This problem is necessary in the three preceding examples, when the feat and inclination of the sun is given on the horizon, in order to find the orthography of the ray upon both elevations; *viz.* upon the front and upon the end.

PROB. XXI.

To find the indefinite shadow of a line perpendicular to the horizon on an inclined plane, given the inclination of the plane to the horizon, and the feat of the sun's rays; the interfection of the inclined plane with the horizon being parallel to the interfection of the plane of representation and the horizon.

Draw any straight line $A B C$, *fig. 5, N° 3*: make $A B$ to $A C$, as the sine is to the cosine of the plane's inclination: make the angle $C A D$ equal that which the feat of the sun's rays makes with a line perpendicular to the interfection of the horizon and the plane of representation: draw $C D$

perpendicular to $A C$, and join $B D$; and $B D$ is the indefinite representation required.

PROB. XXII.

To find the shadow of a plane rectilineal figure intersecting another plane figure, a point through which the shadow is to pass on the plane which receives the shadow, and the orthography of the rays of the luminary, being given.

If the line which throws the shadow meets the interfection of the planes, draw a straight line from the point of concurrence through the given point, and the line thus drawn will be the indefinite representation of the shadow.

But if the line which throws the shadow does not meet the interfection of the planes, continue the line or the interfection of the plane, or both of them, as the case may require, to meet each other, and draw a straight line from the point of concurrence through the given point as before; and the line thus drawn will be the shadow as required.

PROB. XXIII.

Given the orthography of a determinate line, and the indefinite representation of its shadow, also the orthography of the sun's rays, to find the limits of the shadow.

From one or either of the terminations of the line, as the case may require, draw the orthography of a ray to cut or meet the indefinite shadow of the line, and the length comprehended between the point or points thus found in the shadow, will be the extremity, or will terminate the length as required.

Examples.

Ex. 1.—To find the shadow of a chimney shaft on the roof of a house.

Find the indefinite shadow of the vertical line $F L$, *fig. 5, N° 2*, thus:

Let $A C$, *fig. 5, N° 3*, be parallel to $F L$: find $B D$ as in prob. XXI.: draw $F O$, *N° 2*, parallel to $B D$, *N° 3*: now let the parallel of the orthography of the sun's rays be given: from L draw $L O$, the orthography of the sun's rays, and the point O is the termination of the shadow $F O$: produce $F G$ and $L M$ to meet each other in N : draw $O N$, and $O N$ is the indefinite representation of the shadow of the edge $L M$ of the top: draw the orthography $M Q$ of the ray parallel to $L O$, cutting $O N$ at Q : continue the interfection $G H$, and the edge $M L$ of the top, to meet each other in P : draw $Q P$, and $Q P$ is the indefinite representation of the edge of the top, and of the other vertical plane not seen: draw $H R$ parallel to $F O$, and $F O Q R H$ will be the shadow required.

Ex. 2.—*Fig. 6.* is the shadow of a dormer window with a rectangular front, and the top inclined towards the front: find the indefinite shadow $A G$ as in the last example, and the orthography $E G$ of the sun's rays, and join $B G$; and $A G B$ is the shadow required.

Ex. 3.—*Fig. 7.* is the shadow of a dormer window with a pediment top: find $A G$ the shadow of $A E$, as before: then $D E$ being the next line that projects a shadow, $A B$ is the interfection of the plane $A B C D E$; therefore, produce $D E$ and $B A$ to meet in F : join $F G$, which produce to H : find the termination H by the ray $D H$: and $A G H D E$ will be the shadow required.

N.B. If the lines $D E, E G$, had been in the same straight line, or had formed a saliant angle instead of a re-entrant one, the upper side of the shadow would have been the same as in the last example.

Ex. 4.—Fig. 8. exhibits the shadow of a dormer window with a femicircular head: find the shadow AI of the perpendicular line AF : let O be the centre of the femicircular head: draw DL to touch the head of the window at D parallel to the orthography of the sun's rays: draw OD perpendicular to DL , and D is the point of contact: let it be required to find the shadow of any intermediate point, E , of the arc of the circle: now AB is the intersection of the plane $ABCDEF$: therefore draw a chord EF , and produce AB and EF to meet each other in H : join HI : produce HI to K ; and draw the orthography EK ; and the point K will be the shadow of the point E : in like manner draw the chord DE , and produce DE and BA to meet each other in G : join GK ; produce GK to L ; and L will be shadow of the point D : draw a curve from the point I , through K to L , touching the straight lines AI and DL at the points I and L , and $AIKLD$ will be the shadow required.

Ex. 5.—Fig. 9. exhibits the shadow of a dormer window with a kirb-roof top: find the shadows M, K, I , of the points E, F, G , as in the last example; and $AIKMEFGA$ will be the shadow required.

It is hardly possible to conceive any method more expeditious than the present, of finding the indefinite representation of the shadow by producing the line which throws it and the intersection of the plane till they meet each other in the plane in which the shadow is thrown. This principle has never before been generalised, for though it was well known, that if the representation of the shadow of the extremity of a line projecting from a surface, and the representation of the intersection of that line with the surface was found, the representation of the shadow of the line would be determined by joining the representation of the point to the representation of the shadow; yet the method of producing the representation of each successive line, and the intersection of the plane which throws the shadow with the plane on which the shadow is to be thrown, or with the several planes on which the shadow is to be thrown, has never been known as a general rule. This method has great advantages over the common established one, which requires that the seat of every point of the line, or several lines, which throws the shadow, be represented in the plane or several planes on which the shadow is to be thrown, and also that the seat of the luminary be represented in the plane or several planes: this last mode is attended with great labour, when there are more planes than one.

It is true, that in perspective, when the vanishing line of a plane of shade is found, and the vanishing lines of the planes on which the shadows are thrown, the indefinite shadow of the line upon each plane will easily be found: but these vanishing lines are frequently inaccessible, and the construction of them is attended with great labour, and when more lines than one throw a shadow on several surfaces, the labour to find the vanishing line of each plane of shade, and the vanishing lines of the planes on which the shadows are thrown, is very great.

From the great importance of this method in the art of shadows, it will be proper to give a few more examples, in order to shew its universality and expedition.

Ex. 6.—Fig. 1. Plate VI. $N^{\circ} 1$ is the elevation of a prismatic object, as the walls of a building, which form two prisms attached to each other; the lower prism is terminated with an inclined plane in the manner of a roof. The plan, $N^{\circ} 2$, shews the end of the higher prism, to which the lower prism is attached, to be at an obtuse angle with the plane of the front.

Let the ray $BF, N^{\circ} 2$, be drawn on the plan from the corner B , to meet the side CD at F ; then F is the projected point of B on the plan: draw fg , the elevation of the point F , cutting the top of the lower wall at g ; draw lm , the elevation of the sun's ray, as in the preceding examples; produce the intersection hi of the inclined plane to meet the line bl , which projects the shadow in k : through the points k and g draw kgm , meeting the elevation of the sun's rays at m . Now, as the line lo of the top of the end of the prism projects the next shadow, produce lo and the intersection ib to meet each other in n ; draw mn , cutting the upper termination hq of the inclined plane at r ; and $fgmrhief$ will be the shadow required.

Ex. 7.—Fig. 2. $N^{\circ} 1$ is a plane figure representing the gable of a house, of which BA is the base; FG, GH, HU , are the intersections of several planes; FG , parallel to BC , is the intersection of a vertical plane, as the face of a wall; GH and HU are the intersections of two inclined planes, forming two sides of a kirb roof. Now, to find the shadow by the intersecting points of the lines which project the shadow with the plane on which the shadow is thrown, it is evident that the line BC will project a shadow on the plane whose intersection is FG parallel to FG ; and as $BC, N^{\circ} 2$, represents $BC, N^{\circ} 1$, draw pq parallel to BC , cutting the lower inclined plane at q . Then, supposing the side BC also to throw a shadow upon the lower inclined plane, produce its intersection $HG, N^{\circ} 1$, and the line BC , which throws the shadow, to meet in K ; produce $CB, N^{\circ} 2$, to k , and draw Kk parallel to BA , then through the points k and q draw qkr ; draw CC from $C, N^{\circ} 1$, to $C, N^{\circ} 2$, parallel to $BA, N^{\circ} 1$; from the point $C, N^{\circ} 2$, draw the elevation Cr of the sun's rays. $CD, N^{\circ} 1$, is the next line which throws the shadow still upon the lower inclined plane; therefore, produce CD and GH to meet each other in M ; draw Mm parallel to BA , cutting BC at m ; draw also the indefinite shadow rm , cutting the intersection of the two inclined planes at $s, N^{\circ} 2$; then the line CD will also project a shadow upon the upper inclined plane; therefore, produce HU and $CD, N^{\circ} 1$, to meet each other in N ; draw Nn parallel to BA , cutting BC at n ; draw the indefinite shadow sn ; then $d, N^{\circ} 2$, being the corresponding point of $D, N^{\circ} 1$, draw the elevation of the ray $dt, N^{\circ} 2$, and the point $t, N^{\circ} 2$, will be the shadow of $D, N^{\circ} 1$. $DE, N^{\circ} 1$, is the next line that projects a shadow, and U is the intersection of DE and HU , and u the corresponding point to $U, N^{\circ} 1$; therefore join tu , and $Bpqrsttu$ will be the shadow required.

Ex. 8.—Fig. 3. represents an example similar to *fig. 1*, but with two inclined planes; the plan is here omitted, as it is only used in the projection of the first ray; the ray GL , parallel to AB , is drawn at pleasure at any distance from FH , to meet the intersection HP of the two adjoining planes in L ; produce IH to meet the line AB , which throws the shadow in D ; draw DL , and produce DL to S : draw the elevation of the ray BS ; then BC is the next line which throws the shadow: produce BC and HI to meet each other in E ; draw the indefinite shadow SE to cut the intersection IQ of the two inclined planes at M ; then BC will also project a shadow upon the upper plane; therefore, produce BC , and the intersection IK of the upper plane, to meet each other in T ; draw the indefinite shadow MT , cutting the top KR at N ; then $FGLSMNK$ will represent the projection of the shadow by the edges AB, BC , of the plane ABC , as required.

This figure may either represent the vertical plane ABC ,

PROJECTION.

or perpendicular to the first vertical plane F O P H, according as the sides are parallel or oblique to the plane of representation.

Ex. 9.—Let A B C D E (*fig. 4.*) be the figure of a gable, K L M N the upright of a wall, A B the base of the gable, N M the base of the wall; and suppose that the edge B C is joined to N K at any given angle, so that the point B may coincide with the point N. Now let it be required to find the shadow of the gable A B C D E upon the wall K L M N, the side B C of the gable being placed parallel to the edge N K of the wall.

As the vertical sides A E and B C of the gable are parallel, the shadow thrown upon the plane K L M N will also be parallel to the edge N K; therefore, taking N g at pleasure, draw g b parallel to N K; then e being the corresponding point of E, draw e b the elevation of a ray of the sun, and the point b will be the shadow of the point E. E D being the next line that projects the shadow, produce E D and B C the intersection of the plane to meet in F; find f the corresponding point of F, and draw the indefinite shadow b f; find d the corresponding point of D, and draw the elevation d i of a ray, cutting b f at i; C being the concourse of the line which throws the shadow with the intersection B C of the plane, find c the corresponding point of C, and join c i; then e i g b is the shadow of the lines A E, E D, and D C.

Ex. 10.—A B C D E (*fig. 5.*) represents the gable of a building as in the preceding example, S T U V the upright wall and inclined side of a roof, F G and G I the respective intersections of the wall and the roof: then, supposing the edge E D of the gable to be attached to S b, it is required to find the form of the shadow; the intersection F G of the plane being parallel to A B, the breadth of the shadow will also be parallel; therefore, taking the distance S n upon S V at pleasure, draw n o parallel to S T; then b being the corresponding point of B, draw the elevation b o of the ray. B C being the next line which projects the shadow, produce the intersection F G to meet B C in L; find l the corresponding point of L, and draw the indefinite shadow o l, cutting b W at p; B C now projects the shadow upon the inclined plane; therefore, produce the intersection G I, and the edge B C that throws the shadow, to meet in K; find k the corresponding point of K: through k and p draw the indefinite shadow k p q; c being the corresponding point of C, draw the elevation c q of a ray; find i the corresponding point of I; join i q, which completes the shadow on both planes.

PROB. XXIV.

A cylinder being capped with a square abacus, jutting alike over each side of the cylinder, to find the representation of the shadow; the elevation and plan being given, as also the plan and elevation of the sun's rays.

Let A B C D (*fig. 6. N° 1.*) be half the plan of the abacus, E F G half the plan of the cylinder, H I J K the elevation of the same, and L M N O that of the abacus, to project the shadow of any point p' in the elevation of the abacus, p being its corresponding place on the plan; draw the plan of the ray p q, meeting the semicircumference E F G at q; also from p' draw the indefinite elevation of the ray p q; and draw q q' parallel to I J or H K, and q' will be the shadow of the point p'. Find as many other points as may be necessary in the same manner; then, through all the points thus found, draw a curve, which will be the shadow required.

If the ray R T be drawn to touch the circle in V on

the plane, and if V' V'', the elevation of V, be drawn, then V' V'' will be the line of separation of light and shade.

If the rays of the sun be in two planes, one perpendicular to the plane of representation, but inclined 45 degrees to the horizon, and the other equally inclined to the horizon and to the plane of representation; that is to say, making 45 degrees with each; then all the points q' will be in the circumference of a circle, whose diameter is equal to the representation of the diameter of the cylinder.

Fig. 6, N° 2, shews the elevation completely shadowed.

PROB. XXV.

A cylinder being capped with another concentric cylinder, to find the representation of the shadow, *fig. 7, N° 1.*

Proceed to find all the points q' as in the last problem, and a curve being traced through the points q' will give the shadow required.

The point p' on the elevation, corresponding to p on the plan, may be thus found. Draw B R parallel to A C, and A R perpendicular to A C; draw p S parallel to A R, cutting B R at S. In L M make L p' equal to R S, and p' will be the corresponding point of p. N° 2. shews the elevation completely shadowed.

PROJECTION of the Sphere is the representation of all its circles upon a plane, either by rays proceeding to a given point, or parallel among themselves, passing through all the points of these circles till they are intercepted by the said plane.

When the rays are all parallel, the representation may be formed by the rules of orthographical projection: we shall take this case first.

PROJECTION of the Sphere, Orthographic. In orthographical projection, when the rays fall upon the plane of any circle, they will form a cylinder, and if the plane of the circle be parallel to the plane of representation, or in a subcontrary position, the projection of that circle will also be a circle equal to the original; but if the plane of the original circle be parallel to the projecting rays, the representation of the circle will be a straight line equal in length to the diameter of the original circle.

PROB. I.

Given the major axis A B, and a point C in the curve of an ellipsis, to find the minor axis, and thence to describe the curve.

Fig. 1. Plate VII. Bisect A B in E; through E draw F G perpendicular to A B; from C as a centre, with the distance A E or E B, describe an arc, cutting F G at H, and draw C H, cutting A B at I; make E F and E G equal to I C and F G, and F G will be the minor axis required.

This problem belongs to conic sections, but as its application is requisite in the following problems, it is here introduced.

PROB. II.

Given a great circle A B C of the sphere, and the orthographical representation of two points D and E, on the surface; to determine the intersection of a plane passing through the centre of the sphere, and through the original of the points D and E, with the plane of the circle given.

Through the points D and E (*fig. 2.*) draw A B; on A B, as a diameter, describe a semicircle A F G B; draw D F and E G perpendicular to A B: join F and G, and produce F G and A B to meet in H: draw H I, cutting the circle A B C in K; produce K I to meet the opposite circumference

circumference in C, and K C will be the diameter in which the plane will intersect.

Definitions.

1. A primitive circle is a great circle of the sphere, on which the representations of all the other circles are formed. The primitive circle is always supposed to be given.

2. A point is said to be drawn in projection, when the intersection of a straight line with the primitive is given, by drawing the line from the given point in the circle to be projected perpendicular to the primitive.

Hence, if two points be given in the projection of a great circle, the whole circle will be determined, since the centres of all great circles pass through the centre of the sphere; every great circle must, therefore, pass through the centre of the primitive; three points will therefore be given, by which the original circle can be determined.

PROB. III.

Given two points D and E in the projection of a great circle, to find the representation of the circle.

Find C K, (*fig. 3.*) the intersection of its plane, by problem II., and C K is the major axis of the ellipsis which represents the original circle. There is now given the major axis C K, and a point D or E, in the ellipsis; the minor axis L M being found according to problem I., the ellipsis C L K M may be described by the same, and the curve thus drawn will be the orthographical representation required.

PROB. IV.

Given the projection of a great circle of the sphere, and the point of projection of the intersection of that circle with another circle, and the inclination of the planes of these two circles, to find the representation of the other circle.

Let C L K M (*fig. 4.*) be the projection of the circle given, and let the point F be the projection of the intersection of the two great circles. Join F I, and draw F N perpendicular to F I, cutting the primitive A B C in N; produce I F to O, and draw N O perpendicular to I N; through O draw P Q perpendicular to I O; produce I K to meet P Q in R, and produce I O to S; make O S equal to O N, and join R S; make the angle R S T equal to the inclination of the planes of the two great circles, and let S T cut P Q in T; join T I, cutting the circle in U; produce U I to meet the opposite side of the circumference at V; then describe the representation of a great circle, by problem III., upon U V, as a transverse axis through the given point F in projection; and the original of the representation, U W V X, will form the given inclination R S T, with the original of the circle represented by K M C L, and these two original circles will pass through the original of the point F, as was required.

It is evident that I F will be the seat of the common axis of the two great circles, because the original axis passes through the point I; and because the pole is in the common axis, and F is the seat of the pole, therefore F is the seat of another point in the axis. Again, because F I passes through the centre, and F N is perpendicular to F I, let F I be produced to meet the opposite parts of the circumference in Y and W; then Y N W will be a semicircle: if this semicircle be turned round Y W as an axis, the semicircumference will describe the spheric surface, and F N will describe a lesser circle of the sphere perpendicular to the plane of the primitive; let the semicircle Y N W be turned round its diameter Y W, until its plane become perpendi-

cular to the primitive, then the straight line F N will be perpendicular to the primitive, and the point N in the perpendicular F N will be in the intersection of the two great circles in the surface of the sphere. Again, because N O is perpendicular to I N, and I N represents the axis; N O is a section of a plane perpendicular to the axis, and P Q is also a section made by the plane: but O S is equal to O N, and C R is the section of the plane of the great circle and the primitive; let the triangle I N O be raised upon I O, perpendicular to the plane of the primitive; also let the triangle T S R be turned round P Q, until O S coincide with O N, then the point S will fall upon N, and the axis I N will be perpendicular to the plane of the triangle R S T from the point S: now since R C and T V are the intersections of the planes of the original circles, and because the plane R S T is perpendicular to the axis, the angle R S T is the measure of the inclination of the planes.

PROB. V.

About a given point E, as a pole, to draw the representation of a circle, at a given distance from the pole.

Join E I, (*fig. 5.*) and draw E F perpendicular to E I, meeting the circumference of the primitive in F, and join F I; make F G and F H equal to the distance of the original circle from the pole; join G, H, cutting I F at O, and draw G K, O N, and H L perpendicular to I E, cutting I E at K, N, and L: make N P and N Q each equal to O G or O H; on P Q and K L describe the ellipsis P K Q L, which will be the representation required.

By this problem all the parallels of latitude may be drawn, and by problem IV. the meridians may be described; these two problems will, therefore, be sufficient to represent all the principal circles of the sphere.

By this kind of projection, either the convex or concave side of the sphere may be represented; this choice is peculiar to the orthographic projection; but in both these projections the circles will be inverted in respect of each other, since to project each, the eye must be turned on contrary sides of the surface, that is, to the convex and concave sides.

Example.—*Fig. 6.* shews the application of the preceding problems in the orthographic projections of the sphere; the first meridional representative circle is drawn according to problem III., the second according to problem IV., and all the remaining circles in succession, according to the same problem. The parallels of latitude are all drawn according to problem V. The objections to the orthographic method of projection are, that the distances of all the representative parallels of latitude are unequal from the pole, and the distances from all the representative meridians are also unequal as they are reckoned from one parallel of latitude to another, that is, as they are measured upon any such parallel; and that the representative angles continue to increase by inequality from the line of position on each side of it to the circumference of the primitive circle.

PROJECTION of the Sphere by the Rules of Perspective.—Let the primitive circle be called the plane of projection or picture, and let the centre of the primitive be also denominated the centre of the picture. The position of any circle to be projected is determined by a diameter of the primitive, and a straight line at right angles therewith. The eye is supposed to be fixed in this straight line, at a given distance from the centre, in order to view the circle to be projected. The eye and the given diameter of the primitive are supposed to be in a plane, both perpendicular to the primitive and to the original circle to be projected, and to pass through the centre of the said circle.

PROJECTION.

Definitions.

1. The plane passing through the perpendicular in which the eye is fixed, and through the given diameter, is called the vertical plane, or plane of position.

2. The given diameter is called the diameter of position, and produced to any indefinite length, is called the line of position: this diameter is, therefore, the intersection of the primitive and the vertical plane.

3. A great circle of the sphere in the plane of position, having a common centre with the primitive, is called the vertical circle.

In the practice of representing a circle of the sphere, the plane of position is folded upon the plane of the primitive circle, and, consequently, the circumference of the circle of position will coincide with the circumference of the primitive circle.

The position of the original plane to the plane of the picture is determined by producing the chord, which is the diameter of the circle to be projected, and the line of position, till they meet each other; and the angle thus contained is the inclination of the planes.

The distance of the centre of a vanishing line is determined by drawing a straight line through the point of light, parallel to the diameter of the circle to be projected, until it meet in the line of position.

PROB. I. Method 1.

To project any oblique circle of the sphere, the eye being at any given distance from the primitive.

Let $ABCD$ (*fig. 7.*) be the primitive and the circle of position, and AC their common diameter, in which is the centre O ; through O draw the straight line EBD perpendicular to AC , and let FG be the diameter of the circle to be projected; draw EF , cutting AC at f , and EG , cutting AC in g ; produce FG and AC , till they meet in H ; through H draw TU parallel to DB , and produce CA beyond each extremity towards I and N ; draw EI parallel to HF ; make HK equal to EI , HL equal to HG , and HN equal to HF . Upon LN , as a diameter, describe the circle $LMNP$; TU being the intersecting line of the plane of the original circle; $LMNP$ the original circle itself, placed in its real situation; and HK the distance between the vanishing line, that is, from the eye to the centre of the vanishing line; and K the prime directing point: therefore, bisect fg , which is one of the axes in u ; through u draw mp parallel to TU ; draw KM and KP tangents to the circle, cutting TU at R and S ; draw Rm and Sp perpendicular to TU ; then mp and fg are the two axes, by means of which the curve, which is the representation of the circle required, will be described.

Method 2. Without using the directing point.

Fig. 8.—The same lines and point being used as before, except the original circle and directing point, and FG being found as before; bisect GF , the diameter of the original circle, in Q ; from Q , with the radius QG , or QF , describe the semicircle GNF ; bisect fg at u ; through u draw mp parallel to TU ; draw Eu , which produce to meet GF in K ; draw KN perpendicular to GF , cutting the circumference of the semicircle at N ; in TU make HL and HM equal to KN ; draw MI and LI , cutting mp in m and p ; then fg and mp are the axes, as before.

Method 3. By the vanishing and intersecting lines.

Fig. 9.—The same lines and points standing as in the preceding method, excepting the semicircle GNF , the straight line EK , the points L and M in the intersecting line TU , and the axis mp of the representative circle; bisect GF in Q , as before; in TU make HR and HS equal to QF or QG ; draw RI , HI , and SI ; through I draw the vanishing line WX , which is in course parallel to TU ; make HZ equal to HQ , and IW equal to IE , and draw ZW , cutting RI at b , HI at q , and SI at d ; parallel to TU draw ba , bi through q , and cd from c ; the points a, b , being in SI , and the points i and c being in RI ; let ab and dc cut HI respectively at f and g ; then $abcd$ represents a square, circumscribing the original circle; therefore draw the diagonal ac , and draw the ellipsis $gbfi$, which is the representation of the original circle.

PROB. II.

To find a representation of a great circle of the sphere.

Let AC (*fig. 10.*) be the diameter of position, as before, and GF the diameter of a great circle in the vertical plane, which will therefore pass through the centre O ; and the plane of the great circle itself will intersect the primitive in the diameter BD , which is common to both, to the vertical circle and to the primitive, whether these two circles are coincident or placed at any angle with each other; and as BD will be at right angles to AC , the points B and D are points in the representative circle; draw EF , cutting AC in f ; produce EG and AC to meet each other in g , then gf is one of the axes found as before; the axis gf and a point B or D in the curve being given, describe the ellipsis by problem I. *Orthographical PROJECTION.*

PROB. III.

To find the measure of the arc of an original circle, represented by the part ab of the representative circle $fmgp$.

Draw Eg and Ef (*fig. 11.*); produce E to F , and Eg to G , and join GF ; bisect GF in Q ; draw EQ , cutting fg in q ; and draw qa , which produce to meet TU in J ; also draw qb , which produce to meet TU in K ; then if HQ be taken as radius, HK will be the tangent of the angle represented by the portion gb of the representative circle; also HJ , the tangent of the angle represented by the portion ga of the same. But the parts ga and gb make the whole representative arc ab , therefore the whole angle will be found by its tangents thus: draw HL perpendicular to TU ; make HL equal to HQ ; join JL and KL , and KLJ will be the measure of the arc represented by the curve AB .

Demonstration.—For TU is the intersecting line of the plane, and J and K are the intersecting points of the lines represented by qa and qb ; but the lines qa and qb are the representations of the radii. Now the point L , in the original plane, is the original of the centre; therefore JLK is the angle formed by the radii of the original circle.

If the measure of the angle bqc , which represents the supplement of the angle represented by bqa , be required; produce JL to M , and KL is the measure of the angle represented by bqc .

PROB. IV.

To find the original measure of any arc of a representative great circle.

Let

Let $BfDg$ (*fig. 12.*) be the representative great circle, of which it is required to find the original part ab .

Let AC be the diameter of position, and GF the diameter of the great circle in the vertical plane.

Produce CA to Z ; draw EI parallel to GF , meeting CZ in I ; make IZ equal to IE ; draw Za and Zb ; produce Za to meet the primitive in A' , and Zb to meet it in B' ; then will $A'B'$ be the original arc represented by ab .

Again, let it be required to find the arc represented by the portion ij of the other semicircle; draw Zi , cutting the opposite part of the primitive in I ; also draw Zj , cutting the opposite part of the primitive in J ; then IJ is the original of ij , as was required to be done.

Demonstration.—For BD is the intersecting line, and WX the vanishing line; I is the centre of the vanishing line, Z is the place of the eye in the vanishing plane, and $B'GBIJD$ is a circle in the original plane; therefore a is the representation of the point A , according to the principles of *perspective*; which see.

This method, which is entirely founded on the principles of Brook Taylor, has never before this, to our knowledge, been applied to the projection of the sphere, (and so far it is new,) not even by authors who have professed to give complete treatises on perspective. The rule is quite universal, so that it may be used to any distance of the eye whatever; whereas, in the common method, by finding the poles in the stereographic projection, the eye must be confined to the surface of the sphere; or in other words, the pole will not be the point from whence two lines may be drawn, that will intercept corresponding parts of the original circle, and its representative. This problem, moreover, shews the vast superiority over particular methods, which require so much trouble to perform.

PROB. V.

Given the angle which the intersection of the plane of a great circle, and the vertical plane, make with the line of position, and the inclination of the plane of that great circle with the vertical plane; to find the intersection of the great circle on the plane of the primitive.

Let AB (*Plate VIII. fig. 1.*) be the line of position, passing through the centre O of the primitive; and let AOC be the angle which the intersection of the plane of the great circle, and the vertical plane, make with the line of position. From any point C in OC , draw CD perpendicular to OC , cutting AB produced in D ; produce BD to F ; make DF equal to DC ; through D draw GH perpendicular to BF ; make the angle BFI equal to the inclination of the plane of the great circle with the vertical plane, and let FI meet GH at I ; draw IK through O , cutting the primitive in J and K ; and JK is the intersection of the great circle required.

PROB. VI.

Given the inclination of the planes of two great circles, intersecting each other in the vertical plane, the angle which their common intersection makes with the line of position, and the inclination of one of them with the said vertical plane; to find the intersection of the other great circle.

Find the intersection JK of the plane of the great circle, of which its inclination is given to the vertical plane, as in the preceding problem; make IFL equal to the inclination of the two great circles, and let FL cut HG at L ; draw LN through the centre O , cutting the primitive in M and N ; then will MN be the intersection required.

Corol.—Hence, in a series of great circles, intersecting each other in one common diameter in the vertical plane, if the successive inclinations of each two adjoining ones are given, the angle which their common intersection makes with the line of position, and the inclination of one of them with the vertical plane, each successive intersection will be formed by this problem. The present figure shews the intersection of the planes of twelve great circles placed at equal angles, *viz.* that of any two adjoining circles with that of any other two adjoining circles.

PROB. VII.

Two lines tending to an inaccessible point being given, through a given point to draw a third that shall tend to the same point.

Let FP and DH (*Plate VIII. fig. 1.*) be two straight lines, which approach nearer together towards the parts P and H , than at F and D ; and let O be the point through which the other straight line is to be drawn. Join OF , cutting DH in D , and draw PHQ parallel to OF ; find a fourth proportional to FD , DO , PH ; and make HQ equal to the fourth proportional; draw OQ , and OQ is the line required.

This problem is useful in the construction of the two last problems, where the distances of the points of concurrence of the lines forming the angles with the line GH , might be so great as to render the drawing of the radial lines from O impracticable; it is, therefore, introduced in order to remedy this inconvenience.

The diagram, $N^o 2$, shews the construction of finding PH , as is generally done by means of a triangle.

PROB. VIII.

Given the angle which the common intersection of a great circle, and the vertical plane, make with the line of position, and the intersection of the plane of the great circle, to find the inclination of the said plane to the plane of the primitive.

Let AB (*fig. 2.*) be the line of position, CD the intersection of the great circle, cutting each other at the centre O . Make BOG equal to the angle which the common intersection of the great circle and the vertical plane make with the line of position. In OB , or OB produced if necessary, take any point F , and draw GF perpendicular to OF ; produce OF to H , and CD to I , if necessary, and draw FI perpendicular to CI ; make FH equal to FI , and join GH ; then FHG will be the inclination of the plane of the great circle to the plane of the primitive, as was required.

Fig. 3. shews the inclinations of the planes of a series of great circles to the plane of the primitive, the planes being supposed to have a common intersection through a straight line in the vertical plane, and form equal angles with each other.

PROB. IX.

Given the intersection of a great circle, the inclination of its plane to that of the primitive, and the distance of the eye, to find the representation of the great circle.

Method 1.

Let CD (*fig. 4.*) be the intersection given; produce CD to E ; make OE equal to the distance of the eye; through the centre O draw FG perpendicular to CD ; make the angle OEG equal to the inclination of the plane of the great circle to the primitive; draw GH parallel to DC ;

PROJECTION.

DC; make GH equal to GE, the distance of the eye; join DH, cutting FG at I; join also CH, and produce CH to F, and FI is the minor axis; then, having the minor axis FI, and a double ordinate CD, describe the elliptic curve by problem I. *Orthographic Projection of the Sphere.*

It is evident, that DC is the intersecting line of the plane of the great circle, and GH the vanishing line of that plane; the method of finding the representation of the great circle is therefore reduced to a common perspective problem.

It most frequently happens in practice of the projection of the sphere, that the part of the great circle within the primitive, is all that is required to be represented. The following methods, by finding points in the curve, are very eligible for the purpose.

Method 2.

Let GH (*fig. 5.*) be the vanishing line, found as before; and since EC is the intersecting line, the semicircle CAD may represent the circumference to be projected, as well as the semicircumference of the primitive, for the two may now be supposed in a state of coincidence. Let CAD, therefore, be supposed to be the semicircumference of the great circle to be represented. To find the representation *a*, of any point A in the original circle, draw GI perpendicular to GH; make GI equal to GE; through the original point A draw AB, meeting the intersecting line EC at any angle; through I draw IH parallel to AB; join H, B and I, A cutting HB at *a*; then *a* is the representation of the original point A. And in this manner, as many points may be found as will be sufficient to draw the curve.

Method 3. Without the original circle.

Let GH (*fig. 6.*) be the vanishing line, as before; make GH equal to GE, the distance of the vanishing line, GOB being supposed to be previously drawn; join HD, and produce it to B; join also CH, cutting GB at A; through A draw FG parallel to D, and draw DF and CG parallel to AB; divide DF into any number of equal parts, say three; also divide DO into the same number of equal parts, *viz.* three; draw the lines MA, NA; draw also BO and BP; produce BO to meet MA at *q*, and BP to meet NA at *r*, then *q* and *r* are points in the curve. In the same manner the curve AC may also be drawn, which completes the lower semicircle. And thus having a diameter AB, and double ordinate, the curve is described.

Again, if it were required to represent the semicircle next to the eye, it is only dividing DO in the same manner, that is, the division will stand for both; then drawing a line parallel to AB, and another parallel to DO, to meet the line parallel to AB; divide the line parallel to AB into three equal parts, *viz.* into the same number as D; draw lines through the points of division as before, which will give the representation of one of the upper quadrants: the other will be found in the same manner, and thus the whole curve is found geometrically.

PROB. X.

Through a given point P, to draw the representation of a great circle making a given angle with the vertical plane passing P.

Join OP, (*fig. 7.*) and produce it both ways to S and N; draw DE perpendicular to SN; make OE equal to the distance of the eye; draw EP, which produce to meet the circumference in L; join LO, and produce LO to meet the circumference of the primitive in M; draw EM to meet SN at S; draw LX perpendicular to LM, cutting

SN at X; through X draw UV perpendicular to SN; make XN equal to XL. From N, as a centre, with the radius XN, describe the arc WXY; make the angle XNZ equal to the inclination of the vertical plane passing through P with the plane of the great circle to be projected, and let NZ cut UV at Z; draw ZO, cutting the circumference of the primitive in Q; produce QO to cut the opposite part of the same in T; through P draw ZK; then describe an ellipsis through the three points S, T, Q, to touch the straight line KZ at P, and the curve PQRS thus described will be the representation of the great circle required.

Demonstration.—Because SN is the intersection of the vertical plane passing both through the original pole and its representation P, L will be the original pole; and because LM is a diameter of the vertical circle, M will be the other original pole. And because both the projected poles must be in the straight line NS, at right angles to ED, EM being drawn will project the other pole M at S. Now the vertical plane, with all the lines and points therein, being turned round SN perpendicular to the primitive, and a plane being supposed perpendicular to LN passing through the pole S, this plane will be perpendicular to the vertical plane; and since the primitive, by supposition, is also perpendicular to the vertical plane, the intersection of the plane thus touching the pole and the primitive will be perpendicular both to the intersection of the vertical plane with the primitive, and the intersection of the vertical plane with the plane touching the pole; and because the point X is the intersection of the plane touching the pole and the primitive on the vertical plane, therefore the point X is common to the three planes; and therefore UV, passing through X perpendicular to SN, is the common section of the plane touching the pole and the primitive. Let the triangle XNZ be turned round XZ, then XN will describe a plane perpendicular to the primitive, and NS will be the intersection of this plane and the primitive, therefore the line NK will be in the vertical plane. Now, because XN is equal to XZ, let the triangle NXZ revolve upon XZ, until XN coincide with XL, and the point N will fall upon L; and thus XN, coinciding with XL, will be by supposition perpendicular to LO; and therefore the plane XN will be perpendicular to LM. But the measure of the inclination of two planes is the angle contained by the common section of these two planes with a third plane perpendicular to both planes; and because each of these planes intersects UV at Z and X, and the primitive at O, OZ and OX will be the sections of these planes with the primitive; therefore the points Q and T will be the sections of the circle in the plane whose section is TZ, and consequently the representation of that circle will also pass through the points Q and T; but it will also pass through the representative poles S and P; and because UV is the intersection of a plane drawn through the pole L perpendicular to the axis LM, every line drawn from L to the intersection UV will be perpendicular to the axis LM, and will touch the surface of the sphere at L. But P is the representation of the original pole L, and Z is the intersection of a tangent from L; therefore ZP is the representation of a tangent at P, and consequently the representation will pass through the points Q, S, T, and touch the straight line KZ at P.

By this problem all the meridians of the sphere may be drawn, so that their planes may be at given angles with each other, and may be regulated by the first, which may be called the primary projection of the meridian.

Scholium.—In order to save trouble, and yet preserve sufficient accuracy, the following observations will enable the

student to simplify the operation, when only the portion T P Q is required.

The ellipsis which is the representation of the great circle, has its minor axis passing through the centre O perpendicular to T Q, and its major axis parallel thereto; therefore a perpendicular drawn from the point O, will cut the curve T P Q into two equal and similar portions; consequently, if two straight lines be drawn from the line T Q perpendicular thereto, and equally distant from the centre O, till they are intercepted by the curve, these two intercepted perpendiculars are equal to each other: therefore from P draw P a perpendicular to T Q, cutting it in a; in O T make O b equal to O a, and draw also b c perpendicular to T O: make b c equal to a P; then, through the points T, c, P, Q, draw a curve to touch K Z at P, and this curve will represent the semigreat circle of the opposite hemisphere, sufficiently near for the purpose of constructing any map. The points T, c, P, Q, are equivalent to five points, as the tangent at P is equivalent to two.

But if greater accuracy still be required, the curve may be traced round to the representative pole S, which will shew more of the ellipsis, and consequently the degree of curvature required in the various points of the representation.

PROB. XI.

To find the representation of a circle in a plane perpendicular to the plane of projection, given the intersection of the circle, and the distance of the eye.

Method 1.

Let C D (*fig. 8.*) be the intersecting line, E the place of the eye; it is evident that since the plane of the original circle is perpendicular to the plane of projection, the vanishing line A E will pass through the centre of the primitive circle, parallel to the intersecting line C D. Make O E equal to the distance of the eye from the plane of projection; draw P L through O perpendicular to A E; join E D, and produce E D to L; join also E C, cutting P L at J; bisect C D in F. Take any vanishing point v^1 ; draw $v^1 F$, which produce to H; make $v^1 I$ on the vanishing line equal to $v^1 P$; draw I D, and produce I D to H; join C I, cutting $v^1 H$ at G, then G H is the representation of a diameter of the original circle. In the same manner, by taking any vanishing point v^2 and the distance $v^2 z$ equal to $v^2 P$, the diameter I K will be obtained; and as many diameters in the same manner, as will give a sufficient number of points for drawing the curve representing the original circle.

Method 2.

Fig. 9.—The intersecting line C D, the line of position O L, and the distance O E of the eye, being given as before, join E D, which produce to L; join also C E, cutting O L in J; then will the minor axis J L, and the double ordinate C D, describe an ellipsis by problem I. *Orthographic Projection of the Sphere*; and the curve will be the representation of the circle required.

Scholium.—The preceding problems shew several steps, in order to obtain a complete projection of all the circles of the sphere. By problems V. and VI. the intersections of all the great circles on the plane of the primitive are obtained. By problem VIII. the inclination of any plane may be found to the plane of the primitive, by the intersection of the plane and distance of the eye being given. By problem IX. the representation of any great circle may be obtained, when its intersection, the distance of the eye, and the inclination of the great circle to the plane of the primitive, are given. The same method may also be

employed in finding the representation of a small circle. By problem X. the representations of circles perpendicular to the plane of projection are obtained.

Examples constructed on the foregoing problems.

Example 1.—*Plate IX. fig. 1.* is a projection of the meridians upon the plane of a meridional circle. In this the common axis falls into the plane of projection. The distance of the eye is three-fourths of the radius from the sphere. From the choice of this particular distance, the meridians will divide the diameter of position into equal parts very nearly. The figure also shews how each ellipsis is described by means of the axes. The representations for one half of the lower hemisphere are only shewn; the other half being the same, except that each is opposite to its correspondent.

Ex. 2.—*Fig. 2.* is a projection of the parallels of latitude upon the plane of the meridian, the distance of the eye being the same as in example 1. This figure shews the manner of describing the ellipses by their axes; the curves divide the circumference into equal parts, and also the diameter very nearly.

Ex. 3.—*Fig. 3.* is a complete projection of both the meridians and parallels of latitude upon a meridional plane, which combines both the first and second examples. The circumference of the primitive is divided into equal parts, by the representation of the parallels of latitude; the diameter A B is divided into equal parts very nearly, by the same curves; and the diameter C D into equal parts very nearly, by the meridians.

Ex. 4. *Fig. 4.* represents a projection of the sphere, as in *fig. 3*; except that in *fig. 3*, all the circles of the sphere are elliptical, whereas in this figure they are circular; the diameters A B and C D being equally divided, as well as the circumference. This is what the constructors of maps are pleased to call the *globular projection* upon the plane of a meridian. Though this construction answers to the equality of parts in the circumference and diameters of *fig. 3*, yet the curves being all arcs of circles, are not in truth projections; the deformity in the compartments, particularly at the circumference, and near the pole, is obvious, when compared to the true projection, *fig. 3*.

Ex. 5.—*Fig. 5.* is a projection of the circles of the sphere upon the plane of the equator, the distance of the eye being the same as above, namely, three-fourths of the radius; the parallels of latitude divide each of the radii, which represent the meridians, into equal parts very nearly. This is what map constructors term the *globular projection* on the plane of the equator. Though constructions, as in *figs. 4*, and *5*, are sufficiently near for practical purposes, the principle can only be obtained from the preliminary problems necessary in the construction of *figs. 1, 2, and 3*.

Ex. 6.—*Fig. 6.* shews the projections of the meridians, and all the parallels of latitude, according to the general principles of *perspective projection*; the distance of the eye from the plane of the projection, or primitive circle, being three-quarters of the radius, as in the preceding examples. The meridians are all projected according to problem IX.; and as they are at 15° distant from each other, answering to hour circles, the first meridian is described according to the angle which it is required to make with the vertical plane, and all the remaining meridians at 15° from each other, beginning from the first on each side of it, and ending in 90° . The semicircle is thus divided into 12 equal parts, which give 24 angles at the pole in projection; and as all these pass through the centre of the primitive, they divide the remote concave semicircumference, as well as that of the nearer converse half. All the parallels of latitude are projected according to problem I.; the distances of the parallels

parallels are 10° from each other, and are set off on the circumference from the pole on each side of it. By the choice of distance of the eye from the primitive, as employed in this example, the parallels of latitude are nearly at equal distances, reckoned along any straight line drawn from the pole; and the same distance will nearly take place, by producing the straight line upon the opposite side, as far as 40° , where indeed no more can be drawn upon the semicircle, which contains the pole. The picture here shewn is as near the true figure as can be delineated on so small a scale.

This projection ought to be employed, instead of what is improperly called the globular, which in fact is founded upon no principle of projection whatever. The choice of distance, which obtains this equality of division, is founded upon Rhenaudin's property of the circle, which gives nearly equal parts upon the diameter. In short, we do not recollect any other projections made upon what is called the globular method, than those upon the meridian and equator, where, in the former case, the poles are in the primitive circle, and in the latter, in the centre of that circle; so that the globular method, which is only confined to these two cases, is a mere imitation of perspective representation, the distance of the eye being three-fourths of the radius from the surface of the sphere. The only argument that can be used in favour of the globular method is, that circles are much more easy to describe than ellipses; but if *ellipsographs* were brought to general use, they might be described with considerable expedition, and the compartments of the projection would be less distorted.

This is the first specimen that has come to our knowledge of the application of the general principles of perspective to the projection of the sphere, in which pure geometrical principles only have been employed by any English author. It is hoped that the perspective student will reap considerable advantage from this application, in being able to generalize the science. The ingenious Mr. Martin, in his *Mathematical Institutes*, has given some algebraic rules, whereby certain points may be found by calculation; but such cannot be of any use to the student: for though, in an abstract point of view, the result by calculation is complete, or, if in some cases not quite exact, the error may be so reduced as to be less than any assignable difference from truth; yet to apply the numbers thus resulting from the arithmetical operation, recourse must be had to a scale, in order to convert the number into measure, the accuracy of which must then depend upon the division of the scale, and the eye of him who takes the extent as pointed out by the number. The error in this way, when such distance is transferred to the drawing, will in general exceed that occasioned by the obliquity of intersections, besides being more liable to mistake; nor could a drawing be made entirely by calculation, as the time required would exceed all comprehension. This may, therefore, satisfy a few, whose curiosity leads them to delight in nothing but what comes to them in the symbolical language of algebra, but cannot be of the smallest service to the practical student.

PROJECTION of the Sphere, Stereographic. The stereographic projection of the sphere is a perspective representation of all the circles upon the plane of the primitive, the eye being confined to the surface of the sphere at the extremity of a radius perpendicular to the plane of the primitive.

The reader who has made himself master of the science of perspective, and its application to the projection of the sphere, as shewn by the preceding article, will, of course, be able to represent any circle of the sphere stereographically;

but when the eye is brought to the surface of the sphere, certain properties take place, which considerably abridge the labour; one of the most remarkable of these properties is the following.

Theorem 1.—If in a circle (*figs. 7 and 8*), the diameters AG and HI be drawn at right angles, and if DB be any chord, and AB and AD be joined, then let AB cut HI at E , and let AD cut HI at F ; the triangle ABD will be similar to the triangle AFE .

Demonstration.—Join BC ; and because the angle ABC is in a semicircle, it is a right angle; and because the angles ADB and ACB at the circumference stand upon the same base AB , they are equal: and also in the triangles AGE and ABC , the angle CAB is common, and each of the angles ABC and AGE a right angle, therefore the remaining angle AGE of the triangle AGE is equal to the remaining angle ACB of the triangle ACB ; but the angle ACB is equal to the angle ADB ; therefore the angle ADB is equal to the angle AEG ; and because the triangles ADB and AEG have the angle DAB common, and the angle ADB equal to the angle AEG , the remaining angle ABD of the one is equal to the remaining angle AEG of the other; therefore the triangle ABD is similar to the triangle AEG , which was to be proved; and thus also the triangle ABD is subcontrary to the triangle AEG .

Theorem 2.—If from any point A (*fig. 9.*) in the circumference of a circle $AFBG$, a straight line AB be drawn to meet the circumference in B , and if through the point B , a tangent CD be drawn; and if the radius AE be also drawn, and the diameter FG perpendicular to AE , cutting AB in H ; then if GF and DC be produced to meet each other in C , then will the angles CBH and CHB of the triangle CBH be equal to one another.

For DBI is an angle formed by the chord BI and a tangent DB , and the angle BAI is formed in the alternate segment, therefore the angle DBI is equal to the angle BAI ; and because the triangles AEH and ABI are right-angled at E and B , and the angle at A is common to both, the triangle AEH is similar to the triangle ABI ; therefore the angle AHE is equal to the angle AIB ; but the angle CBA is formed by the tangent BC and the chord BA , and BIA is the angle in the alternate segment; therefore the angle CBA is equal to the angle BIA ; but the angle BIA was shewn to be equal to the angle AHE ; therefore the angle AHE is equal to the angle ABC ; but the angles AHE and CHB are opposite; therefore the angle CHB is equal to the angle AHE ; therefore, also, the angle CHB is equal to the angle CBH , which was to be proved.

Scholium.—By theorem 1. it is evident that every circle of the sphere will also be represented by a circle, for the cone of rays will be cut subcontrary. The advantage is very great both in point of accuracy and expedition, in having only to draw circles instead of ellipses. By the second theorem it is evident that the angles which original circles form with each other, will be represented by equal angles; that is, every representative angle will be equal to its original. This is the reason why this particular distance of the eye is to be preferred in the practice to a greater, which, though less distorted, is more laborious and more liable to inaccuracy.

Theorem 3.—If in the circle $AJIH$ (*fig. 10.*) the diameters AI and JH be drawn at right angles, and if OD be any radius of the circle, and AD be joined, and if

AD and OH be produced to meet each other in C , and if AB be drawn perpendicular to OD , meeting OC in B , then will BA be equal to BC .

For, draw AF parallel to JH , and then the angle AED is the angle in the alternate segment, therefore the angle FAD is equal to the angle AED ; because OD is perpendicular to AB , or to the chord AE , AE is bisected; because GA is equal to GE and GD perpendicular to AE , and the angles DGA and DGE are right angles, the triangle DGA is equal and similar to the triangle DGE ; therefore the angle DEG is equal to the angle DAG ; but the angles FAD and DCB are alternate, therefore the angle FAD is equal to the angle DCB ; but the angle DAG is equal to the angle DEG , and the angle DAG is equal to the angle DAF , therefore the angle DAG is equal to the angle DCB , therefore BA is equal to BC .

This theorem shews the coincidence of the general method of projecting the sphere by the rules of perspective in finding the original measure of any representative arc with that of the stereographic projection of the sphere: for if A be considered as the place of the eye, D the pole of a circle to be projected, and if AD and JH be drawn to meet each other in C , it is evident that C is the projected pole of D , as shewn by the rules of stereographic projection. Now, by the rules of perspective, AB may be considered as the parallel of an original plane, whose pole is the point D , B the vanishing point of lines perpendicular to the intersection, and C the place of the eye in the vanishing plane.

Theorem 4.—The plane of every great circle of the sphere divides the primitive into two equal parts, or passes through a diameter.

Demonstration.—Every great circle passes through the centre of the sphere; therefore the planes of any two great circles will bisect each other: but the primitive is a great circle of the sphere, and its centre is the centre of the sphere; therefore the plane of every great circle of the sphere will pass through the centre of the primitive, and therefore through a diameter.

In the following problems the vertical plane is always supposed to pass through a diameter of any great circle to be projected, and therefore the line of position is the seat of that diameter; therefore the diameter itself will always be projected upon the line of position.

PROB. I.

To find the representation of the axes or poles of a great circle, the seat of the axis being given in the line of position, and the inclination of the axis to its seat.

Let $ABCDEF$ (*fig. 11.*) be the primitive circle, FC the diameter of position, and E the place of the eye, in the diameter EB , at right angles to FC .

Make COD equal to the angle which the axis makes with its seat, and produce DO to A , then AD is the axis; draw the visual ray EA , cutting FC in P ; also join ED , and produce ED and FC to meet in Q , then PQ is the representation of the axis, and consequently P and Q are the poles.

PROB. II.

To find the intersection of a great circle, given the line of position, the angle which the axis makes with the line of position, and the inclination which the plane of any great circle makes with the vertical plane.

Make COD (*fig. 12.*) equal to the angle which the axis makes with the line of position: from any point D

in OD draw DG perpendicular to OD ; produce OC to Q , and let OQ cut DG at G ; make GQ equal to GD ; through G draw JG perpendicular to OQ ; make GQJ equal to the inclination of the plane of the great circle with the vertical plane; through O draw JL , cutting the circumference in K and L , and KL is the diameter of the section required.

Corol. 1.—If the point D be in the circumference of the primitive, and if ED be produced to meet the line FQ , the point of concurrence will be at Q ; this appears from theorem 3, therefore the point Q is in the pole of the great circle.

Corol. 2.—If DO be produced to meet the opposite part of the circumference at A , and if AM be drawn perpendicular to AO , cutting OF produced at M ; and if through M , MN be drawn perpendicular to OM ; and if OM be produced to I , and if MI be made equal to MA , and KL be produced to N , and NI joined; and AE be drawn, cutting FC in P , and PN be joined, PN will be equal to NI : for MN and JG are at the same distance from the centre O , and are parallel to BOE , and the triangle MNI is equal and similar to the triangle GQJ , therefore MP is equal to MI . See Prob. X., *Perspective PROJECTION*, where it was shewn that PN is a tangent to the curve at the point N .

PROB. III.

To find the representation of a great circle or any portion thereof, the intersection and the common representative diameter being given.

Let KL (*fig. 13.*) be the given intersection, and PQ the representative of the axis.

Bisect PQ by the perpendicular TS , and draw OS perpendicular to KL ; from S , the point of concurrence of the lines RS and OS , with the distance SP or SQ , describe the arc $QKPL$, which is an arc of the representative of the great circle.

Demonstration.—For since the representation is a circle, and because it passes through the points K and L , the extremities of the intersection, the centre of the representation will be in the line OS : but the representation of the circle also passes through its poles P and Q ; therefore the centre will be in the line TS ; bisecting the representative axis PQ ; but it is also proved to be in the line OS , it will therefore be at the point of concurrence S of the lines TS and OS .

Corol.—Hence the centres of all the representative great circles which have PQ for their representative axis, will be in the line TS ; since every representative circle passes through the points P , Q , they must therefore be in the line bisecting PQ .

Definition.—The line TS , bisecting the axis PQ , is called the locus of the centres of all the great circles which have the same representative axis.

PROB. IV.

Given a common representative diameter of two great circles, and the intersection of one of them, to find the representation of the two circles, so that their original planes may have a given inclination.

Method 1.

Let PQ (*fig. 14.*) be the common representative diameter, and KL the intersection. Find RM the locus of the centres; join KL ; draw OS perpendicular to KL , meeting RM in S ; join SQ , and from S , with the distance SQ , describe the arc $QKPL$; make the angle SQR equal to the inclination of the planes of the two great circles from

PROJECTION.

from R; with the distance R Q describe the arc Q M P N, then Q K P L and Q M P N will be arcs of the circles required.

Demonstration.—Join P R and P S, then P R will be perpendicular to a tangent to the arc M P N at the point P, and P S will be perpendicular to a tangent at the point P, in the arc K P L: but the tangents at the point P forms an angle equal to the original angle; therefore the lines P R and P S, which are perpendicular to these tangents, will form an equal angle: but the angle R Q S is equal to the angle R P S; therefore the angle R Q S is equal to the angle formed by the tangents of the two great circles, that is, equal to the inclination of their planes.

This method is exceedingly useful in describing the representations of great circles, which have a common representative diameter, with compasses; but in many cases it is impracticable, owing to the centres running out to distances without limit, and consequently beyond the reach of any radius: but in the representation of the sphere, seldom more is required than the part of the representation of the great circle contained within the primitive. The instrument called the cyclograph will be much better adapted to the description of the arcs required: we shall therefore construct the problem as adapted to the use of the cyclograph, which perhaps is the most convenient of any that could be used for the purpose.

PROB. V.

Given the angle which the intersection of a great circle and the vertical plane make with the plane of projection, and the inclination of the plane of the great circle and the vertical plane, to describe the representation of the great circle.

Let H C (*Plate X. fig. 1.*) be the line of position; through the centre of the primitive O, draw D E perpendicular to H C; make H O B equal to the angle which the common intersection of the vertical plane and the plane of the great circle make with the line of position, and let O B cut the circumference of the primitive in B; draw B G perpendicular to O B; and let B G meet H C in G; draw G J perpendicular to H C; make the angle G H I equal to the inclination of the plane of the great circle and the vertical plane, and let H I meet G J in I: draw I O, cutting the circumference in N; produce N O to meet the opposite side in M; join B E, cutting H C in P; through the point P, and upon M N as a chord, describe the arc M P N, thus: let A C, N° 2, be the chord, B the given point through which the arc is to pass; lay a straight edge B D upon the points B and A, and another, B E, upon the points B and E; fasten them together at B; then, supposing the angle D B E to be kept stationary while the two pieces are put in motion in the following manner, let the point B be brought to A, and B E laid upon C, and let a pencil be fixed at B; let the instrument be so moved, that B D may be always upon A, and B E upon C, and that the point B may describe a continued line from A to C, and the line thus described will be the arc of a great circle, as required.

Scholium.—By this method every great circle of the sphere may be represented one after the other, and the plane of the one to be projected may either make a given angle with that which is projected, or a given angle with the vertical plane. The projected circles make the same angle with each other at the point of intersection, or the tangents at that point, that the original planes make with each other: thus the projected circles M P N, K P L, or their tangents P I and P J, as I H and J H, which form the inclination of their planes, or the angle contained between the line of position P G, and

the tangent P J to the circle K P L, will be equal to the angle G H J.

PROB. VI.

Fig. 2.—About a given representative point P, to describe the representation of a circle of the sphere, of which the original shall have the original of P for its pole, and be at a given distance from P.

Join P O, and produce P O to A and B; draw O E perpendicular to A B; and make O E equal to the radius of the sphere; draw E P, and produce E P to meet the primitive in F; then F is the original pole: make F C and F D equal to the distance of the circle from its pole; draw the chord C D; draw C E, cutting A B at c; also draw D E, cutting A B at d; on c d, as a diameter, describe the circle c d e, which is the circle required.

Scholium.—By this problem the parallels of latitude may be described at 10° distance from each other, or at 10°, 20°, 30°, 40°, &c. from F.

PROB. VII.

The representation of a circle of the sphere being given, to find the representation of its pole.

Let c d e (*fig. 2.*) be the representation of the circle given; and let G be its centre; join G O, and produce G O to the primitive at A and B, and let A B cut the representative circle in c and D; join E c, and produce E c to meet the primitive in C; also join E d, and produce E d to meet the primitive in D; bisect the arc C D in F; draw E F, cutting A B in P, then P is the pole required to be represented.

Scholium.—This problem is the converse of the former; but when the circles are all parallel, they have one common pole.

PROB. VIII.

Given the representative of a great circle, to find the vanishing line of its plane, the place of the eye in the vanishing plane, and the representation of the centre of the circle.

Let E F G H (*fig. 3.*) be the primitive circle, and A K B D the representation of the circle of the sphere; join O C; draw O E perpendicular to O C; make O E equal to the radius of the sphere, and the point E will coincide with the primitive circumference; produce O C to B and P, cutting the representative circle in A and B; draw E A, and produce E A to meet the primitive circumference in G; also draw E B, and let E B cut the primitive circumference in H, as in N° 2, or produce E B to meet the primitive circumference in H, as in N° 1, and join G H; produce B A to P; draw E S parallel to H G, meeting B P in S, make S P equal to S E; through S draw V L perpendicular to B P; then V L is the vanishing line, and P the place of the eye in the vanishing plane.

Bisect H G in I; draw I E cutting A B in J; and J is the representation of the centre required.

Scholium.—This problem is general for all circles of the sphere, whether great or small; but in finding the representation of the centre of a great circle, the points I and J coincide in the centre O of the sphere; therefore, since H E G is a right angle, and because the points H, E, G, are in the circumference of the circle G E H, and H G is opposite to the right angle, H G is a diameter, which is, therefore, already bisected by the centre O.

The particular construction, which may, therefore, be necessary in N° 2, in order to find the vanishing line, the place of the eye in the vanishing plane, and the representation of the centre, may be as follows:

PROJECTION.

Join OC ; draw OE perpendicular to OC ; make OE equal to the radius of the sphere; draw EA , and produce EA to meet the circumference in G : so far this agrees with the general construction, the difference takes place in the subsequent part. Join GO ; draw ES parallel to GO , cutting BP in S ; make SP equal to SE , then P is the place of the eye in the vanishing plane, VL the vanishing line, and O is the representative centre of the circle, represented by DEK .

PROB. IX.

Given the representation of a great circle, and a point in its circumference; from the given point to cut off a part of the said circumference, that shall represent a given portion of the original circumference.

Let $EFGH$ (*fig. 4.*) be the primitive circumference, and AKD be the representation of the great circle, as in the preceding problem; find the vanishing line VL , P the place of the eye in the vanishing plane, and J the representation of the centre by the said problem. Now let a be the given point; join Ja ; produce Ja to L ; join LP ; make the angle LPV equal to the angle contained by the radii drawn from the extremities of the arc to the centre of the original circle; that is, in the same proportion to four right angles, that the original arc is of the whole circumference of which it is a part; join VJ , cutting the circumference of the representative circle in b , then ab is the representative arc required.

Again, let it be required to represent an arc from the point c on the opposite part of the circumference of the representative circle; join cJ ; produce cJ to L ; join LP ; make the angle LPV as before, and join VJ ; produce VJ to meet the representative circumference in d ; then cd is the arc required.

Lastly, let it be required to represent an arc of the original from the point b towards c ; join bJ ; produce Jb to V ; join VP ; make the angle VPR the same portion of four right angles, that the original arc is of the whole circumference of the circle of which it is a part; join LJ ; produce LJ to c , and bc is the representative arc required.

PROB. X.

With the same data to find the original measure of any part of the representative circumference.

Let it be required to find the original measure of the arc represented by ab ; join aJ , and bJ ; produce Ja to L , and Jb to V ; join LP and VP , and the angle LPV will be the measure of the original arc required.

In like manner it will be found, that LPV is also the measure of the arc represented by cd ; and VPR is the measure of the arc represented by bc ; also OPL is the measure of the arc represented by ad .

Scholium.—These problems are derived from the general principles of perspective. Those who have acquired the elements of that science will be at no loss to comprehend the above. However, in the stereographic projection of the sphere, P is the external pole; therefore, if in $N^{\circ} 2$ lines be drawn from the point P , through the two points a and b , to meet the opposite side of the primitive circumference, the portion of the intercepted circumference will be equal to the original arc represented by ab ; even this method may be derived from the principles of perspective.

The point P , in $N^{\circ} 1$, is also the external pole of the lesser circle, but the original of the lesser circle cannot be obtained with the same facility. In this the intersecting line must be found; and the original circle requires to be put

in its place in the original plane, and then the corresponding parts will be found in the same manner.

With respect to $N^{\circ} 1$, the part ECG of the primitive is already the original of the representative part EAG .

PROB. XI.

Through a given point in the representation of the arc of a great circle, to describe the representation of the arc of another great circle, so that their original planes shall have a given inclination.

Let APB be the given arc, and P the given point, and let C be the centre of the arc APB ; draw PC and PO ; produce PO to H ; and draw CH perpendicular to PH ; produce HC to D , and make CPD equal to the inclination of the planes of the two great circles; from D as a centre, with the radius DP , describe EPG , then the original planes of the circles, represented by APB , EPG , will have the inclination required.

Demonstration.—For the locus of all the circles is in a straight line perpendicular to PO , the line joining the centre of the primitive, and the given point; therefore, if the centre of one of the circles be known, (which is always easy, when the circle or any arc of it is given,) the locus will be a perpendicular through that point; but C is the centre of the circle APB , and DH passes through C perpendicular to PO ; therefore DH is the locus of the centres; and because the tangents of these circles are perpendicular to PC and PD at the point P , CP will make the same angle with PD , that the tangents make with each other; but the angle formed by the tangents of these arcs is equal to the inclination of the planes of the original circles, therefore the representative circle APB is described according to the data, as required to be done.

Scholium.—By this problem the obliquity of the ecliptic may be represented at its proper angle with the equator; or in a spherical triangle an angle may be represented at a given point in the representation of one of its sides; the sides may be determined as in problem IV.; and thus all the cases in spherical trigonometry may be resolved by means of these two problems.

The following are examples shewing the use of the preceding problems in the stereographic projection of the sphere.

Ex. 1.—*Fig. 6.* Projection of the sphere on the plane of the meridian.

Ex. 2.—*Fig. 7.* Projection of the sphere on the plane of the equator.

Ex. 3.—*Fig. 8.* Projection of the sphere on the plane of the horizon.

This species of projection of the sphere is the most useful of all others, as it gives the angles equal to their originals, and as the measures of the angles and the different arcs concerned are so easily obtained.

As it is impossible to develop the surface of a sphere, so it is also impossible to represent its surface upon a plane without considerable distortion throughout the greater part of the representation, by any mode hitherto devised, or perhaps that can be devised. The original measures of distances and angles upon the surface of a sphere may, however, be obtained from any of the foregoing principles, as accurately as upon the sphere itself, and this is all that is indeed necessary in the solution of any question that may arise.

PROJECTION of the Sphere, Gnomonical.

Definition 1.—When the eye is placed in the centre of the sphere as a projecting point, and if from thence rays be drawn through every point of any circle of the sphere, till they are intercepted by a plane, the figure traced out by

PROJECTION.

the intersection of the rays is called the gnomonical projection of that circle, or the circle is said to be projected gnomonically.

2. If the several circles of the sphere be projected gnomonically, the representation is called a gnomonical projection of the sphere.

3. If a straight line be drawn from the eye perpendicular to the plane of projection, until it meet the said plane, the point of concurrence with the plane is called the centre of projection, as in the stereographic projection.

4. If a plane be supposed to pass through the eye perpendicular to the plane of projection, and to the plane of any circle to be projected, the plane thus posited to each is called the vertical plane.

5. The intersection of the vertical plane, and the plane of projection, is called the line of position.

Theorem 1.—Any great circle of the sphere is projected upon a straight line in the plane of projection.

For the centre of the sphere is a point common to every great circle; but the eye is placed in the centre of the sphere, therefore the eye is in the plane of every great circle; and, consequently, every such plane will be projected into its intersection with the plane of projection.

Theorem 2.—The projecting rays passing through any small circle form the surface of a right cone. Since the eye is situated in the centre of the sphere, it cannot be in the plane of any small circle: and since the centre of the sphere, and the centre of a small circle, is in a straight line drawn perpendicular to the plane of the said circle, the rays proceeding from the eye to all points of the circumference of any circle will therefore form the surface of a right cone.

Theorem 3.—Every small circle of the sphere is projected upon a conic section. For the rays form the surface of a cone, and the surface of the cone of rays is terminated by the plane of projection; therefore the section of the intercepted rays will be a conic section, which will either be the ellipse, parabola, or hyperbola.

PROB. I.

Given the centre O , the line PO of position, the inclination of the intersection of a great circle of the sphere, and the vertical plane with the plane of projection, the inclination of the plane of the great circle with the vertical plane, and the radius of the sphere, to draw the representation of the great circle.

Draw OE (*fig. 9.*) perpendicular to PO ; make OE equal to the radius of the sphere, and OEP equal to the complement of inclination of the intersection of the great circle, and the vertical plane with the plane of projection; produce PO to C ; in PE take any point A , and draw AB perpendicular to PE , meeting PC at B ; make BC equal to BA ; draw BD perpendicular to PC , and make the angle BCD equal to the inclination of the plane of the great circle with the vertical plane; join DP , and produce DP to F , and the straight line DF will be the representation of the great circle required.

Scholium 1.—The greater part of this construction is independent of the projection of the sphere, as the same angle DPB , or the opposite one, GPF , would take place, whatever were the distance of the eye; the direct radial OE only determines the distance OP , which would otherwise be variable.

2. It is evident, that with the same data, except a change in the inclination of the plane of the great circle and the vertical plane, the straight line, which is the representation of the great circle, will always pass through the point P :

thus, if the inclination of several great circles of the sphere were BCH , BCD , BCI , BCJ , BCK , their respective representations would be HPQ , DPF , IPN , JPM , KPL .

3. It is also to be remarked, that if BP be the meridian of a place, and if the angle BPE be equal to the latitude, and the angles BCI , BCD , BCH , &c. on the one side, as also BCJ , BCK , &c. on the other side, be respectively 15° , 30° , 45° , &c. on each side, that is, each angle 15° ; then BG will be the 12 o'clock line, and all the others on each side of it the hour lines of a horizontal dial.

4. This construction is not only necessary in the gnomonic projection, but also in the orthographic and stereographic projections, in finding the intersections of all the great circles with the plane of the primitive.

5. The gnomonical projection of the sphere would be very eligible for general practice, if all the small circles could be projected with the same facility as the great ones; but as the small circles (excepting those that are parallel to the plane of projection, which are circles) are projected into ellipses, hyperbolas, or parabolas; it is generally confined to the use of dialling, where it is necessary that the hour lines should be straight, and where few curve lines are employed, seldom more than the solstices being represented.

PROB. II.

To project any small circle of the sphere, its diameter being given as a chord to the circumference of the vertical circle.

Let FG (*fig. 10.*) be the diameter of the circle to be projected, and Og the line of position; draw EO perpendicular to gO ; draw EF , EG ; produce EF to meet gO in F ; also let EG meet gO , if possible, in g ; bisect fg at j ; take half of the difference of the lines Ef and Eg , and set it in the major axis fg , from j to i , and from j to b ; then b and i are the foci of the ellipses; through j draw kl perpendicular to fg ; from i or b as a centre, with the distance ig or jb , describe an arc at l , and another at k , then kl is the minor axis; then about the two axes fg and kl describe the ellipses, and it will represent the circle required.

But if EG (*fig. 11.*) be parallel to Og , they will not meet each other: let this be the case, then the cutting plane will be parallel to the side of the cone, and consequently the projection of the small circle required will be a parabola; produce EF to meet gO in f , and take any distance, fi , for the abscissa of the curve; let kE bisect the angle FEG ; draw il perpendicular to Ek , cutting EG , produced at L , and the axis kE of the cone at k ; draw im perpendicular to il ; and through i draw nq perpendicular to if ; from k , with the distance kl , describe an arc, cutting im at m ; make in and iq each equal im ; then with the abscissa if , and double ordinate nq , describe a , the parabola, which will be the representation required. A very easy method of finding points in the curve is the following:—Draw no parallel to if , and of parallel to ni ; divide ni into parts of any proportion, say three equal parts, and through the points of division draw straight lines to cut the former parallels, and the points r, s , of intersection will be in the curve; therefore through the points n, r, s, f , draw a curve, which is the representation of the circle.

