pencil, and occasionally also used as a handle for holding it.

It is usually four or five inches long, and contrived so that the pencil may be slid up and down it by means of a spring and button. Its outside is filed into eight sides or faces, on which are drawn the sector lines: its inside is round; sometimes it is made round or cylindrical, both withoutside and within, and has its length divided into inches and parts of inches.

PORTCULLICE, called also *berse* and *sarrasin*, in *Fortification*, an assemblage of several great pieces of wood laid or joined across one another, like a harrow, and each pointed at the bottom with iron.

These formerly used to be hung over the gateways of fortified places, to be ready to let down in case of a surprise,

when the enemy should come so quick, as not to allow time to shut the gates.

But now-a-days, the orgues are more generally used, as being found to answer the purpose better.

PORT-DIEU, among the French, is a parish-priest, whose business is to carry the viaticum, or sacrament, to sick people.

PORTE, PETER DE LA, in *Biography*, was first train-bearer to queen Anne of Austria, and afterwards maitre d'hotel, and first valet-de-chambre to Lewis XIV. He was the sole confidant of the queen, who entrusted to him her secret correspondence with the kings of Spain and England, then enemies to France. He was thrown into prison by cardinal Richelieu, who not only caused him to be treated with great rigour, but even threatened him with death, in order to compel him to betray the queen's secrets. He remained firm, and was liberated, but exiled. La Porte was a man of considerable worth, and of elevated sentiments, and executed his office about the young king with a true regard to his master's advantage. Having noticed his fondness of personating a valet, he one day seated himself in the armed chair, with his hat upon his head. On the king's complaining to his mother of La Porte's want of respect, he replied, in his presence, "Since the king has chosen to assume my part, is it not reasonable that I should take his? and, in truth, I am no loser by the exchange." Lewis was desirous of continuing the custom of being read to sleep by the Fairy Tales; but La Porte substituted Mezerai's History of France: when cardinal Mazarin, who would gladly have protracted the period of the king's ignorance, complained that the *domestic* wished to make himself *governor*. He died at Paris in 1680, at the age of 77. His "Memoirs" were published at Geneva in 1756, which contain much curious matter, that bears the stamp of truth and integrity.

PORTE'E, Fr. the five parallel lines on and between which all music is now written. Till the middle of the last century, lutes, guitars, and some other instruments, had peculiar tablatures; but these are no longer in use at present, nor have any new schemes of notation been favourably received in any part of Europe. See STAFF.

PORTEGLO, in the *Glass Trade*, the instrument with which the founder, or conciator, scums the glass while melting.

PORTELA, in *Geography*, a town of Portugal, in Alentejo; 10 miles N.N.W. of Mourao.

PORTELA *das Cabras*, a town of Portugal, in the province of Entre Duero e Minho; 7 miles N.W. of Braga.

PORTELET, a small island near the N. coast of the island of Jersey.

PORTELLA, a town of Naples, in Lavora; 6 miles W. of Fundi.

PORTENDICK, or *Port Addi*, a town of Africa, in the country of Zanhaga, inhabited by Moors, whose chief trade is fishing, and gathering of gum in the neighbouring woods: it is situated on a bay, on the west of the Atlantic. N. lat. 18° 6'.

PORTENDICK, *Little*, a sea-port of Africa; 25 miles S. of Portendick.

PORTER, a lake of Nova Scotia, lying a little E. of Halifax, and emptying its waters into the ocean, about 15 miles E. of that place; 15 miles long, and 1½ mile broad.

PORTER, in the *Manege*, signifies to direct or push on a horse at pleasure; whether forwards, or upon turns, &c.

PORTER, a malt liquor, which is a favourite beverage of the inhabitants of London, and other large towns. The dis-

PORTER.

tinguishing characters of this liquor are its deep brown colour, and an agreeable flavour, which it is difficult to describe, our language having so few words expressive of different tastes. The origin of the name is thus related by the ingenious editor of the *Picture of London*. "Before the year 1730, the malt liquors in general use in London were ale, beer, and two-penny, and it was customary for the drinkers of malt liquor to call for a pint, or tankard, of half and half, *i. e.* a half of ale and half of beer, a half of ale and half of two-penny, or half of beer and half of two-penny. In course of time it also became the practice to call for a pint or tankard of *three-threads*, meaning a third of ale, beer, and two-penny; and thus the publican had the trouble to go to three casks, and turn three cocks, for a pint of liquor. To avoid this inconvenience and waste, a brewer of the name of Harwood conceived the idea of making a liquor, which should partake of the same united flavours of ale, beer, and two-penny; he did so, and succeeded, calling it *entire*, or entire butt, meaning that it was drawn entirely from one cask, or butt; and as it was a very hearty and nourishing liquor, it was very suitable for porters and other working people; hence it obtained the name of porter." The house of Harwood is still a respectable brewery; but an immense trade has, since the period above-mentioned, arisen, and is divided among several brewers.

At first, the only essential difference in the methods of brewing porter and other kinds of beer, was, that it was brewed from brown malt, and this gave to it both the colour and flavour required. Of late years it has been brewed from mixtures of pale and brown malt, and the colour of the present liquor is much less than was formerly esteemed requisite: but finding that pale malt yields a much greater portion of saccharine matter than brown, the greatest number of the London brewers have given up the brown malt altogether, using pale and amber malt, which is intermediate between the two. From these they procure a liquor of proper strength, and they give it both colour and flavour, by the addition of colouring matter made from burnt sugar, or by burning the sugar of concentrated wort. All the London porter is professed to be entire butt, as indeed it was at first; but the system is now altered, and it is very generally compounded of two kinds, or rather the same liquor in two different stages, the due admixture of which is palatable, though neither is good alone. One is mild, and the other stale porter; the former is that which has a slightly bitter flavour, from having been lately brewed; the latter has been kept longer. This mixture the publican adapts to the palates of his several customers, and effects the mixture very readily, by means of a machine containing small pumps worked by handles. In these are four pumps, but only three spouts, because two of the pumps throw out at the same spout: one of these two pumps draws the mild, and the other the stale porter, from the casks down in the cellar, and the publican, by dexterously changing his hold to the handle of the next pump, works either pump, and draws both kinds of beer at the same spout. An indifferent observer supposes, that since it all comes from one spout, it is entire butt beer, as the publican professes over his door, and which vulgar prejudice has decided to be the only good porter, though the difference is not easily distinguished.

By referring to the article BREWING, our readers will obtain correct ideas of the general principles of the art, and under the present we propose to detail the process of brewing porter; and also to describe the utensils and machines used by the London brewers, who, in consequence of the very large scale on which they conduct their processes, have been

induced to study, with the most minute attention, every thing which can tend to improve their beer, or economize the materials; as also to diminish the labour of removing such large quantities of liquor from one part of the works to another: in this their grand agent is the steam-engine, which gives motion to several very capital machines.

There are in London twelve houses, which are considered as the principal porter-breweries, and from the returns of the excise, we find that the quantities of beer they brewed in the course of two years, *viz.* from July 1810 to July 1812, was as follows.

	Barrels in 1810 and 11.	Barrels in 1811 and 12.
Barclay and Perkins, Borough	264,405	270,259
Meux, Reid, and Co., Liquor-pond- street	220,094	188,078
Truman, Hanbury, and Co., Brick- lane	142,179	150,164
Whitbread and Co., Chiswell-street	122,316	122,446
Calvert and Co., Thames-street	105,887	108,212
H. Meux and Co., Marlborough- street	103,152	102,403
Combe and Co.	81,761	100,824
Brown, Parry, and Co., Golden-lane	72,367	—
Goodwynne and Co., Wapping	85,181	81,022
Elliott and Co., Pimlico	58,042	58,385
Cocks and Campbell	—	51,474
Taylor	46,222	51,220
Clowes, Maddox, and Newbury, Tooley-street	36,872	34,010

Of these works, the first that had a steam-engine, and the most complete in its arrangement of the utensils, is Mr. Whitbread's in Chiswell-street. This gentleman having permitted our draughtsman to take drawings from the most interesting parts of his extensive works, we shall proceed to explain them, with the assistance of *Plate Porter Brewery. Figs. 1. and 2.* of this plate are elevations of the whole brewery, being intended to shew the connection of all the parts at one view; but we must premise, that these elevations are in a great degree imaginary, and are not to be considered as taken upon any particular planes, because the different erections would then fall one behind the other, so as to hide them from the view; they are therefore represented in such situations as would be most convenient for explanation; but the relative levels, as also the dimensions of the individual vessels, are correct. A A, (*fig. 1.*) is the building containing the steam-engine, which is of twenty horses power, and gives motion to all the machines by a wheel on the axis of the fly-wheel, turning another upon the horizontal shaft, and this leads to the mill, where it turns the great horse-wheel B B. This wheel drives several other wheels, to convey the power in different directions. It was the original first mover of the mill; and when, (by the invention of Mr. Watt,) the steam-engine was rendered applicable to turn machinery, the horse-wheel was very judiciously retained, as by this means, if the engine should break, or be disabled, during the process of a day's brewing, the work can be continued by putting the horses to the wheel. This is a great advantage, because the delay of a few hours in pumping up the beer, in more than one of the stages, would certainly produce a premature fermentation, and spoil the whole quantity. The water for the brewery is raised from a deep well by a pump placed in it, and this is worked by cranks and rods, *b*, from the beam of the engine. The well is situated out in the yard, and the cranks are placed in an arched passage, which leads from the engine-house to the well. The

pump, by means of a pipe *d*, forces the water up to an immense reservoir, called the *liquor back*, placed at a sufficient elevation to supply the whole brewery. In *fig. 1.* this reservoir is represented as placed over the steam-engine, which indeed is its usual position in the large London breweries, but in Mr. Whitbread's it is erected over some buildings which could not be shewn in our plate: from this the reservoir pipes are laid, to convey the water to any part of the works where it may be required. The principal of these are to the coppers B, of which there are three, placed close together, but only one can be seen. C is the chimney for it, and the same roof, D, covers them all. The water, being heated in the coppers, is conducted by a pipe, *e*, to the mash tuns E: one of these is placed immediately before each of the coppers, though only one is to be seen in the view. During the process of mashing, the malt is kept constantly stirred by machines in each tun, which receive their motion from the steam-engine by the shaft *f*: this passes over the centre of all three, and by means of bevelled wheels, gives motion to a vertical axis in the centre of each tun, which are the principal axes of the machines. The malt, previous to mashing, is ground, or crushed, to render the husks pervious to the water. In most breweries it is ground between mill-stones, such as are used for grinding corn, but in these works it is broken between iron rollers, *g, g*, similar to those used for flattening iron: they are 18 inches in diameter, and two feet six inches in length, and are situated at such a distance asunder, that only a piece of thick brown paper can be passed between them; they are turned by wheels from the long horizontal shaft *a*, and immediately above them is a third roller, which has a number of deep flutes, or cavities, cut in it, from one end to the other, and these, as it revolves, become filled with malt from the hopper above, and then deliver it to the two rollers, which, being in motion, take it between them, and crush all the grains flat. By this, which is called a feeding roller, the supply to the rollers is kept constant and regular, without which they would be in great danger of clogging up, or setting fast. The malt, when it has passed through the rollers, is completely broken, even its most minute grains, but very little of it is cut into flour; for the husks of the malt, though cracked so as to admit the water readily to the contents, still prevent the flour being separated. This is a great advantage over the method of grinding, because that produces a great quantity of flour, which is the richest part of the malt, but when it is ground fine, and separated from the grain, it does not yield so much extract in the mash tun, as when it is preserved in the grain, and the husk sufficiently broken. This is because the flour, when immersed in the water, and wetted, forms a sort of paste, which at first absorbs a considerable portion of water, but will not afterwards quit it, so that very little extract is obtained from that portion of the malt which is separated from the grain, in the state of flour. The store of malt, before it is ground, is kept in the malt lofts over the mill, as represented. When it is brought in waggons to the yard, close by the mill, the sacks are drawn up by the tackle at F into the loft, and here the sacks are shot down, through holes in the floor, into the great store malt lofts, and from these, as it is wanted, is drawn out, through shuttles, into the hoppers of the rollers *g, g*. The store lofts extend much farther than we have been able to represent them in *fig. 1.* but may easily be imagined, as they are only a repetition of eight or ten of those shewn in the figure, the same loft extending over the whole, and the same sack tackle drawing up the sacks from the carts in the yard; though this, of course, is not situated at the end of the mill over the pumps, but at the side, where it could not have been seen. The malt, after passing through the rollers *g, g*, descends into

a chest, whence it is conveyed to the malt bins over the mash tuns E, by the motion of an inclined screw *b*: this is a wooden trunk or trough, in which the screw is fitted to revolve, and thus gradually pushes or raises the malt which is contained in the trough, from the lower end of it to the upper, which, being within the malt binn, and at the farther end of it, the screw completely fills, by distributing the ground malt at all parts of its length. The screw itself is formed of thin iron plates, bent into a screw, and fastened, by nails, to a central wooden axis, which revolves by the mill. When the malt is wanted for mashing, it is let down from the binn into the mash tuns, through sluices, or shuttles, in the bottom of it, and curtains are hung up all round from the binn to the edge of the tun, to prevent loss from the dust or flour of the malt flying in the air. After the process of mashing has continued a sufficient time, the extract or wort is drawn off from the mash tuns into other tuns, G, beneath, which are called the under-backs; here it remains only till the coppers are ready to receive it; and it is thrown up by the pump, H, into the copper-back I. This is a shallow cistern placed above the coppers, and from it the wort can be admitted into any of the coppers, or into their pans: these are vessels which are placed over the coppers, and their contents receive heat from the steam raised by the boiling of the copper itself.

To understand this see *fig. 3.* which is a section taken through the centre of the copper. A A is the fire-grate, B B C the copper itself, containing 350 barrels; its top is a dome, and has a cylinder, G, rising up from it: F F is the pan, erected upon the top of the copper, and enclosing the dome C, within. The pan contains 250 barrels of liquor, which is heated by the steam rising into the cylinder G, and thence descending by pipes *d, d*, down into the liquor, and bubbling up through it. The heat communicated through the dome also assists in heating the contents of the pan. There are two valves in the head G, which are kept shut by steelyards and weights; but these being opened, the steam of the copper is allowed to escape through a copper pipe or chimney, K, (*fig. 1.*) into the open air. E (*fig. 3.*) is an iron door, to allow entrance, into the copper, and also to put in the hops; it is situated on the top of a cylinder rising from the dome, and is fitted so closely by grinding, that it is steam-tight when shut, and forced down upon its seat by a screw. Two flues proceed from the fire-grate at the farther end, and conduct the flame and heated air round in opposite directions, as shewn at D D, to the chimney, which is placed over the fire doors, and thus the heat is applied to the sides, as well as to the bottom of the coppers: this, as the figure shews, is made concave beneath, to allow a greater action to the fire. The chimney is open at the bottom, and, therefore, the draught it occasions through the flues is only by the lateral action of the current of air, occasioned by the column of rarefied air in the chimney; but this draught can be cut off, when it is required to damp the fire, by shutting up two iron doors at the ends of the flues, and then no air can pass through the fire. In some breweries, doors are provided to shut up the bottom of the chimnies, and thus increase the draught, by compelling all the air which enters the chimney to pass through the fire-grate, and thence by the flues into the chimney; this causes the copper to boil much quicker, but the violent heat soon destroys the copper at the bottom, by burning or melting it. When the hops are boiled in the copper, they are kept in constant motion, to prevent their lying upon the bottom and burning to it. This is done by a machine called the *rowser*, contained within the copper; it consists of a vertical spindle, *e*, in the centre of the copper, which at its lower extremity has a cross arm, *g*, curved, to correspond with the bottom, and

from this a number of loops of heavy chain are suspended, to drag round upon the copper when the spindle is turned, and by this means the hops are raked over and continually disturbed. The spindle passes through a stuffing-box in the centre of the top, G, of the copper, and is turned round by a wheel *f*, engaged with another upon a shaft receiving motion from the engine. The direction of this shaft is shewn dotted in *fig. 1*, at *x*, but is there vastly extended in length, as is also the screw for the malt, because the engine and mill in reality stand in the line of the house containing the coppers and mash tuns, and at the end of them, in which position it would have been hidden by the building. The same shaft, *x*, also gives motion to the hop tackle, for drawing the hops up to the top of the copper, where they are thrown in at the door of it, E, *fig. 3*. The rowser can be drawn up from the bottom of the copper when it requires to be cleaned, for which purpose its spindle is suspended by a sort of tackle, that will quickly raise it up six or seven feet. The copper is provided with a float, to shew the height of the liquor within it: this consists of a strong wire, passing down through a tight stuffing-box in the top of the copper, and suspending a stone at the lower end of it: from the upper end of the wire a line is conducted over pulleys, which has a ruler or rod divided into feet and inches suspended from it, with a weight greater than the weight of stone when it is suspended in the liquor, but less than the weight of the stone when it is drawn up out of the liquor. In this situation the stone will always be at the surface of the water, in the same manner as if it floated, and will shew the height of the liquor in the copper. There are several pipes and cocks belonging to the copper, which are as follows: a pipe leading from the liquor back to introduce water into it; this has a cock formed of two passages, one admitting it to flow into the pan, and the other conveying it by a short pipe into the copper itself, and the handle being turned in one direction or the other, shews which way it will run, or turned in another direction it stops up the pipe; there is also a hole in the bottom of the copper back, through which the contents run down into the pan, but can be closed by a plug, and near it is a pipe leading down through the pan into the copper; this is closed by a valve, which can be opened by a lever and screw, when it is required to convey the wort from the copper-back into the copper itself; there is also a valve, which communicates at once from the pan down into the copper. From the bottom of the copper is a large cock with a pipe *e*, which runs horizontally over all the three mash tuns, and at every one a branch descends beneath the bottom of the tun, and turns up, with two or three smaller branches, leading into different parts of the bottom, by which means the hot liquor is admitted from the copper into the tun; it enters in different places at the same time, a precaution which is very necessary to distribute it equally through the whole of the malt in a tun, which like this is twenty feet in diameter; but to do this more effectually, the tun has a false bottom perforated with small holes; upon this the malt lies, and the water, being introduced beneath it, flows upwards through the holes in all parts at once.

The mashing machine, (see an elevation of it in *figs. 4* and *5*.) is composed of several endless chains, R, extended over two wheels in the manner of chain pumps, and the links of the chains have rakes, *d*, fixed upon them, and as the wheels revolve, ascend and descend through the whole depth of malt contained in the tun, and thus effectually stir up the whole to incorporate it with the water. That this action may be performed in all the parts of the tun, the frame containing the wheels and chains is adapted to have a progressive motion round in the tun, by turning round upon the vertical axis, D, in the centre. This axis has a bevelled wheel, E, upon it,

which turns another upon the end of a horizontal shaft F, carrying the wheels, *e*, for the chains R, and extending from the centre of the tun to its circumference, that end being supported in a frame S, which rests with wheels upon the rim or edge, T, of the tun: the interior end is sustained by a frame S, (*fig. 5*.) fitted upon the vertical axis, D. Near the bottom of the tun another horizontal shaft, V, parallel to the former, is placed, and has upon it the lower wheels, *e*, for the endless chains of rakes. The pivots of this shaft are supported in the same frame S, as the upper: this being, as before mentioned, fitted upon the central axis, D, at one end, and the other end resting with wheels upon the edge, T, of the tun, it may be made to traverse round the tun. This is done by having a ring of cogs fixed upon the edge of the tun at T; and an endless screw, which is supported on the frame S, engages the teeth. By means of bevelled wheels, *l*, this screw is turned slowly round from the upper axis, F, of the chain wheels; and it can, by means of a small handle, be disengaged from the motion, or it can at pleasure be engaged with either of two different pairs of the bevelled wheels, one giving it a slow motion and the other a much quicker; the first being used to traverse the machine round the tun till the malt is completely wetted, and then the quicker motion is used to mash the malt up thoroughly. This machine is the invention of Mr. Cooper, who had a patent for it, and has made great numbers. Several other ingenious machines have been invented, but are not yet in general use; one by Mr. Sylvester, another a patent by Mr. W. Jones; (see Repertory of Arts, first series, vol. ix.); a very simple one by Mr. Goodwynne, which he employs in his own brewery; a fifth kind of machine is described in our article BREWING. Mr. Jonathan Dickson has a patent for a method of making mash tuns in cast iron, by which the very heavy expences of constantly repairing, and often renewing, wooden vessels is reduced to a trifle. Messrs. Barclay and Perkins have one of these in use at their brewery. The mash tuns at Mr. Whitbread's brewery are lined with thin sheet copper, applied in the same manner as the sheathing of a ship, to prevent leakage, and keep the vessel sweet and clean. The mash tuns are supported upon a framing of timber, as shewn in *fig. 1*, which leave room within them for the under-back G. The malt-binns are supported over them by an assemblage of pillars between each of the tuns; and to give greater strength to the horizontal beams 1, which are beneath the binns, other horizontal beams, 2, are placed at a considerable height above them, and the two pairs being connected by framing and oblique braces, they form a truss frame similar to a roof, which will bear the weight of the binn, when full, without sinking. The pipe 3, which draws off the wort from the under-back, is conducted to the three-barrelled pump at H, which is worked by the mill: this elevates it to a trough, which extends over the whole length of the copper-back I, and by means of a plug in the bottom the wort can be let down into it.

When the wort has been boiled in the copper with the hops, both together are run off, at *k*, into the jack-back M: this is in reality a large strainer, to separate and retain the hops. It is a very large back, provided with a false bottom, composed of cast-iron plates pierced with small holes. Through these the liquor drains, when the pipe, *l*, from the bottom of the back is opened, and the hops are left upon the false bottom: the pipe, *l*, is conducted to the pump at H, and this raises the wort up to the same trough, over the copper-backs I; but instead of being run into these it is conveyed forwards, by a succession of troughs, and distributed into the different coolers N, N. These are large backs, and very shallow, several being placed in succession over each other, and the windows of the building are made very open,

to admit a current of cold air, to carry the heat off from the beer. In these it remains a sufficient time, till it is cooled to the temperature desired, and then it is drawn off from the coolers into the fermenting house. This is a very large building, placed adjacent to the engine-house. A section of it is given in *fig. 2*: here *p* is the copper pipe, proceeding from the coolers (having numerous branches to all of them), to the gyle-tuns, or squares P, which are large open vats, of sufficient capacity to contain the beer of a whole brewing; here yeast is put to it, and the fermentation commences, and having continued a sufficient time, the beer is distributed into the small tuns, Q, called rounds, where the fermentation is concluded, and the yeast, as fast as it is produced, flows over by a spout into the troughs *m*, which are placed between every two rows: this cleanses the beer, by the separation of the yeast from it; and as by the division into small quantities, (for the rounds only contain nine barrels each,) the temperature is lowered, and as the disposition to fermentation gradually subsides, the beer becomes fit for storing in the vaults or under-ground cisterns T, that it may be kept, till by age it becomes fine and fit for the table. The squares P, (for there are two, one behind the other,) are 22 feet by 24, and 9 feet deep, so that their content is nearly 800 barrels each. The pipe *p*, from the coolers N, (*fig. 1.*) has a branch proceeding to each square, and a double-passaged cock, 4, which will admit it into either, according as the handle is turned to one or the other. The pipe itself proceeds in an inclined direction to the bottom of the square, as shewn by the dotted lines, and thus introduces the beer in the centre, by which means, if there is any variation of temperature in the contents of the square, and that which has recently entered, it will sooner be brought to an equality.

Mr. Richardson, who conducts the brewing at Mr. Whitbread's works, has made an arrangement which deserves particular notice, and is worthy of imitation by other brewers. The pipe, *p*, is made of thin copper, and is enclosed within another pipe, the space between them being supplied with a stream of cold water. To effect this, the main ascending pipe, from the well to the liquor cistern, is not in reality carried up direct, as shewn by *d*, in *fig. 1*, but is placed in the angle of the fermenting house at *dd*, *fig. 2*. A branch, 5, proceeds along the wall thereof, then makes a turn, and joins the external pipe *p*: from the other end of this a branch is conducted to return the water to the main ascending pipe *d*, and in this there is a cock between the two branches, and another upon the branch: now the latter being shut, and the former open, the water ascends at once up the pipe from the well to the reservoir; but when the beer is to be drawn off from the coolers into the squares, the cock in the main pipe, *d*, is shut, and the other opened, by which means all the cold water which the pump throws up from the well is forced through the space surrounding the pipe *p*, in which the beer flows, and thus cools it very effectually. To determine the temperature, the bulb of a thermometer is placed in the centre of the pipe, and its tube comes up through it at 6; then a man is stationed to watch this, and when he observes it sink to the degree at which it is determined that the beer shall be left to ferment, he opens the cock and permits the beer to flow into the square; but still continues to observe the thermometer, and if it sinks lower he opens the cock wider, to admit the beer to flow quicker through the pipe *p*, that it may not be so much cooled by the flow of the cold water; or, if this is not sufficient, he regulates the quantity of cold water, by means of the cocks in the main pipe and the branch: on the other hand, if the thermometer indicates that the beer is not sufficiently cooled,

the cock is closed a little; this retards the passage through the pipe, and lowers the temperature, by subjecting it for a longer time to the action of the cold water. By this simple contrivance, the brewer is at a certainty that his liquor has been put to ferment in the square or gyle-tun P, at the exact heat which he intended, a circumstance which was before very uncertain; because, being drawn from so many different coolers, some would of course be less cooled than others, from their different situations, and it could only be guessed what temperature all these different degrees of heat would make when mixed together in the square, and the larger the scale of operation, the more uncertainty; because such large bodies of liquor take a considerable time to flow, and by passing such great lengths of pipes generally lose some heat; but it cannot be guessed how much. In Mr. Richardson's method, this is accurately determined, and capable of regulation. A long thermometer is fixed in the sides of the squares, to shew the temperature of their contents, and this is found to increase during the fermentation; no yeast is removed from the beer in this stage, indeed scarcely any is formed, for though a very large white head collects upon the surface, it is only light bubbles which instantly fall by the least agitation. The fermentation in the squares is generally concluded in thirty hours, and then the beer is removed to the rounds for cleansing from the yeast. It is first run off by a pipe 7, from the squares, into the filling up vessels R, R, which are in reality placed in the space between the two squares; but could not be so represented. When these are full, the pipe is shut, and another cock, 8, opened, which permits the beer to flow through pipes 9, conducted beneath all the rounds Q, Q; and from these, cross branches are conducted between every two rows, and by short pipes introduce the beer into the casks: thus they are all filled at once, and then the cock, 8, is shut. The casks are 240 in number, being arranged in sixteen of the rows which are seen in our figure, though only eight are drawn there; and each row contains fifteen of these casks. The troughs, *m*, between each pair of rows extend the whole length to receive the yeast produced from them, which in this stage of the fermentation is caused to flow off as fast as it is produced; and by this means it is that the fermentation is allayed, because the yeast which constantly keeps it going on, is not suffered to rest upon the surface of the beer. To render this effective, the rounds have close heads, and rather inclined to one side, where is a spout to conduct the yeast into the trough, therefore this spout is at the highest part; and there is no considerable surface exposed, upon which a head of yeast can float, to keep up the fermentation. But as the rounds gradually diminish in content, they are filled up by fresh beer from the filling-up tuns R, which were previously filled, as a reserve for that purpose. A pipe from the bottom of these enters into a small cistern S, where its orifice is closed by a valve. This is opened by a wire, which is connected with a lever, and a float, which floats upon the surface of the liquor in the cistern; and this is, by means of the communicating pipes 9, kept at the same level with the surface of the beer in all the rounds; there being a free communication amongst them all. Now when, by the wasting of the yeast, the beer in the rounds sinks, the float in the cistern sinks, and opening the valve, admits a sufficiency of beer from the filling-up vessels to restore the level, and then the valve closes again. To prevent the beer in the filling-up vessels having an exposed surface, and to carry off the yeast from them as fast as it is produced, a moveable or floating head, 10, is adapted to the tun. This is a slightly concave pan, or dish, of plate iron, which has a pipe fixed perpendicularly down from the centre

centre of it, and passing through the bottom of the vessel, in a stuffing-box. This dish floats upon the surface of the beer in the filling-up vessel, and as it is not quite so large as the inside of the tun, the yeast runs over in this space, and, falling down the pan to the central pipe, runs through it into troughs placed beneath, which convey it, in common with the produce of all the other casks, to a tank, or receptacle, sunk in the ground. From this tank the yeast is raised by a pump into casks, in which it is sent away, for the use of bakers, distillers, and others who employ it. Whilst remaining in the tank, a considerable portion of beer, which the yeast carries over with it, drains away; and this is drawn off by a pump, which drawing from a lower level than the yeast-pump, raises the beer into a different cistern; and here it remains 48 hours, to ferment and cleanse itself. It is then pumped up into shallow settling backs, V, V, V: in the highest of these it remains some time to settle, and deposit any yeast it may contain, and is then drawn off into a second, and then to the third, by which it becomes clear, and is good strong liquor, though unpalatable; but being introduced into the square, at the same time with a succeeding brewing, it adds to its quantity, without injury of the quality. By this means, no waste takes place in any department of the work.