But if EG (*fig. 12.*) meet gO in P , the other side of the centre O , the representation of the circle will be a hyperbola; find the double ordinate nq , as in *fig. 11*; then with the double ordinate nq , and the abscissa if , and major axis fP , describe a hyperbola, which is the representation

representation required. The following method, by finding points in the curve, is very expeditious: divide ni into any number of parts of any proportion, say three equal parts; from the points of division draw lines to P ; divide no into the same number of parts of the same proportion; that is, because ni is divided into three equal parts, no will also be divided into three equal parts; through the points of division draw lines to f , and the points r, s , of intersection will be in the curve.

Scholium.—Though every kind of projection furnishes the means of ascertaining the distances and angles concerned in the same, and though the representation of the whole surface of the sphere by means of a projection is the most eligible method of all others; yet, when a small portion is required to be represented, the method of developing the surface is preferable, not only on account of the development being more nearly similar to the spheric surface itself, but also on account of the distances being obtained by inspection only, or from a scale of equal parts; and though this mensuration is only an *approximation* to truth, it is sufficient for common use.

The impossibility of forming a true development of the spheric surface has already been observed; if, however, the sphere be supposed to be circumscribed by a polyhedron, the side of the polyhedron, extended upon a plane, will be very nearly a true development of the surface.

In the approximating the development of the spheric surface, there are two different methods of considering the subject; one is, by supposing the polyhedral surface to consist of conic frustums, each touching the surface of the sphere in the middle; and the other is, by supposing the polyhedral surface to be composed of those of a cylinder, meeting each other in planes passing through the centre of the sphere, and intersecting each other in one common diameter, as an axis; and, because conic and cylindric surfaces are developable, the surface of the circumscribing polyhedron will also be developable; and, therefore, may be correctly represented. Now, supposing all the sides to be equal, and increased in number at pleasure, (the greater the number, the nearer will the surface of the polyhedron coincide with that of the sphere); and, consequently, any portion of the surface of the development of the surface of the polyhedron will be very nearly equal and similar to the corresponding portion of the spheric surface.

Each of these different methods of representing the spheric surface has its peculiar advantage and disadvantage, when applied to the art of map-making. The conic method of development is best adapted to represent countries to any extent, in the difference of longitude, or round the whole circumference of the earth, if required; to a certain extent in difference of latitude. And the cylindric method of development is well adapted to represent countries contained between any two parallels of latitude, but not to have any considerable difference of longitude.

Of these two different developments, the conic is attended with the least trouble, on account of the facility of describing the parallels of latitude in concentric circles, and the meridians in straight lines.

With respect to the application of the development of the conic surfaces in the construction of maps, a very excellent method is that given by the Rev. Patrick Murdoch, M.A., F.R.S., in vol. i. part. ii. of the Philosophical Transactions for the year 1788, read Feb. 9, as follows.

I. "When any portion of the earth's surface is projected on a plane, or transferred to it by whatever method of description; the real dimensions, and often the figure and position of countries, are much altered and misrepresented. In the

common projection of the two hemispheres, the meridians and parallels of latitude do intersect at right angles, as on the globe; but the linear distances are every where diminished, excepting only at the extremity of the projection; at the centre, they are but one-half their just quantity, and then the superficial dimensions but one-fourth part; and in less general maps, this inconvenience will always attend the stereographic projection.

"The orthographic by parallel lines would be still less exact, those lines falling altogether oblique on the extreme part of the hemisphere. It is useful, however, in describing the circumpolar regions; and the rules of both projections, for their elegance, as well as for their uses in astronomy, ought to be retained and carefully studied.

"As to Wright's or Mercator's nautical chart, it does not here fall under our consideration; it is perfect in its kind; and will always be reckoned among the chief inventions of the last age. If it has been misunderstood or misapplied by geographers, they only are to blame.

II. "The particular methods of description, proposed to be used by geographers, are so various, that we might, on that very account, suspect them to be faulty; but in most of their works we actually find these two blemishes, the *linear dimensions visibly false*, and the intersections of the circles oblique; so that a quadrilateral space shall often be represented by an oblique-angled rhomboid figure, whose diagonals are very far from being equal; and yet, by a strange contradiction, you shall see a scale of distances inserted in such a map.

III. "The only maps I remember to have seen, in which the last of these blemishes is removed, and the other lessened, are some of P. Schenk's of Amsterdam; a map of the Russian empire; the Germania Critica of the famous professor Meyer, and a few more. In these the meridians are straight lines, converging to a point; from which, as a centre, the parallels of latitude are described. But, as that rule appears to be only an easy and convenient approximation, it remains still to be enquired, *what is the construction of a particular map, that shall exhibit the superficial and linear measures in their truest proportion?* In order to which,

IV. "Let ELP (figure 13) be the quadrant of a meridian of a given sphere, whose centre is C , and its pole P ; EL, El , the latitudes of two places in that meridian, EM their middle latitude. Draw LN, ln , cosines of the latitudes, the sine of the middle latitude MF , and its co-tangent MT . Then, writing unity for the radius, if

in CM we take $Cx = \frac{Nn}{Ll \times MF \times MT}$, and through

x we draw xR, xr equal each to half the arc Ll , and perpendicular to CM ; the conical surface generated by the line Rr , while the figure revolves on the axis of the sphere, will be equal to the surface of the zone that is to be described in the same time by the arc Ll ; as will easily appear by comparing that conical surface with the zone, as measured by Archimedes.

"And lastly, if from the point t , in which rR produced meets the axis, we take the angle CtV , in proportion to the longitude of the proposed map, as MF , the sine of the middle latitude is to radius, and draw the parallels and meridians as in the figure, the whole space $SOQV$ will be the proposed part of the conical surface expanded into a plane; in which the places may now be inserted according to their known longitudes and latitudes.

V. "Let Ll , the breadth of the zone, be 50° , lying between 10° and 60° north latitude; its longitude 110° from 20° east of the Canaries, to the centre of the western hemisphere;

PROJECTION.

PROB. III.

hemisphere; comprehending the western parts of Europe and Africa, the more known parts of North America, and the ocean that separates it from the old continent."

As the rule here given by Mr. Murdoch would be attended with too much trouble, he proposes a shorter method for practice, in a note at the bottom of page 568 of the same vol. and part referred to; which is, "make Cx to CM as the arc ML is to its tangent, and finish the map."

Mr. Martin, in the second volume of his "Young Gentleman and Lady's Philosophy," has shewn a rule, derived from a very well-known principle of the centre of gravity, in order to obtain the distance Cx : the formula is $Cx =$

$$\frac{CM \times LB}{ML},$$

which is very convenient in practice. He

also gives an example, as applied to a map, in the same volume, which rule is thus:

"In this new map, the extent or difference of latitude is 50° , equal to Ll ; therefore $ML = 25^\circ = 2.6179$ inches to a radius of 6 inches. (See Inst. 885.) Also, the sine BL of the same arc is 2.5358 inches; therefore say,

$$\text{As the arc } ML = 2.6179 \quad - \quad 0.417953$$

$$\text{Is to its sine } BL = 2.5358 \quad - \quad 0.404099$$

$$\text{So is radius } CM = 6 \quad - \quad 0.778151$$

$$1.182250$$

$$\text{To the distance } Cx = 5.8116 \quad - \quad 0.764297''$$

The advantage gained by Mr. Murdoch's method of constructing maps is only in facility of description: for though the whole area is truly represented, yet the measures taken along the parallels of latitude are very incorrect, being no where equal to those of the sphere, except where the conic surface intersects that of the latter body. The conic meridians within the intercepted part are less than the true meridians, and those on each side of the intercepted part greater. This method, therefore, ought to be restricted not to exceed 30° of difference of latitude; and in this case, it would be much simpler to take the surface of the cone, a tangent to the sphere in the parallel circle of middle latitude.

From the rule which Mr. Murdoch gives for finding the vertical angle CtV , may be derived that of finding the vertical angle of development, in order to cover any portion of the surface of a cone; the side of the cone, the radius of the base, and the degrees contained in the circumference of the base being given, Mr. Murdoch's rule is,

As radius

Is to the sine of middle latitude,

So is the difference of longitude

To the vertical angle CtV .

But radius is to the sine of middle latitude, as the cotangent is to the cosine; therefore, as the cotangent is to the cosine of middle latitude, so is the difference of longitude to the vertical angle CtV . Now the cone, that would touch the sphere, has its side equal to the cotangent, and the radius of its base equal to the cosine; therefore,

As the side of the cone

Is to the radius of the base,

So is the number of degrees contained in the circumference of the base

To the vertical angle of development.

To construct a map upon the principles of development.

Let AJK (*fig. 14. N° 1.*) be a quadrant of a great circle of the sphere; divide the arc AJ into nine equal parts, and let $B, C, D, E, F, \&c.$ be the points of section; draw the radii $BK, CK, DK, EK, \&c.$ and the tangents $Bb, Cc, Dd, Ee, Ff, \&c.$ Now suppose it were required to draw a map of the whole hemisphere, or the half on one side of the equator, for want of room. Draw $ll, N° 2,$ and AJ perpendicular to ll ; make $AJ, N° 2,$ equal to nine times the chord AB , or BC , or $CD, \&c. N° 1$; from A , as a centre with the radius AJ , describe the semicircle lJl ; divide the radii, Al, Al , each into six equal parts; let $B, C, D, E, F, G, H, I,$ be the points which divide AJ into nine equal parts, and produce AJ to Z : in AZ , make Dd equal to $Dd, N° 1$; Ee equal to $Ee, N° 1$; Ff equal to $Ff, N° 1, \&c.$; and from the points, $b, c, d, e, f, \&c.$ as centres with the radii $Bb, Cc, Dd, Ee, \&c.$ describe the arcs $mm, nn, oo, pp, \&c.$; divide each of the arcs, $Bm, Cn, Do, Ep, \&c.$ into six equal parts, and through the corresponding points draw curves from the points of section in Al to terminate in J ; then the lines $mm, nn, oo, pp, \&c.$ will represent the parallels of latitude; and the other lines, which terminate in J , the meridians.

Another method, by which the parallels of latitude may be made to cut the circumference lJl perpendicularly, is the following: imagine straight lines to be drawn from the point l , and through the points $B, C, D, \&c.$ to meet the concave circumference in $m, n, o, \&c.$; then the tangents from the points $m, n, o,$ will give the centres. If any of the points, $m, n, \&c.$ are out of reach, each curve may be described through the three points $m, B, m,$ and $n, C, n, \&c.$ This process is even more accurate in distant latitudes than the former.

Scholium.—This is a very near development of the surface of the globe. All the meridians and parallels of latitude intersect each other very nearly at right angles; the successive quadrilaterals between any two meridians are nearly equal in area, and similar to those on the globe; and those adjoining the middle meridian AB are almost exactly the same as their correspondents. Every parallel of latitude is equally divided by the meridians, as they are on the globe; and every parallel, as terminated by two meridians on the map, is of the same length exceedingly near as the corresponding part on the globe itself. It must, however, be observed, that the meridians are here represented of different lengths, all longer than those on the globe, except AJ , the central one; but this is also the case with every kind of the projection of the sphere whatever: and in this respect it is even less defective, in the lengths of the meridians, than Murdoch's is with respect to the lengths of the parallels of latitude. However, since the middle meridian answers as a scale, the length of every meridian can be correctly ascertained. This map is perhaps, upon the whole, the most correct and the easiest to be constructed of any yet published. It may be employed in the construction of the largest maps, as well as in the smallest, and will be more exact as the difference of longitude is less.

In drawing a map of any particular country, the perpendicular AJ , or the diameter of which AJ is a part, must be taken as near to the middle of the country as possible, as the parts nearer to AJ are more exact than those which are more remote, and because all the degrees of latitude

tude are exactly equal upon the line AJ to those of the globe, and therefore any measurement with compasses can be more accurately ascertained.

PROJECTION, *Polar*. See POLAR.

PROJECTION of *Shadows*. See SHADOW.

PROJECTION, in *Alchemy*, the casting of a certain imaginary powder, called *powder of projection*, into a crucible, or other vessel, full of some prepared metal, or other matter; which is to be hereby presently transmuted into gold.

PROJECTION, *Powder of*, or of the philosopher's stone, is a powder supposed to have the virtue of changing any quantity of an imperfect metal, as copper or lead, into a more perfect one, as silver or gold, by the admixture of a little quantity of it.

The mark to which alchemists direct all their endeavours, is to find the powder of projection; which every one of them has been within an ace of, a hundred times.

For the characters, properties, virtues, &c. of this powder, &c. see PHILOSOPHER'S *Stone*.

PROJECTION, in *Building*. See PROJECTURE.

PROJECTIVE DIALLING, a manner of drawing, by a method of projection, the true hour-lines, furniture of dials, &c. on any kind of surface whatsoever, without any regard to the situation of those surfaces, either as to declination, reclination, or inclination. See DIALLING.

PROJECTURE, in *Architecture*, the out-jetting, or prominency, which the mouldings and members have, beyond the plane or naked of the wall, column, &c.

These the Greeks call *ecphora*, the Italians *sporti*, the French *saillies*, our workmen frequently *sailings over*, and the Latins *proiecta*, from *projicio*, *I cast forward*; whence the English *projecture*.

Vitruvius gives it as a general rule, that all the projecting members in buildings have their projectures equal to their heights: but this is not to be understood of the particular members or mouldings, as dentils, coronas, the fasciæ of architraves, the abacus of the Tuscan and Doric capital, &c. but only of the projectures of entire cornices, &c. The great point of building, according to some modern architects, consists in knowing how to vary the proportions of projectures, &c. agreeably to the circumstances of the building.

Thus, say they, the nearness and remoteness, making a difference in the view, require different projectures; but it is evident the ancients had no such intention.

The projecture of the base and cornice of pedestals, M. Perrault observes, is greater in the antique than the modern buildings by one-third; which seems to follow, in good measure, from the ancients proportioning this projecture to the height of the pedestals; whereas the moderns make the projecture the very same in all the orders, though the height of the pedestal be very different.

The reason of this change, which the moderns have made of the antique, the same author refers to a view of the appearance of solidity.

PRO INDIVISO, in *Law*, a possession or occupation of lands or tenements, belonging to two or more persons, of which none can say which is his several portion, each having the whole, &c. as coparceners before partition.

PROKOPHEVA, in *Geography*, a town of Russia, in the government of Irkutsk, on the Kirenga; 40 miles S.S.E. of Kirensk.

PROLABIUM, in *Anatomy*, the red part of the lip, intervening between the common skin and the mucous membrane, and forming the very margin of the mouth.

PROLAPSUS, or PROCIDENTIA *Ani*, denotes, in *Surgery*, a very distressing complaint, in which a tumour is produced at the anus by a descent and protrusion of the rectum, or that bowel which forms the lower termination of the intestinal canal. It is not, however, the whole of this intestine which protrudes, but only a part of its internal membrane which becomes inverted and passes out at the anus, forming a red, soft, flattish, circular tumour. (Schacher de Morb. a situ Intestinar. Haller, Disput. Chirurg. Select. tom. iii. p. 14.) Levret, in passing his finger into the vagina of a patient, who had had for twenty years a bleeding, livid, fetid swelling, as large as one's fist, and occasioned by a prolapsus ani, found the vagina and uterus both in their natural situations; a circumstance which could not have been, had the whole of the rectum been concerned in the protrusion, as is commonly supposed. *Traité des Polypes*. p. 162.

A protrusion of the internal membrane of the rectum is frequently observed in children, affected with tenesmus, or dysentery, or tortured with a fit of the stone, or undergoing the operation of lithotomy. Women, having internal hemorrhoids, and in the violent efforts of labour, are also subject to the same accident. *Smellie's Midwifery*, vol. iii.

In the early and most simple stage of this disease, the swelling may be easily reduced by compressing it with the fingers, and the reduction may be maintained by the application of a bandage, which will keep up moderate pressure. The majority of patients get into the habit of assisting themselves in the preceding way. But if the disorder be chronic, if the reduction of the swelling be neglected, if the protrusion occur again from the slightest causes, or the tumour continue exposed to the effect of the external air, the protruded part acquires a larger size, its surface puts on a fungous appearance, and ulcerates and bleeds. By degrees the health is impaired; digestion is disturbed; the patient becomes languid; and the loss of blood weakens and ultimately destroys him. Such was the fate of a child eight years of age, who was afflicted for more than six months with a prolapsus ani, which could not be kept reduced. The tumour, without being absolutely painful, was incessantly bleeding, and the child died of hectic complaints. *Binninger*, obs. 62, centur. 2. p. 198.

Another child, ten years of age, but strong and robust, living in the country, had for upwards of a year a prolapsus ani, forming rather a hard swelling two or three inches in length. Lassus succeeded in reducing it by making rather forcible pressure, which the surgeons, who had previously seen the patient, had been afraid of putting in practice. The cure was complete immediately the reduction was accomplished, nor were any other steps necessary. *Pathologie Chirurgicale*, tom. ii. p. 133.

When a prolapsus ani is chronic, the internal membrane of the rectum, being exposed to the contact of the air, puts on a fungous thickened appearance, and ulcerates and bleeds. The consequence is an habitual weakness, sometimes accompanied with impossibility of reducing the tumour, or of keeping it reduced, provided it have acquired from long duration a considerable volume. In this alarming state of the complaint, the old writers recommended the cauterization of the surface of the tumour. (*Ætius*, *Tetrabibli. quart. ferm. 2. cap. 7. p. 760. Vegetius*, *Mulo medicina*, lib. iii. cap. 11.) Amongst the moderns, Lassus is also a strong advocate for such practice. It is known, says he, that the membranous lining of the rectum sometimes partly,

or totally sloughs, in consequence of gangrenous inflammations, in persons labouring under prolapsus ani and internal highly painful hemorrhoids. Many cases prove, adds this writer, that patients have been cured after such sloughing, whether brought on by the interference of the practitioner, or the salutary operation of nature, provided the inflammation has been sufficiently great to detach a part, or the whole of the internal membrane in the form of sloughs, together with some of the hemorrhoidal swellings. Cheselden, Anatomy, seventh edit. p. 158. Tulpius, cap. 17. lib. iii. Med. Essays of Edinburgh, vol. v. p. 654. Cowper, Anatomy of the Human Body, tab. 39, fig. 7. Levret, Traité des Polypes, p. 162.

With respect to the plan of cauterizing bleeding, ulcerated, inveterate, irreducible cases of prolapsus ani, it is not to be expected that it will now meet with any approbation amongst the surgeons of this country, who, being well acquainted with the mode of stopping hemorrhage by ligatures and compression, would have no fear of attempting the extirpation of such a disease with the knife.

A prolapsus ani is mostly owing to too violent and repeated exertions of the rectum itself, excited by some source of irritation about the extremity of this intestine. Thus, the too frequent employment of aloetic medicines, the action of which particularly affects the large intestines, often occasions the above consequence. The same thing results from small worms, known by the name of ascarides, and which, lodging about the lower part of the rectum, occasionally cause excessive irritation. Habitual costiveness, hemorrhoids; in a word, every thing which, by stimulating the rectum, excites too violent an action of this intestine, may induce the complaint under consideration.

Authors of surgical works have, not uncommonly, recommended fomenting the prolapsed part with emollient and antiseptic decoctions, before making an attempt to reduce it. They even advise the operator, for the purpose of succeeding with more ease, to cover his finger with linen, smeared with wax and oil. But all such preparations are useless, and, when a surgeon is called to a patient afflicted with a prolapsus ani, the greatest service he can render, is to put back the displaced part, as quickly as possible, into its natural situation, without leaving the intestine exposed to the dangerous effects which may arise during the time wasted in employing fomentations, &c. Also, as much greater manual dexterity can be made use of, when the fingers are perfectly uncovered, than when they have greasy gloves on, it is best not to follow the latter method. However, if it should be judged proper to cover the hands with any thing, a piece of fine cotton will best answer the purpose.

The patient being in bed, lying upon his side, or, what is better, on the abdomen, while his buttocks are raised rather higher than the rest of the body, the surgeon is to make strong, but equal pressure, with the palm of his hand on the lower portion of the prolapsed intestine. By continuing such pressure, the intestine may, in general, be easily reduced. But if this plan should not suffice, the upper part of the protruded intestine must be compressed with the fingers of one hand, while the lower part is pressed upward by the palm of the other one. In this way we are almost sure to succeed. It is true, that if, in consequence of having too long delayed the reduction, or from some other cause, the gut has become much swollen and inflamed, it will be impossible to reduce the part before such symptoms have been subdued. For this purpose it may be proper to take some blood from the patient, in such quantity as his strength will allow. The intestine may also be fomented

with a warm solution of the acetate of lead, (*saccharum saturni*.) When the swelling has been diminished by these means, there will be no difficulty in replacing the parts, by pursuing the plan already explained.

The greatest difficulty is not the returning of the intestine, but keeping it in its place. The latter object often gives a great deal of trouble. For, after the bowel has frequently descended, the sphincter sometimes becomes so weakened, that it can no longer keep the part supported. Hence, the complaint not only recurs whenever the patient goes to stool, but even whenever he walks, or places himself in an erect posture, of which there are many examples.

Different bandages have been devised for supporting the anus after its reduction. But it is not an easy matter to invent one, which is in every respect adapted to what such an inconvenience requires. A compress, doubled several times, is usually applied to the anus, and supported in this position by means of a T bandage. In many cases, this method of keeping up the intestine answers very well. A machine was invented by Mr. Gooch, which has the double advantage of supporting the intestine more securely than any other with which we are acquainted, and of allowing the patient to take a great deal more exercise than he could do without its assistance. See Gooch's Surgery.

Elastic gum pessaries were invented a few years ago by M. Bernard, an ingenious artist, who employed this substance for making various articles used by surgeons. The instrument which we have just mentioned, consists of an oblong oval body, rounded at one end, and terminating at the other in a narrow, rather long neck, with a flat border at its extremity. The body of this instrument, when introduced into the intestine beyond the sphincter, dilates and supports the gut, while the sphincter embraces its neck, and the border of this part of the instrument hinders it from ascending too far up the rectum. A string is also attached to the edge, which tends to prevent the occurrence. This pessary is very smooth, and, consequently, cannot do any injury to the parts. It is also very light, being only composed of a very thin, though tolerably solid, substance. As it is pierced at its termination, it does not impede the discharge of air, which might otherwise incommode the patient.

When the intestine is protruded at the time the patient is at stool, the part is to be immediately replaced. This the patient should accustom himself to do without assistance, and then the bandage, or pessary, is to be applied. In order to strengthen the sphincter ani and adjacent parts, the weakness of which must, in the majority of cases, be regarded as the entire cause of the disease, the patient should take preparations of bark and steel, make use of the cold bath, and frequently have cold water dashed against his buttocks and loins. Astringent injections, particularly such as are composed of an infusion of gall-nuts, or oak-bark, are also very serviceable. A small quantity of alum, or sugar of lead, has sometimes been added to these injections; but, in general, all additions of saline substances are to be deemed improper, because salts usually produce an irritation of the intestine.

A much more serious disorder has been confounded with the prolapsus ani; *viz.* one, in which a considerable portion of the colon, cæcum, and even sometimes of the ilium, becomes everted and pushed out at the anus. Former practitioners considered this occurrence in the same point of view as the disease of which we have just been treating. In this case, they believed that the whole of the rectum became everted, in consequence of the relaxation of the sphincter and levatores ani, and that it then drew after it other por-

tions of the intestinal canal. But they ought to have been undeceived by the strangulation, which sometimes occurs under such circumstances, and which not only throws a great obstacle in the way of the reduction of the displaced part, but even sometimes brings on mortification. Besides, the connections of the rectum with the neighbouring parts, by means of the cellular substance which surrounds it, and the attachment of this intestine to the posterior surface of the urinary bladder, render the above origin of the complaint impossible. Such an explanation could only be admitted with regard to those protrusions of the rectum which come on in a very slow manner. This account could not afford a satisfactory explanation of certain cases, in which the everted intestine presents a very enormous tumour. Fabricius ab Aquapendente mentions his having seen tumours occasioned by a prolapsus of the rectum, which were as long as the fore-arm, and as large as the fist. In the "Mélanges des Curieux de la Nature," we find an account of a tumour of this sort, which was two feet long, and occurred in a woman from parturition. Nor is a more satisfactory reason assigned for these cases, by supposing that they originate from a relaxation of the villous coat of the rectum, and its separation from the muscular one. We are not authorized to imagine that such a separation can take place to a considerable extent, nor so suddenly, as to give rise to the phenomena sometimes remarked in this disease.

But more accurate observations have removed all doubt upon this subject. In the fourth volume of the "Mémoires de l'Académie de Chirurgie," we read an account of a pretended prolapsus of the rectum, which, after death, was discovered to be an eversion of the cæcum, the greater part of the colon being found at the lower end of this intestine, and most of the rectum at its upper part. This eversion began at the distance of more than eleven inches from the anus, and terminated about five or six from this opening, the tumour, formed by the disease, having been reduced some time before the child's death. It was impossible to draw back the everted part, in consequence of the adhesions which it had contracted. Another distinction has evinced the same fact. A child, after suffering very acute pain in the abdomen, after receiving a blow, had a prolapsus of the intestine through the anus, about six or seven inches long. This was taken for a prolapsus of the rectum. After death, the termination of the bowel out of the anus was found to be nothing less than the cæcum, which had passed through the colon and rectum, to make a protrusion at the anus. See INTUSSUSCEPTIO.

PROLAPSUS of the Iris. See IRIS.

PROLAPSUS Oculi. See EXOPHTHALMIA.

PROLAPSUS Uteri. This distressing complaint presents itself in two different degrees; in one the uterus descends more or less into the vagina; in the other it protrudes entirely out of this passage, and hangs down between the patient's thighs. A prolapsus uteri may happen, either out of the time of pregnancy, during this period, or at the moment of parturition. Women, who are not pregnant, but who have a large pelvis, are in the habit of carrying or lifting heavy weights, and have already had several children, are particularly subject to the present disorder. It may readily be distinguished by an inspection of the parts. The body of the uterus fills the cavity of the vagina, at the orifice of which the os tinæ may be felt. The patient feels in her groins and about the pelvis dragging pains, which are exasperated by walking, but subside entirely when she keeps her bed, and the uterus has been pushed back with the finger, and kept there with the assistance of a pessary.

If this first degree of the disorder be not obviated, the uterus protrudes altogether from the vagina, and presents itself externally, which may happen either by degrees, or all on a sudden. The uterus, when thus protruded, forms a red oblong tumour, larger above than below, and terminating in the transverse opening of this viscus. The patient can neither walk nor sit down; she experiences pain in the groins and lumbar region; and has difficulty of voiding her urine and feces. The vagina becomes inverted, and one part of the fundus of the bladder being drawn slowly outward, covers the anterior and superior part of the tumour to which it is adherent. A prolapsus uteri of this description degenerates into a chronic disease, which may continue for several years, if not rectified on its first occurrence. (Saviard, obs. 10, &c. p. 49. Ruysch, Observat. Anat. Chirurg. i. 7. et 9. Mem. de l'Acad. de Chirurgie, tom. iii. p. 361.) When it has existed a long while, its reduction can only be effected gradually, by the patient being confined to a horizontal position in bed, by low diet, and by daily covering the swelling, which is hard, thick, and almost insensible, with linen wet with an emollient decoction. As soon as the size of the uterus is a little diminished, an attempt is to be made to replace it by pushing it from below upwards, which operation may be facilitated by raising the pelvis, and taking care to have the bladder and rectum empty. Should the reduction be accomplished, the uterus is to be maintained in its natural situation with a pessary.

When the uterus protrudes completely from the vagina at the period of delivery, and at the moment when the woman makes the most violent efforts, no attempt should be immediately made to reduce the part, a thing that would also be impracticable. It would only be fatiguing the mother and child with useless trials. On the contrary, we ought to support the uterus, gradually dilate its orifice, bring the labour to a conclusion, and carefully extract the placenta. When delivery has taken place, the womb contracts, its size is lessened, and the reduction can then be easily effected. Fabricius, de Fœtus vivi extractione, utero prolapsu. Vide Haller, Disputat. Chirurg. selectæ, tom. iii. p. 431.

About the fourth or fifth month of pregnancy, and sometimes rather later, the uterus, by means of its weight, becomes displaced; and in women who have a large pelvis, and have already had several children, protrudes more or less out of the vagina. The patients experience a sense of heaviness about the rectum, dragging pains in the groins and lower part of the back, and weakness and prostration of strength. At length they are attacked with constipation and retention of urine, which complaints increase as the prolapsus uteri increases. Speedy relief is here essentially required, and the proper mode of procuring it, is by making the patient keep her bed, where she must endeavour to void her urine, and the uterus is to be pushed back with the finger, in order to avoid a recurrence of the retention of urine, which is occasioned by the pressure of the womb on the neck of the bladder.

A woman, twenty-six years of age, and four months with child, slipped and fell down while carrying a heavy burden on her shoulders. At the instant she felt a violent pain in the loins and region of the pubes, accompanied with an absolute inability to void her urine. An ignorant practitioner being called to assist her, prescribed diuretic medicines, instead of introducing a catheter and drawing off the urine. For twelve days the patient suffered inexpressible pain, without being able to discharge a drop of fluid from the bladder, and she at last fell a victim to the ignorance of her

her medical attendant. After death the uterus was found in a state of prolapsus in the vagina, and its cervix protruding at the vulva. The bladder was so considerably distended, that it was two feet long, and one broad, and contained twenty pints of water. "Patet adeoque luculentissimé," says the writer of this case, "quam sinistra illi medici, ad multorum hominum detrimentum, praxim suam excerceant, qui chirurgiam negligent." Kulm, Dissert. de Uteri Lapsu, Gedani 1732, in 4to. Vide Disput. Chirurg. selectæ, Haller, tom. iii. p. 587.

Girls are seldom afflicted with a prolapsus uteri. The disease, however, may take place slowly in them, in consequence of violent exertions.

There is an example on record of a young girl becoming pregnant, and being delivered of a child, notwithstanding she had a prolapsus uteri, which had existed a long while. When she was fourteen, and had her menses upon her, she made a considerable exertion to throw a bundle of herbs over a wall. She felt at the moment a very acute pain in the loins and lower part of the abdomen. The next day the uterus had descended into the vagina, and protruded at the vulva. This young woman lived six years with the complaint, which gradually became worse. At the age of twenty-two she married, but for the space of twenty years never conceived. At length the act of generation was consummated, and the period of pregnancy passed over without any material indisposition. At the time of parturition a very considerable portion of the uterus protruded at the vulva, in form and size resembling a large melon. It was hard and elastic, and seemed as if it had become adherent to the labia, so closely did they embrace it. As the cervix uteri did not dilate, it became necessary to divide it at two opposite points, in order to make the requisite room for the extraction of the child, which was dead. Delivery was followed by no serious consequences: the lochia were discharged in abundance. An attempt was made to reduce, gradually, the uterus which had been so long displaced, by keeping the patient in bed, and using emollient fomentations and the vapour bath. She only pursued this treatment, however, one week, and then resumed her ordinary work. The uterus continued in the same state as it was before pregnancy, with this exception, that its displaced part became rather longer and more cylindrical. This woman, at the age of fifty-three, ten years after her delivery, still enjoyed good health, and followed her usual country-work. *Traité des Maladies de la Vessie*, par M. Chopart, tom. ii. p. 73.

It is generally admitted, that a prolapsus uteri is exceedingly difficult to reduce and keep up in patients who are fat; while, in thin women, the reduction and support of the displaced part can be managed with much less trouble.

For the preceding short and accurate account of the prolapsus uteri, we are indebted to M. Lassus. See *Pathologie Chirurgicale*, tom. ii.

PROLAPSUS of the *Vagina*. See **VAGINA**.

PROLATE, in *Geometry*, an epithet applied to a spheroid produced by the revolution of a semi-ellipsis about its longer diameter.

If the solid be formed by the revolution of a semi-ellipsis about its shorter diameter, it is called an *oblate spheroid*; of which figure is the earth we inhabit, and, perhaps, all the planets too; having their equatorial diameter longer than the polar. See **SPHEROID**.

PROLATIO *Major et Minor*. Prolation, in the beginning of figurative counterpoint, was the manner of regulating the value of notes by signs at the beginning of a movement, which determined whether long notes were to be

regarded as perfect or imperfect, that is, whether ternary or binary, equal to three notes of the next degree, or 2. Points which answer that purpose now were not then in use. The ternary notes in triple time were called *perfect*, as we have often observed elsewhere, and the binary, or common time, *imperfect*. See **MODAL Signs**, or **MOODS**, as they were called.

In the MS. of Waltham Holy Cross, there is a tract entitled "Regulæ Magistri Thomæ Walsingham; de Figuris compositis et non compositis, et de Cantu perfecto et imperfecto, et de Modis." And this comprehensive little tract does not promise more than the author has performed; as the simple and compound figures or notes, their perfect and imperfect powers, the moods and every thing that concerned the time and measure of such music as then subsisted, is very well explained; particularly the moods and signs of prolation, which we do not recollect to have seen represented in any other authors equally ancient. His chapters on rests or pauses, on the signs of perfection and imperfection in the notes, and of the alteration of their value, by position or colour, are very instructive.

The signs of prolation at first were confined to four; two for perfect or triple time, and two for imperfect or common time. The circle with a point of perfection in the centre, thus \odot , was the sign for the great mode perfect, in which all long notes were equal in duration to *three* of the next shorter in degree. The simple circle, unaccompanied by the point, was used for notes of a shorter duration, but with the same triple power. These two moods may be compared with our present measures of $\frac{3}{4}$ and $\frac{3}{8}$, where each note is occasionally rendered perfect, or equal to three others, by a point, instead of the general augmentation implied by the circle, which the old masters placed at the beginning of a movement.

The signs of imperfect, or, as we now call it, common time, were these \odot , \odot , which differ but little from those in present use for dupla proportion, or an equal number of notes in a measure; where each longer note is only equal to *two* of the next shorter kind. This seems to us even clearer than Morley's account "of the prolation of the more, and the prolation of the less—the prick of perfection, &c." which his old English darkens instead of illustrating.

PROLECTATIO, a word used in chemistry to express an extraction of the finer substances of a mixed body by the attenuation of the subtler particles; so that these, being rarefied, separate spontaneously from the rest, and leave the grosser and less valuable part in form of a residuum behind.

PROLEGOMENA, formed of $\pi\rho\omicron\lambda\omicron\gamma\mu\epsilon\tau\alpha$, *I preface*, or *speak before*, in *Philology*, certain preparatory observations, or discourses prefixed to a book, &c. containing something necessary for the reader to be apprized of, to enable him the better to understand the book, to enter deeper into a science, &c.

The generality of arts and sciences require some previous instructions, some prolegomena.

PROLEPSIS, $\pi\rho\omicron\lambda\omicron\gamma\mu\epsilon\tau\alpha$, or anticipation, a figure in *Rhetoric*, by which we anticipate, or prevent what might be objected by the adversary.

It serves likewise to conciliate the audience, while the speaker appears desirous to represent matters fairly, and not to conceal any objection which may be made against him.

Thus, *It may perhaps be objected, &c. You will ask, &c. But some man will say, How are the dead raised, or with what body do they come? Thou fool, that which thou sowest, &c.* Where the objection is turned into an argument against the adversary, as in the last instance, it is called *antistrophe*, or *inversio*.

inverso. Where it is rejected as insufferably absurd, it is called *apodioxis*.

PROLEPTIC, *προληπτικός*, denotes a periodical disease, which anticipates, or whose paroxysm returns sooner and sooner every time; as is frequently the case in agues, &c.

PROLES, Lat. in English progeny, are such issue as proceed from a lawful marriage; though if the word be used at large, it may denote others.

PROLIFER, in *Botany*, a word sometimes used in specific names, or in definitions, to express either a greater assemblage of flowers, in one common integument, than is usual in the genus; witness *Dianthus prolifer*; or, more frequently, a preternatural luxuriance of growth in the herbage or inflorescence of any plant.

PROLIFIC, in *Medicine*, something that has the qualities necessary for generating. See **FECUNDITY**.

PROLIXITY, in *Discourse*, the fault of entering into too minute a detail; of being too long, precise, and circumstantial, to a degree of tediousness.

Prolixity is the vice opposite to conciseness and laconism.

Prolixity is a fault commonly charged on Guicciardini, Gassendus, &c. See **METHOD**.

PROLOCUTOR of the *Convocation*, the speaker or chairman of that assembly.

The archbishop of Canterbury is, by his office, president or chairman of the upper house of convocation. The prolocutor of the lower is an officer chosen by the members the first day of their meeting, and is to be approved of by the higher.

It is by the prolocutor their affairs, debates, &c. are to be directed; and their resolutions, messages, &c. delivered to the higher house; by him all things propounded to the house are read, suffrages are collected, &c. See **CONVOCA-TION**.

PROLOGIA, *Προλογία*, in *Antiquity*, a festival celebrated by the inhabitants of Laconia, before they gathered their fruits. The Romans also celebrated a feast of the same kind.

PROLOGUE, **PROLOGUS**, in *Dramatic Poetry*, a discourse addressed to the audience before the drama or play begins.

The word is formed from *προλογος*; *proloquium*, *fore-speech*, formed of *προς*, and *λογος*; *fermo*.

The original intention of the prologue was to advertise the audience of the subject of the piece, and to prepare them to enter more easily into the action; and sometimes to make an apology for the poet.

The prologue is of a much more ancient standing than the epilogue. The French have left off the use of prologues, except in their operas; those few they now and then make having nothing in them of the genuine prologue, as bearing no relation to the subject, but being mere flourishes or harangues in praise of the king, &c.

In the ancient theatre, the *prologus* was properly the actor who rehearsed the prologue; the prologue was esteemed one of the dramatis personæ, and never appeared in the piece in any other character; so that the learned are surprised to find Mercury, in Plautus's *Amphitryo*, speaking the prologue, and yet acting a considerable part in the play afterwards.

The prologue, therefore, among them, was a part of the piece; indeed, not an essential, but an accessory part. With us the prologue is no part at all; but something entirely distinct and separate: with them the drama was opened with the appearance of the prologue; with us it is not opened till after the prologue is retired; with us, therefore, the curtain is kept close till after the prologue; with them it must have been withdrawn before.

Hence proceeds a still more considerable difference in the practice of the prologue; for with us the prologue speaks in his real or personal character; with them, the prologue spoke in his dramatic character.

With us, he always directs his speech to the audience, considered as in a play-house; to pit, box, and gallery; with them, he ought, in propriety, to have spoken as to a chorus of by-standers, or persons to be present at the real action; but this being in good measure inconsistent with the design of the prologue, their persons spoke in the dramatic capacity to the audience in its principal capacity; which was an irregularity that either the good fortune, or the good sense, of the moderns have freed them from. They had three kinds of prologues; the first, *ὑποθετικόν*, in which the poet delivered the argument of the piece; the second, *συγγλυτικόν*, in which the poet recommended himself, or his piece, to the people; the third, *αποφορικόν*, in which objections were obviated, &c.

PROLONGED FACE. See **FACE**.

PROLUSION, **PROLUSIO**, in *Literature*, a term applied to certain pieces, or compositions, made previously to others, by way of prelude or exercise.

Diomedes calls the *Culex* of Virgil, and his other opuscula, prolusions; because written before the great ones. The prolusions of Strada are very ingenious pieces. The famous M. Huet, bishop of Avranches, had all Strada's prolusions by heart.

PROMACHIA, *Προμαχία*, in *Antiquity*, a festival in which the Lacedæmonians crowned themselves with reeds.

PROMALACTERION, the name of the first apartment in the hot baths of the ancients; this was a hot and close room, in which the person was kept a while before he plunged at once into the warm water.

PROMB, in *Geography*, a town of Austria; nine miles W. of Tauffkirchen.

PROME, or **PRONE**, or *Peenye-mew*, a city of the Birman empire, and capital of a district, situated on the Irrawaddy; containing, as it has been said, above 30,000 inhabitants. Their number, as Col. Symes was informed, was greater than that of Rangoon, and their market was better supplied. This city is renowned in Birman history, as having been the scene of many long sieges and bloody conflicts. It has no remarkable buildings; some of its streets are of considerable length, and they are infested by a great number of dogs, and the inhabitants, men, women, and children, crowd into them to indulge their curiosity at the sight of an European, expressing their astonishment by loud laughs, and clapping of hands, but intending no contempt or offence; respect and kindness to strangers being inculcated by parents, as well as sanctioned by the practice of the Birmans. At the upper end of the present city are the ruins of the ancient port of Prome, which had been a small pentagon, constructed of brick, and, from its situation, very strong. The modern fort is nothing more than a palisaded inclosure, with earth thrown up behind it. Low hills on the eastern side approach the town, in which the rains have formed channels down to the river, that are crossed by wooden bridges. The town has several yards for the accommodation of stone-cutters, who are employed in manufacturing flags for pavements, and slabs and vases for the use of temples, out of a fine free-stone which is found in its vicinity. Adjacent to the town there is a royal menagerie of elephants, consisting of two rows of lofty well-built stables, in which these animals are lodged during the rains. The city of Prome, and the province in which it stands, are the jaghire, or estate, of the second son of the king, who derives his title from them. Prome is sometimes called

'Terreckettaree, or single skin; and the Birmanians have an old legendary tale concerning the origin of this name; it is related, that a favourite female slave of Tutebong-mangoe, or the mighty sovereign with three eyes, importuned her lord for the gift of some ground; and being asked of what extent, replied in similar terms with the crafty and amorous Elifa, when she projected the site of ancient Carthage. Her request was granted, and she used the same artifice. The resemblance of the stories is curious. Col. Symes was informed, that the ruins of a large fort and city, much surpassing the present, stood about a league eastward of the town. Prome is 165 miles N.N.W. of Rangoon. N. lat. 19°. E. long. 95°. Symes's Ava, vol. ii.

PROMETHEIA, Πρωθεΐα, in *Antiquity*, an Athenian solemnity celebrated in honour of Prometheus, with torch races, in remembrance that he was the first that taught men the use of fire.

PROMETHEUS, in the *Ancient Astronomy*, was the name of a constellation of the northern hemisphere, now called Hercules, or Engonasis.

PROMETHEUS, in *Mythology*, the son of Japetus, one of the Titans, and Clymene according to Hesiod, or of Themisa according to Eschylus, whom the poets feign to have formed men of clay, and animated them by fire stole from heaven; at which Jupiter being angry sent Mercury to chain him to mount Caucasus, and to set a vulture to his liver, which grew again as fast as it was devoured.

This fable is variously related by different authors. Prometheus, as some say, being a man of subtle and crafty genius, attempted to impose upon Jupiter in a sacrifice, and thus to find out whether he was really worthy to be reckoned a god. Having for this purpose slain two oxen, he stuffed one of the skins with the flesh, and the other with the bones of the victims, the latter of which was chosen by Jupiter. The god, resolved to be revenged upon all mankind, deprived them of the use of fire; but Prometheus, with the assistance of Minerva, who had already aided him by her advice in forming the body of a man of tempered clay, got up to heaven, and approaching the chariot of the sun, stole from thence the sacred fire, which he brought down to earth in a ferula. (See Hor. Od. 3. l. 2.) Jupiter, incensed at this strange and audacious enterprise, ordered Vulcan to form a woman, endowed with all perfections, whence she was called Pandora. (See her story under PANDORA.) Jupiter failing to ensnare and delude Prometheus by this artifice, ordered Mercury to carry him to mount Caucasus, and chain him to a rock, where an eagle was eternally to prey upon his liver. This part of the history of Prometheus, and his subsequent deliverance either by Hercules or Jupiter himself, abounds with fictions, which are supposed to contain some ancient facts under this fabulous disguise. M. Bannier supposes that this is merely a continuation of the history of the Titans. Prometheus, as he conjectures, was not exempt from the persecutions which harassed the other Titans. As he returned into Scythia, which he durst not quit so long as Jupiter lived, that god is said to have bound him to Caucasus. This prince addicted to astrology, frequently retired to mount Caucasus, as to a kind of observatory, where he contemplated the stars, and was, as it were, preyed upon by continual pining, or rather by vexation, on account of the solitary and melancholy life which he led. This is supposed to have given rise to the fable of the eagle or vulture that incessantly preyed upon his liver. Herodotus, however, alleges, that Prometheus was put in prison for not being able to stop the overflowing of a river, which from its rapidity was called the eagle; or at least that he was obliged to fly with a part of his subjects to the mountains to

escape the inundation, till a traveller, represented by Hercules, undertook to dam it up by a mount, and to kill the eagle, as it may be said, by making its course regular and uniform; thus Prometheus was delivered by this hero from his prison, or retreat. The inhabitants were at this time savage and without laws; Prometheus, who was a polite and well-informed prince, taught them to lead a more rational life, instructed them in agriculture, physic, &c., and thus gave rise to the hyperbolic expressions of his having formed a man, whom Minerva, the goddess of sciences, had animated. Lactantius explains this fable by supposing that Prometheus was the first who taught the art of making statues of clay; whence he is said to have invented the art of statuary. As to his theft of fire, some authors say, that this part of the fable had its rise from his having taught man the use of fire. Diodorus Siculus says that he discovered combustible materials fit for kindling and maintaining fire. Bannier is of opinion, that the origin of this fiction was, that Jupiter, having ordered all the shops where iron was forged to be shut up, lest the Titans should make use of it against him, Prometheus, who had retired into Scythia, there established good forges; hence came the "Calybes," those excellent blacksmiths; perhaps Prometheus also, not thinking to find fire in that country, brought some thither in the stalk of the ferula, in which it may be easily preserved for several days. (See FERULA.) As for the two oxen which Prometheus is said to have slain, that he might impose upon Jupiter, this part of the fable is said to be founded upon his having been the first who opened victims with a view of drawing omens from the inspection of their entrails. According to Le Clerc, Prometheus is the same with Magog, the former being the son of Japetus, and the latter the son of Japhet and grand-son of Noah. Both Prometheus and Magog settled in Scythia; the latter invented or improved the art of founding metals, and of forging iron, which the poets attributed to Prometheus; and Diodorus too says that he invented several instruments for making fire. The appellation Magog signifies vexation, as Prometheus was gnawed by a vulture.

If we rely on the statement of sir Isaac Newton, Prometheus was nephew to the famous Sesostris, who, according to his account, lived about the time of the Argonauts, a few years before the Trojan war. As that prince had accompanied his uncle in his expedition, he was left by him upon mount Caucasus, with a part of his troops, to preserve the conquests he had made in Scythia. Admitting this to be the case, Prometheus would be an Egyptian originally, and his deliverer would be Hercules the Argonaut, the son of Alcmena. But many of the ancients, and particularly Hesiod, represent Prometheus as one of the Titans.

The learned Bryant adopts the opinion of those who consider Prometheus and Noah as the same person. Prometheus raised the first altar to the gods; he constructed the first ship, and transmitted to posterity many useful inventions. He is supposed to have lived in the time of the deluge, and to have been guardian of Egypt at that season. His influence was limited to that region; because the Egyptians, like the people of Phocis, Argos, Thessaly, and Dodona, confined the deluge to the boundaries of their own country. Hence we may plainly see the person who is alluded to under the character of Prometheus. He was the same as Osiris; the same also as Dionusius, the famous husbandman, planter of the vine, and inventor of the plough. (Bryant's Analysis of Mythology, vol. ii. 273.) Prometheus received divine honours, or at least such as were destined to the heroes: accordingly Pausanias tells us (in his Attics), that Prometheus had an altar in the academy itself, and that games were instituted

instituted to him, which consisted in running from that altar to the city with torches that were to be kept perpetually burning.

PROMIESZ, in *Geography*, a town of Lithuania; 35 miles W. of Troki.

PROMISE, in *Law*, is when, upon a valuable consideration, a man binds himself by his word, to do or perform such an act as is agreed on with another: it is in the nature of a verbal covenant, and wants nothing but the solemnity of writing and sealing to make it absolutely the same. See COVENANT and ASSUMPSIT.

PROMISE, in *Moral Philosophy*, is a kind of social transaction between two parties, in which some declaration is made, or assurance given, on the part of one to the other, which brings us under an obligation to act or not to act, from which we should otherwise have been free. What makes a promise is, that it be expressed by one party to the other with understanding, and with an intention to become bound, and that it be accepted by him, and the expression, if it is not accompanied with understanding and will to engage, never makes a promise. Such an obligation never flows merely from declaring a resolution or intention. The intention to perform the promise, or not to perform it, whether the intention be known to the other party or not, makes no part of the promise; this is a solitary act of the mind, and can neither constitute nor dissolve an obligation. A promise must mean more than a declaration of resolution or intention; and the whole difference is, that the one relates to the *present*, the other to *future* time.—When I say I *intend* to do an action, I affirm only a present fact:—but to promise is to declare that such a thing *shall* be done, or that such and such events *shall* happen. In this case, it is not enough to acquit me from the charge of falsehood, that I *intend* to do what I promise, but it must be actually done, agreeably to the assurances given. After declaring a *resolution* to do an action, a man is under no obligation actually to do it, because he did not say he would; his word and veracity are not engaged; and the non-performance cannot infer the guilt of violating truth. On the contrary, when a person declares he *will* do any action, he becomes obliged to do it, and cannot afterwards omit it, without incurring the imputation of declaring falsehood, as really as if he declared what he knew to be a false past or present fact; and in much the same manner as he would have done, if he had pretended to know, and had accordingly asserted, that a certain event would happen at a certain time which yet did not then happen. There is, however, a considerable difference between this last case, and the falsehood implied in breaking promises and engagements; for the object of these is something, the existence of which depends on ourselves, and which we have in our power to bring to pass; and therefore, here the falsehood must be known and wilful, and entirely imputable to our own neglect and guilt. But in the case of events predicted which are not subject to our dominion, the blame, as far as there may be any, must arise from pretending to knowledge which we really want, and asserting absolutely what we were not sure of.

To *promise*, then, being to assert a fact dependent on ourselves, with an intention to produce faith in it and reliance upon it, as certainly to happen; the obligation to keep a promise is the same with the obligation to regard truth; and the intention of it cannot be, in the sense some have asserted, to will or create a new obligation; unless it can be pretended that the obligation to veracity is *created* by the mere breath of men every time they speak, or make any professions. If, indeed, we mean by creating a new obligation, that the producing of a particular effect or performance of

an external action becomes fit, in consequence of some new situation of a person (or some preceding acts of his own) which was not fit before; it may be very well acknowledged; nor is there in it any thing in the least mysterious. Thus, performance becomes our duty after a promise, in the same sense that repentance becomes our duty in consequence of doing wrong, reparation of an injury in consequence of committing it, or a particular manner of conduct in consequence of placing ourselves in particular circumstances and relations of life. As a confirmation of this account, if any confirmation were necessary, it might be observed, that false declarations in general, and violations of engagements, admit of the same extenuations or aggravations according to the different degrees of solemnity with which they are made, and the different importance of the subjects of them.

The account above given of the nature and obligation of a promise, is very different from that of Mr. Hume in the third volume of his “*Treatise of Human Nature* ;” and with respect to the obligation of a promise, it is somewhat different from archdeacon Paley’s mode of reasoning in his “*Principles of Moral and Political Philosophy*,” vol. i. This ingenious writer deduces the obligation of performing promises, not from any innate moral principles, of which a sense of obligation is supposed to be one, but from the necessity of such a conduct to the well-being, or, indeed, the existence, of human society. Men act, he says, from expectation; expectation is, in most cases, determined by the assurances and engagements which we receive from others; and if no dependence can be placed upon these assurances, no judgment could be formed of many future events, nor should we know how to regulate our conduct with respect to them. Confidence, therefore, in promises, is essential to the intercourse of human life; and there could not be this confidence, if men were not obliged to perform them: the obligation, therefore, to perform promises is essential to the same end, and in the same degree. Next to the nature and obligation of promises, the next subject of inquiry is the sense in which they are to be interpreted. If the terms of a promise admit of more senses than one, it is obvious that the promise is to be performed in that sense in which the promisee received it.

Adverting to the account that has been just given of the obligation of promises, it will appear that this obligation has been thought to depend upon the expectations which we knowingly and voluntarily excite. Consequently, any action or conduct towards another, which we are sensible excites expectation in that other, is as much a promise, and creates as strict an obligation, as the most express assurances. This is the foundation of “*tacit promises*.”

A person may either simply declare his present intention, or accompany his declaration with an engagement to abide by it, which constitutes a complete promise. In the first case, the duty is satisfied, if he was *sincere* at the time of the declaration, though he may afterwards change his purpose: but in the latter case, a person has parted with the liberty of changing. Another inquiry of importance in relation to this subject, pertains to the variety of cases in which promises are not binding. Promises are not binding, where the performance is *impossible*. Here, however, the promiser is guilty of a fraud, if he be privately aware of the impossibility at the time of making the promise: and if the promiser himself occasions the impossibility, it is a direct breach of the promise. Promises are not binding, where the performance is *unlawful*. Of this there are two cases; one, where unlawfulness is known to the parties at the time when the promise is made; and the parties are not obliged to perform what the promise requires, because they

were under a prior obligation to the contrary: the guilt of such promises lies in the making, not in the breaking of them. The other case is, where the lawfulness was not known, or did not exist, at the time of making the promise; there the lawfulness becomes a condition of the promise, and when the condition fails, the obligation ceases. It appears in this connection to be a matter of importance, that no persons should ever give a promise which may interfere in the event with their duty. The reason is obvious: because, when this interference occurs, their duty must be discharged, though at the expence of their promise, and, not unusually, of their good name. The specific performance of promises is reckoned a perfect obligation; and it has been laid down by many casuists, in opposition to what is above asserted, that where a perfect and imperfect obligation clash, the former is to be preferred. Paley thinks that there is no reason for this opinion; but that of two contradictory obligations, the one which is prior in point of time ought to prevail. It is the unlawfulness of the performance, and not any unlawfulness in the subject or motive of the promise, which destroys its validity. Again, a promise does not lose its obligation, merely because it proceeded from an unlawful motive. A promise cannot be deemed unlawful, where it produces, when performed, no effect beyond what would have taken place if the promise had never been made: and this is the single case in which the obligation of a promise will justify a conduct, which, unless it had been promised, would be unjust. Moreover, promises are not binding, where they contradict a former promise; because the performance is then unlawful. Promises are not binding before acceptance, that is, before notice given to the promisee; for where the promise is beneficial, if notice be given, acceptance may be presumed. In this case the promiser has not done that which constitutes the essence of a promise: that is, he has not voluntarily excited expectation. Promises are not binding which are released by the promisee. Erroneous promises are not binding in certain cases: as, where the error proceeds from the mistake or misrepresentation of the promisee; and when the promise is understood by the promisee to proceed upon a certain supposition, or when the promiser apprehended he so understood it, and that supposition turns out to be false.

It has been long controverted among moralists, whether promises be binding which are extorted by violence or fear? The solution of this question will depend upon this circumstance, whether mankind, upon the whole, are benefited by the confidence reposed in such promises? This, on many occasions, is a doubtful point, and accordingly the obligation of such promises is doubtful. With regard to promises extorted through fear, Cicero observes (De Off. l. iii. c. 29, 30.) "If you do not pay to robbers the sum you promised as a ransom for your life, you are guilty of no dishonesty, not even though you were sworn to do it." We have the following anecdote in Ramsay's Life of Viscount Turenne, which evinces his high sense of honour. As he was coming home one night, he fell into the hands of robbers, who stopped his coach near Paris. On his promising them 100 louis d'ors to let him keep a ring of much less value, they returned it; and one of them had the boldness to go to his house the next day, and, in the midst of a large company, to whisper him, and demand the performance of his promise. The viscount ordered the money to be paid him, and before he related the adventure, he allowed the robber time to escape; adding, that a promise ought to be kept inviolable, and that an honest man should never break his word, though given to knaves. For other particulars relating to promises, we refer to Price on Morals, p. 260, &c. Grove's System

of Moral Philology, vol. ii. Paley's Principles, &c. vol. i. Reid's Essays, ess. v. See CONTRACT, COVENANT, FIDELITY, and VOW.

PROMISSORY NOTE. See NOTE, and BILL of Exchange.

By 48 Geo. III. c. 149. the stamp duties upon bills, &c. which were imposed by 44 Geo. III. c. 98. (which last act had repealed the former duties) were repealed; and by schedule, part 1, the following stamp duties are imposed; viz. upon every

Inland bill of exchange, draft, or order for the payment to the bearer, or to order, either on demand, or otherwise, of any sum of money amounting to 40s. and not exceeding 5l. 5s.		£	s.	d.
Exceeding 5l. 5s. and not exceeding 30l.	30l.	0	1	0
30l.	50l.	0	2	0
50l.	100l.	0	3	0
100l.	200l.	0	4	0
200l.	500l.	0	5	0
500l.	1,000l.	0	7	6
3,000l.	-	1	0	0

Inland bill, draft, or order, for the payment of any sum of money, though not payable to bearer or to order, if the same shall be delivered to the payee, or some person on his behalf, } The same duty as on a bill of exchange for the like sum, payable to bearer or order.

Inland bill, draft, or order, for the payment of any sum of money, weekly, monthly, or at any other stated periods, if made payable to the bearer, or to order, or if delivered to the payee, or some person on his behalf; where the total amount of the money thereby made payable shall be specified therein, or can be ascertained therefrom, } The same duty as on a bill payable to bearer or order, for a sum equal to such total amount.

And where the total amount or the money thereby made payable shall be indefinite, } The same duty as on a bill for the sum expressed only.

And the following instruments shall be deemed and taken to be inland bills, drafts, or orders, for the payment of money within the intent and meaning of this schedule, and the foregoing act, viz.

"All drafts or orders for the payment of any sum of money, by a bill or promissory note, or for the delivery of any such bill or note, in payment or satisfaction of any sum of money; where such drafts or orders shall require the payment or delivery to be made, to the bearer or to order, or shall be delivered to the payee, or to some person for his behalf.

"All receipts given by any banker, or other person, for money received, which shall entitle, or be intended to entitle, the person paying the money, or the bearer of such receipts, to receive the like sum from any third person.

"And all bills, drafts, or orders for the payment of any sum of money out of any particular fund, which may or may not be available; or upon any condition or contingency, which may or may not be performed or happen; if the same shall be made payable to the bearer or to order, or if the same shall be delivered to the payee, or to some person on his behalf."

Foreign bill of exchange, (or bill of exchange drawn in, but payable out of Great Britain,) if drawn singly, and not in a set, } The same duty as on an inland bill of the same amount and tenor.

Foreign

PROMISSORY NOTES.

Foreign bills of exchange drawn in sets, according to the custom of merchants; for every bill of each set, where the sum made payable thereby shall not exceed 100 <i>l.</i>	£	s.	d.
	0	1	0
Exceeding 100 <i>l.</i> and not exceeding 200 <i>l.</i>	0	2	0
200 <i>l.</i> - - - 500 <i>l.</i>	0	3	0
500 <i>l.</i> - - - 1,000 <i>l.</i>	0	4	0
1,000 <i>l.</i> - - - 3,000 <i>l.</i>	0	5	0
3,000 <i>l.</i> - - - -	1	0	0

Exemptions.

“ All bills of exchange and bank post bills issued by the governor and company of the bank of England.

“ All bills, orders, remittance bills, and remittance certificates, drawn by commissioned officers, masters, and surgeons in the navy, or by any commissioner or commissioners of the navy, under the authority of the 35 Geo. III. c. 94.

“ All bills drawn pursuant to any former act of parliament, by the commissioners for victualling the navy, or by the commissioners for managing the transport service, and for taking care of sick and wounded seamen, upon and payable by the treasurer of the navy.

“ All drafts or orders for the payment of any sum of money to the bearer on demand, and drawn upon any banker, or person acting as a banker, who shall reside or transact the business of a banker, within ten miles of the place where such drafts or orders shall be drawn; provided such place shall be specified in such drafts or orders: and provided the same shall bear date on or before the day on which the same shall be issued; and provided the same do not direct the payment to be made by bills or promissory note.

“ All bills, for the pay and allowances of his majesty’s land forces, or for other expenditures liable to be charged in the public regimental or district accounts, which shall be drawn according to the form now prescribed, or hereafter to be prescribed by his majesty’s orders, by the paymasters of regiments or corps, or by the chief paymaster or deputy paymaster and accountant of the army depot, or by the paymasters of recruiting districts, or by the paymasters of detachments, or by the officer or officers authorized to perform the duties of the paymastership, during a vacancy, or the absence, suspension, or incapacity of any such paymaster as aforesaid, save and except such bills as shall be drawn in favour of contractors or others who furnish bread or forage to his majesty’s troops, and who by their contracts or agreements shall be liable to pay the stamp duties on the bills given in payment for the articles supplied by them.”

By the same act of 48 Geo. III. c. 149. sched. part 1. a duty is imposed upon every

Licence to be taken out yearly by any banker or bankers, or other person or persons, who shall issue any promissory note for money payable to the bearer on demand, and allowed to be re-issued, of	£	s.	d.
	20	0	0
And also upon every promissory note for the payment, to the bearer on demand, of any sum of money not exceeding 1 <i>l.</i> 1 <i>s.</i>	0	0	4
Exceeding 1 <i>l.</i> 1 <i>s.</i> and not exceeding 2 <i>l.</i> 2 <i>s.</i>	0	0	8
2 <i>l.</i> 2 <i>s.</i> - - - 5 <i>l.</i> 5 <i>s.</i>	0	1	0
5 <i>l.</i> 5 <i>s.</i> - - - 20 <i>l.</i>	0	1	6
20 <i>l.</i> - - - 30 <i>l.</i>	0	3	0
30 <i>l.</i> - - - 50 <i>l.</i>	0	4	6
50 <i>l.</i> - - - 100 <i>l.</i>	0	7	6

Which said note not exceeding 2*l.* 2*s.* may be re-issued,

after payment thereof, as often as shall be thought fit; and the said notes for any sum exceeding 2*l.* 2*s.* and not exceeding 100*l.*, may be re-issued from time to time after payment thereof, until the expiration of three years from the date thereof, but not afterwards.

Promissory note, for the payment, in any other manner than to the bearer on demand, of any sum of money	£	s.	d.
Amounting to 40 <i>s.</i> and not exceeding 5 <i>l.</i> 5 <i>s.</i>	0	1	0
Exceeding 5 <i>l.</i> 5 <i>s.</i> - - - 30 <i>l.</i>	0	1	6
30 <i>l.</i> - - - 50 <i>l.</i>	0	2	0
50 <i>l.</i> - - - 100 <i>l.</i>	0	2	0

These notes are not to be re-issued after being once paid.

Promissory note, for the payment, either to the bearer on demand, or in any other manner than to the bearer on demand, of any sum of money	£	s.	d.
Exceeding 100 <i>l.</i> and not exceeding 200 <i>l.</i>	0	4	0
200 <i>l.</i> - - - 500 <i>l.</i>	0	5	0
500 <i>l.</i> - - - 1,000 <i>l.</i>	0	7	6
1,000 <i>l.</i> - - - 3,000 <i>l.</i>	0	10	0
3,000 <i>l.</i> - - - -	1	0	0

These notes are not to be re-issued after being once paid.

Promissory note, for the payment of any sum of money by instalments, or for the payment of several sums of money at different days and times, so that the whole of the money to be paid shall be definite and certain, -

}

The same duty as on a promissory note payable after date, for a sum equal to the whole amount of the money to be paid.

And the following instruments shall be deemed to be promissory notes within the meaning of this schedule, viz.

“ All notes promising the payment of any sum or sums of money out of any particular fund, which may or may not be available; or upon any condition or contingency, which may not be performed or happen: if the same shall be made payable to the bearer or order, and if the same shall be definite and certain, and not amount in the whole to 20*l.*

“ And all receipts for money deposited in any bank, or in the hands of any banker or bankers, which shall contain any memorandum or agreement importing that interest shall be paid for the money so deposited.

Exemptions from the Duties on Promissory Notes.

“ All notes promising the payment of any sum or sums of money out of any particular fund which may or may not be available; or upon any condition or contingency which may not be performed or happen, where the same shall not be made payable to the bearer or order; and also where the same shall be made payable to the bearer or order, if the same shall amount to 20*l.*, or be indefinite.

“ And all other instruments, bearing in any degree the form or style of promissory notes, but which in law shall be deemed special agreements, except those hereby expressly directed to be deemed promissory notes.

“ But such of the notes and instruments here exempted from the duty on promissory notes, shall nevertheless be liable to the duty which may attach thereon, as agreements or otherwise.

“ Exemption as before for the governor and company of the bank of England.”

And if any such bills or drafts for 40*s.* or upwards, by this act intended to be stamped, shall be written or printed on vellum, parchment, or paper, not duly stamped as aforesaid, or with a lower stamp than by this act directed, the full duty shall be charged upon the person who shall draw or make,

PROMISSORY NOTES.

make, and utter and negotiate the same. 31 Geo. III. c. 25. f. 6.

By 48 Geo. III. c. 149. the former duties upon promissory notes and bills of exchange are repealed, excepting arrears: And new duties are by that act imposed, and divers new regulations relating to those instruments enacted. And these new duties are by f. 3. of this act, placed under the care of the commissioners for the stamp duties.

By f. 12. if any person shall, after the expiration of one calendar month from this act, make and issue, or cause to be made and issued, any bill, draft, or order for the payment of money, to the bearer on demand, upon any banker or bankers, or any acting as such, which shall be dated on any day subsequent to the day on which it shall be issued, or which shall not truly specify the place where it shall be issued, or which shall not fall within the exemption contained in the schedule (A) annexed to 44 Geo. III. c. 98. or that annexed to this act, unless the same shall be duly stamped as a bill of exchange, according to the law in force when the same shall be issued, such person shall forfeit 100*l.*; and if any person shall knowingly take any such bill, draft, or order, in payment of, or as a security for the sum therein mentioned, he shall forfeit 20*l.*; and if any banker or bankers, or any acting as such, take any such bill, &c. in payment of, or as a security for the sum therein mentioned, he shall for such a sum forfeit 20*l.*; and if any banker or bankers, or any acting as such, upon whom any such bill, &c. shall be drawn, shall pay or cause to be paid the sum of money therein expressed, or any part thereof, knowing the same to be post-dated, or knowing that the place where it was issued is not duly specified or set forth therein, or knowing that the same does not in any other respect fall within the said exemption, then such banker, &c. shall forfeit 100*l.* for every offence, and moreover shall not be allowed the money so paid, or any part thereof, in account.

And by f. 11. the making, signing, issuing, or causing to be made, signed, or issued, or accepting or paying, or causing or permitting to be accepted or paid, any bill of exchange, draft, or order, or promissory notes for the payment of money liable to any of the duties of this act, without the same being duly stamped, render those so making, &c. liable to a penalty of 50*l.*

And where any promissory or other note payable to the bearer on demand shall not exceed 5*l.* 5*s.* and be marked with a stamp duty of 3*d.* and also where such note shall exceed 5*l.* 5*s.* and not exceed 30*l.* and be marked with a stamp duty of 6*d.* or shall exceed 30*l.* and not exceed 200*l.* and be marked with a stamp to denote the respective duties hereby imposed, shall be paid by the person who made and signed, and first issued and negotiated the same, and at the place where the same was first issued; such person may, notwithstanding such payment, from time to time, so often as there shall be occasion after every such payment thereof, but not otherwise, again issue such note in like manner as the same was first issued; and every such note which at any time shall be paid by any person other than the person making or signing the same, or at any place other than the place of issuing the same, in pursuance of any direction, nomination, or appointment, for the payment thereof, contained or expressed in or upon such note, shall be taken to be thereupon wholly discharged, vacated, and satisfied, and shall be no longer negotiable, but shall be cancelled. And if any person shall again issue any such note, or if the person named or described therein for the payment thereof shall neglect or refuse to cancel the same after payment as aforesaid, he shall forfeit 20*l.* And if any such note shall not be cancelled, but shall be again issued or negotiated, there shall be paid the

like duty which shall appear to have been charged thereon before the first issuing, or by this act charged thereon as aforesaid; which duty shall be charged on the person who shall again issue or negotiate the same. 31 Geo. III. c. 25. f. 7.

But notes payable to the bearer on demand, not exceeding 5*l.* 5*s.* and 30*l.* stamped with the respective duties of 6*d.* and 1*s.* as before directed, may be again issued and negotiated by the person making or signing the same, notwithstanding such notes have been presented to and paid by him, or by any other person in pursuance of any such direction, nomination, or appointment as aforesaid, or otherwise howsoever; and so from time to time as often as occasion may require. f. 8.

And all such notes re-issued as aforesaid, shall be the property of the person holding the same, in like manner as upon the first issuing thereof. 31 Geo. III. c. 25. f. 9. 39 Geo. III. c. 107. f. 7.

By f. 15. it is provided that the bank of England shall be exempt from these duties, upon paying as a compensation the yearly sum of 42,000*l.*, provided that the said compensation shall be reduced to 4000*l.* when they cease to issue promissory notes for less than 2*l.*

By f. 15. after the 10th of October, 1808, it shall not be lawful to issue any promissory notes payable to the bearer on demand, hereby charged with a duty, and liable to be re-issued as aforesaid, without taking out a licence yearly for that purpose, to be granted by two or more commissioners of stamps for the time being, or by some person deputed in that behalf by them or the major part of them, on payment of the duty charged thereon in the schedule hereto annexed: and a separate licence shall be taken out for every town or place where any such promissory notes shall be issued, by, or by any agent or agents for any banker or other person; except that one licence yearly shall be sufficient for all the towns or places where any such banker or other person shall have established a branch of his bank, or have employed an agent for the issuing of such promissory note, previously to this act, so that every such town or place shall be notified to the stamp-office, and be specified in the first licence to be granted in pursuance of this act, and that an affidavit of the fact shall be transmitted to the stamp-office at the time of applying for such licence; and every such licence shall specify the proper name or names, and place or places of abode of the person or persons to whom the same shall be granted, and also the name of the town or place, towns or places where, and the name of the bank, firm, or title, under which such notes are to be issued; and where any such licence shall be granted to persons in partnership, the same shall specify and set forth the names and places of abode of all the persons concerned in the partnership, whether all their names shall appear on the promissory notes to be issued by them or not; and in default thereof, such licence to be absolutely void: and every such licence which shall be granted between the 10th of October, and the 11th of November, shall be dated on the 11th of October; and if granted at any other time, on the day on which granted; and every licence to continue in force from the day of the date till the 10th of October following, both inclusive.

By f. 18. those applying for such licences shall produce and leave with the proper officer, a specimen of the promissory notes proposed to be issued, and if any one by himself or his agent shall issue any such promissory note, allowed to be re-issued as aforesaid, without a licence, or at any other town or place, or under any other firm or title, than shall be specified in his licence, he shall forfeit for each offence 100*l.*

By f. 20. where any such licence shall be granted to any

PROMISSORY NOTES.

persons in partnership, the same shall continue in force for the issuing of promissory notes under the firm or title therein specified, till the 10th of October inclusive, notwithstanding any alteration in the partnership.

If any person shall write or sign, or accept or pay, or cause the same to be done, any such bill, note, draft, or order, liable to any of the duties aforesaid, without being first duly stamped as aforesaid, he shall forfeit 20*l.* s. 10. 39 Geo. 3. c. 107.

But by 37 Geo. III. c. 136. the holder of any bill of exchange, promissory or other note, draft or order, made after the 12th of July, 1797, and liable to any stamp duty, which shall be stamped with a stamp of a different denomination than is required by the aforesaid acts, if the same be of equal or superior value, may produce the same to the commissioners or officers of stamps within the times hereafter mentioned, who shall, upon payment of the duty imposed by the above acts, and the penalty hereafter mentioned over and above the said duty, stamp the same, and give a receipt for such penalty and duty on the back thereof, which shall be valid. s. 5.

And if the same be produced to the said commissioners before payable, according to the tenure and effect thereof, it shall be stamped on payment of the duty, and the penalty of 40*s.*; but if payable before the production thereof, then the same shall not be stamped, but on payment of the duty and the penalty of 10*l.* Id. s. 6.

Provided always, that no person shall have power by virtue of this act to make any bills of exchange, promissory or other notes, drafts, or orders for the payment of money, in any other manner than they might lawfully have done before the passing thereof. 31 Geo. III. c. 25. s. 11.

The aforesaid duties to be under the management of the commissioners of the stamp duties. s. 18. 39 Geo. III. c. 107. s. 23. 41 Geo. III. U.K. c. 10. s. 4.

And all vellum, parchment, or paper, by this act liable to any stamp duty, shall be stamped before the same be written or printed upon, and shall not be stamped afterwards under any pretence whatsoever. 31 Geo. III. c. 25. s. 19.

Persons counterfeiting or forging any stamp hereby directed to be made use of, shall be guilty of felony without benefit of clergy. s. 29.

And all powers given by any former act relating to the stamp duties, shall extend to these acts. 31 Geo. III. c. 25. s. 30. 39 Geo. III. c. 107. s. 24. 41 Geo. III. U.K. c. 10. s. 9.

By 48 Geo. III. c. 149. s. 21. after the passing of this act, no promissory notes for the payment of money, made out of Great Britain, or purporting to be made out of Great Britain; or purporting to be made by or on the behalf of any person or persons resident out of Great Britain, whether the same shall be made payable in Great Britain or not, shall be negotiable, or be negotiated, or circulated, or paid in Great Britain, unless the same shall have paid such duty, and be stamped as the law requires for promissory notes of the like tenor and value made in Great Britain; and if any person shall circulate or negotiate, or offer in payment, or shall receive or take in payment any such promissory note, or shall demand or receive payment of the whole, or any part of the money mentioned in such promissory note, from or on account of the drawer thereof in Great Britain, the same not being so duly stamped; or if any person or persons in Great Britain shall pay or cause to be paid the sum of money expressed in any such note, not being so duly stamped, or any part thereof, either as drawer, or in pursuance of any nomination or appointment for that purpose therein contained, the person or persons so offending shall

forfeit for each offence 20*l.* This not to extend to promissory notes made and payable only in Ireland.

And by 43 Geo. III. c. 139. if any person within any part of the united kingdom of Great Britain and Ireland falsely make, forge, or counterfeit, or cause or procure to be falsely made, forged, or counterfeited, or knowingly aid or assist in the false making, forging, or counterfeiting, any bill of exchange, or any promissory note, undertaking, or order for the payment of money, purporting to be the bill of exchange, promissory note, undertaking or order for the payment of money, of any foreign prince, state, or country whatsoever, or of any minister or officer employed in the service of any foreign prince, &c. or of any person or company of persons resident in any foreign state or country, or of any body corporate and politic, and body in the nature of a body corporate and politic, constituted by any foreign prince or state, with intent to deceive or defraud his majesty, his heirs and successors, or any such foreign prince, state or country, or any person or company of persons whomsoever, or any body corporate and politic, or body in the nature of a body corporate and politic whatsoever, whether the same be respectively resident, carrying on business, constituted or being in any part of the united kingdom, or in any foreign state or country; and whether such bill, note, or order be in English or in any foreign language, or partly in one and partly in the other; or if any person shall, within any part of the said united kingdom, tender in payment or exchange, or otherwise utter or publish as true, any such false, forged, or counterfeited bill, note, undertaking, or order, knowing the same to be false, forged, or counterfeited, with intent to deceive or defraud his majesty, &c. or any foreign prince, state, or country, or any person, or company of persons, or any body corporate and politic, or body in the nature of a body politic and corporate as aforesaid, then every such offender shall be deemed guilty of felony, and on conviction shall be transported not exceeding fourteen years. s. 1.

No person shall, within the united kingdom, engrave, cut, etch, scrape, or by any other means make or knowingly aid in the engraving, &c. or by any other means making in or upon any plate, any bill of exchange, or any promissory note or undertaking, or order for the payment of money, purporting to be the bill, note, undertaking, or order of any foreign prince, state, or country, or of any minister or officer employed in the service of any such prince, &c. or of any person or company of persons, resident in any foreign state or country, or of any body corporate and politic, or body in the nature of a body corporate and politic, or constituted by any foreign prince or state, or any part of any such bill, note, undertaking, or order, without an authority in writing for that purpose from such foreign prince, &c. or from some person duly authorized to give such authority, or shall within any part of the said united kingdom, without such authority as aforesaid, by means of any such plate, or by any other device or means, make or print any such foreign bill, note, undertaking, or order for the payment of money, or any part thereof, or knowingly, wilfully, and without lawful excuse, (the proof thereof shall lie upon the party accused), have in their custody any such plate or device, or any impression taken from the same; and if any person shall offend in any of the cases aforesaid, he shall be deemed guilty of a misdemeanor and breach of the peace, and being thereof convicted, shall be liable for the first offence to be imprisoned for not exceeding six months, or to be fined, or to be publicly or privately whipped, or to suffer one or more of the said punishments, and for the second offence to be transported to any of his majesty's colonies for
the

the term of fourteen years: provided that nothing herein shall extend in any manner whatsoever to repeal or alter any law now in force for the prevention or punishment of the crime of forgery in any respect whatsoever, within any part of the said united kingdom. f. 2.

Any action or suit brought against any person for any thing done in pursuance hereof shall be commenced within three calendar months after the fact committed, and not afterwards, and shall be brought in the country or place where the cause of action shall arise, and not elsewhere, and the defendant in such action or suit may plead the general issue, and give this act and the special matter in evidence; and if it shall appear to be done in pursuance hereof, or if any such action or suit shall be brought after the time limited, or in any other country or place, then the jury shall find for the defendant; and if upon the trial, a verdict shall pass for the defendant, or the plaintiff become nonsuit, or discontinue, or upon demurrer judgment be given against the plaintiff, the defendant shall recover treble costs, and have the like remedy for the same as any defendant hath for costs of suit in other cases by law. f. 9.

PROMONTORY, in *Geography*, a high point of land, or rock, projecting into the sea; the extremity of which to the sea-ward is usually called a *cape*, or *head-land*.

PROMOTERS, PROMOTORES, in *Law*, those persons who, in popular and penal actions, do prosecute offenders in their name and the king's; and are entitled to part of the fines and penalties for their pains.

These, among the Romans, were called *quadruplicatores*, or *delatores*; in English also, *informers*.

Sir Thomas Smith observes, that promoters belong chiefly to the exchequer and king's bench. My lord Coke calls them *turpidum hominum genus*. 3 Inst.

PROMOTER Fiscal. See **INQUISITION**.

PROMPT PAYMENT, ready money. See **PAYMENT**.

In many cases there is a discount for prompt payment.

PROMPTER, in the *Drama*, an officer posted behind the scenes, whose business is to watch attentively the actors speaking on the stage, in order to suggest and put them forward when at a stand, to correct them when amiss, &c. in their parts.

PROMULGATED, PROMULGED, Promulgatus, something published, or proclaimed.

In this sense we say the Jewish law was promulgated by Moses: the promulgation of the new law was chiefly effected by the apostles and disciples.

PROMULGATION of Laws. See **LAW**.

PROMUTHION, in *Rhetoric*. See **FABLE**.

PRONAOS, προναος, in the *Ancient Architecture*, a porch to a church, palace, or other spacious building.

PRONATION, in *Anatomy*, that motion of the upper extremity, in which the radius is carried across the ulna, and the palm of the hand turned to the ground. See **PRONATOR** and **EXTREMITIES**.

PRONATOR, a name given to two muscles of the fore-arm.

The *pronator radii teres* (épitrochlo-radien) is situated obliquely on the anterior and upper part of the fore-arm, and extends from the internal condyle of the humerus to the middle of the outer surface of the radius. It is elongated and flattened, and larger at the humeral than at the radial end. Its anterior surface is covered, in the two-thirds next to the humerus, by the fascia of the fore-arm; in the rest of its extent by the supinator longus, the radial extensors, and the radial artery and nerve. The posterior surface covers the brachialis internus and the flexor sublimis, the median

nerve, and the ulnar artery. The outer edge of the pronator teres lies, in that half which is next to the humerus; in the brachialis internus, and is separated from the supinator longus by an interval, in which the tendon of the biceps, the humeral artery, and the median nerve are placed. The other half of this edge is concealed by the supinator longus, and the radial extensors: it is parallel to the front edge of the supinator brevis, which it covers a little. The inner edge is connected, in the upper two-thirds, to the outer margin of the flexor radialis; in the other third it is unattached. The humeral extremity is fixed to the front of the internal condyle, and strongly connected to the flexor radialis. It has also a small attachment to the coronoid process of the ulna, by a few fibres separated from the rest of the muscle by the median nerve. It passes obliquely across the fore-arm, from the ulnar to the radial side, growing smaller in its course, and is fixed to the middle of the radius by a broad and thin tendon, which turns round the front of the bone, to reach the outer edge. This tendon runs for a short time on the front of the muscle, then enters into its substance, and is continued as far as the middle. The fleshy fibres come from the condyle of the humerus, from the septa which separate the muscle from the flexor radialis and the sublimis, and from the fascia of the fore-arm. From all these points they pass to the tendon just mentioned, and inclose it.

By drawing the radius across the front of the ulna, this muscle turns the palm of the hand to the ground. If the radius is held firm by the supinators, the pronator teres will bend the elbow-joint.

The *pronator quadratus* (cubito-radien) is a square muscle, situated deeply in the anterior part of the carpal end of the fore-arm, and extending straight from the ulna to the radius. Its anterior surface is covered by the flexor profundus, the flexor longus posticus, the flexor radialis, the ulna and radial arteries. The posterior surface is fixed to the lower fourth part of the anterior surface of the radius, and to the same length of the ulna: in the interval of the bones, it lies on the interosseous ligament. Of the four edges of this muscle, the superior and inferior present nothing remarkable. The external is fixed to the lower fourth part of the edge of the radius, and the internal to the same length of the corresponding edge of the ulna.

A broad aponeurosis, arising from the edge of the ulna, covers the inner portion of the anterior surface. Fleshy fibres arise from this aponeurosis, and from the surface of the ulna, and terminate on the anterior surface of the radius: they are slightly oblique from within outwards, and from above downwards.

Its effect must be simply that of drawing the end of the radius across that of the ulna, and consequently turning the palm of the hand towards the ground.

PRONG, the blade or fork part of an implement of the fork kind, that lays hold of the soil or substance to which it is applied. The term is sometimes likewise applied to the tool itself.

PRONG-Hoe, a term used to express an implement to hoe or break the ground, near, and among the roots of plants, with. It consists of two hooked points, of six or seven inches long, which, when struck into the ground, stir and remove it the same depth as the plough; and thus answer both the ends of cutting up the weeds, and opening the land close to the rows of grain.

The ancient Romans had an instrument of this kind, which they called the *bidens*; but they were afraid of its use in their fields and gardens, and only used it in their vineyards.

PRONKCHNA, in *Geography*, a town of Russia, in the government of Upha; 36 miles E. of Buzulutsk.

PRONOMÆA, a word used by some naturalists to express what is usually called the trunk, or proboscis in insects; an instrument somewhat resembling the trunk of an elephant, which most of those small animals are provided with, for the extracting the juices of plants, &c. destined for their food.

PRONOMUS of Thebes, in *Biography*, the inventor, according to Pausanias, of a flute, upon which three different modes could be played.

PRONOUN, PRONOMEN, in *Grammar*, a part of speech used instead of a noun, or name, as its substitute or representative. Whence the denomination; from *pro*, and *nomen*; q. d. *for noun*, or *name*. Accordingly, pronouns are subject to the same modifications with substantive nouns, of number, gender, and case.

As it would have been disagreeable to have been always repeating the same name, there are words invented in all languages, called pronouns, to save the necessity thereof, and to stand in the place of names: as *I*, *thou*, *he*, &c.

As nouns are the marks or signs of things, pronouns are the signs of nouns. Father Buffier, however, shews, that pronouns are real nouns or names; and that all the difference between what the grammarians call nouns and pronouns, is, that the former are more particular, and the latter more general.

They are called pronouns, because used in the place of particular nouns; indeed, sometimes they do not fill the place of nouns entirely, but need other words to assist them, to express the object spoken of: such, *e. gr.* *arc*, *who*, *whoever*, &c. which do not express any determinate object of which a thing may be affirmed, unless accompanied with another word, especially a verb: as, *whoever labours, deserves a reward*.

These father Buffier calls *incomplete* pronouns, to distinguish them from those which express an object *completely*: as, *I*, *thou*, *he*, &c.

Pronouns have three cases; the nominative, the genitive, or possessive, like nouns; and moreover a case, which follows the verb active, or the preposition, expressing the object of an action, or of a relation, which, says bishop Lowth, may be properly enough called the objective case.

Pronouns are distinguished into three several sorts, *viz.* pronouns of the first, the second, and the third person, according as the subject of the conversation is the speaker himself, the party addressed, or some third object different from both. As this third person may be absent, or unknown, the distinction of gender here becomes unnecessary; and accordingly, in English, it has belonging to it the three genders, *he*, *she*, *it*.

The grammarians ordinarily distinguish pronouns into four classes, with regard to their different signification, formation, &c. *viz.* pronouns *personal*, *relative*, *possessive*, and *demonstrative*; to which may be added *indeterminate* pronouns.

PRONOUNS, *Personal*, are those used in lieu of names of particular persons; such are, *I*, *thou*, *he*, *we*, *ye*, *they*.

Our personal pronouns have a case, which answers to the accusative of the Latin; *I*, *me*, *he*, *him*, *who*, *they*.

PRONOUNS, *Relative*, which Buffier calls *modificative*, or *determinative*, are those placed after nouns, or other pronouns, with which they have such affinity, that without them they signify nothing: such are *qui*, *who*, *that*, &c. Frequently the noun or pronoun with which the relative is joined, is understood.

For the proper disposition of the relative pronouns, in the structure of sentences, see SENTENCE.

PRONOUNS, *Possessive*, are those which denote the enjoyment or possession of any thing, either in particular or in common: as, *mine*, *thine*, *his*, &c.

These are pure adjectives, and only differ from the rest by the relation they bear to pronouns, whence they are derived, and by some particular inflections which they have in some languages.

PRONOUNS, *Demonstrative*, those which serve to indicate or point out the subject spoken of: as, *this*, *those*, &c.

PRONOUNS, *Indefinite*, are those which express their subject indeterminately: as, *whoever*, *any*, &c. These coincide with what father Buffier calls *incomplete* pronouns.

Pronouns are likewise divided into *substantive* and *adjective*. To the first belong, *I*, *thou*, *he*; to the second, *my*, *mine*, *who*, *what*, &c.

Pronouns may also be considered in two states: the first, or foregoing state, as *I*, *we*; the second, or following one, as *me*, *us*.

Mr. Harris distinguishes pronouns, which, he says, are words invented to supply pointing or indication by the finger or hand, called *δείξαι*, into *prepositive* and *subjunctive*.

Prepositive pronouns are those which are capable of introducing or leading a sentence, without having reference to any thing previous, and are divided into three orders, called the first, the second, and the third person.

Subjunctive pronouns are those which serve to subjoin one sentence to some other which is previous, as *who*, *which*, *that*, &c. and may be distinguished from other pronouns, as they are not only substitutes, but also connectives. They include the powers of the three orders into which the prepositive are distinguished, having superadded the peculiar force of connective. Hermes, chap. 5.

PRONOUNCING, PRONUNCIATION, in *Painting*, the marking and expressing the parts of all kinds of bodies with that degree of force necessary to make them more or less distinct and conspicuous.

Thus the painters, in speaking of a piece, say, these or these parts are well pronounced; which is a metaphorical way of speaking: as when we say, that a man who talks well has a fine pronunciation.

PRONSDORP, in *Geography*, a town of the duchy of Holstein; 8 miles E. of Segeborg.

PRONSK, a town of Russia, in the government of Riazan; 28 miles S. of Riazan. N. lat. 54° 14'. E. long. 30° 50'.

PRONTIA LAPIS, a name given by the writers of the middle ages to a fossil, of which they relate several extraordinary things; but their resembling it to the head of a tortoise, and giving it the virtue of preserving people from injuries by lightning, seem to make it plain that the word is only a corrupt spelling of the *brontia* of the ancients, of which Pliny has related the same things.

This was a species of echinites, supposed to fall from the clouds in thunder-storms. See BRONTLE.

PRONUNCIATION, PRONUNCIATIO, in *Grammar*, the manner of articulating, or sounding, the words of a language, represented to the eye by writing, and orthography.

From the definition it would seem, that the pronunciation were only the image of the orthography: but as we pronounce before we write, and only write to express what we pronounce, it is more just to lay down the pronunciation as the rule and model of orthography.

Pronunciation makes much the most difficult article of a written grammar: in effect, a book only expressing itself to the eyes in a matter that wholly concerns the ears, the

PRONUNCIATION.

case seems next akin to that of teaching the blind to distinguish colours.

Hence it is, that there is no part so defective in the grammars as that of the pronunciation: for the writer has frequently no term by which to give the reader an idea of the sound he would express: for want of a proper term, therefore, he frequently substitutes a vicious or precarious one. Thus the French grammarians frequently tell us that the vowels *a, e, i, &c.* are pronounced, in French, the same as in Latin; never considering, that there is not any known and determinate pronunciation of the Latin; but each nation, now, pronounces the Roman characters in the Latin, the same as it pronounces those same characters in its own language. Thus the Latin *cacus* is pronounced by the English, *sekus*, and by the Italians, *tebekous, &c.*

Hence it appears, that the relation between sounds and characters, as well as between things and words, is purely arbitrary and national.

Indeed, Plato seems of a contrary opinion, and will have a natural relation between words and the things they express, as there is a natural relation between the signs made by mutes, and the things they would imitate: so that, according to Plato, to every separate word there must be a separate motion of the mouth relative to the action expressed by the word.

Whether or no there might be such a thing in the primitive language, we dare not undertake to say; but it is certain, such a relation would require a facility of contortions in the mouth, to which we are strangers.

To give a just and precise idea of the pronunciation of a language, it seems necessary to fix, as nearly as possible, all the several sounds employed in the pronunciation of that language: this Mr. Lodwick has done, in his attempt towards an universal alphabet, where he enumerates forty-three several simple sounds (some of them, indeed, strangers to the English language); and F. Buffier, who gives thirty-three several sounds in the French tongue, twenty-nine in the Italian, thirty in the German, twenty-two in the Spanish, and twenty-four in the English.

The French language is clogged with a difficulty in pronunciation, from which most others are free; and it consists in this, that most of their words have two different pronunciations; the one in common prose, the other in verse. In prose, *e. gr.* they omit the pronunciation of the final *s* in the plural of nouns, and of the *t* in the third person of the plural of verbs, and of several other final consonants; but in verse they pronounce all.

Thus, in *à qui bon reveiller mes muses endormies?* the final *s* of *musés* is pronounced; and in *mille et mille douceurs y semblent attaches,* the *t* of *semblent* is to be pronounced.

Add to this, that in prose they soften the sound of a great many words; pronouncing *croaire* for *croire*: but in poetry the genuine pronunciation is retained.

PRONUNCIATION is also used for the fourth and last part of rhetoric, called *delivery*, which consists in regulating and varying the voice and gesture agreeable to the matter and words; so as more effectually to persuade and touch the hearers.

The pronunciation is of such importance, that Demosthenes called it the first, the second, and the third part of eloquence. By which he seemed to intimate, that he thought the whole art of oratory did in a manner consist in it. And indeed, if he had not judged this highly necessary for an orator, he would scarcely have taken so much pains himself in correcting those natural defects under which he laboured at first, in order to acquire it. For he had both a weak voice, and likewise an impediment in his speech, so

that he could not pronounce distinctly some particular letters. The former of which defects he conquered, partly by speaking as loud as he could upon the shore, when the sea roared and was boisterous; and partly by pronouncing long periods, as he walked up hill; both which methods contributed to strengthen his voice. And he found means to render his pronunciation more clear and articulate, by the help of some little stones put under his tongue. Nor was he less careful in endeavouring to gain the habit of a becoming and decent gesture, for which purpose he used to pronounce his discourses alone before a large glass. And because he had got an ill custom of drawing up his shoulders when he spoke; to amend that, he used to place them under a sword, which hung over him with the point downward.

Quintilian defines the pronunciation, *vocis, et vultus, et corporis moderatio cum venustate*; a decent agreeable manner of managing the voice, gesture, and action of the whole body.

Cicero somewhere calls it *quidam corporis eloquentia*, a certain eloquence of the body; and in another place, *sermo corporis*, the language or speech of the body.

When we address others by words, it is certainly an intention to make some impression on those to whom we speak; and it is certain, that the tone of our voice, our looks, and gestures, interpret our ideas and emotions no less than words do; nay, the impression they make on others is frequently much stronger than any which words can make. The signification of our sentiments, made by tones and gestures, has this advantage above that made by words, that it is the language of nature. The connection is so close between certain sentiments, and the proper manner of pronouncing them, that he who does not pronounce them after that manner, can never persuade us that he believes, or feels, the sentiments themselves. His delivery may be such as to give the lie to all he asserts. When Marcus Callidius accused one of an attempt to poison him, but enforced his accusation in a languid manner, and without any warmth, or earnestness of delivery, Cicero, who pleaded for the accused person, improved this into an argument of the falsity of the charge, "An tu, M. Callidi, nisi fingeres, sic ageres?" In Shakespeare's Richard II. the duchess of York thus impeaches the sincerity of her husband:

"Pleads he in earnest?—Look upon his face,
His eyes do drop no tears; his prayers are jest;
His words come from his mouth; ours, from our breast;
He prays but faintly, and would be denied;
We pray with heart and soul."

Pronunciation is the same with what we otherwise call *action*; which see. Though if we attend to the proper signification of each of these words, the former respects the voice, and the latter the gestures and motions of the body. Some writers, particularly Mr. Henly, confound it with *elocution*, which is a very different thing. That author, when he styles himself *restorer of the ancient elocution*, means of the ancient pronunciation.

There are three things which come under the pronunciation; the *memory, voice, and gesture*. See each under its proper article.

Augustus, to avoid being baulked by his memory, and at the same time save the trouble of getting off by heart, used to harangue from a writing; as we are told by Dio and Suetonius.

In public speaking a proper attention to pronunciation or delivery is, as we have already stated, of the greatest importance; and the importance of it will farther appear, if we consider the principal objects which every public speaker has

has in view. These are, first of all, to speak so as to be fully and easily understood by all who hear him; and, secondly, to speak with grace and force, so as to please and move his audience. For the attainment of the first object, the four chief requisites are, a due degree of loudness of voice, distinctness, slowness, and propriety of pronunciation. A public speaker, who wishes to be heard by all whom he addresses, should endeavour to fill with his voice the space occupied by the assembly. For this purpose, independently of the power of voice derived from nature, much depends on the proper pitch and management of the voice. Every man, says Dr. Blair, has three pitches in his voice; the high, the middle, and the low one. The first is that which he uses in calling aloud to some person at a distance; the low is when he approaches to a whisper; and the middle is that which he employs in common conversation, and which he should generally use in public discourse. It is a great mistake to imagine, that one must take the highest pitch of his voice, in order to be well heard by a large assembly. This is confounding two things which are different; loudness, or strength of sound, with the key, or note on which we speak. A speaker may render his voice louder without altering the key; and we shall always be able to give most body, most persevering force of sound, to that pitch of voice, to which we are accustomed in conversation; whereas by setting out on our highest pitch or key, we certainly allow ourselves less compass, and are likely to strain ourselves before we have done. We shall fatigue ourselves, and speak with pain; and whenever a man speaks with pain to himself, he is always heard with pain by his audience. Give the voice, therefore, full strength and swell of sound; but always pitch it on your ordinary speaking-key. Make it a constant rule never to emit a greater quantity of voice than you can afford without pain to yourselves, and without any extraordinary effort. As long as you keep within these bounds, the other organs of speech will be at liberty to discharge their several offices with ease; and you will always have your voice under command. But whenever you transgress these bounds, you give up the reins, and have no longer any management of it. It is an useful rule too, in order to be well heard, to fix the eye on some of the most distant persons in the assembly, and to consider ourselves as speaking to them. But it should be remembered, that in public, as well as in conversation, we may give disgust and offence by speaking too loud; because the speaker has thus the appearance of one who endeavours to compel assent, by mere vehemence and force of sound.

Moreover, in order to be well heard and clearly understood, distinctness of articulation contributes more, perhaps, than mere loudness of sound. With this view, every public speaker should give every sound which he utters its due proportion, and make every syllable, and even every letter in the word which he pronounces, be heard distinctly, without straining, whispering, or suppressing any of the proper sounds.

Farther, in order to articulate distinctly, moderation is requisite with regard to the speed of pronouncing. Precipitancy of speech confounds all articulation, and all meaning: and yet the contrary extreme should be avoided; as a lifeless, drawling pronunciation, which allows the minds of the hearers to be always outrunning the speaker, must render every discourse insipid and fatiguing. Rapidity of utterance in early life, however, is pardonable, as it is likely to find its own remedy in advanced age, and to prevent that tedious, tiresome drawl, which is often the attendant of prolonged life. After all, to pronounce with a proper degree of slowness, and with full and clear articulation, is

the first thing to be studied by all who begin to speak in public, and cannot be too earnestly recommended. Such a pronunciation gives weight and dignity to a discourse. It greatly aids the voice by affording pauses and rests, and it enables the speaker to swell all his sounds both with more force, and with more music. It also assists in maintaining a due self-command; whereas a rapid and hurried manner is apt to excite that flutter of spirits, which is very injurious to right execution in the province of oratory. "Promptum fit os," says Quintilian, "non præceps, moderatum, non lentum."

After the attention now recommended to the pitch and management of the voice, to distinct articulation, and to a proper degree of slowness of speech, the public speaker should diligently study propriety of pronunciation, or the giving to every word which he utters, that sound, which the most polite usage of the language appropriates to it, in opposition to broad, vulgar, or provincial pronunciation. This is requisite, both for speaking intelligibly, and for speaking with grace or beauty. In this connection it is not improper to recommend a particular attention to the accent. To what has been already offered under the term ACCENT, we shall here add the following remarks of Dr. Blair. In the English language, he says, every word which consists of more syllables than one has one accented syllable. The accent rests sometimes on the vowel, sometimes on the consonant. Seldom, or never, is there more than one accented syllable in any English word, however long; and the genius of the language requires the voice to mark that syllable by a stronger percussion, and to pass more slightly over the rest. Having first learned the proper seats of these accents, it is an important rule to give every word just the same accent in public speaking, as in common discourse. In this respect many persons err; for, when they speak in public, and with solemnity, they pronounce the syllables in a different manner from what they do at other times. They dwell upon them, and protract them: they multiply accents upon the same word; from a mistaken notion, that it gives gravity and force to their discourse, and that it adds to the pomp of public declamation. Whereas, this is one of the greatest faults that can be committed in pronunciation, it makes what is called a theatrical, or mouthing manner, and gives an artificial affected air to speech, which detracts greatly both from its agreeableness and impression. See Blair's Lect. vol. ii. Sheridan's Lectures on Elocution. See also the articles already referred to, *viz.* ACTION, ARTICULATION, GESTURE, VOICE, and also ELOCUTION, ELOQUENCE, ORATORY, and *Public Speaking*.

The public speaker, as we have above said, has another object besides that of rendering himself intelligible, and that is giving grace and force to what he utters. For this purpose it behoves him to pay particular attention to *emphasis, pauses, tones, and gestures*. See each of these articles.

PRONUNCIATION, in *Painting*. See PRONOUNCING.

PROOF, PROBATIO, in *Arithmetic*, an operation by which the truth and justness of a calculation is examined and ascertained.

The proper proof is always by the contrary rule: thus subtraction is the proof of addition, and multiplication of division: and *vice versâ*. The proof of multiplication by 9 or by 7 is precarious.

There would need no proofs in arithmetic were it not that a man is liable to make mistakes; for all the rules and operations being built on demonstration, it is thence we are assured of their truth and certitude.

The proof, then, does not confirm the rule, but only shews us whether or no we have applied it right.

PROOF, in *Law, Logic, &c.* denotes the mediums or arguments, used to evince the truth of any thing. See **EVIDENCE**.

Proofs, in the ecclesiastical courts, are obtained by witnesses examined, whose depositions are taken down in writing by an officer of the court. These are adduced after the defendant's answer upon oath, if he denies or extenuates the charge. If afterwards the defendant has any circumstances to offer in his defence, he must also propound them in what is called his "defensive allegation," to which he is intitled in his turn to the "plaintiff's answer" upon oath, and may from thence proceed to proofs as well as his antagonist.

By the French law, a *literal proof*, or *proof in writing*, called also *dead proof*, *probatio mortua*, is preferable to a testimonial, or proof *viva voce*, by witnesses. The ordinance de Moulins excludes all proof by witnesses for loans of above 1000 livres.

The proof of crimes was anciently effected among our ancestors divers ways; *viz.* by duel or combat, fire, water, &c.

The proof by red-hot iron was very frequent; the accused, to purge himself, was here obliged to make an oath, as he touched the iron. The formula, ceremonies, prayers, &c. made on this occasion, are still extant in the notes at the end of the Capitularies of Charlemagne. See **ORDEAL**.

This custom was abrogated by the emperor Frederick; but it still obtains in Mingrelia; as we are told by Lamberti, in his relation inserted in Thevenot's voyages.

If they cannot have proof of a crime, a cross is laid at the bottom of a cauldron full of boiling water, out of which the accused is obliged to fetch it with his naked hand and arm: this done, the arm is put up in a bag tied, and sealed, and three days after opened; when, if there be no marks of the burn or scald, the accused is declared innocent.

In the kingdom of Siam, to have proof of a crime, the party is obliged to wash his hands in boiling oil, or to walk on burning coals; from either of which he must come out untouched to be reputed innocent.

Sometimes they oblige the two contending parties to plunge under water; and he who stays there longest, gains the cause; and sometimes to swallow a grain of rice, prepared and charmed by their doctors: he who is able to swallow it, is declared innocent, and carried home in triumph; and the accuser punished. This looks like an imitation of what was done among the Jews to have proof of adultery.

The proof by *combat* is likewise said to subsist among the Mingrelians. See **COMBAT**.

PROOF, in *Artillery*. See **PROVING GUNS**, **GUNPOWDER**, and **POWDER-Triers**.

PROOF, in the *Sugar Trade*, a term used by the refiners in sugar for the proper state of the dissolved sugar when it should be set to harden.

The process in the bringing of sugar to this state may be understood by performing the whole work in little in this manner: take six pounds of coarse, or unrefined sugar, dissolve it over the fire in six pints of lime-water; add to this the whites of four eggs beat up to a froth, stir the whole together; then boil the liquor to a higher consistence than a syrup, or till, when exposed to the cold, it will concrete into grains. This is what the sugar-bakers call *proof*. Pour this syrup into an earthen mould, with a hole at its bottom; stop the hole, and set the vessel in a moderately warm place.

The sugar in a few days will set and harden; then open

the hole at the bottom, and lay over the top of the sugar some tobacco-pipe clay, made into a soft pap with water. The clay must be afterwards wetted at times, and the water from among it will gradually be soaked up by the sugar, and running through it will wash away the treacle without dissolving the grained part. And thus all the treacle will by degrees be drained out of the mass, and a loaf of white sugar procured. See **SUGAR**.

PROOF *Spirits*, among *Distillers*. See **SPIRITS**.

PROOF, *Bead*. See **BEAD**.

PROP, in *Rural Economy*, a term used to signify a shore or support, set up for the purpose of sustaining any thing in its proper situation, as a wall, building, tree, or plant. They should always be sufficiently strong for the purpose intended, whatever it may be, and be so placed, that they may stand securely and without giving way. When used for trees that have been transplanted, they should likewise be so secured at the top part, as to prevent their rubbing and injuring them. It has been remarked by Dr. Darwin, that as the bark is the only living part of the tree, it is liable to receive much injury from its contusion, by the pressure of the props against it, or by the strangulation of the bandage which holds it to them. He hence concludes, that as the internal wood of a tree is not alive, he many years ago fastened one prop, by a strong nail, to each fruit tree of a small orchard which he then planted, and found the tree supported with much less apparent injury than in the usual manner by three props and adopted cordage. But as most fruit-trees are extremely apt to be affected with canker, by being injured in this way by nails or other means, it should probably be adopted with caution for them, especially as where proper care is taken in fixing the supports, the business may be effected without any danger of the trees being hurt in the usual mode.

PROPAGATION, **PROPAGATIO**, the act of multiplying the kind, or of producing the like in the way of natural generation. See **GENERATION**.

Propagation is also applied to the raising of trees or plants from buds, &c. as well as to animals.

PROPECHIO, in *Geography*, a town of Istria; six miles E. of Capo d'Istria.

PROPEMPTICON, Προπεμπτικον, in *Poetry*, a poem in which are expressed ardent wishes and solemn vows for the safety of a person going upon a journey or voyage. Such is that of Horace, lib. i. od. 3, addressed to Virgil on his setting out for Athens. It was otherwise called *apopempticon*. See **APOPEMPTIC**.

The word is derived from προπεμπω, *I send forward*, or *accompany on the way*.

PROPER, **PROPRIUM**, something naturally and essentially belonging to any being.

The school philosophers, after Porphyry, distinguish four kinds of propers, or modes of propriety, which are expressed in the following verse.

"Est medicus, bipes, canescens, risibilisque."

The first, called *proprium primo modo*, what agrees to a single species, but not to all the individuals; this they call *foli, sed non omni*. As, to be a geometrician, a physician, a divine, &c. which are things proper to man; but not to all men.

The second, *proprium secundo modo*, is what agrees to the whole species, but agrees likewise to another; which they call *omni, sed non foli*. Thus, to have two feet is proper to a man, but is likewise proper to a bird.

The third, *proprium tertio modo*, is that which agrees to a single species, but not at all times; *omni & foli, sed non semper*.

per. As to grow grey, according to Porphyry, is proper to a man, but it is to an old man.

The last and highest, *proprium quarto modo*, is that which alone agrees to one kind, to all the individuals of it, and at all times; *omni, soli, & semper*. Thus, the faculty of laughing is proper to man, of neighing to horses, &c. And it is this that Porphyry calls the *true* proper.

The first three species are only accidents of the fifth vulgar predicable, to which they directly belong.

The fourth is an universal agreeing to every individual, or subject of predication of any species in such manner as to be always found absolutely in the species alone, but not at every determinate time; thus man alone is naturally risible; not that he is always laughing, but that he has the faculty of laughing at all times.

PROPER, in respect of *words*, denotes their immediate and peculiar signification, or that directly and peculiarly attached to them.

In which sense the word stands opposed to *figurative*, and *metaphorical*.

PROPER is also used, in a *Moral Sense*, to denote something that is usually found in things; as their particular, or specific virtues, &c.

In which sense we say, magnanimity is the proper virtue of heroes.

PROPER is also used for the natural qualities necessary to succeed in a thing.

In which sense we say, people of a hot vigorous temperament are proper for the army; the cold and phlegmatic are proper for study. The Romans became less proper for war, in proportion as they grew more learned and polite.

PROPER, in *Grammar*, is also applied to nouns or names, which are distinguished into *proper* and *appellative*.

Man is the appellative, Peter the proper name.

The proper name among Christians, is that imposed at baptism. See BAPTISM, and NAME.

PROPER *Feud*. See FEUD.

PROPER *Fraction*. See FRACTION.

PROPER, in the *Civil Jurisprudence*, is used in opposition to *acquired*, for an inheritance derived by direct or collateral succession.

By the old French laws, a testator can only dispose of one-fifth of his proper effects; the paternal relations inherit the paternal *propria*, and the maternal the maternal ones: so that *propria* always turn to the line whence they proceed.

The origin of the law which fixes the difference between proper goods and acquisitions, is not known; neither the Greeks nor Romans having ever made any such distinction. Indeed it seems founded on this principle of natural equity, that men are usually desirous to preserve and attach to their family the goods which they have received from their forefathers, and transmit them to those descending from the same stock.

PROPER sometimes also stands as a reduplicative, serving to mark or design a thing more expressly and formally. In this sense we say, Jesus Christ came to redeem the world in his proper person. The king did such and such a thing of his own proper motion.

PROPER *Motion*. See MOTION.

PROPER *Objects*. See OBJECT.

PROPERNAW, in *Geography*, a town of Prussia, on the Frisch Nerung; 15 miles N.E. of Elbing.

PROPERTIUS, SEXTUS AURELIUS, in *Biography*, a Roman poet, was a native of Umbria, and flourished in the reign of Augustus, by whom, and by Mæcenas, he was favoured, and who, in his turn, makes their praises a fre-

quent theme of his verse. Little is known of the history of this poet; Ovid places him between Tibullus and himself. His father was of the equestrian order, and lost his life in Perugia, among other partisans of Antony. The confiscation of his property followed, and young Propertius came to Rome, where he obtained the patronage of the great. It is not exactly known when he died, but it has been conjectured to have happened about the year 10 B. C. He has always been ranked among the most eminent of the Latin elegiacs: four books of his elegies are remaining. He is often compared with Tibullus, but is not so natural or pathetic, and is more learned, various, and ornamented, abounding in allusions to fable and mythology. He is elegant and ingenious, but frequently obscure. His amatory pieces are addressed to a single object of passion, whom he calls Cynthia, which is the poetical name of a Roman lady named Hostia or Hostilia, and with whom his connection, if real, appears to have been of the licentious kind. The editions of the Elegies of Propertius, both separately and in conjunction with those of Tibullus, are very numerous: among the best are those of Broukhufins, 1702; Vulpius, 1755; Burmann, 1780.

PROPERTY, or PROPRIETY, *Proprietas*, that which constitutes or denominates a thing proper; or it is a particular virtue or quality, which nature has bestowed on something, exclusive of all others.

Thus colour is a property of light; extension, figure, divisibility, and impenetrability, are properties of body.

PROPERTY, or *Propriety*, in *Law*, denotes dominion, or the highest right a man can have to a thing; and such as no way depends on any other man's courtesy.

In this sense, none in our kingdom have the property of any lands or tenements, except the king, in right of his crown; all other lands being of the nature of fee, and held of the king either mediately or immediately. See FEE.

Property, or propriety, however, is used for that right in lands, tenements, &c. which common persons have; importing as much as *utile dominium*, though not *directum*; and consisting in the free use, enjoyment, and disposal of all their acquisitions, without any controul or diminution, save only by the laws of the land.

The original of private property is probably founded in nature: the earth and all things in it became the general property of all mankind, exclusive of other beings, from the immediate gift of the Creator (Gen. i. 28.); and while the earth was thinly inhabited, it is reasonable to suppose, that all was in common among them, and that every one took from the public stock, to his own use, such things as his immediate necessity required. However, this communion of goods seems to have been applicable, even in the earliest ages, only to the substance of the thing, and not extended to the use of it; for, by the law of nature and reason, he who first began to use it, acquired in it a kind of transient property, that lasted so long as he was using it, and no longer: or, the right of possession continued for the same time only that the act of possession lasted.

The first objects of property were the fruits which a man gathered, and the wild animals he caught; next to these the tents or houses which he built, the tools he made use of to catch and prepare his food; and afterwards weapons of war and offence. Many of the savage tribes of America have not even now proceeded any farther; for they are said to reap their harvest, and return the produce of their market with foreigners into the common hoard or treasury of the tribe. Stocks and herds of tame animals soon became property: Abel, the second son of Adam, was a keeper of sheep; sheep, oxen, camels, and asses, composed the wealth

PROPERTY.

of the Jewish patriarchs, as they do still of the modern Arabs. And as the world was first peopled in the East, where water was scarce, wells were, at an early period, made property. See Gen. xxi. 25. xxvi. 18.

In process of time it became necessary to form notions of more permanent dominion; and to appropriate to individuals not the immediate use only, but the very substance of the thing to be used. The labour of cultivation and art of agriculture by degrees introduced and established the idea of a more permanent property in the soil than had been before received and adopted. And as occupancy gave the right to the temporary use of the soil, so occupancy gave likewise the original right to the permanent property in the substance of the earth itself; which excludes every one else but the owners from the use of it. On this head Grotius and Puffendorff insist, that this right of occupancy is founded upon a tacit and implied assent of all mankind, that the first occupant should become the owner: and Barbeyrac, Titius, Mr. Locke, and others maintain, that there is no such implied assent, neither is it necessary that it should be: for that the very act of occupancy alone, being a degree of bodily labour, is, from a principle of natural justice, without any consent or compact, sufficient of itself to gain a title. However, it is agreed on both sides, that occupancy is the thing by which the title was in fact originally gained; every man seizing, to his own continued use, such spots of ground as he found most agreeable to his own convenience, provided he found them unoccupied by any else.

Property, both in lands and moveables thus acquired by the first taker, remained in him, by the principles of universal law, till such time as he does some other act which shews an intention to abandon it; for then it becomes, naturally speaking, *publici juris* once more, and is liable to be again appropriated by the next occupant. But this method of one man's abandoning his property, and another's seizing the vacant possession, could not long subsist in fact. Mutual convenience introduced commercial traffic, and the reciprocal transfer of property by sale, grant, or conveyance. The most universal and effectual way of abandoning property is by the death of the occupant; in which case all property must cease, considering men as absolute individuals, and unconnected with civil society. But such a constitution would be productive of endless disturbances; the universal law of almost every nation (which is a kind of secondary law of nature) has either given the dying person a power of continuing his property by disposing of his possessions by will, or the municipal law declares who shall be the heir of the deceased, or the doctrine of escheats is adopted. Thus we see, that though the origin of property is founded in nature, the modifications under which it now exists, the method of preserving it to the present owner, and of translating it from man to man, are entirely derived from society; and are some of those civil advantages, in exchange for which every individual has resigned a part of his natural liberty.

Long after the institution of many other species of property, when a country became populous, and tillage began to be practised, land became vested in a permanent occupant. The first partition of an estate which we read of was that which took place between Abraham and Lot, and that was one of the simplest possible. In Cæsar's account of Britain, there are no traces of property in land; little of it in the history of the Jewish patriarchs; none of it found among the nations of North America; and the Scythians are said to have appropriated their cattle and horses, but to have left their land in common. Hence we may infer, that the more permanent property in land was posterior in all probability to civil government and laws, and therefore

settled by these, or according to the will of the reigning chief. When, and by what gradations, land, which alone by our laws is called "real" property, and which, in the earliest period of time, was unquestionably common, was taken out of the common, and appropriated with an exclusive right to the owner, has been a subject of dispute.

Some, as we have already stated, maintain, that the occupant was allowed by the joint consent of mankind to retain it; whilst others annex property to the labour bestowed on the land during the period of occupancy. However this be, the real foundation of our right is the "law of the land." As it was the intention of God, that the produce of the earth should be applied to the use of man, this institution could not have been fulfilled without establishing property; and, therefore, such an establishment must have been consistent with his will. The land could not have been divided into separate property, without leaving it to the law of the country to regulate that division; it is, therefore, consistent with the same will, that the law should regulate the division, and, consequently, "consistent with the will of God," or "right," that any individual should possess that share which these regulations assign him. By whatever circuitous train of reasoning, says archdeacon Paley, you attempt to derive this right, it must terminate at last in the will of God: the straightest, therefore, and shortest way of arriving at this will, is the best. But if the right of property be made to depend upon the law of the land, it seems to follow, that a man has a right to keep and take every thing, which the law will allow him to keep and take; and this, in many cases, will authorize the most flagitious chicanery. To obviate this difficulty, the following distinction is proposed. With the law, we acknowledge, resides the disposal of property; so long, therefore, as we keep within the design and intention of a law, that law will justify us, as well in *foro conscientie*, as in *foro humano*, whatever be the equity or expediency of the law itself. But when we convert to our purpose a rule or expression of law, which is intended for another purpose; then we plead, in our justification, not the intention of the law, but the words; that is, we plead a dead letter, which can signify nothing: for words *without* meaning or intention have no force or effect in justice, much less words taken *contrary* to the meaning and intention of the speaker or writer.

The institution of property is, upon the whole, beneficial; and the principal advantages accruing from it are such as follow: it increases the produce of the earth, by subjecting it to cultivation; it preserves the produce of the earth to maturity; it prevents contests; and it improves the convenience of living, by enabling mankind to distribute themselves into distinct professions, and by encouraging those arts, by which the accommodations of life are supplied. With few exceptions, therefore, it may be affirmed, that even the poorest and the worst provided, in countries where property and the consequences of property prevail, are in a better situation, with respect to food, raiment, houses, and what are called the necessaries of life, than any are in places where most things remain in common. Inequality of property, in the degree in which it exists in most countries of Europe, abstractedly considered, is an evil; but it is an evil, which flows from those rules concerning the acquisition and disposal of property, by which men are incited to industry, and by which the object of their industry is rendered secure and valuable. If there be any great inequality unconnected with this origin, it ought to be corrected.

The laws of England are, in point of honour and justice, extremely watchful in ascertaining and protecting the right of property. Upon this principle the great charter has de-

clared, that no freeman shall be disseised or divested of his freehold, or his liberties, or free customs, but by the judgment of his peers, or by the law of the land. And by a variety of ancient statutes, *viz.* 5 Edw. III. c. 9. 25 Edw. III. stat. 5. c. 4. 28 Edw. III. c. 3. it is enacted, that no man's lands or goods shall be seized into the king's hands against the great charter, and the law of the land; and that no man shall be disinherited nor put out of his franchises or freehold, unless he be duly brought to answer, and be forejudged by course of law; and if any thing be done to the contrary, it shall be redressed, and holden for none. So great is the regard of the law for private property, that it will not authorize the least violation of it; no, not even for the general good of the whole community.

The objects of dominion or property are things, as contradistinguished from persons; and things are by the law of England distributed into two kinds, *viz.* things real, and things personal. Things real are such as are permanent, fixed, and immovable, which cannot be carried out of their place, as lands, tenements, and hereditaments of all kinds; things personal are goods, money, and all other moveables, which may attend the owner's person wherever he thinks proper to go. Hence property is divided into *personal* and *real*.

Moreover, the rights of personal property may be considered as in possession or in action. Those in possession are liable to two species of injuries, *viz.* the deprivation of that possession by unjust and unlawful taking them away, or by unjust detaining them, though the original taking might be lawful; and the abuse or damage of the chattels, while the possession continues in the legal owner.

Rights of property in action are such as are founded on, and arise from contracts, which are either express or implied: the former sort includes debts, covenants, and promises; and the latter are either such as are necessarily implied by the fundamental constitution of government, to which every man is a contracting party, or such as do not arise from the express determination of any court, or the positive direction of any statute; but from natural reason, and the just construction of law.

Real property is liable to various kinds of injury, the principal of which are the following, *viz.* ouster, trespass, nuisance, waste, subtraction, and disturbance; which see respectively. Blackst. Com. books i. ii. iii.

There are three manners of right or property, *viz.* absolute, qualified, and possessory. See TITLE.

For offences or crimes against private property, see LARCENY, *Malicious MISCHIEF*, and FORGERY.

PROPERTY, *Landed, Valuation of.* See VALUATION of Land.

PROPERTY, *Literary.* See LITERARY.

PROPERTY *by Prerogative*, is that property in personal chattels, a right to which may accrue either to the crown itself, or to such as claim under the title of the crown, as by grant or by prescription; such are all tributes, taxes, and customs; all forfeitures, fines, and amercements due to the king, which accrue by virtue of his ancient prerogative, or by particular modern statutes; wreck, treasure-trove, waifs, estrays, royal fish, swans, &c. and those animals known by the denomination of game. See GAME.

PROPERTY, *Right of, jus proprietatis*, is that which is vested in a man without either possession, or even the right of possession. This is often spoken of under the name of the mere right, *jus merum*; and the estate of the owner is, in such cases, said to be totally divested, and *put to a right*. A person thus circumstanced may have the true ultimate

property of the lands in himself; but by his own negligence, the solemn act of his ancestor, or the determination of a court of justice, the presumptive evidence of that right is strongly in favour of his antagonist, who has thereby obtained the absolute right of possession.

Incumbents have not the propriety of benefices, they have only the enjoyment of them. The monks have a long time disputed whether they had the propriety of the bread they eat, or only the use.

One may give the propriety of an estate, yet reserve the usufruct; in which case, by the death of the usufructuary, the usufruct is consolidated to the propriety.

In the law of England, strictly speaking, that which is called an estate in lands and tenements is termed a property in personal chattels; the law considering the first as permanent, the other as temporary and precarious.

PROPHECY, Πρῶφῆσεια, a prediction, made by divine inspiration.

One of the strongest evidences for the truth of revealed religion, is that series of prophecies which is preserved in the Old and New Testament; and a greater service, says an excellent writer, could not be done to Christianity, than to lay together the several predictions of scripture with their completions, to shew how particular things have been foretold, and how exactly fulfilled. A work of this kind was desired by the lord Bacon (*vide de Augmentis Scientiarum, lib. ii. cap. 11.*), and he entitles it the History of Prophecy; in which he proposes, that every prophecy of the scripture be sorted with the event fulfilling the same throughout the ages of the world, both for the better confirmation of faith, and for the better illumination of the church, touching those parts of prophecies which are yet unfulfilled; allowing, nevertheless, that latitude which is agreeable and familiar unto divine prophecies, being of the nature of the author with whom a thousand years are but as one day, and therefore they are not fulfilled punctually at once, but have springing and germinant accomplishment throughout many ages, though the height or fulness of them may refer to some one age. A work of this kind has been actually executed by the learned bishop Newton in his "Dissertation on the Prophecies," in three vols. 8vo. to which we refer, as containing a detail of all the prophecies in the Old and New Testament, with an account of their accomplishment.

With regard to the credibility of prophecy, it may be observed in general, that it is not at all incredible that God should, upon special occasions, foretell future events; and, if he affords an extraordinary revelation of his will to mankind, that he should attest its divine original by this kind of evidence; an evidence which, if the prophecies point to the events, and the events correspond with the prophecies, is in the highest degree conclusive and convincing. No previous conjecture nor accidental coincidence is sufficient to counteract and invalidate this kind of evidence.

As to most of the scripture prophecies, they comprehend such a variety of particulars; they so minutely describe distant events, to be accomplished in circumstances which no human sagacity could foresee or conceive likely to occur; and they accord so exactly with the facts to which they refer, that there is no way of evading the conclusion, but by either denying the premises that such prophecies were ever delivered and recorded, against which fact and history militate, or by pretending that what we call predictions are only histories written after the events had happened, in a prophetic style and manner. But it is alleged in answer to this absurd plea, that there are all the proofs and authorities, which can be had in cases of this nature, that the prophets prophesied in one age, and that the events happened in another and subsequent

PROPHECY.

sequent age ; and we have as much reason to believe these, as we have to believe any ancient matters of fact whatever ; and by the same rule which leads us to deny these, we may as well controvert and contradict the credibility of all ancient history ; but, besides, Christian writers undertake to prove the truth of prophecy, and consequently the truth of revelation, not by an induction of particulars long ago foretold and long ago fulfilled, the predictions of which may be supposed to have been written after the histories, but by instances of things which have confessedly many ages ago been foretold, and have in these later ages been fulfilled, or are fulfilling at this very time ; so that there is no pretence for asserting such prophecies to have been written after the events ; but it must be acknowledged that the events many ages after correspond exactly with the predictions many ages before. The evidence, therefore, which prophecy furnishes in favour of the truth of religion is a growing evidence ; and the more prophecies are fulfilled, the more testimonies there are and confirmations of the truth and certainty of divine revelation. One of the greatest difficulties in Christianity turns upon the manner of completion of the scripture prophecies. In the prophets of the Old Testament are frequent predictions of the Messiah ; which the writers of the New frequently urge to the Jews and heathens as fulfilled in Jesus Christ ; and on this principle evince the truth of his mission ; but these texts, thus urged from the Old, in the New Testament, are sometimes not to be now found in the Old ; and at other times are not urged in the New in the literal and obvious sense which they seem to bear in the Old ; whence most of the Christian commentators, divines, and critics, ancient and modern, judge them to be applied in a secondary, typical, allegorical, or mystical sense. Thus, *e. gr.* St. Matthew, (if we allow the authenticity of the two first chapters of his gospel, see MATTHEW,) after an account of the conception of the Virgin, and the birth of Jesus, says, "All this was done that it might be fulfilled which was spoken by the prophet, saying, Behold a Virgin shall be with child, and shall bring forth a son, and they shall call his name Emmanuel." But the words, as they stand in Isaiah, whence they are supposed to be taken, do, in their obvious and literal sense, relate to a young woman who was to bring forth a child in the days of Ahaz ; as appears from the context, and as is owned by Grotius, Huetius, Castalio, Curcellæus, Episcopius, Hammond, Simon, Le Clerc, Lamy, &c.

This prophecy, then, not being fulfilled in Jesus, in the primary, literal, or obvious sense of the words, is supposed, like the other prophecies cited by the apostles, to be fulfilled in a secondary, typical, or allegorical sense ; *i. e.* this prophecy, which was first literally fulfilled by the birth of the prophet's son in the time of Ahaz, was again fulfilled by the birth of Jesus, as being an event of the same kind, and intended to be signified either by the prophet, or by God, who directed the prophet's speech. Grotius observes this to be the case in most, if not all, the prophecies and citations quoted from the Old in the New Testament ; and Dodwell, with sir John Marsham, refers even the famous prophecy in Daniel, about the seventy weeks, to the time of Antiochus Epiphanes ; shewing, that the expressions taken thence by Christ, and urged by him as predicting the destruction of Jerusalem by the Romans, have only in a secondary sense a respect to that destruction.

And even that famous prophecy in the Pentateuch, "A prophet will the Lord God raise up unto thee, like unto me ; to him shall ye hearken ;" which St. Luke refers to as spoken of Jesus Christ, is by Simon, Grotius, Stillingfleet,

&c. understood to signify, in its immediate sense, a promise of a succession of prophets ; though the ultimate and principal object of the prophecy was the Messiah, who resembled Moses in a greater variety of respects than any other person ever did. The resemblance is pointed out by Eusebius (*Dem. Evang.* l. 3. c. 2.) in a number of particulars, and with enlargements and additions by Jortin. *Eccles. Hist.* vol. i.

Many have allowed that the apostles applied the prophecies which they quote from the Old Testament, in a typical sense ; but, unhappily, the rules by which they quoted them are lost. Dr. Staehope laments the loss of the Jewish traditions or rules for interpreting scripture received among the rabbins, and followed by the apostles. But this loss, Surenhusius, Hebrew professor at Amsterdam, thinks he has retrieved from the Jewish Talmud, and the ancient Jewish commentaries ; and has accordingly published to the world the rules by which the apostles quoted the Old Testament.

But the truth is, these rules are too precarious, strained, and unnatural, to gain much credit.

It is well known that several of the fathers interpreted the scripture in a mystical sense, and were fond of that method of interpretation. Origen was very famous for this, inasmuch that he is sometimes led to speak of the literal sense of scripture in a very degrading manner, and as bishop Smallbroke, in his answer to Mr. Wollston, observes, with too great contempt. But he did not absolutely deny the reality of the literal sense, though he gave the preference to the mystical. Origen sometimes pleaded for a three-fold sense of scripture, and so did Jerome. Nay, Augustin pleaded for a four-fold sense of scripture. (See Glassii *Philolog. Sacra.*) But both the last-mentioned fathers seem to have abandoned, or at least depreciated, the mystical interpretations of their youth in their riper years. (See bishop Patrick's Preface to his Paraphrase on the Psalms.) Arnobius has expressed himself very decidedly concerning the uncertainty, and small authority, of the allegorical interpretation of the pagan mythology, and his observations are no less applicable to the allegorical interpretation of scripture. Mainonides (*More Nevoch.*) gives us the opinion of the Jewish rabbies concerning allegorical interpretations of scripture, in the following words. "Our rabbies were wont to be mightily delighted with allegories, and to use them frequently ; not that they are of opinion, that the allegorical interpretation is the true sense of scripture ; but that it has somewhat enigmatical in it, that is pleasant and entertaining."

Dr. Lightfoot (*Works*, vol. i.) is of opinion, that the fathers took this method of interpreting scripture from the Jews ; and that seems to be the most common opinion of learned men among the Christians. Le Clerc, and some others, however, think that allegories arose among the Heathens. Photius assures us that Philo, the Jew, taught the mode of allegorizing scripture to the Christians. See *Phot. Cod.* 105.

Grotius, as we have already suggested, maintained that the greatest part of the prophecies of the Old Testament had a double sense, and a double accomplishment. Limborch, in his Commentary on the Acts of the Apostles, accedes to his opinion. Father Baltus, a Jesuit, in the year 1737, published his "*Défense des Prophétiques de la Religion Chrétienne*," and in this work he purposely examines and refutes the opinion of Grotius at great length ; and shews that the most ancient fathers of the church, as Justin, Martyr, Tertullian, &c. never thought of interpreting the prophecies of the Old Testament in a double sense ; but

PROPHECY.

applied them in their literal meaning to the Messiah. Mr. Whiston, in his sermons preached at Boyle's lecture in 1707, had supported the same sentiment before Baltus. He condemns all allegorical explanation of the prophecies of the Old Testament cited in the New, as weak, enthusiastic, &c. and adds, that if a double sense of the prophecies be allowed, and there be no other method of shewing their completion than by applying them secondarily and typically to our Lord, after having been in the first and primary intention long ago fulfilled in the times of the Old Testament, we lose all the real advantages of the ancient prophecies, as proofs of Christianity.

He therefore sets up a new scheme in opposition to it; he owns that, taking the present text in the Old Testament for genuine, it is impossible to expound the apostles' citations of the prophecies of the Old Testament on any other than the allegorical foundation; and therefore, to solve the difficulty, he is forced to have recourse to a supposition contrary to the sense of all Christian writers before him, *viz.* that the text of the Old Testament has been greatly corrupted since the apostolic age by the Jews. His hypothesis is, that the apostles made their quotations out of the Old Testament rightly and truly from the Septuagint version, which, in their time, was in vulgar use, and exactly agreed with the Hebrew original; and that as they made exact quotations so they argued justly and logically from the obvious and literal sense of the said quotations, as they then stood in the Old Testament; but that, since their times, both the Hebrew and Septuagint copies of the Old Testament have been so greatly corrupted, and so many apparent disorders and dislocations introduced in them, as to occasion many remarkable differences and inconsistencies between the Old and New Testament in respect to the words and sense of those quotations.

As to the manner in which these corruptions were introduced, he says, the Jews, in the second century, greatly corrupted and altered both the Hebrew and Septuagint, especially in the prophecies cited by the apostles, to make their reasoning appear inconclusive; that, in the third century, they put into Origen's hand one of these corrupted copies of the Septuagint; which Origen mistaking for genuine, inserted in his Hexapla, and thus brought into the church a corrupted copy of the Septuagint; and that, in the end of the fourth century, the Jews put into the hands of the Christians, who, till then, had been almost universally ignorant of the Hebrew, a corrupted copy of the Hebrew Old Testament.

The disagreement, then, between the Old and New Testament, in respect to the said quotations, he contends, has no place between the genuine text of the Old Testament, (now no where existing,) but only between the present corrupted text of the Old and New Testament; and, therefore, to justify the reasonings of the apostles, he proposes to restore the text of the Old Testament, as it stood before the days of Origen, and as it stood in the days of the apostles; from which text, thus restored, he doubts not, it will evidently appear, that the apostles cited exactly, and argued justly and logically from the Old Testament. But this scheme of accomplishing prophecies labours under difficulties at least as great as the allegorical scheme. Its foundation is incredible, and its superstructure, from first to last, precarious. In effect, it is inconceivable, that the Old Testament should be so corrupted; and it may be even made appear, that the Hebrew and Septuagint disagreed in the times of the apostles: add to this, that the means by which he proposes to restore the true text will never answer that end;

nor has he himself, from all the means he is yet possessed of, been able to restore one prophetic citation, so as to make that seem literally, which before only seemed allegorically applied.

In 1710, archdeacon Claggett animadverted on this notion of Whiston, and undertook the vindication of those Christian commentators, who had explained some prophecies concerning the Messiah, as not solely relating to him, in a treatise, entitled "Truth defended, and Boldness in Error rebuked."

Upon this head it may be observed, that the double sense of prophecies, for which some have zealously contended, and which others have as strenuously opposed, ought not to be understood, as if a prophecy equally and indifferently referred to many persons or events; or as if, literally referring to a lower person, it was only figuratively and allegorically to be interpreted of the Messiah (for a passage only capable of being accommodated to him is not by any means a prediction of him); but it is to be so explained, as that it may appear the Messiah was principally intended, and the prophecy literally referred to him, though it might in part be applied to some other person; and might have been understood as referring to that inferior person alone, if farther light had not been thrown upon it, by comparing other prophecies, or by the testimony of those whom, on other accounts, we have reason to regard as authentic interpreters. Nevertheless, it must be acknowledged, that though the tracing of the Messiah in such prophecies may serve to illustrate the unity of design, which is a considerable additional proof of the truth of a revelation, yet the main stress is to be laid upon such prophecies as evidently and solely relate to the Messiah and his kingdom, rather than on those which are capable of reference to other persons or events.

The learned and judicious Dr. Clarke has given double senses of several passages in the four gospels: Matt. xx. 1, &c. Matt. xxiv. 6, &c. The celebrated Mr. Locke has quoted, in his admirable preface to his Commentary on the Epistles, a passage from the learned and judicious Mr. Selden, to shew that no text of scripture has more than one meaning, which is fixed and limited by the connection; and yet Mr. Locke has, in some few instances, contended for double senses of one and the same text. 2 Cor. iii. 6. Gal. iv. 21, &c.

There are, it is said, several persons, who would be pleased with double senses, and who would be glad to have the truth and authority of them established and confirmed. Such are all mystical divines and enthusiasts, who plead for double, or manifold senses of the holy scriptures: the Papists also contend for many senses of holy scripture, because they are thus greatly helped in the proof of a number of their peculiar tenets: the Jews are highly delighted with manifold senses of scripture: and the enemies of revelation are glad to see Christians pleading for double senses, because, as they conceive, it affords the greatest advantage to them and their cause. In this number we may reckon Mr. Collins, Mr. Woolaston, and the author of "Christianity as old as the Creation," and the author of "Christianity not founded in Argument."

Collins's "Discourse on the Grounds and Reasons of the Christian Religion" was published in 1724; and in this publication he revived the objections of Faultus, and other early writers, who had endeavoured to prove that the prophecies of the Old Testament had no direct relation to Jesus Christ. We refer to Leland's "View of the Deistical Writers," and to Fabricius's "Lux Evangelica," for an account

account of the several answers which were published to this, and to another work of the same author, entitled "The Scheme of literal Prophecy considered." Bishop Warburton also, in the sixth book of the "Divine Legation of Moses," has answered what Collins had objected against a second sense of prophecy; and in the first volume of Dr. Jortin's "Remarks on Ecclesiastical History," we have some very judicious observations, both concerning prophecy in general, and concerning a double sense of some prophecies.

Dr. Sykes, in his "Connection between Natural and Revealed Religion," has a whole chapter, to shew that the ancient prophecies contained only one sense. The author of an "Essay concerning the Unity of Sense, to shew that no Text of Scripture has more than one single Sense," prefixed to Dr. Benson's Paraphrase on St. Paul's Epistles, and contained in bishop Watson's Collection of Theological Tracts, vol. iv., has particularly examined this subject, obviated the difficulties that attend the interpretation of particular passages, evinced the advantage which his hypothesis affords him for this purpose, and answered the objections that have been urged against it.

Dr. Newton, late bishop of Bristol, at the conclusion of his "Dissertations" already mentioned, has shewn how the argument from prophecy avails in proof of the truth of divine revelation. Waving any reference to those prophecies that received their full accomplishment in ancient times, and confining the attention to those of later ages, you can have no reason to doubt of the truth of prophecy, and consequently of the truth of revelation, when you see instances of things, which could no ways depend upon human conjecture, foretold with the greatest clearness, and fulfilled hundreds of years afterwards with the greatest exactness. Nay, you see prophecies, the latest of which were delivered about 1700 years ago, and some of them above 3000 years ago, fulfilling at this very time, and cities, countries, and kingdoms, in the very same condition, and all brought about in the very same manner, and with the very same circumstances, as the prophets had foretold.