When the beer has been sufficiently fermented, and the flow of yeast ceases, by which the brewers say it has sufficiently purged itself, it is drawn off from the rounds, Q, to be stored. That is done either in large tuns W, or otherwise in the cisterns, or underground vaults T: the former is the general system of the London brewers; but the latter, which is only practised at Mr. Whitbread's, is undoubtedly the best method, because of the equality of temperature they preserve both in summer and winter; and their durability, compared with the wooden vats, is no small recommendation. Many breweries have wooden store vats of immense capacity, being as much as 40 feet in diameter, and 20 feet deep. They are placed upon timbers, and supported by pillars, that small casks may be kept beneath them; and the beer can be drawn off into these, when it is to be sent away from the works. The vaults, T, T, are arched, and lined with stone, well bedded in cement, or pozzolana, and the joints very carefully made. They were built under the directions of the late Mr. Smeaton; but the Roman cement, which has been discovered since his time, would be the best material for jointing and lining them. A very superior cement of this kind, which is now manufactured in the north of Yorkshire, may be procured at Mr. Atkinson's wharf, Narrow-wall, Lambeth, and would enable brewers, who choose to adopt the cisterns, to have them made perfectly tight; whereas in these works they had at first much difficulty, from the defective nature of the cement; though they have remedied this, by employing resinous substances in the joints. Each cistern contains 4000 barrels, and the store is thus kept without the loss of any room in the building; a great consideration in London, where the rent of premises is so high, not to mention the saving in the repairs, and renewal of the wooden vats.

Mr. Richardson has applied an useful contrivance in this brewery, for cooling the beer previous to storing it in summer time: it is done by collecting the beer from the rounds, Q, into a cistern thirty feet square, sunk in the ground, and having a copper pipe conducted round its sides, making three turns in it: through this pipe a constant stream of cold water is conducted, in the same manner as before described, and this cools the beer to as low a temperature in summer as it will naturally have in winter, and then it is not liable to any fermentation in the store vats, which probably

takes place in a slight degree in the ordinary process, and is one reason why beer brewed in summer is seldom so fine as if brewed in winter. In this cistern the beer, being kept quiet and cool, deposits some sediment, apparently of farinaceous matter, which, if the slightest fermentation existed, would be held in the beer, and make it turbid; but here it seems to deposit more, and fine itself to a greater extent, in a very short time, than it would for a long period in the store vats; for we should observe, that one principal object of storing the beer is, that it may by age become fine and transparent, which it does by very slowly depositing the excess of vegetable matter, at the bottom of the vat, in the form of slime: but if the slightest fermentation is excited in the vat, it is put into an agitation, which wholly suspends this deposition, as long as it lasts; hence the great advantage which the brewers have found from employing such large vats as are not liable to sudden variations of temperature; and, for the same reason, subterraneous vaults are better than either.

We have now described the whole of the brewery, excepting only the several store-houses for the hops and coals, of which very great stores must be kept, for such extensive works: the latter are kept in the lower parts of the buildings, in the vaults or arches upon which the coppers are erected, and any other convenient part of the ground floor; and, in like manner, the hops are stowed away in large bags, in the lofts over the malt stores, or any other parts. The number of the rounds, Q, in the fermenting house is not correctly represented in the drawing, nor the extent of the store vats W, which last, at Mr. Whitbread's brewery, are situated in a large establishment on the opposite side of Chiswell-street.

The management of the brewing is thus conducted: A sufficiency of pale and brown malt, mixed, is broken between the rollers two or three days before it is wanted; and for this reason, the malt-bins are made large enough to contain 400 quarters of ground malt. Some kinds of malt, which, the brewers say, have too much *fire* in them, are found to improve by keeping some time before they are broken; but a few days keeping after they are broken will produce the same effect. The water is pumped up into the reservoir till it is full, and in this state the work begins, at two or three o'clock, by lighting the copper fires, and the engine fire, filling the coppers with water, and also their pans. The mash-tuns have the required quantity of malt let down from the binn, the curtains before mentioned being hung up to prevent the dust flying. All this is done by a few men, and the liquor (water) in the coppers is heated to the proper degree, which is generally about 150° for the first mash, its quantity being proportioned to the quantity of the malt, nearly in the proportion of two barrels to the quarter. But both these circumstances vary in different breweries, and from various causes, as has been explained under BREWING; though, we should observe, that the remarks there made, refer rather to the process of brewing on a small scale, than in the large way of manufacture; and though the principles are the same, the actual heats in the large way are much lower, because the loss of heat in the process is so much less in the large vessels.

The liquor being heated is *turned on*, that is, introduced into the mash-tun, by opening the cock, *e*, (*fig. 1.*) and admitting it to flow up through the malt, till in ten minutes time it has completely filled it: the mashing machine is now set in motion by the steam-engine, and works round the tun, with the slow motion for twenty minutes; then the quick motion is cast on for four minutes to complete the mashing; and after this it stands still for two hours to make

make the extract, and settle clear. The tap or cock into the under-back is now set running to drain off the wort, and this is left open, until the water for the second mash is sufficiently heated. This is the water which was at first filled into the pan; and immediately the first liquor quitted the copper, the contents of the pan were let down into it; and having acquired some heat while in the pan, is soon sufficiently heated, perhaps to 160° , and at the rate of one barrel to the quarter, being only half the quantity of the first mash, because so much of that is left in the malt. The mashing machine is worked for this as before, but it only stands one hour instead of two, because the malt was completely saturated before: in this period the first mash is pumped up into the copper, and the hops being added to it, the boiling is begun. The under-backs being thus cleared, the second wort is run off into them, and stands to drain from the malt, till the third liquor (water) is ready: this has been heating in one of the other coppers, till it is at 180° , and is then, in its turn, let down into the mash tuns, is mashed, and stands an hour, during which the second wort is pumped up into the copper back of the second copper, ready for boiling, and is admitted into the pan, that it may gradually heat. If a fourth mash is taken, that no waste may be made, it is heated in another copper, and is not brewed that day, but is reserved for the next brewing, and is then used instead of fresh water for the first mash. Some brewers do not practise this method, because there is in warm weather some danger of a premature fermentation, called *foxing*, taking place in the wort which is kept; but in cold weather it may be safely done, and is a saving. We have now to attend to the boiling: this is continued for the first wort one hour; and the second, being in the pan, receives considerable heat by the steam rising from the copper. When sufficiently boiled, the first wort, together with the hops, is run off into the jack-back M, and hence it is pumped up to the coolers N. The first wort is placed in these coolers, which, being least exposed to the air, will cool slowest, because the object is to get all the different worts cooled by the same time, ready for fermentation. The second wort is let down into the copper the instant the first is run off; and the hops which are left in the jack-back are filled into buckets, and drawn up by the hop-tackle, to be returned into the copper, for boiling with the second wort; but as this continues for two hours, the third wort is thrown up, towards the end of the time, to the second copper, and the boiling begun; for the instant the second wort is distributed into the coolers, the hops are put to the third wort, and boiled with them for four hours. This boiling of the worts, coagulates great part of the solid matters which the wort extracted from the malt, and by thus collecting those minute particles which were before diffused so equally throughout the wort, as only to render it cloudy, into distinct fecula, they are disposed to deposit themselves in the coolers, which they do in great quantities; and it is by this process that the beer is first separated from the grossest part of the extract. The cooling is conducted as expeditiously as possible, and when sufficient, as shewn by the thermometer, all the three worts together are, as before explained, drawn off into the square P, which contains 800 barrels, which is the full quantity of a day's brewing; the yeast is here put to it, and the fermentation begins, and it is by this process the porter acquires its spirituous quality, and is rendered clearer, from the great quantity of mucilaginous matter which is thrown off in the yeast. The fermentation first shews itself, by the whole body of the liquor teeming with innumerable small bubbles rising to the surface, each enveloped in a thin film of yeast, which, as the bubbles

burst, collect into a head or froth, and float on the top of the liquor. The temperature of the fluid increases considerably, and the noise of these bubbles, rising through the fluid, causes a continual singing. Part of the bubbles bursts before they arrive at the surface, and the film of yeast which envelopes them, sinks until it is borne up again by the ascending bubbles. These films form at first a white covering to the surface of the beer, which the brewers call the lamb's back, and as the process advances it becomes yellow, having the appearance of rocks; but this yeast is only a thin watery substance, which quickly melts down into a fluid. When the fermentation has advanced so far, that the head of the yeast begins to sink, it shews the process is past its greatest pitch, and the brewer must check it, or it would soon be succeeded by a second stage of fermentation, which produces vinegar. This check is given by the operation of cleansing, in which, as we have before stated, the yeast is carried off as fast as it is produced, and the fermentation gradually subsides.

To review the several processes of the brewery of porter, it should be observed, that it is required, in the mashing, to extract from the malt all the saccharum it contains; but the heat at which this must be done is also favourable for extracting a great proportion of the mucilage and glutinous parts of the malt, which must afterwards, in some degree, be separated from the wort, and the portion which is left will determine the flavour and colour of the beer. If the heat of the mashing liquor is too low, it will extract so much of these matters, that all the subsequent processes can never separate them sufficiently to make the liquor fine; and at the same time it will not extract much saccharum. But by increasing the heat, the mucilage becomes, in a measure, coagulated in the tun, and is not extracted in so great a degree, whilst the saccharum is taken up by the wort in a full proportion. On the other hand, an excessive heat carries this too far, for it makes a complete paste of the malt, by melting the gluten, and the whole resembles a hasty pudding. This disaster, which the brewer calls *setting the goods*, spoils the whole process, as a great proportion of the water becomes combined with the malt, in the state of paste, and will not run off; whilst that proportion which does remain unmixed, and can be drained out, has extracted little or nothing, either of saccharum or gluten, from the malt. This state of things takes place, in a greater or less degree, whenever the extracting heat is taken too high: the other extreme we have spoken of. Between these the brewer endeavours to keep, and by his success in this simple point, the quality and strength of his beer will be influenced most materially. No precise rules can be given for the actual heats, as they depend upon the nature of the malt, the heat used in drying it, (the brown requiring less heat than pale); the quality of the water has also its share, and the quantity of malt mashed at once, (because a great mash-tun loses less of its heat during the mashing than a smaller one); also the temperature of the atmosphere.

Having been thus necessitated to extract more of the solid matters from the malt that he wishes to retain, the brewer, in the succeeding processes, turns his attention to the most effective means of expelling the superabundant mucilage, and without losing the sugar, to leave a fine transparent and palatable liquor.

By the process of boiling, the grossest part of the mucilage extracted by the wort is coagulated, and in a manner precipitated into distinct fecula, leaving the liquor, which was before thick and muddy, comparatively clear between the flakes, which are so large as to be individually visible. The boiling also extracts the bitter of the hops, which is necessary

necessary to make the beer keep, till it becomes fine and fit for the table; it also concentrates the wort, by evaporating a part of the water used in the mashing: on spreading the wort thin in the coolers, the fecula subsides, and is left behind.

The fermentation in the squares, P, does not expel any of the extract matter, but the chief object of it is, to convert the saccharum into alcohol or spirit, and at the same time it disposes the grosser parts to a more favourable state for the separation which takes place in the second fermentation in the rounds, and by the great quantity of yeast which is thrown off, the beer becomes finer, at the same time that the production of spirit continues, and it loses its sweet taste. When this fermentation subsides, the beer is stored, and remains quiet, the longer time the better, to become clear and transparent; but this is, provided the quantity of hops it had is sufficient to prevent its becoming sour, because the extract of the hop is inimical to fermentation, and prevents that process going on in the store vat, which, if it did, would produce vinegar. What is really intended in the store vat is, to deposit those finer particles of superabundant matter which have escaped the other processes, and the beer improves in its strength.

The porter brewed for the supply of London is kept a very short time, and therefore has a small share of hops; and as it would not have time to become fine, it is fined by a process on purpose, which, indeed, is necessary; for if the beer was kept till it became fine, it would, by the shaking of carriage, when sent from the brewery, be rendered cloudy; the beer is therefore sent away in the rough, and requires fining, which is done by the consumer putting into the cask a small quantity of fining, sent by the brewer with the porter. These finings are made of isinglass dissolved in sour beer, made from the wort of the fourth mash, or sour beer obtained from the waste of any of the processes. A small quantity of this fining being put into the cask, precipitates the minute feculæ to the bottom, and soon renders the liquor quite fine.

In Mr. Whitbread's works no *colouring* matter is employed, as he uses a portion of brown malt; but most of the other brewers use pale malt, and colour the beer, by the addition of certain colouring matter, which being obtained from burning the same substance that causes the brown colour of the highly dried malt, produces a similar liquor, at a far less expence of materials, than when brown malt alone is used; because the pale malt yields a much greater proportion of saccharine matter than the brown, in which a share of the saccharum is burnt up in the kiln, only for the purpose of producing a colour and flavour which may so easily be communicated to the beer of pale malt, by a small quantity of burnt sugar. Many brewers, to avoid the censure of the public, who require them to use malt and hops alone, concentrate a quantity of their best first wort, by boiling in an iron pan, and burn this instead of sugar, from which it does not materially differ.

The process, in either case, is to put a quantity of coarse brown sugar, (or the concentrated wort,) into an iron pan, with a small quantity of water, keeping it constantly stirred up; it is then set on fire, and burnt for a few minutes, to give it the colour and flavour which might be obtained from brown malt. The fire is extinguished by putting on a cover. The residuum is now mixed up with water to the consistency of treacle, and makes the colouring, which is put to the beer while working in the square, and gives it very near the same colour and flavour it would have derived from being brewed from brown malt.

Some of our readers may have met with pamphlets pro-

cessing to describe the process of brewing porter, and mentioning a variety of ingredients, such as liquorice, essential bina, treacle, capsicum, ginger, lime, coriander seeds, cocculus indicus, &c. &c., but the writer of this article, having visited nearly all the great porter breweries in London, where he has been shewn into all their store-houses, and examined every process, can safely assure our readers that no articles more than malt and hops, except the colouring and finings, are used in their works, whose beer is reputed to be the best of any, nor has he ever met with any brewer who employs such articles for brewing porter.

PORTER, in the *Circuit of Justices*, is an officer who carries a verge, or white rod, before the justice in cyre; so called à *portando virgam*.

PORTER of the *Door of the Parliament House*, is a necessary officer belonging to that court; who enjoys the privileges accordingly.

PORTER, *Groom*. See *GROOM Porter*.

PORTERS, *Tackle-house*, who have ticket porters under them, are regulated by the city of London. They have the privilege of performing the labour of unshipping, landing, carrying, and housing the goods of the South-sea company, the East India company, and all other goods, except from the East country, the produce of the British plantations and Ireland, and goods coastwise. They give bond for 500*l.* to make restitution in case of loss or damage, and are limited to rates regulated by the city of London.

PORTERS, *Ticket*, who are upwards of a thousand, are persons appointed by the city of London, and have granted to them the exclusive privilege of unshipping, landing, and housing pitch, tar, soap, ashes, wainscoat, fir, poles, masts, deals, oars, chests, tables, flax, and hemp, brought to England from the East country; also iron, cordage, and timber, and all goods of the produce of Ireland and the British plantations, and all goods coastwise (except lead). They give security in 100*l.* for fidelity, and have their names and numbers on a metal badge. In performing the labour of the port, if ticket-porters are not at hand, the tackle-porters may employ any person that offers.

PORTERAGE, a kind of duty paid at the Custom-house to those who attend the water-side, and belong to the package-office. These porters have tables set up, ascertaining their dues for landing of strangers' goods, and for shipping out the same. The charges of ticket porters, &c. are subject to regulations, which serve to prevent impositions, &c. See *COMPANY*.

By stat. 39 Geo. III. c. 58, it is enacted, that no inn-keeper, warehouse-keeper, or other person, to whom any box, basket, package, parcel, truss, game, or other thing whatsoever, not exceeding fifty-six pounds weight, or any porter or other person employed by such inn-keeper, warehouse-keeper, or other person, in the portage or delivery of any such box, parcel, &c. within the cities of London, Westminster, or Southwark, and their respective suburbs, and other parts contiguous, not exceeding the distance of half a mile from the end of the carriage pavement, in the several streets and places within the above-mentioned limits, shall ask or demand, or receive, or take, in respect of such portage or delivery, any greater rate or price than as follows:

	Distances.	
Not exceeding	a quarter of a mile,	three-pence.
Ditto ditto,	half a mile,	four-pence.
Ditto ditto,	one mile,	six-pence.
Ditto ditto,	one mile and a half,	eight-pence.
Ditto ditto,	two miles,	ten-pence.

For every further distance, not exceeding half a mile, three-pence additional.

Persons asking or receiving more than the above rates, shall, for every such offence, forfeit a sum not exceeding 20s. nor less than 5s.

Before any parcel shall be sent from the inn, warehouse, &c. there shall be made out and given to the porter, or other person employed in the delivery thereof, a card or ticket, whereon shall be distinctly printed, written or marked, the name and description of the inn, warehouse, or other place, from whence the same is sent, and the sum due for the carriage thereof, and also the sum due for the portage or delivery thereof, according to the rates above-mentioned, and the christian and surname of the porter or other person employed in such delivery, which card or ticket shall be delivered by the porter or other person employed with such parcel, under penalty not exceeding 40s. nor less than 5s.; and any porter not leaving such card or ticket, or wilfully altering, obliterating, or defacing the same, shall for every such offence forfeit 40s.; or any porter asking, demanding, or receiving any larger sum for the carriage of such article than is written or expressed as aforesaid, shall forfeit the sum of 20s. for every such offence.

Every parcel, &c. brought to any inn, warehouse, &c. by any public stage-coach or carriage, other than stage-waggons, for the purpose of delivery within the limits aforesaid (except where the same shall be directed to be left till called for), shall be delivered according to the direction thereof within six hours after its arrival at such inn, warehouse, or other place, unless such arrival shall be between the hours of four in the evening and seven in the morning, and in that case every such delivery shall be made within six hours after such hour in the morning, under penalty of any sum not exceeding 20s. nor less than 10s.

Every parcel, &c. brought to any inn, warehouse, &c. by any public stage-wagon, for the purpose of delivery within the aforesaid limits, except where directed to be left till called for, shall be delivered twenty-four hours after arrival, under penalty of not more than 20s. nor less than 10s.

Every parcel, &c. directed to be left till called for, shall, upon demand of the person properly authorised to receive the same, be delivered to such person without any charge or deduction whatsoever, other than what is justly due for the carriage thereof, and the additional sum of two-pence for the warehouse room thereof; and if the same be not delivered to such person upon such demand, or any charge other than as aforesaid be made or received in respect thereof, every inn-keeper, warehouse-keeper, &c. to whose inn, warehouse, &c. such parcel shall be brought, shall forfeit for every such offence or overcharge a sum not exceeding 20s. nor less than 10s.

If such parcel, &c. so left to be called for, be not sent for within one week after the same shall have been brought to such inn, the inn-keeper, warehouse-keeper, &c. may charge one penny *per* week for warehouse-room.

If any such parcel, &c. not directed to be left till called for, shall, before the same shall be sent for delivery from such inn, warehouse, &c. be demanded by any person lawfully authorised to receive the same, such parcel shall be thereupon delivered to such person so demanding the same; and it shall in such case be lawful for such inn-keeper, &c. to charge and take the sum justly due for the carriage thereof, and also the sum of two-pence for the warehouse-room thereof; but if the same be not delivered to such person on such demand, or any charge other than as aforesaid be made or received in respect thereof, such inn-keeper, ware-

house keeper, &c. shall forfeit for every such offence any sum not exceeding 20s. nor less than 10s.

For preventing misbehaviour in persons employed to deliver parcels or other things, upon any complaint made of any non-delivery, neglect, misconduct, or misbehaviour, in such employment, the parties offending may be brought before any justice of the peace within whose jurisdiction the offence has been committed, or the offender shall reside, who may impose a fine or penalty upon such porter or other person, not exceeding the sum of 20s. nor less than 5s.

Persons neglecting to pay to the porters, or other persons employed by them, the money justly due for carriage and portage, according to the above-mentioned rates, may be brought before a justice, who, upon proof made thereof upon oath, may award reasonable satisfaction to the party grieved, for his damage and costs, and for his loss of time in recovery of the same; and in case of non-payment the magistrate may levy the same by distress.

Informations of this act to be laid within fourteen days.

This act not to authorise the employment of any porter contrary to the usage of the city of London.

The remaining sections of this act relate to the recovery and application of penalties, enforcing the attendance of witnesses, allowing an appeal to the quarter-sessions, &c.

PORTERFIELD, in *Geography*, a small settlement of America, in York county and state of Maine, consisting of 272 inhabitants.

PORTERO, a river of Chili, which discharges itself into the sea, at the city of Maldivia.

PORTEROS, a small island in the Mediterranean, near the coast of France. N. lat. 43°. E. long. 6° 28'.

PORTES, PHILIP DES, in *Biography*, a French poet, who greatly improved the French language, and was presented by Henry III. with 10,000 crowns, on account of his great merit. Charles IX. gave him 800 crowns of gold for a poem; and admiral de Joyeuse conferred on him an abbey for a sonnet. He refused a bishopric that was offered him. He died in 1606, and was author of a translation of the Psalms; imitations of Ariosto; Christian poems; sonnets; elegies, &c.

PORTESIA, in *Botany*, so called in honour of a French physician and botanist of the name of Desportes, who wrote on the plants, as well as the diseases of Hispaniola, Juss. Gen. 265. See TRICHILIA.

PORTETE, in *Geography*, a harbour in the Caribbean sea, on the coast of Caraccas, having before it a rock of the same name. N. lat. 12°. W. long. 71° 16'.

PORTEUS, BELBY, in *Biography*, a late eminent prelate of the church of England, was born at York in the year 1731. His parents were natives of Virginia, in North America, who came to England in 1720, for the sake of obtaining a good education for their son. He was placed in a small school, from which he was removed to Rippon, where he became qualified for academical studies. He was entered at Christ's college in the university of Cambridge, where his attention, while he was an under-graduate, was directed principally to mathematical studies. In 1752 he was admitted to the degree of B. A., and in the same year he gained the second of two honorary medals, annually bestowed, as the reward of eminent classical literature. In the spring of the same year he was elected fellow of his college, and became a resident at Cambridge. His worth, as well as his talents, now began to be known, and in 1754 he was nominated one of the esquire beadles of the university, an office that was ill-suited to his turn of mind; but in consequence of the exertions of his friends, and his anxiety

anxiety to relieve his father from any farther expence, he accepted it, but he retained it not quite two years, having resolved to make up the deficiency in his income in a way more agreeable to himself, by taking private pupils. In 1755 he proceeded M. A., and two years afterwards he was ordained deacon. About the same time he was appointed one of the preachers at Whitehall chapel. It was not till 1759 that Mr. Porteus was known as an author. He then obtained a Seatonian prize for the best poetical "Essay on Death," which he published in conformity with the will of the founder. This was his first poetical essay, and it obtained for the writer a considerable portion of fame, and was regarded as a prelude to still greater celebrity. In this poem is the passage on WAR, that has been so frequently quoted, and which we shall introduce into our own pages.

" One murder makes a villain,
Millions a hero ; princes are privileged
To kill, and numbers sanctify the crime.
Ah ! why will kings forget that they are men ?
And men that they are brethren ? Why delight
In human sacrifice ? Why burst the ties
Of nature, that should knit their souls together
In one soft bond of amity and love ?
They yet still breathe destruction, still go on,
Inhumanly ingenious to find out
New pains for life—new terrors for the grave !
Artificers of DEATH ! Still monarchs dream
Of universal empire growing up
From universal ruin. Blast the design,
Great God of hosts ! nor let thy creatures fall
Unpitied victims at Ambition's shrine !"

On the demise of George II., Mr. Porteus wrote some verses on the occasion, which were excellent, and well received. His earliest prose publication was a sermon preached before the university of Cambridge, in the year 1761, entitled "The Character of David, King of Israel, impartially stated," intended to counteract the tendency of a publication, entitled "The History of the Man after God's own Heart," which exhibits David as an example of perfidy, lust, and cruelty, fit only to be ranked with the very worst of the Roman emperors. To this sermon the future fortunes of Mr. Porteus may be in a good measure attributed, for it immediately obtained for him the patronage of Dr. Thomas Secker, who had a few years before been translated from the bishopric of Oxford to the archiepiscopal throne of Canterbury. He was immediately appointed one of his lordship's domestic chaplains, who soon after presented him to two rectories in Kent and one in Middlesex, also to a prebendal stall in the cathedral church of Peterborough. In the year 1765 he married Miss Hodgson, a lady of some fortune, from Ashbourne in Derbyshire ; and in 1767 the rectory of Lambeth was bestowed upon him, and he was at the same time raised to the degree of doctor of divinity. On the death of the archbishop, in 1768, he, in conjunction with Dr. Stinton, edited and published his works, consisting of seven volumes ; to this was prefixed a life composed by Dr. Porteus, which obtained the praise of Dr. Johnson. Having now acquired considerable reputation as a preacher, and being highly spoken of for the excellence of his private character, the queen was pleased to become his patroness ; and in 1769, through her recommendation, he had the honour of being appointed chaplain to his majesty. Soon after, he became master of the hospital of St. Cross, near Winchester, dean of the chapel royal, and provincial dean of Canterbury. He is said to have assisted at the clerical meeting held at the Feathers tavern, London, in

1772, in which it was determined to petition the legislature for relief from subscription to the thirty-nine articles. The fact, however, is doubted, and with more probability it is stated that he was a member of another assembly that met at Tennison's library, with a view "to request a revival of the articles of liturgy, and forms of subscription," but they judged it fitting to consult first their spiritual superiors, and to be directed by them. Upon application to the archbishop of Canterbury, Dr. Cornwallis, he replied, that he would lay their wishes before his brethren. When the archbishop afterwards informed them that it was the opinion of his brethren, "that it was neither prudent nor safe to do any thing in the matter," Dr. Porteus and his associates readily acquiesced in the judgment of the governors of the church, contenting themselves with circulating a printed paper to inform the clergy what had been done, that they might not suppose the matter was wholly dropped.

About this time Dr. Porteus made great exertions in a cause not at all deserving of the zeal which he manifested in it. This was to set apart, as a day of fasting, Good Friday. He was, however, in a good measure successful, and the labours of the loom and the field have been suspended in many parts of the kingdom, on every successive Good Friday from that time to the present. This, if we understand the Christianity of the New Testament, is contrary to the injunctions of our holy religion ; and it is certainly in hostility to good policy in a national point of view. It was, however, so well received by the court, that he was immediately raised to the bishopric of Chester, through the influence of her majesty, whose bishop he was at this time emphatically called.

This effort for reviving the strict observance of an old popish fast-day, was by many, as well as her majesty, highly commended, as a pious endeavour to restore the purity of ecclesiastical discipline, and to promote the vital interests of Christianity, while others as loudly condemned it, as calculated to serve the cause of superstition and fanaticism. It called forth a very able pamphlet from the Rev. Robert Robinson, entitled "The History and Mystery of Good Friday," in which the writer's learning, argumentative powers and humour, were displayed to great advantage. In the year 1779, the bill for the relief of Protestant dissenting ministers and schoolmasters was brought into the house of lords, and bishop Porteus concurred in the unanimity with which it passed, and has left it on record that he considered it to be "a measure, no less consonant to the principles of sound policy, than to the genuine spirit of the gospel." In 1783 our prelate published a "Volume of Sermons" on various subjects, which soon passed through several editions. In the same year, being called to preach before the Society for propagating the Gospel in Foreign Parts, his lordship took the opportunity to plead the cause of the wretched African negroes, and when it was afterwards brought before the legislature, he steadily supported the repeated efforts which were made on their behalf by the advocates of justice and humanity, till he had the happiness of seeing the result of their labours, viz. the statute for the abolition of the slave trade. He took an active part also in the establishment of Sunday schools, an object that owed much to his recommendation, and was greatly forwarded by his zeal.

Upon the death of the learned and excellent bishop Lowth, in 1787, Dr. Porteus was translated from the see of Chester to that of London ; and in 1790 he made the primary visitation of his new diocese, and published the charge which he delivered on the occasion, in which he strongly pointed

out the necessity of an attention in the clergy to their personal duties, and exposed the criminality of non-residence on their cures. In 1794 he published a second volume of sermons, which, like the former, was well received by the public. During the Lent of 1798, he commenced a series of discourses on the truth of the gospel history, and the divinity of our Lord's mission, which he delivered every Friday at St. James's church, Westminster, to crowded audiences. These discourses were continued during Lent in some succeeding years, and were in 1802 published under the title of "Lectures on St. Matthew's Gospel," in two vols. 8vo. Previously to this Dr. Porteus had published "A Summary of the principal Evidences of the Truth and divine Origin of the Christian Revelation, designed chiefly for the Use of young Persons," in which he has compressed into a narrow compass the most forcible arguments for the truth of Christianity, that are, for the most part, to be found in our best writers, with additional observations of his own. We must notice another small tract which his lordship published in the year 1806, entitled "The beneficial Effects of Christianity on the temporal Concerns of Mankind, proved from History and Facts." This, like the bishop's other works, is an impressive and very useful tract. Dr. Porteus had for some years been subject to ill health, which at length brought on a general debility, and on the 14th of May, 1808, he sunk under the pressure of accumulated disease, being in the 78th year of his age. He left behind him a justly acquired reputation for propriety of conduct, benevolence to the clergy, and a strict attention to episcopal duties. As a preacher, he obtained the character of an accomplished orator; his language was chaste; his manner always serious, animated, and impressive, and his eloquence captivating. He seemed to speak from conviction, and being fully persuaded himself of the truth of those doctrines which he inculcated, he the more readily persuaded others. In private life he was mild, affable, easy of access, irreproachable in his morals, of a cheerful disposition, and ever ready to listen to and relieve the distresses of his fellow creatures. In his behaviour towards dissenters from the established church, he discovered great moderation and candour. He, probably, was a sincere believer in the leading doctrines contained in the thirty-nine articles, but could make allowance for those who did not exactly come up to the same standard. Toward the latter part of his life, he was accused of becoming the persecutor of the Rev. Francis Stone, a clergyman of his own diocese, against whom he formally pronounced a sentence of deprivation for preaching and publishing a sermon in direct hostility to the doctrines of the church to which he belonged. Mr. Stone had for many years avowed his disbelief of the articles of faith which he had engaged to defend, and for the support of which he had long received a handsome income, but no notice whatever was taken of the unsoundness of his creed. He preached the offensive sermon before many of his brethren of different ranks in the church, yet we have good reason to believe that this attack, which could scarcely be deemed prudent or even decent, would have been unnoticed, had he contented himself with promulgating his opinions from the pulpit only; but when he made the press the vehicle of disseminating opinions contrary to the articles of his church, the prelate was goaded on to the part which he took, and which, perhaps, was not in the least unbecoming the high office which he held. Every beneficed clergyman, not tacitly, but avowedly, undertakes the performance of certain duties, on account of which he receives the annual stipend; if, therefore, he ceases to perform those duties, it may be thought by some that he gives up his claim to the remuneration. This, however, is a subject which involves in it a variety of considerations, which we have neither leisure nor inclination to

discuss. But, if we have been rightly informed, Mr. Stone obtruded himself without necessity upon the public notice; and those who applaud his integrity have blamed his imprudence. His friends pitied and relieved him; but death has terminated his humiliation and suffering.

As a lord of parliament, Dr. Porteus, we suspect, uniformly voted with the minister, and as such supported that system of war and bloodshed which he had so finely deprecated in his poem on DEATH. It was on one of the debates in the house of peers in 1794, that the lines already quoted were repeated in that house, as supposed to come from his pen, and his lordship was asked by a noble earl, then accustomed to stand alone in the discussions of the house, if he were really the author of those excellent lines, to which the bishop replied, "They, my lord, were not composed for the present war."

The benefactions of the bishop of London were numerous, public as well as private. While he was living, he transferred nearly seven thousand pounds in three *per cents* to the arch-deacons of the diocese of London, as a permanent fund for the relief of the poorer clergy of his diocese. He also transferred stock to Christ's college, Cambridge, directing the interest arising from it to be appropriated to the purchase of three gold medals, to be annually contended for by the students of that college: one medal, value fifteen guineas, for the best Latin dissertation on any of the chief evidences of Christianity: another of the same value for the best English composition on some moral precept in the gospel; and one of ten guineas, to the best reader in and most constant attendant at chapel. He bequeathed his library for the use of his successors in the see of London, together with a liberal sum towards the expence of erecting a building for its reception at the episcopal palace at Fulham. At Hyde-hill, near Sundridge, in Kent, where the bishop had a favourite rural retreat, he built a chapel, under which he directed his remains to be deposited, and he endowed it with an income of 250*l.* a-year. Hodgson's Life of Porteus. Monthly Mag. vol. xxvii. Gent. Mag. for 1809.

PORT-FIRE, a paper tube, about ten inches long, filled with a composition of meal-powder, sulphur, and salt-petre, rammed moderately hard; used to fire guns and mortars instead of match.

These port-fires are distinguished into wet and dry; the composition of wet port-fires is four parts of salt-petre, one of sulphur, and four of mealed powder; when the composition is well mixed and passed through a sieve, it is moistened with a little linseed-oil, and well rubbed with the hands, till the oil is thoroughly mixed with the other ingredients.

The composition of dry port-fire is four parts of salt-petre, one of sulphur, two of mealed powder, and one of antimony. These compositions are driven into small paper cases, and so kept till they are used.

PORT-GLAIVE, *Sword-bearer*, an order of knights in Poland, called by the Latins *ensiferi*.

It was confirmed by pope Innocent III., and by him sent into Livonia to defend the preachers of the gospel against the infidels at the first conversion of that country. Being too weak to effect that business, they united themselves with the Teutonic, or Marian knights, by the pope's authority; and, instead of knights of the sword, were called *knights of the cross*. They separated again under Univivus, their great master, anno 1541; or, according to others, in 1525. The Teutonic knights being then dispossessed of Prussia, the Port-glaives, going into Luther's opinions, soon dwindled away; for in the year 1557 they fell out with the bishop of Riga, of the house of Brandenburg, because he

would not embrace their notions; and he, to secure his own estate, put Riga into the hands of the Polanders.

Afterwards, the knights, having had most of Livonia taken from them by the Muscovites, put themselves under the protection of Sigismund Augustus, king of Poland, anno 1559; but William of Furstemburg, their great master, being betrayed by his own mercenaries into the hands of the Muscovites, Gothard Ketler, his successor, followed the example of Albert, the great master of Prussia, transacted with the aforesaid Sigismund for the whole estate, which he surrendered to his own use in the castle of Riga, together with his cross, the seal of the order, the charters and grants of the several popes and emperors, which concerned the same; as also the keys of the city and castle of Riga, the office of great master, the rights of coinage, and all the powers and privileges appertaining to it; receiving back again from Radzivil, the king's commissioner, the dukedom of Courland to him and his heirs for ever.

PORTGLENONE, in *Geography*, a post-town of the county of Antrim, Ireland, situated on the river Bann, over which it has a bridge. It is 105 miles N. from Dublin, and 13 N.W. from Antrim.

PORT-GREVE, or PORTGRAVE, was anciently the principal magistrate in ports, and other maritime towns.

The word is formed from the Saxon *port*, a port, or other town, and *gerefa*, a governor. It is sometimes also written *port-reve*.

Camden observes, that the chief magistrate of London was anciently called *port-greve*; instead of whom, Richard I. ordered two bailiffs; and soon afterwards king John granted them a mayor for their yearly magistrate. The charter of William the Conqueror to the city of London runs thus: "William king, grete William bishop, and Godfrey port-greve, and all the burges within London, French and English. I grant you, that I will that ye be all your law-worth that ye were in Edward's day the king. And I will that each child be his fader's eyer, and I will not suffer that ony man you any wrongs breed, and God you keepe."

PORTHDINLLEYN HEAD, in *Geography*, a cape or promontory of North Wales, in the county of Caernarvon; six miles west of Pwllhely. N. lat. $52^{\circ} 58'$. W. long. $4^{\circ} 47'$.

PORT-HOLES, or PORTS, in a *Ship*, are the embrasures, or holes, in the sides of a ship of war, in which the artillery is ranged in battery upon the decks above and below.

The ports are formed of a sufficient extent to point and fire the cannon, without injuring the ship's side by the recoil; and accordingly the shipwrights cut them in proportion to the size of the cannon. The lower and upper edges of the ports are always parallel to the deck, so that the guns, when levelled in their carriages, are all equally high above the lower extremity of the ports, which is called the *port-cells*.

Large ships have three rows of port-holes, or batteries; each usually consisting of fifteen port-holes.

In storms, they use to shut up the port-holes, to prevent the water's driving through them.

In English, Dutch, and French ships, their valves, or casements, called port-lids, are fastened by hinges at top of the apertures; in Spanish vessels aside of them.

PORT-HOOKS, in *Ship-building*, iron hooks driven into the side of the ship, over the ports, to which the port-hinges are attached.

PORTHORION ROAD, in *Geography*, a bay in the Irish sea, near the S.W. extremity of the county of Caernarvon.

PORTHYNON POINT, a cape of South Wales, in the county of Glamorgan; 6 miles S.S.W. of Penrice.

PORTICA TERRA, in *Ancient Geography*, a country of India, towards the mouth of the river Indus. Diod. Sic.

PORTICELLO, in *Geography*, a bay on the W. coast of Sardinia. N. lat. $40^{\circ} 40'$. E. long. $8^{\circ} 20'$.

PORTICI, a small town of Italy, about six miles from Naples, on the sea-shore, at the foot of Vesuvius. Its principal ornament is a royal palace. Under this town and palace lies buried, at the depth of 70 feet under accumulated beds of lava, the city of "Herculaneum," the first victim of the fires of Vesuvius. Under the article HERCULANEUM we have stated, that the prince d'Elbœuf, after the first discovery was made by accident, purchased the spot, and continuing the excavations that had been begun, discovered various statues, pillars, and even a whole temple of the finest marble, adorned with statues. Upon the interposition of the Neapolitan government the work was stopped for 20 years; however, the excavations were occasionally continued, and a basilica, two temples, and a theatre, were successively discovered and stripped of their numerous pillars and statues. Streets were observed, that were paved and flagged on the sides, and private houses, and even monuments explored. A prodigious number of statues of bronze, of different sizes, pillars of marble and alabaster, and paintings and mosaics, many of them entire and in high preservation, others fractured and damaged, have been drawn from the edifices of this subterraneous city, and give a high idea of its opulence; to these we may add many species of ornaments used in dress, of weapons and armour, of kitchen utensils and domestic furniture, of agricultural and chirurgical instruments. The theatre is at present the only part open to inspection. Of all the articles drawn from Herculaneum, the most curious and valuable are the MSS. Of these many dissolved into dust as soon as they were exposed to the air: while others, though scorched or rather burnt, resist the action of that element. The number of the latter, as it is conjectured, may be about 1800. The first MSS. that have been unfolded were Greek, and as Herculaneum was known to be a Greek city, it was presumed that the whole collection was in that language: but several Latin works have been found since, and there is every reason to believe that in a city so rich, and inhabited by so many wealthy Romans, there must have been considerable libraries, both public and private, and of course complete collections of Roman authors.

The mode of unrolling these MSS. was invented by a priest of the congregation of the Somaschi (a body of clergy who devote themselves entirely to the education of youth); but as the government of Naples, though it employed him and an assistant whom he instructed in the process, did not give much encouragement to the undertaking, the work languished, and the MSS. long remained a neglected treasure. At length the prince of Wales (now prince regent), with a munificence that does equal honour to his taste and his public spirit, undertook to defray the expence, and selected a person not only qualified for the task by his deep and extensive information, but peculiarly adapted to it by his zeal and perseverance. This gentleman is Mr. Hayter, a clergyman of the church of England, who, being established at Portici, has superintended the process of unfolding the papyri with indefatigable assiduity. The nature and difficulty of the undertaking, and the want of competent assistants, render its progress slow and almost imperceptible; and therefore centuries must probably elapse before the MSS. now in hand can be unrolled, and their contents given to the public. To which we may add, that such is the extreme frailty of the papyri themselves, that with all the care and precaution imaginable, not one probably can escape

escape mutilation, and pass through the process without some detriment, or rather without material defalcation. Eustace's Classical Tour through Italy, vol. i.

PORTICO, in *Architecture*, a kind of gallery on the ground; or a piazza encompassed with arches supported by columns, where people walk under cover.

The roof is usually vaulted, sometimes flat. The ancients called it *lacunar*; which see.

Though the word portico be derived from *porta*, gate, door, yet it is applied to any disposition of columns which form a gallery without any immediate relation to doors or gates.

The most celebrated porticos of antiquity were those of Solomon's temple, which formed the atrium or court, and encompassed the sanctuary; that of Athens, built for the people to divert themselves in, and in which the philosophers held their disputes and conversations; which occasioned the disciples of Zeno to be called *stoics*, from the Greek *στοιχος*, *porticus*; and that of Pompey at Rome, raised merely for magnificence, consisting of several rows of columns supporting a platform of vast extent; a draught of which Serlio gives us in his views of antique buildings.

Among the modern porticos, the most celebrated is the piazza of St. Peter of the Vatican. That of Covent Garden, London, the work of Inigo Jones, is also much admired.

PORTICOS were numerous buildings erected in Rome for the convenience of the public in sultry or inclement weather; and they are thus distinguished from those which formed the vestibules or decorated the entrance of temples. Of these we shall mention some of the principal: the *porticus duplex*, so called from its double row of pillars, was erected by Cneius Octavius, after the defeat of Perseus; it was of the Corinthian order, and ornamented with brazen capitals; the walls were decorated with paintings representing the achievements of the founder. It stood near the "Circus Flaminius." The *portico of Pompey*, annexed to his theatre, was supported by 100 marble columns; it opened on both sides into groves of plane trees, and was refreshed by fountains and streams, and in summer time it was the favourite resort of the young, the gay, and the gallant. Augustus erected several porticos, and prompted by his example, several of his most distinguished and opulent friends vied with each other in similar works of magnificence. Among the former were the porticos of Caius and Lucius, with a basilica annexed to it; that of Octavia, which rose near the theatre of Marcellus, and contributed not a little to its beauty as well as convenience; that of Livia, near the Roman forum. This latter was ornamented with a collection of ancient pictures, and shaded by a vine of prodigious luxuriance. Ovid alludes to it in his usual lively manner. But this and every edifice of the kind prior to this era, was eclipsed by the splendour of the *Palatine portico*, dedicated to Apollo. It was supported by pillars of Numidian marble, enlivened with exquisite paintings and statues, and emblazoned with brass and gold. It inclosed the library and temple of Apollo, so often alluded to by the writers of the Augustan age, and was deservedly ranked among the wonders of the city. It is described by Propertius, lib. xi. 81.

Another portico, erected by this emperor, was called *Ad nationes*, from the statues with which it was furnished, representing various nations in their respective habits. It was perhaps still more remarkable for a statue of Hercules, lying neglected on the ground, though it had been brought from Carthage, and was that to which the Carthaginians were accustomed to offer human victims: "Sacrum," as Livy remarks, "minime Romanum." The *Porticus Septo-*

rum was finished or repaired by Agrippa, as Pliny says, and inclosed not the "Septa tributa Comitii," where the people assembled to vote, but "Diribitorium," or place where the legions were mustered and paid. These edifices were all of marble, and the latter in particular unusually magnificent. Agrippa also built and gave his name to another portico, which, as some suppose, was connected with the present portico of the Pantheon, and carried around it. But as he had erected "Thermæ," and other noble fabrics near that edifice, it is more probable that his portico inclosed the whole, and united them together in one grand circumference. That it was extensive is evident from Horace, who represents it as a public walk, much frequented. The materials were, as in all Agrippa's works, rich marbles, and the ornaments paintings and statues. The portico of *Hercules*, or of *Philippus*, was so called because it was rebuilt by the latter at the instigation of Augustus, and dedicated to Hercules, whose temple it inclosed, under the appellation of "Musagetos," a leader of the Muses. It was erected solely for the ornament of the city, and of course was decorated with an unusual profusion of splendid objects; the paintings of Apelles, Zeuxis, and Antiphilus, forming part of its furniture. Several porticos took their names from the temples to which they were annexed, and seem to have formed either vast squares or courts before, or immense galleries round their respective temples, thus detaching them from ordinary buildings, and giving them a distinguished and solitary grandeur. The portico of *Quirinus*, and that of *Europa*, are mentioned by Martial as fashionable places of resort, and must consequently have been very spacious. That of *Isis* was remarkable not only for paintings but mosaics. We shall here add, that the approach to the curiæ, the basilicæ, the forums, was generally by porticos; that several ranges of porticos led to the Capitol, and lined the sides of the declivity; that the Campus Martius was surrounded by an uninterrupted colonnade; that almost every emperor distinguished himself by the erection of a new edifice of the kind; and that Nero is said by Suetonius to have lined the streets of Rome (those probably which he himself had rebuilt,) with a continued portico. Several porticos were erected by latter emperors of astonishing extent; such were that of Gallienus, extending nearly two miles along the Via Flaminia; and that of Gordian in the Campus Martius, which was a mile in length, and formed of one range of pilastres and four of columns, opening upon plantations of box, cedar, and myrtle.

PORTILLA, in *Geography*, a town of Spain, in the province of Leon; 10 miles E.S.E. of Valladolid.

PORTIO, **PORTION**, a part or division of any thing.

PORTIO dura, and *mollis*, in *Anatomy*, a partition of the fifth pair of nerves of the brain; which, before its egress out of the dura mater, is apparently divided into two branches; the one pretty tough and firm, called portio dura; the other soft and lax, called portio mollis. See **NERVES**.

PORTION, in the *Canon Law*, is that allowance, or proportion, which a vicar ordinarily has out of a rectory, or impropriation; be it certain or uncertain.

PORTIONER, **PORTIONARIUS**. Where a parsonage is served sometimes by two, sometimes by three ministers, alternately; as Bromyard, Burford, &c. in Shropshire; the vicars or incumbents are called portioners, because they have but their portion or proportion of tythes, or profits of the living.

PORTISCULUS, among the Romans, an officer who had the direction of the rowers in a galley. He was otherwise called *pausarius* and *hortator remigum*.

PORTISHEAD POINT, in *Geography*, a cape of England, on the N.W. coast of the county of Somerset, on the Severn; three miles S.W. from the mouth of the river Avon. N. lat. $51^{\circ} 28'$. W. long. $2^{\circ} 56'$.

PORTIUS PISCIS, in *Ichthyology*, a name given by some to a fish called by others the *mugil ater*, or black mullet. It is a very scarce fish, much resembling the common mullet in shape, but all over of a fine black, and having several lines of a deeper black than the rest, running longitudinally from the gills to the tail; it has a very wide mouth, and has seven or eight prickles on the back, separate from one another, and joined into a fin by a membrane in the usual way; these are placed immediately before the back-fin.

PORTLAND, in *Geography*, a post-town and port of entry of America, in Cumberland county and district of Maine; being the largest town of that district; situated on a promontory in Casco bay, and formerly a port of Falmouth: 50 miles S. by W. of Wiscasset, and 123 from Boston. In July 1786, this part of the town, being the most populous and mercantile, and seated on the harbour, together with the islands which belong to Falmouth, was incorporated by the name of Portland. Its harbour is safe and capacious, seldom or never completely frozen over; near the main ocean, and easy of access. The inhabitants carry on a considerable foreign trade, build ships, and are much occupied in the fishery; so that it is reckoned one of the most thriving commercial towns in the commonwealth of Massachusetts. In 1775 it was laid in ashes by the British fleet; but it has since been entirely rebuilt, and by the last census contained 7169 inhabitants. Among its public buildings are seven churches, three for Congregationalists, one for Episcopalians, one for Baptists, one for Methodists, and one for Friends, and a handsome court-house. A light-house was erected in 1790, on a point of land called Portland head, at the entrance of the harbour; the capital of its bank is 300,000 dollars. N. lat. $43^{\circ} 39'$. W. long. $69^{\circ} 52'$. The works erected in 1795 for the defence of Portland consist of a fort, a citadel, a battery for ten pieces of cannon, an artillery store, a guard-house, an air-furnace for heating shot, and a covered way from the fort to the battery. Morse.

PORTLAND Isle, a small island, or rather a peninsula, in the liberty of Portland, Dorchester division of the county of Dorset, England, is situated in the English channel, nearly opposite to Weymouth, at the distance of 15 miles from Dorchester, and 133 miles S.W. by W. from London. It is connected with the mainland by a ridge of pebbles, which extend nearly seventeen miles along the coast, and from which it is separated by a narrow arm of the sea, called the Fleet. The etymology of the name Portland is uncertain; some deriving it from *Port*, a Saxon free-booter, who is said to have settled here A.D. 501, and others from the proximity of the isle to the port of Weymouth. This spot is early noted in history, and has been the scene of several important transactions in the military annals of England. Baxter conjectures that it was the Vindelis, or, as he writes it, the Vindenis of Antoninus. In the year 787, a party of the Danes landed here, and put to death the governor, Præpositus, or Gerela, who commanded for Bithric, king of the West Saxons. In 1052 it was again seized upon and plundered by Godwin, the banished earl of Kent.

Portland isle had been fortified with a castle before the year 1142, as in that year it was taken possession of by Robert, earl of Gloucester, in the name of the empress Maud, the governor having espoused her cause in the contest for the throne against the usurper Stephen. This castle is now an inconsiderable ruin, but was doubtless formerly of great ex-

tent; and was distinguished for the unusual boldness and romantic appearance of the rock on which it stood. When it was dismantled does not appear upon record. It is reasonable, however, to conclude, that its demolition preceded the erection of the present fortress, called Portland castle, by king Henry VIII. This fortress is of great strength, and completely commands Weymouth road, with a view to which object it was originally constructed. It is the residence of the governor during his visits to the peninsula. In the time of the grand rebellion, it was garrisoned at first for the parliament; but having been taken through stratagem by a party of the king's forces, it was among the last which was compelled to abandon the royal cause.

Portland isle extends about four miles and a half in length, by two in breadth; and in a mineralogical point of view, may be regarded as one continued mass of freestone rock. This, however, is frequently intersected by strata of black and red schistus, and of a species of stone called sugar-candy stone; and is also interspersed with a great variety of petrified shells, among which are some *cornua ammonis*. From many indubitable marks still remaining, as well as from history, we learn that this isle has sustained frequent convulsions of nature. In 1665 the great pier was entirely demolished, and the channel filled up with rubbish: the roads leading from the piers to the quarries were destroyed, and nearly 100 yards of earth slid into the sea. In December 1734, about 150 yards on the east side of the isle likewise gave way, and fell into the ocean, occasioning by the shock huge chasms, in one of which, between the pier and the castle, several large skeletons were discovered, buried between stones set edge-ways, with another superincumbent. But the greatest slide occurred in 1792, and is thus described in Hutchins's History of Dorsetshire. "Early in the morning the road was observed to crack: this continued increasing, and before two o'clock the ground had sunk several feet, and was one continued motion; but attended with no other noise than what was occasioned by the separation of the roots and brambles, and now and then a falling rock. At night it seemed to stop a little, but soon moved again; and before morning, the ground, from the top of the cliff to the water side, had sunk in some places fifty feet perpendicular. The extent of ground that moved was about a mile and a quarter from north to south, and 600 yards from east to west."

This isle constitutes only one parish, but contains several considerable villages or hamlets. According to the parliamentary returns of 1811, the houses amounted to 383, and the inhabitants to 2079 in number. There is but one church in the whole island, which was lately erected in lieu of an old one now in ruins. The agricultural produce on the arable lands here is wheat, oats, pease, and barley: and about three thousand sheep are kept on the pasture-grounds. The corn is of an excellent quality; and the sheep, of a peculiarly small breed, have been long famous for their delicacy of flavour. Most of the husbandry concerns in Portland are managed by the women, the men being chiefly engaged in the quarries, which are scattered, more or less, over every part of the isle, and produce the celebrated free-stone, which bears its name. This stone was first brought into repute in the reign of James I., who employed it, by the advice of his architects, in the construction of the banquetting-house at Whitehall; and it has since been used in the erection of almost all the public edifices of note in the English metropolis. The principal quarries are situated near the village of Kingstons, where there is a pier, whence upwards of 6000 tons of stone are shipped annually. The method of conveying the blocks from the quarries to the shore is simple and easy.

As the navigation in the vicinity of Portland is extremely dangerous, two light-houses have been erected on the island. One of these was constructed in 1716, and the other in 1789. The latter was built by William Johns, architect of Weymouth, at the expence of the Trinity corporation, and is a circular cone structure, sixty feet in height, situated at the distance of 1608 feet from the shore, which here exhibits a remarkable cavern, called Cave-hole, about fifty feet square, and twenty-one deep at the entrance. About twenty years ago, a vessel of 40 tons burthen was driven into this cavern, and dashed to pieces; and smaller craft frequently share the same fate. How far it penetrates under the land has not hitherto been ascertained; but on the west side it appears to separate into two apartments.

The manor of Portland, in the time of the Saxon dynasty, belonged to the crown; and was granted by Edward the Confessor to the church of Winchester. It seems, however, again to have reverted to the crown, before the compilation of the Domesday book, as it is there mentioned under the title of *Terra Regis*, and is said to have yielded sixty-four pounds of pure silver. By Henry I. it was re-granted to the church of Winchester. In the reigns of Edward IV. and Richard III. it had again become royal property; and was first granted to Cecilia, duchess of York, and afterwards to George, duke of Clarence. Henry VIII. bestowed it successively on his queens, Catharine Howard and Catharine Parr. In the reign of James I. it was given to the princess, afterwards queen Anne; and remained in the possession of the crown till 1800, when it was sold by public auction.

The custom of gavel-kind has prevailed from time immemorial in this district, as has likewise another very singular custom, (resembling the American one of bundling,) called by the natives *Portland-custom*. Here the women never marry before they have become pregnant by their intended husbands. Should this not happen after a limited period of cohabitation, the parties are supposed not to have been destined for each other by providence, and the match is consequently broken off; and that without any imputation on the character of the female, who as readily obtains another suitor, as if she had never cohabited with man.

The *Chefil-Bank*, connected with the mainland, says Dr. Maton, is "one of the most extraordinary ridges, or shelves, of pebbles in Europe, and perhaps the longest, except that of Memel, in Polish Prussia." As already mentioned, it extends about seventeen miles in length, and in most places nearly a quarter of a mile in breadth, a narrow arm of the sea interposing between it and the southern coast of England. The pebbles forming this immense barrier consist chiefly of a white calcareous kind; but there are many of quartz, jasper, chert, and other substances. What is singular, they gradually diminish in size, from the Portland end of the bank to that which attaches to the mainland; and are, throughout its whole extent, so loosely thrown together, that horses' legs sink almost knee deep at every step. Several ingenious theories have been advanced to account for the formation of this curious work of nature; but they have hitherto been accounted unsatisfactory. It is a problem of no very easy solution. History and Antiquities of Dorsetshire, 3 vols. folio, by the Rev. John Hutchins, and Richard Gough. Maton's Tour to the West of England, 2 vols. 8vo. Beauties of England, vol. iv., by John Britton and E.W. Brayley.

PORTLAND Canal, an inlet on the W. coast of North America, extending about 70 miles to the north. S. lat. 54° 42'. Long. of the entrance 229° 42' E.

PORTLAND Creek, a small bay on the W. coast of Newfoundland.

PORTLAND Island, an island in the South Pacific ocean, near the E. coast of New Zealand, visited by Capt. Cook in 1773. S. lat. 39° 25'. E. long. 178° 12'.—Also, one of the cluster called Queen Charlotte's islands, in the South Pacific ocean, of a triangular figure, and about eight miles in circumference. S. lat. 10° 43'. E. long. 164° 15'.

PORTLAND Islands, a cluster of small islands in the East Indian ocean, W. of New Hanover, so named by Capt. Carteret in 1767; about six or seven in number, and appearing to be fertile. S. lat. 2° 27'. E. long. 148° 3'.

PORTLAND Key, a small island near the S. coast of the island of Jamaica; two miles E. from Portland Point, which is a cape of Jamaica. N. lat. 17° 44'. W. long. 76° 57'.

PORTLAND Point, a cape in Hudson's Bay. N. lat. 58° 50'. W. long. 78° 20'.