You see the descendants of Shem and Japheth ruling and enlarged in Asia and Europe, and perhaps in America, and the curse of servitude still attending the wretched descendants of Ham in Africa. You see the posterity of Ishmael multiplied exceedingly, and become a great nation in the Arabians; yet living like wild men, and shifting from place to place in the wilderness; *their hand against every man, and every man's hand against them*; and still dwelling an independent and free people, in the presence of all their brethren, and in the presence of all their enemies. You see the family of Esau totally extinct, and that of Jacob subsisting at this day; *the sceptre departed from Judah*, and the people living no where in authority, every where in subjection; the Jews still dwelling alone among the nations, while the remembrance of Amalek is utterly put out from under heaven. You see the Jews severely punished for their infidelity and disobedience to their great prophet like unto Moses; *plucked from off their own land, and removed into all the kingdoms of the earth; oppressed and spoiled evermore, and made a proverb and a by-word among all nations*. You see Ephraim so broken as to be no more a people, while the whole nation is comprehended under the name of Judah; the Jews wonderfully preserved as a distinct people, while their great conquerors are every where destroyed; their land lying desolate, and themselves cut off from being the people of God, while the Gentiles are advanced in their room. You see Nineveh so completely destroyed, that the place thereof is not, and cannot be known; Babylon made a desolation for ever, a possession for

the bittern, and pools of water; Tyre become like the top of a rock, a place for fishers to spread their nets upon; and Egypt a base kingdom, the basest of the kingdoms, and still tributary and subject to strangers. You see of the four great empires of the world the fourth and last, which was greater and more powerful than any of the former, divided in the western part thereof into ten lesser kingdoms; and among them a power *with a triple crown differs from the first, with a mouth speaking very great things, and with a look more stout than his fellows, speaking great words against the most High, and changing times and laws*. You see a power cast down the truth to the ground, and prosper and praise, and destroy the holy people, not regarding the God of his fathers, nor the desire of wives, but honouring Mahuzzim, gods-protectors or saints-protectors, and causing the priests of Mahuzzim to rule over many, and to divide the land for gain. You see the Turks stretching forth their hand over the countries, and particularly over the land of Egypt, the Libyans at their steps, and the Arabians still escaping out of their hand. You see the Jews led away captive into all nations, and Jerusalem trodden down of the Gentiles, and likely to continue so until the times of the Gentiles be fulfilled, as the Jews are by a constant miracle preserved as a distinct people, for the completion of other prophecies relating to them. You see one who opposeth and exalteth himself above all laws divine and human, sitting as God in the church of God, and showing himself that he is God, whose coming is after the working of Satan, with all power, and signs, and lying wonders, and with all deceivableness of unrighteousness. You see a great apostacy in the Christian church, which consists chiefly in the worship of demons, angels, or departed saints, and is promoted through the hypocrisy of liars, forbidding to marry, and commanding to abstain from meats. You see the seven churches of Asia lying in the same forlorn and desolate condition that the angel had signified to St. John, their candlestick removed out of its place, their churches turned into mosques, their worship into superstition. In short, you see the characters of the beast and the false prophet, and the whore of Babylon, now exemplified in every particular, and in a city that is seated upon seven mountains; so that if the bishop of Rome had sat for his picture, a greater resemblance and likeness could not have been drawn.

PROPHECIES, False, are those delivered by persons pretending extraordinary commissions from God, to raise jealousies in the people, or terrify them with impending judgments, &c. Such persons are punishable at common law as impostors. This was a capital offence by stat. 1 Edw. IV. cap. 12. which was repealed in the reign of queen Mary. By statute 5 Eliz. cap. 15. none shall publish or set forth any false prophecy, with an intent to raise sedition, on pain of 10*l.* for the first offence, and a year's imprisonment; and for the second offence to forfeit all his goods and chattels, and suffer imprisonment during life; the prosecution to be within six months. (3 Inst. 128, 129.) To prophesy when the king shall die, hath been anciently held to be treason. Roll. Rep. 88.

PROPHECYINGS, a name given to certain assemblies held by the ancient Puritans in this kingdom; where alternately, says Mr. Hume, as moved by the spirit, they displayed their zeal in prayers and exhortations, and raised their own enthusiasm, as well as that of their audience, to the highest pitch, from that social contagion, which has so mighty an influence on holy fervour, and from the mutual emulation which arose in those trials of religious eloquence. Such dangerous societies, as the historian calls them, had been suppressed by queen Elizabeth; and the ministers in the Hampton-Court conference moved king James I. for their

their revival. But the king sharply replied, "if you aim at a Scottish presbytery, it agrees as well with monarchy as God and the devil. There Jack and Tom and Will and Dick shall meet and censure me and my council. Therefore I reiterate my former speech: *Le Roi s'avisera*. Stay, I pray, for one seven years, before you demand; and then, if you find me grow purfée and fat, I may perchance hearken to you. For that government will keep me in breath, and give me work enough." Such were the political considerations, which determined the king in his choice among religious parties. Hume's Hist. of England, vol. vi. p. 14. 8vo.

PROPHET, PROPHETA, προφητης, a person inspired by God with the knowledge of future events; and commissioned to declare his will, &c. to the world.

The word is derived from the Greek προφ, and φησι, said; of φημι, I say; whence also the Latins derive their *fatus*, spoken.

Among the canonical books are those of sixteen prophets; four of which are denominated the *greater* prophets, viz. Isaiah, Jeremiah, Ezekiel, and Daniel; so called from the length or extent of their writings, which exceed those of the others; viz. Hosea, Joel, Amos, Obadiah, Jonah, Micah, Nahum, Habakkuk, Haggai, Zechariah, and Malachi; who are called the *lesser* prophets, from the shortness of their writings.

The writings of the prophets form one of the three divisions of the canon of the Old Testament; and to those already enumerated, called the books of the latter prophets, are added those of the former prophets; viz. Joshua, Judges, Samuel, and Kings.

The Jews only reckon three greater prophets; Daniel they exclude as no more to be ranked among the prophets than David; not but that both the one and the other foretold many important things, but because their manner of life differed from that of the other prophets; David being a king, and Daniel a peer.

In the Greek church, the lesser prophets are placed in order before the great ones; apparently because many of the lesser prophets are more ancient than the greater.

Among the Greeks, too, Daniel is ranked among the lesser prophets. In the forty-eighth chapter of Ecclesiasticus, Isaiah is particularly called the *great* prophet; both on account of the great things he foretold, and the magnificent manner in which he did it.

Spinosa says, the several prophets prophesied according to their respective humours: Jeremiah, *e. g.* melancholy and dejected with the miseries of life, prophesied nothing but misfortunes.

Dacier observes that among the ancients, the name poet is sometimes given to prophets; as that of prophet is, at other times, given to poets.

PROPHETS, *Sons of the*, in *Scripture History*, an appellation given to young men who were educated in the schools or colleges under a proper master, who was commonly, if not always, an inspired prophet, in the knowledge of religion and in sacred music, and thus were qualified to be public preachers, which seems to have been part of the business of the prophets on the Sabbath-days and festivals. That such colleges or schools existed even from the earliest times of the Hebrew republic, is evident from many parts of the sacred history. In these the candidates for the prophetic office, removed altogether from an intercourse with the world, devoted themselves entirely to the study and exercises of religion; and over each of them some prophet of superior authority, and more peculiarly under the divine influence, presided as the moderator and preceptor of the whole assembly. It is

probable, that God generally chose the prophets, whom he inspired, out of these schools.

Although the Sacred History affords us but little information, and that in a cursory manner, concerning their institutes and discipline; we nevertheless understand that a principal part of their occupation consisted in celebrating the praises of Almighty God in hymns and poetry, with choral chants accompanied by stringed instruments and pipes. A remarkable passage to this purpose occurs in 1 Sam. x. 5—10. Saul being nominated king, and, pursuant to the command of God, consecrated by a solemn unction, a company of the prophets, as Samuel had foretold, descending from the mount of God (that being the place in which the sacred college was situated) met him; and preceded by a variety of musical instruments, *prophesied*; upon hearing which, he himself, as if actuated by the same spirit, immediately joined them, and prophesied also. The same thing again occurred to him as related in 1 Sam. xix. 20—24. Concerning the nature of this mode of prophesying all are agreed, understanding by it the celebration of the praises of God, under the impulse of the Holy Spirit, with music and song. (See also 1 Chron. xxv. 1—3.) From these instances it sufficiently appears, that the word "Nabi" was used by the Hebrews in an ambiguous sense, and that it equally denoted a prophet, a poet, or a musician, under the influence of divine inspiration. To these we may add the prophetesses, Miriam the sister of Aaron, and Deborah, who were distinguished by that title, not only because they pronounced the oracles of Jehovah, but on account of their excellence in music and poetry; sister arts, which were united by the Hebrews, as well as by all other nations, during the first stages of society. See HERREW *Music*, and HEBREW *Poetry*.

PROPHETIC POETRY, denotes that species of poetry which is found to pervade the predictions of the prophets, as well those contained in the books properly called prophetic, as those which occasionally occur in other parts of the scripture. As to the peculiar character of the prophetic poetry, bishop Lowth observes, that this species of poetry is more ornamental, more splendid, and more florid than any other. It abounds more in imagery, at least in that species of imagery which, in the parabolic style, is of common and established acceptation, and which, by means of a settled analogy, always preserved, is transferred from certain and definite objects to express indefinite and general ideas. Of all the images proper to the parabolic style, it most frequently introduces those which are taken from natural objects and from sacred history: it abounds most in metaphors, allegories, comparisons, and even in copious and diffuse descriptions. It possesses all that genuine enthusiasm, which is the natural attendant on inspiration; it excels in the brightness of imagination and in clearness and energy of diction, and consequently rises to an uncommon pitch of sublimity; hence also it often is very happy in the expression and delineation of the passions, though more commonly employed in the exciting of them; this indeed is its immediate object, over this it presides as its peculiar province.

With respect to the order, disposition, and symmetry of a perfect poem of the prophetic kind, no certain definition will admit of general application. Naturally free, and of too ardent a spirit to be confined by rule, it is usually guided by the nature of the subject only, and the impulse of divine inspiration. There are not wanting, it is true, instances of great elegance and perfection in these particulars. Among the shorter prophecies it will be sufficient to mention those of Balaam, each of which is possessed of a certain accuracy

of arrangement and symmetry of form; they open with an elegant exordium, they proceed with a methodical continuation of the subject, and they are wound up with a full and graceful conclusion. There are many similar instances in the books of the prophets, and particularly in Isaiah, which deserve the highest commendation, and may, with propriety, be classed with the most perfect and regular specimen of poetry. The following example is selected from that most accomplished writer, and it is embellished with all the most striking ornaments of poetry. The 34th and 35th chapters of Isaiah contain a remarkable prophecy under the form of a simple, regular, perfect poem, consisting of two parts, according to the nature of the subject, which, as to its general properties, is explained with the utmost perspicuity. The first part of the prophecy contains a denunciation of extraordinary punishment, indeed nothing short of total destruction against the enemies of the church of God; and, afterwards, in consequence of this event, a full and complete restoration is promised to the church itself. For the development and illustration of the whole, we must refer to Lowth, *ubi infra*. As a specimen of a prophetic poem complete in all its parts this learned author has selected one of the prophecies of Balaam, of which he says that the whole scope of the Hebrew poetry contains nothing more exquisite or perfect. This abounds in gay and splendid imagery copied immediately from the tablet of nature, and is chiefly conspicuous for the glowing elegance of the style, and the form and diversity of the figures. Numb. xxiv. 5—9. Lowth's Lectures on the Sacred Poetry of the Hebrews, translated by Dr. Gregory, pt. iii. See *HEBREW Poetry*.

For the peculiar character of each of the prophets, see their respective names.

PROPHETICAL Types. See *TYPE*.

PROPHYLACTICE, *προφυλακτική*, that part of the art of medicine which directs the preventing or preserving from diseases.

PROPTIATION, in *Theology*, is, as some have defined and represented it, a sacrifice offered to God to assuage his wrath, and render him propitious.

Among the Jews there were both ordinary and public sacrifices; asholocausts, &c. offered by way of thanksgiving; and extraordinary ones offered by particular persons guilty of any crime, by way of propitiation.

If it were a crime of ignorance, they offered a lamb, or a kid; if done wittingly, they offered a sheep: for the poor, a pair of turtles was enjoined as a propitiation.

The Romish church believe the mass to be a sacrifice of propitiation, for the living and the dead. The reformed churches allow of no propitiation, but that one offered by Jesus Christ on the cross.

There has been a considerable difference of opinion among divines concerning the meaning of the term propitiation; more especially as it is used in the New Testament, with a particular reference to the sufferings and death of Christ: but whatever efficacy some have ascribed to them as the means of obtaining pardon for the penitent and establishing their title to eternal life, it has been generally supposed, that they have been verbal declarations or memorials, that God is propitious, and not the cause of a merciful disposition in God or the means of rendering him propitious, who was before implacable. In this respect, those who maintain that sacrifices in general, and that of our Saviour in particular, which they consider as a sacrifice, were a proper expiation, or a real propitiation, affirm they neither were nor could be proper expiations. On this subject many unfounded, not to say unwarrantable, expressions have been used by controversial writers. Accordingly some have

taken occasion, from the redemption that is in Christ, to represent the blessed God as being in himself implacable, and that his inclination or disposition to shew mercy was owing merely to Christ's interposing on our behalf. In Scripture, the love of God and his compassion to sinners are represented as the very spring of this constitution, and the whole scheme of our redemption, whatever may be our ideas of its nature, efficacy, and extent, is attributed to the contrivance of the Father. Thus our Lord himself represents it: "God so loved the world, that he sent his only begotten son, that whosoever believeth in him should not perish, but have everlasting life;" and to the same purpose are the subsequent declarations of the apostles in all their writings. But if God himself was originally disposed to shew mercy, it may be asked, how is then the death of Christ a propitiation? Just in the same manner, say these divines, as a propitiation is accounted for under the Mosaic constitution. There God first orders a mercy-feat (*ἱλαστήριον*, the term used for propitiation in Rom. iii. 25.); then he requires that application be made to him as residing there, by sacrifice and by mediation of an high priest. Thus also, God resolves to shew mercy to sinners, determining at the same time that his only begotten son (not without his own consent) shall suffer death, the penalty which the original law hath denounced against transgressors; merely to demonstrate his regard to the righteous sanction of the law, and his displeasure against sin. Hence it has been said, Christ by dying for accomplishing the purpose of divine mercy, and in consequence of the appointment and will of the father and fountain of mercy, may, with the utmost propriety and strictness, be regarded and described as a "propitiation for our sins:" inasmuch as by his suffering death he hath prevented or warded off those effects and consequences of sin which would otherwise have befallen the sinner. In this scheme, as the advocates of it say, we see mercy, pure, unsolicited, unconstrained, unpurchased mercy to sinners; but God appoints that the mercy and favour, and particularly the grant of eternal life, which he designs for sinners of a particular description and character, shall be conveyed to them or conferred upon them in this way, *viz.* that Christ shall die as a sacrifice, and not as a priest, for them. This being stipulated, and Christ having complied with it, his death and his mediation, originating in the benevolence of the Deity and accepted by him, are justly represented as the means of procuring for qualified recipients the blessings which the Gospel promises. For different views of this subject, see the article *ATONEMENT*. See also *SACRIFICE* and *SATISFACTION*.

PROPTIATION also gives the name to a solemn feast among the Jews, celebrated on the tenth of the month Tisri, which is their seventh month, and answers to our September.

It was instituted to preserve the memory of the pardon proclaimed to their forefathers by Moses on the part of God; who thereby remitted the punishment due for their worship of the golden calf.

PROPTIATORY, among the Jews, was the cover or lid of the ark of the covenant; which was lined both within and without with plates of gold; inasmuch that there was no wood to be seen.

Some even take it to have been one piece of massive gold.

The cherubims spread their wings over the propitiatory. This propitiatory is said by some divines to be a type or figure of Christ, whom St. Paul calls the propitiatory ordained from all ages. See *ARK of the Covenant*.

PROPLASM, *PROPLASMA*, *προπλάσμα*, is sometimes used

used for a mould in which any metal or soft matter, which will afterwards grow hard, is cast.

PROPLASTICE, *προπλαστικη*, the art of making moulds for casting things in.

PROPOLIS, *προπολις*, a thick, yellow, odorous substance, smelling like storax, nearly akin to wax, but more tenacious; with which the bees stop up the holes and cranies of their hives, to keep out the cold air, &c.

These wary animals not only stop up in this manner all the cracks they can find, but even examine all the weak places of the hive, and will eat away a rotten or too weak part, and make up the deficiency with this propolis. Hence it derives its name from *προπολις*, *before the city*.

This was elegantly seen in the case of some of M. Reaumur's glass hives, which were framed of wood, and had squares of glass in their proper places: these squares of glass were fastened in with slips of pasted paper. The bees finding this a much weaker part of the hive than any other, and capable of being eaten through by their enemies, soon gnawed to pieces all the paper and paste, and covered those parts with the propolis in the place of that matter.

It might seem that the bees might use wax on this occasion; but this would be no defence against those of their enemies, which devour and feed on wax; and nature has guarded them against these, by supplying them with a matter which spreads more easily, is of a greater tenacity, and fixes itself much more strongly in the small crevices than wax could do. It has been known from the earliest times, that the bees made use of this substance. Pliny mentions it, and tells us, that the authors of his time distinguished three kinds of it; the first they called *metys*, the second *pissoceron*, and the third *propolis*. The last of these names is only retained among the later writers, and seems to have stood with the ancients for the pure substance, the other kinds differing from it only as they were more or less mixed with wax.

The propolis itself is a substance perfectly different from wax; it is found to be soluble in spirit of wine, or in oil of turpentine; and is soft and very extensible when laid on by the bees, but grows hard afterwards; it may, however, even in its hardest state, be softened by heat, even by that of the fingers, so as to acquire the ductility of wax; but more rosy and tenacious. Like wax it may be kneaded between the teeth, without any perceptible taste. In the mass it is blackish, but semitransparent when in thin plates. By all these observations it appears very plainly, that propolis is a true genuine vegetable resin, of the nature of many others which we have in common use. The authors who have treated of this substance, have described it very differently; George Pictorius, who has written of bees, says that it is of a yellow colour, and an agreeable smell, like that of storax, and that it would spread when warmed properly. Pliny and the old authors describe it as being of a rank and strong smell, and being used as a succedaneum for galbanum, and at present we usually find it of an aromatic and agreeable smell, resembling that of melilot, and balsam of Peru, or of the Banana poplar, insomuch that some rank it among the perfumes. The apothecaries, in some places, keep it as a medicine in their shops; but it is to be observed, that it is very various in its nature; for, according to the description of authors, it is sometimes sweet and sometimes stinking. The truth is, that the bees, who collect it as a thing to be used for a cement, not for food, are not over-curious what plants they gather it from; and hence in different hives it is found of very different colours and consistencies. In general, the propolis is of a brownish-

red colour on the surface; the red sometimes predominating, sometimes the brown; but when broken it is yellowish, or approaching to the colour of wax. It very readily dissolves in spirit of wine or oil of turpentine; and this solution is of a fine gold colour, and will serve extremely well as a varnish to colour silvered picture-frames, or other the like work, into the appearance of gold. It gives a fine gold-like appearance, indeed, to any white metal of a polished surface; all that it wants is a little more brilliancy, which is easily given it by mixing a small quantity of mastich, or of sandarach, in the solution.

It is the general opinion of those who have studied bees, that the willow and the poplar are the trees which principally furnish them with this resin, which, when it has passed through their management, we call propolis. It is very certain, however, that these are not the only trees which afford it, since the bees are not found to want this necessary material for their work, in places where there are no trees of that kind in the neighbourhood of the hives.

Mr. Thorley declares, as he tells us likewise upon the fullest evidence, that the combs, both in their foundation and superstructure, are framed of nothing but pure wax. Besides the uses of the propolis already mentioned, there is another very singular one, which must by no means be passed over in silence; this is the embalming and preserving, by means of it, certain bodies which they know not how to dispose of otherwise. Notwithstanding the care that the bees take to guard the entrance of their hives, enemies of one kind or other will often get in: these usually fare very ill; for the bee's sting is a weapon very capable of punishing such an intrusion, and the swarm is so numerous, that it is not easy for the intruder to escape repeated wounds. When a creature of small size has thus entered, and thus been killed for it, the bees with great care and pains carry him out; for they will bear no sort of foulness in the hive. It sometimes happens, however, that an unlucky snail, particularly of the large naked kind, crawls into the hive; in this case he never ceases crawling over the combs so long as he lives. It is no wonder that such cleanly creatures as the bees are highly enraged at this nasty visitor; they soon surround and kill him with their stings; but then as he is a load too heavy to allow a possibility of their carrying him out, they prevent the mischief attending the stinking of the carcase, by covering it over with a thick coat of this propolis, which perfectly well preserves it from putrefaction.

The common garden snail, with the shell, sometimes also visits these industrious and cleanly animals; and this creature they secure in a different manner, and that at the expence only of a very small quantity of the propolis: but Reaumur had an opportunity of observing the method of destroying this enemy in a very accurate and easy manner, in one of his glass hives. The snail had entered the hive early in the morning, and after crawling about for some time, had fixed itself to one of the glass squares by the same glutinous matter, by means of which it is frequently found fixed to old walls and trees; when the bees found their enemy thus fixed, they surrounded him, and in a few minutes formed a border of propolis round the verge of the mouth of the shell: to this they continually added more and more, till they had formed so thick a coat round it, that the snail could never move from the place again.

The snail is easily able to loosen the fastening which it gives itself to any place, because this is done by means of a gum, which water will dissolve; therefore the first shower of rain, or the moisture which the animal is able

to secrete from its own body, releases it in this case ; but the fastening which the bees use to fix the shell to the glass being a resin, this remains untouched by water, and must keep the animal fixed in its place till death, and even long afterwards. Reaumur's Hist. Inf. vol. x. p. 77, &c.

Mr. Thorley observes, that he has frequently seen snails, within the boxes and at the back-window, moving about, changing their situation, and continuing at times for several days together, but not so much as a single bee assaulting the offensive animal, or offering the least resistance, but, on the contrary, shunning or flying from him. He adds, that he has often observed snails coming out of the colonies, in no respect hurt or wounded, but in full health and vigour. Thorley's Enquiry, &c. p. 136.

It seems probable, that the bees are not over-curious in the choice of the matter of the propolis ; but that many vegetable resins indifferently serve for this purpose : it has been tried, however, whether they would use common turpentine, and some other of the resins in use among us by laying them before their hives ; but without success. This is an experiment, however, that requires frequent repetition ; since there are many seasons at which the bee has no occasion for this matter.

The propolis is by some esteemed sovereign in diseases of the nerves. It is also used to make holes in abscesses ; and being heated on the fire, its vapour is received for inveterate coughs.

M. Vauquelin has analysed this substance. For this purpose 100 grammes of it were digested, for twenty-four hours, in very pure alcohol. The liquor acquired a deep red tint ; and was thus filtered. Fresh spirit of wine was put to the residue, and left to digest again in the cold during twenty-four hours. As it had gained but little colour, a third quantity of alcohol was added to the marc, then boiled for a few minutes : and filtered quite hot. Six portions of alcohol were successively added to the marc and boiled : finally, to deprive it of the fat matters it retained from fragments of bees, as well as some vegetable substances and grains of sand, boiling sulphuric ether was poured on it, and the mass was pressed through a fine strainer. The residue dried, weighed 14 grammes.

To obtain the substance which had been dissolved by the alcohol, the whole quantity that had been employed in the different washings was collected, and passed through a fine strainer, which stopped all the matter precipitated by the cold. This residue was wrapped in unsized paper and pressed ; when dried and melted, it weighed 14 grammes.

All the alcohol was then distilled and reduced to three-fourths of its quantity. The liquor which came over had an aromatic odour ; but it did not render water turbid, nor was it acid. What remained in the retort was of a deeper colour. Its precipitate by water was ropy, like the resins which are obtained by the same means. By diluting this liquor with water and boiling it, a resiniform mass was obtained, on cooling, of a red-brown colour, semi-transparent, and very brittle, which weighed 57 grammes. The water in which this matter had been dissolved, contained an acid.

This resinous mass, or pure propolis, melts readily on the fire : it yields by distillation a volatile oil, white and of a very agreeable smell. The fixed part then acquires a deeper colour and becomes harder : it is soluble in fixed and volatile oils. It is a true resin, very similar to balsam of Peru, of which it contains the acid.

The 14 grammes of precipitate produced by cooling, were true wax, possessing all its properties. It remains to be known whether this wax is actually mixed with the pro-

polis by the bees ; or whether, in collecting the latter with too little care, the wax is not united to the resin.

PROPOMA, a name given by the ancients to a potion prepared of honey and wine boiled together : the proportions were four parts of wine to one of honey.

PROPORTION, PROPORATIO, in *Arithmetic*, the identity or similitude of two ratios.

Hence quantities that have the same ratio between them, are said to be proportional ; *e. gr.* if A be to B, as C to D ; or 8 be to 4, as 30 to 15 ; A, B, C, D, and 8, 4, 30, and 15, are said to be in proportion, or are simply called proportionals.

Proportion is frequently confounded with ratio ; yet the two have, in reality, very different ideas, which ought by all means to be distinguished.

Ratio is properly, that relation or habitude of two things, which determines the quantity of one from the quantity of another, without the intervention of any third ; thus we say, the ratio of 5 and 10 is 2 ; the ratio of 12 and 24 is 2.

Proportion is the sameness or likeness of two such relations ; thus the relations between 5 and 10, and 12 and 24, being the same, or equal, the four terms are said to be in proportion. Hence ratio exists between two numbers ; but proportion requires at least three.

Proportion, in fine, is the habitude or relation of two ratios, when compared together ; as ratio is of two quantities. See RATIO.

Proportion again is frequently confounded with progression. In effect, the two often coincide : the difference between them only consists in this, that progression is a particular species of proportion ; in which the second of the three terms is a mean proportional between the other two, or has the same ratio to the third, which the first has to the second.

Add to this, that proportion is confined to three terms, but progression goes on to infinity (so that progression is a series or continuation of proportions) ; and that in four terms, 3, 6, 12, 24, proportion is only between the two couples 3 and 6, and 12 and 24 ; but the progression is between all the four terms. See PROGRESSION.

Proportion, as Dr. Clarke has shewn in his correspondence with Leibnitz (see his "Works," vol. iv. p. 681, fol. 1), is sometimes confounded with quantity. Proportions, he says, are not quantities, but the proportions of quantities. If they were quantities, they would be the quantities of quantities, which is absurd. Also, if they were quantities, they would (like all other quantities) increase always by addition : but the addition of the proportion of 1 to 1, to the proportion of 1 to 1, makes still no more than the proportion of 1 to 1 ; and the addition of the proportion of $\frac{1}{2}$ to 1, to the proportion of 1 to 1, does not make the proportion of $1\frac{1}{2}$ to 1, but the proportion only of $\frac{1}{2}$ to 1. That which mathematicians sometimes inaccurately call the quantity of proportion is (accurately and strictly speaking) only the quantity of the relative or comparative magnitude of one thing with regard to another ; and proportion is not the comparative magnitude itself, but the comparison or relation of the magnitude to another. The proportion of 6

to 1, with regard to that of 3 to 1, is not a double quantity of proportion, but the proportion of a double quantity, and in general, what they call "bearing a greater or less proportion, is not bearing a greater or less quantity of proportion or relation," but "bearing the proportion or relation of a greater or less quantity to another:" it is not a greater or less quantity of comparison, but the comparison of a greater or less quantity. Thus, also, the logarithmic expression of a proportion is not (as Leibnitz styles it) a measure, but only an artificial index or sign of proportion: it is not the expressing of a quantity of proportion, but barely a denoting of the number of times that any proportion is repeated or complicated. The logarithm of the proportion of equality is 0; and yet it is as real and as much a proportion, as any other: and when the logarithm is negative, as $\bar{1}$, yet the proportion of which it is the sign or index, is itself affirmative. Duplicate or triplicate proportion does not denote a double or triple quantity of proportion, but the number of times that the proportion is repeated. The tripling of any magnitude or quantity *once* produces a magnitude or quantity, which to the former bears the proportion of 3 to 1. The tripling it a *second* time produces (not a double quantity of proportion, but) a magnitude or quantity, which to the former bears the proportion (called *duplicate*) of 9 to 1. The tripling it a *third* time produces (not a triple quantity of proportion, but) a magnitude or quantity, which to the former bears the proportion (called *triplicate*) of 27 to 1, &c.

Proportion is said to be *continual*, when the consequent of the first ratio is the same with the antecedent of the second; as, if 3 be to 6, as 6 to 12.

The proportion is said to be *discrete*, or interrupted, when the consequent of the first ratio differs from the antecedent of the second; as, if 3 be to 6, as 4 to 8.

Proportion, again, is either said to be *arithmetical*, or *geometrical*; as the ratios are.

PROPORTION, *Arithmetical*, is the equality of two or more arithmetical ratios, or the equality of difference between three or more separate quantities.

Thus, 1, 2, 3, and 2, 5, 8, 11, 14, are in arithmetical proportion; because there is the same difference betwixt the numbers compared, which are 1 to 2, and 2 to 3; or 2 to 5, and 5 to 8, &c.

If every term have the same ratio to the next, as the first has to the second, the terms are said to be in continual arithmetical proportion; as 5, 7, 9, 11, 13, 15.

If the ratio between any two terms differs from that of any others, the terms are said to be in arithmetical proportion discrete, or interrupted; as where 2 : 5 :: 6 : 9, the ratios of 5 and 6 being different from that of 2 and 5.

A series of more than four terms in arithmetical proportion, forms an arithmetical *progression*; which see.

1. If three numbers be in arithmetical proportion, the sum of the extremes is equal to double the middle term: thus, in 3, 7, 11, the sum of 3 and 11 is equal to twice 7, *viz.* 14.

Hence we have a rule for finding a mean arithmetical proportional between two given numbers; half the sum of the two being the mean required: thus, half the sum of 11 and 3, *viz.* 14, is 7.

2. If four numbers be in arithmetical proportion, the sum of the extremes is equal to the sum of the middle terms: thus, in 2 : 3 :: 4 : 5, the sum of 5 and 2 is equal to the sum of 3 and 4, *viz.* 7.

Hence, four terms in arithmetical proportion are still proportional, if taken inversely, 5 : 4 :: 3 : 2; or alternately,

thus, 2 : 4 :: 3 : 5; or inversely and alternately, thus 5 : 3 :: 4 : 2.

3. If two numbers in arithmetical proportion be added to other two, the less to the less, &c. their difference is in a duplicate ratio, *i. e.* double that of the respective parts added: thus, if to 3 : 5 be added 7 : 9, the sums are 10 : 14; whose difference 4, is double the difference of 3 : 5, or 7 : 9. And if to this sum you add other two, the difference of the last sum will be triple the sum of the first two, and so on.

If two arithmetical proportionals be subtracted from two others in the same ratio, the less from the less, &c. the arithmetical ratio of the remainder is 0. Thus, from 9 : 7 taking 5 : 3, the remainders are 4, 4.

Hence, if arithmetical proportionals be multiplied by the same number, the difference of their products will contain the first difference as oft as the multiplier contains unity: thus, 3 : 5, multiplied by 4, produce 12, 20, whose difference 8 is equal to 4 times 2, the difference of 3 and 5.

4. If two numbers in arithmetical proportion be added to, or multiplied by other two in another ratio of the same kind, less by less, &c. the sums are in a ratio which is the sum of the ratios added or multiplied: thus 2 : 4 and 3 : 9 being added, the sums are 5 : 13, whose difference is 8, the sum of 2 and 6, the difference of the numbers given.

PROPORTION, *Geometrical*, is the equality of two geometrical ratios, or comparisons of two couples of quantities.

Thus 4 : 8 :: 12 : 24, are in geometrical proportion; the ratio of 4 and 8 being equal to that of 12 and 24; *i. e.* 4 is contained as often in 8 as 12 is in 24. Again, 9, 3, 1, are in geometrical proportion, 9 being triple of 3, as 3 is of 1.

If, in a series of terms, there be the same ratio between every two terms, that there is between the first and second, they are said to be continual geometrical proportionals; as 1 : 2 :: 4 : 8.

If any two terms have a different ratio from that of the first and second, they are said to be in a disjunct, or interrupted geometrical proportion; as are 2 : 4 :: 3 : 6; where 2 is to 4, as 3 to 6; but not so as 4 to 3.

A series of progression of more than four geometrical proportionals is called a geometrical *progression*; which see.

1. If three quantities be in continual geometrical proportion, the product of the two extremes is equal to the square of the middle term: thus, in 6 : 12 :: 12 : 24, the product of 6 and 24 is equal to the square of 12, *viz.* 144. Hence we have a rule,

2. To find a mean geometrical proportional between two numbers, *e. gr.* 8 and 72.

Multiply one of the numbers by the other, and from the product 576, extract the square root 24; this will be the mean required.

3. To find a fourth proportional to three given numbers, *e. gr.* 3, 12, 5; or a third proportional to two given numbers.

Multiply the second 12 into the third 5, in the first case; and in the latter multiply the second into itself; divide the product by the first 3, the quotient 20 is the fourth proportional sought in the one, or the third in the other.

The solution of this problem is what we popularly call the *rule of proportion*, or the *golden rule*, or *rule of three*.

4. If four numbers be in geometrical proportion, the product of the extremes is equal to the product of the two middle terms: thus, in 2 : 5 :: 4 : 10, the product of 10 and 2 is equal to that of 5 and 4; *viz.* 20. Hence,

5. If four numbers represented by $a : b :: c : d$, be either

in arithmetical or geometrical proportion; they will also be in the same, if taken inversely, *viz.* $d:c::b:a$; or alternately, as $a:c::b:d$; or alternately and inversely, as $d:b::c:a$.

6. If the two terms of a geometrical ratio be added to, or subtracted from other two in the same ratio, the less to or from the less, &c. the sums or differences are in the same ratio: thus in $6:3::10:5$, where the common ratio is 2, 6, added to 10, makes 16, as 3 to 5 makes 8; and $16:8$ is in the same ratio as $6:3$, or $10:5$. Again, if 16 be to 8 as 6 to 3, their differences 10 and 5 are in the same ratio.

The reverse of which proposition is likewise true; *viz.* if to or from any two numbers be added or subtracted other two, if their sums or differences be in the same geometrical ratio as the first two, the numbers added or subtracted are in the same ratio. Hence,

7. If the antecedents, or the consequents, of two equal geometrical ratios, $3:6$, and $12:24$, be divided by the same 3; in the former case, the quotients 1 and 4 will have the same ratios to the consequents, *viz.* $1:6::4:24$; and in the latter, the antecedents will have the same ratio to the quotients, *viz.* $3:1::12:4$.

8. If the antecedents or consequents of similar ratios, $2:6$, and $3:9$, be multiplied by the same quantity 6; in the former case, the facta 12 and 18 have the same ratio to the consequents, *viz.* $12:6::18:9$; and in the latter, the antecedents have the same ratio to the products, *viz.* $2:36::3:54$.

9. If in a geometrical proportion $3:6::12:24$, the antecedents be multiplied or divided by the same number 2, and the consequents be multiplied or divided by the same number 3; in the former case, the facta, in the latter, the quotients, will be the same proportion, *viz.* $6:18::24:72$, and $1:3::4:12$.

10. If in a proportion $4:2::10:5$, the antecedent of the first ratio be to its consequent, as the antecedent of the second to its consequent; then by composition, as the sum of the antecedent and consequent of the first ratio is to the antecedent or consequent of the first, so is the sum of the antecedent and consequent of the second to the antecedent or consequent of the second; *viz.* $6:2::15:5$, or $6:4::15:10$.

11. If in a proportion $6:4::15:10$, as the antecedent of the first ratio is to its consequent, so is the antecedent of the other to its consequent; then, by division, as the difference of the terms of the first ratio is to its antecedent or consequent, so is the difference of the terms of the second ratio to its antecedent or consequent, *viz.* $2:4::5:10$, or $2:6::5:15$.

12. If in a proportion $4:2::6:3$, as the antecedent of the first ratio is to its consequent, so is the antecedent of the second to its consequent; and as the consequent of the first ratio is to another number 8, so is the consequent of the second to another number 12; *viz.* $2:8::3:12$; then will the antecedent of the first be to 8, as the antecedent of the second to 12, *viz.* $4:8::6:12$.

13. If in a proportion $8:4::12:6$, as the antecedent of the first ratio is to its consequent, so is the antecedent of the second to its consequent; and as the consequent of the first ratio is to another number 16, so is another number 3 to the antecedent of the second, *viz.* $4:16::3:12$; then will the antecedent of the first be to 16, as 3 to the consequent of the second, *viz.* $8:16::3:6$.

14. Suppose any four proportional quantities, *viz.* $3:6::12:24$; and any other four proportional quantities, $1:3::9:27$; if you multiply the several terms of the latter into

those of the former, the products will likewise be proportional, *viz.* $3:18::108:648$.

15. If there be several quantities continually proportional, A, B, C, D, &c. the first A is to the third C, in a duplicate ratio; to the fourth D, in a triplicate ratio, &c. of the first A to the second B.

16. If there be three numbers in continual proportion, the difference of the first and second will be a mean proportional between the difference of the first and second term, and the difference of the second and third, and the first term.

PROPORTION, in *Musick*, equality between two ratios. There are four kinds of proportion: arithmetical, geometrical, harmonical, and contra-harmonic. In order to comprehend all these proportions, it is necessary to understand the calculations with which authors have loaded the theory of music.

PROPORTION, *Harmonical* or *Musical*, is a third kind of proportion formed out of the other two, thus: of three numbers, if the first be to the third as the difference of the first and second to the difference of the second and third; the three numbers are in harmonical proportion.

Thus 2, 3, 6, are harmonical, because $2:6::1:3$. So also four numbers are harmonical, when the first is to the fourth as the difference of the first and second to the difference of the third and fourth.

Thus 24, 16, 12, 9, are harmonical, because $24:9::8:3$. By continuing the proportional terms in the first case, there arises an harmonical progression, or series.

1. If three or four numbers in harmonical proportion be multiplied or divided by the same number, the products or quotients will also be in harmonical proportion: thus, if 6, 8, 12, which are harmonical, be divided by 2, the quotients 3, 4, 6, are also harmonical; and reciprocally their products by 2, *viz.* 6, 8, 12.

2. To find an harmonical mean between two numbers given; divide double the product of the two numbers by their sum, the quotient is the mean required; thus suppose 3 and 6 the extremes, the product of these is 18, which doubled, gives 36; this divided by 9 (the sum of 3 and 6), gives the quotient 4. Whence 3, 4, 6, are harmonical.

3. To find a third harmonical proportional to two numbers given.

Call one of them the first term, and the other the second; multiply them together, and divide the product by the number remaining after the second is subtracted from double the first: the quotient is a third harmonical proportional: thus, suppose the given terms 3, 4, their product 12 divided by 2 (the remainder after 4 is taken from 6, the double of the first), the quotient is 6, the harmonical third sought.

4. To find a fourth harmonical proportional to three terms given: multiply the first into the third, and divide the product by the number remaining after the middle or second is subtracted from double the first; the quotient is a third harmonical proportional: thus supposing the numbers 9, 12, 16, a fourth will be found by the rule to be 24.

5. If there be four numbers disposed in order, of which one extreme and the two middle terms are in arithmetical proportion; and the same middle terms, with the other extreme, are in harmonical proportion, the four are in geometrical proportion: as here, $2:3::4:6$, which are geometrical; of which, 2, 3, 4, are arithmetical, and 3, 4, 6, harmonical.

6. If betwixt any two numbers you put an arithmetical mean, and also an harmonical one, the fourth will be in geometrical proportion: thus, betwixt 2 and 6, an arithmetical

mean is 4, and an harmonical one 3; and the four 2 : 3 :: 4 : 6, are geometrical.

We have this notable difference between the three kinds of proportion; that from any given number we can raise a continued arithmetical series increasing *in infinitum*, but not decreasing; the harmonical is decreasable *in infinitum*, but not increasable; the geometrical is both.

PROPORTION, *Contra-harmonical*. See CONTRA-HARMONICAL.

PROPORTION, *Extreme and Mean*. See EXTREME.

PROPORTION, *Inordinate*. See INORDINATE.

PROPORTION, *Reciprocal*. See RECIPROCAL.

PROPORTION *of Equality*. See EQUALITY.

PROPORTION, *Composition of*. See COMPOSITION.

PROPORTION, *Rule of*. See RULE.

PROPORTION, *Terms of*. See TERM.

PROPORTION is also used for the relation between unequal things of the same kind, by which their several parts correspond to each other with an equal augmentation, or diminution.

Thus, in reducing a figure into little, or enlarging it, care is taken to observe an equal diminution, or enlargement, through all its parts; so that if one line, *e. gr.* be contracted by one-third of its length, all the rest shall be contracted in the same proportion.

The making of reductions of this kind is the great use of the proportional compasses.

PROPORTION, in *Law*. See PRO RATA and ONE-RANDA.

PROPORTION, in *Architecture*, denotes the just magnitude of the members of each part of a building, and the relation of the several parts to the whole; *e. gr.* of the dimensions of a column, &c. with regard to the ordonnance of the whole building.

One of the greatest differences among architects, M. Perrault observes, is in the proportions of the heights of entablatures with respect to the thickness of the columns, to which they are always to be accommodated. See ENTABLATURE.

In effect there is scarcely any work, either of the ancients or moderns, in which this proportion is not different; some entablatures are even nearly twice as high as others; yet it is certain, this proportion ought of all others to be most regulated: none being of greater importance, as there is none in which a defect is sooner spied, nor any in which it is more shocking.

PROPORTION is likewise understood of the magnitudes of the members of architecture, statues, or the like, with regard to the distance whence they are to be viewed.

The most celebrated architects are much divided in their opinions on this subject; some will have it, that the parts ought to be enlarged in proportion to their elevation; and others, that they ought to remain in their natural dimensions. See STATUE.

PROPORTION, in *Painting*, is the just magnitude of the several members of a figure, a group, &c. with regard to one another, to the whole figure, the group, and the entire piece.

Proportion makes one of the most important articles in the art of painting, the principal subject it is employed in being the human body: for which reason, the curious in that art will not be displeas'd with the following scheme of the rules and laws of it.

By the way let it be observed, 1. That to measure and set off proportions, they either divide the module into twelve parts, and subdivide each of these into four; or else they divide the face into three lengths of the nose, subdivi-

ding each length into twelve; or, lastly, divide the whole face into three, and subdivide each of those into four; which last method is what we shall here follow.

2. That the multiplicity of little measures is to be studiously avoided, because they confound, and because they require great skill in osteology to hit justly.

3. That in measuring there be a regard had to the relief or juttings out of figures.

PROPORTION, *Rules of*. In the proportions of the human figure, regard is had to the *age, sex, and quality*. See FACE.

As to *age*, we consider the stages of it, infancy, youth, and manhood. For the first, at three years of age, we count five lengths of the face from top to toe; *viz.* from the tip of the head to the bottom of the belly, three; thence to the foot, two; breadth about the shoulders, one face one-eighth; and in the place of the hips, one face.

At four years, the height is six faces one-third; *viz.* from the top of the head to the bottom of the belly, three faces one-third; thence to the sole of the foot, three faces; the breadth about the shoulders, one face two-thirds; about the haunches, one face one-third.

At five years, the height of six faces one-half, one-third abated, the lower being shorter.

In youth, at twelve years, we have two proportions; the one from nature, which gives nine faces for the height; for the breadth about the shoulders, two faces; about the haunches, one face one-third; the other from the antique statues, as that of Laocoon, &c. which gives the height, ten faces one-half; the breadth from one shoulder to another, one face two-thirds; at the haunches one face two-thirds; at the place of the muscle called *vastus externus*, two; at the thigh, one; the knee, two-thirds and one-half, a subdivision; and at the ankles, one-third.

In the state of manhood, when the proportions are arrived at perfection, we reckon the height ten faces; the first, from the top of the head to the nostril; the second, to the hole in the neck between the clavicles; the third, to the pit of the stomach, called *cartilago ensiformis*; the fourth, to the navel; the fifth, to the pyramidal muscles; thence to the knee, two faces two-thirds; and as much to the sole of the foot. The extent of the arms is the same with the height; *viz.* from the tip of the long finger to the joint of the wrist, one face; thence to the elbow, one face one-third; thence to the juncture of the shoulders, one face one-third; thence to the hole in the neck, one face one-third; in all, five heads: which, with the five of the other arm, give ten: the thickness of the arms to be adjusted by the quality or character.

As to the breadth of the figure seen frontwise, the width of the shoulders across the deltoides is two faces two-thirds; breadth of the pectoral muscle, to the juncture of the arm, two. About the haunches, where the obliqui externi are, one face two-thirds, and the subdivisions. The thighs, at the biggest place, one. The knee one-third, three subdivisions one-half. The leg, at the thickest, two-thirds, and one subdivision. The extreme of the ankle one-third, one subdivision one-half. The feet, one-third, and one-half a subdivision. Their length, one face one-third, one subdivision. Others, measuring by the length of the whole head, make only eight heads in height and breadth, thus; the head, one; thence to the bottom of the breasts, one; thence to the navel, one; thence to the yard, one; thence to the middle of the thigh, one; thence to the lower part of the knee, one; thence to the small of the leg, one; thence to the bottom of the foot, one.

The breadth thus: from the end of the long finger to the wrist,

wrist, one; thence to the bend of the arm, one; thence to the bottom of the shoulder, one; thence over to the other shoulder, two; thence to the end of the other long finger, three.

To these general proportions may be added others, which usually obtain; as, that the hand is to be of the length of the face, the thumb the length of the nose; and the great toe the same; the two nipples, and the hole in the neck, make a just equilateral triangle; the space between the eye is the breadth of an eye; the breadth of the thigh, at the thickest, is double that of the thickest part of the leg, and treble that of the smallest: from the top of the head to the nose, the same as from the top of the nose to the chin. The distance from the chin to the throat-pit, is the breadth of the throat; the distance of the centre of the eye to the eye-brow, the same as the prominence of the nostrils, and the space between them and the upper lip; the length of the fore-finger the same as the space thence to the wrist; the space from the tip of the fore-finger to the wrist, the length of the face.

For the *sex*, the proportions of man and woman differ in height, in that the woman has a longer neck; the parts at the breasts, and the lower parts of the belly, bigger by half a part; which makes the space from the breast to the navel less by one part; and the thigh shorter by a third part.

As to breadth, a woman hath her breasts and shoulders narrower, and her haunches larger; and thighs, at the place of their articulation, larger; arms and legs thicker, feet straighter; and because women are more fat and fleshy, their muscles are less seen, and therefore the contours are more smooth and even.

Young maids have little heads, long necks, low or down shoulders, slender bodies, haunches big, legs and thighs long, feet little.

Young men have the neck thicker than women, the shoulders and breasts larger, the belly and haunches narrower, legs and thighs slenderer, and feet larger.

As to the *quality* of subjects, we are either to follow simple nature, or fine and agreeable nature, or to choose nature, or exceed it. In following *simple* nature, in common and country subjects, men of dull wit, and a moist temperament, are to be of a heavier and rougher proportion, the muscles appearing but little distinguished, the head big, neck short, shoulders high, stomach little, knees and thighs thick, and feet large.

In nature, as *fine* and *agreeable*, for serious histories, &c. the figures of the heroes to be well shaped, the haunches high and upright, the joints well knit, little, and compact, and free from flesh and fat.

Military men are to have their head little, neck thick and nervous, shoulders large and high, body and paps elevated, haunches and belly little, thighs muscular, principal muscles raised up and knit together at the heads; the legs smooth, feet slender, soles hollow.

Nature is sometimes to be *selected*, *i. e.* made up of parts from various good originals, to form extraordinary and perfect figures for great and heroic subjects; as in Roman histories; giving, thus, a character of force sufficient to execute actions agreeable to the description the poets, &c. make.

Lastly, sometimes nature is to be *exceeded*, as in representations of fabulous deities, of heroes and giants: in these the great pieces, which serve to form the body, are to be set out in measures agreeable to the height; only diversifying them by the bigness.

In the rule of proportions, it is to be observed, that there is a difference in the contours of some parts, when put in different postures: thus, when the arm is bent, it is larger than when straight; and the same is true of the foot and knee, as is shewn by Leonardo da Vinci.

PROPORTION, *Rule of*, in *Arithmetic*, a rule whereby we find a fourth proportional to three numbers given.

This is popularly called the *golden rule*, and sometimes the *rule of three*.

PROPORTION, *Compass of*, a name by which the French, and after them some English authors, call the *sector*. See its construction and use under the article SECTOR.

PROPORTIONS, *Definite*, in *Chemistry*, the limited proportions in which the elementary bodies combine, to form compound bodies.

When the constituents of any compound are presented to each other under the most favourable circumstances, they are found to unite in certain definite proportions. If one of the elementary bodies be in excess, the proportions of the compound will not be varied, except by some definite quantity. The excess will always be found distinct from the compound. When metallic zinc is added to sulphuric acid and water, the oxyd of zinc, formed at the expence of the water, continues to be dissolved by the acid to a certain point, beyond which no more of the metal will be dissolved, whatever quantity may be present. If to a given quantity of nitric or muriatic acid, lime be added from time to time, the lime will be dissolved in the acid, forming a transparent solution. This, however, can go on only to a limited extent. Beyond this point, if more lime be added, it will fall to the bottom of the vessel, and will not be changed. If oxygen and hydrogen gases be mixed in any other proportions by volume, than one of the former to two of the latter, and exploded by the electric spark, the excess of the one will remain unchanged in its gaseous form. Numerous examples might be quoted to shew the truth of this law of mutual saturation, while very few, if any, can be adduced to prove the contrary. This law is found to be more conspicuous where the strength of chemical affinity is great, as in the oxydation of metals, and the formation of salts.

It is rather remarkable, that chemists, with so many facts before their eyes, have frequently adopted a loose language, completely at variance with all these facts. We often read in chemical books, of salts having slight excesses of acid or base, and of metals oxydated by slight degrees; at the same time that they were aware, agreeably to the general opinion, that each of the salts afforded an uniform analysis, under whatever circumstances they were formed, and that each of the metals had a determined number of oxyds, in each of which the doses of oxygen were uniform.

No one seems to have investigated this important branch of chemical science, till the cause of limited proportions began to be sought for. We may with great truth assert, that twenty years ago no chemist had an idea that the proportions of compound bodies would ever be obtained with more accuracy than is afforded by analysis. We may see, that Bergman and Black were aware that bodies combined in limited doses or proportions. Richter adopted numbers to express the quantities of each of the acids to saturate a given quantity of base. Mr. Higgins of Dublin, in a work entitled "A Treatise on Phlogiston," makes use of the language of atoms, or particles, in a way that proved he had a clear idea of the laws of definite proportions, but not to a greater extent than was known to Bergman and Black. So little had he any idea of its real importance, that he does not even dwell in particular upon it; so that nothing more is known

PROPORTIONS.

known of his opinions, than what is gathered from the language used to shew the inconsistency of the phlogistic theory. In some parts of his work he adopts a language very discordant with the laws of limited proportions, so much so, that if it had been found that bodies unite in any proportion, Mr. Higgins might have had an equal claim to prior discovery.

What had hitherto been done in the theory of definite proportions, did not admit of being used to any advantage in chemical science. Mr. John Dalton of Manchester was the first who gave it a systematic form. Richter, although he found that the relative quantities of the acids to saturate a given quantity of base might be expressed by numbers, did not seem to be aware, that all bodies susceptible of combination might be expressed by numbers, which would determine the ratios of the component parts. This theory, which has been strongly confirmed by facts, is as important in chemical science, as a knowledge of the laws of motion is to mechanical science.

It is worthy of remark, that many of our modern discoveries have been anticipated by the comprehensive mind of sir Isaac Newton. In the latter part of the 31st query to his Optics, at a time when so little was known of chemistry, he not only points out and develops the laws of chemical affinity, but he lays the foundation of the theory since discovered by Dalton, and to a certain extent embraced by the most eminent chemists of the present day. The passage is so remarkable, that we feel justified in giving a quotation of the most striking part.

After speaking of the laws of chemical attraction, he proceeds as follows (page 375.): "All these things being considered, it seems probable to me, that God in the beginning formed matter in solid, massy, hard, impenetrable, moveable particles, of such sizes and figures, and with such other properties, and in such proportion to space, as most conduced to the end for which he formed them; and these primitive particles being solids, are incomparably harder than any porous bodies compounded of them; even so very hard as never to wear or break in pieces: no ordinary power being able to divide what God himself made one in the first creation. While the particles continue entire, they may compose bodies of one and the same nature and texture in all ages; but should they wear away or break in pieces, the nature of things depending upon them would be changed. Water and earth composed of old worn-out particles, and fragments of particles, would not be of the same nature and texture now with water and earth composed of entire particles in the beginning. And, therefore, that nature may be lasting, the changes of corporeal things are to be placed only in the various separations and new associations and motions of these permanent particles, compound bodies being apt to break, not in the midst of solid particles, but where those particles are laid together, and only touch in a few points."

Although sir Isaac Newton, with mathematicians in general, might conceive the infinite divisibility of matter, he seems to have been well aware, that in nature its divisibility is limited to the hard and impenetrable atoms to which he alludes in the above quotation. The idea of atoms which are hard and unchangeable appears very plausible, even in the aggregation of a mass of simple matter. We cannot well account for the change of volume from change of temperature, without supposing the body to be constituted of atoms or particles, placed at different distances from each other, by the change of force existing in them, which is always the difference between the attraction of the atoms, and the repul-

sion of the caloric with which they are surrounded. How much more, however, the existence of definite atoms appears probable in the contemplation of a compound body. Nothing is more evident, than that the composition must commence with masses of the elementary matter of some magnitude. If their magnitude were to vary under different circumstances, and to any extent arising from the infinite divisibility of matter, there would not only arise an infinite number of compounds of the same elements, from a variety in their proportions, but we should find compound bodies to vary even with the same proportion of their elements, owing to a different size in the integrant particles. We find, however, in nature, that the proportions of bodies are definite, and we have no instance of compound bodies being different in their properties, when they afford the same analysis. Hence we have strong grounds to conclude with the great luminary of science, that matter is not infinitely divisible, and that all simple bodies consist of small masses, which are called atoms, beyond which divisibility is impracticable, and that in the composition of simple matter the union takes place between these primitive atoms only, and not between any other masses greater or less than them.

Mr. John Dalton, whose industry and patience can only be equalled by his ingenuity and profound thinking, began with the idea of primitive atoms, which combined with each other to form the different compounds. He supposes the simple atoms to be spherical, and that they can only combine 1 atom to 1, 1 to 2, 1 to 3, and so on; the number of atoms of one element being some multiple by a whole number of the atoms of the other: so that it would be absurd to suppose that an atom can be divided, or that 2 can unite with 3, 3 with 4, and so on. It is from this impossibility that the proportions of bodies are limited. We will endeavour to illustrate this theory by several examples. Hydrogen is found to enter into compounds in less proportion than any known element; hence it is concluded to be the least of all the atoms of the known simple matter. On this account Mr. Dalton has fixed its weight at 1, or unity. If, in the composition of water, which appears to be the only compound of oxygen and hydrogen, we call the hydrogen 1, we must call the oxygen 7. The latter is therefore used to express the relative weight of the atom of oxygen. In the analysis of the first oxyd of lead it is found to consist of 95 of lead, and 7 of oxygen, in 102 parts. It may be inferred that the relative weight of the atom of lead is 95, or 95 times heavier than hydrogen. Again, if galena, or the sulphuret of lead, which contains the least proportion of sulphur, afford on the analysis of 109 parts, 95 of lead, and 14 of sulphur, it is inferred that the atom of sulphur is 14 times heavier than hydrogen, and 14 will be therefore the number to represent the weight of an atom of sulphur. In burning carbon in oxygen gas, the bulk of the gas is not changed, but its specific gravity is increased from 14 to 19.4. This proves that the carbon, added to 14 of oxygen, to form carbonic acid, is 5.4. Hence the weight of the atom of carbon is rated by Mr. Dalton at 5.4. In like manner, the relative weights of the atoms of the other inflammable bodies may be found, knowing the quantity of oxygen with which they combine, and whether the oxyd contains the least proportion of oxygen. If the oxyd be the first oxyd, and the oxygen be 7, the weight of the inflammable base will be the number for its atom. If it be in the second stage of oxydation, then call the oxygen 14, and the weight of the inflammable base reduced to the same ratio will be the weight of the atom of the same. Of this we shall say more

PROPORTIONS.

more hereafter. We will now point out the inferences to be drawn from the above facts, which will at once develop the beauty and importance of the atomic theory, as laid down by Mr. Dalton. The numbers being found for hydrogen 1, oxygen 7, sulphur 14, lead 95, and carbon 5.4; it will follow, that the proportions in which oxygen and hydrogen unite to form water, are 7 to 1. Lead and oxygen, to form the protoxyd of lead, will be 95 to 7; to form the deutoxyd of lead, 95 to 2×7 . This will be obvious, since nothing less than a whole atom of oxygen, which is 7, can combine with an atom of lead; and hence the limitation of the proportions. We shall also see that lead cannot combine with sulphur, except in the proportions 95 to 14, 95 to 2×14 , and so on, since no less than 14 of sulphur can be added or combined with the lead. Carbonic oxyd contains the least proportion of oxygen, and since the atom of carbon, if oxygen be called 7, must be called 5.4, we are to conclude that no less than 7 of oxygen can combine with 5.4 of carbon: this forms the carbonic oxyd. The next portion of oxygen must be 7 more, which will give 5.4 to 2×7 . This gives the carbonic acid. All this was well known to chemists before the researches of Dalton, but he was the first to point out the means by which the composition of other compounds may be inferred, without the aid of experiment. The compounds we have just given are the results of experiment as regarding the least proportion, but the atomic theory will enable us to go farther. We have, in the above, for instance, no experimental data for the combinations of sulphur with oxygen, hydrogen, or carbon, nor for carbon with hydrogen. But it will be found that the numbers given will express the ratios of these compounds as correctly as those derived from experiment. For instance; sulphur, when combined with oxygen in the least proportion, will be 14 to 7; the next stage will be 14 to $2 + 7$, forming sulphurous acid; the third, 14 to $3 + 7$, which gives sulphuric acid. Sulphur, with hydrogen in the least proportion, will be 14 of sulphur to 1 of hydrogen, forming sulphuret of hydrogen. The compounds of carbon with sulphur will be 5.4 carbon to 14 of sulphur, the first compound; and 5.4 to 2×14 , for the second: the latter gives the component parts of the volatile liquid, formerly called alcohol of sulphur, and now properly called super-sulphuret of carbon.

It will appear from the above statement, that if by analysis we can obtain a number for each of the elementary bodies, which is only a distant approximation to the truth, these numbers will become corrected by trying them with all their different combinations, till they finally agree among themselves. This will fix the science of chemistry upon a mathematical basis. Experiment, which in chemistry was till lately considered the only test of truth, will be now considered as a rude approximation, minute accuracy depending upon calculation.

It will be obvious, that the number which will express the weights of the atoms of the compound bodies, will be equal to the sum of the weights of the elementary atoms. For instance, the weight of the atom of sulphuric acid will be 14 sulphur, added to 3×7 oxygen, equal to 35. In the same way, the weight of the atom of oxyd of lead will be 95 added to $7 = 102$. The sulphate of lead will now be formed by 35 of sulphuric acid, added to 102 of oxyd of lead, equal to 137, which is the weight of the atom of this salt.

In order to give greater clearness to this theory, Mr. Dalton has used symbols to represent the elementary atoms, which he combines together to make compound symbols

representing the compounds. The general character is a circle. The atoms are distinguished from each other by signs or letters placed within them. This method gives a much clearer idea of the constitution of bodies than can be conveyed by any language, particularly to those commencing the study of chemistry. Mr. Dalton's reason for using the circle as his general character is, from its near analogy to spherical particles of simple bodies. This idea holds good with binary and ternary compounds only; the quaternary compound being a tetrahedron, cannot be written upon paper, except by perspective representation. In the representation of a salt, the symbol could not at all represent the form of the geometrical solid which would be formed in nature, and therefore might as well be represented by some symbol in which the elementary symbols are more simple. For this purpose we would recommend, as the general character, the half of a square divided diagonally. The bodies are distinguished by figures within the half square of the inflammable bodies, that for oxygen being blank. If it should be confirmed that there are other bodies of the same class with oxygen, as is supposed by sir Humphry Davy, they may be represented by placing letters in the half square.

The atomic theory, as advanced by Dalton, was for some years treated almost with ridicule. Some agreed with him so far as it admitted the doctrine of definite proportions, but did not hold with him in the atomic hypothesis, as regarded his numbers being the ratios in which the elements existed in any compound, although it completely explained the well-known fact of the neutrality of two salts, after mutual or double decomposition. Among his strenuous opposers, sir Humphry Davy was not the least conspicuous. Previous, however, to writing his "Elements of Chemical Philosophy," he became a warm advocate for the doctrine of definite proportions, and adopted a set of numbers to express the relative proportions in which simple bodies combine.

What, however, is very strange, he denied the existence of definite atoms, or at least appeared to do so in some remarks which occur in his work. Yet he admits, that masses of some magnitude unite to form compounds, to which he gives the appellation of proportions. He uses this word precisely in the same sense in which Dalton uses the word atom, and if he had not particularly objected to this part of Dalton's theory, we should have thought he had entirely adopted it.

What does sir Humphry mean to convey by the word proportion, different from the idea conveyed by atom? Does he suppose that masses of different magnitudes, of the same simple matter, may unite to form a compound? This cannot be the case, since such data would establish the idea of an infinite number of compounds varying in their proportions, and an infinite number varying in their mechanical structure, from a difference in the magnitudes of the ultimate elementary masses. The idea of definite proportions cannot for a moment exist, without the admission of the fact, that compounds are never formed but by the union of atoms, which are unchangeable in their figure, weight, and dimensions. Nothing, therefore, can be more absurd, than to admit the doctrine of definite proportions, without admitting the existence of definite atoms.

The numbers of sir Humphry's proportions agree with Dalton's in a few instances only. They each make hydrogen unity. Sir Humphry, for reasons best known to himself, has doubled the weight of Dalton's oxygen, making it 15; and in order to make this agree with the combination of oxygen, he has nearly doubled the weights of the inflammable bodies. In order to make this arrangement explain the

PROPORTIONS.

the composition of water, he holds it to be composed of 2 atoms of hydrogen with 1 of oxygen, while Dalton holds them to be 1 to 1. His atom of azote, which is 26, is a little more than four times greater than Dalton's, which has obliged him to make nitric acid consist of 1 atom of azote and 5 of oxygen, and ammonia to consist of 1 atom of azote with 6 of hydrogen. It is difficult to imagine how so many atoms of hydrogen of such great elasticity should be retained upon an atom of azote, which has so little affinity for hydrogen. Dalton's atom of azote is 5, and he makes ammonia to consist of 1 atom of azote with 1 of hydrogen. His compounds of azote with oxygen are very simple, and agree with facts much better than by sir Humphry's numbers. Dalton's nitrous oxyd is formed by 2 atoms of azote with 1 of oxygen: his nitric oxyd by 1 of each. This explains the fact of nitrous oxyd being a heavier atom than nitric oxyd. Sir Humphry's numbers make nitrous oxyd the lightest of the compounds of azote with oxygen, which is inconsistent with fact.

Berzelius, a Swedish chemist, has established, by numerous experiments, the truth of the doctrine of definite proportions. He has given us a set of numbers almost entirely derived from his own facts. He, like sir Humphry, appears to reject the hypothesis of atoms, and makes use of the word volume in the same sense in which Dalton uses the word atom, and in which Davy uses the word proportion. His reason for adopting the word volume is founded on the pretended law of Gay Lussac, of gaseous bodies uniting in definite volumes. Hence Berzelius's numbers are the specific gravities of bodies in their gaseous form, under the same pressure. As for those bodies which do not assume the gaseous form at convenient temperatures, he determines the weight of their atoms by Dalton's method, and calls it the volume of the body, presuming, at the same time, that the same number would express the specific gravity of the body in the gaseous form. He begins his scale with oxygen, which he calls 100: that is, if any volume of oxygen be 100 in weight, the same volume of hydrogen will be 6.636; an equal volume of sulphur in the elastic form will be 201; a volume of phosphorus 167.512; one of arsenic 839.9, and of mercury 2531.6, and so on. Now, if all these bodies are capable of the elastic form at a moderate heat, it would, therefore, be important to know how far experiment would agree with this very ingenious idea. We see no reason why such an hypo-

thesis might not be defended, if there were no attraction between the particles of gases, and if their repulsion were uniform. This would occasion the distance of the particles to depend upon the pressure of the atmosphere, the particles would stand at equal distances from each other, and the specific gravity of equal volumes would be as the weight of the atoms.

It would also follow from this law, that the compounds in the gaseous form would possess a specific gravity, which would be equal to the sum of the specific gravities of these elementary gases. There are many striking facts in favour of this law, but there seem at present many insurmountable objections to it. Fortunately, to a certain extent, the subject is within the reach of experiment; and we are happy to learn it will soon be put to the test. Should this hypothesis completely agree with experiment, Berzelius can have no better ground than sir H. Davy for objecting to Dalton's doctrine of atoms. We can no more conceive how bodies should unite by volumes, than we can of any magnitude of one uniting to that of another. We have no instance of one grain or one ounce of one body uniting to any similar weight of another, to form a chemical compound. If the masses or volumes which unite were indefinite, the proportions could not be definite. It must, therefore, be the same ultimate atoms, to which Newton alludes, and which Dalton maintains, that enter into combination to form compounds, in order that the proportions may be limited. The atoms of Dalton, the proportions of Davy, and the volumes of Berzelius, must, therefore, be the same, so long as they all advocate the doctrine of definite proportions.

Dr. Thomson has given an account of the Daltonian theory in his Annals of Philosophy, in which he has made great alteration in certain numbers. This principally arises from his taking different authorities for the analysis of compounds. He has fixed the atom of oxygen at unity. His reasons for this are plausible. Oxygen enters into combination more frequently than any other of the elements, and it will be easier to add unity than any other number. If hydrogen were unity, oxygen would be a number much encumbered with decimals. Since the publication of the elementary numbers, Dr. Thomson has made some alterations, particularly in the atom of azote. We shall subjoin a table, exhibiting the numbers of Dalton, Davy, Thomson, and Berzelius.

TABLE of the relative Weights of Simple Atoms.

NAMES.	Symbols.	Elementary Numbers of				The same, Oxygen being 1.

Explanation of the Table.

The first column contains the names of the elementary bodies; the second, the symbols; the third, the numbers of Dalton, in which he considers hydrogen unity; the fourth column contains the numbers adopted by Davy, in which hydrogen is considered unity, and oxygen a little more than the double of Dalton's; in consequence of which, almost all the other elementary numbers have been also doubled. The fifth column contains the numbers proposed by Berzelius. He makes the number for oxygen 100. The sixth column contains the numbers proposed by Dr. Thomson. He fixes oxygen at unity: the rest of the numbers are derived from different authorities, and some from his own experiments.

The other three columns contain the numbers of Davy, Dalton, and Berzelius; the number for oxygen being reduced to unity.

These columns, with the sixth, serve to show how far the different authors agree. They will be found to correspond with sufficient exactness, to confirm the truth of the doctrine of definite proportions. It will be only by long comparing the elementary numbers with each other in the different compounds, that they can become perfectly correct. Analysis can only furnish a distant approximation to the truth of the numbers. Each elementary number will undergo greater correction, by tracing its progress through

all its combinations. In the four last columns it will be observed, that the numbers of one are sometimes about double that of another. This arises from a difference of opinion respecting the number of atoms combined. Berzelius conceives potash to be the second oxyd of potassium, and hence makes the number for potassium 9.78; while the others, who consider potash as the first oxyd, make the number to be 5, nearly half the former.

It must be observed, that some difference of opinion prevails among these philosophers, which it will be necessary to explain. The substance in the table called chlorine is held by sir Humphry Davy to be a simple body. Berzelius, and most other chemists, hold it to be a compound of what is called in the table muriatic radical and oxygen. The latter chemist is also of opinion, that azote is a compound of a peculiar base, which has been called *nitric radical* and oxygen. Davy's and Dalton's list do not contain the latter, nor do Dalton and Berzelius admit the chlorine of Davy into theirs. They are, however, all introduced into one column to save room.

Berzelius makes use of letters and figures, instead of arbitrary symbols, to express his simple and compound bodies. These will be more familiar to the reader than the characters of Dalton, or those we have proposed. We shall, therefore, omit giving any other than those of Berzelius. With these we shall give some examples of the compounds, according to the opinions of each of these philosophers. These

PROPORTIONS.

are exhibited in the following table. The first column contains the names of the compounds. The second, third, fourth, and fifth contain the symbolic representation of each body, according to the opinions of each of the above

philosophers. The figures which precede, or are placed over a symbol, express the number of atoms of Dalton and Thomson, the number of volumes of Berzelius, and the number of proportions of Sir Humphry Davy.

TABLE of Simple Compounds.