PORTLAND Stone, *Saxum Arenarium Portlandicum* of Da Costa, and *Pseudurium Hebes, Albidum, Laxius*, of Hill, is an alkaline sand-stone, of a dull whitish colour, heavy, moderately hard, of a somewhat flat texture, and is composed of a large roundish grit, cemented together by an earthy spar, and intermixed with numerous glittering spangles of pure spar; the grit splits in the cutting of the stone, so that it is capable of being brought to a surface very smooth and equal; it will not strike fire with a steel, and burns to a slight ashen hue. The Portland stone belongs to the third variety of the compact limestone, under the calcareous genus, whose fracture is earthy, according to Kirwan's arrangement. Its specific gravity is 2.461. There are vast quarries of it in the island of Portland, in Dorsetshire, whence its name. It is brought from thence in large quantities to London, and much used in building. This and all similar sorts of stone, that are composed of granules, and are not of a laminated texture, will cut and rive in any direction, as well in a perpendicular, or in a diagonal, as horizontally and parallel to the site of the strata. For this reason they have obtained the name of *free-stone*. Da Costa's Fossils, p. 125.

This stone is very soft when it comes out of the quarry, works very easily, and becomes in time very hard. The piers and arches at Westminster bridge are built with it.

PORTLAND's Powder for the Gout and Rheumatism. See GOUT.

PORTLANDIA, in Botany, was so named by Dr. Patrick Browne, in compliment to the late Margaret duchess dowager of Portland, a lady long celebrated for her knowledge and patronage of various branches of natural history, especially of conchology, and who cultivated, in her garden at Bulstrode, a rare collection of English as well as exotic plants, with which she was scientifically conversant. See our biographical article of the Rev. JOHN LIGHTFOOT.—Browne Jam. 164. Linn. Gen. 91. Schreb. 121. Willd. Sp. Pl. v. 1. 935. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 1. 367. Juss. 202. Lamarek Illustr. t. 162. Gært. t. 31. (Coutarea; Aubl. Guian. v. 1. 314. Juss. 202.)—Class and order, *Pentandria Monogynia*. Nat. Ord. *Rubiaceæ*, Juss.

Gen. Ch. *Cal.* Perianth superior, of five, sometimes four or six, oblong-lanceolate permanent leaves. *Cor.* of one petal; tube much longer than the calyx, funnel-shaped, somewhat inflated; limb shorter than the tube, in five, sometimes four or six, deep, broad, acute segments. *Stam.* Filaments as many as the segments of the corolla, inserted into

into the base of its tube; anthers terminal, linear, erect, as long as the corolla. *Pist.* Germen inferior, roundish, with several angles; style simple, the length of the stamens; stigma oblong, obtuse. *Peric.* Capsule obovate, angular, abrupt, of two cells, finally separable from the top downwards into two parts, contrary to the partition. *Seeds* numerous, roundish, compressed, imbricated, more or less bordered.

Eff. Ch. Corolla funnel-shaped, inflated. Anthers longitudinal. Capsule angular, abrupt, with two cells and many seeds, crowned with the permanent calyx.

1. *P. tetrandra*. South sea Portlandia. Linn. Suppl. 143. Willd. n. 1. Forst. Prodr. 15.—Flowers four-cleft, with four stamens. Calyx awl-shaped. Leaves obovate, obtuse.—Native of several islands in the South seas, where it has, according to the Linnæan and Banksian collections, been gathered by Forster, Cook, and David Nelson. A figure in outline exists among the unpublished plates, which Sir Joseph Banks has caused to be engraved from Forster's sketches, but we know of no other. The *stem* is shrubby, with rugged branches. Every part of the plant is smooth. *Leaves* about the ends of the branches, opposite, crowded, stalked, broadly obovate, obtuse, entire, coriaceous, about three inches long. *Stipulas* short, annular, intrafoliateous. *Flowers* axillary, solitary, on stalks about an inch long. *Corolla* white, longer than the leaves, with a rather slender tube, and short dilated limb. The *calyx-leaves* are awl-shaped. *Fruit* with a ribbed soluble coat, which leaves the two cells entire, till they split of themselves and discharge the seeds.

2. *P. grandiflora*. Large-flowered Portlandia. Linn. Sp. Pl. 244. Willd. n. 2. Ait. n. 1. Browne Jam. t. 11. Sm. Ic. Pic. t. 6. Curt. Mag. t. 286. Schneev. Ic. t. 4.—Flowers five-cleft, with five stamens. Calyx ovate. Leaves elliptical, acute.—Native of rocky places at the foot of mountains in Jamaica. It is said to have been introduced into England, in 1775, by Mr. Ellis, a gentleman long resident in that island, distinguished for his love of natural history. We have never seen this noble and elegant plant in perfection, except in the late marchioness of Rockingham's garden, at Hillingdon, where it flourished exceedingly in a small, low, very hot stove, and bore frequently near twenty flowers at a time, chiefly in the summer months. The *stem* is shrubby, but weak, and trailing along the rocks, smooth. *Leaves* opposite, on short stalks, elliptical, pointed, channelled, entire, of a fine dark shining green, very smooth, a span long. *Flowers* white, rather longer than the leaves, axillary, solitary, highly fragrant, expanding near three inches; their tube angular, buff-coloured in the bud. *Calyx-leaves* ovate, tinged with red, veiny.—Jacquin's plant, Amer. 62, t. 44, is probably the same with our's, though he erroneously represents the leaves as unequal at the base.

3. *P. coccinea*. Scarlet Portlandia. Swartz Ind. Occ. v. 1. 384. Willd. n. 3.—Flowers five-cleft, with five stamens. Calyx lanceolate. Leaves ovate, coriaceous.—Found by Dr. Swartz on mountain precipices in the western part of Jamaica, but rarely. This is smaller than the last in all its parts, with rounder, more ovate *leaves*, and deep-scarlet *flowers*, whose *corolla* is not half so long as that of the *grandiflora*.

4. *P. hexandra*. Laurel-leaved Portlandia. Linn. Mant. 45. Willd. n. 4. Ait. n. 2. Jacq. Amer. 63. t. 182. f. 20. (Coutarea speciosa; Aubl. Guian. v. 1. 314. t. 122.)—Flowers terminal, six-cleft, with six stamens; tube curved. Calyx awl-shaped. Leaves ovate.—Native

of Guiana. Introduced at Kew in 1803, but it has not yet flowered. The *leaves* are shaped like the last, but more pointed and less coriaceous. *Flowers* numerous, red, very handsome, terminal, and somewhat corymbose; their *corolla* about two inches long, inflated, in six divisions. Leaves of the *calyx* awl-shaped, very narrow, except at the base. In its native country this fine shrub blossoms in February and June.

PORTLANDIA, in *Gardening*, contains plants of the trailing, evergreen, exotic kind for the stove, of which the species cultivated is the great-flowered portlandia (*P. grandiflora*).

Method of Culture.—These plants may be raised either from seeds or cuttings.

The seeds, when procured, should be sown in pots, filled with light earth, in the spring, plunging them in the tan-bed, in the stove. When the plants are sufficiently strong, they should be removed into separate pots, and be replunged in the bark hot-bed, where they must be constantly kept.

The cuttings of the young shoots should be planted out singly, in pots filled with the same sort of mould, plunging them in the bark bed of the stove: when they have taken good root, they should be removed into larger pots, replunging them into the tan-bed, where they must remain.

They afford a fine effect, when trained on the back part of the stove in their larger flowers.

PORT-LAST, in a *Ship*, denotes the gunwale.

When a yard is down on the deck, they say, the *yard is down a port-last*.

PORTLAW, in *Geography*, a post-town of the county of Waterford, Ireland, between Waterford and Carrick, and 89 miles S.W. from Dublin.

PORT-LIDS, in *Ship Building*, the shutters hung with hinges at their upper edges, which inclose the ports in rough weather.

PORTLOCK, in *Geography*. See PORLOCK.

PORTLOCK'S Harbour, an inlet on the W. side of King George Third's Archipelago. N. lat. 57° 44'. E. long. 224°.

PORTLOGO, a town of Africa, in the country of Sierra Leone, on the N. branch of the Sierra Leone river. N. lat. 8° 40'. W. long. 12° 36'.

PORTMAHALLOCH HARBOUR, a bay on the S. side of the Frith of Dornoch. N. lat. 57° 48'. W. long. 3° 47'.

PORTMANNIMOTE, in *Old Records*, the port-men's court, held in any city or town.

PORT-MANTEAU, a piece of joiner's work, fastened to the wall, in a wardrobe, armoury, &c. proper for the hanging on of cloaks, hats, &c.

PORT-MANTEAU is also used for a cloak-bag of cloth, leather, or the like, in which the cloak and other habiliments of travellers are disposed, and laid on the horse's crupper.

PORT-MANTEAU was also an officer under the late king of France, of whom there were twelve: their business was to keep the king's hat, gloves, cane, sword, &c., to take them from him, and to bring them to him again when wanted.

The dauphin had also his port-manteau. Answerable to these were the cardinals caudataries, or tail-bearers.

The Romish bishops have also their port-croix, port-mitres, &c. *i. e.* crozier-bearers, mitre-bearers, &c.

PORT-MEN, the twelve burgeses of Ipswich; thus called in the stat. 13 Eliz.

Camden adds, that the name was common to the inhabitants of all the cinque-ports.

PORTMOTE, formed from the Saxon *port*, port, and *gemot*, *conventus*, meeting, *q. d. portgemot*, signifies a court kept in port or haven towns; as Iwanimote in the forest. It is sometimes also called the *portmote court*.

Portmotes are also held in some inland towns, as at Knolst in Cheshire.

PORT-NAILS, in a *Ship*, such as are used to fasten the hinges to the ports.

PORTNEUF, in *Geography*, a town of Canada, on the river St. Laurence; 20 miles S.W. of Quebec.—Also, a river of Canada, which runs into the St. Laurence, N. lat. $48^{\circ} 45'$. W. long. $68^{\circ} 50'$.

PORTO, a town of Sicily, in the valley of Mazara; two miles E. of Palermo.

PORTO. See OPORTO.

PORTO, a town of Spain, in the province of Leon; 43 miles S.W. of Astorga.—Also, a small sea-port town of the Patrimonio, situated on the W. side of the Tiber, the remains of a town built by Claudius and Trajan. It is the see of a bishop, who is generally a cardinal, and dependent only on the pope; 10 miles S.W. of Rome.—Also, a town of Italy; 19 miles N.W. of Como.—Also, a sea-port town of the island of St. Mary, one of the Azores.

PORTO Bello, or *St. Philippe de Puerto Bello*, a sea-port town of America, on the N. coast of the isthmus of Darien, consisting of about 130 houses, mostly built of wood, or of wood intermixed with stone, and situated nearly opposite to Panama on the southern side of the isthmus, very near the sea, on the declivity of a mountain, which surrounds the whole harbour. The town consists of one principal street, extending along the strand, and recrossed by several others passing from the declivity of the mountain to the shore, with some lanes parallel to the principal street. It has two squares, a custom-house, and a stone church, which is served by priests that are natives of the country, and two convents. At the east end of the town, on the road to Panama, is a quarter, called "Guinea," inhabited by negroes of all sexes, whether slaves or free. This quarter used to be much crowded, when the galleons were at Porto Bello, at which time the town, generally but thinly inhabited, becomes one of the most populous places in the world. Its situation on the isthmus, between the South and North seas, the goodness of its harbour, and its small distance from Panama, gives it a preference to all other places, for the rendezvous of the joint commerce of Spain and Peru, at the time of its fair. When advice was received at Carthagena, that the Peru fleet had unloaded at Panama, the galleons hastened to Porto Bello, in order to avoid the distempers, springing from idleness, which afflicted the seamen. The concourse of people on this occasion was so great, that houses and every kind of accommodation were extravagantly dear. As soon as the ships were moored in the harbour, the seamen erected in the square a large tent with sails, where they deposited all the cargo, that each owner might distinguish his goods by their respective marks. The bales of goods were drawn on sledges by the seamen, and the money paid for their labour was equally divided. At the same time, while the seamen and European traders were thus employed, the land was covered with droves of cattle from Panama; each drove consisting of above 100, loaded with chests of gold and silver, on account of the merchants of Peru. When the ships were unloaded, and the merchants of Peru, with the president of Panama, arrived, the formalities of the fair commenced: the deputies of the several

parties repaired on board the ships, where, in the presence of the commander of the galleons and of the president of Panama, the former as patron of the Europeans, and the latter of the Peruvians, the prices of the several kinds of merchandise were settled, and the contracts signed and publicly announced, so that every one might by them regulate the sale of his effects; and thus all fraud be precluded. The purchases and sales, as well as the exchange of money, were transacted by brokers from Spain and Peru. After this every merchant began to dispose of his own goods; the Spanish brokers embarked their chests of money; and those of Peru sent away their purchased goods in vessels up the river Chagre, and thus the fair of Porto Bello ended. But since the mode of commerce by galleons has been abandoned, Porto Bello has also declined, and the dereliction of this mode of commerce has also greatly impoverished all the cities and towns between Carthagena and Lima.

This was discovered Nov. 2, 1502, by Columbus, who was so charmed with its extent, depth, and security, that he called it "Porto Bello," or "The Fair Harbour." Its mouth, though three quarters of a mile broad, is well defended by fort St. Philippe de Lodo Hiarro, or Iron Castle, situated on the N. point of the entrance; for the S. side being full of water, ships are obliged to keep in the middle, and consequently within 660 yards of the castle, in from nine to fifteen fathoms of water, with a bottom of clayey mud, mixed with chalk and sand. On the S. side of the harbour, and about 200 yards from the town, is a large castle, called "St. Jago de la Gloria," having before it a small point of land, projecting into the harbour, and upon it a small fort, called "St. Jerom," within 20 yards of the houses. All these were demolished by admiral Vernon in 1739, with six ships only.

The inclemency of the climate of Porto Bello is notorious. The excessive heat is augmented by the situation of the town, which is surrounded by high mountains, that obstruct every current of wind, by which it might otherwise be refreshed. The trees on the mountains are so thickly set, that they intercept the rays of the sun, and thus the earth under their branches is prevented from becoming dry, and some copious exhalations form large heavy clouds, which burst down in violent torrents of rain; and then the sun breaks out again with its former splendour; and by this kind of alternate succession of rain and heat, no interval of refreshing coolness occurs. These torrents of rain are often accompanied with tempests of thunder and lightning, which being reflected and reverberated from the mountains, and their caverns, and rendered still more terrible by the hideous howlings of monkeys of all kinds, that in immense numbers inhabit the forests, are sufficient to appal the most intrepid. The fatigue which the seamen undergo in their labour, added to the heat of the climate, occasions a very profuse perspiration, which debilitates and dispirits them; so that they have recourse to brandy, of which a great quantity is consumed, for relief. All these circumstances concur to injure the best constitutions, and to produce those deleterious diseases that are common in this country. The diseases of the seamen attack other inhabitants that do not engage in their exhausting employment; so that the causes of their diseases must be attributed, not merely to labour and fatigue, and excess of drinking, but to the insalubrity of the climate; 60 miles N. of Panama. Porto Bello is less sickly since a passage was cut through a hill to admit a current of air. N. lat. $9^{\circ} 42'$. W. long. $79^{\circ} 45'$.

PORTO Bello, a small island in the East Indian sea. S. lat. $0^{\circ} 57'$. E. long. $107^{\circ} 58'$.

PORTO Balabatatella, a harbour on the S. coast of Sicily. N. lat. $37^{\circ} 8'$. E. long. $13^{\circ} 53'$.

PORTO Bufalo, a sea-port on the S.W. coast of the island of Negropont. N. lat. $38^{\circ} 13'$. E. long. $24^{\circ} 15'$.

PORTO Caballo, Cabello, or Cavello, a sea-port town of South America, in the government of Caraccas, with an excellent harbour, and about 7500 inhabitants; 25 miles N.E. of Caraccas. Porto Cabello was raised into importance, on account of the excellence of its harbour, by the company of Guipuscoa, who established there one of its principal factories. They also constructed a superb pier, 92 feet long and 12 wide, for the accommodation of their vessels, and some forts for their defence. The city, properly so called, is situated so near the sea, that it occupies many spots very lately under water, and which have been raised by encroachments above the level of the ocean. The original town is surrounded by the sea, if we except about 100 toises on the W., where is contrived a canal, that affords a communication between the southern and northern part of the sea, and consequently makes the city an island, from which there is no exit, but over a bridge, at the end of which is placed the main guard, and a gate that is shut every evening. The general occupation of the white inhabitants consists of commerce and navigation. Their principal and almost only connections are with the ports of the same continent and the neighbouring colonies. Four or five ships carry every thing that arrives annually from Spain, and whatever is sent thither; whilst more than 60 vessels are employed in the coasting trade. Porto Cavello is the deposit of all the eastern part of the province of Venezuela; its commerce is carried on by twenty Europeans. This port is the place of resort for the vessels of the neighbouring ports, for refitting, calking, and even building. It wants only a greater degree of salubrity to be the first port in America. Its water is conducted into the city from a river that falls into the sea at a quarter of a league to the west by canals, and distributed to the public in cisterns placed at convenient distances. As a fortified place, it is chiefly under the orders of a military commander, who exercises almost every kind of authority. It has only one parish church, which is situated near the harbour; it has two hospitals, one for the troops and one for private persons. Porto Cavello is 30 leagues from Caraccas by the way of Guayra, and 48 by Valencia, Maracay, Tuemero, Victoria, and San Pedro. S. lat. $10^{\circ} 20'$. W. long. $70^{\circ} 31'$ from Paris.

PORTO Cairo, or Porto Gabriel, a harbour on the W. coast of the island of Metelin. N. lat. $39^{\circ} 17'$.—**P. Canfado**, a harbour on the W. coast of Africa. N. lat. $28^{\circ} 4'$. W. long. $11^{\circ} 50'$.—**P. Casideb**, a harbour on the coast of Natolia, in the gulf of Stanchio. N. lat. $37^{\circ} 7'$. E. long. $27^{\circ} 44'$.—**P. Cavaleiri**, a port on the S. coast of Natolia, opposite to the island of Rhodes. N. lat. $36^{\circ} 40'$. E. long. $27^{\circ} 44'$.—**P. de Castellanos**, a sea-port on the island of St. Sebastian. —**P. de Comboa**, a town of Portugal, in Estramadura, on the W. coast; 2 miles N.E. of Peniche.—**P. Condea**, a harbour on the S. coast of the island of Stalimene. N. lat. $32^{\circ} 50'$. E. long. $25^{\circ} 16'$.—**P. Digoro**, a small place of Italy, at the mouth of the Po.—**P. Farina**, a sea-port of Africa, in the kingdom of Tunis, called by the ancients "Rufcicon," and by the natives "Gar el Mailah," or the Cave of Salt. The harbour is safe in all weathers, and opens into a navigable lake or large pond, formed by the river Mejerdah, which runs through it into the sea. N. lat. $36^{\circ} 30'$. E. long. $10^{\circ} 16'$.—**P. Fermo, or Fermano**, a port of the marquise of Ancona, on the Adriatic; 3 miles N. of Fermo. — **P. Ferrajo**, a sea-port on the N. coast of

the island of Elba. N. lat. $42^{\circ} 53'$. E. long. $10^{\circ} 28'$.—**P. Fino**, a sea-port of Genoa, situated between two mountains; anciently called "Portus Delphini;" 12 miles E. of Genoa. N. lat. $44^{\circ} 19'$. E. long. $9^{\circ} 8'$.—**P. Gaurio**, a sea-port on the S.E. coast of the island of Andros. N. lat. $37^{\circ} 51'$. E. long. $24^{\circ} 45'$.—**P. Genovesa**, a harbour on the coast of Natolia, in the gulf of Satalia; 30 miles S. of Satalia.—**P. Grato**, a sea-port on the S. coast of the island of Scarpanto. N. lat. $35^{\circ} 31'$. E. long. $26^{\circ} 45'$.—**P. Greco**, a town of Naples, in Capitanata, on the sea-coast; 9 miles S. of Vieste.—**P. Gruaro**, a town of Italy, in Friuli, on the Lamene, containing three churches and four convents; 2 miles N. of Concordia. N. lat. $45^{\circ} 48'$. E. long. $12^{\circ} 51'$.—**P. Hercule**, a sea-port in the Stato de gli Præfidii, situated on a peninsula; 4 miles S. of Orbitello. N. lat. $42^{\circ} 25'$. E. long. $11^{\circ} 8'$.—**P. Jero**, a bay on the S.E. coast of the island of Metelin.

PORTO Legnano, a town of Italy, in the Veronese, on the N. side of the Adige, opposite to Legnano.—**P. Leoni, or Lione, or Pireo**, a sea-port of Athens, in European Turkey, and province of Livadia. N. lat. $37^{\circ} 56'$. E. long. $23^{\circ} 40'$.—**P. Livadi**, a sea-port on the E. coast of Livadia. N. lat. $37^{\circ} 55'$. E. long. 24° .—**P. Longone**, a strong sea-port on the S.E. coast of the island of Elba, seated on a promontory, in a large bay, defended by a castle on a projecting rock; 2 miles S.E. of P. Ferrajo. N. lat. $42^{\circ} 52'$. E. long. $10^{\circ} 32'$.—**P. Madera**, a port on the E. coast of St. Jago, one of the Cape Verd islands. It is a good harbour, and though the entrance is narrow, it is neither difficult nor dangerous.—**P. Maggiore**, a town of Italy, in the department of the Lower Po, on the coast of the Adriatic; 3 miles S.E. of Comacchio.—**P. Mandri**, a harbour on the E. coast of Livadia. N. lat. $37^{\circ} 43'$. E. long. $24^{\circ} 2'$.—**P. Marmora**, a harbour on the E. coast of the island of Paros. N. lat. $37^{\circ} 3'$. E. long. $25^{\circ} 17'$.—**P. Mastico**, a sea-port on the W. coast of the island of Scio. N. lat. $38^{\circ} 15'$. E. long. $25^{\circ} 57'$.—**P. Maurizio, or Morizzo**, a sea-port of Genoa, on a small gulf, which separates it from Oneglia; 8 miles W. of Oneglia. N. lat. $43^{\circ} 55'$. E. long. $8^{\circ} 3'$.—**P. Mefta**, a harbour on the W. coast of the island of Scio. N. lat. $38^{\circ} 20'$. E. long. 26° .—**P. Morone**, a town of Italy, in the department of the Tesino; 12 miles E. of Pavia.—**P. de Moz**, a town of Portugal, in the province of Estramadura; 10 miles S. of Leyria.—**P. de Mugon**, a town of Portugal, in the province of Estramadura, on the Tagus; 7 miles below Santaren.—**P. de Naos**, a harbour on the S. coast of Lancerotta, and one of the principal ports of that island. The access to the harbour is unsafe, on account of the rocks that form it, which lie under the water; but as they break the swell of the water, the inside is as smooth as a mill-pond. As there is no other convenient place among the Canary islands for repairing large vessels, this is much used for that purpose.—**P. Novo**, a town of Hindoostan, in the Carnatic, where the Dutch have a resident. Upon its capture by Aurungzebe, he called it "Mahomet Bender;" a name now given to it by the natives.—**P. Novo**, a town of Africa, in Benin, possessed by the Portuguese. N. lat. $6^{\circ} 24'$. E. long. $1^{\circ} 45'$.—**P. Novo**, a town of Portugal, in Estramadura; 23 miles N.W. of Lisbon.—**P. Paglia**, a harbour on the W. coast of Sardinia. N. lat. $39^{\circ} 23'$. E. long. $8^{\circ} 31'$.—**P. Paradiso**, a harbour on the E. coast of the island of Rhodes. N. lat. $36^{\circ} 25'$. E. long. $27^{\circ} 45'$.—**P. Pavone**, a harbour on the S. coast of the island of Nisida, in the gulf of Naples.—**P. Petera**, a harbour on the N. coast of the island of Metelin. N. lat. $39^{\circ} 27'$. E. long. $26^{\circ} 10'$.—**P. Petriais**, a harbour on the N.E. coast of Negropont. N. lat. $38^{\circ} 24'$. E. long.

E. long. 24'.—*P. Phanari*, a port on the coast of Livadia, belonging to Athens. N. lat. 37° 56'. *E. long.* 23° 42'.—*P. Phylco*, a bay on the S. coast of Natolia. N. lat. 36° 48'. *E. long.* 26° 54'.—*P. Pin*, a harbour on the S. coast of Asiatic Turkey, in the Mediterranean. N. lat. 36° 36'. *E. long.* 33° 54'.—*P. Portesi*, a harbour on the N. coast of Sardinia. N. lat. 41° 8'. *E. long.* 9° 20'.

PORTO Praya, a town of St. Jago, one of the Cape Verde islands, situated at the foot of an elevated plain, on the E. side of the island. This town, or rather hamlet, is the residence of the governor-general, for the crown of Portugal, of the Cape de Verde on the main land of Africa, and of the Cape de Verde islands opposite to it. His abode is a little wooden barrack, pleasantly situated at one extremity of the plain, looking down a valley over a grove of cocoa-nut trees, and having a view of the bay and shipping. The governor's garden is about two miles inland, distant from his habitation. Here a small clear rivulet issues from a source at the bottom of some rocks, and wherever it is made to run, every species of vegetable near it flourishes. This rivulet supplies many of the principal inhabitants of Praya, who have that distance to get good water. The cattle near it are relieved from thirst, and the fields adjoining it appear like a bleach-ground, from the quantity of linen washed in the little streams, and dried close to it. The whole hamlet consists of about 100 very small dwellings, one story high, scattered on each side of the plain, which extends near a mile in length, and about the third of a mile in breadth, and falls off, all around, to the neighbouring vallies, and to the sea. Not being commanded by any neighbouring eminence, it is a situation capable of defence: the fort, however, or battery, is almost in ruins; and the few guns mounted on it are mostly honey-combed, and placed on carriages which barely hold together. The militia is said to consist of three regiments, of about 700 men, chiefly officered by Mulattoes and Negroes; and not above ten white officers in the whole, one of whom is an inn-keeper. The best building is the gaol, and the next the church, at which officiates a priest, who is a dark-coloured Mulatto. Such is the account given of Praya by sir G. Staunton. The bottom of the bay, in seven fathoms water, is better than at a depth of 12 or 14 fathoms, beyond which it is uncertain and rough. The bay is open to the wind from S.E. to W. by S.; but it is never supposed to blow here so hard, or to bring in so much sea, as to endanger a ship's continuing to ride at her anchors steadily. The latitude of the bay is 14° 56' N., and its longitude 23° 29' W. The variation of the compass is 12° 48' W. The tides, in the full and change of the moon, rise nearly five feet perpendicular. English men of war salute with eleven guns, on an assurance of a return of an equal number. This bay has for several years been frequented by ships bound to the southward, as bullocks, sheep, hogs, goats, poultry, and fruits, were abundant and reasonable. Fish may be likewise taken by the seine. An excellent kind of rock-cod may be caught from the rocks with rod and line. Port Praya has long been a place where the outward-bound Guinea and Indiamen have been accustomed to touch at for water and refreshments, but few of them call here on their return to Europe. The inhabitants barter their provisions and fruits for shirts, drawers, handkerchiefs, breeches, hats, waistcoats, and all kinds of clothing.—*P. Primero*, a small harbour at the mouth of the Po.—*P. del Principe*. See *VILLA del Principe*.

PORTO Rico, an island in the West Indies, belonging to Spain, about 120 miles in length, and 40 in breadth. The climate is temperate, and the soil is rich and fertile. It is

beautifully diversified by hills, woods, and vallies, and well watered by streams that flow from the mountains. The northern part, which is the most barren, is said to contain mines of gold and silver. Its chief products are fugar, ginger, cotton, flax, coffee, cassia, incense and hides. Of the latter more than 2000 are sent every year to Europe. The cattle, which are abundant, were originally imported from Old Spain. Its mules, which are not numerous, are much esteemed in Jamaica. The woods abound with parrots, wild pigeons, and other fowl. European poultry is plentiful, and the coasts afford an ample supply of fish. The inhabitants are well supplied with fruits of various kinds, both for consumption and exportation, and good salt. The dogs of this island, furnished by a breed brought over to America, by the Spaniards, for the purpose of hunting and tearing in pieces the defenceless inhabitants, roam in the woods near the sea-shore, in a wild state, and subsist on land crabs, that burrow in the earth. Porto Rico was discovered by Columbus in 1493, and was subjugated by Ponce de Leon, the first explorer of Florida, about the year 1509. In 1597 this island was taken by the duke of Cumberland; and in 1797 the capture of it was unsuccessfully attempted by the English. This island, though beautiful, fertile, and productive, is very subject to hurricanes, and a terrible one, in 1742, destroyed its fertility for many years. The number of its inhabitants is estimated at about 10,000 persons. The chief town is Porto Rico, situated on a little isle, and founded in 1510; it was formerly a chosen abode of smugglers. On the S.W. of the town is a fort called St. Antonio. The Spanish inhabitants of the town are supposed to be about 500. See *St. JUAN de Porto Rico*. N. lat. 18° to 18° 35'. W. long. 65° 30' to 67° 45'.

PORTO Santo, a small island of the Atlantic, N.E. of Madeira, and probably discovered by the Portuguese about the same time with the latter. It derived its name from the protection which it afforded to its discoverers during a storm. It was then uninhabited; but was peopled by the Portuguese, and continued ever since in their possession. It has a good harbour, with one bay, in which ships may ride securely from all winds, except the S.W. It is occasionally visited by East India ships, which afford the island all the trade they enjoy. Although small, not exceeding 15 miles in compass, it is fertile, producing wheat and corn in abundance; also cows, wild boars, and rabbits, the latter in great numbers. But its most valuable productions for export, are dragon's blood, honey, wax, and silk. N. lat. 33° 0'. W. long. 16° 50'.

PORTO Santo, a sea-port of South America, in the government of Caraccas.

PORTO St. Antonio, a harbour on the S. coast of Stalimene; six miles E. of Condea.

PORTO de St. Pedro, a sea-port town of Brazil, near the mouth of the river Iguay. S. lat. 31° 55'. W. long. 52° 6'.

PORTO Seguro, a province of Brazil, which was the first land discovered by the Portuguese in 1500, and the name of the haven was given to it by Cabral. It was erected into a marquisate, in favour of Don Alonzo de Lancaster, by Philip II., king of Spain and Portugal, and remained in that family until the year 1758, when it reverted to the crown. Its mountains are said to contain precious stones of various kinds; but after the subjection of Portugal to Spain, the discoveries to this purpose that had been made were lost; and the passages to the mines are now held by ferocious tribes, so that the mountains have not been explored. Near the church of Aguda, in this province, is a fountain said to have sprung up miraculously, as the pious Portuguese believe,

lieve, when water was wanted for mortar to complete the work. The capital of the same name contains four churches with a fortified castle, the residence of the governor; and it has a convenient and safe harbour, with good anchorage, in a bay at the mouth of a river of the same appellation. S. lat. $16^{\circ} 45'$. W. long. $40^{\circ} 46'$.

PORTO *Sigri*, a sea-port town on the N. coast of the island of Metelin, near cape Sigri.

PORTO *Symbolo*, a harbour on the coast of Natolia, in the gulf of Macri; 18 miles S.S.W. of Macri.

PORTO *Tigani*, a port on the S. coast of the island of Samos. N. lat. $37^{\circ} 44'$. E. long. $26^{\circ} 54'$.

PORTO *Vecchio*, a sea-port town of the island of Córfrica, (department of Liamone and district of Sartenc,) situated on a gulf on the E. coast, which forms a spacious harbour, in the midst of marshes, which render it insalubrious; 60 miles S. of Bastia. The canton contains 2515 inhabitants. N. lat. $41^{\circ} 25'$. E. long. $9^{\circ} 27'$.

PORTO *di Venero*, a sea-port town of Genoa, at the entrance of the gulf of Spezza; five miles S. of Spezza. N. lat. $44^{\circ} 5'$. E. long. $9^{\circ} 38'$.

PORTO *Vico*, a town of Italy, in the department of the Mela; 18 miles S.S.W. of Brescia.

PORTO *Vourcaria*, a harbour on the S. coast of the island of Samos. N. lat. $37^{\circ} 47'$. E. long. $27^{\circ} 1'$.

PORTODAL, or *Porto d'Ally*, a sea-port of Africa, in the kingdom of Baol, on the coast of the Atlantic; trading chiefly in hides, teeth, gold, and ambergris. N. lat. $14^{\circ} 36'$. W. long. $16^{\circ} 56'$.

PORTOIN, a town of Sweden, in the province of Wafa; 20 miles S. of Wafa.

PORTOISE, aboard a *Ship*, is the same with *port-last*, or the *gun-wale*; and as they say, *the yard is down a port-last*, when it lies down on the deck; so for a ship to ride a *portoise*, is to ride with her yard a *port-last*, or struck down to the deck.

PORTOLA, in *Geography*, a town of Istria; 10 miles S. of Capo d'Istria.

PORTOPENA, in *Ancient Geography*, a town of Asia, in the interior of the Perside, marked by Ptolemy between Axima and Persepolis.

PORTORARIUM, in *Anatomy*, a name given by some authors to the duodenum.

PORTORIUM, in *Antiquity*, a name given among the Romans to the duties laid upon merchandize brought through the gates of cities, and into sea-ports, or taken out of them.

PORTOSPANA, in *Ancient Geography*, a town of Asia, in the interior of Caramania.

PORTOZERO, in *Geography*, a town of Russia, in the government of Olonetz, on the river Andoma, near the Oneskoe lake; 20 miles S. of Pudoga.

PORTPATRICK, a sea-port town in the district of the Rhyns, shire of Wigtown, and ancient principality of Galloway, Scotland, is situated on the eastern coast of the Irish sea, at the distance of 132 miles S.W. by S. from Edinburgh. It is the nearest point of land in the island of Great Britain to Ireland, and is considered the best place for crossing from one kingdom to the other, the distance being only 21 miles. The etymology of its name evidently points it out as the port whence the celebrated St. Patrick sailed on his first holy mission to the country which afterwards adopted him as its patron saint; but other ports, both of Scotland and England, likewise claim this distinction. In several old charters it is called port Montgomery, from a family of that name, who possessed extensive property in the vicinity, and strove, in vain, to change its original designation. Portpatrick has the advantage of a fine southern

aspect; and being defended from the northern winds by a semicircle of small hills, enjoys a warmer climate than most places in the same latitude. It is an excellent sea-bathing place, and is much frequented during the summer months. Formerly the harbour here was a mere inlet, between two ridges of rocks which advanced into the sea; but now there is a very fine quay, which is accommodated with a reflecting light-house upon it; and four packet boats regularly sail between this town and Donaghadee, on the Irish coast, with the mail and passengers. Mail coaches are also established from Edinburgh and London to Portpatrick, and from Dublin to Donaghadee. The principal support of this place arises from the importation of black cattle and horses, and from the great concourse of travellers constantly passing here. Almost every house is an inn, where strangers may find accommodation adapted to their circumstances. A fishery was some time ago attempted here; but the velocity of the tide frequently carrying away the nets, operated so much to the discouragement of the fishermen, that it is now entirely abandoned as a branch of trade. A body of men, about twenty in number, act at the harbour as porters, and are distinguished by the name of the *robbery*, from their supposed depredations on the public; but though their impositions deserve reprehension, they are perhaps necessary evils at this port. It is remarkable that the sea ebbs and flows here nearly an hour later than at the opposite port of Donaghadee; and that a similar variation happens with respect to particular parts of the coast on the Scottish side. Within four miles of the Irish shore, when the flood returns, there is a regular current sets off rapidly for the mull of Galloway; it runs at the rate of seven knots an hour, and is so forcible, that when the wind opposes it, it exhibits for a great way the appearance of breakers. This circumstance rendered the harbour of Portpatrick formerly somewhat unsafe, especially when the wind blew strong from the west or north, but the inconvenience is completely remedied since the improvements brought about by the exertions of the late sir David Hunter Blair.

The parish of Portpatrick is about four miles and a half square, and contains, according to the parliamentary returns of 1811, 247 houses, and 1302 inhabitants. The surface is uneven and hilly, and consists of a great proportion of moor-land. The only remain of antiquity within its boundaries is Dunskey castle, which stands about half a mile from the town of Portpatrick, on the edge of a tremendous precipice, or rocky cliff, projecting into the Irish sea. At what period the present structure was erected, is uncertain; but we learn from history, that the spot on which it stands was fortified with a castle as early as the year 685, when Eugene V. began his reign. This fortress was defended on the land side by a deep ditch, now nearly filled up, over which a drawbridge was thrown. The buildings occupy the whole breadth of the cliff in front, but there is an area or parade behind about twenty yards broad. Adjoining to Dunskey is a cave, which has long been held in superstitious veneration by the people. At the change of the moon it is usual to bring, even from a great distance, infirm persons, and particularly ricketty children, whom their parents often suppose bewitched, to bathe in the stream which pours from the hill, and then dry them in the cave. Beauties of Scotland by Rob. Forsyth, vol. ii. Carlisle's Topographical Dictionary of Scotland.

PORT-RAFT. See RAFT.

PORTRAIT, from the French verb *peindre*, to draw or paint; a representation of any specific object in nature, as a man, a horse, a tree, &c. &c. Although this word is equally applicable to all pictures imitative of peculiar objects,

objects, yet, when used simply and alone, it is generally considered as allusive to those of the human face or figure. When any other productions of nature are represented, we commonly add its name in description; as a portrait of a horse, of a dog, of a tree, &c., and this distinction arises solely from the painter being called upon more frequently to exercise his art in imitation of his fellow mortals, than upon any other subject.

PORTRAITURE, the art of painting portraits. This peculiar application of the art of painting constitutes one of the four grand divisions of its exercise; the others being history, landscape, and still life.

As we have above observed, portraiture is principally considered as applied to the human form; and as the principles upon which the just imitation of all other natural productions ought to be conducted, are necessarily included in that of the most beautiful and variable among them, we shall confine our remarks to that peculiar application of it.

In contradistinction to the grander elements of historical art, which demand only a representation of generic form, and of actions and expressions descriptive of the various classes of mankind, to the exclusion of individual varieties, merely as such; those of portrait painting, moving in an opposite course, have the meaner varieties for their basis; and we can only attempt to add dignity and beauty, so far as will still leave a just and distinguishing character of imitation, in a perfect and full resemblance of the peculiarities of the individual selected.

Portrait painting, when justly considered and executed, is not, as may be imagined, a tame business of imitation, a mere laborious exactness in copying the precise form which is placed before the artist. Mere likeness is a matter produced, as we see every day, by the dullest of the dull; or by men who will copy to deception the turn of a hair, or the folds of drapery. But while such artists make the features of exact form, they leave them void of animation, of just colour, or of any degree of sense or sentiment; and instead of exhibiting taste or grace in the drapery, present us with a correct list of folds, duly connected indeed, but very fortunately arranged in the models, if they convey any just idea of the form beneath; or more particularly if they display it with propriety or beauty.

Imitation is, however, the true and only sound foundation of painting; but in the higher branches of the art, it must be accompanied by selection, and conducted upon a system subjected to the demands of character, of expression, and locality. In portraiture it will be found that the same principle of selection must be exerted, when works, really excellent, are hoped for; though a more precise degree of it be required, maintained within narrower bounds, and more exactly balanced.

It is a very mistaken notion, therefore, although exceedingly prevalent in the world, and apparently just, that likeness depends upon the representation of every minute undulation of line in the features, or variety of colour, even of those which are considered as defects; such as spots, moles, wrinkles, &c. &c.; and the portrait painter has not a greater torment to endure, than the perplexities in which he is constantly involved by the weak interference of friendly visitors, who desire to be indulged with seeing such absurd and useless things attended to; so diametrically is that trifling at variance with his own knowledge, that they rather tend to weaken, than increase, the general and interesting points of resemblance. Yet disinclination to bend his judgment to this caprice, is considered as arising from conceit or obstinacy, and an unwillingness to oblige; and the very circumstance which he feels, and which ought to obtain for him most

estimation, loads him with unfavourable opinion, and retards his success; even obstructs the free exercise of his imagination, and prevents the indulgence of those feelings, which, unrestrained, might, in the end, afford more gratification to his employers, than the most minute attention to their untutored wishes possibly can.

The great delight afforded by sir Joshua Reynolds' portraits, rests upon this enlarged principle of imitation; yet who will say they lack identity? or that they do not exhibit it more fully, than was ever done by the works of any other artist? Witness his pictures of the duke of Orleans, lord Rodney, lord Ashburton, bishop Newton, and numbers of others which the world has lately seen exhibited. He, fortunately, both by talents and exterior circumstances, was enabled to act upon his own exalted principles; and not content with the practice alone, has, in his eleventh discourse, told us, that "the excellence of portrait painting, and we may add even the likeness, the character, and countenance, depend more upon the general effect produced by the painter, than on the exact expression of the peculiarities, or minute discrimination of the parts."

Likeness is, however, the object and end of portrait painting; and the question, therefore, arises,—What are the main points to which the artist's attention must be directed to ensure success? We answer,—Proportion, air, or action, colour, and expression. The first of these, necessarily including form, is of the utmost importance, and, when considered in all its bearings, a "fine qua non" in the practice of this branch of the art; with which alone, should the other qualities lack somewhat of their utmost perfection, the work may be redeemed, by retaining somewhat of character at least; as we frequently see exemplified in caricatures, where no precise correctness of form or colour is maintained. It is by this quality principally that we recognise our friends at a distance, before a feature is distinctly visible, and while they are at rest; but aided when they are in motion, by their peculiar modes of action. This is the principal medium by which corporeal resemblance is attained; and then follow the mental agents, air and expression.

The mode in which a man turns his head, or disposes of his limbs, either in action or at rest, is not unfrequently quite peculiar to himself; and when it is not of a nature too far diverging from what is agreeable, it is certainly desirable that it be retained in a portrait. Even extravagant peculiarities may frequently be so modified by the hand of taste, as to become picturesque, and even agreeable. All depends upon the selection of the moment, the direction of view, and the chiaro-scuro. At any rate, all set actions, not founded upon the character, either mental or personal, of the subject, ought to be avoided.

The selection of actions characteristically appropriate to his sitters, forms a grand feature in the practice of our great artist above-mentioned; and perhaps if there be one thing more than any other which elevates him above all other portrait painters, it is this very peculiar circumstance, by which we are more immediately informed of mental character, than by physiognomical traits alone. In Vandyke's pictures generally, and in many of Titian's, the actions of the figures seem to have been the offspring of study, rather than of nature; to have been composed, not selected; formed rather to shew the figures than the characters of the subjects; and were probably arranged without them. In those of sir Joshua Reynolds, on the contrary, in most cases where there was any character to display, the actions appear so congenial to the known characters of the subjects, that we conceive them to have been their own; seized in happy moment, and rendered permanent by his clear perception,

PORTRAITURE.

and consummate judgment. We would strongly recommend this practice to all artists; but it must of course be subject to some judicious controul. A hint of the general line of an action may be taken, its character being improved in composition, by slight variations, and by well-managed illumination; and in pursuing this system, one very great advantage is acquired, which is, that the action being natural to the man, an unconstrained expression of features will be found to accompany it; and thus his natural character will be most easily and most effectively displayed.

It is not always, perhaps not often, that a portrait painter enjoys the opportunity of knowing enough of his subject, or sees enough of him, to avail himself decidedly of his natural propensities. In many cases, on the very first introduction, a sitting takes place; and then the only means of studying the character is by making unnoticed observations on the general manner of carriage, or of expression, by prolonging discourse before the sitting, by making occasional interruptions, and by throwing objects of attention in the way, which may in some measure elicit an unconfined freedom of action. But it is only by doing this unobtrusively, that actual character can be discovered. The instant a person is aware that he is noticed, farewell to nature: restraint immediately usurps dominion, and baffles the most quick and intuitive perception. It will happen, however, very frequently in this portrait painting age and country, that those who, by the calls of affection or of vanity, become subjects for the painter, have no decided stamp of character, which sufficiently distinguishes them from their fellow-mortals; and in these cases, the painter is entirely at liberty to choose his own action, and indulge his fancy, according to the sex, the age, and quality of his employer. His object, of course, will be to make it as agreeable as possible; to place it in the light most favourable to beauty, or force; and to make amends, as well as he can, for the deficiencies of his model, by a skilful application of the general principles of his art.

It is scarcely necessary to say, that different ages require different actions. It must be felt by all, that the aged should be represented calm, serious, and dignified; and may be so placed as to receive great strength of illumination, with beneficial effect: whilst the young should be animated and graceful; and they will produce more agreeable models for the pencil, if illuminated with a weakened tone of light, which softens the harsher projections of feature, and adds gentleness to beauty.

In conjunction with the character of mind, conveyed by the action of a portrait, should be the expression of the features, singly and combined; and herein lies the greatest difficulty the artist has to contend with: consequently he is the most worthy of praise as a painter of portraits, who succeeds in this arduous task, the stumbling-block of thousands; for which no efficient rules can be given, since it is the offspring of feeling alone. From the want of this feeling arises the dissonance, and even distortion, so often visible in portraits, where the features individually are correctly drawn, and exquisitely coloured. In some we see displayed a mouth contracted by melancholy, united to eyes sparkling with enjoyment; or a brow elevated by sentiment, with cheeks and lips inanimate and dull. In others, a head or hand raised or advanced with energy, while the features are lifeless; or the nostrils dilated as with passion, but the eyes uninfluenced, and the mouth closed or opened by stupidity itself. These are errors which arise from an artist copying what he sees at various times, without reference to the whole; without being guided by a spirit of unity; and attempting to give animation, without judgment: errors

which unfortunately cannot be remedied, or prevented, if nature has not implanted the sense to feel the indispensable nature of the union required, and understanding to apply it. The study of physiognomy is perhaps the best guide to its acquirement, or rather for the improvement of those who possess it.

Oftentimes the best attention of the skilful painter will be foiled, by want of co-operation on the part of the sitter; and he will be obliged to combine his expression, more from a conception of what properly belongs to the person he has before him in general character, than from what he immediately sees, unless assisted by some fortuitous circumstance. Indeed it is upon such a possession of character in the artist's own mind, that he must principally depend in this point, even under the most favourable circumstances. The living model varies too much during a sitting, both mentally and physically, to allow of mere copying; and whenever any very marked or peculiar expression is required, the general impression must be the governing principle in effecting its representation. The artist, therefore, should be very careful and minute in observation of the first favourable moments of an action or expression, when the mind of his sitter is animated, and his person alert and untired; before that weariness, which necessarily takes place when the mind is unengaged, and the body confined to one action, has displayed its influence, and destroyed the energy of the expression.

One prime object of attention more immediately required by portrait painting is colour, in which a more precise imitation of individual nature is of necessity demanded, than will answer the purposes of historical painting. Yet, although the peculiar varieties of hues and tints in complexion must be produced, in order to give correct resemblance, still somewhat of general system may be admitted in the management of them, as well as in drawing, not only without detriment, but with considerable advantage. This may be done by making the general tone of colour the governing principle, and avoiding too perplexing a degree of attention to the more minute transitions of hues; by employing such a degree of generalization as takes place when the object is removed from a very close inspection, or a very brilliant degree of illumination. It then approaches the character of historic colour, and is certainly an elevated mode of treating portraiture, if truth be the companion of the simplicity it generates. Indeed it is next to impossible to copy exactly the astonishing varieties of nature seen in a healthy, or even in a delicate complexion; and the attempt very frequently destroys the form, and weakens the impression of the whole. The best practice of the best painters agrees with this principle; of Titian more particularly. But individuality, it must never be forgotten, is the indispensable requisite of portrait painting, and must therefore be perfectly maintained; in proportion absolutely; in action, in expression, and in colour, whatever may be omitted or introduced to improve or exhibit a subject to the best advantage; whether the distance of the view be enlarged, to simplify or generalize the effect; or the quantity of illumination and management of *chiaro-scuro* be regulated, to produce beauty or force; under all circumstances, the peculiar character of the sitter must controul the pencil of the artist, and limit the bounds of his imagination.

The principles upon which colouring in portraiture depends, and the technical mode of producing it, are necessarily the same as in painting all other subjects, and are elsewhere discussed. See COLOURING, HARMONY, and HALF-TONE, in *Painting*.

By acting upon general principles of the art, when individual

PORTRAITURE.

dual representation is the object, is engendered that kind of imitation which is called flattery, but which does not deserve that appellation, unless those principles are carried to excess; and that is too frequently most imperatively demanded of an artist who depends for subsistence upon the pleasures he affords the public. Gay's ingenious fable of the painter who pleased nobody and every body, is so nearly allied to facts, so exactly drawn from what is occurring every day, that, substituting names, it may be regarded as a piece of history far too true for sensible delight. Yet something of this "key to recesses of folly and pride" seems absolutely necessary; as far, at least, as may be produced by a combination of the most favourable turns of feature, and hues of colour, belonging to the subject; or relieving those parts which are most agreeable, and presenting them to the eye with as much advantage as possible; and losing such as are less pleasing in the ground of the picture. It is surely no great violence to nature, if an artist can take a review of former years, and in painting the portrait of a lady past the meridian of beauty, repair a few of the depredations committed by the ruthless hand of time, and restore her somewhat of the bloom of youth: or if, in the portrait of a man of renown, he adds a little more elevation of external appearance than may generally be displayed by the original: provided he take care, that the addition or omission he makes be congenial to the character of the subject, whatever that may be. The artist has this only way left him, to combat successfully with reality; with the advantages of motion, sense, and substance enjoyed by the living subject.

It requires much dexterity, however, to wield so dangerous yet necessary an instrument with success; and nothing is more common than to see it abused; employed to the destruction of a reputation for beauty or sense; exciting expectations which are disadvantageous to the original, and rob the natural face of its just praise or estimation, by representing too captivating an image. As it is frequently practised, even by able hands, it becomes a discreditable means of indulging vanity in the sitter, or conceit and bombast, if we may so speak, in the artist; or at best, on his part, an artful means of promoting interest at the expence of honesty, by soothing and cherishing the overweening self-love of his employers. The object in these cases seems to be, to produce a rich piece of furniture, pleasing to the eye; rather than a just representation of character, interesting and attractive to the heart.

But all pictures intended for ornament, or to excite agreeable sensations, ought to be pleasing and captivating to the eye! Granted. Yet surely it is not necessary for this end that fictitious appearances should be resorted to! that a man of humble and meek demeanour should be exhibited attempting to ape the bolder and more determined of his fellow men in action and expression! That one of a station in the middle rank of life, should be placed in a colonnade, and surrounded by the rich trappings of nobility or royalty, merely to afford an opportunity of introducing rich colours and brilliant chiaro-scuro, &c. &c. till station, rank, and character, become confounded.

Such, nevertheless, are the errors into which portrait painters, who forsake the just object of their profession, are constantly falling. If invention were justly applied, it would surely provide actions and expressions appropriate to the subject, rather than assume artificial ones; and find proper accompaniments, which, without lowering the rank or character of a man, or indeed rather elevating it, would at the same time become his station, and illustrate his peculiar capacity and inclinations. These being arranged with skill, and assisted by an ingenious management of chiaro-scuro, may

at all times be made to produce an agreeable effect. Much of the odium which attaches to the innumerable instances of this species of folly, (with which our exhibitions so frequently present us,) must, however, be removed from the shoulders of the painters, and placed to the account of that idle vanity of emulating appearances which unfortunately prevails in the world, and asserts its influence in this, as in other matters, counteracting the suggestions of reason and propriety.

In all the surrounding parts of a portrait, or those which constitute the ground from which it is relieved, or by which it is accompanied, the same knowledge of nature and of art is required for their introduction and management, as in the composition of an historical picture; but with this disadvantage to the portrait painter, that he is less at liberty to choose his materials than his rival in history; and has too frequently to work up to an uninteresting principal object, which it must be his aim to set off to the best advantage. All the technical knowledge and skill which can avail in the art, as employed in imitating every branch of nature, is required of him; and the difficulties he has to encounter fall short of those opposed to the progress of the historical painter, only in the labour of balancing extended compositions, and producing varieties of expression: in lieu of which, he has to overcome the arduous task of relieving and supporting a single figure with becoming grace or dignity, of displaying its appropriate character, and decorating it with suitable accompaniments. Oftentimes he has to render it historical, and display some particular event by action, by expression, and the introduction of explanatory matter.

On the whole, from a little reflection upon the difficulties which encompass the path of the portrait painter, it will be seen, that if he be exempt from the necessity of that general study of human nature which is required of him who undertakes to illustrate the pages of history, or embody the more fascinating illusions of poetry; he is not less called upon for exertions in other matters, which require a mind as fertile in expedient, as assiduous in labour. Nor are his productions less interesting, when we consider the object of his study as attached to the preservation of that remembrance we all love to cherish of the great and good, the wise and the beautiful; of those who in their lives made the happiness of their fellow creatures the object of their contemplation, and left them lessons of instruction, or were the sources of delight and admiration. Not to mention the more confined and individual gratification which parents, children, relatives, lovers, friends, derive from his art; the endearing sensations of affection, or of gratitude, which it is his delightful business to cherish: or the useful emulation so often excited by recollections of character, aided by so much of personal acquaintance as a portrait presents, when the original no longer enlivens society.

Most of the renowned painters, both of ancient and modern times, have blended the peculiar practice of portraiture with their other studies; and some have devoted their time to it as a principal object of attention.

Among those whose talents assisted to embalm the memory of ancient Greece by the cultivation of this delightful art, the names of Panæus, Polygnotus, Apelles, Aristides, and some few others have escaped oblivion: but unfortunately we enjoy only their renown; and must be content to form a judgment of their merits through the feelings and language of others. By the authors who mention their works, we are led to believe that they carried portraiture to the utmost degree of perfection; particularly Apelles, in honour of whose transcendent abilities, the whole vocabulary

lary of eulogium has been exhausted. See PAINTING, *History of*.

On the revival of the art of painting, in the thirteenth century, portraiture soon became an object of attention, since we find that Giotto, who died in 1336, practised it with very considerable success; and to him we are indebted for the portraits of many of the most conspicuous characters of his time. His historical pictures, as well as those of Massaccio, and all the older artists, are full of figures which bear every appearance of portraits, and some are known to be such. Most probably they painted from those heads of their friends, which suited the character they wished to introduce; and certainly that is a means of obtaining a greater degree of natural expression than mere fancy can supply. Raphael in his greatest work, the labours of the Vatican, employed the same means. Engaged by Julius II. and Leo X. to adorn the pontifical palace by the exercise of his extraordinary talents, and to celebrate the principles and triumphs of the Christian church, he did not lose sight of the renown due to such munificent patrons; and by introducing their portraits in the series of pictures he there painted, cancelled in measure the obligations conferred upon him and the art, and secured to them a portion of his own immortal fame. Many portraits of the cardinals and nobility of Rome, who were either immediate friends of the artist or promoters of the work, were also admitted; but it must be acknowledged that the anachronisms created by it, are frequently offensive to the judgment, since it is scarcely possible to separate the ideas associated with the figure of one man, whose history we are acquainted with, and imagine it to be the image of another of prior date, and character totally distinct. When portraiture is attached to an historical subject, and the real actors of the scene are introduced, it then adds a tenfold interest to the work; but in doing this, great care must be taken to treat the portraits themselves in a manner correspondent to that dignified and free style of design required of historical painting; with the omission of the minuter parts, and displaying only the distinguishing and characteristic features and forms. Both the Roman and Venetian schools have produced numberless works abounding with the anachronisms we have above-mentioned, but great examples never justify false principles, or improper conduct; and happily more modern art is free from this impurity at least.

It was not in historical pictures alone that Raphael practised portraiture, he has also left us several superior examples of portraits specifically such, of which those of Leo X. and of Julius II., in the gallery of the Louvre, demand the warmest praise for their individuality, dignity, and character. His works of this kind, however, were but few, compared with those of his great contemporary Titian, who is generally regarded as the father and head of this peculiar branch of the art, having executed it with a greater mixture of truth, simplicity, and grandeur, than any other. Giorgione died so young, that his productions in portraiture are necessarily few; but some of those are exquisitely beautiful; witness the small picture he painted of Gaston de Foix, and a servant putting on his armour; formerly in the Orleans gallery, but now in possession of the earl of Carlisle.

Lionardo da Vinci, Sebastian del Piombo, and most of the men who obtained celebrity at the period when the art of painting flourished in Italy, attended to portraiture, and there are very few of whom some examples do not remain; but the number of those who attached themselves to it entirely was small. In Spain, Velasquez attained a degree of perfection nearly rivalling Titian; but we have very few of his works in England: more rich in the labours of Vandyke,

we are better enabled to appreciate his powerful taste and talents, and may well boast of the treasures we possess, wrought by his inestimable skill. Next to him, Holbein, Janfen, More, Lely, and Kneller, are the names of those most estimable for their portraits, among the number of artists with which this country has abounded from the days of the former, till the sun of our pictorial hemisphere arose in Reynolds, the father of British art; of whom it may be doubted whether the art he displayed in uniting taste and truth, with style and effect in portraiture, in a degree far surpassing any other painter, added to a just feeling of character, does not more than counterbalance acknowledged deficiencies in drawing, and sometimes in execution; and decidedly place him at the head of this branch of the art of painting.