NAMES.	Symbolic Compounds of			
	Dalton.	Davy.	Thomson.	Berzelius.
Sulphurous acid - - -	S + 2 O	S + 2 O	S + 2 O	S + 2 O

Nitrate of potash - - -	2 AO ² + PoO	—	AO ³ + PoO	2 NO ⁶ + PoO ²
Carbonate of lime - - -	CO ² + CaO	—	CO ² + CaO	

The preceding table contains only a very few of the compound bodies. In the present state of chemistry it would be impossible to give all the compounds correctly, for want of facts relative to the number of atoms in each compound, particularly in the salts. We have given this table to shew the method of combining the elementary symbols to express the compounds. When the constitution of all the compounds is known, a general list of the compounds expressed in a similar form might be of great importance to practical chemists, as it would not only shew the number of atoms or doses in each compound, but the proportions of the elements in round numbers may be immediately known. If we refer to sulphuric acid in the table of compounds, we shall see that in all the columns it consists of 1 atom of sulphur and 3 atoms of oxygen. By Thomson's numbers, in which oxygen is unity, we find in the elementary table that sulphur is 2, which added to 3 atoms of oxygen, is equal to 5. This is the number for the atom of sulphuric acid. In the table of compounds we find the second oxyd of copper to consist of 1 atom of copper, which in the table of simple bodies in Thomson's column, is 8, and 2 atoms of oxygen. These

added, give 10 for the atom of black oxyd of copper. If, now, we look in the table of compounds for sulphate of copper, we shall see that this salt is constituted by 2 atoms of sulphuric acid, 2 × 5, added to 1 atom of oxyd of copper 10, making 20 for the atom of sulphate of copper. These, however, give the salt free from water of crystallization. According to Dr. Wollaston's scale, this salt in its crystallized form contains 36 per cent. of water, so that it would be complete when formed of 2 atoms of sulphuric acid = 10, 1 atom of oxyd of copper = 10, and 10 atoms of water = 11.43, the atom of water being 1, atom of hydrogen = .143, and 1 of oxygen = 1, making 1.143; the whole atom of salt being 10 + 10 + 11.43 = 31.43.

In the table of compounds, we find carbonic acid constituted by 1 atom of carbon = 77, added to 2 atoms of oxygen = 2, making 2.77. In the same table we find potash formed by 1 atom of potassium = 5, added to 1 of oxygen = 1, making 6 for the atom of potash. If, now, we look in the table of compounds for carbonic acid and bicarbonat of potash, we shall find the former to consist of

1 atom of carbonic acid = 2.77, and 1 atom of potash = 6; the whole atom of this salt being 8.77. The bicarbonat will be seen to consist of 2 atoms of carbonic acid = $2 \times 2.77 = 5.54$, added to 1 of potash = 5, together being 10.54 for the atom of bicarbonat.

These examples will be sufficient to shew the importance of the atomic theory, particularly when we are in possession of a sufficient number of facts to form a complete table on a similar plan to those here given.

Before closing the present subject, a few observations may, with advantage, be added, on the value of the above doctrine as a means of improving the language of chemical science. Under the article NOMENCLATURE its general application has already been noticed; but this, as will be now seen, is capable of still farther extension than was then detailed. So complete is the system capable of being rendered, that if we merely remember the weight of the elementary atom of each acid and base of which a salt is composed, (a task by no means difficult,) the name of the compound alone will lead us to a knowledge of the proportions in which its ingredients are united. This, from what has been premised, will be obvious after a short illustration. When one atom of acid and one atom of base are employed in the constitution of any particular salt, as of phosphoric acid and of lime, for example, the title of the resulting compound, as was explained under NOMENCLATURE, is simply that of *phosphat of lime*. If two atoms of acid are present, it then becomes a *super-phosphat*, and if two atoms of base, a *sub-phosphat*. The addition of any farther number of particles may be conveniently registered by the aid of short prefixes derived from the Greek numerals. Thus, three atoms of either acid or base will be called a *trito-phosphat* (from τρίτος, *tertius*); four atoms, a *tetra-phosphat* (from τέταρτος, *quartus*); five atoms, a *pempto-phosphat* (from πέμπτος, *quintus*); six atoms, an *hexto-phosphat* (from ἕκτος, *sextus*); seven atoms, an *ebdo-phosphat* (from ἑβδομος, *septimus*); eight atoms, an *ogdo-phosphat* (from ὀγδοος, *octavus*); nine atoms, an *ennato-phosphat* (from ἑνάτος, *nonus*); and ten atoms, a *decato-phosphat* (from δέκατος, *decimus*). The same source will furnish a sufficient means of distinction to any increased extent; but there are few instances in which this will be requisite, and had it not been for some recent researches of Mr. Dalton into the various combinations of the salt here quoted, it might almost have been doubted whether even so great a provision as the above would have been at all necessary. One addition remains yet to be made to the foregoing nomenclature, as a means of distinguishing salts with excess of base from those with an excess of acid. This is readily accomplished by retaining the word *sub* as a prefix to the former, and reserving the names, as they stand above, without any alteration, to denote the latter. A compound of two atoms of phosphoric acid and one of lime, therefore, will be *super-phosphat of lime*, and three atoms of acid, and one of lime, *trito-phosphat of lime*. The combination of one atom of phosphoric acid with two of lime will, in like manner, be *sub-phosphat of lime*, and one of acid with three of lime, *sub-trito-phosphat of lime*; and so of the remainder.

PROPORTIONAL, relating to proportion. Thus we say, proportional compasses, parts, scales, spirals, &c. See COMPASSES, &c.

PROPORTIONALS, in *Geometry*, are quantities, either linear or numeral, which bear the same ratio, or relation to each other.

Thus, if 3, 6, 12, be proportionals, then will $3 : 6 :: 6 : 12$.

To find a fourth proportional to three given lines, A B, A C, and B D (Plate XI. *Geom.* fig. 13.) draw an angle F A G

at pleasure; from A set off the first of the lines to B; from A, the second, to C; and from B, to D, the third; draw B C; and at D make an angle equal to A B C; then is C E the fourth proportional sought; and $A B : A C :: B D : C E$.

If a third proportional be required to two given lines, A B and A C; make B D equal to A C; *i. e.* let A C be repeated twice: then $A B : A C :: A C : C E$.

To find a mean proportional between two given lines, A B and B E (fig. 14.), join the two given lines into one continued right line, and bisect in C. From C, with the interval of A C, describe a semicircle A D E; and from B erect a perpendicular B D; this is the mean proportional sought; and $A B : B D :: B D : B E$.

The geometricians have been these two thousand years in search of a method for finding two mean proportionals.

The ancients performed it mechanically, by the mesolabe described by Eutochius; and many of them attempted to give the demonstration; some by the solid loci, as Menechmus; others by the plain loci, as Nicomedes, Diocles, and, in our times, Vieta; and others by implicit motions, as Plato, Archytas, Pappus, and Sporus; others tentatively, by the description of circles, as Hero and Apollonius, &c. but all in vain. See DUPLICATION of a Cube.

To find a mean proportional between two numbers: half the sum of the two given numbers is an arithmetical mean proportional, and the square root of the product a geometrical mean proportional. See PROPORTION, *Arithmetical* and *Geometrical*.

To find a mean harmonical proportional, see PROPORTION, *Harmonical*.

PROPORTIONALS, in *Grammar*. See NUMERALS.

PROPORTIONAL Compasses, an instrument consisting of two equal and narrow thin slips of metal, terminating at each extremity in a point, the slips being connected together by a cylindrical pin, which, when they are made to coincide, is moveable along a slit through both pieces; so that the axis or centre of the pin, and the two extreme points of each piece, may be in the same straight line, and fixed at any point which will keep its situation in each of the pieces, whether the instrument be opened at any angle or shut.

The two surfaces of the instrument which appear when it is shut are called the sides.

The four parts of the instrument from the centre of motion are called legs.

It is evident from the definition given, that two legs will be equal to each other, and of the same invariable length, whatever angle these legs make with each other; and that the two which include the opposite angle will also be equal to each other, and their length also invariable at any angle formed by these legs.

Plate I. fig. 7. of *Drawing Instruments*, is the perspective representation of a pair of proportional compasses; *de* and *cf* are the two slips, constructed so as to turn round the centre of motion *a*, which remains in the same point of each slip *ce* or *df*, while the legs of the instrument are made to turn round it, but which may be moved when the adjoining surfaces of *ce* and *df* are made to coincide, and thereby divide the length of the instrument in any proportion required.

Fig. 8. is another proportional compass, with an adjusting beam or screw, so contrived as to move the slider the smallest quantity required, or to keep the instrument fixed at any angle in dividing a line of equal parts.

The application of the proportional compass with regard to the division of lines into any number of equal parts from 2 to 10, and the circumferences of circles into any number of

PROPORTIONAL COMPASS.

equal parts from 6 to 20, and with regard to being used as a scale, has already been shewn under the article COMPASSES, as also some other applications with regard to its being used as a sector. In this article it is proposed to treat of its application to perspective, and some other branches of geometry and architecture, to which purposes it has never yet been applied.

PROBLEM I. *Fig. 1.*

To set the proportional compasses in the ratio of a line divided into any two parts.

Take a line equal to the length of the instrument, and divide this line in the ratio required; then apply the shorter or longer part of the line thus divided on the length of the instrument when shut, from the extremity of the longer or shorter legs to an intermediate point, to which bring the axis of the pin, and the compasses will be set in the ratio required. Thus, let AD be a straight line divided in E ; make AB equal to the length of the instrument; join DB , and draw EC parallel to DB , cutting AB at C ; shut the instrument; take either distance CA or CB , say the shorter, CB , and apply it from the shorter end of the instrument; push the slider along the slit until the centre of the pin coincides with the other extremity, and the instrument will be set in the ratio required.

As this problem is essential in most of the following, the reader is desired not to pass it, but to understand it thoroughly before he proceeds farther.

PROB. II. *Fig. 2.*

Given any number of lines, $AB, CD, EF, GH, \&c.$ (*fig. 2.*) to find a series of other lines, which will have the same ratio in every two corresponding lines, given one line ab of the series required, corresponding to AB of the series given.

Set the proportional compasses in the ratio of AB to ab by problem I.; then if AB be greater than ab , take the distance CD , with the remote extremities, and make cd equal to the distance contained between the near extremities, and ab will have the same ratio to cd , which AB has to CD : in like manner take the distance EF , with the remote extremities, and make ef equal to the distance contained between the points of the near extremities, and cd will have the same ratio to ef , that CD has to EF ; or ab will have the same ratio to ef , that AB has to EF , and thus the remaining lines $gh, \&c.$ will be found in the same manner; but if the line AB in the given series be less than ab , the given line of the series required, the lengths $CD, EF, \&c.$ must be taken with the shorter ends of the compasses, and the lines $cd, ef, \&c.$ made respectively equal to the corresponding distances contained between the extremities of the longer ends.

PROB. III. *Fig. 3.*

To divide a given line in the same proportion as another given line is divided.

Let AE be a given line, divided into the parts AB, BC, CD, DE , and let it be required to divide the line ae in the same proportion.

Set the compasses in the ratio of the whole lines AE and ae , then take the distances AB, BC, CD, DE , with the same legs which were applied in taking the distance AE , and with the other legs corresponding to the distance ae , make ab, bc, cd, de , respectively equal to the distance between the points of these legs, and ab, bc, cd, de , will have the same ratio to one another, that AB, BC, CD, DE , have to one another.

PROB. IV.

To divide a straight line, $AX, N^o 2$, in continued proportion, given the extreme part AB .

Set the compasses in the ratio of AX to BX by problem I.; contract the points of the longer legs to BX , then with the shorter legs cut off the distance XC ; again contract the distance between the points of the longer legs to XC , thus found, and with the shorter legs cut off the distance XD ; and thus by setting the distance between the points of the longer legs to the last distance found, the shorter legs will give the succeeding part by transferring the distance between the shorter legs from X towards A . By continuing this operation, as many points may be found as may be necessary for the purpose required; then $AB : BC : CD : DE : EF : FG, \&c.$; that is $AB : BC :: BC : CD$, and $BC : CD :: CD : DE, \&c.$

Any question in the rule of three may be resolved by the proportional compass and a plane scale: thus, suppose three articles of the same kind to cost two shillings; what will eight cost? Set the compasses in the ratio of 2 to 3 by problem I.; extend the points of the shorter legs to 8 on the scale; then apply the longer legs to the scale, and 12, the measure indicated, will be the fourth proportional, as required.

Where there is a great disproportion in the terms of the ratio, it would be more eligible to use two scales; thus, suppose it were required to find a fourth proportional to the numbers 30, 3, and 45, take any convenient scale for the antecedents 30 and 45, and any convenient larger scale for the consequents 3 and the answer; then by problem I. set the compasses in the ratio of the distance 30 on the scale of the antecedents to the distance 3 in the scale of the consequents; then take 45 from the scale of the antecedents with the legs first applied to the same scale, and the other legs will give the distance 4.5, or $4\frac{1}{2}$, the answer as required, by applying the distance between their points on the scale of the consequents.

By this any proportion, whether in lines or numbers, may be resolved.

PROB. V. *Fig. 4.*

Given two straight lines AB and CD , tending to an inaccessible point, and a point E in position, to draw a straight line through the point E , so that all the three straight lines AB, CD , and that which is required to pass through the point E , may have the point of concurrence.

Through the given point E , draw FG , meeting AB at F , and CD at G ; draw HI parallel to FG , cutting AB at H , and CD at I ; set the proportional compasses in the ratio of the two straight lines FG and HI ; then FG being greater than HI , take the distance GE with the longer legs, and make IK equal to the distance between the points of the shorter legs; draw a straight line through the points E and K ; then if the straight lines AB, CD , and EK be produced, they would have one common point of concurrence.

Corollary.—Hence, if AB and CD (*fig. 5.*) be two straight lines, and if E, G, I, L , be several points in a straight line PQ , meeting AB in P , and CD in Q ; then drawing any line RS parallel to PQ , cutting AB at R , and CD at S , and setting the proportional compasses in the ratio of PQ to RS ; then PQ being longer than RS , take the distances QE, QG, QI, QL , with the longer legs, and apply the distances contained between the points of the shorter legs respectively from S to F , from S to H ,
from

PROPORTIONAL COMPASS.

from S to K, and from S to M; and drawing the lines EF, GH, IK, LM, the lines thus drawn would all have one common point of concurrence, if produced with AB and CD.

Fig. 12. shews the application of this problem and its corollary, in drawing the representations of the horizontal lines which regulate the heights of doors and windows in the perspective representation of a building, when the vanishing points of the sides *Ak* and *Ch* are not in the picture, and when all the points through which these lines pass are in the corner of the building, or any other convenient line.

PROB. VI. *Fig. 6.*

Given two straight lines AB and CD, tending to an inaccessible point, and any number of points E, G, I, in position, not in a straight line; to draw a straight line through each of the points E, G, I, tending to the same point with AB and CD.

Through the point E, draw any line AC; through the point G, draw LM parallel to AC, cutting AB at L, and CD at M, and through the point I, draw NO also parallel to AC, cutting AB at N, and CD at O; draw any line PQ parallel to AC; set the proportional compasses in the ratio of AC to PQ; take the distances CM, CO, with the longer legs, and make QR, QS respectively equal to the distances contained between the points of the shorter ends; draw RT, SU parallel to PQ, cutting AB in T, U; make Qe, Rg, Si, respectively equal to CE, MG, OI; and draw the straight lines Ee, Ii, Gg, and Ee, Ii, Gg, will tend to the same point with AB and CD.

Fig. 7. is added in order to shew the great use of these problems in perspective, and completely exemplifies problem VII., by shewing that if any section of the original object made by the plane of the picture be obtained, such as the mouldings on the face of a building, it will be very easy to draw lines from all the points of such a section that will tend to the proper vanishing point, two lines tending to the same point being given.

PROB. VII. *Fig. 8.*

Given the representation $a'' b'' c'' d'' e'' f''$ of the end of a right cylinder, the original having its axis parallel to the picture, the vanishing line VL of the plane of that end, through a given point *a* in any perpendicular $a'' a$ to VL, to draw the representation of the other end of the cylinder.

Let $a'' a$ cut the vanishing line VL at *u*; draw $b'' b, c'' c, d'' d, e'' e, f'' f$, parallel to $a'' a$, cutting VL respectively at *v, w, x, y, z*; set the proportional compasses in the ratio of $u a''$ to $u a$; then $u a''$ being greater than $u a$, take the distance *vb* with the longer legs, and make *vb* respectively equal to the distance contained between the points of the shorter ends; find the remaining points *c, d, e, f*, in the same manner, and through the points *a, b, c, d, e, f*, draw a curve, which will be the representation of the other end of the cylinder.

Or, if the base *abcdef* were given, the top would be found in the same manner by making the ratio of the shorter legs to the longer legs as $u a$ to $u a''$, and taking *vb* with the nearer extremities, and making vb'' equal to the distance of the remote extremities, and finding the remaining points c'', d'', e'', f'' , in the same manner.

In the same manner any section $a' b' c' d' e' f'$ may be found.

This application of the proportional compass is exceedingly useful in the representation of bows, when required in the fronts of buildings, as is shewn by *fig. 9*, which exhibits

the elementary lines of the perspective of a house. Here the horizontal terminations of the apertures are readily represented by only drawing perpendicular lines which may be the vertical terminations of the said apertures, and which would therefore be required at all events. The same description of words as in the problem, apply to this figure, as in figure 9, to which the problem refers.

PROB. VIII.

Given the representation of any point on the picture, and the intersecting and vanishing lines of the plane it is in, to find the height of a representative line, the original of which is parallel to the picture.

Set the proportional compasses in the ratio of the distance between the intersecting and the vanishing lines, and the distance of the point from the vanishing line, then take the length of the original line with the longer legs, and the opposite points will give the height of the line required.

Example.—Suppose the distance between the vanishing and intersecting lines to be three inches, and the distance between the representation of the point or foot of the line to be two inches, and the height of the original line to be six inches, required the perspective height of the same. Set the proportional compasses in the ratio of 3 to 2; extend the longer legs of the compasses to six inches, and the extent between the opposite shorter legs will be the height of the line required, which, in this case, will be four inches.

Scholium.—By this method all the heights of the representation of a solid may be found without any additional lines whatever; but in order to expedite the work when the original object is of different heights in the same plane parallel to the picture, or where the same height is required to be found upon two or more points, it will be eligible to draw a straight line through one of the points, cutting the one or more lines on which the heights are to be found, and the same setting of the compasses will do for as many heights as are to be raised upon the line so drawn.

Example.—Suppose a cylinder to be represented, its base is an ellipsis, to find any two points in the height of the cylinder; draw a straight line parallel to the vanishing line, to cut the representation of the base of the cylinder in two points; upon each point of section draw a perpendicular; set the proportional compass in the ratio of the distance between the intersecting and vanishing lines, and either point and the vanishing line; then take the height of the cylinder between the points of the long legs, and the distance of the opposite points, and the distance between the opposite points will give the perspective height upon each perpendicular from the foot thereof.

In the application which has hitherto been made of the proportional compasses, the sides of the instrument have not required any gradations of parts; the construction of the scales to be affixed on the proportional compass for this purpose is as follows.

PROB. IX.

To construct the scale of sines for the proportional compass. Let AC be a scale of sines, found in the usual manner; and let CA be produced to R, making AR equal to the radius; draw RD at any convenient angle with RC; make RD equal to the length of the proportional compasses, and join CD; draw Aq parallel to CD, and as q at the point C is the chord of 90, the point q in RD will be the point for the index of the slider to be set to; then if the legs of the compasses be set to any angle, the distance between the points corresponding to D will be to the distance between the points corresponding to R,

PROPORTIONAL COMPASS.

as the sine of 90 is to radius. In like manner, join D 8 and the next point 8 in the line A C, and draw A 8 parallel to D 8, cutting R D in 8; then the point 8 in R D will be the point for the index of the slider to be set to; then if the ends of the proportional compasses corresponding to R be opened to any radius, the extent of the ends corresponding to D is the sine of 80 degrees corresponding to that radius: in like manner, the points 6, 5, 4, 3, 2, 1, will be found in R D, so that 1, 2, 3, 4, 5, 6, 7, 8, 9, in R D, are the gradations on the side of the proportional compasses corresponding to 10°, 20°, 30°, 40°, 50°, 60°, 70°, 80°, 90°; so that if the index be set to any of these numbers, and the points corresponding to R be extended to the radius, the distance between the opposite points will be the sine of that number of degrees. The cosines have the same divisions as the sines, but are numbered the contrary way.

In the same manner, by placing the radius in the same straight line with a common scale of sines or tangents from zero on A, so as to lengthen the line A C of tangents, by adding the said radius A R, and forming the extension R C, and drawing R D at any convenient angle with R C, then dividing B D as in the problem; then R D will contain the gradations of a scale of tangents, to be inserted on the side of the proportional compasses; so that when the index or mark upon the slider is brought to any of these numbers, the end corresponding to R being opened to the radius, the end corresponding to D will be the sine or tangent of the angle corresponding to that number. See the figure.

Fig. 10. shews the application of the method to a scale of tangents.

Examples.

Ex. 1. Fig. 13.—To make an angle of 30° at a given point A in the straight line A B.

With any convenient radius A B describe an arc B C; set the index to 30° on the line of chords, then extend the points of the instrument corresponding to B to the radius A B, and with the opposite points set off the distance B C on the arc, and join C A, then C A B is the angle required.

Ex. 2.—To find the tangent of 40° to any given radius within the limits of the points corresponding to R.

Set the index to 40° on the line of tangents, and extend the points R to the radius, then the extent between the opposite points will be the tangent of 40°, as required.

Ex. 3.—To find the sine of 20° to any given radius within the limits of the points corresponding to B.

Set the index to 20° on the line of sines, then extend the points corresponding to R to the radius given, and the extent between the opposite points will be the sine of the angle, as required.

Ex. 4.—To find the cosine of 50°, the radius being given within the limits of the instrument.

Set the index to 50° on the line of cosines; extend the points corresponding to R to the radius, and the opposite points will be the cosine of the angle required.

Ex. 5.—The chord, sine, cosine, or tangent of any number of degrees being given, to find the radius.

Extend the points corresponding to D to the chord, sine, cosine, or tangent, and the opposite points corresponding to R will be the radius of the circle required.

PROB. X.

To draw the representation of a house, by making the centre of the picture the dividing point, having the dimensions of the building given.

Fig. 12.—Let V L be the vanishing line, h k the intersecting line, and C the centre of the picture; and let the building touch the intersecting line in A, also let the vanishing points of the sides be supposed to be given.

Set the proportional compasses to the cosine of the angle which the one side of the building (*viz.* say that on the right) makes with the intersecting line by *Ex. 4. Prob. IX.* say 30°; then with the ends of the instrument corresponding to R, take the original measures from a plan; or if the measures are known in feet, &c. take them from a scale without being at the trouble of drawing a plan; take the distance of the corner of the building, and the nearest side (say 3 feet 6 inches) from the scale, with the remote points, and with the opposite points set off the distance A b on the intersecting line; take the breadth of the window from the scale (say 3 feet) with the remote points, and with the opposite points set off the distance b c on the intersecting line; take the breadth of the next pier from the scale (say 4 feet) with the remote points, and with the opposite points set off the distance c d: proceed in this manner to h, so that the whole extent A h will represent a distance of 24 feet. Let us now proceed with the end of the building, which is supposed to be on the left hand; as the angle of the building is supposed to be a right angle, and as the right-hand side was supposed to make an angle of 30° with the intersecting line, the left-hand side will therefore make an angle of 60°; set the index of the proportional compass to 60° in the line of cosines; then from the scale take the breadth of the end (say 20 feet) with the remote ends, and with the opposite ends set off the distance A k; set off the breadth of the piers from h to j, and from A to i in the same manner; draw the lines A h and A k to the vanishing points of the sides.

From the points b, c, d, e, f, g, h, as also from i, j, k, draw lines to C, cutting A b at b, c, d, e, f, g, h, and A k at i, j, k; from the points of section draw perpendiculars to V L; set the heights of the apertures, and the height of the building itself, upon the corner A A': say that the sills of the lower windows are three feet high, the windows six feet, the space between the lower windows and the upper four feet, the upper windows four feet also, and the distance to the parapet three feet; therefore make A l equal to three feet, l m equal to six feet, m n equal to four feet, n o equal to four feet, and o A' equal to three feet, exactly to the scale or natural measures of the building: from these points of section draw lines to the vanishing points, and complete the whole representation. In setting up the heights, common dividers may be used. By the last setting of the proportional compass, if the thickness of the walls are taken from the scale by the remote ends marked R, and the distance of the two opposite points be set upon the intersecting line from the points c, e, g, towards A; and if from the points of section lines be drawn to C, the centre of the picture, to cut the representative base line A b of the building, and perpendiculars be drawn from the points of section in A b, these perpendiculars will give the reveals of the windows, that is, they will shew the thickness of the walls on the sides of the windows.

PROB. XI. Fig. 13.

From a given point A, in a given straight line A B, to draw a straight line A C, so that A B and A C shall contain an angle of a given number of degrees.

Set the index of the proportional compasses to the chord of the angle; then from the point A, with any radius describe the arc B C of a circle; extend the longer legs to the radius A B, and with the opposite legs set off a chord

PROPORTIONAL COMPASS.

BC upon the arc from the point B, where it cuts the leg, and draw the line AC, and BAC will be the angle required.

PROB. XII.

Given the vanishing line of a plane, its centre and distance, and the inclination of a line in that plane to the intersection, to find the vanishing point of the line, without having recourse to draw any lines in the vanishing plane.

Let the angle which the original line makes with the intersection be 30° ; subtract 30° from 90° , and 60° will remain; bring the index of the proportional compasses to 60° on the line of tangents; extend the extremities of the compasses marked R to the radius; then set the distance of the opposite extremities from C to v (*fig.* 14.), on the vanishing line VL, and v will be the vanishing point of the line, as required.

The proportional compasses will answer to any distance of the eye from the vanishing line, however great, by taking one-half, one-third, one-fourth, &c. of the distance of the vanishing line, as will be found most convenient with the extremities marked R; then repeating the distance between the points of the opposite extremities two times, three times, four times, &c. accordingly.

Example.—Let it be required to find the vanishing points of a rectangle, supposing the right-hand side to be placed at 40° with the intersecting line.

Subtract 40° from 90° , the number contained in a right angle, and the remainder, 50° , will give the angle made by the primary or shortest radial, and the radial of the right-hand side, or the angle made by the original side of the rectangle on the right hand, and a perpendicular in the original plane to the intersecting line; then the angle contained between the primary radial and the radial of the left-hand side of the rectangle will be 40° . Now suppose the length of the picture to be 12 inches, and the spectator to stand at 2 feet, or 24 inches, from the centre of the vanishing line; and suppose the proportional compasses to be $6\frac{1}{2}$ inches, which is the usual length: divide 24 into 6 equal parts, each of these parts in this instance will contain 4 inches; slide the index of the instrument to 50° on the line of tangents, then with the legs R take the extent of 4 inches, or the sixth part of 2 feet, and repeat the distance of the opposite points on the vanishing line from the centre C of the picture towards the right hand six times to v , and v will give the vanishing point. To find the vanishing point of the left-hand side: as the radial of this side makes 40° with the primary radial, slide the index of the instrument to 40° on the line of tangents; then with the legs marked R take the extent of 4 inches, or the sixth of 2 feet; then repeat the distance between the points of the opposite ends from the centre of the picture towards the left hand six times to V, and V will be the vanishing point of the left-hand side of the rectangle.

The vanishing points of all lines whatever may be found in this manner, having the angle formed by the intersecting line and the original: for this is always equal to the angle formed by the radial and the parallel of the eye; and because that the distance of a vanishing point from the centre of the picture is the tangent of the angle made by the primary radial and the radial of the line, the primary radial being radius, the proportional compasses being set as above, will give the true vanishing point.

Scholium.—None of the lines on the proportional compasses, except the tangents, require the slit to be less than half the length of the shank, deducting that part of the slide from the centre of the pin; the tangents therefore can-

not be inserted higher than 45° ; and indeed the higher tangential numbers would be of little use, as the radius would be shortened by every such increase: now this would be attended with greater inaccuracy and more labour. If the gradations, however, do not exceed 45° , the distance of the extremities of the compasses may still be extended to six inches: but in order to find the tangent of any greater number of degrees than 45, we have only to subtract that number of degrees from 90, and the remainder is the complement of the angle; then it will be as the tangent of the complement is to radius, so is radius to the tangent itself.

From these observations it will be very easy to find the vanishing point of any line, whatever number of degrees the radial of that line forms with the primary radial, as may be seen in the following problem.

PROB. XIII.

To find the vanishing point of a line, the radial of which makes a greater angle with the primary radial than 45° , the vanishing line and its centre being given, as also the primary radial.

Subtract the given angle from 90; set the index of the compasses to the tangent of the remaining angle; take a convenient aliquot part of the distance of the eye from the vanishing line, and set the legs marked R to that distance; and upon any straight line AE, with the ends R, set off the distance AB; take the distance AB with the opposite ends, and set off the distance AD; then let VL be the vanishing line and C its centre; then, according as the original line or its radial is on the right or left, the distance AD must be set to the right or left of the centre of the picture, as often as the radial is supposed to contain the distance of the points upon the legs marked R.

Example.—Suppose the radial of the line to make an angle of 50° with the primary radial, and the length of the primary radial to be three feet, to find the distance of the vanishing point from the centre of the picture.

Subtract 50° from 90° , and the remainder is 40° ; set the index to the tangent of 40° ; take the ninth part of the primary radial, or 4 inches, and extend the ends opposite to those marked R to 4 inches, or the ninth part of the distance, and repeat the distance of the legs marked R on the vanishing line nine times from the centre to the right or left hand accordingly, and the extremity of the distance so repeated from C is the vanishing point required.

The reason of this operation is evident, since the radius is a mean proportional between the tangent of the angle and the tangent of its complement, and therefore as the tangent of the complementary angle is to the radius, so is the radius to the tangent itself.

If the object to be drawn be a rectangle, making unequal angles with the intersecting line, the angles made by the radials of the sides, and the primary radial, being equal to the angles made by the sides of the rectangle and the intersecting line, or a line drawn through the other corner parallel to the intersecting line; set the proportional compasses to the tangent of the least angle; extend the legs marked R to the distance, or to any part of the distance that the compasses will admit of; set the distance of the opposite legs, or repeat that distance as often as the primary radial contains parts, from the centre to the right or left, and the point of extension will give the vanishing point of that side of the rectangle; extend the ends opposite to R to the primary radial, or that portion of it before-mentioned that the compasses will admit of, and the extension between the extremities of the legs marked R being set from the centre on the other side of it of the vanishing line, or repeated

PROPORTIONAL COMPASS.

peated according to the number of parts into which the primary radial is divided, will give the vanishing point of the other side of the rectangle, viz. of that side which makes the greatest angle with a line perpendicular to the intersection, and therefore the vanishing point so found must be upon the same side of the centre of the picture that the angle itself is upon, being nothing more than the tangent of that angle.

Scholium.—The vanishing points of a rectangular building may be found arithmetically upon the foregoing principles; viz. as the tangent of the angle made by the radial of one side and the primary radial is to the primary radial itself, so is the primary radial to the tangent of the angle made by the radial of the other side and the primary radial. Now, admitting the shortest tangent was to the primary radial as 2 to 3, and the length of the primary radial was 3 feet 6 inches, or 42 inches; to find the vanishing points, it will be

$$3 : 2 :: 42$$

$$\begin{array}{r} 2 \\ \hline 3)84 \\ \hline \end{array}$$

28 inches, the distance of the vanishing point of the least angle. And again,

$$2 : 3 :: 42$$

$$\begin{array}{r} 3 \\ \hline 2)126 \\ \hline \end{array}$$

63 inches, the distance of the vanishing point of the greater angle; or because the distance is a mean proportional between the two tangents, it will be

$$28 : 42 :: 42$$

$$\begin{array}{r} 42 \\ \hline 84 \\ \hline 168 \\ \hline \end{array}$$

$$28)1764(63 \text{ inches, the tangent of the greater angle, the same as before.}$$

$$\begin{array}{r} 84 \\ \hline 84 \\ \hline \end{array}$$

The distance of the vanishing points is sometimes required. In this case, the square root of the sum of the squares of each tangent, and the primary radial, will give the distance from each respective vanishing point; but if the vanishing points are inaccessible, subtract each tangent from the respective distance so found, and set the remainder on each side of the centre of the picture.

This method of finding the distance would be thought by many artists rather troublesome. The following method, by the proportional compasses, is very easy: Suppose the one radial to make an angle of 30°, then the other will be 60° with the primary radial; add 30° to 90°, the sum is 120°; take the half of 120, which is 60; then 30 from 60, there remains 30°; the tangent of 30, set upon the other side of the primary radial, will give the distance of the vanishing point. Again, add 60 to 90, the sum is 150, the half is 75°; subtract 60 from 75, and the remainder is 15°; then the tangent of 15°, set from the centre of the picture on the other side of the angle of 60°, will give the distance of the vanishing point of the line that makes 30° with the intersection.

Again, suppose one of the angles 40°, the other will be 50°; add 40 to 90, the sum is 130; the half of 130 is 65; subtract 40 from 65, and the remainder is 25°; then the tangent of 25°, set on the other side of 40 from the centre of the picture, will give the distance of the vanishing point of the line, the radial of which makes 40 with the primary radial. Again, add 50 to 90, the sum is 140, the half is 70; subtract 50 from 70, and the remainder is 20°; then the tangent of 20° being set from the centre of the picture upon the other side of the angle formed by the primary radial, and the other radial containing 50, will give the distance of the said radial.

In general, suppose the less angle to be called v , and the greater w ; then $\frac{v + 90}{2} - v = \frac{90 - v}{2} = 45 - \frac{v}{2}$, then the tangent of this angle set upon the other side, gives the vanishing point of the same. Again, $\frac{w + 90}{2} - w = \frac{90 - w}{2} = 45 - \frac{w}{2}$, gives the distance of the other vanishing point set on the contrary side of the centre: thus, if $w = 60$, then $45 - \frac{w}{2} = 15$, then set the tangent of 15° as directed; and thus the tangent of the remainder of half the angle contained by the primary radial, and the radial from 45°, gives the vanishing point; or take the tangent of half the complement of the said angle, and set it on the vanishing line from the centre of the picture on the other side, and it will give the vanishing point.

PROB. XIV.

Given the angle which the radials of any two original lines make with each other, and the angle which one of them makes with the primary radial, to find a dividing point which shall be common to the same measures or scale, so as to cut off a portion from the indefinite representation of each line, such that the portions may be the representations of the two original lines.

N.B. When one of the angles which the primary radial makes with the one radial is given, that with the primary radial and the other radial may be found by subtracting the one given from the whole angle contained by the radials. This being obtained, proceed as follows: subtract the less angle formed by the one radial and the primary radial from half the angle contained by the radials of the original lines; then if the tangent of the remaining angle be set on the vanishing line, on the side of the primary radial which has the greatest angle, it will give the dividing point required.

Let us call the whole angle A , then the half is $\frac{A}{2}$; call the less angle made by the primary radial and the one radial B , then $\frac{A}{2} - B$ is the difference; find the tangent of $\frac{A}{2} - B$; then the greater angle made by the primary radial and the other radial being $A - B$, set the tangent of $\frac{A}{2} - B$ from C , on the vanishing line on the side of $A - B$, and the extremity of the distance will give the dividing point required.

Example 1.—Suppose the angle contained by the two radials to be 100°, and the lesser angle to be 40°, then the

PROPORTIONAL COMPASS.

greater will be 60° : now the half of 100 is 50; subtract 40° , the lesser angle, from 50° , there remains 10° : set the index of the proportional compasses to 10° on the line of tangents; take the length of the primary radial with the legs marked R, and set off the distance contained by the opposite points from the centre of the picture on the vanishing line, on the side of the primary which has the angle of 60° , and the extremity of the distance is the dividing point.

Example 2.—Suppose the angle contained by the radials to be 80° , the lesser angle to be 30° , and consequently the greater 50° ; the half of 80° is 40° ; subtract 30° from 40° , and 10° remain. Set the index of the proportional compasses to the tangent of 10° ; take the length of the radial with the legs marked R, and set the distance of the point contained by the opposite legs from C on the vanishing line, on the side of the angle of 50° , and the extremity gives the dividing point.

PROB. XV.

Given the sun's altitude on a plane, the height of a line, and the length of its shadow on that plane, the orthographical representation of a cornice, with a section of the same, also the seat of the sun's rays, to find the shadow of the cornice.

Let *fig. 15*, $N^\circ 1$, be the cornice or architrave, and $N^\circ 2$ be a profile or section perpendicular to the arrises, or edges of the mouldings; draw *bB* for the indefinite representation of the shadow of a line represented by the point *b*, $N^\circ 1$, and let *bB* be the distance the shadow is thrown from the point *b*, and consequently *B* will be the shadow of *b*: from all the external angles draw *cC*, *eE*, *gG*, *iI*. Now *kl*, $N^\circ 2$, is the length of the line represented by the point *b*, $N^\circ 1$: set the proportional compasses in the ratio of *kl*, $N^\circ 1$, to *bB*, $N^\circ 2$: make *cC*, $N^\circ 2$, equal to *bB*, $N^\circ 1$: take *op*, $N^\circ 2$, with the shorter ends, and make *eE*, $N^\circ 1$, equal to the distance between the points of the remote ends; take *qr*, $N^\circ 2$, with the shorter legs, and make *gG*, $N^\circ 1$, equal to the distance between the points of the remote ends; join *BC*; draw *CD* parallel to *Mc*, and draw *ED* parallel to *ed*; draw *EF* parallel to *eK*, and *GF* parallel to *gf*; draw *GH* parallel to *gI*, and *bBCDEFGHI* will be the shadow from one side; draw the lines *ML*, *KJ*, parallel to *bB*, *cC*, &c. to meet *Kb* and *Ii* at *L* and *J*, then will *ML* and *KJ* be the shadows upon the other side. To find the shadows upon the planes of the face: in the representation *cM* of the arris line, take any point, *v*, and draw *vw* parallel to *bB*, or *cC*, &c.; also, in the representation *eK*, of the next arris line, take any point, *x*, and draw *xy* parallel to *bB*, or *cC*; take the distance *dc* with the shorter ends of the proportional compasses, and make *vw* equal to the distance between the points of the longer legs; also take the projection *fe* with the shorter legs, and make *xy* equal to the distance contained between the points of the remote ends; through the points *w* and *y* draw *Lz* and *JQ* parallel to *Mc*, which will terminate the breadth of the shadow upon the face.

The reason of this operation is evident, since the distance that a shadow will be thrown by a line perpendicular to a plane, is as the length of the line; and the shadow of a line parallel to a plane will be projected on the plane parallel to the line which projects the shadow, and that every two parallel lines in the original object are also represented by parallel lines.

PROB. XVI.

The representation of a cylinder with a square abacus or cap being given, to find the shadow of the cap upon the

cylindric surface, the axis of the cylinder being parallel to the plane of projection, and the shadow of a line perpendicular to the axis of the cylinder, and in a plane passing along the said axis, and through the luminary.

Let *ABCDEFG* (*fig. 16.*) be the plan of the semi-cylinder, and *HIMN* that of the cap; and let *WXYZ* be the elevation of the semi-cylinder, and *imvu* that of the cap, and let *IB* be the projection or representation of a ray on the plan, from the corner of the abacus at *I*, cutting the plan of the cylinder at *B*; draw *LF* parallel to *IB*, to touch the semicircle in *F*, and to cut *IM* at *L*; draw *FV* perpendicular to *LF*, *V* being the centre of the semicircle, and *F* will be the point of contact; in *IM* take any number of intermediate points *J*, *M*, *K*, and draw *JC*, *MD*, *KE*, parallel to *IB*, cutting the semicircle in *C*, *D*, *E*; draw *Bp*, *Cq*, *Dr*, *Es*, *Ft*, parallel to the axis of the cylinder, cutting the under edge *im* of the abacus in *p*, *q*, *r*, *s*, *t*; set the proportional compasses in the ratio to the distance which *IB* will throw the shadow, and suppose *IB* to be greater than the length of its shadow; take the distance *IB* with the longer legs; make *pb* equal to the distance contained between the points of the opposite ends; take the distance *JC* with the longer legs, and make *qc* equal to the distance contained between the shorter legs; take the distance *MD* with the longer legs, and make *rd* equal to the distance contained between the opposite points; and the points *b*, *c*, *d*, will be obtained. In the same manner, the points *e* and *f* will be found; through the points *b*, *c*, *d*, *e*, *f*, draw a curve, and the curve thus drawn will be the shadow of the lower edge of the abacus; the sun's rays will be in a tangent plane to the cylindric surface at *Ff*. The part of the edge of the shadow which falls upon the representation of the cylindric surface from *i* to *b* will be straight.

In the same manner, if the representation of a cylinder capped with a cylindric abacus, having the same axis with the cylinder, be given, and the representation of the sun's rays on the plan, supposing the axis of the cylinder perpendicular to the plane of projection, the shadow of the abacus may be found upon the cylindric surface, and thus for every other prismatic object.

PROB. XVII.

To describe the logarithmic spiral by a series of points to be found in the curve, the centre, and two opposite points in a straight line passing through the centre, being given in the curve.

Let *Z*, *fig. 17*, $N^\circ 1$, be the centre, and let the straight line *AE* pass through *Z*, and let *A* and *E* be two opposite points, the one, *A*, on the one side, and the other, *E*, on the other side of the centre *Z*; through *Z* draw *GC* at right angles to *AE*; bisect the angle *AZC* by the straight line *BF*; also bisect the angle *EZC* by the straight line *DH*; find *ZC* a mean proportional between *ZA* and *ZE*; also find *ZB* a mean proportional between *ZA* and *ZC*; draw any straight line *aX*, $N^\circ 1$, and set the proportional compasses in the ratio of *ZA* to *ZB*; take the distance *ZA* with the points of the longer legs, and set that distance from *X* to *a*, $N^\circ 1$, and make *Xb* equal to the distance contained between the shorter legs; contract the points of the longer legs to *Xb*, and with the shorter legs set off the distance *Xc*; contract the distance between the points of the longer legs to *Xc*, and make *Xd* equal to the distance contained between the points of the shorter legs, and the parts *ab*, *bc*, *cd*, of the straight line *Xa*, will be in geometrical progression. In the same manner, the points *e*, *f*, *g*, *h*, *i*, &c. may be found, which will continue the series of parts as far as there may be any occasion; make *ZA*, $N^\circ 1$, equal

equal to Xa , $N^{\circ} 2$, Zb equal to Xb , ZC equal to Xc . In the same manner the points D, E, F, G, H, I , &c. may be continued through any number of revolutions; a curve being drawn through all the points will give the spiral required.

Scholium.—As the tracing of the curve depends very much on the eye of the person who performs this operation, by the following method a curve may be drawn with a pair of compasses, provided that the points do not approach very rapidly to the centre. To describe any quadrant, take the length of the radius that bisects it from one extremity of the curve, describe an arc, and with the same radius from the other extremity describe another arc cutting the former; then from the point of intersection with the same distance, describe an arc between the two extremities, and it will pass through the middle point very nearly; thus, take the distance ZB as a radius; from the extremity A of the arc ABC describe an arc near the centre; from the point C , with the same radius, describe another arc, cutting the former near the said centre Z ; then from the point of intersection describe the arc AC , and the arc thus described will pass through the point B very nearly. In the same manner the successive arcs CE, EG, GI , &c. may be described. The curve thus formed will be so near as not to be detected by the eye.

PROB. XVIII.

To draw the representation of the meridians of a solid of revolution upon a plane parallel to the axis of the solid, given an axial section, that is a section of the solid passing along the axis upon a plane parallel to the said axis.

Let $abcdevkjihgf$, (*fig. 18.*) be the axial section, and qv the axis itself, af the base perpendicular to qv ; in qv take any number of points r, s, t, u ; through these draw bb, ci, dj , and ek , meeting the curve on the one side at b, c, d, e , and on the other at h, i, j , then it is obvious that the lines bb, ci, dj, ek , will be bisected; now, supposing the meridians to be formed on the surface of the solid by the intersections of five planes at equal angles round the axis, and that one of these planes is parallel to the plane of projection, and let $avfa$ be the representation of that plane; draw AB parallel to af ; produce vq to meet AB at w ; from w as a centre, with the radius qA or qf , describe the semicircle $A1234B$; divide the semicircle into five equal parts by the points of section $1, 2, 3, 4$; draw $3x$ and $4y$ perpendicular to AB , cutting AB at x and y ; make ql equal to wy . Set the proportional compasses in the ratio of qa to ql ; take the distance rb with the longer legs, and with the opposite legs set off the distance rm ; then take the distance sc with the longer legs, and with the opposite points set off the distance sn ; then take the distance td with the longer legs, and with the shorter legs set off the distance to ; lastly, take the distance ue with the longer legs, and with the shorter legs set off the distance up ; then draw the curve $Imnopv$, which will be one of the meridians as required. In the same manner, all the others may be found.

Besides the uses of the proportional compasses, which have already been shewn, they may be applied to trigonometry in finding the sides and angles of triangles; suppose in a right-angled triangle, that the two legs were given to find the angles; the analogy is, as the one side is to the other side, so is radius to the tangent of the angle opposite the latter side; set the proportional compasses in the ratio of the two sides containing the right angle; then the index will shew the tangent of the angle on the line of tangents.

Again, suppose the hypotenuse and one of the legs were given to find the angles, the analogy in this will be, as the hypotenuse is to the given leg, so is radius to the

sine of the angle opposite to that leg; set the proportional compasses in the ratio of the hypotenuse to the given leg, and the index will be against the sine of the angle.

Lastly, suppose the angles and the hypotenuse to be given, the method of proceeding in this case is exactly the reverse of the last; thus, set the proportional compasses to the sine of the angle, then extend the longer legs to the hypotenuse of the angle, and the shorter legs contain the length of the leg required.

In the same manner, if the angles and one of the legs were given to find the other leg, set the proportional compasses to the tangent of the leg required, then take the length of the given leg with the longer legs, and the distance between the points of the shorter legs will be the leg of the triangle, as required.

PROPORTIONAL Part. See PART.

PROPORTIONAL Scales, called also *logarithmical scales*, are the artificial numbers or logarithms, placed on lines, for the ease and advantage of multiplying, dividing, &c. by means of compasses, or of sliding rules.

They are, in effect, only so many lines of numbers, as they are called by Gunter, but made single, double, triple, or quadruple; beyond which they seldom go. See GUNTER'S Scale, SCALE, &c.

PROPORTIONAL Spirals. See SPIRAL.

PROPORTIONALITY, a term used by Gregory de St. Vincent, for the proportion that subsists between the exponents of four ratios.

PROPURTUM, or PURPORT, in our *Law Books*, the intention or meaning of any thing. "Secundum propurtum dicti chirographi, inter eos confecti."

PROPOSITION, PROPOSITIO, in *Logic*, part of an argument, in which some quality, either negative or positive, is attributed to a subject.

Chauvin defines proposition, a complete, consistent sentence, indicating or expressing something either true or false, without ambiguity: as *Xantippe is a bad wife. If an ass fly, he must have wings.*

Others, more philosophically, define proposition, a speech uttered or produced, to signify some judgment of the mind. Or, again, a proposition may be defined, a sentence in which two or more ideas or terms are joined and disjoined by one affirmation or negation.

A proposition consists of two terms; the one, that of which we affirm or deny, called the *subject*; the other, the thing affirmed or denied, called the *attribute*, or *predicate*. These two are either joined, or separated, by the intervention of some copula or disjunctive.

Thus in the proposition, *God is just*; the subject, *God*, is joined with the attribute, *just*, by the verb substantive, *is*. The schoolmen call the two terms the *matter*, and the copula the *form* of the proposition.

Now, as terms may be either singular, or common and universal, if the subject of a proposition be a common term, taken in all its extent, the proposition is called *universal*: as, *every atheist is blind.*

This is called a division according to the *subject*, or a division arising from the *quantity*.

If the common term be only taken in an indeterminate part of its extent, the proposition is called *particular*: as, *some atheists are wicked.*

If the subject of the proposition be singular, the proposition is called *singular*: as, *George is king of England.*

If no note, either of universality or particularity, be prefixed to a subject, in its own nature general, the proposition is *indefinite*: as, *angels are noble creatures.*

Those propositions which have only one subject, and one predicate,

predicate, are called *single*. And these are again either *simple* or *complex*: a *purely simple* proposition is that whose subject and predicate are made up of single terms, but if either or both be made up of complex terms, the propositions are called *complex*; which see. Those that have several subjects or predicates, are called *compound*: each proposition of this kind contains in it two or more propositions, which are either plainly expressed, or concealed and implied. The former sort are distinguished into six kinds, *viz. copulative, disjunctive, conditional, causal*, where two propositions are joined by causal particles, *relative* and *discretive*. The latter sort comprehend *exclusives, exceptives, comparatives*, as, *pain is the greatest affliction; inceptives*, and *desitives*, which relate to the beginning or ending of any thing, and *continuatives*, as, *Rome remains to this day*.

Some writers add under this class of propositions, another division of them into *direct* and *indirect*. A *direct* proposition is that in which a higher or more general thing is predicated of a lower and more particular: as, *man is an animal*. Others will have it, that in which the subject stands as a matter receiving, and the predicate as a form received: as, *Peter is learned*. An *indirect* proposition, according to some, is that in which an inferior is predicated of an higher: as, *an animal is man*. According to others, it is that in which the subject stands as the form, and the predicate as the matter: as, *every rational is man*.

Propositions considered with regard to their *form* or *copula*, or according to their *quality*, are divided into *affirmative* and *negative*. An *affirmative* proposition is when the idea of the predicate is supposed to agree to the idea of the subject, and is joined to it by the word *is* or *are*, as, *God is a spirit*. A *negative* proposition is when the predicate is not supposed to agree with the subject, and is disjoined from it by the particles *is not, are not, &c.* as, *Man is not innocent*.

There is another division of propositions among scholastic writers, into *pure* and *modal*; which may be called a division according to the *predicate*. Propositions are said to be *pure*, when they imply or involve nothing besides their matter and form, or when they merely express that the predicate is connected with the subject: as, *Man is rational*. A *modal* proposition is that which, beside the pure matter and form, involves some mode, or manner of connection between the predicate and the subject: as, *it is necessary man be rational*. Hence such a proposition is said to consist of a mode and a diction; the mode denotes some circumstance which affects the proposition; as, *it is necessary*: the diction is the rest of the proposition, *that man be rational*.

There are four of these modes very famous; *viz. necessary, possible, impossible, and contingent*. Others produce other modes; as, *true, false, certain, uncertain, probable, &c.*

To modal propositions, some philosophers refer *exclusive, exceptive, and restrictive* propositions; all which are denoted by a common name, *exponible* propositions, because requiring some explanation to make them clearly understood.

Propositions, according to their sense or signification, are distributed into *true* and *false*. A *true* proposition represents things as they are in themselves, or joins those ideas and terms together, whose objects are joined and agree; or disjoins those ideas and terms, whose objects disagree or are disjoined; as, *every bird has wings; a brute is not immortal*. A *false* proposition is that which represents things otherwise than they are in themselves, or joins those ideas or terms whose objects disagree, or disjoins those whose objects agree; as, *birds have no wings; brutes are immortal*.

Propositions according to their *different degrees of evidence*, are distinguished into *certain* and *dubious*. A *certain* propo-

sition is that where the evidence of the agreement or disagreement of the ideas is so strong and plain, that we cannot withhold nor delay our assent; which assent is distinguished by the name of *knowledge*; which see. (See CERTITUDE and EVIDENCE.) A *dubious* or *uncertain* proposition is where there is any obscurity upon the agreement or disagreement of the ideas, so that the mind does not clearly perceive it, and is not compelled to assent or dissent; such uncertain propositions are called *opinions*. See on this subject, Watts's excellent Introduction to Logic, part ii. chap. 1. and 2.

A syllogism consists of three propositions, major, minor, and conclusion. An enthymeme, of two.

The schoolmen make several other species and divisions of propositions, as, a proposition *de primo adjacente*, where the subject and predicate are both included under the verb: such are, *veni, vidi, vici*. Proposition *de secundo adjacente* is, where either the subject or predicate is included in the verb; as *I love, or I write*. Proposition *de tertio adjacente* is, where both the subject and predicate are expressed, and stand distinct from the verb: as, *the king is just*. This proposition is the rule or standard of all the others; so that whatever proposition can be reduced to it, is legitimate; and what cannot, is not.

PROPOSITIONS, *Contradictory, Contrary, Reduplicative*. See the adjectives.

PROPOSITIONS, *Conversion, Opposition, and Reduction of*. See CONVERSION, &c.

PROPOSITION, in *Mathematics*, is either some truth advanced and shewn to be such by demonstration; or some operation proposed, and its solution shewn.

If the proposition be deduced from several theoretical definitions compared together, as this: a parallelogram is double of a triangle, standing on the same base, and of the same altitude; it is called a *theorem*.

If it be deduced from a praxis or series of operations, it is called a *problem*; as to find a third proportional to two given quantities.

Indeed, in strictness, the proposition is only part of a theorem; *viz.* that which shews what agrees to such a thing under such conditions, and what not: in which sense it is distinguished from the *demonstration*, which shews the reason why the understanding conceives that to agree to it.

Again, strictly speaking, the proposition is only a member of a problem, *viz.* that which shews what is required to be done; in which sense it is distinguished from the *solution*, which rehearses the several things to be done in order to effect what is required; and from the *demonstration*, which proves, that by doing the things enjoined in the solution, the thing required in the proposition is truly done.

PROPOSITION, in *Poetry*, denotes the first part of an epic poem, in which the author proposes, or lays down, briefly and in general, what he has to say in the course of his work.

The proposition, F. Bossu observes, is to contain the bare matter of the poem, *i. e.* the action, and the persons that are to execute it, both human and divine.

This is what we have in the Iliad, the Odyssey, and the Æneid. The action proposed in the Iliad, is the wrath of Achilles; that of the Odyssey, the return of Ulysses; and that of the Æneid, the translation of the Trojan empire into Italy.

The same author observes, that the divine persons are named in all three propositions. Homer, *e. gr.* declares, that what happens in the Iliad, is by the will of Jupiter; and that Apollo was the cause of the quarrel between Agamemnon and Achilles: the same poet says, it was

Apollo prevented the return of Ulysses's companions; and Virgil mentions the Destinies, the will of the gods, and the anger of Juno. But they all three dwell chiefly on the person of the hero, as if he were the matter of the poem.

Yet there is some difference, in this respect, in the three poems; in that Achilles is named in the Iliad; but Ulysses and Æneas are not: they are only pointed at, and that in such general terms, as if it were supposed they were known before.

This practice seems to fall in with the first intention of the poet; who is to feign an action without names, and who, as Aristotle says, does not relate the action of Achilles, nor Ulysses, nor Æneas, nor any particular person, but of an universal, general, and allegorical person.

Add to this, that the character which the poet is to give his hero, and his whole work, is expressed in the proposition, both by Homer and Virgil.

The whole Iliad is anger and violence: it is Achilles's character, and it is what the poem commences with: *Μηδὴν αἰεὶ δεῖ*. The Odyssey presents us in the first verse with the prudence, dissimulation, and address, which make the character of Ulysses, and the business of the poem: *Ἀνδρῶν πολυτροπῶν*. And we see the piety and mildness of Æneas in the beginning of the Latin poem: "Insignem pietate virum."

As to the manner of the proposition, Horace contents himself to prescribe modesty and simplicity; not to promise much, nor raise great expectations in the reader. *Do not begin*, says he, *like that wretched poet, who set out with, Fortunam Priami cantabo, & nobile bellum. How much better is that of Homer, Dic mihi, Musa, virum? &c. He does not spend all his fire at once, and leave nothing but smoke: from this feeble beginning, you shall soon see him rise to the wonders of Antiphates, Scylla, Charybdis, and Polyphemus.*

The same modesty we find in the proposition of the Æneid: if that of the Iliad be a little more furious, it is, perhaps, in conformity to the character of the poem, which is a series of violences and extravagances.

Add, that if the poet be to speak with modesty of his hero, much more is he to do so of himself: thus Virgil only says, *I sing the action of Æneas*. Homer begs his Muse to *say*, or to *sing*. How far does Claudian swerve from these examples?

"—————Audaci promere cantu
Mens congesta jubet; gressus removete, profani:
Jam furor humanos nostro de pectore sensus
Expulit, & totum spirant præcordia Phœbum."

A short poem, *e. g.* an ode, &c. in which the violent strain could be pursued to the end, might admit of such a pompous beginning. Thus we find Horace begin an ode much after the manner of Claudian:

"Odi profanum vulgus, & arceo——
——Carmina non prius
Audita Musarum sacerdos
Virginibus puerisque canto."

But the length of an epic poem quite excludes all pompous propositions.

There is scarcely any fault we have yet observed a proposition liable to, but there is an instance of it in the proposition of Statius's Achilleid: he bids his *Muse rehearse the deeds of the magnanimous son of Æchus, who was formidable even to the Thunderer*. He adds, *That he has worthily discharged a*

former undertaking; and that Thebes esteems him a second Amphion.

"Magnanimum Æacidem, formidatamque Tonanti
Progeniem, & patrio vetitam succedere cœlo,
Diva, refer.——
Tu modo, si veteres digno delevimus haustu,
Da fontes mihi, Phœbe, novos, &c."

PROPOSITION, in *Rhetoric*, is that part of a just and regular discourse, in which the speaker lays down or proposes the subject upon which he designs to treat, in a distinct and express manner. This first employs his thoughts, though it usually follows both the introduction and narration in the order of the discourse. As the proposition is the basis of his whole design, it is necessary, in the first place, that this be duly weighed, and represented to his mind in all the different views, in which he can place it; that he well considers the nature of it, the several parts of which it consists, and the particular force of each part. By this means he will be the better enabled to offer such arguments, as may be proper, in its defence, and to refute any objections which may be brought against it.

Orators use several methods of laying down the subject of their discourses. Sometimes they do it in one general proposition. We have an instance of this in Cicero's speech to the senate, the day after Cæsar was killed, as it is given us by Dion Cassius, lib. xlv. p. 250. ed. Leunclav. in which his design was to persuade them to peace and unanimity. *This*, says he, *being the state of our affairs, I think it necessary that we lay aside all the discord and enmity which have been among us, and return again to our former peace and agreement*. And then he proceeds to offer his reasons for this advice.

At other times, in order to give a clearer and more distinct view of their discourse, they subjoin to the proposition, the general heads of the argument by which they endeavour to support it. This method Cicero uses in his seventh Philippic, cap. 3. where he says: *I, who have always commended and advised to peace, am against a peace with Mark Antony. But why am I averse to peace? Because it is base, because it is dangerous, and because it is impracticable; and I beseech you to hear me with your usual candour, while I make out these things*. See PARTITION.

But some orations, especially of the demonstrative kind, do not require any particular proposition, being little more than a continued narrative or illustration of the subject: of this sort is that of Cicero, in which he returns thanks to Cæsar, in the name of the senate, for pardoning Marcellus; and his invective against Piso: as likewise Pliny's panegyric in praise of the emperor Trajan. Not but that such discourses are disposed in a regular order, and under proper heads, though they are not laid down at first in distinct propositions.

Quintilian, Inst. Orat. lib. iv. cap. 5. observes, that orators sometimes avoid laying down any direct proposition, when the chief thing they have in view may be disagreeable to those whom they address; for which reason they take them off from attending to it, till they have first prepared them for it, by offering something else, which, when proved, the other may with less difficulty be admitted. Cicero makes use of this art in his defence of Ligarius. Ward's Or. vol. i. lect. 14.

PROPOWANG, in *Geography*, a town on the W. coast of the island of Celebes. N. lat. 1° 16'. E. long. 119° 13'.

PROPRÆFECT, PROPRÆFECTUS, among the Romans, the

the prefect's lieutenant; or an officer whom the prefect of the pretorium commissioned to do any part of his duty in his place.

In Gruter, p. cccclxx. the third inscription mentions prefects of the pretorium under Gratian, in the city of Rome, and the neighbouring parts.

PROPREMENT, Fr. Rousseau has given this word a place amongst French musical technica; which in the execution of vocal or instrumental music, seems equivalent to our words, *neat* and *clean*.

PROPRETE', Fr. *Neatness*, English. The same author defines the execution of French melody, with all its appropriate agréments, or graces, *propreté*, where it means propriety.

PROPRETOR, or PROPRAETOR, a Roman magistrate, who, having discharged the office of pretor at home, was sent into a province to command there with his former pretorial authority.

PROPRETOR was also an appellation given to those who, without having been pretors at Rome, were sent extraordinarily into the provinces, to administer justice with the authority of pretors.

PROPRETOR is also a denomination given by some to those sent by the emperors into the provinces, which, upon partition in Augustus's time, fell to their lot: as the name *proconsul* was given to those sent into the provinces that fell to the people's share.

PROPRIETARY *Governments in America*. See the account of *CHARTER Governments*.

PROPRIETARY *Monks*, were such as had reserved goods and effects to themselves, notwithstanding their formal renunciation of all at the time of their profession.

They are frequently mentioned in the *Monast. Anglic. &c.* and were to be very severely dealt with; to be excommunicated, deprived of burial, &c. "Monachi proprietarii excommunicentur ab abbatibus; & si in morte proprietarius inventus fuerit, ecclesiastica careat sepultura, &c." *Addit. ad Matt. Pat.*

PROPRIETATE PROBANDA, in *Law*, is a writ to the sheriff to inquire of the property of goods distrained, when a defendant claims a property upon a replevin sued.

Where a property is proved by the defendant, a replegiari properly lies not.

PROPRIETATIS ELIXIR. See *ELIXIR*.

PROPRIETOR, or PROPRIETARY, he who has the property or propriety of any thing.

PROPRIETOR, in *Law*, is strictly such a one as has, or possesses, any thing as his own in the utmost degree: "Quæ nullius arbitrio est obnoxia."

The term was formerly applied, in a particular manner, to him who had the fruits of a benefice to himself, and his successor; as in ancient time, abbots and priors had.

PROPRIETORS of *Land*, in *Agriculture*, such persons as hold landed property. It is observed by the author of the "Present State of Husbandry in Great Britain," that the lands in England and Wales were, at no very remote period, chiefly in the possession of the crown, the church, and great proprietors; but that, owing to several causes, noticed below, landed property has become of late more widely diffused, and new orders of proprietors have risen into consequence, which has proved greatly advantageous to the state, not only in regard to improvements in husbandry, but also to the advancement of all the other arts.

The extent of landed property formerly vested in the crown, was very considerable; but during several reigns many improvident grants were made to particular favourites, whereby it became much diminished. From the report

given into parliament some years ago by the commissioners appointed to inquire into the landed revenues of the crown, it appears that the old and improved rent then payable, amounted only to 16,784*l.* 12*s.* 3¼*d.* The real annual value, however, far exceeds this sum; for, in the same account, it is stated, that the lands and estates from which the above-mentioned rent is payable, were, by the latest surveys, ascertained to be worth 102,626*l.* 14*s.* 1½*d.* *per annum*. The writer, however, disclaims any intention of throwing out the most distant personal reflection to the prejudice of those in the management of the crown-lands. It is well known, that these estates are commonly let on leases of one, two, or three lives, or for a great number of years, on every renewal of which, fines (in Scotland called *grassums*) are exacted. These fines, paid at the commencement of the leases, and improved by compound interest during the currency of them, may perhaps in the end exceed, in some cases, any yearly additional rent that could be demanded.

It is supposed that it is impossible to form any correct idea of the lands now in possession of the church. They are commonly let on leases of twenty-one years, renewable every seven, on payment of a fine; and therefore the rent-roll must be rather nominal, than such as can convey any information in regard to the real annual value of the property. Suppose the clergy of England had a right to the tythes over the whole kingdom; that all the parishes were inclosed; and that an allotment of land was given in every case, in lieu of tythes, a judgment might be formed of the extent of land that would fall to be possessed by them, from the rule frequently adopted by those who act as commissioners under acts of parliament past for inclosing certain parishes, namely, giving the clergymen one-sixth of the arable, and one-ninth of the pasture, or two-thirteenths of the whole. Including the lands in the possession of the religious corporations, it is probable they might amount to nearly one-fifth of the whole kingdom.

And it has been observed, that while the feudal system existed, the lords and great proprietors parcelled out considerable parts of their estates among their vassals and dependents. Since the abolition of that system, the possessors of these lands have been generally known by the name of yeomen; a most useful and valuable class of men, who are at present proprietors of no inconsiderable share of the landed property of England. And the recent very great increase in trade and manufactures, and the consequent influx of money, have tended still more to the division of property, by the creation of a great number of small freeholds. Proprietors of extensive manors, who find it necessary to dispose of their estates, (and this will happen in every country where the practice of entailing landed property does not prevail,) judged it for their interest to parcel them out in small lots, rather than sell them in entire manors. This having been for years the general practice, especially when the estates were situated in the vicinity of great cities, or large manufacturing towns, merchants, and manufacturers, and the officers of our fleets and armies, have had opportunities of exercising that degree of genius and persevering industry in planning and executing agricultural improvements, which in the early part of life enabled them to lay the foundation for becoming proprietors. It is, therefore, concluded that the proprietors of England and Wales may be classed into two divisions. The crown, the religious corporations, or clergy, and the great landholders, or those who possess from 5000*l.* to 50,000*l.* a-year and upwards, form the first class; and probably possess nearly three-fifths of the whole. The second division, consisting of that great body of gentlemen, holding

PROPRIETORS.

ing estates from 400*l.* or 600*l.* to 4000*l.* or 5000*l.* a-year; and the yeomanry, or those who possess from 30*l.* or 40*l.* to 500*l.* or 600*l.* of yearly rent; who are in possession of the remainder. These divisions have been much extended in the course of the last half century, and are still extending very rapidly.

In Scotland, however, the writer remarks, the crown can hardly be said to possess any landed property. But it is only a few years since that was the case; for, in consequence of the rebellions which happened in the years 1715 and 1745, the estates of several noble and respectable families were forfeited and annexed to the crown, on account of the active concern which the then proprietors took in those rebellions, in opposition to the established government. Highly to the honour of the British legislature, however, such of these estates as were unfold and annexed to the crown, were lately restored to the representatives of those families by act of parliament; an act which experience has already proved was politically right; as almost all the proprietors of those estates are now evincing their gratitude to their king and country, by exerting their utmost endeavours in the defence of both.

But here, previous to the abolition of popery in the year 1560, the clergy possessed landed property to a very great extent, but at that period the great proprietors who had (with a view to promote their own interests) encouraged and supported the promoters of the Reformation, when it was effected, seized on all the church lands, and in lieu thereof, and of the tythes which were formerly payable, allotted a certain quantity of money, or grain, or both, with a house, and a few acres of land, for the support and accommodation of each Protestant clergyman. As proprietors, therefore, this respectable, useful, well-informed, and deserving body, amounting to upwards of 900, rank very low, in comparison of what their predecessors did; for, in consequence of their offices, they only possess about 6000 acres of arable land. In this part of the kingdom, the feudal system was not only carried to a greater extent, but continued much longer in force than it did in England; and as manufactures and commerce began to flourish here only since the middle of the last century, a greater proportion of the landed property still remains in the hands of great proprietors, especially in the northern and more remote districts, where trade and manufactures are comparatively but little known. In Scotland, great proprietors alone, or those holding estates from 4000*l.* or 5000*l.* to 25,000*l.* a-year and upwards, may be said to be invested with the one-half of the whole kingdom. The other half is more generally divided; the greatest part of it being possessed by a numerous and respectable body of gentlemen in estates varying from 300*l.* or 400*l.* to 4000*l.* or 5000*l.* a-year, and the remainder by such as possess from 30*l.* or 40*l.* to 300*l.* or 400*l.* of yearly rent. There are not many of this last description, who, like the English yeomen, cultivate their own estates; being for the most part engaged in the naval, military, or civil departments of the state, few of them reside constantly in the country.

Mr. Marshall has remarked, in his work on landed property, in speaking of the management of estates, that the principal objects to be regarded are tenanted farms, and their inhabitants, whether occupiers or labourers. And that the others are woodlands; which are now generally, and properly, kept distinct from tenanted farms; excepting such plots as are requisite to the due occupancy of the farm lands. Also the waters and quarries that are not let with the tenanted lands; and mines, whether in hand or tenanted: together with the abstract rights attached to an estate; as tithes, manorial rights, chief rents, &c. &c.

And, lastly, demefne lands, whether they are kept in hand, for domestic purposes, or as a seminary of improvements for the use of the estate. The importance of which are, he thinks, obvious, for, says he, it were folly to purchase an estate, and equally imprudent to improve one, unless to be afterward duly managed; so as to secure a profitable return for the money laid out. But that, beside the profits which issue from landed property, there are other considerations which the proprietor of a tenanted estate cannot overlook. He differs essentially from the possessor of ordinary property. He is not in possession of the lands only, but also of their inhabitants. For, although in England tenantry are not bought and sold, as other live stock; yet when an estate is under lease, tenants may be said to be as firmly rooted in the soil as the oaks are which grow upon it. And even where tenants are at will, and labourers without certainty, such are, in general, their attachments to their native soil, and their natural connections, that to be driven from them is banishment:—a patriot prejudice, which is planted in human nature, and which ought at all times, and especially at present, to be kindly cherished. And in this country the possessor of an extent of territory has infinitely more power over its inhabitants than government itself. He may not only banish the native inhabitants, but he may depopulate the country, or may increase its population, as to his pleasure may seem meet. By changing the inhabitants, he may change the manners of a country, as from vice to virtue, or the reverse; and has it thus in his power to render the little world around him, as well as himself, miserable or happy; according to the principles of management he pursues. What inducements these are to men of fortune, to bend their minds cheerfully to their territorial concerns, and improve them in the best and most advantageous manner. See TENANT, and FARM.