PORTREATH, in *Geography*, a small bay of England, on the N.W. coast of the county of Cornwall; about five miles N. of the town of Redruth. See REDRUTH.

PORTREE, or PORT-A-ROI, *i. e.* the King's-harbour, is a parish in the isle of Skye, Scotland, in the presbytery of Skye, and synod of Glenelg. The resident population in 1811 was 2729: the parish is about nine computed miles in length, by three in breadth, and its surface is diversified with hills, vallies, and plains. On the eastern side of the island the coast presents a very rugged appearance, and in many places the cliffs are nearly perpendicular. In these rocks are many caves of great extent and dimensions. A remarkable hill in this parish, called *Ait Suidhe-Thuin*, *i. e.* Fingal's sitting-place, is of rugged form, and commands very extensive prospects, in every direction. In the fresh-water lakes of Loch-fad, Loch-leathan, or the long and broad lochs, are abundance of white and red trout, flounders, and eels: the discharged water from the latter lake falls over a high and steep precipice, and constitutes a grand cascade. Here are two forts attributed to the Danes, and an old castle, formerly the seat of the lords of Raafay. Game and wild fowls are abundant here. King James I., when he visited these islands, anchored in this port, and hence arose the present name. In this village are held two annual fairs, in May and July, and are generally continued for several successive days. These are very much frequented, and at both a great number of black cattle is disposed of. In the parish are four places of worship, but only one church, which was built in 1726, when the parish itself was first constituted. Carlisle's Topographical Dictionary of Scotland, vol. ii.

PORT-ROPES, in a *Ship*, those which serve to haul up the ports of ordnance.

PORT-ROYAL, a term that makes a considerable figure in the republic of learning. Its origin is this:

Philip Augustus, wandering from his company in hunting, near Chevreuse, westward of Paris, found a little chapel, where he put up, expecting that some of his attendants might meet him. This happening accordingly, he gave the place the name of the *King's port*, *Port du roi*, or *Port-royal*; and, to give thanks for his deliverance, he resolved to erect a monastery there.

Odo, bishop of Paris, apprised of his intention, prevented him; and, with the concurrence of Mathilda, wife of Matth. Montmorenci, first lord of Marly, built a nunnery in 1204, filling it with Cistercians, who continued under the jurisdiction of the general of that order till the year 1627, when they were removed to a house given them in the Fauxbourg St. Jacques, at Paris.

In 1647, they quitted the habit of Cistercians, and embraced the institution of the perpetual adoration of the sacrament. The same year the archbishop of Paris allowed them

them to remand some of their religious to their former abbey, and to re-establish the same.

Some time after, the formulary of Alexander VII. being appointed to be subscribed throughout the kingdom, the religious of Port-royal in the city signed it: those remitted to the former abbey scrupled it extremely, and, at last, only signed it with great restrictions.

Still persisting in the same sentiments, the king finding no way to reduce them but by dispersing them, that was executed in 1709, and the revenues given to the other monastery.

Upon this evacuation, several ecclesiastics, and others, who had the like sentiments with regard to the subscription as the religious, retired to Port-royal, and had apartments there; and there published several books, both on the subject of this dispute, and other topics; whence all that adhered to that party took the name of *Port-royalists*; and their books, *books of Port-royal*.

Hence we say, the *writers of Port-royal*, *Messieurs de Port-royal*, the translations of *Port-royal*, the Greek and Latin methods of *Port-royal*, which are grammars of those languages.

PORTRUSH, in *Geography*, a small fishing town of the county of Antrim, Ireland, near the mouth of the river Bann. It is on a small peninsula, which is very interesting to the geologist, and is five miles from Coleraine.

PORT-SALE, a public sale of goods to the highest bidder. Port-sale, in the stat. ann. 35 Hen. VIII. cap. 7. denotes the sale of fish presently upon its arrival in the port or haven. It also signifies a sale of goods upon the key.

PORTSBOROUGH, or **PORTSBURGH**, in *Geography*, in the parish of St. Cutlibert and shire of Edinburgh, Scotland, is a burgh of barony, with peculiar and separate jurisdiction and privileges, although only a suburb to the city of Edinburgh. Its origin is said to have been owing to the king's stables and a chapel, which were formerly standing here, and of which some vestiges remain. Near them was a royal tilting ground. The districts of Portsborough and Potter-row, forming one jurisdiction, are governed by a baron, one of the magistrates of Edinburgh, and two bailiffs, his assistants, who are appointed by the common-council of Edinburgh. In their court of barony, these officers try all causes, both civil and criminal, except capital offences. Besides these officers the following also belong to this district: a town-clerk, a fiscal, two constables, and two sergeants, or town officers. In this neighbourhood are two ancient buildings, called Wrights-houses, and the mansion house of Marchilton. The latter was the seat of the celebrated John lord Napier, baron of Marchilton, well known for his admirable discovery of the logarithms; and to whom, says Hume, "the title of great man is more justly due, than to any other whom his country ever produced." Carlisle's Topo. Dict. of Scotland.

PORTSEA, an island of England, about 14 miles in circumference, between Portsmouth harbour and Langston harbour; separated from the main land of Hampshire by a narrow channel, over which is a bridge. In this island are Portsmouth and Portsea.

PORTSEA. See **PORTSMOUTH**.

PORTSMOUTH, a town of America, the metropolis of New Hampshire, in the county of Rockingham, and the largest town in the state, and its only sea-port, situated about two miles from the sea, on the S. side of Piscataqua river. Its harbour is one of the best on the continent, having depth of water sufficient for vessels of any burden, so defended against storms by the adjacent land, that ships may securely ride there in any season of the year; and not liable

to be frozen. It is almost impregnable by its natural situation. A light-house stands on Newcastle island, at the entrance of the harbour, in N. lat. 43° 5'. W. long. 70° 41'. Ships of war have been built in this place. Portsmouth contained 6934 inhabitants in 1810, three congregational churches, one episcopal church, one for Universalists, a state house, a school-house, a work-house, and two banks. The town was incorporated in 1633, 10 miles S.W. of York, 22 N. of Newbury-Port, 65 N.N.E. of Boston. N. lat. 43° 3'. W. long. 70° 45'.—Also, a township of good land on the N. end of Rhode island, Newport county, containing 1795 inhabitants; on the road from Newport to Bristol.—Also, a small sea-port town of North Carolina, in Carteret county, on the N. end of Corebank, near Ocrecock inlet; chiefly inhabited by fishermen and pilots.—Also, a post-town, pleasant, flourishing, and regularly built, in Norfolk county, Virginia, on the W. side of Elizabeth river, opposite to Norfolk and a mile distant from it; both which constitute one port of entry. In 1810 it contained about 300 houses, and 1702 inhabitants, including 1616 slaves, 111 miles E. by S. of Petersburg.—Also, a town on the N.W. side of the island of Dominica, in the West Indies, in Prince Rupert's bay, between the salt-works and the coast. N. lat. 15° 41'. W. long. 61° 18.

PORTSMOUTH, a large borough, sea-port, and market-town, including within its jurisdiction the town and parish of Portsea, is situated on the isle of Portsea, on the coast of the English channel, in the hundred of Portsdown and county of Southampton, England. It is distant 18 miles S.E. by E. from Southampton, the county town, and 73 miles S.W. from London. According to Camden, its origin was owing to the retiring of the sea from the upper parts of the harbour, which rendering Portchester less convenient, the inhabitants removed hither and built Portsmouth. The earliest historical notice of it occurs in the Saxon chronicle, A. D. 501, when it is mentioned by the name of Portesmuthe, as the place at which a Saxon chief, called Porta, landed, in order to assist Cerdic in the subjugation of the Belgic provinces in England. Here also Robert, duke of Normandy, disembarked a strong army in 1101, with the intent of disputing the succession to the throne with his brother king Henry I.; but the interference of the great barons forced him to relinquish his design and agree to terms of conciliation. About this period Portsmouth seems to have attained a considerable degree of importance, as it appears from history that the monarch last mentioned passed the Whitsun-week here in 1123; and that the empress Maud landed at this port with her brother Robert, earl of Gloucester, in 1140, when she came to force king Stephen to resign his usurped sovereignty to its rightful possessor.

The first charter to this town upon record was granted in 1193, by king Richard I., in which, after declaring that he retains *Portesmue*, he confers upon the burghesses an annual fair for fifteen days, and a weekly market, together with all other immunities enjoyed by the citizens of Winchester and Oxford. As a consequence of this charter, the inhabitants requested the presence of the itinerant justices, and presented Henry III. with three casks of wine, in order to prevail on him to command their attendance. About the commencement of the succeeding reign, the French, jealous of the growing trade of this town, attacked and burnt it; but it gradually revived from its embers; and in the reign of Edward IV. had again risen to such importance, that he began to secure it by fortifications, which were carried on and greatly extended by his successor, Richard III., who, though generally represented as a bloody tyrant, was unquestionably

PORTSMOUTH.

tionably a wife and politic monarch. From that period Portsmouth increased rapidly both in strength and importance, till, in the reign of Henry VIII., it had become the principal naval arsenal in England. Leland, who visited it in this reign, describes it as follows in his Itinerary: "The land heere, on the est side of Portesmuth haven, rennith farther by a great way strait into the se, by south-est at the haven-mouth, than it doeth at the west poynte. Ther is at this point of the haven Portesmuth toun, and a great round toure, almost doble in quantitie and strenkith to that that is on the west side of the haven right agayn; and heere is a mighty chayne of yren, to draw from toure to toure. About a quarter of a mile above this toure is a great dok for shippes, and in this dok lyeth part of the rybbes of the *Henry Grace of Dieu*, one of the biggest shippes that hath been made in *hominum memoria*. Ther be above this dok crekes in this part of the haven. The toun of Portesmuth is murid from the est tour a forough length with a muddle waulle armid with tymbre, whereon be great pieces both of yren and brazen ordinauns; and this piece of the waulle having a ditch without it rennith so far flat south-south-est, and is the place most apt to defend the town ther open on the haven. Ther rennith a ditch almost flat est for a space, and wythin it is a waulle of mudde like to the other, and so theus goith round aboute the toun to the circuit of a myle. Ther is a gate of tymbre at the north-este end of the toun, and by it is caste up a hille of erth ditched, wherein be gunnes to defend entre into the toun by land. Ther is much vacant ground within the toun waulle. Ther is one fair stret in the toun from west to north-est. I lernid in the toun that the toures in the haven-mouth were begon in king Edwarde the 4th's time, and sette forward in buylding by Richard the 3d. King Henry the 7th ended them at the procuracion of Fox, bishop of Winchester. King Henry the 8th, at his first warres into Fraunce, erected on the south part of the toun three great bruing houses, with the emplements to serve his shippes at such tyme as they should go to the se in time of warre. One Carpenter, a riche man, made of late tyme in the mydle of the High-streate of the toun, a toun-houfe. The toun is bare and little occupied in time of peace."

Henry VIII. was the first monarch under whom the English navy obtained a systematic establishment; for though his predecessor had made Portsmouth a royal dock, and had built the ship called *the Great Harry*, yet he continued the old practice of applying to the merchants, and to the different ports of the kingdom, for the supply of ships wanted for the public service. That custom Henry abolished, and rendered the building and equipment of the national fleet a public concern. For this purpose he erected a navy office, and ranged all his ships into different classes, keeping a regular inventory of them and of the various stores. (See Derrick's Memoirs, &c. of the Royal Navy, 4to. 1806.) In his reign Francis I. of France attempted the destruction of Portsmouth; but the armament which he dispatched on the enterprise was so gallantly received by the English fleet lying at anchor off Spithead, that after a series of attacks, during two days, it was forced to retire without effecting its errand. In this engagement the English lost one of their largest ships, which was commanded by sir George Carew.

Even in the time of Edward VI. Portsmouth was the only dock-yard that could be considered as a national one; indeed, it was almost the only naval station in England. All the ships in the public service, amounting to fifty-three in number, lay in this port, with the exception of three, two of which lay at Deptford and one at Woolwich. The crews belonging to these vessels, including soldiers, marines,

and gunners, did not amount to 8000 men; yet from such beginnings has the naval power of England risen to a height unparalleled in the history of the world. Edward, sensible of the great consequence of this port to the future glory of his kingdom, augmented its fortifications by the addition of two strong castles. In the time of Charles I. some improvements were likewise made in the defences of Portsmouth; and here the armament, destined to relieve the Protestants in Rochelle, assembled under the eye of the king's favourite, the duke of Buckingham, who was assassinated in a house in High-street by Felton, a lieutenant in one of the regiments ordered for embarkation.

During the civil wars, this town was garrisoned for the parliament. Charles II., who married here Catharine, infanta of Portugal, greatly enlarged its fortifications, particularly by surrounding South-sea castle with a kind of star fort. William III. also made considerable additions to the works; and since the year 1759, when the star fort was nearly destroyed by an accidental explosion, several grants have been made by parliament to repair the fortifications, and render them more complete. The most recent additions are the fortifications on the Portsea side; and here the line is so well secured, that the approaches of an enemy can only be made in front; and even there but on few points. From the elevation of the works, the whole adjacent country is commanded by them; the ditches are wide and deep, and the entire line is further secured by strong and capacious outworks. At the head of the creek which separates Portsea from Portsmouth, is an extensive ravelin, connecting these works with the fortifications of the latter town, which extending along the beach to South-sea castle, form a noble semicircular terrace, upwards of a mile in length.

Early in the last century, the scite within the then fortifications of Portsmouth having become too limited for its increased population, an open common on the north side of the town was chosen as a convenient spot for the erection of additional buildings. As these became inhabited, more were constructed, till at length the offspring outgrew its parent town, and assuming consequence with extent, discarded its original appellation of "Portsmouth Common," and acquired, under the sanction of the legislature, the title of "The Town of Portsea;" but it is properly only a part of Portsmouth, being locally situated within the borough, and subject in every respect to the jurisdiction of its magistracy. It is, however, unquestionably the more important division of the town, for though, from its greater antiquity, Portsmouth preserves its dignity and precedence in still being the seat of the civil and military establishments, and the residence of the port-admiral, Portsea has the advantage of having both the dock-yard and the gum-wharf within its precincts. The first, which must be considered as the germ of all the modern consequence of the port, is of great extent, and contains within its boundaries every article which can possibly be wanted for the supply of the navy. It is entered from the town by a lofty gateway, after passing which, the first objects that attract attention, are the porter's residence, the malt-houses, and a large modern guard-house. A little further on stands the pay-office; and beyond it is the royal naval academy, which consists of a centre and two wings. This building is furnished with every requisite accommodation for naval instruction, and has an excellent observatory on its summit. The commissioner's house next appears, and to it succeeds an immense range of store-houses, to the right of which is a handsome modern chapel; thence a visitor is generally conducted through the anchor-wharf, where hundreds of anchors of every size and description

PORTSMOUTH.

description are piled up ready for immediate service; then to the rope-house, a spacious pile three stories high, 54 feet broad, and 1094 feet long. Here the cables are formed with immense labour; but of late years the operation is much facilitated by the use of machinery. The operations in this division of the yard are particularly ingenious and highly interesting. Leaving it, and passing various store-houses, stables, and other buildings, and many vast piles of timber for the service of the yard, a sort of square presents itself to the view, and displays in its centre a statue of William III. in a Roman habit. On the east side of this square is a row of handsome houses appropriated for the residence of the chief officers of the yard, and on the north and south sides are various offices, store-houses, &c. Proceeding onwards, the next impressing object that arrests the attention, is the vast building called the anchor forge, and on entering it, both the eye and ear are confounded by the terrific noise and cyclopean scenes, which spread throughout this Vulcanic abode. Many of the anchors which are here wrought weigh from 70 to 90 tons each. Approaching nearer to the harbour the visitor now beholds numerous ships of war upon the stocks, either building or repairing; a sight peculiarly calculated to excite the most lively interest in the breasts of all Englishmen, who feel solicitous about the safety and the glory of their native country. The jetty heads, with the basins and docks, are next in order, and, with the shipping in the haven, present a very grand and imposing spectacle, to which the extraordinary capaciousness of the new range of docks greatly contributes. These immense works are all peculiarly adapted for their respective purposes, and while the ships are under repair are kept completely dry; but in their immediate vicinity, the depth of water is sufficient to float the largest vessels in the navy. Many other parts of this celebrated arsenal, and particularly the rigging houses, claim the examination of the curious, but our limits forbid us even to mention them in detail. The number of workmen employed in this dock-yard is very great, but varies considerably. In time of peace seldom fewer than 2000 are kept at constant work in its different departments; and during war this amount is frequently doubled, and even tripled. The officers, who have regular appointments, are a commissioner, with three clerks, a clerk of the cheque, a store-keeper, a master shipwright, a surveyor's clerk, two master attendants, an extra master attendant, three assistant master shipwrights, a clerk of the rope-yard, a master rope-maker, a boatswain, a purveyor, a master boat-builder, a chaplain, surgeon, &c. Here, as at Plymouth, the workmen receive sixpence a day as a commutation for their former perquisite of chips.

Notwithstanding that every precaution that can be devised is taken to guard against the destructive element of fire, three great conflagrations have occurred in this dock-yard since the year 1760. The first, which appears to have been accidental, broke out in the night of the 3d of July, 1761, and raged for a long time with dreadful fury. The night had been extremely tempestuous; and the fire was attributed to the lightning striking upon the hemp store-house, the windows of which had been left open to air it. By this conflagration many hundred tons of tar, 500 tons of cordage, 700 sails, and 1050 tons of hemp, were totally consumed. The second fire occurred on the morning of the 27th of July, 1770, when the damage done was still greater; and it was even for some time doubtful whether any part of the yard would escape destruction. From its bursting forth at different places at one time, and various other circumstances, great suspicions were entertained of its having been occasioned intentionally, but the officers were

unable to discover the offenders. The third fire happened on the 7th of December, 1776, and in this instance was undoubtedly the effect of design, as the incendiary was traced, tried, condemned, and executed, upon incontestible proof, afterwards confirmed by his own confession. The real name of this malefactor was John Aitken; but the appellation by which he is commonly known is that of "Jack the painter." He is supposed to have acted under foreign influence, and had previously attempted to destroy the docks at Plymouth and Bristol, but failed in both those attempts, though he excited very considerable alarm. His plans were laid with great sagacity and forethought; and in order the more effectually to ensure their success, and avoid suspicion, he had invented a very ingenious machine, which he contrived to lodge among the cordage over night, and setting fire to it, left it, and passed out of the gates in the morning unmolested. In the course of the same day the fire broke out, as it luckily happened, several hours before the incendiary had purposed, for had it not begun to display itself till after the fall of night, the destruction would probably have been much greater than it was. The immediate and effective assistance which was given to check the progress of the flames, and the favourable direction of the wind, confined the damage to the rope-house, and a few adjoining store-houses. Jack immediately quitted Portsmouth, but was apprehended about two months afterwards, and his villainy being distinctly traced, he suffered the penalty of the law on the 7th of March, 1777, having previously made all the reparation to his country in his power, by pointing out some effectual measures for securing the dock-yards from similar attempts.

The gun-wharf, as before mentioned, is likewise included in the Portsea division of the town. This arsenal contains several ranges of buildings for the reception of the naval and military artillery, stores, &c. Some of the store-houses are vast piles, particularly two, which, with their dependencies, are adapted to contain all kinds of necessaries for the sudden equipment both of a fleet and an army. On the wharf is the grand depot for guns, carronades, and mortars, with shot and shells of almost every weight and size, all of which are arranged in immense piles of a pyramidal form. Here also in times of peace, the guns from the ships in ordinary at this port are lodged; each ship's guns being kept in a separate tier, while the carriages are deposited away in the same regular manner in proper store-houses; so that the whole may easily and readily be re-embarked. The small armoury is a spacious building of late erection, capable of containing 25,000 stand of arms, and furnished with apartments appropriated to the artificers employed to keep the arms in complete readiness for service. The houses of the store-keeper, and of other officers, who have the charge of the gun-wharf, are large and handsome structures.

Of the buildings dependent on this grand naval emporium, which are situated in the Portsmouth division of the town, the principal are the victualling-office, the government-house, the houses of the lieutenant-governor and port-admiral, and the marine and military barracks. The victualling-office comprehends several extensive ranges of building, including a very magnificent house for the agent victualler; and a large store-house, occupying the whole length of St. Thomas-street, in which the provisions and liquors prepared for the supply of the navy are kept. Other houses are appropriated to the business of salting and baking. The grain for the latter purpose is ground at King's mill, on the Portsea side, which is put in motion by a stream of salt water, admitted from the harbour by means of a great sluice on the creek, which separates the towns. This sluice, or mill-dam, is

PORTSMOUTH.

closed at high water, and on the ebbing of the tide, the water is again passed off into the harbour.

The government-house is situated at the upper end of the grand parade, and is said to have formed originally part of an ancient hospital, mentioned by Leland as having been founded by bishop Peter de Rupibus, for twelve poor men. At present, however, it possesses but few traces of its monastic origin, owing to the frequent additions and alterations it has sustained. During the governorship of the late sir William Pitt, K. B., many improvements were made in this mansion, so that it is now a most elegant and eligible residence. Near it stands the ancient chapel of the hospital, now converted into apartments for the use of the officers and soldiers of the garrison. The houses of the lieutenant-governor and the port-admiral are likewise handsome and convenient buildings; especially the latter, which is situated in High-street.

The borough of Portsmouth, as before mentioned, received its first charter of incorporation from king Richard I. Since his time, however, various charters have been granted by his successors, confirming its former privileges, and adding others. The last charter is that of Charles I., in virtue of which the government of the town is now vested in a mayor, recorder, twelve aldermen, and an indefinite number of burgessees, with some inferior officers. This borough sends two members to parliament, who are elected "by the mayor, aldermen, and burgessees." The number of voters is usually about 110, but as the burgessees are unlimited, it occasionally varies. Some very curious particulars relative to the parliamentary history of Portsmouth, are mentioned in the History of Boroughs; but as our limits prevent us from stating them in detail, we must content ourselves with referring the reader to that work. The town-house, in which the business of the corporation is transacted, and the borough courts, are held in a large building injudiciously situated near the middle of the High-street. This edifice was repaired and enlarged in 1796. Beneath it is an open space, which serves as a market-house; and at a short distance from it stands the White-house, or town prison, which is fitted up and regulated in a manner highly creditable to the magistrates, and officers under whose superintendance it is placed.

Portsmouth and Portsea, being parochially distinct, have each a separate parish church. That of Portsmouth, dedicated to St. Thomas à Becket, is a spacious structure, and has been erected at different periods. It contains behind the altar a large and elaborate cenotaph, in memory of the duke of Buckingham, the favourite of Charles I. Portsea parish church being two miles distant from the town, at a hamlet called Kingston, cannot of course be conveniently attended by the inhabitants. Its place, however, is sufficiently supplied by several handsome chapels, of which the principal are respectively dedicated to St. James and St. John. The latter, which was consecrated in 1789, is particularly elegant in its interior decorations. Besides these places of worship, there are a number of meeting-houses, belonging to various denominations of dissenters.

Among the charitable institutions here, was a free grammar-school, founded in the last century by Dr. Smith, a physician of Portsmouth, but this has already become a sinecure. There are, however, several other schools of more effective use, particularly one under the patronage of a friendly society, which is held in Society-hall, and includes among its members many gentlemen of the first respectability in Hampshire. Here are also an alms-house for eight poor widows; and two poor houses, one belonging to Portsmouth, and the other to Portsea. In the latter parish, the parish officers virtually hold their appointments for life,

and are generally nominated, by the chief officers, from among the shipwrights in the dock, who are deemed worthy of preferment. These manage their duties much better than their neighbours in Portsmouth, and comparatively at a far inferior expence. Both towns are now completely paved, though the paving of Portsea only commenced in 1792. The ancient regulations of watch and ward are still in force in the latter town; but in Portsmouth regular watchmen are established, who are paid by a rate collected from all the housekeepers.

The commercial character both of Portsmouth and Portsea, in common with most of the great sea-ports of England, was greatly improved during the second half of the last century; so that even in time of peace, the trade was considerable. It is, however, in a great measure owing to the long continuance of the late wars, that they owe their present affluence and prosperity. What effect the return of peace will have upon them remains to be seen; but that event must naturally be expected to retard their progress for a time, till the inhabitants are enabled to turn their capital and industry into channels different from those which convey nourishment to the sinews of war. The custom-house is situated in Broad-street, which forms part of the western suburb, or Portsmouth Point, which is admirably situated for commerce, and possesses every requisite accommodation for shipping and goods. At the Point, and close to the mouth of the harbour, is a large commodious bathing-house.

Portsmouth, according to the parliamentary returns of 1811, contains 1103 houses, and 7103 inhabitants; Portsea 6011 houses, and 33,464 inhabitants, making together a population of 40,567 persons. The market-days here are Thursday and Saturday weekly; and there is an annual fair, or free mart, originally granted by king Richard I., which continues for fifteen days after the 10th of July; during which period, no person can be arrested for debt within the precincts of the borough. This fair is held in High-street. Here are several extensive breweries; and besides the public buildings already mentioned, are a bank, erected on the parade, and a theatre, which is the chief place of public amusement in the town, and remains open the greater part of the year.

For capaciousness, depth, and safety, Portsmouth harbour decidedly excels every other in Great Britain. Secure from the most violent storms, the largest first-rates may ride here at the lowest ebb, without touching ground; and its extent is almost sufficient to contain the whole navy of England, great and numerous as it is. Every where the anchorage is good; and the whole harbour is so completely free from bars or impediments, that even a first-rate can make sail at any time of the tide, and quit it by the deep water under South-sea Castle. It is moreover almost completely secured from assault, by the strength and number of the batteries which defend it, particularly towards the sea, where the guns are nearly on a level with the edge of the water. But though safe from storm and attacks, it cannot be secured from the effect of fire, occasioned either by accident, design, or carelessness. It has, therefore, been at different times the scene of awfully grand and calamitous spectacles, from the rage of that destructive element. During the war of 1793, the *l'Impetueux* of 74 guns and the *Boyne* of 98 guns were both destroyed by fire in this harbour, and occasioned considerable damage to other vessels, and loss of lives, by the explosion of their magazines. For some further account of this harbour, see *SPITHEAD*. Beauties of England and Wales, vol. vi. by John Britton, F. S. A., and E. W. Brayley. History of Boroughs.

PORT-SOKEN, or **PORT-SOKA**, the suburb of a city; or a place within the liberties or jurisdiction of it.

The word is formed from the Saxon *port*, *city*, and *soka*, *jurisdiction*. "Concessi, quod nullus de civitate, vel port-foka sua captus, &c." *Sonn. Gavelkind*.

PORTSOY, in *Geography*, in the parish of Fordyce, and shire of Bamff, Scotland, is a market town and place of considerable consequence for fishing concerns. It is seated on the shore of a bay of its own name, on the Moray Firth, at the distance of 171 miles N. of Edinburgh. A species of jasper, called Portsoy-marble, abounds here, and is manufactured into various and curious ornaments. A beautiful granite, of a flesh colour, is also obtained in this parish. It contains a quantity of felspar, which is nearly as brilliant as the Labrador spar. In the first volume of the Edinburgh Philosophical Transactions is an interesting and particular account of this singular stone, by Dr. James Hutton. It is found only at Portsoy, and in Arabia. In Portsoy are a considerable manufacture of thread, and three public schools. *Carlisle's Topographical Dictionary of Scotland*.

PORT-VENT, in an organ, is a wooden pipe, well closed, which serves to convey the wind from the bellows to the found-board of the organ.

PORTUGAL, in *Geography*, a country of Europe, bounded on the N. and E. by Spain, on the S. and W. by the Atlantic ocean, and lying between 37° and 42° N. lat., and between 9° 40' and 5° 50' W. long.; being about 360 British miles in length, and 120 in breadth, and supposed to contain about 27,280 square miles, which, allowing the population to be 1,838,879, will give 67 inhabitants to each square mile. Others have computed that Portugal contains 2740 Portuguese leagues, of 17 to the degree; and have stated its population as exceeding the above-mentioned number by nearly half a million. Its ancient name was Lusitania; but its boundaries were different. (See **LUSITANIA**.) Its present name is derived from that of an ancient town called "Calle," on or near the site of the present Oporto, which was called "Porticale," or the port of Cale; and in process of time the name of this port was extended to the whole country, and hence was formed Portugal. The old name of Lusitania is said to have been discontinued, and the new one to have been substituted for it under Ferdinand the Great, king of Castile and Leon. The most ancient writing extant in which the name of Portugal occurs, is dated in the year 1069.

Portugal was anciently occupied by the Phœnicians and Carthaginians, and from them it passed to the Romans, under whose dominion it was made by the emperor Augustus a Roman province. Towards the end of the fifth century the Alans, about the year 440 the Swabians, and about the year 582 the Visigoths, took successive possession of this country. In the eighth century it was over-run by the Moors and Saracens, and recovered from them by the Christians. Henry, duke of Burgundy, having aided Alphonso VI. king of Castile, against the Moors, obtained his daughter Theresa in marriage, in 1093 was created earl of Portugal, and in 1110 received from him the absolute property of this kingdom. Henry died in 1112. His son and successor, Alphonso Henriques, having gained a signal victory in the battle of Ourique over five Moorish kings, A. D. 1139, was proclaimed king by his army on the field of battle. In 1148, by the assistance of a fleet of Crusaders, he seized Lisbon, the capital of the kingdom; about the same time he also assumed the title of king; so that this may be considered as the epoch of the Portuguese monarchy, his right to the throne being confirmed in 1179. In 1181 he held an assembly of the states at Lamego, in which the succession to the

crown was settled. Alphonso died in 1185, aged upwards of 90. About the year 1254, Alphonso III. completed the conquest of Algarve. In the year 1290 Dionysius founded an university at Lisbon, which he removed in 1308 to Coimbra. Alphonso IV. A. D. 1340, gained over the Moors the famous battle of Saladin, in which, according to the reports of Spanish writers, 200,000 Moors fell victims. He was likewise successful at sea against the Moors of Africa. From the year 1369 to 1431, the kings of Portugal had frequent contests with those of Castile, but with various success. In the fifteenth century Portugal attracted the admiration of Europe by her naval expeditions and commercial discoveries. In 1415, John the Great, king of Portugal, carrying his arms into Africa, and taking the city of Ceuta, gave an impulse to the national spirit, and in 1420 the Portuguese were in possession of Madeira. In 1422, the computation of time by the years of the Christian era was introduced into this kingdom. The Portuguese discoveries in Africa proceeded under John's successors, Edward and Alphonso V., and the auspices of prince Henry, until in the reign of John II. they extended to the Cape of Good Hope; and in that of Emanuel, A. D. 1498, Vasco de Gama opened the passage to the East Indies. By this successful adventure the trade of Asia was diverted from its old channel across the isthmus of Suez, and down the Red sea, and thus the commercial pre-eminence of Venice was destroyed by the wise and resolute measures of this magnanimous sovereign. The Portuguese in 24 years erected a commercial empire in the East, which, for extent, opulence, and splendour, had no rival in the history of nations. In the same reign Brasil was discovered and taken possession of by the Portuguese. The Inquisition was introduced into Portugal by John III. in 1526; from which time this monarchy rapidly declined. Sebastian, the son and successor of John III., led a powerful army into Africa on an unwise expedition in 1577, the event of which was his own destruction and that of his army by Muley Moloch, emperor of Morocco; the consequence of which fatal measure was, that upon the death of cardinal Henry, Sebastian's uncle and successor, Portugal, thus enfeebled and dispirited, was seized by Philip II. king of Spain, A. D. 1580. The male line of the kings of Portugal failing, the kingdom was united to that of Spain; and this event was followed by the loss of the foreign acquisitions of the Portuguese, and by a degree of oppression, which induced them, A. D. 1640, to shake off the Spanish yoke, and to elect John, duke of Braganza, a descendant of the ancient royal family by the male line, for their king, under the appellation of John IV. After his death the Spaniards made frequent attempts to regain the kingdom, but his queen, aided by Charles II. of England, vigorously resisted their efforts, till at length, in 1665, the signal victory of Montes Claros terminated the war. In November 1807, the French invaded Portugal, and caused the royal family, with their servants and treasures, and many friends, to embark on board a fleet in the Tagus, and to sail to Brasil. Since that time, the English, affording powerful assistance to the Portuguese, have driven the invaders out of the kingdom; and the Portuguese themselves, under the auspices of Wellington and Beresford, have in a considerable degree recovered that reputation for bravery and skill, which their ancestors had manifested in their contests with the Moors and Spaniards.

Portugal is divided into six provinces, as follow: 1. Entre Douro e Minho; 2. Tras-os-Montes; 3. Beira; 4. Estramadura; 5. Alentejo; 6. Algarve: the two first being situated on the N. of the kingdom, the next two in the middle, and the two last in the south. See each under its appropriate

PORTUGAL.

appropriate arrangement. The population of the whole is, according to Boetticher, 1,838,879; and by Murphy's statement, 2,588,470, which last is probably an exaggerated enumeration. The cities of Portugal are computed at 22 or 23, some of which are very small; the villas or municipalities are 350; the villages are very numerous; and the parishes not fewer than 4262. The following state of the population was drawn up by the researches of the magistrates, and published in 1802.

	Parishes.	Hearths.
Entre Douro e Minho -	1327	181,593
Tras-os-Montes - -	711	77,054
Beira - - - -	1292	224,449
Estremadura - - -	420	120,333
Alentejo - - - -	369	76,246
Algarve - - - -	71	25,523
Lisbon and the <i>banlieue</i> - -	72	54,954
	4262	760,152

It is supposed that 10 fires give 38 persons, because many live solitary, who in other countries are with their relations and friends; but in Lisbon five persons may be allowed to each hearth, because many persons live together, and there are more domestics. But when the total population is computed at 2,900,000, there seems to be some exaggeration. Of the colonies belonging to Portugal, that established in Brasil is the chief; and it has still many settlements on the coasts of Africa, with Goa and Macao in the East Indies, which are now mere relics of former great power and authority.

The government of Portugal is an absolute and hereditary monarchy; but in case of the king's demise without male issue, he is succeeded by his next brother, whose sons, however, have no right to the crown till confirmed by the states. The prince of Brasil was appointed regent by his mother, the heiress of the kingdom. The chief articles of the constitution are contained in the statutes of Lamego, issued by Alphonso I. in 1145. The king's titles are numerous; that of the heir apparent is prince of Brasil; his eldest son prince of Beira. The councils of state are, 1. That of the palace, which is supreme in justice, and has all the powers of a lord chancellor. 2. That of the inquisition, declared *royal* by king Joseph, though before it was only *papal*, with four inferior chambers at Lisbon, Evora, Coimbra, and Goa. 3. That of the finances. 4. That of the colonies. 5. That of honour, or the affairs of knights. 6. That of war. 7. The admiralty. There are five sovereign courts of justice, at Lisbon, Porto, Bahia, Rio Janeiro, and Goa. The administration lies with four ministers and secretaries of state, one at the head of the treasury or finances, another minister of the interior, another of war and foreign affairs, and the fourth, of the marine and colonies. The council of state, nominated by the prince in 1796, and consisting of thirteen members, is only assembled on solemn occasions. There are five royal councils which judge without appeal; two for Europe, at Lisbon and Oporto; two for Brasil, at Bahia and Rio Janeiro; and one for Asia, at Goa. By an edict of August the 4th, 1769, no law has positive authority except the ordinances of the king; but the Roman law may be consulted as "written equity." The military governments are seven; the six provinces and the government of Oporto, consisting of a part of Beira and a part of Entre Douro e Minho. There are twenty-eight regiments of infantry, twelve of cavalry, five of artillery, one of light troops, all strengthened according to circumstances. In 1798 there were forty-three regiments of regular militia. The army is

usually computed at about 24,000; and the militia amounts perhaps to the same number. The naval force, which was once considerable, is now reduced to thirteen sail of the line and fifteen frigates. The revenue is calculated at 2,000,000 sterling; and the gold of Brasil mostly passes to England in return for articles of industry. According to MS. notes, cited by Pinkerton, the revenue may be computed at more than 70,000,000, and the national debt, about 100,000,000 French livres. Portugal retains small influence in the political scale of Europe: her commerce is almost wholly dependent on England; and by land she is exposed to no danger except from Spain, or by consent of Spain. What will be her condition, now the troubles of Europe have, it is to be hoped, terminated, time must discover.

The religion of Portugal is the Roman Catholic, and a strict observance of its external ceremonies forms one of the national characteristics. Here are two archbishoprics in Europe, the title of patriarch being given by brevet to the archbishop of Lisbon, and three in the colonies; 14 bishoprics in Europe, and 16 in the colonies; the number of parishes is about 4000; the convents of men in Europe are 417, and of women about 150; the secular clergy about 22,000, monks 14,000, nuns 10,000, all in Europe.

The manners and customs of the Portuguese are discriminated into those of the northern and southern provinces; the former being more industrious and sincere, the latter more polite and indolent. In general, the Portuguese are an elegant race, with regular features, embrowned by the sun, and dark expressive eyes. The women are commonly of small stature, but graceful and beautiful. The Portuguese admire round limbs, and a green, or sea-green, eye. Ladies of rank resemble their ancestors in industry, by spinning flax from the distaff; the dress resembles the Spanish, but the men prefer the French, with the exception of a large loose cloak. The peasantry remain the miserable vassals of the Fidalgos, or gentlemen. In diet, the Portuguese are temperate, or rather abstemious. The games are billiards, cards, and dice; but the chief amusement is that of bull-fights. The arts and sciences are almost wholly neglected, except by a few among the clergy. Pombal introduced the sciences by force; but since his administration, they have daily diminished.

The Portuguese language is grave and solemn; but would have been little known among foreigners, if it had not been diffused by the fame of the Lusiad. The literature of Portugal may be said to have commenced with Deniz, the sixth sovereign, who cultivated poetry and the belles lettres, and founded the university of Coimbra. Many of her poets have acquired reputation. In mathematics Pedro Nunez distinguished himself at the beginning of the 16th century. Natural history has lately engaged attention; but Portugal is the last of nations in this department. Education has been much neglected. At Coimbra the students are computed only at 800. The university at Evora, founded in 1533, has remained suppressed since 1759; and the royal academy at Lisbon no longer exists.

The Portuguese manufactures are few, and of little importance. Hats and paper have been lately fabricated at Lisbon; but the chief manufactories are those of woollen cloth at Covilhã, Portalegre, and Azeitão. A considerable commercial intercourse subsists with England; and the balance in favour of the latter appears to be about 400,000 sterling, and Ireland gains by her exports about 63,000 annually. Besides woollens and hardware, England transmits to Portugal large cargoes of salted and dried fish, the last article amounting to about 200,000 annually. The exports of Portugal are chiefly wine, oil, oranges, lemons, figs,

figs, fugar, cotton, cork, drugs, and tobacco. Portugal also maintains a considerable trade with Brasil, the inhabitants of which are computed at about 900,000. The articles exported to America are chiefly woollens, linens, stuffs, gold and silver lace, fish dried in Portugal, hams, sausages, &c. with glass manufactured at Maranhã. Brasil returns gold, silver, pearls, precious stones, rice, wheat, maize, fugar, molasses, ornamental timber, &c. The drugs, spices, and articles used in dyeing ought also to be mentioned. The trade with the East Indies is inconsiderable, and that with the other European nations hardly worthy of notice.

The climate of Portugal is well known to be excellent and salubrious. The face of the country is generally fertile, though not without many declivities, especially in the N.E. corner, where is found a considerable cluster of mountains. The numerous vineyards, and groves of orange and lemon trees, conspire with the crystal streams and verdant vales, to impart great beauty and diversity to this favoured country. The soil is generally light; but agriculture is neglected.

Of the rivers of Spain, those most worthy of mention are the Tajo, the Mondego, the Soro and the Cadaon. The lakes are not deserving of notice. Of mountains, besides the cluster already mentioned, we might enumerate the chains of Idubada, Arrabeda, which is chiefly calcareous, and affords beautiful marble, of Toledo, Estrella, and Monte Junto. The zoology of Portugal is much the same with that of Spain (which see); the horses, however, are much inferior, but the mules are hardy and strong. The oxen are sometimes equal in size to those of Lincolnshire, but cows are rare, as the pastures are not duly regarded. Sheep also are neglected; but swine abound, and being fed with excellent acorns, the Portuguese hams are justly esteemed. The mineralogy of Portugal has been as much neglected as its agriculture. In the northern provinces there are traces of ancient mines which have been disregarded for many ages. Gold is still found in the sand of some streams; a mine of silver was worked near Braganza about the year 1628; tin was also found in the northern provinces, and near Miranda was formerly a manufactory of pewter. At Murfa, Lamego, and Cogo, there are lead mines; and the galena ore is very productive of silver. Copper is found near Elvis, and in other districts; iron mines are neglected for want of fuel; nevertheless, coal is found in different parts of the kingdom; and that of Buareos in particular supplies the royal foundery at Lisbon. Emery is found near the Douro, and beautiful marbles are abundant in various parts of the kingdom. Fine granite, talc, amianthus, felspar, fuller's earth, antimony, manganese, bismuth, and arsenic, are obtained in various places. Near Castello-Branco are mines of quicksilver. Portugal furnishes rubies, jacinths, beryl, and in short minerals of almost every description, and nothing is wanting to render them profitable but fuel and industry. Here are also various kinds of mineral waters and baths. For other particulars we refer to our account of the principal cities, towns, mountains, rivers, &c. and also to Murphy, Link, Pinkerton, and Playfair's Geography.

PORTUGALETE, a town of Spain, in the province of Biscay, situated on a bay of the Atlantic; 12 miles N.W. of Bilbao. N. lat. $43^{\circ} 20'$. W. long. $3^{\circ} 2'$.

PORTUGALICA TERRA, *Earth of Portugal*, in the *Materia Medica*. See LUSITANICA rubra bolus, and BOLE.

PORTUGHESSA, in *Geography*, a river of South America, formed by the union of the Pao and Bariquicemeto, which joins the Apura, 40 miles N.W. of Cabruta.

PORTUGUESE *Man of War*, in *Natural History*, a name which the seamen give to the *holothuria physalis* of

Linnaeus. It consists of a small bladder, about seven inches long, very much resembling the air-bladder of fishes, from the bottom of which descend a number of strings, of a bright blue and red, some of them three or four feet in length, which, upon being touched, sting like a nettle, but with much more force. On the top of the bladder is a membrane, which is used as a sail, and turned so as to receive the wind which way soever it blows. This membrane is marked in fine pink-coloured veins, and the animal is in every respect an object exquisitely curious and beautiful.

PORTUGUESE *Coins*. See COINS.

PORTUGUESE *Measure*. See MEASURE.

PORTULA, in *Botany*. See PEPLIS.

PORTULACA, an ancient Latin name, whose supposed origin has exercised the ingenuity of the learned, but concerning which we find nothing worth explaining or controverting.—Linn. Gen. 240. Schreb. 323. Willd. Sp. Pl. v. 2. 859. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 3. 147. Juss. 312. Tourn. t. 118. Lamarek Illustr. t. 402. Gærtner. t. 128.—Class and order, *Dodecandria Monogynia*. Nat. Ord. *Succulentæ*, Linn. *Portulacæ*, Juss.

Gen. Ch. *Cal.* Perianth superior, cloven, small, permanent, compressed at the summit. *Cor.* Petals five, flat, erect, obtuse, larger than the calyx. *Stam.* Filaments numerous, capillary, half the length of the corolla; anthers simple. *Pist.* Germen superior, roundish; style simple, short; stigmas five, oblong, the length of the style. *Peric.* Capsule covered by the calyx, ovate, bursting all round, of one cell, with an unconnected receptacle. *Seeds* very numerous, small, roundish.

Ess. Ch. Petals five. Calyx in two divisions. Capsule of one cell, bursting transversely.

From this genus, as it stands in Linnaeus, is now separated the TALINUM of Adanson and Jussieu; see that article hereafter. This last-named genus has a capsule of several valves, separating vertically, in the usual manner, and the seeds are tunicated. *Portulaca* therefore, in Willdenow, consists of but five species, four of which are enumerated in Hort. Kew.

1. *P. oleracea*. Garden Purslane. Linn. Sp. Pl. 638. Willd. n. 1. Ait. n. 1. Decand. Pl. Grasses, t. 123. (*Portulaca domestica et sylvestris*; Ger. Em. 521.)—Leaves wedge-shaped. Flowers sessile.—Native of Europe, America, and the East Indies. It is also said to be one of the few plants found on the little island of Ascension. With us it is only a kitchen-garden herb, of no very general use at present. It was formerly much eaten in salads; nor is it unpalatable, though very mucilaginous, when boiled. Nothing can be more easy of culture than this hardy annual, which sows itself spontaneously. The whole herb is smooth and succulent, much branched, and spreading widely in a decumbent manner; the stem round and purplish. Leaves clustered, stalked, obovate, above an inch long. Flowers clustered, sessile, terminal, small, yellow, opening but for a short time towards noon.

2. *P. pilosa*. Hairy Purslane. Linn. Sp. Pl. 639. Willd. n. 2. Ait. n. 2. Gærtner as above. (*P. corasfatica lanuginosa procumbens*; Herm. Parad. 215. t. 215.)—Leaves awl-shaped, alternate; with axillary hairs. Flowers sessile, terminal.—Found in the West Indies, and brought early to this country, where it is sometimes cultivated for curiosity in the stove, being a tender biennial, flowering in summer. The stem is branched, either erect or procumbent. (The former variety, as it is esteemed, being described and figured by Hermann, at p. 214.) The leaves are copious, slender, accompanied by bristly hairs. Flowers terminal, of a beautiful pink, surrounded with similar hairs.

3. *P. quadrifida*

3. *P. quadrifida*. Creeping Annual Purslane. Linn. Mant. 73. Willd. n. 3. Ait. n. 3. Jacq. Coll. v. 2. 356. t. 17. f. 4.—Flowers usually four-cleft, with four floral leaves. Stem creeping, with hairy joints. Leaves obovate.—Native of Egypt, and the East Indies. A small trailing annual, with yellow flowers, flowering in the stove in autumn.

4. *P. Halimoides*. Downy-headed Purslane. Linn. Sp. Pl. 639. Willd. n. 4. (*P. erecta*, *fedi minoris facie*, *capitula tomentosa*; Sloane Jam. v. 1. 205. t. 129. f. 3.)—Leaves oblong. Stem corymbose, erect. Flowers sessile, in terminal hairy heads.—Native of dry meadows in Jamaica, coming up after the wet season. This is a small bushy annual herb, unknown in our gardens.

5. *P. meridiana*. Noonday Purslane. Linn. Suppl. 248. Willd. n. 5. Ait. n. 5.—Leaves elliptical, flat. Stem creeping, with hairy joints. Flowers solitary, sessile, terminal.—Native of the East Indies. Linnæus had it in the Upsal garden, and it was introduced at Kew by sir J. Banks in 1791. This is also a small bushy herb, but creeping, not erect. Leaves opposite, sometimes quaternate. Flowers yellow, encompassed with wool. Their stamens are few, varying from four to eight. The younger Linnæus well observes that this plant has no pretensions to form a new genus, though his illustrious father had thought otherwise.

PORTULACA, in Gardening, contains plants of the herbaceous and shrubby kinds, of which the species cultivated are, the garden purslane (*P. oleracea*); and the round-leaved purslane (*P. anacampseros*.)

There are several varieties of the first. The garden purslane differs from the wild, only in having larger and more succulent leaves. If it be permitted to scatter the seeds, in two years it will become in every respect like the wild plant. Of the two other varieties, one is with deep-green leaves, and the other with yellow leaves, which is called golden purslane.

Method of Culture.—These plants may be increased by seeds and cuttings, according to the different kinds.

In the first sort the seeds should be sown in slight-drills, or broad-cast over the surface, at different times, in the spring and summer, from March to June, or later, at the distance of three weeks, the early sowing being made on slight hot-beds, but the late ones in the open borders, where the ground is light and dry, occasional light waterings being given afterwards, both before and after the plants appear, which must remain where they come up, and are mostly fit for cutting in the course of a month or five weeks. In gathering them, the young tops should be cut off with a knife, and they afterwards shoot out fresh tops.

In the second sort the cuttings should be planted in pots filled with light dry mould, and plunged in the tan-bed, in order to promote their rooting, moderate shade and waterings being given till they have stricken good root, being kept in the stove, and afterwards managed as the succulent kinds of aloes.

The last affords variety among other stove potted plants.

PORTULACARIA, in Botany, a genus founded by Jacquin in his *Collectanea*, v. 1. 160, and adopted by Schreber, Gen. 203, as well as by Willdenow and Aiton. It consists of the Linnæan *Claytonia Portulacaria*, and the character is as follows.

Calyx of two leaves. Petals five. Seed one, with three wings.

This is an African shrub, named *P. afra*, and figured in Decand. Pl. Grasses, t. 132, as well as in Dill. Hort. Elth. t. 101. f. 120.—How good soever the genus may be, the name is bad, and inadmissible.

PORTULACARIA, in Gardening, furnishes a shrubby plant of the succulent green-house kind, of which the species cultivated is the African purslane (*P. afra*).

Method of Culture.—It is readily increased by cuttings of the stems or branches, planted during any of the summer months, having been laid to dry for some days before, in pots filled with sandy earth, being placed in a frame, and shaded in hot weather, and protected from wet. They are also much forwarded by being plunged in the bark-bed of the stove. It must be placed in a warm glass case in winter, where it may enjoy the full sun, and should have very little water during that season. In summer the plants should be placed abroad in a sheltered situation, and in warm weather be refreshed with water twice a week; but the stalks being very succulent, too much wet is always hurtful.

These afford variety among other green-house plants.

PORTULACASTRUM, in Botany. See TRIANTHEMA.

PORTULACEÆ, a natural order of Jussieu, the fourth of his 14th class, and named from the first and best-known genus among those of which it is composed. See FICOIDEÆ, MELASTOMÆ, MYRTI, for other orders of this class.

The characters of *Portulacææ* are as follows. Calyx inferior, divided at the top. Corolla of a determinate number of petals, rarely of one petal, or wanting, inserted into the middle or base of the calyx, and when its divisions are equal to those of that part, they are disposed alternately therewith. Stamens inserted into the same part, definite, rarely indefinite, in number. Germen superior, simple. Styles one, two, or three, rarely wanting. Stigmas often several. Capsule of one cell or many, each cell with one or many seeds. Corculum incurved, surrounded by a farinaceous or fleshy mass. Herbs or shrubs, rarely small trees, of a succulent habit. Leaves opposite or alternate, often succulent.

Section 1. Fruit of one cell.

This comprehends *Portulaca*; *Talinum*; *Turnera*; *Bacopa* of Aublet; *Montia*; *Rokejeka* of Forskall; *Tamarix*; *Telephium*; *Corrigiola*; *Scleranthus*; and Forskall's *Gymnocarpus*.

Section 2. Fruit of many cells.

Triantema; *Limeum*; *Claytonia*; and *Gisckia*.

PORTUMNA, in Geography, a post-town of the county of Galway, Ireland. It is situated on the river Shannon, where it falls into lough Deirgeart, and had formerly a wooden bridge over it, but this having been broken down in time of war, was not rebuilt, and at present there is only a ferry. Portumna has some ruins, especially of a monastery, and a castle belonging to the marquis of Clanricarde. It is 76 miles W. by S. from Dublin.

PORTUMNALIA, among the Romans, a festival in honour of Portumnus, who was supposed to preside over ports and havens, celebrated on the seventeenth of August.

PORTUS, QUINQUE. See QUINQUE *Portus*, and CINQUE *Ports*.

PORTUS, in Ancient Geography, a town of Italy, at the mouth of the Tiber, 126 stadia from Rome.

PORTUS Augusti, or *Portus Romanus*, *Porto*, a port of Italy, at the right mouth of the Tiber. The first port which the Romans had at the mouth of this river was that of Ostia, constructed by Ancus Martius. Claudius built another with an immense basin. Two extensive moles formed a secure haven. Between the old and the new port two arms of the Tiber formed an island, called "Infula sacra." No trace now remains of these ports.

PORTUS Magnus, a port on the southern coast of the isle of Albion, between the mouth of the river Alaunius and that of Trifanton. Ptolemy.

PORTUS, FRANCIS, in *Biography*, born at Candia in 1511, was brought up at the court of Renée of France, wife to the duke of Ferrara, in which city he taught the Greek language. He imbibed the principles of the reformed religion, and when Renée, after the duke's death, returned to France, he went to Geneva, in 1561, in order that he might worship, undisturbed, his maker according to the dictates of his conscience. He was there presented with the privilege of citizenship, and made professor of Greek, an office which he held till his death, in 1581. He published commentaries and annotations upon Pindar, Sophocles, some of the works of Xenophon, Thucydides, Aristotle's Rhetoric, Longinus, and some other writers, a Latin version of the Psalms, and the Hymns of Synesius, an improved edition of Constantine's Greek Lexicon, a reply to Charpentier's defence of the bloody massacre of St. Bartholomew, and other pieces. He had a son, Æmilius, born in 1551, who pursued a similar course of study, and was successively regent of the second and first classes at Geneva, Greek professor at Lausanne in 1581, and at Heidelberg in 1592. He published editions, with commentaries, notes, &c. of various ancient authors, as Aristophanes, Dionysius Halicarnensis, Suidas, notes on Thucydides and Euripides, also dictionaries of the Doric and Ionic dialects.

PORVEAR, in *Geography*, a town of Hindoostan, on the coast of Malabar; 18 miles W. of Travancore.

PORUR, a town of Hindoostan, in the circar of Kerleh; 32 miles N.W. of Maltoy.

PORUS OPTICUS, in *Anatomy*, the opening in the centre of the optic nerve, through which the arteria centralis oculi enters the eye. See **EYE**.

PORUS, in *Natural History*, a name given by authors to a peculiar kind of fossil coral, of which there are many different species: these are all of a beautifully laminated structure, and seem allied to the mycetizæ or fungitæ; they are seldom found loose, but usually bedded in hard marble, and with their pores filled up with sparry or mineral matter.

PORUS is also the name of the *tophus*; which see.

PORUS Cervinus, a name given by authors to a species of marine substance, found among the rocks in the coral fisheries, and in other places. It grows at different depths, and seems to adhere to the rocks by a simple base, having no root, nor any thing in the place of one. It is branched in such a manner, that with the help of a little imagination, it has been forced into the resemblance of a stag's horn; its height is about an inch and a half, often less when newly taken out of the sea; and is of a fine snow-white colour; but when it has lain some time to dry, it becomes of a dusky yellow; it is very thin, perfectly transparent, and seems composed of several fine membranes. When examined by the microscope, an admirable structure is discovered in it; the whole being composed of a membranous matter, in which is an infinite number of holes, and all these arranged into regular lines.

Count Marfigli has distinguished this, which is the common kind of porus cervinus, or buck's-horn porus, by the name of *minor*, in order to prevent its being confounded with another less common kind, which Ferrante Imperato has described under the name of *porus cervinus*, and which is a species of *fuflra* (the *fuflra-foliacea*), and broad-leaved hornwrack of Ellis.

This larger kind is also found growing on the rocks in the coral fisheries; but it always is found at great depths, never near the surface, as the other often is. It grows to the rock by a small base, and from thence rises to a short trunk, which spreads itself out into several flat branches, divided every where into two, as those of most of the sea-

fuces are; and these are so expanded as to form, what people imagine, a resemblance of a stag's horn. This grows to a little more than two inches in height, and is of a beautiful pale yellow, or straw colour, even while growing, and looks glossy and shining, as if covered with a thin coat of varnish. It is as thin as the finest paper; and when viewed by the microscope, is found to be of a particular texture. It is sometimes found growing to the shells of sea-fishes; but of those only which live in great depths of water. Count Marfigli has given elegant figures both of this and the smaller kind, not only in their natural state, but as they appear to the microscope.

PORUS Cervinus is also a species of *fasciola*, in the class of *Vermes Intestina*.

PORZANA, in *Ornithology*, the spotted gallinule of Pennant and Latham, a species of *rallus*; which see.

PORZANO, in *Geography*, a town of Italy, in the department of the Mela; 10 miles S. of Brescia.

POSADAS, a town of Spain, in the province of Cordova, on the Guadalquivir; 17 miles S.W. of Cordova.

POSATA, a town on the E. coast of Sardinia; 45 miles E.S.E. of Castello Aragonese.

POSCA, the name of a mixture of vinegar and water, which was the common drink of the Roman soldiers.