However, though the promotion of such improvements be obviously of the greatest consequence and advantage to such proprietors as well as the public, they are in many cases strangely neglected, and even in some discountenanced. It has, indeed, been observed in a paper in a useful periodical work, the writer of which, after stating that the situation is highly favourable, the tenantry, eager to improve their farms, knowledge disseminated, and capital accumulated, that strange as it may appear, many very considerable land owners rather betray a disposition to retard, than to expedite real improvements. The terms of the leases are often arbitrary, and the landlord is too often reluctant in contributing a reasonable proportion towards permanent improvements, which are in themselves absolutely necessary, and of which it is equally preposterous and unjust to exact or expect the execution totally at the tenant's expence, more especially as the usual duration of his lease is seldom adequate to indemnify him. Even some proprietors do not only contribute reluctantly, but nearly refuse every assistance upon any terms. They accept the highest offer for the naked farm, and provided the stipulated rent be regularly paid, they appear indifferent how the tenant accommodates himself. They, indeed, express wishes to see their lands improved, but the honour of their motives may be doubted. Straightened circumstances do not by any means seem to form an excuse for this backwardness. It perhaps ought to be attributed to jealousy against their inferiors, and a desire of immediate aggrandisement, by pocketing an additional income without deduction. Such reasons as these are, however, entitled to no merit. But he does not intend to throw out reflections on all the land owners in his part of the country; for if some of them had not adopted a more liberal way of proceeding, agriculture would never have made the progress
amongst

amongst us which it has already done; at present, it would, however, be easy to prove that the landlords are, upon the whole, more backward than the tenantry. Many do not choose to become converts to their real interests, or to the lasting good of their country, but prefer a continuance of their illiberal policy of laying hold of what they can at the time, and allowing futurity to shift for itself. Under such a system, the tenant must be a drudge: his mind, broken down by his situation, disqualifies him for exertion, even though the necessary means were to come into his possession. His family, rudely educated, are only fit for labourers or low mechanics; and one great link of the chain which connects an enlightened society is thus rejected or destroyed.

It is the advice of Mr. Middleton, that every proprietor of a large landed estate should occupy one of his own farms, which, by being cultivated on the most improved scientific principles, may teach the neighbouring tenantry the best practice, by the most powerful of all means, that of *example*. If this, which seems to be at present more attended to, was general, much advantage no doubt would be the consequence of the proceeding.

PROPRIETY, in *Grammar*, is where the direct and immediate signification of a word agrees to the thing it is applied to.

In which sense propriety is used in opposition to a figurative or remote signification. Propriety of language denotes the selection of such words as the best usage has appropriated to those ideas, which we intend to express by them; in opposition to low expressions, and to words and phrases which would be less significant of the ideas that we mean to convey. To preserve propriety in our words and phrases, we must avoid low expressions; supply words that are wanting; take care not to use the same word in different senses; avoid the injudicious use of technical phrases, equivocal or ambiguous words, unintelligible expressions, and all such words and phrases as are not adapted to our meaning. See Murray's Eng. Gram. vol. i. p. 411, &c.

PROPTOMA, or PROPTOSIS, from προπτω, to fall out, in *Surgery*, a falling down, or displacement, of any part of the body.

PROPYLÆUM, Προπυλαίων, the porch of a temple, or great hall. See ATHENS.

Hence propylæum is also used figuratively, in matters of learning, for an introduction, apparatus, or prodromus, to some greater work. In this sense, we say, the propylæum of the Jesuits at Antwerp, &c.

PROQUESTOR, PROQUÆSTOR, the questor's lieutenant, or a person who discharged the office of questor in his stead, without the deputation of the senate.

The word is chiefly applied to an officer appointed by the governor of a province to discharge the questure after the decease of the questor, or when he went to Rome without being succeeded by another questor, till the senate and people should send a new one.

PRORÆ OS, in *Anatomy*, a bone of the cranium, called also os occipitis.

PRO RATA, in *Commerce*, a term sometimes used among merchants, for in proportion.

Thus, when speaking of any undertaking, they say, each person must reap the profit, or sustain the loss, *pro rata* to his interest; it is meant, each shall gain or lose, in proportion to the sum he put in stock.

PRO RATA Portionis, in *Law*. See ONERANDO *pro rata portionis*.

PROROGANDA ASSISA. See ASSISA.

PROROGATION, PROROGATIO, the act of prolonging, adjourning, or putting off, to another time.

PROROGATION of Parliament. See PARLIAMENT.

The proroguing of the lower house of convocation is a power vested in the archbishop with the consent of the suffragans.

PROSAIC NUMBERS. See NUMBERS.

PROSASCO, in *Geography*, a town of Italy, in the Friuli; eight miles N. of Friuli.

PROSCARABÆUS, in *Zoology*, the name by which some call the *meloe*, a genus of four-winged flies. See OIL BEETLE.

PROSCENIUM, in the *Ancient Theatre*, was an eminence on which the actors performed their parts.

The proscenium answered to our stage. It consisted of two parts among the Greeks; one particularly so called, where the actors performed; the other was the *logeion*, where the singers and the mimics acted their parts. Among the Romans, the proscenium and pulpitum were the same thing.

PROSCHÆRETERIA, Προσχαιρέτρια, in *Antiquity*, a day of rejoicing, kept when a new-married wife went to cohabit with her husband.

PROSCHEWA, in *Geography*, a town of Prussia, in the palatinate of Culm; 18 miles N.E. of Thorn.

PROSCHOWITZ, a town of Austrian Poland; 55 miles E.N.E. of Cracow.

PROSCLYSMA, a word used to express an irroration, or sprinkling of any part with a fluid, as the throwing water in the face in cases of fainting, &c.

PROSCRIPTION, PROSCRIPTIO, a publication made in the name of the chief or leader of a party, by which he promises a reward to any one who shall bring him the head of one of his enemies.

Sylla and Marius, by turns, proscribed each other's adherents. Under the triumvirate, a great part of the best and bravest of the Romans fell by proscription.

The term took its rise from the practice of writing down a list of the person's names, and posting it in public; from *pro*, and *scribo*, I write.

PROSDOCEMUS DE BELDEMANDIS, in *Biography*, was one of the earliest writers on music, at the beginning of counterpoint. Among the Vatican MSS. there is a treatise on music in parts or counterpoint, by an Italian of this name, written in 1412. It is chiefly an exposition and commentary of the doctrines contained in the "Practica Mensurabilis" of John de Muris, in his "Speculum Musicæ." Padre Martini was in possession of the tract of John de Muris, under the title of "Practica Mensurabilis Cantas: Mag. Joan. de Muris, di Normandia, alias Parisiensis, cum expositio Prosdocemi de Beldemandis patav. MS. an. 1404."

PROSE, PROSA, the natural language of mankind, loose, and unconfined by poetical measures, rhymes, &c. In which sense it stands opposed to *verse*.

The word comes from the Latin *prosa*, which some will have derived from the Hebrew *paras*, which signifies *expedit*; others deduce it from the Latin *prorsus*, or *prorsus*, going forwards; by way of opposition to *versa*, or turning backwards; as is necessary in writing verse.

Though prose hath its connexions, which sustain it, and a structure which renders it numerous, it ought still to appear free: its character consists in running easy, and unrestrained.

Poets very rarely have the talent of prose; the habit of wearing chains fits fast upon them, even when the chains are off.

St. Evremond compares prose writers to foot-travellers, who walk with less noise, but more security, than the cavaliers.

PROSECKEN, in *Geography*, a town of the duchy of Magdeburg; seven miles N. of Wismar.

PROSECUTION. To make men liable to criminal prosecutions

prosecutions by the law of England, it is required that they have the use of reason, and that they be *sui juris*. On the first account the law indulges infants under the age of discretion, ideots, and lunatics, whatever the nature of the fact may be; and even against the person of the king, as it has been held of late; neither will it suffer one who becomes *non compos* after he has committed a capital offence, to be either arraigned or executed. See LUNATIC, and INFANT.

As to an offender's being *sui juris*, it is to be observed, that neither a son, nor a servant, nor any other person, except a feme covert, is excused on the account of acting by command or coercion of another. See FEME COVERT.

The prosecution in the process towards the punishment of offenders succeeds their commitment, and denotes the manner of their formal accusation. This is either upon a previous finding of the fact by an inquest, or grand jury, or without such previous finding. The former mode is either by *presentment*, or *indictment*, which see. The other methods of prosecution are without any previous finding by a jury, to fix the authoritative stamp of verisimilitude upon the accusation. One of these, by the common law, was when a thief was taken *with the mainour*. (See MAINOUR.) This was taken away by several statutes; so that the only species of proceeding at the suit of the king, without a previous indictment or presentment by a grand jury now seems to be that of *information*, which see. There is another method of prosecution, at the suit of the subject, called an *appel*, which see.

PROSECUTION of Felons. See LARCENY and REWARDS.

PROSECUTOR, in Law, is he that pursues a cause in another's name.

In criminal proceedings, or prosecutions for offences, the king is prosecutor. All offences are either against the king's peace, or his crown and dignity; and are so laid in every indictment. For though in their consequences they generally seem (except in the case of treason and a very few others) to be rather offences against the kingdom than the king; yet, as the public, which is an invisible body, has delegated all its powers and rights, with regard to the execution of the laws, to one visible magistrate, all affronts to that power, and breaches of those rights, are immediately offences against him, to whom they are so delegated by the public. He is therefore the proper person to prosecute for all public offences and breaches of the peace, being the person injured in the eye of the law. See KING and PREROGATIVE.

PROSEG, or PROSECO, in Geography, a town of Istria, celebrated so long ago as the time of Augustus for its wine, so that his wife Livia used it as a cordial in her old age; its qualities are described by Pliny. The ancient name of this town was "Pencinum;" seven miles N.W. of Trieste.

PROSELYTE, PROSELYTUS, a new convert to the faith.

The word is Greek, *προσηλυτος*, which, in Latin, signifies *advēna*; in English, *stranger*, or one arrived out of another country.

The term was much used in the primitive church. The Jews too had their proselytes, who, from being Gentiles, embraced Judaism; either wholly, or in part.

Among the Hebrews there were two sorts of proselytes; one called *proselytes of righteousness*, or *proselytes of the covenant*, who became complete Jews, by submitting to the rite of circumcision, and were in all respects united to the Jewish church and nation: they were denominated proselytes of the covenant, because they were received into the covenant of God by circumcision, which was named the blood of the covenant, because, according to St. Paul (Gal. v. 3.) men were bound by it to observe the ceremonial law; and they

were called proselytes of righteousness, on account of their acknowledging and observing the whole ceremonial law, to which the Jews, and the Pharisees in particular, attributed their being accounted righteous before God. At their admission there were three ceremonies performed, *viz.* circumcision, baptism, and a sacrifice, generally consisting of two turtle doves and two young pigeons. After these ceremonies the proselyte received a new name, and no longer owned any relations in the world. See John, iii. 3. Luke, xiv. 21. 2 Cor. v. 16, 17. 1 Pet. ii. 2.

It is said in the Talmudical writings, that though they were regarded as Jews, they were admitted to no office, and were treated with great contempt.

The latter were called *proselytes of the gate*, who did not embrace the Jewish religion, so as to be obliged to receive or observe the ceremonial law, and yet were suffered to live among the Jews under certain restrictions; as that they should not practise idolatry, nor worship any other god beside the God of Israel; that they should not blaspheme the God of Israel; that they should keep the Jewish sabbath, so far at least as to refrain from working on that day. Besides forsaking idolatry, they were under an obligation to observe the seven precepts, which, as the Talmudists pretend, God gave to Adam and afterwards to Noah, who transmitted them to posterity. The first of these precepts forbids idolatry, and the worship of the stars in particular; the second recommends the fear of God; the third forbids murder; the fourth adultery; the fifth theft; the sixth enjoins respect and veneration for magistrates; and the seventh condemns eating of flesh with the blood. This last, as the Rabbins say, was added after God had permitted Noah to eat the flesh of animals. No ceremony was performed at the admission of these proselytes. Maimonides expressly says, that they were not baptized. These strangers were permitted to worship the God of Israel in the outer court of the temple, which, for that reason, was called the court of the Gentiles.

Dr. Lardner, with whom Dr. Doddridge and others also agree, is of opinion that there was but one sort of proselytes among the Jews. They were circumcised, and thus they became Jews by religion, and were admitted to eat the passover, and to partake of all religious privileges, as the Jews by descent did. They were called "strangers, or proselytes within the gates, and sojourners," as they were allowed to dwell, or sojourn among the people of Israel. And they were so called, because they could not possess land. For according to the law of Moses, the whole land of Canaan was to be given to the 12 tribes of Israel, the descendants of the patriarch Jacob. (See Exod. xii. 48. 49. Lev. xvii. 8. 13. 15. Numb. ix. 14. xv. 15.) A proselyte was a man circumcised according to the law of Moses, or a Jew by religion. This is the sense of the word in all the texts of the New Testament where it is used. (Matt. xxiii. 15. Acts, ii. 10. vi. 5. xiii. 43.) Dr. Lardner thinks that the notion of two sorts of Jewish proselytes cannot be found in any Christian writer before the 14th century or later. Cornelius is not called a proselyte in the New Testament. This learned writer pays no regard to what the later Jewish Rabbins say of the method of initiating proselytes by circumcision, baptism, and sacrifice. See Lardner's Works, vols. vi. and xi. Doddridge on the Acts.

PROSELZHEIM, or BROSSELSHEIM, in Geography, a town of the duchy of Wurzburg; seven miles N.E. of Wurzburg.

PROSENDORF, a town of Bavaria; five miles N.N.E. of Bamberg.

PROSERPINA, in Botany, a name given by some authors to chamomile.

PROSER-

PROSERPINACA, said by Linnæus to be derived à *proserpendo*, from its creeping. It is also, according to Martyn, an ancient name in Apuleius, and Pliny has a genus called *Proserpina*, from the queen of the infernal regions. Gronovius seems to have chosen the name for the present plant, because it grows in low places infested by frogs and newts.—Linn. Gen. 41. Schreb. 56. App. 818. Willd. Sp. Pl. v. 1. 488. Mart. Mill. Dict. v. 3. Pursh. v. 1. 28. Michaux. Boreal-Amer. v. 1. 76. Juss. 68. Lamarck Illustr. t. 50. (Trixis; Mitch. 23. Lamarck. Dict. v. 8. 117. Gærtn. t. 24.)—Class and order, *Triandria Trigynia*. Nat. Ord. *Inundate*, Linn. *Hydrocharides*, Juss.

Gen. Ch. Cal. Perianth superior, of three erect, acute, permanent leaves. Cor. none. Stam. Filaments three, awl-shaped, spreading, the length of the calyx: anthers twin, oblong, acute. Pist. Germen inferior, triangular, very large; style none; stigmas three, downy, thickish, the length of the stamens. Peric. Drupa small, dry, ovate, triangular, three-winged, crowned by the permanent, closed calyx. Seed. Nut rather bony, triangular, three-celled; kernels oblong, affixed to a thread.

Ess. Ch. Calyx superior, three-cleft. Corolla none. Nut inferior, three-celled.

1. *P. palustris*. Linn. Sp. Pl. 129. Act. Ups. for 1741. 81. (Trixis palustris; Gærtn. t. 24. f. 8.)—Leaves linear-lanceolate, serrated, the bottom ones pinnatifid.—Native of ditches and pools between Canada and Carolina, flowering in July.—Root annual, creeping. Stems a foot high, roundish. Leaves alternate, stalked; lower ones immersed, pinnatifid, with linear segments. Flowers axillary, solitary. Nut whitish, with a pale reddish kernel. Linnæus says the fruit is like that of a *Polygonum*.

2. *P. pectinata*. Pursh. v. 1. 92. Lamarck Illustr. t. 50. f. 1.—Leaves all pinnatifid in a pectinate manner.—Found in overflowed places, and ditches, from New Jersey to Carolina, flowering in July and August.—Michaux considers this but as a variety of the last species, and calls it *P. palustris* β , but Pursh thinks it is certainly a distinct species. He never found the two growing promiscuously, or near one another. We adopt this entirely on the authority of the latter author, having never seen either a specimen, figure, or description.

PROSERPINE, in *Mythology*, the daughter of Jupiter and Ceres, wife of Pluto, stolen by him out of Sicily, and carried to his subterranean dominion, where she was the partner of his empire. The poets and painters represent her with a dark complexion, and a melancholy air in her face. Statius (Theb. 8. v. 11.) assigns her the employment of keeping a register of the dead, and marking down all that should be added to that number. He also says, (lib. 5. Sylv. 1. v. 257.) that when any woman dies who has been a remarkable good wife in this world, Proserpine prepares the spirits of the best women in the other to make a procession to welcome her into Elysium with joy, and to strew all the way with flowers where she is to pass. See CERES and COREIA.

PROSEUCHÆ, derived from *προσευχη*, *prayer*, or *oratories*, in *Antiquity*, were the places of prayer among the Jews, and nearly the same as their synagogues. But the synagogues were originally in the cities, and were covered places; whereas, for the most part, the proseuchæ were out of the cities, and upon the banks of rivers, having no covering, except, perhaps, the shade of some trees, or some covered galleries.

Dr. Prideaux mentions another distinction in respect to the service performed in them: in synagogues, he says, the prayers were offered up in public forms in common for the

whole congregation; but in the proseuchæ they prayed as in the temple, every one apart for himself. Conu. part 1. book 6. vol. ii. p. 556. &c. edit. 10.

After all, it remains a question with some whether the synagogues and the proseuchæ were any thing more than two different names for the same place; the one taken from the people's assembling in them, the other from the service to which they were more immediately appropriated, *viz.* prayer.

PROSKAU, or PRUSKAU, in *Geography*, a town of Silesia, in the principality of Oppeln; 6 miles S. of Oppeln. N. lat. 50° 31'. E. long. 17° 51'.

PROSKEN, a town of Prussia, situated on the Lick; 10 miles S.E. of Lick.

PROSLAMBANOMENOS, in the *Ancient Greek Music*, was the first note of their scale, whether ascending or descending.

It was usual among the Greeks to consider a descending as well as an ascending scale; the former proceeding from acute to grave, precisely by the same intervals as the latter did from grave to acute. The not distinguishing of these two scales has led several learned moderns to suppose, that the Greeks, in some centuries, took the proslambanomenos to be the lowest note in their system; and in other centuries to be the highest. But the truth of the matter is, that the proslambanomenos was the lowest or highest note, according as they considered the ascending or descending scale. The learned author of this remark, thinks this distinction of the ascending or descending scales conducive to the variety and perfection of melody: but he says, he never met with above one piece of music, where the composer appeared to have any intelligence of that kind; and this piece was above one hundred and fifty years old.

We wish the author had told us where this piece of one hundred and fifty years old was to be seen, and by whom it was composed: as we are not yet convinced of the Greeks having a *descending* as well as an *ascending* scale; though Dr. Pepusch asserts roundly, and without the least modification of doubt, or even condescending to allege a single reason or proof in defence of his opinion, that "it was usual among the Greeks to consider a descending as well as an ascending scale; the former proceeding from acute to grave, precisely by the same intervals as the latter did from grave to acute. The first found of each was the proslambanomenos." Phil. Trans. N° cccclxxxi. p. 226, and Martyn's Abridg. vol. x. part 1. p. 261.

No instances of these inverted scales are to be found, however, in Aristoxenus, Euclid, or any of the oldest and best writers. Boethius, Bryennius, and some other of the more modern compilers, have, indeed, puzzled the cause by ambiguous expressions, which seem to bear such construction. Meibom. in Gaudent. p. 33, et Wallis in Bryennio, p. 364, et seq.

It seems, however, as if all this doubt and perplexity had arisen from the want of precision in the musical nomenclature of the Greeks. The prepositions *ὑπο*, *sub*, *ὑπερ*, *super*, and the adjectives *ὑπάρτος*, *summus*, and *ὑπέρτος*, *imus*, have manifestly been applied to sounds more to express their situation in the lyre and diagrams, than the length of the strings, or the gravity and acuteness of their tones.

Dr. Wallis, in his Appendix to Ptolemy's Harmonics, explains this difficulty in the following manner.

"The Greeks called hypate, *supreme*, though it is the lowest sound or string of the tetrachord; and nete, *last*, or *lowest*, though the most acute. (This Henry Stephens acknowledges at the word *ἡπτε*, which he defines *ultimam seu imam*: and parnete, *ima proximam*): therefore those who

first made use of these names, applied them differently from us, calling grave, *high*, and acute, *low*. And thus Nicomachus, p. 6, calls Saturn, the highest of the planets, Hypate; and the moon, the lowest, with respect to us, Nete. Boethius, likewise, in his Treatise on Music, places, in all his diagrams, the low sounds at the top, and the high ones at the bottom. But, he concludes, that we must not attend to the original import of these words, *summus* and *imus*, but understand hypate and nete as *first* and *last*, or *principal* and *extreme*, as Aristides Quintilianus has done, p. 10."

In the first, or Mercurian lyre, the longest string, which produced the lowest sound, from being placed highest in the instrument, as is the case with the modern harp, was called hypate, the *highest* sound; and nete, for the same reason, was afterwards, upon the extension of the scale, called *lowest*, though the most acute. Trite, the third string from the top of the two last tetrachords, had its name, as in our violins, by comparison with the smallest strings. From a passage in Aristides Quintilianus, it seems as if the Greeks, in naming and numbering the notes of their scale, made it a rule always to go *towards* mese, and end with it, as being the regulator of the other notes, and situated in the *medium* of the voice. This is confirmed by the problem of Aristotle already cited, and this confirms what has been already observed of the order of the alphabetic notation, in which mese is always expressed by omega. It seems, therefore, as if the Greeks ascended the lower octave of the diatonic, and descended the upper one; otherwise it is not easy to see why the strings of the upper octave should have names referring, as they evidently do, to a descending series, in an order opposite to those of the lower octave.

Παρεα, in the compound names of the notes, evidently means *next in order*; parypate, in the lower octave, then is *ascend*; paranete, in the upper octave, plainly *descent*. The same is implied in trite. But the term nete, *last*, looks very like ascent again—*And darkness was upon the face of the deep!*—These contradictions may account in some degree for the great perplexity about the scale; they are curious however, and as well worth observing, perhaps, as any matters of this kind.

The proslambanomenos was one of those sounds which the ancients called *stables*, from their remaining fixed throughout all the genera and species.

For a farther account of the proslambanomenos, see GREEK Music.

PROSNITZ, or PROSTIAGOW, in *Geography*, a town of Moravia, in the circle of Olmutz; 8 miles S.S.W. of Olmutz. N. lat. 49° 35'. E. long. 17° 3'.

PROSODIA, Προσοδία, in *Antiquity*, a sacred song, or hymn sung in honour of the gods. It differed from the prosodia with an omega, προσωδία, which was a song sung in concert with some musical instrument.

PROSODIUM, προσωδιον, according to Jul. Pollux, was the name of a canticle in honour of Apollo, composed by Eumelus of Corinth, cited by Pausanias and Athenæus, as one of the most ancient musicians of Greece.

PROSODY. Though it has been observed that prosody, according to its derivative acceptation from προσωδία, chiefly signifies the accent of syllables, yet both in its generally received and enlarged sense, as well as from its derivation προς and ὤδη, it implies, as the sequel will exemplify, all that can affect articulated harmony, in verse or prose. It is common, therefore, to include under this term, *accent*, *emphasis*, *quantity*, *pause*, *tone*, and the laws of *versification*. Our remarks concerning the two former have been already given, as our readers will find, in the alphabetic series of this work; and on which we shall here offer nothing

more than what is required by a precise and accurate explanation of the third particular of this article, or

QUANTITY.—From the many that have written on this subject, and that have assigned, with such precision and care, rules to determine the quantity of the syllables composing the ancient languages, we might almost naturally infer, that what syllabic quantity actually was among the ancients, is, at this time, known amongst the moderns; but the case is otherwise. To determine whether a syllable is long or short, and to produce our rule from the grammarian or the poet, are by no means difficult; but to define what quantity was, in the age when its nature was not determinable from the mouldering manuscript, or the hieroglyphic symbols of our modern copyists; when the criteria for the ear, which Quintilian declares cannot be ocularly intimated, were obtained from the only legitimate and effectual source, the viva vox, is a task too arduous for us to undertake; at least at a time when the lip and the tongue, the sole proprietors of this faculty, are fallen into dust; and all that was once argumentative in the senate, eloquent in the forum, and harmonious on the stage, are now but silence and oblivion. From the ashes, however, we, together with every tribe of antiquarians, have gleaned our quota; and from the scattered fragments, the imperfect records, the broken monument, the sepulchral mansion, and the relics of the general ruin, have very shrewdly, in common with our sagacious brethren, collected, what we call, our rules, when, alas! they are but conjectures.

To obtain an adequate idea of the difficulties attending a just perception of the ancient elocution, we must recollect, that not only were there fifteen vowel sounds, represented by six letters, but each of these was again susceptible of one of the three accents, the acute, the grave, or the circumflex. And though the Greeks remedied this in part, by two additional characters, yet to express the mere duration of their syllables, there remains an obvious deficiency. Besides, every intelligent observer will admit, that elocution is nothing but a species of music, since every thing implied by the duration of a syllable, the mood or general time of delivery, accent, emphasis, pause, tone, and cadence, are properties which may be very adequately expressed on paper, in musical composition, or, more completely, by a good organ. The duration of a syllable is perfectly analogous to the relative difference between a minim and a crotchet; the mood, to the general time, whether quick or slow, observed in the whole composition; accent and emphasis, being an elevation or depression of the voice, are actually the variation from one note to another; pause is, by musicians, under the term a *rest*, only changed in name; tone, implying all that modulation of the voice effected by the tranquil, plaintive, or impassioned mind, is what the complete organ very nearly effects by the different tones termed the diatonic, semiquarter, principal, and, occasionally, by the swell; and the cadence is but the return of the air and notes to the same key to which the whole composition is set. Though these several properties are comprehended but seldom in the idea of all that is requisite to read an oration, or a poem, yet they do not exceed, but are really short of the qualities that constitute the complete orator, or the poet. Hence we easily perceive, that of all that once gave eloquence to the orations of Cicero, and harmony to the strains of Virgil, we now retain but a concatenation of vowels and consonants, and, comparatively speaking, but a lifeless syllabication. Notwithstanding, however, this latitude for doubt, and the difficulties to which the question is liable, several, with little hesitation, define the quantity of a syllable to be the duration of the voice in pronouncing it. But whilst this, on the

the one hand, renders the whole poetic fabric consistent, it is, on the other, not a little at variance with the customary and established pronunciation of many who are amongst the principal advocates of prosodial orthoepy, as well as with the manner in which the language is frequently pronounced among the moderns, at least by the British nation at large. To the youth committed to our care, we prescribe the laws of quantity, and we oblige them, on pain of disciplinary consequences, to pronounce the first syllable of *prōfugus* short, and that of *cōpia* long, because the former is a tribrac, and the latter a dactyl; but we not only allow them, but accustom ourselves to pronounce *nēpos*, *fīdes*, *glōbus*, and *conjūgium*, as though those several syllables were respectively long. And thus, whilst we contend that every syllable, foot, and verse, ought to have their due and requisite quantity, and, in partial instances, discountenance the violation of either; and whilst we define this quantity to be a duration of the voice, in such a manner that a long syllable shall occupy twice the time of a short one, and that a dactyl shall equal, in the duration of time, a spondee, in any case where habit, however degenerate, has formed our prepossession, we admit violations, with the loss of metre, equally incompatible. Thus, in pronunciation, we give the same time to the iambic foot, the pyrrhic, and the dactyl; as we do to the spondee, the choree, and the tribrac; and with equal facility convert the tribrac and the anapæst into the dactyl; and the acatalectic hexameter into the brachycatalectic, or rather into what is at once destitute of all rule or definition. This is certainly an evident inconsistency, the discreditable continuance of which becomes a greater impediment to the prosodial acquisitions of youth than is generally imagined, and demands not only the consideration, but the agreed and united decision of all that advocate the cause of classical erudition.

The English are accused, not only of departing from the genuine sound of the Greek and Latin vowels, but of violating the quantity of these languages more than any other European nation. The author of the Essay on the Harmony of Languages, gives us a detail of the particulars by which this accusation is proved; and this is a picture of the English pronunciation of Latin, so accurate as to give it every claim to our citation.

“The falsification of the harmony by English scholars in their pronunciation of Latin, with regard to essential points, arises from two causes only: first, from a total inattention to the length of vowel sounds, making them long or short merely as chance directs; and secondly, from founding doubled consonants as only one letter. The remedy of the last fault is obvious. With regard to the first, we have already observed that each of our vowels has its general long sound, and its general short sound totally different. Thus, the short sound of *e* lengthened is expressed by the letter *a*, and the short sound of *i* lengthened is expressed by the letter *e*. And with all these anomalies usual in the application of vowel characters to the vowel sounds of our own language, we proceed to the application of vowel sounds to the vowel characters of the Latin. Thus, in the first syllable of *sīdus* and *nōmēn*, which ought to be long; and of *mīser* and *ōnus*, which ought to be short; we equally use the common long sound of the vowels; but in the oblique cases, *fīderis*, *nōminis*, *mīseri*, *oneris*, &c. we use quite another sound, and that a short one. These strange anomalies are not in common to us with our southern neighbours the French, Spaniards, and Italians. They pronounce *sīdus*, according to our orthography, *seedus*, and in the oblique cases preserve the same long sound of the *i*. *Nomen* they pronounce as we do, and preserve, in the oblique cases, the same long

sound of the *o*. The Italians also, in their own language, pronounce doubled consonants as distinctly as the two most discordant mutes of their alphabet. It is a matter of curiosity to observe with what regularity we use these solecisms in the pronunciation of Latin. When the penultimate is accented, its vowel, if followed but by a single consonant, is always long, as in Dr. Foster's examples. When the antepenultimate is accented, its vowel is, without any regard to the requisite quantity, pronounced short, as in *mirābile*, *frīgidus*; except the vowel of the penultimate be followed by a vowel, and then the vowel of the antepenultimate is, with as little regard to true quantity, pronounced long, as in *maneo*, *redeat*, *odium*, *imperium*. Quantity is, however, vitiated, to make *i* short, even in this case, as in *oblivio*, *vineā*, *virium*. The only difference we make in pronunciation between *vineā* and *venia*, is, that to the vowel of the first syllable of the former, which ought to be long, we give a short sound; to that of the latter, which ought to be short, we give the same sound, but lengthened. *U*, accented, is always, before a single consonant, pronounced long, as in *hūmerus*, *fugiens*. Before two consonants, no vowel sound is ever made long, except that of the diphthong *au*, so that whenever a doubled consonant occurs, the preceding syllable is short.”

In speaking of improper pronunciation as arising from the want of due attention to quantity and accent, Mr. Pickbourn, the ingenious author of a Dissertation on the English Verb, justly observes, (Monthly Magazine, N^o 135.) “That scholars err in their pronunciation of, 1st, words of two syllables having the first short, as *equēs*; 2dly, words of three syllables having the first long and the second short, as *fīdera*; 3dly, polysyllables accented on the antepenultimate; as *juvenilibus*, *interea*, &c.; and lastly, words ending in a long vowel, as *domini*, or in a long vowel and a single consonant, as *dominis*. These errors arise in part from the want of distinguishing between the long and short powers of the vowels, and in part, from the indistinct and confused notion which we have of accent. For, when it falls on a short syllable, we often make that syllable long; and when it falls on a long one, we sometimes make it short. Accent does certainly affect quantity; that is, it makes the accented syllable a little longer than it would be without it. But its operation is never so great, as to make a short syllable become long, nor does the privation of accent make a long syllable become short; for there are degrees of time both in long and short syllables. All short syllables are not equally short; nor are all long ones equally long.” This remark is fully confirmed by a passage quoted by Dr. Warner (in his Metron Ariston) from Quintilian: “Et longis longiores, et brevibus sunt breviores syllabæ.” The second syllable of *amāvit*, being accented, is a little longer than the second syllable of *amaverunt*, though they are both long syllables; and the first syllable in *lēgi*, being accented, is a little longer than the first syllable of *legisti*, which is deprived of accent, though they are all long syllables. In pronouncing such words as *animus*, *dominus*, *oculus*, &c. though the vowels retain their short sound, yet the stroke of the voice laid on the first syllable increases the impression which that syllable makes on the ear, and consequently, diminishes the impression made by that which follows it.

We have already observed, that since in the English language, dissyllables accented on the first syllable, generally have that syllable long, we have, very improperly, applied this rule to all Latin dissyllables, because they are accented on the first syllable. Hence we say, *ēquēs*, *cōmes*, *mīser*, *nēmus*, *vīgor*, *rīgor*, *līquor*, *tīmor*, &c. making the first syl-

iable long, or at least nearly so. Why do we not pronounce the first syllables of *ēques, cōmes, miser, nēmus*, as we do the first syllables of their genitives, *ēquitis, cōmitis, miseri, nēmoris*? And why do we not pronounce such words as *vīgor, rīgor, liquor*, as we do the English words *vigour, rigour, liquor*? And the first syllable of *tīmor*, as we do the first syllable of *tīmoris*, and of the English word *timorous*? If we pronounced the first syllable of the adjective *mālus*, as we do the first syllable of the English word *malice*, we should properly distinguish it from *mālus*, an apple tree. By an attention to this rule we should easily distinguish between the present and perfect tenses of many verbs, as *vēnit* and *vēnit*, *fūgit* and *fūgit*, *lēgit* and *lēgit*, &c. Again, since many English words of three syllables accented on the first have that syllable short, we have, therefore, hastily concluded that all Latin trisyllables, accented on the first, must have that syllable short, unless it be long by position, and therefore, very improperly, we say, *līmīna, līmīte, sēmīne, vīribus, dīcere*, &c. Why do we not pronounce the first syllable of these words with a long vowel sound, in the same manner in which we pronounce the first syllables of *līmēn, līmēs, sēmēn, vīres, dīco*, &c? An attention to this remark would shew the difference between *pōpulus*, a people, and *pōpulus*, a poplar tree. In polysyllables accented on the antepenultimate we sometimes err in a similar manner, by giving a short sound to a vowel long by nature, as *juvēnīlibus*; and, at other times, by giving a long sound to a vowel naturally short, as in *intērea*. But in words of this kind, we do not universally err, for few pronounce such words as *depōsitum, consīlium, exīlium, exīdium*, &c. improperly. Lastly, words ending in a long vowel, as *domīni*, or in a long vowel followed by a single consonant, such as datives and ablatives of the first and second declension, and genitives singular, nominatives, accusatives, and vocatives plural of the fourth declension, as *domīnis, gradūs*, should always be uttered with a long vowel sound, though the accent or stress can never fall on such syllables except by a very singular poetic licence. The same judicious critic, in an ingenious little treatise on Metrical Pauses, adds, that, in accented antepenults, a short is commonly pronounced right, as in *animal*, but sometimes wrong, that is, with a long vowel sound, as in *gālea, fāteor, tāceo, cesāries, Mānālios*; a long is generally pronounced wrong in trisyllables, as *pābulum, grāmina, māchina*; but right in some polysyllables, as *mortālia, navālia*; and wrong in others, as *spectācula, levāmine, imāgine*. *E* short is sometimes improperly made long, as in *sēnior, sēnibus, mēlior, obsēquium, vēniet, invēniet*; but it is generally pronounced right in *trēpidus, gēmitus, ēpula, vulūcribus*, &c. *E* long is generally pronounced right in polysyllables, as *carchesia*; but wrong in trisyllables, as *semīna, legibus*. *I* short is always right, as *tīmīdus, consīlium*; *i* long, always wrong, as *frīgīdus, mīlite, frīgore, spīritus, formīdīne, sīdere*, (noun and verb,) *convīvium, senīlia, dīvīnitus, oblīvia*. *O* short is generally pronounced right, as in *dōminus, incōlumis*, but sometimes wrong, as in *ōdium, mōriens, mōveo, infōdiunt*. *O* long in some words is pronounced right, as *ōtium*, but in many others wrong; as *pōculum, honōribus*. *U* short generally wrong, as *incūbuit*, but not always, for *subīgit* is commonly pronounced right. *U* long always right, as *lūmine, cacūmine*, &c.

Since in making these observations on quantity, we have been under the necessity of incidentally introducing Mr. Pickbourn's opinion on the influence of accent on quantity, in justice to this part of the subject we are here obliged to offer a remark, which we find in Dr. Valpy's excellent Greek Grammar. This latter gentleman, in some degree, differs from

the former. He observes, "that the elevation of the voice does not lengthen the time of that syllable, so that accent and quantity, by the best critics, are considered as perfectly distinct, and by no means inconsistent with each other. In our language the accent falls on the antepenultimate equally in the words *liberty* and *library*, yet, in the former, the tone only is elevated, in the latter, the syllable is also lengthened. The same difference exists in *bāron* and *bācon*, in *lével* and *léver*. In words of two and of three short syllables, the difference between the French and English pronunciation is striking. The former make iambs and anapæsts, the latter chorees and dactyls. The French say, *fugis, fugimús*; the English, *fúgis, fúgimus*. In many instances both are equally faulty; thus we shorten the long *is* in *fāvīs*, the plural of *fāvus*; they lengthen the short *is* in *ōrīs*, the genitive of *os*. Indeed, both may be said to observe neither accent nor quantity."

This deviation from ancient quantity is not, however, peculiar to the English; for Beza complains in his country. "Hinc enim fit ut in Græca oratione vel nullum, vel profus corruptum numerum intelligas, dum multæ breves producuntur, et contra plurimæ longæ corripuntur." (Beza de Germ. Pron. Græc. Ling. p. 50.) Middleton makes the same remark concerning the Latin: "Erasmus se adfuisse olim commemorat, cum, die quodam solenni, complures legati ad Maximilianum Imperatorem salutandi causâ advenissent; singulosque, Gallum, Germanum, Danum, Scotum, &c. orationem Latinam, ita barbarè ac vastè pronunciâsse, ut Italis quibusdam, nihil nisi risum moverint, qui eos non Latinè sed suâ quemque linguâ, locutos jurassent." Middleton de Lat. Pron.

We have now stated at length the manner in which ancient quantity is violated by the moderns, and more particularly by the English. Every symptom of the disease being thus known, our following remarks will be a regular series of inquiries directed to its remedy. In the course of these investigations we are circumscribed by the following alternatives, one or the other must be the object of our decision: whether, in our pronunciation of the ancient languages, shall we adhere to the grammatical metre, though it certainly will in many instances occasion a practice discordant to our habitual predilection; or shall we maintain the English usage, though it should render dactyls, spondees, hexameters, pentameters, &c. merely ideal; at least, subjects not of auricular but of ocular perception.

Since the adoption of prosodial pronunciation occasions, in many instances, a practice so discordant to habitual usage and prepossessions of the schools, there are not wanting some, that contend for the continuance of the English custom. But since the inconsistencies of this, as we have already pointed out, with any idea we can form of quantity, either in a poetic foot, a verse, or a poem, are so notorious, and manifestly render the pentameter and hexameter verse, and every poetic metre, imaginary and speculative, we cannot enter the lists on this side of the question. For he that shall choose to employ his time in enlarging on the beauties of the poet, beauties of which he has no apprehension, except through the medium of their violation, is certainly nearly allied to the virtuoso, that never gives his sentiments on the beauty and proportion of an edifice, except on an actual demolition of all that constitutes them; and having reduced the whole into mutilated and disorganized confusion, he, with much apparent discernment, descants on the beautiful order and symmetry of their coherence and general arrangement.

But, on the other hand, it may be asked, however an adherence to prosodial quantity might prove at variance with our current usage; and, however, with the inconsiderate

derate it might, until a more mature judgment was formed, be liable to the charge of affectation, would it not be one of the most successful auxiliaries to secure the retention of quantity in the memory of every learner? And as an adherence to it is grammatically unimpeachable, would it be the part of temerity and presumptive innovation, to make the coincidence of pronunciation and the prosodial rule, the reciprocal echo and *memorial* auxiliary? We may add, that if we adhere to poetic quantity, the "Norma loquendi" is immutable and certain, but if we warp to fashion, like some erratic sphere, we seem to move in an eccentric orb; especially when we consider that there are the Italian, Spanish, French, German, and English fashions, and each of these, no doubt, is susceptible of variations tinged by every subordinate provincialism.

Three methods present themselves to enable us to preserve the prosodial quantity. 1st. To allow every vowel its prescribed duration, without altering the customary division of syllables; as *nō-ta*, *lō-cus*, &c.; but this will oblige us to throw the accent on the second syllable, as *glō-būs*, contrary to the laconic canon of Sanctius:

"Accentum in se ipsa monosyllaba dictio ponit.
Exacuit sedem dissyllabon omne priorem.
Ex tribus extollit primam penultima curta.
Extollit se ipsam quando est penultima longa."

And it will very frequently occasion the following vowel to be long; as, *tē-nē-o*, contrary to, "Vocalis ante alteram in eadem dictione ubique brevis est."

2dly. If then we must abandon the preceding method, we have the alternative left of uniting to the preceding vowel the succeeding consonant; as, *nōt-a*, *lōc-us*. But still some difficulty occurs, for, first, this method would in many instances occasion pronunciations very harsh to our customary prepossessions; as, *grād-us*, *cād-o*, *plīc-o*, *stūp-e-o*, *bōn-us*, *jūb-e-o*, *tēn-e-o*, *mān-e-o*, *īnūm-e-rus*, *trīb-us*, *hōn-os*, *fāv-or*, *fūt-u-rus*, *jūg-um*, *fīd-es*, *pēt-o*, *tīm-or*, *tīm-e-o*, *vīd-e-o*, "Homines tuentur illum glōb-um." "Per-tāsum est con-jūg-ii," &c.

But is this really an objection? Have not custom and long established usage the power of warping the mind, and giving it prejudices against that which in its unbiassed state it would have adjudged to be agreeable and elegant? This from innumerable instances we are assured to be a fact. But the argument need not rest here. For we may very reasonably inquire, is all this harshness of pronunciation of which we appear to be so sensible, actually chargeable on the ancients? Does it not arise rather from the mistaken ideas we have formed of the power of their vowels and consonants, which, if rectified, would render the harmony of pronunciation and prosodial quantity again consistent? It is here, however, incumbent on us to offer a few leading remarks, as may, under the further inquiries of the patient and persevering philologist, tend to reconcile what might otherwise remain at variance.

Concerning the quantity of vowel sounds, Lipsius (de Pronun. Ling. Antiq.) has some singular remarks; and as they are calculated to afford some further information on this doubtful subject, we cannot with propriety withhold them. "Aliter omnino vocales longas pingere veteres soliti, aliter contractas. Nam has solitarias ponebant ad exemplum hodiernum, illas geminabant, ut duplicatione ipsā, duplicem et productum in iis ostenderent illum sonum. Hunc usum scriptores prisca mihi firmant; ut Victorinus Afer, Nævius et Livius: 'cū longa syllaba scribenda esset, duas vocales ponebant.' Quintilianus id vult, his verbis, 'correctas syllabas geminis vocalibus scribere.'

Attius inquit, 'geminatis vocalibus scribi naturā longas syllabas voluerunt, posteaquam adjecto vel sublato apice, quantitatem vocalium expresserunt.' Qui bene, tamen, de apice monet, quem secuta ætas ut compendium faceret, pro geminatione usurpavit. Apicem appello, lineam transversam, quam superjicere vocalibus longis soliti, hoc modo, *ā, ē, ō, ū*: nam *i* consultò omisi, quæ sola nec geminata olim nec apicata, ut dicam infra. Hæc linea est, quam Græci τὴν μακράν dixere A longa, velut, *a, æ*, geminata, est. Sic dices *amaabam*, *essaari*, *faatam*. Sic distingues *maalum* in navi aut in pometo, ab homine *malo*. Sic *lingua* tibi secernetur à *linguaa*, in sexto casu. Hæc Suevorum in sua linguâ, etiam hodie, pronuntiatio et scriptura est: hæc veterum fuit. Sic in libris antiq. et lapidibus invenitur: ut hæc scriptura, C. NVMONIVS VAALA, apud Horatium in Mitis est. In lapide, L. BETILIENUS, L. F. VAARUS. *Abala*, an rectè, et an non veriùs *Ala*, frustra litigant viri docti. Ego eos moneo, *Aala* fuisse olim, ex ratione geminandi, quam dixi, et flatum solitum interponi sæpe ad sustentandum, sive etiam molliendum. Simile est, quod mehe pro me, antiqui litteratores notant, et mehecum. Nec ab alio fonte prehendo, vehemens. E, pinguis enunciata ut *ee* duplex: enunciata sed et scripta. In nummis legimus, 'Faustus felix;' in lapide, 'Basilicam, Calecandam, Seedes.' Quæ autem hæc pronuntiatio? Me judice, illa, quæ apud Gallos, in plerisque Latinis vocibus hæsit, *miel, fiel* dicunt pro *melle, felle*: ipsis verbis prisca, et fortasse, Germano sono. Nam olim fuit *meel, feel*. Sonum I primum longum, et verè longum. Quia non, ut ceteræ geminatur, aut apice insignitur; sed productior fit, et longitudine velut duplâ; ut *pliso, vlvvs, ædlis*; idèο *αα* *εε* *οο* inter omnes literas hæc proprie dicta longa. Plautus hoc scivit, et jocum captavit in personâ Staphylæ, 'ex me unam faciam litteram. De O, Aufonius ait,'

'Ω quod et O Græcum, compensat Romula vox O.'

In eodem modo, *o* longa, dicebant *populus* de arbore, *voocem, ooram, prætoorem*, et talia; propemodum ut nos Galli, *foy, voix, noife*; vos Belgæ, (ita docuere me tui populares), melius, qui et scribitis pariter et effertis *Broot* (panem), *Schoot* (sinum), *Boom* (arborem). *o* mihi superest, latus et exilis. Ille, qui *α* Græcum exprimit, iste qui *o* eorundem. Varro sic discriminat, his verbis, 'Quidam reprehendunt quòd *pluit* et *luit* dicamus in præterito et præsentis tempore. Falluntur, nam est, ac putant, aliter. Quod in præterito *u* dicimus longum, *pluit, luit*, in presenti breve.' Hoc enim vult, *pluit, luit*, in presenti tenuiter efferrî, in præterito, *plouit, louit*." And this mode of expressing the sound, by French orthography, will in ours be expressed by *plooit* and *looit*.

"E, in Latin as well as Greek," says Ainsworth, "was pronounced *u*." But from the circumstance of their anciently writing ΤΕΙ ΑΓΑΘΕΙ ΤΥΧΕΙ for τῆ ἀγαθῆ τυχῆ, it is to *η* that he attributes the power of *u*. But since it is ambiguous, and the attempt inconclusive, to explain the sound of one ancient vowel by another, the most satisfactory and decisive method, as far as it can be done, is to have recourse to the more immutable sounds of nature. Monsieur Launcelot, the learned author of the Port Royal Greek Grammar, in order to convey the sound of the long Greek vowel *η*, tells us "it is a sound between the *e* and *a*; and that Eustathius, who lived towards the close of the 12th century, says that βῆ, ἐῆ, is a sound made in imitation of the bleating of a sheep; and to this purpose quotes the following verse of an ancient writer, Cratinus.

PROSODY.

“ Ο δ' ἠλίθιος, ὡσπερ πρόβατον, βῆ, βῆ, λεγὼν βᾶδιζει.”

“ Is fatuus perinde ac ovis, bē, bē, dicens incedit.”

“ He, like a silly sheep, goes crying baa.”

In a similar manner, the sound of the long *i* is preserved to us by the word *pīpio*, which signifies to pip like a chicken; and since their note is nearly what we may express by *pee-ep*, the long power of that letter seems to have been equivocal to our *ee*. Eustathius likewise remarks on the 499th v. of Iliad I. that the word βλοψ̄ ἐστὶν ὁ τῆς κλειψύδρας ἤχος μιμητικῶς κατὰ τὴν παλαιὰς βί' ἔχει μίμησιν προβάτων φωνῆς. Κρατινος, i. e. βλοψ̄, is, according to the ancients, an imitation of the sound of the clepsydra; et βῆ imitates the bleating of sheep. The clepsydra was an instrument to measure time by water; (and, it should be particularly observed, was occasionally employed to measure time for the regulations of orators, and in other recitations.) Abstracting the *o* in βλοψ̄ from the effect of position before ψ, it will, as we shall determine hereafter, have the power of our *o*; and *blops* adequately imitates the noise of water running with intermissions out of a narrow-mouthed vessel; and, with the French pronunciation, with equal propriety, is signified by the word *glouglou*; but not quite so happily by us, by the word *guggle*. Ainsworth seems to consider, that the long sound of *o*, was equal to *ε*. To determine this, it may be useful to quote the word *glōcio*, to cluck as a hen (from κλωζω), particularly since this word, amongst many others, will prove an irrefragable proof that *c* amongst the ancients was equivocal to *z*, or hard, since *glouk*, *glouk*, is the sound produced by the hen after the period of incubation. The sound of the long *u* is no less sincerely preserved by Plautus in Menæch. page 622. edit. Lambini, in making use of it to imitate the cry of an owl:

“ Men. Egon' dedi? Pen. Tu, Tu, istic, inquam, vin' afferri noctuam,

Quæ tu, tu, usque dicat tibi? nam nos jam nos defessi fumus.”

It appears here, says Mr. Foster, in his defence of the Greek accents, page 129, that an owl's cry was *tu, tu*, to a Roman ear; *tou, tou*, to a French; and *too, too*, to an English one. Lambin, who was a Frenchman, observes on the passage, “Alludit ad noctuæ vocem *tu, tu*, seu *tou, tou*.” On this Mr. Walker remarks, that the English have totally departed from this sound of the *u* in their own language, as well as in their pronunciation of Latin. Ausonius confirms this power of *u*: “Cecropiis ignota fonis, ferale fonans U. Ferale idèò, quia refert feralem illam avem.” This also explains the reason of the Latin word *būbulo* expressing the cry of an owl. Aristophanes has handed down to us the pronunciation of the Greek diphthong *ᾶν ᾶν*, by making it expressive of the barking of a dog. This is what is exactly preserved by nurses and children to this day in *bow*, *wow*. This is the sound of the same letters in the Latin tongue, not only in proper names derived from Greek, but in every other word, where this diphthong occurs. Most nations in Europe, perhaps all but the English, pronounce *audio* and *laudo*, as if written *owdio* and *lowdo*; the diphthong sound like *ou* in *loud*.”

In prosecuting a further enquiry on the sounds of ancient vowels, as preserved to us by the sounds of nature expressed by words, on the etymology of which lexicographers judge the most appropriate remark to be “*verba ex sono facta*,” what light may result from the following and similar expressions, the further investigations of philologists may determine. *Balo*, βᾶ, to *bleat* as a sheep; *boō*, from βωω, to *low* as an ox; *crocio*, from κρόραξ or κρώζω, which was, it

appears, not pronounced *crofio*, but *crokio*, to *croak* as a crow; to which we may add, *crepo*, to *creak* as a door; *su-furrus*, a *buz* or *ruffling*; and *strix*, a *screech owl*. But *gannio*, to *yelp* as a fox; *hinnio*, to *neigh* as a horse; *tinnio*, to *tinkle*; are not, perhaps, sufficiently abstract from consonant admixture to afford much additional intimation.

These remarks, however, may already serve to remove the harshness in some of the words which we have exemplified. For since the long *u* has been so fully proved to have been equivocal to *oo*, which Dr. Carey confirms, by considering it equivalent to the Greek *ε*, and to the sounds in the Italian *pur*, the French *pour*, and the English *poor*, we may suppose, that the ancients pronounced *lumen*, according to our orthography, *loomen*, and allowed the power of the middle *u*, as in *cube*, to their short accented *u*, and that of *ū*, as in *cub*, to their short unaccented *u*, i. e. when the accent rested on the following consonant. Hence, instead of being compelled to divide *nūm'-er-us*, *fū'-u-rus*, *flūp'-e-o*, *jūb'-e-o*, so as to throw the accent on the latter consonant of the first syllable, we may adopt a distribution more reconcileable, at least with our habits, and by placing the accent on the first vowel instead of the following consonant, may give the short Roman accented *u*, the sound of *u* in *tube*, and pronounce nearly as usual, *nū'-me-rus*, *fū'-tu-rus*, *jū'-be-o*, &c. Relative to *jugum* and *conjugium*, we shall here avail ourselves of a remark from Dr. Carey. “The word which in England we pronounce *jugum*, is in reality *yugum*, as the Germans, in fact, at this day, pronounce it. Of this, indeed, there is little doubt, since *יאכׁב* was properly *yakōb*, and the Hebrew *י*, before a vowel, had the power of *y*. Now, by these remarks being warranted, first, to place the accent on the first vowel of the root *jū'-gum*; secondly, to give the power of the middle *u* to the short Roman accented *u*; and thirdly, that of *y* to *j* before a vowel, we may avoid nearly all the harshness for which these words would otherwise have been notorious; as *yū'-gum*, *con-yū'-gium*. The same unpleasantry may be removed from *glōb'us*, since the long Roman *o* is considered to have been equal to *ε*, which is more exactly represented by our *au*; for *hōra* was probably pronounced *haura*, since it is borrowed from the Hebrew *אור*, *aur*, and *aurōra* from *אור*, *aur* (propitious light), or *owraura*. Therefore the middle *o*, as in *note*, may be ceded to the short Roman accented *o*, and for *glōb'-us*, we may, more agreeably, say *glō'-bus*.

Whatever may be done, however, in this way, we cannot but consider, here, as partial hints, given rather in the hope of calling forth the future investigations of the literati to an enquiry, the want of which has been long felt, than propose the present as a mature and established system. Doubtless it may not be easy to remove every difficulty, so as, in every instance, to reconcile the prosodial pronunciation with our prejudices. Nor will it, perhaps, be done, until the influence of accent on quantity is more fully understood, nor unless it be clearly considered, whether the accent falls on the *vowel* or *succeeding consonant*. Many have undertaken to assign the syllables, which constitute the seat of the accent, but few distinguish the *accented vowel* from the *accented consonant*. And here, perhaps, the solution of the whole may be found. It is evident, that *nī'-les* has the accent on the first syllable, and on the vowel of that syllable; hence it is easily preserved long. And, it is equally obvious, that *honorificus* has the accent on the antepenultimate, and on the consonant *f* of that syllable; and, therefore, it more rapidly inclines to an increased brevity. And the same distinction should have been allowed by the writer we have already cited, in the words he has quoted to prove the

the independence of accent and quantity. It is certainly true, that *liberty* and *library* are accented on the first syllable, which in the first instance is short, in the second long; but the former has the accent on the consonant, *lib'-er-ty*; the latter on the vowel, *li'-bra-ry*. The same distinction exists in the words *báron* and *bácon*, *lével* and *léver*. Now, in such words as *grádu*s, *cádo*, *plíco*, *fídes*, *tríbus*, *tímor*, all which are accented on the first syllable, the question is, did the ancients throw the accent on the final consonant of the syllable? If so, that syllable will be pronounced with rapidity, to throw the stress on the accented consonant; and that pronunciation will be aptly expressed by the following distribution, *grád'-us*, *cád'-o*, *plí'co*, *fíd'-es*, *tríb'-us*, *tím'-or*. Or did they rather allow a distinction between an accented short vowel, and an unaccented short vowel, lengthening, in some degree, the former, in the same manner, as we have seen that a difference exists between an accented long, and an unaccented long syllable, in the examples *amāvi* and *amāvé-runt*; which will fully illustrate the remark of Quintilian, which we have cited before. This influence might allow an increase to their short accented *a*, *e*, and *i*, nearer to their unaccented long sound; so that, on this ground, consistent at once with quantity and our prepossessions, we might pronounce, *grá'-dus*, *cá'-do*, *plí'-co*, *fí'-des*, *trí'-bus*, and *tí'-mor*.

The second difficulty to which we are liable in our apprehension of the nature of ancient quantity, arises from that, which is said to be long by *position*. From this some have deduced an objection against the attempt to conform the present pronunciation to quantity; observing, that "if we would be consistent and unexceptionable in our adherence to prosodial metre, we have to recollect, that the same word is often both long and short; as *nēc*, when single, or not followed by a consonant; which by position we find long; as *Fulgura nēc diri toties arsere cometa*. Then, if we invariably echo the quantity, we must, *pro re natá*, say *nēc*, and *nēc diri*, i. e. *neck*, and *neck diri*. And the improbability, that the ancients were so ready on every occasion to pronounce the same word both long and short, would incline us to infer, that we have no idea of what they meant by quantity."

This has given rise to a series of remarks in Mr. Walker's Treatise on Classical Pronunciation, which, if they are not, in every instance, the most decisive, are at least the most ingenious that we have seen on the question, and with which it is impossible to dispense, in a full and impartial consideration of this subject.

"The long quantity of the ancients must arise either from a prolongation of the sound of the vowel, or from the delay of the voice, which the pronunciation of two or more consonants in succession are supposed naturally to require. Now, vowels were said to be either long by nature, or long by position. Those vowels which were long by position, were such as were succeeded by two or more consonants; as the first *o* in *sponsor*. If the long quantity of the ancients was the same distinction of the sound of the vowel as we make in the words *cadence* and *magic*, then the *a* in *māter* and *pāter* must have been pronounced like our *a* in *paper* and *matter*: and those vowels which were long by position, as the *a* in *Bāchus* and *cāmpus*, must have been sounded by the ancients as we hear them in the words *bake* and *came*. But if the long quantity of the ancients was no more than a retardation of the voice on the consonants, or that duration of sound which an assemblage of consonants is supposed naturally to produce, without making any alteration in the sound of the vowel, of such long quantity as this an English ear has not the least idea. Unless the sound of the vowel be altered, we have not any conception of a long or short

syllable; and the first syllables of *banish*, *banner*, and *banter*, have, to our ears, exactly the same quantity. The same may be observed of *senate*, *seminary*, *sentence*, and *sentiment*;" (and if, as an ingenious inquirer into this subject has asserted, the ancients pronounced both the consonants in *callidus*, *fallo*, &c. this seems to shorten, rather than lengthen, the vowel of the first syllable.) "If, however, the quantity of the ancients lay only in the vowel, which was lengthened and shortened in our manner by altering the sound, how strange must have been their poetical language, and how different from the words taken singly! And when these observations on the quantity of the ancients are collectively considered, shall we wonder that the learned and ingenious author of the Elements of Criticism should go so far as to assert that the dactyls and spondees of hexameter verse, with respect to pronunciation, are merely ideal, not only with us, but that they were so with the ancients themselves? Few, however, will adopt an opinion, which will necessarily imply that the Greek and Latin critics were utterly ignorant of the nature of their own language; and every admirer of those excellent writers will rather embrace any explanation of accent and quantity, than give up Dionysius of Halicarnassus, Cicero, Quintilian, and Longinus. Suppose, then, as a last refuge, we were to try to read a Greek or Latin verse both by accent and quantity, and see what such a trial will produce.

"By quantity, let us suppose the vowel lengthened to express the long quantity; and by the acute accent, the rising inflexion; thus:

"Títýre, tú pátulæ récubans fúb tégmíne fági,
Sýlvéltrem ténuí múfam medítáris avéna.

"Títýrē, tū pátulā rēcūbāns fūb tēgmínē fāgī,
Sýlvéltrem tēnuī mūfām mēdítāris āvēnā.

"Teétyre toó pátulæ récubanes foób teégmíne fági,
Seélveeltrem ténuí moófame medítáris avena.

"Μῆνιν ἄειδε θεὰ, Πηληϊάδεω Ἀχιλῆος
Οὐλομένην, ἣ μυρὶ Ἄχαιοῖς ἄλγε' ἔθηκεν.

"Μῆνιν ἄειδ'ε θεᾶ, Πηληϊάδεω Ἀχιλῆος
Οὐλομένην ἣ μυρὶ Ἄχαιοῖς ἄλγε' ἔθηκεν.

"Mein-en á-eye-de The-áy Pei-lei-e-á-dyo A-kil-lei-ose
Ow-lom-én-ein heì moo-ré a-kay-oês al-ge éth-ei-kei.

"Now there are but four possible ways of pronouncing these verses, without going into a perfect song. One is to pronounce the accented syllable with the falling inflexion, and the unaccented with the same inflexion in a lower tone; which is the manner in which we pronounce our own words, when we give them the accent with the falling inflexion. The second is to pronounce the accented syllable with the rising inflexion, and the unaccented syllables with the same inflexion in a lower tone; which we never hear in our own language. The third is to pronounce the accented syllable with the falling inflexion, and the unaccented syllables with the rising, in a lower tone. And the fourth, to pronounce the accented syllable with the rising inflexion, and the unaccented with the falling, in a lower tone. None of these modes, but the first and last, do we ever hear in our own language: the second and third seem too difficult to permit us to suppose that they could be the natural current of the human voice in any language. The first leaves us no possible means of explaining the circumflex; but the last, by doing this, gives us the strongest reason to suppose that the Greek and Latin acute accent was the rising inflexion, and the grave the falling inflexion, in a lower tone."

To render Mr. Walker's remarks, as they relate to the influence of accent on quantity, a little more familiar to our readers, it may be useful to state, that his ideas of accent comprehend the qualities of *high* and *low*, *rising* and *falling*. His acute accent is higher than the grave, effected by a rising *slide* of the voice; the grave is lower than the acute, and effected by a falling *slide*. All this may be very conveniently illustrated by the violin; for whilst the *tone* (louder or softer) is produced by the greater or less strefs of the bow, the finger *sliding* upwards on the first string, in slow time, will give the acute or *rising* accent, as on a *long* syllable, or when the vowel is accented. The same upward slide, with a *quicker* movement, will express the same accent on a *short* syllable, or when the accent *falls* on the following consonant. And by a *downward slide*, either in *slow* or *quick* time, the *grave* accent is equally imitated on a *long* or *short* syllable.

Our opinion, however, deducible from the analogy of quantity long by position, is not such as to occasion our hesitation relative to the nature of quantity in general. But we are persuaded, *first*, that quantity long by nature, and long by position, were, *as it respects the vowel*, different. We are confirmed in this by Lipsius, whose remark is, "Syllaba quæ natura longa est, ab ea distingui debet, sola positione longa existit. Id est idcirco tantum quod duabus consonantibus adjuncta sit, quibus pronuntiandis necesse est moram interponendi, ut in τυπιτητον productior est penultima quam in τυπισηθα. Præterea pro qualitate consonantium quæ vocales ipsas præcedunt, vel consequitur, inter longas aliæ aliis longiores, inter breves aliæ aliis breviores reperiuntur. Sed hæc subtilius persequi, nostri non est instituti. Admoneri tamen pueri debent et assuescieri, ut hæc omnia discrimina expedite observent, sine quorum cognitione et usu fieri non posse puto ut de numeris orationis rectè judicent."

But an irrefragable argument that quantity long by position was really different from that long by nature, is deducible from such sounds as nature has faithfully handed down to us; as in the word *scloppus* or *floppus*, which signifies the noise produced by the percussion of inflated cheeks, which *scloppus* pronounced short, *as it respects the vowel*, will very well resemble; but that similarity becomes entirely lost, on lengthening it. On this word, see Priscian. lib. i. cap. 4, Facciolatus, and Perf. sat. 5. 13. "Nec scloppo tumidas intendis rumpere buccas." The same observation may be made from the word βλοψ, already quoted, which signifies the noise effected by water, flowing with intermissions, from a narrow-mouthed vessel.

Hence it appears, that syllables indifferently spelt with one or two consonants, which are always long, are not strictly entitled to the quantity equal to that of a vowel long by nature; as in *litus* or *littus*, *literæ* or *litteræ*, *scïroma* or *scïrroma*, &c.

Secondly. If then quantity long by nature was different from that long by position, we may suppose that the quantity of the former consisted in the *duration of the vowel sound*, and that of the latter in the *length of the syllable*. To explain this more particularly, let us suppose, *first*, that the regular quantity of a *short* syllable, generally, συλλαμβανει, comprehends either, 1st, a single syllable, as the first syllable of *ä-mo*; or, 2ndly, a consonant and a vowel, as *gē-na*: or, 3dly, a mute and a liquid, which could be sounded as a single letter, followed by a vowel, as *tri-fer*: or, 4thly, even three consonants and a following vowel, provided the three consonants could be sounded as one; as *Arō-pus*. So that the *regular quantity of a short syllable is reducible to two letters*. The only exceptions to this were in

such syllables, as custom, for some special reason, as in the case of derivation from *r, u, e, &c.* had made long; and as in the case of monosyllables, as *mē, tē, sē, &c.* which properly are long, since there being no haste of the voice to leave the first and proceed to the coalition of a second syllable, the first receives, from this exemption, a more leisure-effect, or such a compensation as its diminutive and detached condition seems naturally to require. *Secondly*, that if to the end of this short syllable we join a consonant, this forms that addition in quantity, which is to be considered rather as a *syllabic augmentation*, than any *temporal* duration of the voice: it may *alter* the sound, but it does not, in every case, perceptibly protract it; as $\zeta\lambda\epsilon\delta$ equal to $\zeta\lambda\epsilon\delta$, $\phi\lambda\omicron\zeta$ to $\phi\lambda\omicron\gamma\zeta$, $\sigma\alpha\epsilon\zeta$ to $\sigma\alpha\epsilon\gamma\zeta$, and *rexi* to *rek-si*. Hence all monosyllables and final syllables, beginning and ending with a consonant, are long; except they end in *b, d, t, l, r, is, us*, or in consonants preceded by the Greek short vowels, and a few other exceptions established by poetic usage. But if such syllables occur in the middle of a word, the following syllable must begin with a consonant; as *κοσ-μο*, *glof-sa*, &c.: otherwise the consonant is joined to the following syllable, as *glō-mus*. And, *lastly*, when the succeeding syllable begins with a mute and a liquid, in consequence of the coalition and unity of sound, having the effect only of one consonant, they are joined to the following syllable, and thus the first may remain short: *i. e.* instead of *πατ-ρος*, *τεκ-νον*, and *pāt-ris*, which would be long, we may divide and pronounce *πα-τρος*, *τε-κνον*, and *pā-tris*.

Now, concerning the question whether the ancient poetry should be read chiefly according to accent or quantity, which has lately been much agitated, may we not reasonably infer, that since the precise nature of accent does not seem to be determined, and therefore if, in reading, either must give way to the other, (for which, however, there is no absolute necessity,) it is certainly better, that what is in some degree uncertain should yield to that which is more accurately ascertained. By reading according to quantity, is not, however, meant the breaking down, splitting, or destroying the words by attending to the feet only; but pronouncing the words of a verse, so as to give, as much as possible, its due quantity, in real time, to every syllable. And as much as to this mode of reading, we can add an attention to accent, emphasis, tone, pause, and cadence, whether metrical or sentential, inasmuch, doubtless, will the pronunciation be the more correct and harmonious. Although it cannot, perhaps, in every case, be determined in what manner, precisely, the ancients sounded the vowels; one thing, however, seems certain, that they did not give a long sound to a short vowel, nor a short sound to a long vowel. In whatever way we pronounce them we ought to attend to their quantity; with only this licence, that since, as has been now fully proved, a syllable long by nature was a reduplication of the same vowel, as *dicere*; *maalus*, an apple tree; *populus*, a poplar tree; and that that long by position had no other length than its being sustained by the following consonants, as *divi*, we are authorized to consider the prolongation of such syllables to consist not in the *vowel*, but in the *consonant* reduplication.

We have now had an opportunity of offering our sentiments on the nature of ancient quantity. But the nature of quantity, as observed in the English language, is at once so simple, unique, and, in general, so well known, that any enlargement on this part of the subject becomes unnecessary. It is sufficient to observe that a vowel or syllable is, in the English language, long, and requires double the

the time of a short one, when the accent is on the vowel; which occasions it to be slowly joined in pronunciation with the following letters; as *fäll, bälē, hōūse, fēature*. And that a syllable is short, and only of half the length of a long one, when the accent is on the consonant; which occasions the vowel to be quickly joined to the succeeding letters; as *ärt, bönnēt, hüngēr*. For such rules as are necessary to the determination of quantity in each of the three principal languages, we refer our readers to the article QUANTITY. See also VERSIFICATION.

Profody might be applied to music as well as grammar: as the true pronunciation, or execution and accents of passages, constitute their true expression.

PROSONOMASIS, Προσωνομασια, a figure in Rhetoric, by which allusion is made to the likenesses of a sound in several names or words; much the same with *paronomasis*, or *agnominatio*.

PROSOPIS, in Botany, said by professor Martyn to be derived from προσωπις, *persona*, five *larva*, a mask.—Linn. Mant. 10. Schreb. 706. Willd. Sp. Pl. v. 2. 547. Mart. Mill. Dict. v. 3. Juss. 348. Lamarck. Illustr. t. 340.—Class and order, *Decandria Monogynia*. Nat. Ord. *Lomentaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, hemispherical, slightly four-toothed. Cor. Petals five, lanceolate, sessile, equal. Stam. Filaments ten, thread-shaped, equal; anthers twin, obtuse. Pist. Germen superior, oblong; style thread-shaped, the length of the petals; stigma simple. Peric. Legume long, inflated, of one cell. Seeds many, roundish-oblong, coloured.

Ess. Ch. Calyx bell-shaped, four or five-toothed. Stigma simple. Legume many-seeded.

1. *P. spicigera*. Linn. Mant. 68. Roxb. Coromand. v. 3. 45. t. 63. (*P. spicata*; Burm. Ind. 102. t. 25. f. 3.)—Common on the Coromandel coast, flowering at the close of the cold and beginning of the hot season.—According to Roxburgh this is a large tree, with a tolerably erect trunk. Bark deeply cracked, ash-coloured. Branches irregular, numerous, forming a globular shady head; some of the younger ones prickly. Leaves alternate, abruptly pinnate; leaflets from seven to ten pair, opposite, obliquely lanceolate, smooth, entire. Flowers in numerous, terminal spikes, small, yellow. Legume attenuated at both ends, jointed, smooth, pendulous. Seeds lodged in a brown mealy substance, which is eaten by the native Indians. It has a sweet, agreeable taste, and may be compared to the Spanish *Algaraba*, or Locust tree, *Ceratonia Siliqua*.

PROSOPOLEPSIA, Προσωποληψια, in Ethics, is used by some writers for that bodily impression, which inclines to the love or hatred, esteem or contempt of persons or things, on account of some slight or trivial circumstances attending them.

PROSOPOPŒIA, Προσωποποιια, formed from προσωπον, *person*, and ποιειν, *I make*, or *feign*, or *Personification*, in Rhetoric, a figure, by which we make persons that are absent, or dead; or even things which are inanimate, as cities, &c. to speak.

The poets, in their fictions, make frequent use of the prosopopœia; as also do the orators, in their painting of violent passions, which seem to transport, and make them forget themselves.

This figure is of very extensive use to the orator: when he thinks his own character not of sufficient weight to affect his audience in the manner he desires, he substitutes a person of greater authority than himself to engage their attention. When he has severe things to say, and which may give offence, as coming from himself, he avoids this by putting

them in the mouth of some other person, from whom they will be better taken; or makes inanimate nature bring a charge, or express a resentment, to render it the more affecting. And by the same method he chooses sometimes to secure himself from a suspicion of flattery, in carrying a compliment too high. In the management of this figure, care should be taken, that what is said be always consistent with the character introduced, in which both the force and beauty of it consist.

There are two kinds of prosopopœias; the one *direct*, the other *indirect*. For an instance of the latter: *Just gods, protectors of the innocent, permit the order of nature to be interrupted for one moment, and let this carcase resume the use of speech.*

Instances of the former are found every where among the orators and poets: that which follows is a very beautiful one; found, by way of epitaph, on a tomb-stone: the dead wife addresses her surviving husband thus:

“Immatura peri: sed tu felicior, annos
Vive tuos, conjux optime, vive meos.”

This figure is of such importance both to the orator and poet, and contributes so much to give both beauty and effect to their respective productions, and to render them animated and impressive, that we shall enlarge on its origin, and its various kinds, and subjoin several appropriate examples of its use. Its origin may be traced to the constitution of human nature, which disposes us to animate all objects, and to those passions and affections, proceeding probably from our senses of pain and pleasure, which express themselves in an aversion from an attachment to certain objects, either animate or inanimate. A child turns to beat the ground, or the stone, that has hurt him, and most men feel some degree of affection for the old inanimate companions of their happiness, such as the house, in which they have passed many agreeable years, and the fields, trees, and mountains, among which they have often sauntered with delight. This strong impression of life, produced, more especially, by the more magnificent and striking objects of nature, has been, Dr. Blair conceives, one cause of the multiplication of divinities in the Heathen world. The belief of Dryads and Naiads, of the genius of the wood and the god of the river, among men of lively imaginations, in the early ages of the world, easily arose from this turn of mind. When their favourite rural objects had often been animated in their fancy, it was an easy transition to attribute them to some real divinity, or some unseen power or genius which inhabited them, or in some peculiar manner belonged to them. From such dispositions evidently originates the figure called prosopopœia, which is the distinguishing ornament of poetry, and which appears so conspicuous in all compositions, where imagination or passion has any concern. This figure is nearly allied to the metaphor, and still more to the metonymy: it is to the latter what the allegory is to the metaphor. Thus when we say, “Youth and beauty shall be laid in the dust” for persons possessing youth and beauty, it is hard to determine whether it be a metonymy or a prosopopœia. Lyric poetry, in which the imagination seems to have the fullest indulgence, and which abounds with strong figures, is most favourable to personification. Of this figure, according to Dr. Lowth, there are two kinds: one, when action and character are attributed to fictitious, irrational, or even inanimate objects; the other, when a probable but fictitious speech is assigned to a real character. The former evidently partakes of the nature of the metaphor, and is by far the boldest and most daring of that class of figures. Dr. Blair reckons three different degrees of

this figure; the first, when some of the properties or qualities of living creatures are ascribed to inanimate objects; the second, when those inanimate objects are introduced as acting like such as have life; and the third when they are represented, either as speaking to us, or as listening to what we say to them. The first, and lowest degree of this figure is exemplified, most commonly, by adding an epithet to the object, as "a raging storm," "a deceitful disease," "a cruel disaster," &c. and it raises the style so little that it hardly deserves the name of personification, and might be classed with simple metaphors. On some occasions, however, it adds beauty and sprightliness to an expression. In the second degree of this figure the personification becomes more sensible. It is observed by Dr. Blair, that the genius of our language affords us an advantage in the use of this figure. As with us, no substantive nouns have gender, or are masculine and feminine, except the proper names of male and female creatures; by giving a gender to any inanimate object, or abstract idea, that is, by substituting the personal pronouns, *he* or *she*, in place of the pronoun *it*, we raise the style, and begin to *personify*. In solemn discourse this may be done to good purpose, when speaking of religion or virtue, or our country, or any such object of dignity. An instance of this kind, in which natural religion is beautifully personified, occurs in a sermon of bishop Sherlock's, in which he is comparing our Saviour with Mahomet. "Go," says he, "to your natural religion; lay before her Mahomet, and his disciples, arrayed in armour and blood, riding in triumph over the spoils of thousands who fell by his victorious sword. Shew her the cities which he set in flames, the countries which he ravaged and destroyed, and the miserable distress of all the inhabitants of the earth. When she has viewed him in this scene, carry her into his retirement; shew her the prophet's chamber; his concubines and his wives; and let her hear him allege revelation, and a divine commission to justify his adultery and lust. When she is tired with this prospect, then shew her the blessed Jesus, humble and meek, doing good to all the sons of men. Let her see him in his most retired privacies; let her follow him to the mount, and hear his devotions and supplications to God. Carry her to his table, to view his poor fare; and hear his heavenly discourse. Let her attend him to the tribunal, and consider the patience with which he endured the scoffs and reproaches of his enemies. Lead her to his cross; let her view him in the agony of death, and hear his last prayer for his persecutors: 'Father, forgive them, for they know not what they do!'—When natural religion has thus viewed both, ask her, which is the prophet of God? But her answer we have already had, when she saw part of this scene through the eyes of the centurion, who attended at the cross. By him she spake, and said, "Truly, this man was the son of God." This passage, says Dr. Blair, is more than elegant, it is truly sublime. Personifications of this kind are the life and soul of poetry. They occur frequently in Homer, Shakspeare, and Milton, as well as in other poets. The following personification by Milton, on occasion of Eve's eating the forbidden fruit, is peculiarly striking:

"So saying, her rash hand, in evil hour
Forth reaching to the fruit, she pluck'd, she eat;
Earth felt the wound; and Nature, from her seat
Sighing, through all her works, gave signs of woe,
That all was lost." Book ix. 780.

The third and highest degree of personification is the boldest of all rhetorical figures; it is the expression of strong feeling and passion; and ought never to be attempted,

unless the mind is considerably heated and agitated. Of this figure Milton has given a very fine example, in that moving and tender address, which Eve makes to Paradise, just before she is compelled to leave it:

"Oh! unexpected stroke, worse than of death!
Must I thus leave thee, Paradise! thus leave
Thee, native soil, these happy walks, and shades,
Fit haunt of Gods! where I had hope to spend
Quiet, though sad, the respite of that day,
Which must be mortal to us both. O flowers!
That never will in other climate grow,
My early visitation, and my last,
At ev'n, which I bred up with tender hand,
From your first op'ning buds, and gave you names!
Who now shall rear you to the sun, or rank
Your tribes, and water from th' ambrosial fount?"

B. ii. l. 268.

This is altogether, says Blair, the language of nature, and of female passion.

This excellent writer proposes two great rules for the management of this sort of personification. The first is, never to attempt it, unless when prompted by strong passion, and never to continue it, when the passion begins to flag. The second is, never to personify any object in this way, but such as has some dignity in itself, and can make a proper figure in this elevation to which we raise it.

In prose compositions, this figure requires to be used with still greater moderation and delicacy; for here the imagination is not allowed the same liberty as in poetry, nor can the same assistances be obtained for raising passion to its proper height by the force of numbers, and the glow of style. Nevertheless, addresses to animate objects are not excluded from prose; but they have their place only in the higher species of oratory. This figure has uncommon force and expression, as it is used by Hebrew writers. What can be conceived more apt, more beautiful, or more sublime, than that personification of wisdom, which is so frequently introduced by Solomon? (See Prov. viii. 27—31.) How admirable is that celebrated personification of the divine attributes by the Psalmist? (Ps. lxxxv. 11.) Such also are that in Habakkuk, of the pestilence marching before Jehovah, when he comes to vengeance (Hab. iii. 5.); that in Job, in which destruction and death affirm of wisdom, that her fame only had come to their ears (Job. xxviii. 22.); and that tremendous image, in Isaiah, of Hades, extending her throat, and opening her insatiable and immeasurable jaws. (Is. v. 14.) There is another beautiful species of personification, which originates from a well-known Hebrew idiom; or that form of expression by which the subject, attribute, accident, or effect of any thing is denominated the Son. Isaiah, pronounced by Dr. Lowth to be the sublimest of all poets, furnishes, in one short poem, examples of almost every form of the prosopopœia, and indeed of all that constitutes the sublime in composition. (See Is. xiv. 4—27.) After a critique upon this sublime ode of Isaiah, our learned writer concludes in the following manner: "How forcible is this imagery, how diversified, how sublime! how elevated the diction, the figures, the sentiments!—The Jewish nation, the cedars of Lebanon, the ghosts of departed kings, the Babylonish monarch, the travellers who find his corpse, and last of all Jehovah himself, are the characters which support this beautiful lyric drama. One continued action is kept up, or rather a series of interesting actions are connected together in an incomparable whole: this, indeed, is the principal and distinguished excellence of the sublimer ode, and is displayed in its utmost perfection in this poem of Isaiah, which may be considered as one of the most ancient, and

and certainly the most finished specimen of that species of composition, which has been transmitted to us. The personifications here are frequent, yet not confused; bold, yet not improbable: a free, elevated, and truly divine spirit pervades the whole; nor is there any thing wanting in this ode to defeat its claim to the character of perfect beauty and sublimity. If, indeed, I may be indulged in the free declaration of my own sentiments on this occasion, I do not know a single instance in the whole compass of Greek and Roman poetry, which, in every excellence of composition, can be said to equal, or even to approach it." Blair's Lectures, vol. i. Lowth's Lectures, &c. vol. i.

PROSOR, in *Geography*, a town of Bosnia; 8 miles E. of Kralam.

PROSPECT, a town of America, in Hancock county, and district of Maine; containing 1300 inhabitants.

PROSPECT Harbour, lies on the S. coast of Nova Scotia, with cape Samboe and island eastward, and two leagues N.E. of St. Margaret's bay.

PROSPECT Hill, a town of Fairfax county, in Virginia; 14 miles from Washington.

PROSPECTIVE. See PERSPECTIVE.

PROSPECTIVE Glafs. See OPERA Glafs.

PROSPER, in *Biography*, a saint in the Roman calendar, was a native of Aquitain, or Guienne, and born about the commencement of the fifth century. Some writers have ranked him with the ecclesiastical order, as bishop of Riez, in Provence, and others say, that he held the see of Rhegium in Italy. No ancient writer before the 12th century, has ever spoken of him in any other character than that of a layman, and the ablest critics concur in assigning him that rank. He embraced, in early life, the sentiments of Augustine, and was the occasion of that father writing his treatise concerning predestination and perseverance. After the death of Augustine, he defended his character and doctrine against the attacks made upon them by the priests of Marseilles. In the year 431 he went to Rome, and preferred accusations of heresy against the Gallican clergy who ventured to deviate from the system of his master, and obtained a letter from pope Celestine to the bishops of Gaul, in which the pontiff warmly supported the opinions of Augustine. Sanctioned by the authority of his holiness, Prosper returned home, and redoubled his zeal and industry in opposing the rapid progress which the Pelagian notions were making among his countrymen, both by disputations and conferences, and by his writings. After the year 440, he was sent for to Rome by pope Leo I., who made him his secretary, and principal combatant against the Pelagians in Italy. In the year 443 he was employed by the same pope in a mission against those heretics in Campania. The time of his death is not known, but it is tolerably well ascertained that he was alive beyond the year 460. In Dupin we have a list of his works, and also of others imputed to him which are not genuine. He was possessed of much learning and eloquence, and the style of such pieces as are universally acknowledged to be his, is concise, vigorous, and elegant. Dupin. Moreri. See also Lardner, vol. v. edit. 1788. ch. 134-5.

PROSPEROUS, in *Geography*, a village in the county of Kildare, where extensive cotton-works were erected at a great expence by Capt. Brooke, with parliamentary aid; but, says Mr. Rawson, "he had no knowledge of the business; he committed it to the care of others; of course every thing went to ruin." Prosperous is 18½ miles W. by S. from Dublin.

PROSPHYSIS. See ADHESION.

PROSTANTHERA, in *Botany*, received that name from Labillardiere, in allusion to the spurs of its anthers;

the word being derived from *περσθηξ*, an appendage, and *ανθηρα*, the anther.—Labill. Nov. Holl. v. 2. 18. Brown Prodr. Nov. Holl. v. 1. 508. Ait. Hort. Kew. v. 3. 426.—Class and order, *Didynamia Gymnospermia*. Nat. Ord. *Verticillatae*, Linn. *Labiatae*, Juss.

Ess. Ch. Calyx two-lipped; tube striated; lips undivided, converging when in fruit. Corolla ringent; upper lip cloven half way down; middle segment of the lower largest and two-lobed. Anthers with spurs beneath.

Mr. Brown defines thirteen species of this genus, most of them natives of the country near Port Jackson, New South Wales, or of Van Diemen's island. They are strong smelling shrubs, besprinkled with sessile glands. The leaves are mostly toothed or crenate. Flowers either racemose and terminal, accompanied by deciduous bractes; or axillary and solitary. The flower-stalks always bear a pair of bractes near the extremity. Lower lip of the calyx sometimes abrupt. The spurs of the anthers are different in different species. Their usual number is two, but one of them is sometimes wanting. Each is barbed, or tufted, at the point.

The only species of which we have any knowledge is

P. lasianthos. Villous-flowered Prostanthera. Labill. t. 157. Andr. Repos. t. 661.—Leaves lanceolate, smooth, with tooth-like serratures. Clusters paniced. Corolla hairy on both sides. Longer spur twice the length of the anther. Native of Van Diemen's island, and of New South Wales. Introduced at Kew by A. B. Lambert, esq. in 1808. It flowers in the greenhouse in June and July. Mr. Andrews says it was first raised from seed in 1807, in lord Grenville's beautiful garden at Dropmore, near Marlow. This is a luxuriant smooth shrub, whose leaves are opposite, stalked, two or three inches long. Flowers numerous, elegant, reversed, of a light purple hue, and sweet-scented.

PROSTATE, in *Anatomy*, a glandular body surrounding the urethra just at its commencement from the bladder. See GENERATION.

PROSTATE Gland, *Disease of*, in *Surgery*. The prostate gland, when diseased and enlarged, may produce obstruction of the neck of the bladder, and occasion a difficulty of voiding the urine. This species of retention of urine is much more serious than that proceeding from obstructions in the canal of the urethra, because the means of cure are less within our reach. In the first of these cases, however, it is generally more practicable than in the second, to relieve the patient by an artificial evacuation of the urine, since the catheter admits of being introduced with greater facility.

An enlargement of the prostate gland is far more common in persons advanced in years, than in young subjects.

When the prostate swells, the internal surface of that part of the canal of the urethra which it embraces undergoes no diminution; but, on the contrary, is rather augmented. For the enlarged gland, being situated principally at the sides of the urethra, compresses these together, so that this passage, instead of being round, is flattened, and forms a narrow fissure. Sometimes the gland swells more on one side than the other; and hence the canal which passes through it is rendered oblique.

Besides this effect, caused by the swelling of the lateral portions of the prostate gland, we have to notice another change produced by a small part of this gland, situated quite at the commencement, and on the posterior surface of the urethra. This particular portion of the prostate swells in the direction forward, and projects into the bladder, occasioning a sort of little valve just at the beginning of the urethra. Such an eminence may be observed in the dead body, even when the swelling is not very considerable, if

the surgeon will open the upper part of the bladder, and view the orifice of the urethra from above downward. But, in certain instances, it is alleged to be so considerable, that it projects some inches into the interior of the bladder. Such enlargement increases the bend of the urethra, and produces an impediment to the passage of the catheter, or bougie. Frequently, also, it raises the end of a sound, so as to make it pass above a calculus, which, therefore, is not perceived. It is sometimes, likewise, such an impediment to the entrance of the sound into the bladder, as cannot be surmounted without the utmost difficulty.

When the prostate enlarges, its consistence generally becomes much firmer than what is natural. The effects of such enlargement are very serious; for the sides of the urethra are then pressed together, while the projecting point of the gland in some measure prevents the urine from freely entering this canal, and, in many instances, stops it altogether. Besides, as the firmness of the gland is increased, its suppleness is diminished, so that it does not yield to the impulse of the urine, and little or none of this fluid is evacuated. The symptoms which this disorder produces, resemble those of a retention of urine arising from other causes.

When, in a case of difficulty of making water, the surgeon has had recourse to the catheter, and ascertained that such instrument may be readily introduced, he must next endeavour to learn whether the complaint depends upon the presence of a stone in the bladder. Should circumstances prove, however, that this is not the case, a disease of the prostate gland is to be suspected; especially if the catheter, or bougie, made use of, should meet with a sudden impediment, or pass with great difficulty, when the point of the instrument is near the neck of the bladder.

The attention of the practitioner must then be directed to the prostate, the state of which cannot be ascertained, unless the finger, properly oiled, be passed into the anus, and turned towards the pubes. If a hardness should be felt in the situation of the prostate, extending as far as the finger can reach; if the indurated part should cause a projection, that can be distinctly felt through the coats of the rectum; and if, when the finger is moved about, in order to examine the extent of the swelling, the hardness should be found to reach beyond the length of the finger, the surgeon may be certain that the prostate is considerably enlarged, and that it is the cause of all the patient's complaints.

In cases in which only the sides of the gland are enlarged, a bougie, or catheter, may readily be passed into the bladder; but the point of the gland which projects into this organ, frequently hinders the instrument from actually passing into its cavity. When the size of the prominence here alluded to is considerable, a bougie, or catheter, cannot be got over it without the utmost difficulty, because its apex then forms an angle with the passage. In such a case, it is necessary to be very cautious in the trials to pass an instrument, particularly when a metallic catheter is employed, as otherwise the part causing the obstruction would be injured. Here, certainly, a flexible catheter ought to be preferred; but the point of this sort of instrument may likewise hurt the prominent part of the gland; and should it be forced, its extremity will sooner bend backward than forward, so that it cannot be got into the bladder, but will rather penetrate the substance of the tumour.

Mr. Hunter, from whom we borrow these observations, has recorded an instance of this kind, where a surgeon pushed a catheter quite through the prominent part of the gland, in such a way, that the instrument at length reached the cavity of the bladder, and let out the urine; but the blood which flowed from the wounded part of the prostate passed into the

bladder. A second attempt was made to introduce a catheter; but without success. Mr. Hunter was consulted: he introduced a catheter as far as the part forming the impediment, and having discovered the enlargement of the prostate, he inclined the upper part of the catheter, so as to elevate its other end, and thus succeeded in getting it over the prominence. Unfortunately, the coagulated blood in the bladder stopped up the holes of the instrument, and obliged Mr. Hunter to withdraw it several times, for the purpose of cleaning it. As the same inconvenience continued, he proposed performing a similar operation to lithotomy, in order to discharge the extravasated blood from the bladder; but the patient's death prevented the operation. An examination of the body fully proved the nature of the accident which had given rise to the extravasation.

Instructed by the observation of several facts of this description, Mr. Hunter made it a rule, whenever the urine did not flow out immediately the catheter was introduced, to push the instrument more forward, by inclining its handle so as to raise the other end of it, and get it into the cavity of the bladder. In following this method, Mr. Hunter never failed.

There are no means to be depended upon for dispersing a swelling of the prostate. Cicuta, burnt sponge, and sea bathing, are said to have sometimes answered the purpose. The pilula hydrargyri, with the extract of cicuta, has been recommended. Mr. Home has found suppositories of opium and hemlock, passed up the fundament, not only relieve the irritation, but even lessen the projection of the gland.

Some abscesses and ulcerations of the prostate, which have been occasioned by strictures in the urethra, may be cured by removing the latter disease.

Whoever wishes a more particular account of the diseases of the prostate gland, should consult Baillic's *Morbid Anatomy*; Hunter's *Treatise on the Venereal Disease*; Home on *Strictures*, and on *Diseases of the Prostate Gland*.

PROSTATES, Προστατίς, among the Athenians, was used to signify any patron to whose protection sojourners in that city committed themselves.

He was allowed to demand several services of them, in which, if they failed, or neglected to choose a patron, an action was commenced against them before the polemarchus, and their goods were confiscated. See SOJOURNERS.

PROSTHAPHÆRESIS, formed from *προσθη*, *ante*, *super*, and *αφαίρεσις*, *ademptio*, in *Astronomy*, the difference between the true and mean motion, or true and mean place, of a planet; called also *equation of the orbit*, or *of the centre*, and simply *the equation*.

Prosthaphæresis amounts to the difference between the mean and equated anomaly.

Thus, suppose the circle A L M P N R (*Plate XIX. Astron. fig. 7.*) the orbit of the earth, surrounded by the ecliptic γ, ⊕, ☽, &c. and suppose S the sun, and the earth in R, the mean anomaly will be the arc A P R, or casting away the semicircle, the arc P R, or the angle P C R: and the true anomaly, rejecting the semicircle, will be P S R, which is equal to P C R, and C R S: if then to the mean anomaly we add the angle C R S, we shall have the true anomaly P S R, and the earth's place, in the ecliptic.

And here the angle C L S, or C R S, is called the *prosthaphæresis*, or *equation*, by reason it is sometimes to be added, and sometimes to be subtracted from the mean motion, that we may have the true motion or place of the earth. See EQUATION of the Centre.

PROSTHESIS, Προσθεσις, in *Grammar*, a species of *metaplasm*;

metaplasm; being the prefixing of some letter or syllable at the beginning of a word: as in *gnavus*, *pro navus*.

This is also called *apposition*.

PROSTHESIS, among *Surgeons*, is the filling up of what was before wanting, by the apposition of new matter. Such, *e. gr.* is the filling up fistulous ulcers with new flesh.

PROSTHETA, Προσθητα, from προσθημι, *to apply*, signify in Hippocrates, subditiuous medicines, whether suppositories or pessaries.

PROSTITUTES and PROSTITUTION. See BAWDY-HOUSE, CONCUBINAGE, &c.

PROSTYLE, Προστυλο, formed from προ, *before*, and στυλος, *column*, in the *Ancient Greek Architecture*, a range of columns in the front of a temple.

PROSTYPA, Προστυπα, in the *Sculpture of the Ancients*, images carved in such a manner as to be only half raised above the ground, or plain, on which they are formed. They seem to adhere to it, and have only one side exposed to view. To *prostypha* is opposed *επitypa*.

PROSYLLOGISM, PROSYLLOGISMUS, is used, by some school-writers, for a reason or argument produced to strengthen or confirm one of the premises of a syllogism.

Others define prosyllogism, an argument composed of two syllogisms, so disposed, as that the conclusion of the former is the major or minor of the latter: *e. gr.* Every rational is risible: but every man is rational, therefore, every man is risible: but no ass is risible, therefore no ass is a man.

The major, or the second syllogism, may be omitted or understood; and some even contend, that it ought to be so: so that, on their principle, a prosyllogism, or redundant syllogism, is when two syllogisms are so contained in five propositions, as that the conclusion of the former is the major or minor of the latter.

PROSZOWICE, in *Geography*, a town of Austrian Poland; 16 miles E. of Cracow.

PROTAGORAS, in *Biography*, a celebrated Greek philosopher, was born at Abdera, in Thrace, in the year 619 B.C. He appears to have been of humble origin, and when young was obliged to gain his livelihood by working as a porter. In this capacity he was frequently employed in carrying loads of wood from the adjacent country to Abdera. Democritus met him with one of his usual burdens, and being struck with the neatness with which it was packed, asked if he had done it himself, to which he replied in the affirmative; the philosopher pleased with the ingenuity, desired the youth to follow him, saying he would present him with greater and better objects for the exercise of his talents. The young man readily complied, and Democritus took him home, maintained him at his own expence, and instructed him in the principles of philosophy. After this Protagoras went to Athens, where he opened a school, and acquired great reputation for eloquence, wisdom, and that subtlety in reasoning which was so much admired by the sophists. His public lectures attracted great numbers, who paid him liberally, and he became exceedingly rich. While he was growing in reputation and wealth, he incurred the displeasure of the Athenian state, by advancing doctrines favourable to impiety. Of this he was accused by different persons, and among others by one of his scholars, *viz.* Eualthus, who asserted, that in one of his books he had said, "concerning the gods I am wholly unable to determine whether they have any existence or not; for the weakness of the human understanding, and the shortness of human life, with other causes, prevent us from attaining this knowledge." Similar opinions were also to be met with in some of his other writings, and, on this ac-

count, they were ordered to be collected, and burnt in the market place, while the author himself was banished from Attica. He took refuge in Epirus, where he lived many years. Intending to remove to Sicily, he lost his life by shipwreck on his voyage thither, when he was about 70, or, as others say, 90 years of age. He was author of various pieces upon logic, metaphysics, ethics, and politics, but none of them are extant. He had, unquestionably, a leaning to scepticism, and is said to have taught that contradictory arguments may be advanced upon every subject; that all natural objects are perpetually varying; that the senses convey different reports to different persons, and even to the same person at different times; that nevertheless, we have no other criterion of truth than our own perception, and cannot know that any thing is otherwise than it appears to our own senses, which are the essence of the soul. Adopting the doctrine of Democritus, that the atoms of which bodies are composed are in perpetual motion, Protagoras conceived that external objects are liable to such continual fluctuation, that nothing can certainly be known of them, and hence he concluded that nothing can be pronounced to exist, but that which is at any instant perceived by the senses, and that since these are perpetually varying, things themselves accordingly vary, so that, upon the same evidence, that of the senses, contradictory opinions may be advanced. Enfield's Hist. Phil.

PROTASIS, προτασις, formed from προτινω, *porrigo*, *I hold forth*, in the *Ancient Drama*, the first part of a comic or tragic piece; in which the several persons of the play are shewn; their characters and manners intimated; and the action, which is to make the subject of the piece, proposed and entered upon.

The ancient protasis might go about as far as our two first acts. See ACT.

Where the protasis ended, the epitasis commenced.

PROTATICUS, προτατικός, a person who never appeared but in the protasis, or first part of the play: as *Sofia*, in Terence's *Andria*, &c.

PROTE, in *Geography*, one of the Prince's islands, in the sea of Marmora, about three miles in circumference; healthy and uncultivated. The port is filled up.

PROTEA, in *Botany*, a name well chosen by Linnaeus, to express the great diversity of habit in the species of this genus; at least as he understood it; for other botanists, both before and after him, have much contracted its limits; see PROTEACEÆ. Linn. Gen. ed. 1. 22. Brown Tr. of Linn. Soc. v. 10. 74. Ait. Hort. Kew. v. 1. 188. Gærtn. t. 51. (Leucadendron; Linn. Gen. ed. 6. 46.) See PROTEA; Schreb. 62. Willd. Sp. Pl. v. 1. 506. Mart. Mill. Dict. v. 3. Juss. 78. Lamarck Illustr. t. 53.) Class and order, *Tetrandria Monogynia*. Nat. Ord. *Aggregata*, Linn. *Protea*, or *Proteaceæ*, Juss. Brown.

Gen. Ch. *Common calyx* many-flowered, of numerous, loosely imbricated, permanent scales; the innermost much the longest, expanded, and coloured. *Cor.* of one petal; tube simple, finally splitting longitudinally; limb in four concave segments, three of which cohere laterally. *Nectary* of four glands, alternate with the segments of the corolla, at the base of its tube. *Stam.* Filaments four, very short, inserted into the base of each segment of the limb; anthers oblong, incumbent, in the hollows of the segments. *Pist.* Germen superior, oblong; style awlshaped, permanent, the length of the corolla; stigma undivided, cylindrical, erect, more slender than the style. *Peric.* none. *Seed.* Nut solitary, bristly all over, crowned with the hardened style, of one cell. *Common Receptacle* dotted, clothed with short permanent scales.

Eff. Ch. Corolla separable into two unequal parts; limb four-cleft, with concave segments, bearing the stamens. Stigma cylindrical, more slender than the style. Nut superior, bristly all over, crowned with the permanent style. Common receptacle scaly. Common calyx imbricated, permanent.

Of this genus, as it now stands, Mr. Brown enumerates 39 species, 35 of which have terminal, the rest lateral, heads of flowers. All are natives of Southern Africa, except *P. Abyssinica*, found only by Bruce in the country whose name it bears. Twenty-three are mentioned in Hort. Kew. as known in the British collections. The habit of the whole is shrubby; the height very various. Some few are almost stemless. *Leaves* entire, coriaceous. The *flowers* in many cases are remarkable for their beauty and magnitude, the inner scales of the common *calyx* being sometimes elegantly silky, so as to resemble black velvet. See the following examples.

P. speciosa. Splendid Protea. Linn. Mant. 191. Brown n. 6. Ait. n. 3. Curt. Mag. t. 1183.—*Leaves* obovate-oblong, contracted at the base, smooth as well as the branches. All the scales silky; the inner ones somewhat dilated at the top; the middle ones likewise fringed. Style downy. Segments of the corolla with woolly points. Sent from the Cape of Good Hope, in 1786, by Mr. Masson. It flowers in the greenhouse from March to June. The *stem* forms a large shrub. The *leaves* are obtuse, three or four inches long, and nearly half as broad. *Flowers* as big as a small artichoke, with rose-coloured scales, finely fringed with brown, and bearded with white.

P. mellifera. Honey-bearing Protea. Thunb. Diff. n. 37. Brown n. 16. Ait. n. 9. Curt. Mag. t. 346. (*Leucadendron repens*; Linn. Sp. Pl. 135, z.)—*Leaves* lanceolate, tapering at the base. *Calyx* turbinate; scales smoothish, beardless, viscid. Tips of the corolla woolly. Style smooth, simple at the summit. An inhabitant of the Cape, long known in our gardens and herbariums, distinguished by its very glutinous, rose-coloured, smooth *calyx*, which is almost as large as the foregoing. The *branches* are red and smooth. *Leaves* slightly obovate, or spatulate.

P. mucronifolia. Dagger-leaved Protea. Salisb. Parad. t. 24. Brown n. 20. Ait. n. 12. Curt. Mag. t. 933. Andr. Repof. t. 500.—*Leaves* linear-lanceolate, sharp-pointed; broad at the base. Scales of the calyx lanceolate, pointed, smooth. Stem erect, many-flowered.—Found at the Cape by Mr. Niven. Mellis. Lee and Kennedy are said to have first raised it from seed, about the year 1803. It flowers in autumn. This is much smaller, in every part, than either of the above-mentioned, being a bush, only two or three feet high, with numerous, pungent, rather glaucous, single-ribbed *leaves*, scarcely two inches long. *Flowers* flesh-coloured, with a spreading, taper-pointed *calyx*, expanding above two inches.

P. cordata. Heart-leaved Protea. Thunb. Diff. n. 60. t. 5. Brown n. 36. Ait. n. 20. Andr. Repof. t. 289. (*P. cordifolia*; Curt. Mag. t. 649.)—*Flowers* lateral. *Leaves* roundish-heart-shaped, many-ribbed. Scales of the calyx smooth.—Sent from the Cape, by Mr. Masson, about the year 1790. It blossoms in the spring, and is remarkable for the situation of its dull-crimson rosaceous *flowers*, which grow out of the creeping *stem*, near the *root*, the leafy *branches* rising high above them, in a zigzag nearly upright position. The *leaves* are alternate, distant, nearly sessile, broad, red-edged, of a very rigid coriaceous texture.

P. humilis. Low-flowering Protea. Brown n. 38. Ait. n. 22. (*P. humiflora*; Andr. Repof. t. 532.)—*Flowers* lateral. *Leaves* linear-lanceolate, acute. Receptacle conical,

with acute scales.—Found at the Cape, by Mr. Niven, who sent it to his patron Mr. G. Hibbert, about the year 1802. This is still more singular than the last, for its crowded radical *flowers*, whose colour is a dull-brownish red. The leafy *branches* are numerous, erect, a foot high. *Leaves* numerous, nearly linear, acute, smooth, two or three inches long.

PROTEA, in *Gardening*, contains plants of the ornamental, shrubby, exotic kind, of which the species cultivated are, the cone-bearing protea (*P. conifera*); and the silvery protea (*P. argentea*). But there are several other species that may be cultivated for variety.

Method of Culture.—These plants are increased by seeds, procured from the places of their native growth; which, as soon as obtained, should be sown in pots filled with sandy loam, and placed in a moderate hot-bed; and when the plants are come up, moderate air should be given, or they should be placed in an airy glass case, or towards the front of a greenhouse; and be afterwards managed as other similar exotics of that kind.

They are also sometimes raised by cuttings, in spring and summer, by the assistance of a hot-bed, in the same manner. They should not have much water afterwards, nor be treated in too tender a manner.

They are ornamental among other potted plants.

PROTEACEÆ, in *Botany*, a natural order of plants, the third in Jussieu's sixth class, (where it is termed *Protea*;) and the twenty-sixth of his general system. For other orders of this sixth class, see ELÆAGNI, LAURI, and POLYAGONEÆ. The characters of the order in question are thus given by Jussieu.

Calyx, (rather *corolla*;) in four or five deep divisions, or tubular, with four or five segments, sometimes accompanied below by minute down or scales. *Stamens* equal in number to the divisions of the flower, and inserted into their middle part. *Germs* solitary, superior; style simple; stigma mostly solitary. *Seed* one, either naked or enclosed in a seed-vessel; very rarely the latter is a capsule of one cell, with many seeds. *Albumen* none. *Radicle* inferior. *Stem* shrubby. *Leaves* either alternate, or clustered in a somewhat whorled manner. *Flowers* either distinct, or variously assembled upon a common receptacle, within the imbricated scales of a common calyx. Sometimes the *stamens* and *pisils* are in separate individuals.

The genera in Jussieu are *Protea*, *Banksia*, *Roupala* of Aublet, *Brabeium*, and *Embothrium*.

Mr. R. Brown, in *Transf. of Linn. Soc.* v. 10. p. 15—226, has given a masterly dissertation on this natural order, full of important remarks on the systematic distinctions, as well as on the geography of plants. In this treatise the *Proteaceæ* are divided into no less than 38 genera; *Aulax*, *Leucadendron*, *Petrophila*, *Isopogon*, *Protea*, *Leucospermum*, *Serruria*, *Mimetes*, *Nivenia*, *Sorocephalus*, *Spatalla*, *Adenanthos*, *Guevina*, *Brabeium*, *Persoonia*, *Cenarrhenes*, *Agastachys*, *Symphionema*, *Bellendeua*, *Franklandia*, *Sinisia*, *Conospermum*, *Synaphea*, *Anadenia*, *Grevillea*, *Hakea*, *Lambertia*, *Xylomelum*, *Orites*, *Rhopala*, *Knightia*, *Embothrium*, *Oreocallis*, *Telopea*, *Lomatia*, *Stenocarpus*, *Banksia*, and *Dryandra*. Most of these will be found in their proper places. Our *Dryander* however is properly superseded by that of Mr. Brown, as being not really distinct from *Alcurites* of Forster.

PROTECTION, PROTECTIO, the shelter, defence, authority, and aid, employed by any one in behalf of the helpless or unhappy.

Active protection supposes power, interest, favour, &c. in the person that protects. *Passive* protection, on the contrary,

trary, implies necessity, weakness, and dependence, in the person protected.

PROTECTION is also used for a privilege belonging to ambassadors, members of parliament, &c. by which they and their domestics are secured from arrests, &c. See EMBASSADOR and ARREST.

PROTECTION is sometimes also understood of the person of the protector. Such a cardinal has the protection of France. The protection of Spain is become vacant by the death of such a cardinal.

PROTECTION, in *Law*, in its general sense, denotes that benefit and safety which every subject, denizen, or alien, specially secured, hath by the laws.

PROTECTION, in a more special sense, is used for an exemption or immunity given by the king to a person, to secure him against suits in law, or other vexations, upon reasonable causes moving him thereunto, and for a certain time.

Of this, Fitzherbert makes two kinds: the *first* he calls a protection *cum clausula volumus*; of which he mentions four cases: 1. A protection, *quia profecturus*, for him that is to pass over sea, in the king's service. 2. A protection, *quia moraturus*, for him who is already abroad in the king's service; as an ambassador, &c. 3. A protection for the king's debtor, that he be not sued, or attached, till the king be paid his debt: but by the statute 25 Edw. III. stat. 5. cap. 19. notwithstanding such protection, another creditor may proceed to judgment against him, with a stay of execution till the king's debt be paid; unless such creditor will undertake for the king's debt, and then he shall have execution for both. (See ARREST.) 4. A protection for a person in the king's service beyond sea, or in the marches of Scotland.

The *second* form of protection is *cum clausula nolumus*, which is most commonly granted to a spiritual company, for their immunity from having their cattle taken by the king's ministers. But this may be also granted to a single person, either spiritual or temporal.

Protection extends not to pleas of dower, quare impedit, assize of novel disseisin, darrein presentment, attainments, nor pleas before justices in eyre.

PROTECTION *from Impressing*, is a privilege allowed to certain persons to be exempt from being impressed. This is granted to apprentices to the sea-service, persons employed in the fisheries, coasting trade, &c.

PROTECTION *Island*, in *Geography*, a small island in the gulf of Georgia, at the entrance of Port Discovery. N. lat. 48° 9'. E. long. 237° 20'.

PROTECTOR, a person who undertakes to shelter and defend the weak, helpless, or distressed.

God, and the magistrate, are the protectors of the widow and orphan. Among the heathens, Minerva was esteemed the *protectors* of arts.

Every Catholic nation, and every religious order, has a protector residing at the court of Rome, who is cardinal, and is called the *cardinal* protector.

PROTECTOR is sometimes also used for a regent of a kingdom, made choice of to govern it during the minority of a prince.

Cromwell assumed the title and quality of *lord protector of the commonwealth of England*.

PROTELARII, among the Romans, were the poorer sort of citizens, whose estate did not exceed fifteen hundred pieces of silver. They were distinguished from those who were worth little or nothing; these last being called *capite censi*.

PROTESIS, in *Ancient Music*, a rest or pause, equal to a long syllable; differing from the *limma*, which was the rest for a short time or syllable.

PROTEST, in *Law*, is used for a caution, or call of witness, or an open affirmation, that a person does, either not at all, or but conditionally, yield his consent to any act; or to the proceeding of any judge in a court, in which his jurisdiction is doubtful; or to answer upon his oath farther than by law he is bound.

Any of the lords in parliament have a right to protest their dissent to any bill passed by a majority, with their reasons for such dissent; which protest is entered in form. This privilege is said not to be very ancient: the commons have no right to protest.

PROTEST, in *Commerce*, is a summons made by a notary public to a merchant, banker, or the like, to accept or discharge a bill of exchange drawn on him; after his having refused either to accept or pay the same.

It is called a protest, because it contains a protestation, that the party will return the bill, and even take up money at interest; and charge all costs, damages, carriage, and re-carriage, on the refuser.

There are two kinds of protests, the one for want of acceptance, and the other for want of payment.

The first is to be made by the bearer of the bill, at the time of presenting it, in case the person on whom it is drawn refuses to accept it for the time, or the sum there expressed. See BILL of *Exchange*.

This protest must be made within the regular hours of business, and in sufficient time to have it sent to the holder's correspondent by the very next post after acceptance refused; for if it be not sent by that time, with a letter of advice, the holder will be construed to have discharged the drawer and the other parties entitled to notice; and noting alone is not sufficient; there must absolutely be a protest to render the preceding parties liable. (Bull. N. P. 271. 2 Term Rep. 713.) But in this case the holder is not to send the bill itself to his correspondent: he must retain it, in order to demand payment of the drawee when it becomes due. When the bill becomes due, whether it was accepted or not, it is again to be presented for payment within the days of grace, and if payment be refused, the bill must be protested for non-payment; and the bill itself, together with the protest, sent to the holder's correspondent, unless he shall be ordered by him to retain the bill with the prospect of obtaining its discharge from the acceptor. As this protest on foreign bills must be made on the last day of grace, and immediate notice sent to the parties concerned, it seems established, that such a bill is payable, "on demand made at any time that day" within reasonable hours; and that the acceptor has not the whole day to pay the bill. 4 Term Rep. 170.

Besides the protest for non-acceptance, and for non-payment, there may be also a protest for better security. This is usual when a merchant who has accepted a bill happens to become insolvent, or is publicly reported to have failed in his credit, or absents himself from 'Change, before the bill he has accepted becomes due; or when the holder has any reason to suppose that it will not be paid: in such cases he may cause a notary to demand better security, and on that being refused, make protest for want of it; which protest must also be sent to the parties concerned, by the next post. (Mir. 27. Lord Raym. 743.) In such cases, however, the most general practice is to wait the regular time till the bill becomes due. Where the original bill is lost, and another cannot be had of the drawer, a protest may

PROTEST.

may be made on a copy, especially where the refusal of payment is not for want of the original bill, but merely for another cause. 1 Show. 164.

But if a bill left for acceptance be lost, the person with whom it was left must bind himself to payment, or else the bill may be protested immediately. It is customary, as a precaution against accident or miscarriage, to draw three copies of a foreign bill, and to send them by different posts. They are denominated the *first*, *second*, and *third of exchange*; and when any of them is paid, the rest become void and of no value.

The effect of protest for non-acceptance, or non-payment, is to charge the drawer, or indorsers, not only with the payment of the original sum, but with interest, damages, and expences; which latter consist usually of the exchange, re-exchange, commission, and postage, together with the expences of the protest. (Stra. 649.) The exchange is reckoned according to the course at sight from the place where the protest is made, to the place where the bill is to be paid by the drawer; and if it be not paid there, the re-exchange is then reckoned from the same place to that where the bill is paid, and also double commission. The interest commences from the day when the demand was made. Whenever interest is allowed, and a new action cannot be brought for it, which is the case on bills and notes, the interest is to be calculated up to the time of signing final judgment. 2 Burr. 1086-7. 2 Term. Rep. 52.

The principal difference between foreign and inland bills of exchange at common law seems to have been this. A protest for non-acceptance or non-payment of a foreign bill was, and still is, essentially necessary to charge the drawer on the default of the drawee; nothing, not even the principal sum, could or can at this time be recovered against him without a protest; no other form of notice having been admitted by the custom of merchants as sufficient: but on inland bills, simple notice, within a reasonable time, of the default of the drawee, was held sufficient to charge the drawer, without the solemnity of a protest; the disadvantage arising from thence was this, that notice entitled the holder to receive only the sum in the original bill, which in many cases might be a very serious disadvantage: to remedy this inconvenience in some degree, the stat. 9 & 10 W. III. c. 17. and afterwards the stat. 3 & 4 Anne, c. 9. were passed; the professed intention of which acts was to put inland bills on the same footing as foreign ones; so far as relates to the recovery of damages, interest, and costs, (*i. e.* expences), by means of the protest they have done it; but there are several minute particulars, in which, from an attentive perusal of the acts, it will appear they still differ.

To the constitution of a *BILL of Exchange*, (which see), it is not necessary that the words "value received" should be inserted; and the want of these in a foreign bill, cannot deprive the holder of the benefit of a protest; but that benefit in case of non-payment is not given by the statutes to inland bills, which want these words, and therefore they cannot be protested for non-payment; and the second act provides, that "where these words are wanting, or the value is less than 20*l.* no protest is necessary, either for non-acceptance or non-payment," the safest construction of which seems to be, that inland bills, without the words "value received," or under 20*l.* shall continue as at common law, and shall not be entitled to the privilege of a protest, either for non-acceptance or non-payment.

An inland bill, payable at so many days after "sight," cannot be protested at all, and no inland bill can be pro-

tested, till after the expiration of the three days of grace; notice of which protest is by the statute to be sent within fourteen days after the protest. 4 Term Rep. 170.

There appears to be also another difference subsisting between foreign and inland bills of exchange; for where acceptance and payment both are refused on foreign bills, it seems necessary that there should be a protest for each; but under the stat. 3 & 4 Anne, c. 9, it seems, that one protest for either, on an inland bill, is sufficient. On inland bills, where damages, interest, and costs, (expences), are to be recovered, there is more indulgence in the time allowed for notice of non-payment than where only the principal sum is to be recovered; for when there is no protest for non-payment, presentation for payment must be made so early as the last day of grace, that the holder may give notice of non-payment by the next post. That part of the stat. 3 & 4 Anne, c. 9, which puts notes on the same footing with inland bills, makes no express provision for protesting them for non-payment; but there can be doubt that the practice under which such a protest is frequently made is founded in justice.

After a bill has been protested, it is sometimes accepted by a third person to save the reputation of the drawer, or of an indorser: such an acceptance is called an acceptance "supra protest." The acceptor must then appear in person, with witnesses, before a notary, and declare that he accepts it for the honour of such a person, and subscribe the bill thus:—Accepted, "supra protest," in honour of, &c. The same may happen when the person upon whom a bill was drawn, having doubts about the drawer, protests it, but afterwards accepts it for the honour of one of the indorsers; in this case the bill must be sent to the said indorser without delay. The person for whose honour a bill was accepted must reimburse the acceptor the amount of the bill, commission, and other charges, even though the acceptance should have taken place without his knowledge. If such a person approves of the acceptance, the bill may be paid without any farther protest; but if he should return no answer, or express his disapprobation of the acceptance, the bill must be formally protested for non-payment against him to whom the bill was directed; and on his persisting to refuse payment, the acceptor may safely pay it for his account, as he can recover the amount.

As to several niceties relative to qualified acceptance, and protests under peculiar circumstances, see *Beaves Lex. Merc.* See also 1 *Wils.* 185. *Doug.* 249.

At Paris the protest is to be made within ten days; at Hamburgh within twelve days; at Venice, where all bills are paid in banco, the protest for want of payment is to be made within six days; but then the bank is supposed open, otherwise no protest to be made; however, in 1808, the bank was discontinued, Venice having been incorporated with the kingdom of Italy in 1805: at Rome, protests for want of payment are to be made within fifteen days: at Leghorn, Milan, and Bologna, there is no time fixed; at Amsterdam, they are to be made within six days.

The negotiators of some places, as those of Rome, M. Savary observes, do not look on themselves as obliged to protest in default of payment: but this opinion is contrary to universal custom, and natural reason; since, till after protestation, they have no remedy or resource against the drawer, or indorser, nor any title to be reimbursed.

M. Ricard adds, that bills of exchange drawn from Amsterdam, or Antwerp, or Spain, are to be protested, in default of payment, within fourteen days after they fall due; after which time the bearer stands the risk and chance of the non-protested

protested bill (not the drawer, or indorser), in case the party happens to fail after the said fourteenth day. See *BILL of Exchange*.

PROTEST, in *Sea Language*, is an instrument drawn up in writing, attested before a justice of the peace, by the master and a part of the ship's crew, after the expiration of a voyage, describing the severity of the said voyage, occasioned by tempestuous weather, heavy seas, an insufficient crew, or any other circumstances by which the ship has suffered, or may suffer, either in her hull, masts, rigging, or cargo. It is chiefly intended to shew, that such damages or misfortunes did not happen through any neglect or ill conduct of the master or his officers. Falconer.

The protest of the captain, so long as he is living, is in no case evidence on the one side or the other: the only use that can be made of it is to contradict his testimony, if he varies from it.

PROTESTANDO, in *Law*, is a word made use of to avoid double pleading in actions; it prevents the party that makes it from being concluded by the plea he is about to make, that issue cannot be joined upon it; and it is also a form of pleading, where one will not directly affirm or deny any thing alleged by another or himself. In the first case, it is where a man pleadeth a thing which he dares not affirm, or that he cannot plead for fear of making his plea double; as in title to lands by two descents, the defendant must plead one of them, and put the word *protestando* instead of *dicit*; as to the other, that such a one died seized, &c. and in the last case, when one is to answer to two matters, and by the law he ought but to plead to one; then in the beginning of the plea he may say *protestando*, that such matter is not true, and add to his plea *pro placito dicit*; and so he may take issue upon the other part of the matter. Plowd. 276. Finch 359.

PROTESTANT, a name first given in Germany to those who adhered to the doctrine of Luther; because, in 1529, they *protested* against a decree of the emperor Charles V. and the diet of Spire; and declared, that they appealed to a general council.

In a former diet, held at Spire in 1526, it was unanimously agreed to present a solemn address to the emperor, beseeching him to assemble, without delay, a free and a general council; and it was also agreed, that in the mean time, the princes and states of the empire should, in their respective dominions, be at liberty to manage ecclesiastical matters in the manner they should think the most expedient, yet so as to be able to give to God and to the emperor an account of their administration, when it should be demanded of them. This decree was considered by the adversaries of the Reformation as almost equivalent to a toleration of Luther's opinions, and therefore, as soon as the emperor had concluded a treaty of peace with Clement VII., who now sat in the papal chair, he assembled the new diet at Spire in 1529; where the power which had been granted by the former diet to every prince, of managing ecclesiastical matters as they thought proper, until the meeting of a general council, was revoked by a majority of votes; and every change was declared unlawful, that should be introduced into the doctrine, discipline, or worship of the established religion, before the determination of the approaching council was known. Against this decree, the elector of Saxony, the marquis of Brandenburg, the landgrave of Hesse, the dukes of Lunenburg, the prince of Anhalt, together with the deputies of fourteen imperial or free cities, entered a solemn protest.

The name has been since also given to those who adhere to the sentiments of Calvin; and is now become a com-

mon denomination applied indiscriminately to all the sects, of whatever denomination, which have revolted from the Roman see.

PROTESTANTS, *French*. See HUGUENOTS.

PROTESTANT *Dissenters*. See DISSENTERS, and NON-CONFORMISTS.

PROTESTANT *Succession*. See *Right of Crown*.

PROTESTATION, in *Law*, a solemn declaration made by some judiciary act, or proceeding against any oppression, violence, or injustice; or against the legality of a sentence, judgment, decree, or other procedure; importing, that the party is determined to oppose it at the proper time, &c. See PROTEST.

Protestation is defined by justice Walsh, a defence, or safeguard, to the party that makes it, from being concluded by the act he is about to do; so that issue cannot be joined upon it.

Protestation is defined by Plowden, a form of pleading, when one does not either directly affirm or deny any thing alleged by another, or which he himself alleges. Plowd. fol. 276. See PROTESTANDO.

PROTEUS, in *Mythology*, the son of Neptune and Phœnice, or Oceanus and Tethys, who was reputed one of the gods of the sea, and supposed capable of foretelling future events, and of transforming himself into any shape at pleasure.

According to Diodorus Siculus, he was king of Egypt, and, after the manner of their kings, he sometimes used a lion, and sometimes a bull for his crest. He is said to have reigned two hundred and forty years after Moses, and by his distinguished knowledge of astronomy to be able to predict the revolutions of the planets.

No character in mythology is more celebrated than this sea-god, and the two greatest poets of antiquity, Homer (*Odyss. lib. iv.*) and Virgil (*Georg. 4.*), have vied with each other in delineating it. In order to separate the truth of history from fiction, we should recollect and compare the accounts which ancient writers, such as Homer, Herodotus, Diodorus Siculus, Clemens Alexandrinus, Lycophron, and several others, have given us of Proteus. All agree, that about the time of the Trojan war, Proteus was a king of Egypt, who kept his court at Memphis. According to Herodotus, he was the successor of Pheron, and had a temple at Memphis, which was splendid and magnificently adorned: and in this temple was a chapel dedicated to Venus. Diodorus Siculus calls him Cetes. The circumstance which seems to have given rise to the metamorphoses of Homer and Virgil seems to have been this: Proteus was a wise and eloquent prince, and the precaution which led him to avoid every danger answered the purpose of a prophetic spirit, which is ascribed to him. Homer and Virgil, by the qualities which they attribute to him, seem to be giving an allegorical description of a king, wise and provident, artful and insinuating, and not of a sea-monster, or a camæleon, that changed his form and figure. Nothing is more usual in the poets, and even in scripture, than those symbolical descriptions that figure a character under obscure terms; accordingly Proteus is denominated the son of Neptune, because he was powerful at sea, and master of Carpathia, an island near Egypt, and hence he was afterwards styled a sea-god; and that he himself was a native of Pallene, in Thessaly.

Some authors allege, that Proteus was a skilful orator, who could easily prevail with those who conversed with him, to alter their sentiments. Heraclides of Pontus says, that the fable of Proteus comprehends the mystery of the formation of the world, and that his changes were designed

to teach us, that matter was capable of receiving all sorts of forms, and that Eidotea, who advises to bind her father, is divine Providence, which fixes this matter to certain subjects. According to Bryant, he was the patriarch Noah.

PROTEUS, in *Natural History*, an animalcule discovered by Baker in the slime-like matter taken from the side of a glass jar, in which small fishes, water-snails, and other such creatures, had been kept alive for two or three months, by giving them frequently fresh water. In substance and colour it resembles a snail: its shape is somewhat elliptical, but pointed at one end, whilst from the other a long, slender, and finely proportioned neck stretched itself out, and was terminated with a kind of head. Mr. Baker has described and given a figure of this microscopic animal, and denominated it Proteus from its various sudden transformations. Employment for the Microscope, vol. ii. c. 5.

PROTHESIS, *προθεσις*, derived from *προτιθημι*, *I expose to view*, among the Greeks, the ceremony of laying the dead near the door till the time of their interment, with their feet outwards; on which account the Romans called them *positi*.

PROTHESIS, a little altar in the Greek churches, on which a ceremony is performed, called by the name *προθεσις*.

On this altar the priest, with the other ministers, prepare every thing necessary to the celebration of mass, *viz.* the bread, wine, &c. After which they go in procession from this to the great altar to begin mass; carrying with them the species thus prepared.

PROTHONOTARY, PROTHONOTARIUS, *Protonotary*, a term properly signifying *first notary*; and which was anciently the title of the principal notaries of the emperors of Constantinople.

With us prothonotary, called also *preignotary*, is used for an officer in the courts of king's bench and common pleas; the latter of which has three, the former one. See COURT, &c.

PROTHONOTARY of the king's bench records all actions civil, sued in that court; as the clerk of the crown-office doth in all criminal causes.

PROTHONOTARIES of the common pleas enter and inroll all declarations, pleadings, assizes, judgments, and actions: they also make out all judicial writs, as the venire facias, after issue joined; except habeas corpus, and distringas jurator, for which there is a separate office; writs of execution and seisin, of superfeudas, of privilege, &c.; they inroll all recognizances acknowledged in that court, all common recoveries, make exemplifications of records, &c.

PROTHONOTARY, or *Protonotary*, is also an officer in the court of Rome, who has a degree of pre-eminence over the other notaries.

There is a college of twelve prothonotaries, called *participantes*; because partaking in the fees of the expeditions in chancery.

They are ranked among the number of prelates, and wear the violet rochet, the hat, &c. They assist at all grand ceremonies, and have a place in the pope's chapel.

Their office is to dispatch the acts in grand causes, which the simple apostolical notaries dispatch in lesser causes: they may create apostolical notaries and doctors, to officiate out of the city.

Those out of the college have none of the privileges of the others, except the habit.

The prothonotaries were first established at Rome by pope Clement I. with design to write the lives of the martyrs.

PROTHYRIS, in the *Ancient Architecture*, is some-

times used for a quoin, or corner of a wall; otherwise called *anco*. See CONSOLE.

Sometimes, also, for a cross-beam, or over-thwart rafter.

PROTHYRIS is also used, by Vignola, for a particular sort of key of an arch: an instance of which we have in his Ionic order, consisting of a roll of water-leaves, between two reglets and two fillets, crowned with a Doric cymatium; its figure being much like that of a modillion.

PROTHYRUM, *προθυρον*, a porch at the outer door of a house or portal.

PROTIPULA, in *Entomology*, a name given to a species of fly resembling the tipula, or long-legs, in many respects; but differing in regard to the essential character, which, in the tipula, is the having two beards growing on the anterior part of the head, and occasionally falling over the mouth, and closing its aperture; these the protipula wants.

PROTIWIN, in *Geography*, a town of Bohemia, in the circle of Prachatitz; four miles N. of Wodnian.

PROTO, formed from *πρωτο*, *first*, a word used in composition with divers terms in our language, to express a relation in priority; as in proto-martyr, proto-type, &c.

PROTO-Canonical. See DEUTERO-Canonical.

PROTOCOLLUM, *πρωτοκολλον*, a term used in the ancient jurisprudence for the first leaf of a book, in which was the mark of the paper, or parchment.

It was even sometimes used for the mark itself; which was usually in the margin, but sometimes at the top of the page.

The forty-fourth Novel of Justinian forbids cutting the protocollum of charters, which shew the year in which the paper or parchment was made, and the officer commissioned for the delivery of them; by means of which frauds were frequently detected.

PROTOCOLLUM was also used for the first minute, draught, or summary, of an act to be passed, which the notary drew up, in short, in little table-books, to be afterwards enlarged at leisure.

PROTOFORESTARIUS was he whom our ancient kings made chief of Windsor forest, to take cognizance of all causes of death or mayhem there; after the manner of a lord chief justice in eyre.

PROTOGALA, the term used by the ancients for what we call *beeflings*, the first milk of a cow or other animal after her having brought forth young.

PROTOGONUS, in *Mythology*, the first man in the cosmogony of the Phœnicians, whose wife was Eon; and of their posterity Sanchoniathon has given an account. According to Bryant, in his Analysis of Mythology, Protogonus was designed to represent the great patriarch Noah; who is described in the Orphic Hymn. 5, as the first of men; of a twofold state or nature, who wandered at large under the whole heavens, inclosed in an ovicular machine, (whence he was termed *Ωογενης*, ovo genitus,) and who was (hieroglyphically) depicted with golden wings. The same was the parent of all mankind, who dispelled the mist and darkness with which every thing had been obscured.

PROTO-MARTYR, compounded of *πρωτο*, *first*, and *μαρτυρ*, *witness*, the *first martyr*, or witness, who suffered death in testimony of the truth; as Abel, improperly reckoned so by some, in the Old Testament, and St. Stephen in the New.

PROTONOTARY. See PROTHONOTARY.

PROTOPASCHITÆ, *προτοπασχισται*, in *Church History*, heretics, who, after the manner of the Jews, celebrated the feast of Easter with unleavened bread. They were likewise called Sabbatiani.

PROTOPLAST, PROTOPLASTUS, a title sometimes given to our first father Adam, from the Greek *πρωτοπλαστος*, q. d. *first formed*.

PROTOS, Gr., the name of the first tone or ecclesiastical mode, in the Ambrosian chant.

PROTOTYPE, *πρωτοτυπος*, the original, or model, by which a thing is formed.

It is chiefly used for the patterns of things to be engraven, moulded, or cast.

PROTOTYPON, *πρωτοτυπον*, in *Grammar*, is sometimes used for a primitive, or original word.

PROTRACTING, or PROTRACTION, in *Surveying*, the act of plotting, or laying down, the dimensions taken in the field, by means of a protractor, &c.

Protracting makes one part of surveying.

PROTRACTING-Pin, a mathematical instrument, or rather an appendage of an instrument called a protractor.

The protracting-pin is a fine needle, fitted into a handle, used to prick off degrees and minutes from the limb of the protractor.

PROTRACTOR, a name of an instrument used in *Surgery*, to draw out any foreign or disagreeable bodies from a wound or ulcer, in like manner as the forceps.

PROTRACTOR is also an instrument used in *Surveying*, by which the angles taken in the field with a theodolite, circumferentor, or the like, are plotted, or laid down, on paper.

This protractor consists of a semicircular limb, A D B (*Platc I. Surveying, fig. 1.*) of brass, silver, horn, or the like, divided into 180° , and subtended by a diameter B A, in the middle of which is a little notch, or lip, C, called the *centre of the protractor*.

For the convenience of reckoning both ways, the degrees are numbered from the left hand towards the right, and from the right hand towards the left.

But this instrument is made much more commodious by transferring the divisions on the same circumference to the edge of a ruler, whose side E F is parallel to A B, which is easily done by laying a ruler on the centre C, and the several divisions on the semicircumference A D B, and marking the intersections of that ruler on the line E F: so that a ruler with these divisions marked on three of its sides, and numbered both ways, as in the protractor, (the fourth or blank side representing the diameter of the circle), is of the same use as a protractor; and much better adapted to a case.

On the limb of the protractor are sometimes also placed numbers, denoting the angles at the centres of regular polygons: thus against the number 5, denoting the sides of a pentagon, is found 72, the angle at the centre of a pentagon.

PROTRACTOR, *Use of the*: 1. *To lay down an angle of any given quantity, or number of degrees, e. gr. of fifty degrees, at any point, and with any given line, e. gr.* Lay the centre of the protractor on the given point, and the diameter of the protractor on the given line: make a mark against the given degree 50, on the limb of the protractor; through which, from the given point, draw a line: this gives the angle required.

2. *To find the quantity of a given angle.*—Lay the centre of the protractor on the point of the angle, and the diameter on one of the lines forming it. The degree of the limb cut by the other line, *viz.* 50, is the number of degrees of the angle required.

3. *To inscribe any given regular polygon, e. gr. a pentagon, in a circle.*—Lay the centre and diameter of the protractor on the centre and diameter of the circle, and make a dot

against the number of degrees of the angle at the centre, *viz.* 72. Through this dot and the centre of the circle draw a line, cutting the circumference of the circle. To the point of intersection, from the point where the diameter cuts the circumference, draw a right line; this line will be a side of the pentagon, which, being taken in the compasses, and set off as often as it will go in the circumference, will give points, which, being connected by lines, will form the pentagon required. See POLYGON.

4. *To describe any regular polygon, e. gr. an octagon, on a given line.*—Subtract the angle at the centre, which the protractor gives, *e. gr.* 45° from 180 , the remainder 135 degrees is the angle included between two sides of the octagon, one-half of which is $67\frac{1}{2}$. Applying then the diameter of the protractor over the given line, with the centre over one extreme; make a dot against $67\frac{1}{2}$, to which from the centre draw a line: apply the protractor to the other end of the line, so as the centre be over the extreme, and there set off another angle of $67\frac{1}{2}^{\circ}$.

From the point where the two lines thus drawn intersect, as a centre, describe a circle with the interval of the given line.

The given line will be one side of the octagon; which, being set off as often as it will go in the circumference thus drawn, will give points, which, being connected, will form the octagon required.

PROTRACTOR, *Improved*, is an instrument much like the former, only furnished with a little more apparatus, by which we are enabled to set off an angle to a minute; which is impracticable on the other.

The chief addition is an index fitted on the centre, and moveable on it, so as to play freely and steadily over the limb. Beyond the limb the index is divided, on both edges, into sixty equal parts of the portions of circles, intercepted by two other right lines drawn from the centre, so that each makes an angle of one degree with lines drawn to the assumed points from the centre.

To set off an angle of any number of degrees and minutes with this protractor, move the index, so that one of the lines drawn on the limb, from one of the fore-mentioned points, may fall upon the number of degrees given; and prick off as many of the equal parts on the proper edge of the index as there are minutes given: thus, drawing a line from the centre to that point so pricked off, you have an angle with the diameter of the protractor, of the proposed number of degrees and minutes.

Indeed it may be of good use to lay down an angle to a minute, when we are able to take it to a minute: but, till we have better needles, and juster theodolites, than are yet made, the old protractor may serve very well.

PROTRUSORIS *Ordo Exterior*, in *Anatomy*, a name given by Santorini to certain fasciculi of the great zygomatic muscle, running under the fleshy part of the lower lip. See LIPS.

PROTRUSORIS *Interior Ordo*, a name given by Santorini to a muscle of the face, called by Albinus orbicularis oris; and by Cowper and Douglas constrictor labiorum and sphincter labiorum. See LIPS.

PROTRYGIA, *Προτρυγία*, in *Antiquity*, a festival in honour of Neptune, and of Bacchus, furnished *πρωτρυγης*, or *πρωτρυγας*, *απο της τευ ος*, i. e. *from new wine*.

PROTTES, in *Geography*, a town of Austria; 10 miles S. of Zittersdorf.

PROTUBERANCE, PROTUBERANTIA, in *Anatomy*, denotes an eminence, whether natural, or preternatural, that projects or advances out beyond the rest.

The orbicular protuberances of the third ventricle of the

brain are called *nates*; and the apophyses of the orbicular protuberances are called *testes*.

The annular protuberance is the process of the medulla oblongata, in form of a ring; whence its name, first given it by Willis.

PROTZEN, in *Geography*, a town of Bohemia, in the circle of Leitmeritz; 22 miles N. of Prague.

PROVADSCIK, a town of European Turkey, in Bulgaria; 46 miles W. of Varna.

PROVAT, or PRUAT, a town of European Turkey, in Bulgaria; 16 miles N.W. of Varna.

PROVEDITOR, PROVEDITOUR, or *Proveditore*, an officer in several parts of Italy, particularly at Venice.

There are various kinds of proveditors in Venice; as proveditor of the commons, who is nearly the same with the ædile among the Romans, consul in Languedoc, and eschevin in other cities. Of these proveditors there are three.

The *proveditores alle ragioni vecchie, alla biave, alla giustizia*, &c. have the direction of matters relating to policy, throughout the signiory.

PROVEDITOR *General of the Sea*, is an officer whose authority extends over the whole fleet, when the captain-general is absent. He has, particularly, the disposal of the cash; and pays the seamen, and the soldiers.

The captain-general and proveditor are mutually spies over one another: though the proveditor be inferior to the general, yet is the power so divided, that one has authority without strength, the other strength without authority.

PROVEN, or PROVENDE, in *Geography*, a town of France, in the department of the Lys; 9 miles W. of Ypres.

PROVENCA *a Velha*, a town of Portugal, in the province of Beira; five miles N.W. of Idanha à Velha.

PROVENÇAL POETS, in the *History of Literature*, a name given to certain professions of men who sprang up in Provence about the end of the tenth century, comprehending those that were called Troubadours, or Trouverres, Jongleurs, Cantadours, Violars, and Musars, in whom the faculties both of music and poetry seemed to be united. The first of these were so denominated from the art which they professed of inventing or finding out, as well subjects and sentiments as rhymes, constituting what at that time was deemed poetry. The jongleurs are supposed to have taken their name from some musical instrument, on which they played, probably of a name resembling in its sound that by which their profession was distinguished: whence spring the jugglers, *quasi joculariores*, as Menage conjectures, who went about singing their verses in courts and the houses of noblemen, with a viol or harp, or other instrument, and were dressed in a peculiar habit, for the sake of entertaining in a burlesque manner their protectors and patrons. M. de Ravaliere derives jongleur from *ongle*, a nail, whence *ongleur*, a trimmer of instruments with the nails. This etymology, says Dr. Burney (*Hist. Mus.* vol. ii. p. 267.), is probable; as the lyre, cithara, harp, lute, and guitar, the most ancient stringed instruments, have at all times been played with the nails and ends of the fingers. The cantadours, called also chanteres, were singers of songs and ballads, as were also the musari; and the violars were players on the viol.