POSCENIUM, or **POSTCENIUM**, among the Romans, the back part of the theatre, where the actors retired to undress themselves. Danet. in voc.

POSCENIUM was sometimes used to signify a lady's dressing-room, where the paint and washes were kept and used, and where men were not allowed admittance. See **PARASCENIUM**.

POSCHECHONE, in *Geography*, a town of Russia, in the government of Jaroslavl; 44 miles N.N.W. of Jaroslavl. N. lat. 58° 12'. E. long. 39° 14'.

POSCOSA, a town of the county of Tyrol; 9 miles S.E. of Trent.

POSE', in *Heraldry*, denotes a lion, horse, or other beast, standing still, with all four feet on the ground; to denote thereby that it is not a moving posture.

POSEGA, or **POSZEGA**, in *Geography*, a town of Sclavonia, and capital of a county of the same name; 19 miles N.E. of Gradisca. N. lat. 45° 35'. E. long. 17° 48'.

POSEN, or **POSNA**, a handsome, but not very large, town of the duchy of Warsaw, late capital of a palatinate in Great Poland, situated on the Warta, and inclosed with a double wall and deep moat; having on the other side of the Warta two suburbs, viz. Szrodka and Waliszewo, which are surrounded with a large morass. The town and suburbs are subject to the frequent inundations of the river. The castle stands on an island in the Warta. The town contains several churches and convents, and is the see of a bishop, whose palace, situated near the cathedral, is a fine structure. This is the first in rank, and the most ancient episcopal see in Poland. This city is indebted for a great part of its prosperity to its trade with Germany. It is a staple town, having a court of judicature, and many privileges. This palatinate belonged to the king of Prussia, being annexed to his dominions in 1773; but by the treaty of Tilsit in 1807, it was given to the king of Saxony; 145 miles W.N.W. of Warsaw. N. lat. 52° 22'. E. long. 17°.

POSEN, a town of Prussia, in Bartenland; 9 miles S.S.E. of Rastenburg.

POSERITZ, a town of Anterior Pomerania; 11 miles S.W. of Bergen.

POSIDEIUM, in *Ancient Geography*, a town built by Amphilocus, son of Amphiaræus, upon the frontiers of Cilicia and Syria, over-against the isle of Cyprus.

The Greeks gave a similar appellation to several places and promontories, in reference to Neptune, ποσειδων, *posidon*, who had a temple in them, appropriated to his honour.

POSIDIA, Ποσιδια, in *Antiquity*, a festival in honour of Neptune, called Ποσειδων.

POSIDIUM, Ποσειδειον, in *Chronology*, the seventh month of the Athenian year. It consisted of thirty days, and answered to the latter part of our December, and the beginning of January.

It had this name from the festival Posidonia celebrated in it.

POSIDONIA, Ποσιδωνια, in *Antiquity*, the same with *posidia*.

POSIDONIA, in *Ancient Geography*. See PÆSTUM.

POSIDONIUS, in *Biography*, an astronomer and mathematician of Alexandria, was the disciple of Zeno of Citticus, and was a contemporary with, or lived soon after, Eratosthenes. He probably flourished about the year 260 B.C. He is particularly celebrated on account of his having employed himself in endeavouring to ascertain the measure of the periphery of the earth, by means of the altitude of a fixed star. He, according to Cleomedes, concluded that it was 240,000 stadia; but according to Strabo, he made it 180,000 stadia only. He is the reputed author of a treatise on military tactics, which is mentioned by Ælian in the first chapter of his work on the same subject. No fragments of his writings are extant.

POSIDONIUS, a celebrated Grecian philosopher of the Stoic sect, who flourished about 50 or 60 years before Christ, was a native of Apamea, in Syria. He taught philosophy at Rhodes with so much reputation, that Pompey, on his return towards Rome, after the successful termination of the war against Mithridates, came thither with the design of attending his lectures. "When he came to the house," says the historian, "he forbade his licitor to knock at the door, but, by ordering him to lower the fasces at the gate of Posidonius, this mighty conqueror of the eastern and western world paid a respectful homage to philosophy. Posidonius being confined with a severe attack of the gout, Pompey visited him in his chamber, and expressed his regret that the philosopher's situation would deprive him of the pleasure of hearing his discourses. Upon this Posidonius made an effort for the gratification of his illustrious visitor, and delivered a discourse, to prove that nothing could be deemed good that was not honourable. He studied astronomy as well as morals, and constructed a kind of sphere, with which he exhibited the apparent motions of the sun, moon, and planets round the earth. Cicero says that he himself attended the lectures of this philosopher, and it is asserted, upon the authority of Suidas, that he was brought to Rome by Marcellus, in the 702d year from the building of the city, which was the 52d year B.C. He is thought to have written a continuation of the history of Polybius in a polished and elegant style. There were two other distinguished ancients of the name of Posidonius; one an architect and engineer, who attended the armies in the latter capacity. He is said to have been the inventor of a moveable tower, contrived for approaching the walls of a besieged place. The other was a native of Olbiopolis, and an historian as well as natural philosopher. The time when he flourished is not known. He was author of the history of Attica, in four books; a history of Africa, in eleven books; an account of the Tyrian territory; and a treatise on the ocean and its productions.

POSILIC, in *Geography*, a town of Prussia, in Pomeralia; 8 miles E. of Marienburg.

POSINARA, in *Ancient Geography*, a town of India, near the Ganges, but beyond it, near Pandaa.

POSING, in *Geography*, a town of Hungary; 11 miles N.N.E. of Presburg.

POSQUIT, in *Ornithology*, a name given by the people of the Philippine islands to a small bird very common among them, and approaching to the nature of the canary bird, but smaller, and wanting its harmonious voice.

POSITI, among the Romans, an appellation given to the dead when placed at the door with their feet outwards, till the time of their interment.

POSITION, in *Physics*, *site*, or *situation*; an affection of place, which expresses the manner of any body's being therein.

POSITION, in *Architecture*, denotes the situation of a building, with regard to the points of the horizon.

Vitruvius directs the position of a building to be such as that the four corners point directly to the four winds.

POSITION, in *Astronomy*. The position of the sphere is either right, parallel, or oblique; whence arise the inequality of our days, difference of seasons, &c. See SPHERE.

POSITION, *Circles of*. See CIRCLES.

POSITION, in *Dancing*, the manner of disposing the feet with regard to each other.

There are four regular positions: the first is, when the feet are joined in a line parallel to the shoulders: the second, when the heels are perpendicularly under the shoulders; and of consequence the width of the shoulders apart: the third, when one foot is before the other, in such a manner, as that the heel is in the cavity formed by the rotula and carpus of the foot: the fourth, when one foot is the width of the shoulders apart from the other, the heel still answering to the cavity above-mentioned, which is the only regular manner of walking.

POSITION, in *Arithmetic*, a rule so called, for *supposition*.

The rule of *false position* consists in calculating on several false numbers, taken at random, as if they were the true ones; and, from the differences found in them, determining the number sought.

Position is either *single* or *double*.

POSITION, *Single*, is when there happens in the proposition some partition of numbers into parts proportional; in which case, the question may be resolved, at one operation, by this rule: imagine a number at pleasure, and work with it, according to the tenor of the question, as if it were the true number: and what proportion there is between the false conclusion and the false position, such proportion the given number has to the number sought.

Therefore, the number found by argumentation shall be the first term of the rule of three; the number supposed the second term; and the given number, the third.

E. gr. A school-master being asked how many scholars he had, replied, if he had as many more, half as many, and one-fourth as many, he would have but one less than 100; how many had he? Suppose the number 20: then $20 + 20 + 10 + 5 = 55$ instead of 99; therefore $55 : 20 :: 99 :$
 $\frac{99 \times 20}{55} = 36$, the number required.

POSITION, *Double*, is when there can be no partition in the numbers to make a proportion.

In this case, therefore, you must make a supposition twice; proceeding therein according to the tenor of the question.

If neither of the supposed numbers solve the proposition, observe the errors, and whether they be greater or less than the

POSITION.

the resolution requires, and mark the errors accordingly, with the signs + and -.

Multiply, contrariwise, the one position by the other error; and if the errors be both too great, or both too little, subtract the one product from the other, and divide the difference of the products by the difference of the errors.

If the errors be unlike, as the one +, and the other -, add the products, and divide the sum thereof by the sum of the errors added together. For the proportion of the errors is the same with the proportion of the excesses or defects of the numbers supposed, to the numbers sought.

Having found the errors, say, as the sum of the errors, when they are of different kinds, or, as the difference of the errors, when they are of the same kind, is to the difference of the suppositions, so is the least error to the correction of the supposition belonging to this error; which must be added to or subtracted from it according to the following conditions; viz. if the errors be of the same kind, add the correction to this supposition if it is greater than the other supposition, and subtract when it is the less; but if the errors be of different kinds, do the contrary, viz. add when that supposition is the less, and subtract when it is the greater of the two: and the sum or difference will be the number sought.

E. gr. 1. If 100*l.* be divided between A, B, and C, in such a manner, that B had three times as much as A, and C as much as A and B together, and their respective sums be required. Suppose, first, A's = 12, B's will be = 36, and C's = 48, the sum of which will be 96 instead of 100, and leave an error in defect, or - 4.

Suppose, 2dly, A's = 14, then B's = 42, and C's = 56, and the sum = 112 instead of 100; hence we shall have an error in excess, or + 12. And $4 \times 14 = 56$, and $12 \times 12 = 144$, and $144 + 56 = 200$: and $\frac{200}{16} = 12\frac{1}{2}$ for A's real share.

E. gr. 2. A party of soldiers marching, came up with a shepherd, and drove off half his flock and half a sheep; another party carried off half the remainder and half a sheep; and a third plundered him of half the remainder and half a sheep, and after all he had twenty sheep left: what was the number of the whole flock?

1st. Suppose it 21: of which the first party took $\frac{21}{2} + \frac{1}{2} = 11$, the second took $\frac{10}{2} + \frac{1}{2} = 5\frac{1}{2}$, the third took $\frac{4\frac{1}{2}}{2} + \frac{1}{2} = 2\frac{3}{4}$; so that the remainder was $1\frac{3}{4}$ instead of 20, which gives an error in defect, or - $18\frac{1}{4}$.

2dly. Suppose the number 23: then $\frac{23}{2} + \frac{1}{2} = 12$; $\frac{11}{2} + \frac{1}{2} = 6$; $\frac{5}{2} + \frac{1}{2} = 3$; and the remainder will be 2 instead of 20, and leave an error in defect, or - 18. Then $18 \times 21 = 378$, and $18\frac{1}{4} \times 23 = 419\frac{3}{4}$; and $419\frac{3}{4} - 378 = 41\frac{3}{4}$, which divided by $\frac{1}{4}$, gives a quotient 167 for the true number.

To the rule of position belong such questions, in which the required number or numbers do not ascend above the first power; such, *e. gr.* as most of the questions usually brought to exercise the reduction of simple equations in algebra. But it will not bring out true answers, when the numbers sought ascend above the first power; for then the results are not proportional to their positions, nor the errors to the difference of the true number and each position: yet

in all such cases it is a very good approximation; and in exponential equations, as well as many other things, succeeds better than perhaps any other method.

The above rule of position is found in the earliest writers on arithmetic, and has been retained by nearly all modern authors; though as an arithmetical rule, it is not only useless, but has a tendency to lead to error; there being only a few questions to which it will apply, and these it is difficult to distinguish from those, in which it will not give a correct answer, without an investigation, which is more than sufficient to obtain the correct result. It is, therefore, to be regretted that this, as well as some other useless or superfluous rules, are not expunged by modern authors on arithmetic, to make room for some others, which are as improperly omitted.

The only case in which the rule of position can be advantageously employed, is in the approximation to the roots of numerical and exponential equations; and here, particularly in respect of the latter, it sometimes furnishes a method of solution, which it would be difficult to obtain upon any other principle. When, therefore, we state the rule to be useless in arithmetic, it must not be understood that we wish it to be totally laid aside, but to be transferred from books of arithmetic to those of algebra, to the latter of which sciences it more particularly belongs.

The simplest form of the rule for the latter purpose is as follows:

Find, by trial, or otherwise, two numbers as near the true root as possible, and substitute them in the given equation, instead of the unknown quantity; noting the results that are obtained from each.

Then, as the difference of these results is to the difference of the two assumed numbers, so is the difference between the true result and either of the former to the correction of the number belonging to the result used; which correction, being added to that number when too little, or subtracted from it when too great, will give an approximate value of the root sought.

Again: using the root thus obtained as a new supposition, and another number either in excess or defect, as the case may require, another approximation may be obtained, and so on to any degree of accuracy at pleasure.

There is here, as in all other methods of approximation, except Lagrange's, this defect, that we never can tell the exact degree of approximation obtained. However, in most cases, we may depend upon doubling the number of figures each operation; that is, if we begin with one figure, we may obtain two; and using these two, we may find four; and these four will give eight, and so on.

Let us illustrate this by an example.

Given $x^3 + x^2 + x = 100$, to find an approximate value of x .

Here it is found by a few trials, that the value of x lies between 4 and 5; whence assuming these numbers, the first operation will stand as follows:

4	=	x	=	5
16	=	x^2	=	25
64	=	x^3	=	125
—				—
84	results			155
—				—

Hence the difference of the results is 71, of the suppositions 1; and the difference between the least result (84) and the given number (100) is 16: whence by the rule;

As $71 : 1 :: 16 : 2$, the correction; so that the first approximation gives $x = 4.2$.

POSITION.

Assume now $x = 4.2$, and 4.3 , and we have as before :

$$\begin{array}{rcl} 4.2 & = & x = 4.3 \\ 17.64 & = & x^2 = 18.49 \\ 74.088 & = & x^3 = 79.507 \end{array}$$

$$\begin{array}{rcl} 95.928 & \text{results} & 109.297 \end{array}$$

$$\therefore \left\{ \begin{array}{l} 102.297 \\ 95.928 \end{array} \right. \begin{array}{l} 4.3 \\ 4.2 \end{array} \begin{array}{l} 100 \\ 95.928 \end{array}$$

$$\text{As } 6.369 : .1 :: 4.072 : .64$$

Therefore $x = 4.2 + .064 = 4.264$ nearly.

Assume again $x = 4.264$, and 4.265 , and the operation gives the following result :

$$\begin{array}{rcl} 4.264 & = & x = 4.265 \\ 18.1817 & = & x^2 = 18.1902 \\ 77.5267 & = & x^3 = 77.5813 \end{array}$$

$$\begin{array}{rcl} 99.9724 & \text{results} & 100.0365 \end{array}$$

$$\therefore \left\{ \begin{array}{l} 100.0365 \\ 99.9724 \end{array} \right. \begin{array}{l} 4.265 \\ 4.264 \end{array} \begin{array}{l} 100 \\ 99.9724 \end{array}$$

$$.0641 : .001 :: .0276 : .0004299$$

Therefore $x = 4.264 + .0004299 = 4.2644299$ nearly.

In an example of this kind, however, very little, if any, advantage is gained by the rule of position; the solution being obtained with equal ease, and to the same degree of accuracy, by Newton's, or rather Raphson's well-known method of approximation; but in more complicated cases, this rule ought to be preferred. Thus, in such an example as the following, the rule of position is particularly applicable.

Given $(\frac{1}{2}x^2 - 15)^2 + x\sqrt{x} = 90$, to find an approximate value of x .

Here, by a few trials, it is found that the value of x lies between 10 and 11, which, therefore, let be the two assumed numbers, and the operation will stand as follows :

$$\begin{array}{rcl} 10 & = & x = 11 \\ 25 & = & (\frac{1}{2}x^2 - 15)^2 = 84.64 \\ 31.622 & = & x\sqrt{x} = 36.482 \end{array}$$

$$\begin{array}{rcl} 56.622 & \text{results} & 121.122 \end{array}$$

$$\therefore \left\{ \begin{array}{l} 121.122 \\ 56.622 \end{array} \right. \begin{array}{l} 11 \\ 10 \end{array} \begin{array}{l} 121.122 \\ 90 \end{array}$$

$$64.5 : 1 :: 31.122 : .4$$

Therefore the correction is .4, belonging to the greatest supposition; whence $x = 11 - .4 = 10.6$.

Assume now $x = 10.6$, and 10.5 ; then,

$$\begin{array}{rcl} 49.7025 & = & (\frac{1}{2}x^2 - 15)^2 = 55.830784 \\ 34.0239 & = & x\sqrt{x} = 34.511099 \end{array}$$

$$\begin{array}{rcl} 83.7264 & & 90.341883 \end{array}$$

$$\therefore \left\{ \begin{array}{l} 90.341883 \\ 83.7264 \end{array} \right. \begin{array}{l} 10.6 \\ 10.5 \end{array} \begin{array}{l} 90.341883 \\ 90 \end{array}$$

$$6.614683 : .1 :: .341883 : .005168$$

Whence $x = 10.6 - .005168 = 10.594832$ nearly.

We will add one other example of an exponential equation, for the solution of which no other method can be so advantageously applied as that of position.

Let it be proposed to find the value of x , in the exponential equation $x^x = 100$.

For more easily resolving such kind of equations as this, it is more convenient to take the logarithms of them, and

compute the terms by means of a table of logarithms: thus the logarithms of the two sides of the present equation are,

$$x \times \log. x = \log. 100 = 2.$$

Assuming; therefore, this as the proposed equation, it is found, by a few trials, that the value of x is between the numbers 3 and 4, and a farther trial shews it to be between 3.5 and 3.6; therefore taking these for the two suppositions, the work will stand as follows :

$$\begin{array}{rcl} 3.5 & = & x = 3.6 \\ 0.544068 & = & \log. x = 0.556303 \\ \times 35 & & \times 3.6 \end{array}$$

$$\begin{array}{rcl} 1.904238 & \text{results} & 2.002689 \end{array}$$

$$\therefore \left\{ \begin{array}{l} 2.002689 \\ 1.904238 \end{array} \right. \begin{array}{l} 3.6 \\ 3.5 \end{array} \begin{array}{l} 2.000000 = \log. \text{ of } 100 \\ 1.904238 \end{array}$$

$$.098451 : .1 :: .095762 : .09727$$

Whence $x = 3.5 + .09727 = 3.59727$ nearly.

Again: assume $x = 3.59727$, and 3.59728 ; then,

$$\begin{array}{rcl} 0.555973 & = & \log. x = 0.555974 \\ \times 3.59727 & & \times 3.59728 \end{array}$$

$$\begin{array}{rcl} 1.9999854 & \text{results} & 1.9999953 \end{array}$$

$$\therefore \left\{ \begin{array}{l} 1.9999953 \\ 1.9999854 \end{array} \right. \begin{array}{l} 3.59728 \\ 3.59727 \end{array} \begin{array}{l} 2.0000000 \\ 1.9999953 \end{array}$$

$$.0000099 : .00001 :: .0000047 : .0000474747$$

Whence the value of x is $3.59728 + .00000474747 = 3.59728474747$, which is a degree of approximation scarcely obtainable by any other method. See Dr. Hutton's Course of Mathematics, vol. i. p. 253; and Bonnycastle's Algebra, vol. i. p. 174.

POSITION, in *Geometry*, is a term sometimes used in contradistinction to *magnitude*. Thus a line is said to be *given in position*, *positione data*, when its situation, bearing, or direction, with regard to some other line is given: on the contrary, a line is given in magnitude, when its length is given, but not its situation.

Sir Isaac Newton shews how to find a point, from which three lines, perpendicularly let fall to three other lines given in position, have any given ratio, &c.

POSITION, *Geometry of*, is a species of geometry first treated of by Carnot, in his work entitled "De la Correlation des Figures de Géométrie," and afterwards more fully in his "Géométrie de Position:" it seems, however, that some idea of such a system had been entertained both by Leibnitz and d'Alembert. There exists between the several parts of every geometrical figure, two kinds of relation or ratio, *viz.* the ratio of magnitude, and the ratio of position. The first are those which have place between the absolute value of the quantities, the other is that which expresses their relative situations; indicating whether such a point is above or below a given line, to the right or left of a certain plane, within or without a given circle, &c., which latter relations it is the object of the geometry of position to determine and exhibit. In order to this, some determinate figure is fixed upon, to which all others of the same kind are referred, and which is called the *primitive system*, while that compared with it is called the *transformed system*; and as long as the different parts of the transformed system have the same directions or positions with regard to each other, their correlation is said to be *direct*, but when they are different, *inverse*. These positions, in the analytical representation of geometrical figures, are commonly indicated by the signs

POSITION.

signs prefixed to the letters or symbols representing these lines or quantities; and the geometry of position, at the same time that it gives an uncommon facility to the investigation of many very interesting researches, sets in a clear and indisputable light, all those apparent mysteries and anomalies connected with the introduction of the negative sign into analytical investigations. The peculiar nature of the subject, however, its definitions, and notation, are such, as to prevent our giving the reader such a description of it as would be at all intelligible, without occupying a greater space than can be allowed for this article; all we can do, therefore, is to give one or two of his propositions, which, if they do not explain the method adopted by this author in his researches, they will at least display his ingenuity, and excite the curiosity of the reader to obtain farther information on this subject, than is consistent with the nature of this work to afford him.

Prop.—Let it be required to trace a figure which shall

1.		AB	=	$\text{cof. } n$
2.		AC	=	$\text{cof. } m$
3.		BD	=	$\text{fin. } m$
4.		CD	=	$\text{fin. } n$
5.		BC	{	$= \text{fin. } (m + n)$

11.		AE	{	$= \frac{1}{2} \text{cof. } (m - n) + \frac{1}{2} \text{cof. } (m + n)$
			{	$= \text{cof. } m \cdot \text{cof. } n$
12.		DE	{	$= \frac{1}{2} \text{cof. } (m - n) - \frac{1}{2} \text{cof. } (m + n)$
			{	$= \text{fin. } m \cdot \text{fin. } n$
13.	$BC \cdot BF$		{	$= \text{fin. } (m + n) \cdot \text{fin. } (m - n)$
			{	$= \text{fin.}^2 m - \text{fin.}^2 n$
			{	$= \text{cof.}^2 n - \text{cof.}^2 m$
14.	$AD \cdot AH$		{	$= \text{cof. } (m - n) \cdot \text{cof. } (m + n)$
			{	$= \text{fin.}^2 m - \text{fin.}^2 n$
			{	$= \text{cof.}^2 n - \text{cof.}^2 m$
15.	$AB^2 + DC^2$		{	$= \text{fin.}^2 n + \text{cof.}^2 n$
			{	$= 1$
16.	$AC^2 + B^2$		{	$= \text{fin.}^2 m + \text{cof.}^2 n$
			{	$= 1$
17.	$AE^2 + BE^2 + CE^2 + DE^2$		{	$= 1$

The demonstration of these formulæ is contained in a few sentences, premising as lemmas the following well-known geometrical properties, *viz.*

1. When the diameter of a circle is 1, the chord which subtends any angle formed at the circumference of the circle, is equal to the sine of that angle to radius 1.

2. The rectangle of any two sides of a triangle, is equal to the rectangle of the perpendicular demitted upon the third side, and the diameter of the circumscribing circle: which perpendicular is, therefore, expressed by the rectangle of the sides, when the diameter of the circle is taken as unity.

3. The cosine of an angle is the same as the sine of the complement of that angle, and the sine of an angle is the same as the sine of the supplement of that angle. Therefore, in any quadrilateral inscribed in a circle, the sines of the opposite angles are equal to each other, and the sine or

represent the principal relations between the sines and cosines of two angles, the sines and cosines of their sum, and the sines and cosines of their difference. Let the two proposed angles be represented by m and n , each of which we will at first suppose to be such that their sum ($m + n$) is less than a right angle; suppose also m to be greater than n , and let π represent a quadrant of the circumference, or a right angle.

Construction.—Draw any right line AD (*Plate XI. Geometry, fig. 14.*), and at one extremity, as A , make the angle $BAD =$ the angle m , and on the other side of the same line the angle $CAD = n$. In AD assume any point E at pleasure, and through it draw BC perpendicular to AD ; then through the three points A, B, C , describe a circle, and for the greater simplicity, let its diameter be equal to 1. Draw the two right lines BD, CD , and make $EF = CE$, and $EH = DE$; then we shall have the following formulæ, which exhibit all the cases of the sines and cosines of the angles $m, n, m + n, m - n$, as required, *viz.*

cosine of any one of the angles, is the same as the cosine or sine of either of the adjacent angles.

Hence we draw immediately the following conclusions.

1. $AB = \text{fin. } (\pi - n) = \text{cof. } n$.
2. $AC = \text{fin. } (\pi - m) = \text{cof. } m$.
3. $BD = \text{fin. } m$.
4. $CD = \text{fin. } n$.

Also from lemma 2 above, $BE = \text{fin. } m \cdot \text{cof. } n$; $EC = \text{fin. } n \cdot \text{cof. } m$; $AE = \text{cof. } m \cdot \text{cof. } n$; $ED = \text{fin. } m \cdot \text{fin. } n$; therefore,

5. $BC = \text{fin. } (m + n) = \text{fin. } m \cdot \text{cof. } m + \text{fin. } n \cdot \text{cof. } m$.

6. $AD \begin{cases} = \text{cof. } (m - n) = \text{fin. } \pi - (m - n) \\ = \text{cof. } m \cdot \text{cof. } n + \text{fin. } m \cdot \text{fin. } n. \end{cases}$

Again, since $BF = \text{fin. } (m - n)$, and $BE = EC$, by construction we have

7. BF

$$7. \text{BF} = \sin. (m - n) = \sin. m \cdot \cos. n - \sin. n \cdot \cos. m.$$

And on the same principle,

$$8. \text{AH} \begin{cases} = \cos. (m + n) = \sin. \pi - (m + n) \\ = \cos. m \cdot \cos. n - \sin. m \cdot \sin. n. \end{cases}$$

As to the rest of the formulæ in the table, they are derived from the above by the usual operations; and, therefore, need not be repeated in this place. This method of exhibiting the several cases of the sines and cosines of angles, though of a novel kind, does not arise out of the peculiarities of this species of geometry; the object of which is now to generalize the results here found, these having been all obtained upon the supposition of the two angles being such, that their sum is less, or at least does not exceed a right angle. The author, therefore, after having laid down certain theorems, with regard to the correlation of these quantities, such that no quantity can change from direct correlation to inverse, or according to the usual expression, from positive to negative, or from negative to positive, without passing through 0 or ∞ . With some other rules of a similar kind, he proceeds to shew what change will take place in these formulæ, on the supposition of the different lines of the figure moving in directions parallel to themselves, till some of them have passed through nothing, or infinity; and hence deduces, in the most unexceptionable manner, all the general results for these cases: but, as we before observed, it is not easy to explain his method without too much extending the limits of this article, and the reader, therefore, who wishes to pursue this interesting subject, must consult the works above quoted, *viz.* Carnot, "De la Correlation des Figures de Géométrie," and "Géométrie de Position" of the same author; the former published in 1801, 8vo., and the latter in 1803, 4to.

POSITION, in *Grammar*. See QUANTITY.

POSITION is also used for a thesis or proposition maintained in the schools.

POSITION, *Traiterous*. See TRAYTOROUS.

POSITION, in *Music*, has various significations. In the old *modal* notation, the effect of position was a more difficult study than prolation. (See MODES, and MODAL Signs.) In modern music, the position of notes on the staff among the lines and spaces, ascertains their gravity or acuteness. In beating time, the position of the hand or foot up or down ascertains the parts of a bar; and in instruments with a neck, the French call *position*, what we call *shift*; as first shift, double shift, triple shift; first position, second, third, &c.

POSITIONAL LIBEL. See ARTICULATED *Libel*.

POSITIVE, a term of relation sometimes opposed to *negative*.

Thus we say, the commandments are some of them positive, others negative.

POSITIVE *Quantity*, in *Algebra*. See QUANTITIES.

POSITIVE is also used in opposition to *relative* or *arbitrary*. Thus we say, beauty is no positive thing, but depends on the different tastes of the people.

POSITIVE is also used in opposition to *natural*.

Thus we say, a thing is of positive right, meaning, it is founded on a law which depends absolutely on the authority of him who made it.

The prohibition of eating certain beasts, under the old law, was of positive right; the command to honour father and mother, of natural right.

POSITIVE *Degree*, in *Grammar*, is the adjective in its simple signification, without any comparison.

Or, positive degree, is that termination of an adjective,

which expresses its subject simply and absolutely, without comparing it with any other.

Thus, good, *bonus*, fair, *pulcher*, &c. are in the positive degree; better, fairer, &c. in the comparative.