All these arts were comprehended, in the French language, under the general denomination of menestruadic, menestrandise, and jonglerie.

The Provençal poets were not only the inventors and composers of metrical romances, songs, ballads, and rhymes, to so great a number, and of such a kind, as to raise an emulation in most countries of Europe to imitate them; but,

if we may credit the Italian writers, the best poets of Italy, namely, Petrarch and Dante, owed much of their excellence to their imitation of the Provençals: and it is also said that the greater part of the novels of Boccace are taken from Provençal or ancient French romances. The learned Dr. Percy, in his Essay on the ancient English Minstrels, has given a very curious and satisfactory account of these fathers of modern poetry and music; and although he agrees that the several professions above enumerated were included under the general name of minstrel, he has, in the notes to that Essay, p. 42. with great accuracy assigned to each his distinct and peculiar office. Of the ancient writers of romance, a history is extant in the lives of the Provençal poets, written in French by J. Nostradamus, compiled and published at Lyons in 1575; but a much more satisfactory account of them is contained in the translation of this work into Italian, with many additions, by Gio. Mario de Crescimbeni, and published, in 1710, under the title of "Commentari Intorno all' Istoria della Volgare Poesia." See Hawkins's *Hist. of Music*, vol. ii. p. 44, &c.

PROVENCE, in *Geography*, the name, before the revolution, of one of the richest provinces of France, bounded on the E. by Piedmont, on the S. by the Mediterranean, on the W. by the Venaissin and the Rhône, which separates it from Languedoc. It produces wine, corn, and oil; its capital was Marseilles. It now comprehends the departments of the Var, the Mouths of the Rhône, and the Lower Alps.

PROVEND, or PROVENDER, is properly a sort of vessel containing the measure of grains daily given to a horse, or other beast of labour, for his subsistence.

Some derive the word from the Latin *præbenda*, or *prebend*.

Hence provender is also become a general name for all food of cattle. In monasteries, when the religious go to meals, they are said to go to provend.

PROVENZALE, MARCELLO DA CENTO, in *Biography*, born in 1575, was a disciple of Paolo Rosetti, and became very eminent as a painter of history and portrait. But his superior merit consisted in mosaic, which he executed with uncommon skill.

In the palace of cardinal Borghese, at Rome, there is a portrait of Paul V. in mosaic, by this master. It is wrought in imitation of the mosaic of the ancients; but is such an imitation as excels all that can be seen of the originals. The face alone consists of more than two millions of pieces, many of them being of no larger dimensions than a grain of sand, and it is most deservedly esteemed one of the greatest curiosities of Rome.

The first altar piece in mosaic for the Basilica of St. Peter, was wrought by Giambatista Calandra of Verelli, under the pontificate of Urban VIII. It was a St. Michael, from a design of Cesare d'Arpino: a considerable progress was then already made towards the modern style of art, which since has been carried to a still higher degree by the two Cristofori, Fabio, and T. Paolo his son, who made the mosaics of the St. Petronilla, from the original of Guercino; the Communion of St. Jerome, from Dominichino; and the baptism of Christ, from Maratta. Fuseli's Pilkington.

PROVER, in *Law*, *probator*, an approver, or person who confessing felony, appeals, or accuses another of the same. He is thus called because he must prove what he alleges in his appeal; which proof is either by battle, or by the country, at his election who is appealed.

In 39 Edw. III. coram rege, rot. 97. Suff. a man became an *approver*, and appealed five, who all joined battle with him, and he overcame them all: four of them were accordingly

cordingly hanged, and the fifth pleaded he was a clerk. The prover was pardoned. See APPROVER.

PROVERB, among *Jewellers*, an instrument by which they examine the size and depth of diamonds. It is a spring in shape not unlike a pair of caliber compasses, kept at the proper distance by means of a spring.

PROVERB, *Proverbium*, is defined, by Camden, a concise, witty, and wise speech, grounded upon long experience; and containing, for the most part, some useful caveat.

Such are, *A close mouth catches no flies. A high building, a low foundation. A carrion kite will never be a good hawk. A short horse is soon curried. A man may love his house well, though he ride not on the ridge. A false knave needs no broker. Better to spare at brim, than at bottom, &c.*

The late learned bishop Lowth has furnished us with many excellent remarks on the ancient method of instruction by parables or proverbs. It was adopted in very remote antiquity, by those who, by genius and reflection, exercised in the school of experience, had accumulated a stock of knowledge, and who were desirous of reducing it into the most compendious form, and comprising, in a few maxims, those observations which they apprehended most essential to human happiness. This mode of instruction was peculiarly adapted to a rude stage of society, and more likely to produce effect than any other; for it professed not to dispute, but to command; not to persuade, but to compel; it conducted men not by a circuit of argument, but led them immediately to the approbation and practice of integrity and virtue. In order to render it more pleasing, as well as powerful, the instructors of mankind added to their precepts the graces of harmony, and illuminated them with metaphors, comparisons, allusions, and the other embellishments of style. Among the Hebrews it prevailed much, and continued to the latest ages of their literature; and obtained among them the appellation of "Mashalim" (or Parables,) partly because it consisted of parables, properly so called, (see PARABLE,) and partly because it possessed uncommon force and authority over the minds of the auditors. Solomon, whose book of Proverbs (see the next article) is an admirable specimen of this didactic poetry, has explained the principal excellencies of this form of composition; exhibiting both a complete definition of a parable or proverb, and a very happy instance of what he describes:

"Apples of gold in a net-work of silver,
Is a word seasonably spoken." Prov. xxv. 11.

Thus insinuating, that grave and profound sentiments are to be set off by a smooth and well-turned phraseology, as the appearance of the most beautiful and exquisitely coloured print, or the imitation of it perhaps in the most precious metals, is improved by the circumstance of shining, as through a veil, through the ramifications of a silver vessel exquisitely carved.

The first excellence of a proverb is brevity; without which it can neither retain its name nor nature. The discriminating sentiment should be expressed in few words, or otherwise the sentence that conveys it becomes a declamation or harangue, and can no longer be regarded as a proverb; and thus force itself upon the mind by a single effort; and not by a tedious process. Accordingly, the language must be strong and condensed. Horace insists upon this as one of the express rules of didactic poetry, assigning the reason on which it is founded:

"Short be the precept, which with ease is gain'd
By docile minds, and faithfully retain'd."

Art of Poetry, v. 455.

Solomon expresses the same sentiment in his own, parabolic, manner:

"The words of the wife are like goads,
And like nails that are firmly fix'd." Eccl. xii. 11.

That is, they instantaneously stimulate or affect the mind; they penetrate deeply, and are firmly retained. Even the obscurity that is generally attendant on excessive brevity has its use, in keeping alive the attention, and exercising the genius by the labour of the investigation; and also in the gratification accompanying knowledge, gained in some degree by our own efforts.

Another quality essential to a parable or proverb is elegance, which is inconsistent neither with brevity, nor with some degree of obscurity. Elegance in this connection respects the sentiment, the imagery, and the diction. Those proverbs, which are the plainest, most obvious, and simple, which contain nothing remarkable either in sentiment or style, are not to be accounted as destitute of their peculiar elegance, if they possess only brevity, and that neat, compact form, and roundness of period, which are of themselves sufficient to constitute a parable. See 1 Sam. xxiv. 13. Prov. x. 12.

PROVERBS, in *Scripture History*, is the name of one of the canonical books of the Old Testament, containing a collection of moral sentences and maxims, adapted to the regulation of the conduct in every period and condition of life, and ascribed to Solomon; though some writers, among whom is Grotius, have expressed their doubts, whether Solomon was the author of this book.

This work, which affords a specimen of didactic poetry, belonging to the first rank of this kind of writing, consists of two parts. The first, serving as a proem or exordium, includes the nine first chapters; and is varied, elegant, sublime, and truly poetical; the order of the subject is in general excellently preserved, and the parts are very aptly connected among themselves. It is embellished with many beautiful descriptions and personifications; the diction is polished, and abounds with all the ornaments of poetry; in so much, that it scarcely yields in elegance and splendour to any of the sacred writings. The other part, which extends from the beginning of the tenth chapter to the end of the book, consists almost entirely of detached parables or maxims, which possess little of the sublime or poetical, except a certain energetic and concise turn of expression.

PROVEZENDE, in *Geography*, a town of Portugal, in the province of Tras os Montes; 10 miles N.E. of Lamego.

PROVIDEN, a small island near the N. coast of Ceylon; 28 miles S.S.E. of Trincomaly.

PROVIDENCE, PROVIDENTIA, the conduct and direction of the several parts of the universe, by a superior intelligent Being.

The notion of a providence is very ancient, even in the heathen theology; we find Thales mentions it. It is founded on this supposition, that the Creator has not so fixed and ascertained the laws of nature, nor so connected the chain of second causes, as to leave the world to itself; but that he still preserves the reins in his own hands, and occasionally intervenes, alters, restrains, enforces, suspends, &c. those laws, by a particular providence.

Some use the word providence in a more general sense, signifying by it that power or action by which the several parts of the creation are ordinarily directed.

Thus Damascenus defines providence to be that divine will by which all things are ordered and directed to the proper end. Which notion of providence supposes no laws at all fixed by the Author of nature at the creation; but that

PROVIDENCE.

that he reserved it at large, to be governed by himself occasionally.

The ancients called providence by the names of *fate, fortune, nature, destiny, necessity, &c.*

The ancient Egyptians seem to have been the first who had the notion of a divine providence. Arnobius observes they reasoned thus. "Providence is so essential to a prince, that without it he cannot be, nor even be called, a prince; and the more august a prince is, the more perfect ought his providence to be. Since, then, God is the greatest and most august of all princes, to him must belong the most perfect providence."

The Epicureans deny any divine providence, as thinking it inconsistent with the ease and repose of the divine nature, to meddle at all with human affairs.

Others deny the existence of a providence, from the seemingly unjust distribution of good and evil; which appear to fall indiscriminately on the just and unjust.

Simplicius argues thus for a providence: if God do not look to the affairs of the world, it is either because he cannot, or will not; but the first is absurd, since, to govern cannot be difficult where to create was easy; and the latter is both absurd and blasphemous.

In Plato's 10th Dialogue of Laws, he teaches excellently that (since what is self-moving is, by its nature, *before* that which moves only in consequence of being moved) *mind* must be *prior to matter*, and the cause of all its modifications and changes; and that, therefore, there is an universal mind possessed of all perfection, which produced and which actuates all things — εκ γε των ειρημενων ουδ' οσιον αλλως λεγειν η πασαν αριστην εχουσαν ψυχην περιαιρειν παντα. After this he shews that the Deity exercises a particular providence over the world, taking care of small no less than great things. Ως επιμελεις σμικρων επι θεοι, ουχ ηττου η των μεγαθει διαφεροντων. In proving this he observes, "that a superior nature of such excellence as the Divine, which hears, sees, and knows all things, cannot, in any instance, be subject to negligence or sloth; that the meanest and the greatest parts of the world are all equally his work or possession; that great things cannot be rightly taken care of without taking care of small; and that, in all cases, the more able and perfect any artist is, (as a physician, an architect, or the ruler of the state,) the more his skill and care appear in little as well as great things. Let us not then (says he) conceive of God as worse than even mortal artists." Ουδε γαρ ανευ σμικρων της μεγαλης θασιν οι λιθολογοι λιθους ευ κειθαι — μη τον γε θεοι αξιωσωμεν ποτε θνητων δημιουργων φαυλοτεροι: οι τα προσηκοντα αυτοις εργα οσω περ' αν αμεινους ωσι τοσω ακριβεστερα και τελωτερα μια τεχνη σμικρα και μεγαλα απεργαζονται.

The term providence, in its primary signification, simply denotes *fore-sight*; and if we allow the existence of a Supreme Being who formed the universe at first, we must necessarily allow, that he has a perfect foresight of every event, which, at any time, takes place in the natural or moral world. Matter can have no motion, nor spirit any energy, but what is derived from him; nor can he be ignorant of the effects which they will, either separately or conjointly, produce.

A common mechanic has knowledge of the work of his own hands; when he puts the machine, which he has made, in motion, he foresees how long it will go, and what will be the state and position of its several parts at any particular point of time: or, if he is not perfectly able to do this, it is because he is not perfectly acquainted with all the powers of the materials which he has used in its construction; they are not of his making, and they may therefore have qualities which he does not understand, and consequently

cannot regulate. But in the immense machine of the universe there is nothing except that which God has made; all the power and properties, relations and dependencies, which created things have, they have both in kind and degree from him. Nothing, therefore, it should seem, can come to pass at any time, or in any part of the universe, which its incomprehensible Architect did not, from the moment his Almighty Fiat called it into existence, clearly foresee.

The providence of God is implied in his very existence as an intelligent creator: and it imports not only an abstract foresight of all possible events, but such a predisposition of causes and effects, such an adjustment of means and ends, as seems to us to exclude that contingency of human actions, with which, as expectants of positive rewards and punishments in another world, we firmly believe it to be altogether consistent.

By providence we may understand, not merely foresight, but an uniform and constant operation of God subsequent to the act of creation. Thus, in every machine formed by human ingenuity, there is a necessity for the action of some extraneous power to put the machine in motion; a proper construction and disposition of parts not being sufficient to effect the end: there must be a spring, or a weight, or an impulse of air or water, or some substance or other, on which the motion of the several parts of the machine must depend. In like manner, the machine of the universe depends upon its creator for the commencement and the conservation of the motion of its several parts. The power by which the insensible particles of matter coalesce into sensible lumps, as well as that by which the great orbs of the universe are reluctantly, as it were, retained in their courses, admits not an explanation from mechanical causes: the effects of both of them are different from such as mere matter and motion can produce; they must ultimately be referred to God. Vegetable and animal life, and increase, cannot be accounted for, without recurring to him, as the primary cause of both. In all these respects the providence of God is something more than foresight; it is a continual influence, an universal agency; "by him all things consist—and in him we live, and move, and have our being."

Much labour has been employed to account for all the phenomena of nature by the powers of mechanism, or the necessary laws of matter and motion. But this, as we imagine, cannot be done. The "primary causes" of things must, certainly, be some powers and principles not mechanical; otherwise, we shall be reduced to the necessity of maintaining an endless progression of motions communicated from matter to matter, without any "first mover," or of saying, that the first impelling matter moved itself. The former is an absurdity too great to be embraced by any one; and there is reason to hope, that the essential inactivity of matter is at present so well understood, and so generally allowed, notwithstanding some modern opposers of this hypothesis, that there can be but few who will care to assert the latter. All our reasonings about bodies, and the whole of natural philosophy, are founded on the three laws of motion, laid down by sir Isaac Newton at the beginning of the "Principia." These laws express the plainest truths; but they would have neither evidence nor meaning, were not inactivity contained in our idea of matter. Should it be said, that matter, though naturally inert, may be made to be otherwise by divine power: this would be the same with saying, that matter may be made not to be matter. If inactivity belong to it at all, it must belong to it *as* matter, or solid extension, and therefore must be inseparable from it. Mat-
ter

PROVIDENCE.

ter is figured, moveable, discernible, inactive, and capable of communicating motion by impulse to other matter: these are not *accidental* but *primary* qualities of matter. Besides, matter void of inactivity, if we were to suppose it possible, could produce no effects. The communication of motion, its direction, the resistance it suffers, and its cessation, in a word, the whole doctrine of motion, cannot be consistently explained or clearly understood without supposing the inertia of matter. (See MATTER and RESISTANCE.) Self-moving matter must have thought and design; because, whenever matter moves, it must move in some particular direction, and with some precise degree of velocity; and as there is an infinity of these equally possible, it cannot move itself without selecting one of these preferably to and exclusively of all others, and therefore not without design. Moreover, it may be plainly proved that matter cannot be the *ultimate* cause of the phenomena of nature, or the agent, which, by any powers inherent in itself, produces the general laws of nature, without possessing the highest degree of knowledge and wisdom: which might be easily evinced or exemplified by adverting to the particular law of *Gravitation*; which see. The philosopher, says an excellent writer, who overlooks the laws of an all-governing Deity in nature, contenting himself with the appearance of the material universe only, and the mechanical laws of motion, neglects what is most excellent, and prefers what is imperfect to what is supremely perfect, finitude to infinity, what is narrow and weak, to what is unlimited and almighty, and what is perishing to what endures for ever. (Maclaurin's Account of Sir Isaac Newton's Discoveries, b. iv. c. 9. §. 1.) Sir Isaac Newton thought it most unaccountable to exclude the Deity *only* out of the universe. It appeared to him much more just and reasonable to suppose that the whole chain of causes, or the several series of them, should centre in him as their source; and the whole system appear depending on him the only independent cause. Id. §. 5.

If, then, the Deity pervades and actuates the *material* world, and his unremitting energy is the cause to which every effect in it must be traced; the *spiritual* world, which is of greater consequence, cannot be disregarded by him. Is there not *one atom of matter* on which he does not act; and is there *one living being* about which he has no concern? Does not a *stone fall* without him; and does then a *man suffer* without him? The inanimate world is of *no* consequence abstracted from its subserviency to the animate and reasonable world: the former, therefore, must be preserved and governed entirely with a view to the latter. But it is not mere energy or the constant exertion of power that is discernible in the frame or laws of the universe, in maintaining the succession of men, and in producing men, and other beings; but wisdom and skill are also conspicuous in the structure of every object in the inanimate creation. After a survey of the beauty and elegance of the works of nature, aided by the perusal of Matt. vi. 28, &c. we may ask ourselves, Has God in the *lowest* of his works been *lavish* of wisdom, beauty, and skill, and is he *sparing* of these in the concerns of *reasonable* beings? Or does he less regard order, propriety, and fitness in the determination of their states? The answer is obvious.

Providence also implies a particular interposition of God in administering the affairs of individuals and nations, and wholly distinct from that general and incessant exertion of his power, by which he sustains the universe in existence. Some speculative men, however, conceive it to be very conformable to the nature of the supreme Being, as investigated by sober reasoning, that events deriving their existence

from his immutable will as the primary cause of every thing, should succeed each other in a determinate order; or, in the language of one of the fathers, they held "the will of God to be the necessity of nature." In this providence, or predisposition of all events, they acquiesce with gratitude and confidence; believing that it fully answers the ends of a constant superintendency, accompanied by occasional interposition; that confusion and chance are removed out of the universe; that all things have been, are, and will be working together for the final good of all; and that every particular thing, even what we call a miracle itself, comes to pass in its own proper time, according to a plan established by infinite goodness and wisdom before time was. To this reasoning, though not chargeable with Atheistic fatality, or subversive of all piety, it may be objected, that it renders all supplication unprofitable, (see PRAYER,) the supreme Being inexorable, the human race impeccable, the order of nature immutable, and the future fates of individuals and nations irreversible. Nevertheless, the weight of these objections will not be great in the opinion of those, who either acknowledge no religion but that of nature, or who think that the doctrine of the final happiness of all mankind is not inconsistent with the principles of Christianity.

Many, however, are of opinion, that an original establishment, such as that to which we have now suggested, implies universal fatalism; and that in events happening amongst reasonable agents there must be infinite variations and uncertainties not possible to be regulated by it; and therefore they will think, that the other method of administering providence by interposition and constant influences will be the best adapted for bringing about a perfect regulation of events. Some persons are probably led into mistakes on the subject, by thinking of the manner in which it is most becoming the Deity to act, too strictly in conformity to that in which men are obliged to act. They have but little power, and therefore are obliged to be as frugal of it as possible. But to the Deity there is nothing difficult, and consequently nothing to influence him to choose one way of acting rather than another, besides its being more agreeable to rectitude, and more conducive to his end. The reason why the Deity has chosen to establish a course of nature is, the necessity of it as a means to produce happiness, and to give his reasonable creatures room for a proper exertion of their faculties, and for the practice of virtue. But independently of these observations, it must be very evident, that influences, consistent with the agency of free beings, and uniformly exerted to exclude every event fit to be excluded, and to produce perfect order in the administration of the world, are so far from not becoming the almighty and omnipresent parent, that we can conceive of nothing more worthy of him, or that can make his character appear more amiable. Nor is there any more reason to be prejudiced against them, than against the influence which the constitution of the world allows to every agent over events, in proportion to his power and knowledge. It is reasonable to believe, that his influence over events extends as much farther than that of any other being, and is as much more constant, as the relation in which he stands to beings is nearer, and his power and wisdom greater. Many persons, says the excellent writer of whose observations we are now availing ourselves, who think that there are no constant influences of the Deity in directing events, are ready to acknowledge, and every one who believes that Christianity was proved by miracles, must acknowledge, that there are particular emergencies in which he does interpose in the affairs of the world. Allowing that the Deity has ever once interposed since the original establish-

ment

PROVIDENCE.

ment of things, there will remain no tolerable reason for imagining, that he does not interpose continually, as far as there is any occasion.

The doctrine of providence, as it has been above explained, may be evinced from the consideration of the divine perfections. The first cause of all things must be regarded as a being absolutely perfect; and the idea of absolute perfection comprehends infinite power, wisdom, and goodness: hence we deduce the doctrine of providence. The Deity cannot be an indifferent spectator of the series of events in that world to which he has given being. His goodness will as certainly engage him to direct them agreeably to the ends of goodness, as his wisdom and power enable him to do it in the most effectual manner. This conclusion is conformable to all our ideas of those attributes. Could we call that being good who would refuse to do any good which he is able to do without the least labour or difficulty? God is present every where. He sees all that happens, and it is in his power, with perfect ease, to order all for the best. Can he then possess goodness, and at the same time not do this? A God without a providence is undoubtedly a contradiction. Nothing is plainer than that a being of perfect reason will, in every instance, take such care of the universe as perfect reason requires. That supreme intelligence and love which are present to all things, and from whence all things sprung, must govern all occurrences, and exclude from the constitution of nature all real ill and disorder. These considerations prove what has been called a *particular* in opposition to a *general* providence. We cannot conceive of any reasons that can influence the Deity to exercise *any* providence over the world, which are not likewise reasons for extending it to *all* that happens in the world. As far as it is confined to generals, or overlooks *any* individual, or *any* event, it is incomplete, and therefore unsuitable to the idea of a perfect being.

One common prejudice against this doctrine arises from the apprehension that it is below the dignity of the Deity to watch over, in the manner implied in it, the meanest beings, and all the minutest affairs. To which it may be replied, that a great number of minute affairs, if they are each of them of *some* consequence, make up a sum which is of *great* consequence; and that there is no way of taking care of this sum, without taking care of each particular. This objection, therefore, under the appearance of honouring God, plainly dishonours him. Nothing is absolutely trifling in which the happiness of any individual, even the most insignificant, is at all concerned; nor is it beneath a wise and good being, to interpose in any thing of this kind. To suppose the Deity above this, is to suppose him above acting up to the full extent of goodness and rectitude. The same eternal benevolence that first engaged him to produce beings, must also engage him to exercise a particular providence over them; and the very lowest beings, as well as the highest, seem to have a kind of right to his superintendance, from the act itself of bringing them into existence. Every apprehension that this is too great a condescension in him is founded on the poorest ideas; for, surely, whatever it was not too great condescension in him to *create*, it cannot be too great a condescension in him to *take care of*. Besides, with regard to God, all distinctions in the creation vanish. All beings are *infinitely*, that is *equally*, inferior to him.

Another prejudice by which some minds may be influenced with respect to this subject, arises from the notion, that it must be some trouble to the Deity to superintend and direct all the immense variety of events in the universe. In order to obviate this prejudice, it should be considered that the whole of possibility is alike easy to *infinite* power and

knowledge; and that it is a contradiction to imagine, by transferring human imperfections to the Deity, that they can become incumbered or perplexed.

But the chief and most common objection is that which is deduced from the supposed inconsistency of a particular providence with the liberty of reasonable agents, and the general laws of the world. Some persons, conscious of their inability to reconcile the notion of human agency with that of divine prescience or foresight, have considered men as machines, and denied that they have any agency at all. Others have conceded to the human race freedom of thought and action; but have denied that God can certainly foresee free and contingent actions. (Socini Opera, tom. i. p. 549.) The objection now stated is excellently answered in the "Religion of Nature delineated" (§ 5.), where it is shewn how by secret influences on the minds of men; by the introduction of different characters on the stage of the world at different times, and in proper places; by the ministry of invisible beings, and a suitable adjustment of physical and moral causes and events to one another, it may be possible, consistently with the laws of nature and the liberty of mankind, to direct all occurrences in such a manner, that nothing on the whole unfit to be allowed, or unsuitable to any use, shall come to pass. We may here add, that if we ourselves had a greater acquaintance with the powers of nature, and nearer access to the minds of men, we could easily overrule and direct many events not at present in our power, agreeably to our own purposes, without the least infringement of the general laws of the world, or of the liberty of mankind. But how much easier must it be for that Being to do this absolutely and perfectly, to whom all the powers of nature are subject, who sees through all dependencies and connexions, and has constant access to the heart of every man, and can turn it whithersoever he pleases? Where then can be the difficulty of believing an invisible hand, an universal and ever-attentive providence, which guides all things agreeably to perfect rectitude and wisdom: at the same time that the general laws of the world are left unviolated, and the liberty of moral agents is preserved? Some able writers on this subject have contented themselves with acknowledging that foresight appertains to God, and freedom to man, though they cannot, in any wise, comprehend the possibility of their co-existence. "I own freely to you," says Mr. Locke (Letter to Molyneux), "the weakness of my understanding, that though it be unquestionable that there is omnipotence and omniscience in God, our maker, and I cannot have a clearer perception of any thing than that I am free; yet I cannot make freedom in man consistent with omnipotence and omniscience in God, though I am as fully persuaded of both as of any truths I most firmly assent to. And therefore I have long since given off the consideration of that question, resolving all into this short conclusion; that if it be possible for God to make a free agent, then man is free, though I see not the way of it."

Here we may observe that it would be very difficult, if not impossible, to prove that it is more conformable to the nature of a wise and beneficent Being, to form a system whose parts, material and spiritual, shall all be linked together in a fatal chain, than one which shall admit the contingency of human actions, and consequently seem to require, as a means of its perfection, the interposition of divine agency.

As to the argument against the interposition of God in the government of the world, which is taken from experience, it will impress different minds differently. Those who are acquainted with and believe the history of the Jewish nation, as delivered in the bible, will find no great difficulty in admitting, that what has happened to one people may have happened

happened to another; that God may have governed the other families of the earth, if not in so visible, yet in as effectual a manner as he hath governed that of Judah. They will acknowledge the interposition of God, in what others will esteem the ordinary operation of physical or moral causes; in storms, earthquakes, famines, pestilences, foreign wars, domestic dissensions, peace, prosperity, and, indeed, in every event tending to exalt or depress a nation. But those who are not acquainted with the Jewish history, and others who disbelieve the miraculous part of it, and attribute the singularity of their condition to the operation of their religious polity, will be able to deduce no evidence of God's government of the world from the history of the Jews; and reasoning logically, they will incline to maintain, that it cannot certainly be deduced from the history of any other nation, ancient or modern. Could we, indeed, acquaint ourselves minutely, not merely with the civil or military transactions of particular ages and countries, but with the virtues and vices, the happiness and misery of all ages and all countries, from the beginning of the world; or, in other words, could we obtain a distinct and complete history of the human race, from the commencement of its existence to the present time, we should, without doubt, discern the arm of God clearly displayed in effecting the rise, regulating the progress, and accomplishing the destruction of particular states, in strict conformity to, or deviation from, the rule of moral rectitude. But the limitation of our views, and the momentary period of our existence, do not allow of our comprehending the whole of the divine economy, even in this world; and we should not therefore be surprised, that, as Dr. Clarke observes (*Evid. of Nat. and Rev. Rel.*) there should not in many ages be plain evidences enough either of the wisdom or of the justice and goodness of God, or of so much as the interposition of divine providence at all, to convince mankind clearly and generally of the world's being under his immediate care, and inspection, and government. If, indeed, the experience of the most perfect uniformity in the moral government of the world, could not, for such reasons as we have above stated, certainly enable us to decide concerning the manner of its being administered, whether by occasional interposition, or primæval ordination, we may properly enough conclude, that no argument can be justly drawn against this interposition from the want of such experience, from the real or imagined irregularity of that government. We see but a small part of this government, either as to its extent or its duration. It may be more regular than it appears to us to be; there may be, which is most probable, no irregularity at all in it; but allowing it to subsist, and to be very considerable, it will be impossible for us to determine whether that irregularity proceeds from a want of God's interposition in the government of the world, or from what some might be apt, unwisely enough, to call a defect of power, wisdom, or goodness, in its original constitution. Our faculties are annihilated in the immensity of the divine nature: the eyes of our understanding are blinded by the inaccessible brightness of the Lord's glory; it sheweth in us and around us, adorning with ineffable splendour all his works, not suffering us to doubt, for a moment, concerning either the existence or the skill of the great architect of the universe; but checking our presumption, and baffling all our efforts, when we would explore the nature of his existence, or the mode of his operation. If our reason be inadequate, as it certainly is, to the investigation of the manner in which God administers the affairs of this world, we ought thankfully to embrace the light which revelation affords us in so obscure an enquiry. A single page of that gospel conveys to us more

knowledge concerning the attributes of God and our relation to him than all the volumes of philosophy which unassisted reason ever produced. Open but the bible, and a subject before dark to the human understanding, becomes as clear as the mid-day sun. The whole history contained in the scriptures is one uniform display of the divine superintendence of our affairs. Between the sacred history and other histories there is this striking difference, that whilst the latter seldom go higher than the passions of men and the power of nature for the sources of the events they relate, the former always carries up our thoughts to the *first* cause, and directs our views to God, as the guide and governor of whatever happens. (See *Is. xlv. 7. Amos, iii. 6. Psal. cxlviii. Prov. xvi. 33. Matt. x. 29, 30. Rom. xi. 36.*) The scriptures also afford us a convincing argument for Providence, arising from the completion of the prophecies which they record. See PROPHECY.

From the variety of considerations above suggested, and on which our restricted limits will not allow of our enlarging, we may reasonably infer, that there is a wise and benevolent providence, which extends to all events: and that its interposition and influence are not discernible by us, or distinguishable, in its exertions, from the common operations of natural causes, and the course of our own thoughts, is no more any reason for denying its reality, than it is for denying the real subsistence of our own souls, or the ubiquity of the divine essence, because they are not the immediate objects of sensible observation. In some instances, indeed, the interpositions of the Deity have been open and sensible, but such interpositions are very extraordinary; and to expect them in any common cases would be madness. The delusions of enthusiasm take their rise from hence, and consist chiefly in ascribing particular feelings, without reason, to supernatural suggestion; or in imagining that the directions of God's providence, and his influence on the soul, are capable of being particularly observed. It ought also to be remarked, with respect to the doctrine of providence, that it ought never to be explained in such a manner as to destroy the value of the agency of created beings. For other reflections on the subject of this article, tending to establish the doctrine of providence, to solve difficulties and answer objections against it, and to point out the practical uses to which the acknowledgment of it is subservient, we refer to Clark's *Evidence of Natural and Revealed Religion*; Butler's *Analogy*; Price's *Dissertations*, *diff. i.*; and the Bishop of Llandaff's *Sermons*, *serm. vi.*

PROVIDENCE, in *Mythology*, a divinity among the ancients, whom they commonly represented under the figure of a woman leaning upon a pillar, holding in her left hand the cornucopia, and in the right a baton, which she points to a globe, at once to shew that all goods are derived from her, and that she extends her care over the whole universe. Sometimes she has other symbols, but this manner of representing her was the most common. The ancients, however, believed providence to be an attribute of the gods, as appears by several medals, upon which we read PROVIDENTIA DEORUM.

PROVIDENCE, in *Geography*, one of the Bahama islands, and the second in size, being about thirty miles long and eight broad. Its chief commerce arises from ships driven on its coast, or making a winter's voyage to the continent of America, which put in here in order to obtain a supply of provisions. The provisions are brought hither from Carolina, and laid up in storehouses for this purpose: but the island itself produces little else than salt and Brailette wood, which are carried over to Carolina. The inhabitants sow peas, which are gathered in six weeks, and Indian wheat,

which is productive in twelve weeks. Various kinds of fish are plentiful on the coast, and some parts of the island yield trees and plants in abundance. The principal harbour is dangerous on account of a bar, having only sixteen feet of water. The chief town is Nassau. N. lat. $25^{\circ} 2'$. W. long. $77^{\circ} 20'$.

PROVIDENCE, an uninhabited island on the coast of Honduras, eleven miles long and four broad. It has a fertile soil, salubrious air, and plenty of water, and might be easily fortified, as it was formerly by the Buccaneers. It is separated from the continent by a narrow channel. This island has neither serpents nor venomous reptiles. N. lat. $13^{\circ} 26'$. W. long. $80^{\circ} 45'$.—Also, a small island in the Indian sea. N. lat. $5^{\circ} 6'$. E. long. 78° .—Also, a small island in the Indian sea. S. lat. $9^{\circ} 10'$. E. long. $52^{\circ} 36'$.—Also, a small island in the Pacific ocean. N. lat. $4^{\circ} 2'$. E. long. $127^{\circ} 12'$.

PROVIDENCE, a county of America, in the state of Rhode island, bounded N. and E. by Massachusetts, W. by Connecticut, and S. by Kent county. It contains (1810) 10 townships, and 30,769 inhabitants.—Also, the chief town of the fore-mentioned county, and the third town in New England, in point of population. It was settled in 1636, and is situated at the head of Narraganset bay, about a mile above the mouth of the Pawtucket. It is accessible by ships of any size, which sail up and down the channel, and a bridge, over a narrow part of the bay, connects both sides of the town. The streets in this town are level and well paved. Most of the business is carried on in a street on the E. side of the bay, nearly on a level with the water and parallel to it. The houses W. of the bay are chiefly new and well-built, but most of the elegant and splendid houses are on the other side. W. of the bay are four churches, one French, two Congregational, and one Baptist, and on the other side are three, one Congregational, one Baptist, and one Episcopalian. The three last are some of the handsomest edifices of the kind, in the Union. The town library is deposited in the court-house. The population in 1810 amounted to 10,071 persons. The inhabitants are industrious and enterprising, and their commerce is extensive. Here are two spermaceti works, a number of distilleries and sugar-houses, and several large cotton manufactories. The towns in Connecticut and Massachusetts, bordering on the Rhode island frontier, trade chiefly with Providence. The town is rapidly increasing, and the new buildings are erected chiefly on the W. side of the bay. The Rhode island college is situated in this town. (See COLLEGE.) Providence is 44 miles S. by W. of Boston, and 291 N.E. of Philadelphia. N. lat. $41^{\circ} 49'$. W. long. $71^{\circ} 23'$.—Also, a township of New York, in Saratoga county, taken from Galway, and incorporated in 1796.—Also, a town of Bedford county, in Pennsylvania, containing 1492 inhabitants.—Also, a town of Essex county, in New Jersey; containing 756 inhabitants.—Also, a town of Luzerne county, in Pennsylvania; containing 589 inhabitants.—Also, a river which falls into Narraganset bay on the W. side of Rhode island, navigable as far as Providence for ships of 900 tons, 30 miles from the sea, and affording fine fish, oysters, and lobsters.

PROVIDENCE, *Lower*, a town of Montgomery county, in Pennsylvania; containing 904 inhabitants.

PROVIDENCE, *Nether*, a town of Luzerne county, in Pennsylvania; containing 594 inhabitants.

PROVIDENCE, *North*, a township of Providence county, in Rhode island, situated N. of Providence, and separated from the state of Massachusetts on the E. by Pawtucket river; containing 1758 inhabitants.

PROVIDENCE, *Upper*, a town of Montgomery county, in

Pennsylvania; containing 1395 inhabitants.—Also, a town of Luzerne county, in Pennsylvania; containing 561 inhabitants.

PROVIDENCE, *Great*, a small island in the Pacific ocean, discovered by Dampier in 1699. S. lat. $0^{\circ} 24'$. E. long. $135^{\circ} 53'$.

PROVIDENCE, *Little*, a small island in the Pacific ocean, discovered also by Dampier in 1699. S. lat. $0^{\circ} 11'$. E. long. $135^{\circ} 29'$.

PROVIDENTIÆ, in old *Law Books*, were provisions of meat and drink.

“Providentia vini ante adventum suum in cellaria erat centum deliorum.” Knighton, anno 1354.

PROVIDENTIAL CHANNEL, in *Geography*, a channel between some shoals in the South Pacific ocean, through which the Endeavour passed, near the N.E. coast of New Holland; 40 miles E. of Cape Weymouth.

PROVIDENTIAL *Bank*, a small circular strait near the S.W. coast of New Guinea. S. lat. $5^{\circ} 38'$. E. long. $137^{\circ} 50'$.

PROVINCE, PROVINCIA, among the Romans, was a country conquered by them, without the bounds of Italy; governed by a deputy, or lieutenant, and having peculiar laws and privileges. See LEGATORY.

Nicod derives the word à *procul vivendo*, living afar off; but it is better deduced from *pro* and *vinco*, I overcome. Of these countries that part of France next the Alps was one; and it still retains the name *Provençe*.

PROVINCE is now chiefly used for a canton, or division of a kingdom or commonwealth, comprehending several cities, towns, &c. all under the same government; and usually distinguished by the extent either of the civil or ecclesiastical jurisdiction.

The provinces were anciently duchies, counties, &c. which have been since all reunited under the same chief.

The church distinguishes its provinces by archbishoprics, each containing a certain number of bishoprics.

In this sense England is divided into two provinces, Canterbury and York.

The monks make particular divisions of provinces, according to the antiquity and number of convents in each.

The United Provinces are the seven northern provinces of the Low Countries; which, revolting from the Spanish dominion, made a firm and perpetual alliance, offensive and defensive, at Utrecht, in the year 1579. They have lately undergone several revolutions, and their permanent condition is not yet decided.

PROVINCE, in *Geography*, an island in Delaware river, six miles below Philadelphia; joined to the main land by a dam.

PROVINCE *Town*, a town of America, situated on the hook of Cape Cod, in Barnstable county, Massachusetts, three miles N.W. of Race Point. Its harbour, which is one of the best in the State, opens to the southward, and has depth of water for any ships. This was the first port entered by the English, when they went to settle in New England, in 1620. It has undergone various changes of prosperity and decline. It is now said to be rising, and contains 936 inhabitants, who depend upon the cod fishery, for which they employ about 30 sail, great and small, and in which they are very expert and successful. Their houses are one story high, and set upon piles, that the driving sands may pass under them. Their lands yield nothing, so that they are dependent upon Boston and the neighbouring towns for every vegetable production. Their cows, of which they have about 50, are fed in winter on sedge, cut from the flats, in the spring upon beach grass, growing at intervals

on the shore, and in summer on what they find in the sunken ponds and marshy places that lie between the sand-hills, where they are seen wading, and even swimming, plunging their heads into the water up to their horns, and picking a scanty subsistence from the roots and herbs produced in the waters; 120 miles by land from Bolton. N. lat. 42° 3'. W. long. 70° 9'.

PROVINCIAL, PROVINCIALIS, something relating to a province.

Thus we say, provincial council, or synod, &c. See SYNOD and COUNCIL.

PROVINCIAL Constitutions. See CONSTITUTION.

PROVINCIAL Establishments in America. See the account of CHARTER Governments.

PROVINCIAL, in the monastic sense, denotes a person who has the direction and superintendency of several convents of a province, according to the division established in that order.

The general of the order has several provinces under him; the provincial several priors, abbots, &c.

PROVINE, PROVIN, a branch of a vine laid in the ground to take root.

PROVING of Guns, is an operation performed in order to determine whether they will bear the quantity of powder allotted for this purpose, or whether they are sufficiently strong for service. The rule of the board of ordnance is, that all guns under twenty-four pounders be loaded with a charge of powder, which weighs as much as the shot; *i. e.* a brass twenty-four pounder with 21 lb.; a brass thirty-two pounder with 26 lb. 21 oz.; and a forty-two pounder, with 31 lb. 8 oz.; the iron twenty-four pounder with 18 lb., the thirty-two with 21 lb. 8 oz., and the forty-two pounder with 25 lb. The brass light field-pieces are proved with a quantity of powder that weighs half as much as their shot; except the twenty-four pounder, which is loaded only with ten pounds. See GUN.

In the proof of all forts of small arms, the quantity of powder used is the weight of the ball exactly. For the number of bullets used in proving muskets, carabines, and pistols, see BULLET.

When guns of a new metal, or of a lighter construction, are proved, then, besides the common proof, they are fired two or three hundred times, as quick as possible, loaded with the common charge allowed for actual service. In proving cannon, with a view of ascertaining their being well cast, without any cavities in the metal, and their being fit to resist the effort of their charge of powder, the piece is laid upon the ground, supported only by a log of wood in the middle, of about five or six inches thick, to raise the muzzle a little; and then the piece is fired against a solid butt of earth. The instruments used in the proof of cannon are the searcher and reliever. Lieutenant-general Defaguliers has lately invented a curious instrument for finding the principal defects in pieces of artillery, which is no sooner introduced into the hollow cylinder of the gun than it discovers its defects, and particularly its not being truly bored, to which most of the injuries incident to pieces of artillery are owing. In the proof of mortars and howitzers, they are placed upon the ground, with some part of their trunnions or breech sunk below the surface, and resting on wooden billets at an elevation of about seventy degrees. The mirror is generally the only instrument for discovering the defects in these pieces. In order to use it, the sun must shine; the breech must be placed towards the sun, and the glass over-against the mouth of the piece, and thus the flaws in the bore and chamber are observed. The Prussians prove their battering train and garrison artillery with a

quantity of powder equal to half the weight of the shot, and by firing seventy-five rounds as quick as in real service, *i. e.* two or three rounds in a minute. Their light field-train, from a twelve-pounder or upwards, are proved with a quantity of powder equal to one-third of the weight of the shot, and fired a hundred and fifty rounds, at three or four rounds in a minute. From a twelve-pounder downwards, they are proved with a quantity of powder equal to one-fifth of the shot's weight, and fired three hundred rounds, at five or six rounds each minute, properly sponged and loaded. Their mortars are proved with the chambers full of powder, and the shells loaded. Three rounds are fired as quick as possible. The Dutch prove all their artillery by firing each piece five times; the first two rounds with a quantity of powder equal to two-thirds of the weight of the shot, and the three last rounds with a quantity of powder equal to one-half the weight of the shot. The French method of proof is the same with that of the Dutch. The Portuguese prove their artillery in the following manner.

42 } pounders, { 1st shot 30lb. } then diminishing 2lb. each
32 } 6 rounds { ——— 26lb. } round.
24 } ——— { ——— 18lb. }

12 } pounders, { 1st shot 10lb. } diminishing 1lb. each round.
6 } 6 rounds { ——— 5lb. } ——— ½lb. each round.
8 } ——— { ——— 2½lb. } ——— ¼lb. each round.

They are fired only once every minute. Their mortars are proved by filling the chambers full of powder, a loaded shell, and the mortar rammed full of earth.

PROVING of Gunpowder. See GUNPOWDER, and POWDER-Triers.

PROVING of Wills, in Law. See PROBATE, EXECUTOR, and WILL.

PROVINS, in Geography, a town of France, and principal place of a district, in the department of the Seine and Marne; 11 posts S.E. of Paris. The town contains 5503, and the canton 9747 inhabitants, on a territory of 130 kilometres, in 14 communes. N. lat. 48° 34'. E. long. 30° 21'.

PROVISION, PROVISIO, any thing got or procured, as necessary for the subsistence of life.

Salting of unwholesome provisions is prohibited by 51 Henry III. stat. 6. cap. 7. under pain of amercement for the first offence, pillory for the second, fine and imprisonment for the third, and abjuration of the town for the fourth. And by 12 Car. II. c. 25. § 11. any brewing or adulteration of wine is punished with the forfeiture of 100*l.*, if done by the wholesale merchant; and 40*l.* if done by the vintner or retail trader.

PROVISIONS, *Preservation of*, is an art essential to the existence of a very numerous class of men who reside in situations where they must be furnished with provisions transported from a distance, or so preserved that they can be carried with them, as is the case at sea, and in remote colonies. To others it is of great importance in reserving the produce of fruitful seasons for future supplies.

The modes of preservation which are in use are as follow:

1. By salting either with dry salt, or in salt pickle.
2. By sugar, which is, however, confined to fruits and vegetable matters.
3. By drying up the juices and parts liable to the putrefactive fermentation, as is practised with a variety of herbs, as thyme, mint, balm, &c. and hay.

Drying is sometimes performed on fish and animal substances. The native Americans had a practice of preserving

PROVISIONS.

flesh for many months, by cutting it into slips, and drying it slowly and completely: the Buccaneers of the West Indies imitated this custom, and derived their appellation from this circumstance. Their method is described in our article BUC-CANEERS. The food, thus prepared, may have been considered good by the American savages; but with us a slight salting is usually given to the meat before it is attempted to be dried, and hence our present method of drying does not differ from dry salting, except that the salting is more slight, and the drying more complete than used for hams or bacon, and the flesh must be cut into thin pieces, to render the drying effective.

4. By pickling in vinegar, as for vegetable pickles, and fish, as salmon, mackarel, sprats, &c. Another mode of pickling is in alcohol or spirits; though this is not practised for provisions (except some choice kinds of fruits), on account of the great expence of spirits: the custom of anatomists preserving their preparations in spirits, shews that it will succeed with animal matters.

5. By so packing up the provisions in bottles, or other cases, as to effectually exclude the air, and thus prevent fermentation: there are of this class potted meats, which are covered up in melted suet, fat, or butter.

6. Another mode, discovered in France by M. Apert, has been brought to a high degree of perfection in this country, by Messrs. Donkin, Hall, and Gamble, whose process we shall describe further on.

7. By freezing meat or fish, and packing it in snow or ice, it may be preserved as long as the freezing is continued. This is very extensively practised in some cold countries; and has of late years been successfully employed in the bringing of fresh salmon from the northern Scotch fisheries.

Of all the methods of preserving meat, *salting* is the most universal, mariners being almost exclusively supported upon salted provisions; and to the inhabitants of towns and districts, where provisions are scarce, it offers a valuable supply, by importation, from places where they have abundance: such is the case of Ireland, where a very principal trade is in salted pork and beef, for the supply of the English navy, and its coasting towns. Newfoundland is alike famous for its salted cod-fish, and the Dutch for their herrings.

Meat which is to be dry salted, such as bacon, hams, hung-beef, &c. is first rubbed very effectually with a mixture of salt, bay salt, and saltpetre over every part; for should any of the surface escape, that part would not be preserved; and to avoid this defect, the rubbing must be repeated several times. The meat being kept in leaden pans or casks, will by its juices form a brine with the salt; which is from time to time taken up and poured over the meat repeatedly as it runs down. This is continued for a fortnight or three weeks, according to the size of the pieces of meat, till the salt has pervaded the whole substance. The meat is now removed from the brine, and the salt being rubbed off with dry coarse cloths, it is hung up to dry in a warm place, or in a chimney, if a smoky flavour is desired, as in hams, hung-meat, and red herrings. When properly dried, it will keep for a long time. For further particulars, see HAM, HERRINGS, &c.

Salting in pickle is conducted very nearly in the same manner, except, that after the meat has imbibed the salt, it is packed in casks, and filled up with very strong brine, or salt pickle: indeed, if it is to be kept a long time, as for a sea voyage, it is packed solid with salt. In salting, a mixture of sugar is sometimes used, but this is more for producing a good flavour, than for the preservation.

In salting beef and pork on a large scale for the navy, it is begun immediately after the beast is killed, and before the

meat is cold. The salt used is an equal mixture of bay-salt and saltpetre, pounded together, and prepared by heating in an oven; with this the warm meat is sprinkled over at the rate of about two ounces to the pound, if intended for long keeping; it is then laid by upon shelving boards for twenty-four hours, and a strong pickle drains from it: the salting is now repeated, the pieces are turned over, and then they lie for another twenty-four hours, by which time the salt will be all melted, and have penetrated the meat; it is now drained off, and each piece wiped with a dry coarse cloth. Previous to packing it in the cask, it must be well rubbed with common salt, mixed with sugar, (the salt being made hot in an oven before it is mixed,) and then applied, whilst hot, in the proportion of one-half the weight of the meat, and this will be a sufficient quantity to pack the casks up solid, the interstices between the pieces of meat being filled up, which must be very carefully done, and the coopering effectual, to render the cask tight. The size of the casks should be such, that their contents will be consumed very quickly after opening the cask, as the less the meat is exposed to the air the better. A great deal depends upon the meat being salted whilst it is warm, and with hot or dried salt; probably because its affinity for moisture is increased, and it thus strikes more readily into the meat, to mix with the juices thereof. Pork is treated in the same manner, but a smaller proportion of sugar is used. Meat thus preserved will keep good for the longest voyages, in any climate.

Salted meats are by far less nutritious than fresh, particularly when so highly salted, as is requisite for long keeping at sea. This is the principal cause of the scurvy, which so commonly afflicts seamen. Duhamel, in his "Santé des Marins," says: "The salt meat with which the crews of vessels are fed, is known to be one of the principal causes of the scurvy; it seems that the same causes which operate to prevent the fermentation of meat, also render it difficult of digestion; though a small quantity of salt may be an obstacle in the way of putrefaction, the too abundant and frequent use which is made of it, must cause great obstructions in the smaller vessels of the body; and these obstructions cannot fail to overload the stomach of men who have to digest dry vegetables and biscuits, which sailors advanced in years are not always able to chew completely. Bad digestion and obstruction in the lower vessels, may occasionally give rise to those ulcers in the mouth, and spots which denote the scurvy."

Salt communicates an unpleasent rough flavour to substances preserved by it, hardens the animal fibre, and renders it difficult of digestion: the longer the meat is kept, the more forcibly these objections apply. Another great defect is, that it is necessary to remove it, by washing away great part of the salt employed; and therefore all parts of the meat which are soluble in water, are carried away with the salt. The usual mode of washing practised by the seamen, is to suspend the pieces of meat from the end of the ship's bowsprit, and thus by the waves and the pitching of the ship, it is constantly dipped in the water, and drawn out again till the superfluous salt is washed away, and it becomes fit for cooking. From some experiments which have been communicated to us on the salted beef used in the navy, it appeared that a keg of 56lbs. weight, when it had been a month in pickle, was opened, the bones were separated, and found to weigh 5lbs. 6 oz.; the meat was boiled by steam, and lost 15lbs. 10 oz. in that operation; the produce of meat fit for eating was, therefore, 35lbs., the total loss being 21lbs., or about 40 per cent.

Another barrel, containing 100lbs. of prime mess beef, was opened eight months after it was pickled, and was found

PROVISIONS.

found to weigh 103lbs., having gained 3lbs. from being saturated with the pickle; the bones being cut out, weighed 9lbs. 10oz.; and in boiling it diminished 42lbs. 14oz.; leaving only 47lbs. 8oz.; i.e. that more than half was lost. In a third experiment, a barrel containing 26 pieces of beef, of 8lbs. each, when opened, had gained 5lbs., as it weighed 213lbs.; the bones in this weighed 13lbs. 8oz., and the waste in boiling was 90lbs. 14oz., leaving 103lbs. 10oz. of good meat, after a loss of rather more than half.

The preservation of provisions by sugar is rarely practised in the large way, being chiefly confined to preserving fruits for winter consumption, or for the decoction of plants, when reduced to syrups and essences. The general method is to put the fruit, with a sufficient quantity of sugar, into a vessel, which is placed on the fire, till the sugar, mixing with the juices which exude from the fruit, forms a strong syrup. The same effect will be produced by baking the fruit in a jar containing the sugar: after the heat has caused the syrup to sufficiently penetrate the fruit, it is suffered to cool, and then put close into pots or jars, which are filled up with the syrup, and covered close by paper, and a cover of a skin of bladder or leather is tied over the mouth. The paper which immediately covers the fruit is dipped in brandy, or other spirits, to preserve the surface from becoming mouldy, as it otherwise might do, and taint the whole.

Sugar, from the strength of its own flavour, conceals and destroys all other flavours in a greater or less degree, even that which we wish to preserve the enjoyment of, such as the pleasant acidity of certain fruits. A second inconvenience is this, that a large quantity of sugar is required, in order to preserve a small quantity of some other vegetable matters, and hence the use of it is not only very costly, but even in many cases very pernicious. Thus, the juice of certain plants used in medicine cannot be reduced to a syrup or essence which will keep a long time, but by means of nearly twice the quantity of sugar: it results from this, that those syrups or essences contain much more of the properties of sugar than any other medicinal substance, and frequently the sugar, by counteracting the operation of the medicine, is hurtful to the patient.

Vinegar is used for preserving salmon, and some other kinds of fish; such are generally slightly salted first, and then boiled in the casks, that they may be fit for the table when the casks are opened; they are packed for keeping in barrels, which are filled up with good vinegar, and it is this which preserves them.

Many vegetables, such as cabbages, cucumbers, onions, &c. are preserved by pickling; the former of these is prepared in a very large way for the navy, it being found advantageous for the men, in long voyages, to use both vinegar, and vegetable food, to prevent scurvy: they call it *four kroust*. The largest and finest cabbages are used; they are cut up and salted some time in strong brine, then packed in the casks, and filled up with vinegar which has been boiled with some spice, and is poured hot upon the cabbage. It requires no cooking when opened.

Potted meats are generally cooked and minced very fine before they are put up: this is done in jars, which being well filled, are then covered up by butter poured over the meat while in a melted state; this preserves the meat, by preventing the access of air. Mutton suet melted, and poured upon the meat, is still better, if it is to be kept long, or in a warm climate, as the butter then becomes too fluid. Whole joints, enveloped in this substance, may be kept in the West Indies, but not for a sufficient length of time to

render it an effective method: the suet should be made from the fat of a sheep's kidney.

By Messrs. Donkin and Co's method, the meat or vegetable to be preserved is first partially cooked, by boiling, baking, roasting, or otherwise, and then enclosed in canisters, or cases of metal, or in bottles of glass or glazed stone ware, which are very carefully closed, with every attention, to render them perfectly air-tight. In this state the cases or bottles are subjected to a second boiling, which is sufficient to complete the cooking. This boiling completely deprives that small quantity of air which is contained in the vessel of its oxygen, and consequently of its fermentation, and if the vessel is sound, the contents will remain unchanged for the longest periods of time which can ever be required. Nor do they become any worse for longer keeping, as salt provisions do by undergoing a progressive decomposition and change for the worse, and imbibing a greater quantity of salt, till at length they are not eatable. After the boiling of the vessels, a considerable diminution in the bulk of the contained air is found to take place, which is shewn by the sides of the vessel (when made of a yielding substance, such as tinned plate) becoming concave on the outside, from the pressure of the atmosphere: from this circumstance, the atmospheric air has always a tendency to enter the vessel, and therefore the most minute leak will spoil the provisions. To render the vessels tight is the great difficulty in the process, and in this the English patentees have perfectly succeeded.

M. Apert, in France, was rewarded by the French government in 1810, and published an account of his process, which has since been translated into English. In this he observes, that his method consists in inclosing the substances to be preserved in bottles, and corking them with the utmost care, for it is chiefly on the corking that the success of the process depends.

These inclosed substances are boiled in a water-bath for a greater or less length of time, according to their nature, and are then withdrawn from the bath. M. Apert describes his laboratory to consist of four apartments, the first a kitchen, furnished with stoves, and all the utensils necessary for cooking the animal substances which are to be preserved; the second is a dairy, and appropriated to the preparation of milk, cream, and whey; the third apartment is used for corking the bottles, and tying the corks down with wires, also inclosing the bottles in bags, to preserve their contents in the event of their breaking during the boiling; the fourth apartment is for the boiling; it contains three large but shallow copper boilers, placed upon stoves, raised on brick-work. These boilers are each furnished with a stout lid, fitted to rest upon the vessels within; and each boiler is furnished with a large cock below, to let out the water at a proper time. These large boilers are destined to receive the bottles or vessels containing the objects intended to be preserved, in order to apply the action of heat to them in a suitable manner, and thus they constitute so many water-baths. The reason why it is necessary that the boilers should be furnished with cocks is, that it would take up too much time to leave so large a body of water over a heated stove till it became cool; and that, on the other hand, it would do great injury to the substances to let them remain too long exposed to the heat.

The principle by which all substances of food are preserved and kept fresh is invariable in its effects; but the result in particular cases will depend upon the fitness of each individual application of the principle to the substance which is to be preserved, attention being paid to its peculiar qualities. In every case the exclusion of air is a precaution

PROVISIONS.

of the utmost importance to the success of the operation; and a perfect knowledge of bottles, or other vessels to be used, of corks and corking, is requisite. Glass is to be preferred, as being the matter most impenetrable by air; and M. Apert has not ventured to make any experiment with a vessel made of any other substance. The necks of ordinary bottles are generally too small; they are also ill made, and too weak to resist either the blows from the bat which drives the corks, or the action of the fire. He therefore caused bottles to be made with a rim or ring projecting within the interior surface of the neck, placed below, and resembling the form of the rim which is at the top of the exterior surface of the necks of ordinary bottles. The object of this was, that when the cork had been driven into the neck of the bottle three-fourths of its length, it should be compressed in the middle. In this manner the bottle becomes perfectly corked on the outside as well as within: the cork then opposes an obstacle to the swelling or expansion, which arises from the operation of heat upon the substances inclosed within the bottle. This mode of forming the neck of the bottle is the more indispensable, as the swelling will sometimes be so strong as to push out corks of three or four lines in length, though confined by two iron wires crossed. The bottles and vessels should be made of a tough substance; and the glass ought to be of equal thickness in every part, or it is liable to break in the water-bath. Too much attention cannot be given to the good quality of the corks, which should be of eighteen or twenty lines in length, and of the finest quality: they should be compressed by biting the cork three-fourths of its length, by means of an instrument already described in our article CORK, beginning at the small end. The cork is by this operation made more supple, its pores are brought closer, it is somewhat lengthened, and its thickness is so much diminished at the extremity which is put into the mouth of the bottle, that a large cork may be made to enter a very moderate opening. The action of the heat within the vessel causes the cork to swell within, and the corking is thus rendered perfect. Before corking, care should be taken that those bottles containing liquor are filled only within three inches of the outer rim, lest they should burst, from the expansion occasioned by the application of heat to their contents. When the bottles contain vegetables, fruits, &c. they may be filled up to within two inches of the rim. The bottles are corked by driving the corks down with a bat or mallet, and being thus well stopped, the corks are fastened down with a couple of iron wires crossed over the cork, and twisted round the neck of the bottle: each bottle is then inclosed in a bag of canvas, or coarse linen cloth, made for the purpose, sufficiently large to inclose the whole of the bottle up to its neck. These bags are made in the shape of a muff, open at both ends; one of these ends is drawn with a string, leaving an opening of about the width of a crown-piece; the other end is provided with a couple of small strings to tie the bag close round the neck of the bottle.

For preserving solid and bulky substances, such as poultry, game, meat, fish, &c. M. Apert employs glass jars, which have necks of two, three, or four inches diameter, and are of a larger or smaller size, according to the article they are to contain; they are furnished, like the bottles, with a projecting rim, not only to strengthen the neck, but also for receiving the iron wires which are to bind the corks: but he observes, that to cork up these vessels completely, is rendered more difficult, and demands especial care, from the large size of the mouth or neck, and the thinness of the cork, also from the ascending

pores of the cork being against the grain of the bark; he therefore formed stoppers of three or four pieces of cork, from twenty to twenty-four lines in length, cemented together the proper way of the grain, the pores of the cork being placed horizontally: he joined the pieces by means of isinglass.

Having driven the stopper into the jar by means of the bat, he makes use of a compound luting, which is lime slaked in the air, by being sprinkled with water till it becomes reduced to a powder. This lime, mixed with cheese made of skimmed milk (*fromage à la pie*), and formed to the thickness of paste, produces a luting, which hardens rapidly, and which withstands the heat of boiling water; he covers the whole of the outside of the stopper with this luting, and covers the edge of the jar with hemp and strips of linen, placed above, close to the stopper, and hanging down to the rim. The bottles, or jars, being thus prepared, are placed upright in the boiler, or water-bath, which is filled with cold water up to the necks of the vessels; then closing the boiler with its lid, which is made to rest upon the vessels, the upper part of the lid is covered with a piece of wet linen, in order that the sides of the lid may exactly fit, and all evaporation from the water-bath be impeded as much as possible.

The fire being lighted, when the water-bath begins to boil, care must be taken to maintain the same degree of heat during the greater or less length of time required by the substances exposed to its influence, and then the fire put out as quickly as possible.

A quarter of an hour after the fire has been extinguished, the water is let out of the bath by means of the cock, and half an hour afterwards the boiler is opened; but the bottles are not moved till one or two hours after the uncovering, and this terminates the operations.

The utmost attention to cleanliness in all the utensils employed for the preparation of the substances to be preserved, is absolutely indispensable.

The author gives detailed instructions for the preparation of all kinds of provisions; as meat, game, soup, gravy, jelly, eggs, milk, whey, vegetables of all kinds, &c.; but as the directions do not give any farther insight as to the principle, we shall conclude this account with the periods which he advises for boiling in the water-bath. Thus, for preserving boiled meat, the bones are taken out, and the meat half cooked; then inclosed in the jars, which are filled up with the broth or gravy of the meat, corked, luted, and tied up in the bags; the jars are after this boiled in the water-bath for one hour. Meat prepared in this way was found perfectly fresh at the end of a year and a half.

Nutritious gravy, for the use of sick soldiers and sailors, was put up in bottles, and boiled in the bath two hours.

Jelly, which has a previous cooking for a considerable time, requires only a quarter of an hour boiling in the bottles to preserve it.

Round of beef, mutton, fowls, and young partridges, are dressed as if for common use, but only three-fourths done, then packed up and boiled half an hour; the same for eels, carp, pike, &c. These have been sent to sea for four months, and returned perfectly fresh, without the least change.

These results prove sufficiently that the preserving principle, applied with the same preparatory process, and with equal care and precaution, will in general preserve all animal productions. But it is to be observed, that in the previous cooking of each article, it is to be only three-fourths dressed at most, in order that the remainder of
the

PROVISIONS.

the requisite cooking may be communicated by the heat of the water-bath.

There is a number of articles which can bear an additional hour of boiling in the water-bath, without any danger, such as broth, gravy, jellies, and the essences of meat, poultry, and ham, the juice of the grape, and of plants, &c. But there are also others which will sustain a great injury from a quarter of an hour, or even a minute too much boiling: thus the result will always depend upon the dexterity, intelligence, and judgment of the operator.

Meat which has, in the preparatory dressing, as well as the boiling it received in the water-bath, obtained its due quantity of cooking, will, when it is taken out to be used, require only to be properly warmed, in order to produce both soup and meat; likewise poultry, game, and fish, which have received three-fourths of their dressing in the preparatory process, and the remainder in the water-bath, as already pointed out, may, when taken out of the vessels, be heated to the proper degree, in order to be instantly served at table. If, for instance, the substance taken from the bottle, or jar, had not received either enough previous dressing, or enough heat from the water-bath, it is immediately put on the fire to supply what is deficient. Consequently, when the operator has taken due care in making his preparations, having properly seasoned and dressed the provisions, the use to be made of them afterwards will, at all events, be easy and convenient, for they will need only to be warmed; or they may, if necessary, be eaten cold.

Substances thus prepared and preserved do not, as might be imagined, require to be consumed as soon as they are opened. Provisions may be used from a vessel eight or ten days after they have been uncorked, care being taken only to replace the cork as soon as the necessary part of the provision has been taken out. Besides, it is easy to regulate the size of the vessels according to the rapidity of the expected consumption.

New laid eggs are to be put up in a jar, and packed with raspings of bread, to prevent their breaking; the jars are then boiled in the water-bath, heated to 200° : they were preserved six months by this process. Milk is to be boiled in an open pan, placed in the water-bath, till it is reduced to one-half its quantity, frequently skimming it, and half an hour before it is taken out of the bath it is to have the yolks of eight new eggs added to a quantity of about 15 pints of the concentrated milk; which being put into bottles, they are to be boiled in the water-bath for two hours. Cream, condensed by boiling to four-fifths of its quantity, and then boiled in the bottles for one hour, was so effectually preserved for two years, that it was made into butter at the end of that period.

For vegetables it is observed that the difference of climate renders the productions of different countries more or less early, and varies their qualities, kinds, and denominations; attention must, therefore, be given by the operator to the circumstances of the spot in which he resides.

At Paris and its environs, June and July are the best months for preserving green peas, small Windsor beans, and asparagus. At a later period, these vegetables suffer greatly from heat and dryness. In August and September, artichokes, French beans, and cauliflowers may be preserved.

In general, all vegetables intended to be preserved should be used as recently gathered as possible, and prepared with the utmost rapidity, so that there should be, as it were, but one step from the garden-bed to the water-bath.

Green peas are recommended to be taken when in a middling state of growth, and the larger being separated from the rest, they are bottled without previous boiling, and

boiled in the water-bath an hour and a half, if the weather is cool and moist, or two hours in dry hot weather: the large peas are boiled by themselves for two hours, or two hours and a half, under similar circumstances.

Asparagus, instead of previous boiling, is merely dipped into boiling water, then put heads downwards into the bottles, which are only suffered to remain in the water-bath until the water boils.

Windsor beans are bottled, and, without previous boiling, are boiled one hour in the water-bath; or if the skins of the beans have been first taken off, they are boiled one hour and a half.

Cauliflowers have their useless leaves taken off, and are plunged into boiling water, and then immediately into cold water, and being well drained, are closed up in jars, which are boiled for half an hour in the water-bath.

As the seasons vary, and are sometimes dry, and sometimes moist, it is obvious that it is necessary to study, and adapt the various degrees of heat required according to the season. Attention to this circumstance must never be disregarded. For instance, in a cool and damp year, vegetables are more tender, and consequently more sensible to the action of fire. In this case the water-bath should be made to boil seven or eight minutes less; and in dry seasons, when vegetables are firmer and better able to support the action of fire, seven or eight minutes more boiling should be added to the time specified.

The first notice of this important discovery in England was by a patent taken out in 1810, by Mr. Durand, who received the communication from France; the patent-right has since been transferred to Messrs. Donkin, Hall, and Gamble, who have established a considerable manufactory in Blue Anchor road, Bermondsey, which they permitted us to inspect. Their kitchen for cooking, and larder for cooling the meat before it is packed up, are very complete, and they have considerably improved upon the French mode above-described, by substituting, in most cases, canisters of tinned iron for the glass jars and bottles; they are made by very carefully soldering up the tin plates to form circular or oval boxes, of dimensions suited to what they are intended to contain; and these, when filled with the prepared meat, have lids soldered down upon them very closely: they are then boiled in the water-bath, but do not require that precaution of gradually heating and gradually cooling, which must be observed with glass vessels, which would otherwise be subject to break. The canisters may be put into the bath when the water is boiling, and taken out when finished, another set being put in, so as to keep constantly going. Immediately the canisters are withdrawn, they are carefully examined, to discover and stop the leaks, and the boxes are then well varnished, to prevent rust. Another great advantage arises from the use of tin canisters, *viz.* that they will, in the course of a fortnight's trial, afford a criterion to judge of the process being effectually performed; for as the vessel cools after the operation of the water-bath, the lid and bottom of the canisters become concave; and their remaining so, infallibly indicates that their contents will keep fresh; but if fermentation takes place, gases will continue to be generated until the top and bottom become convex, which circumstance denotes the contents to be spoiled. After every precaution has been taken to render the closure of the canisters perfect, they are ticketed, to explain their contents, weight, and the date of preparation, and are hung up in a room, heated to that temperature which is found most conducive to fermentation, if any can be generated: here they remain from three weeks to a month, and if their sides continue concave, they are

are then considered as being fit to send out. This criterion of perfect preservation is obtained by the English patentees, which was not the case with M. Apert, who describes no method of trial, except an examination of the glass bottles after the boiling, to find if they had any stars or flaws, or faults in the corks, which could admit the air. Indeed the tin canisters are more likely to be tight than the glass vessels, from the circumstance that they admit of being more nearly filled up with the meat or gravy; because the expansion which takes place in the boiling, is in some degree permitted by the sides, top, and bottom of the canisters becoming convex. In the subsequent cooling also, the yielding of the sides to a concave form relieves the pressure of the atmosphere; whereas, in a bottle which cannot yield, there is always a partial vacuum or rarefaction within the vessel, and the atmospheric air presses to enter at the most minute leak in the cork, with much more force than on the tin vessel, in which the elasticity of the tin plates to assume their plane surfaces, is the only force to cause the air to enter into the vessel.

For milk, soups, peas, and other similar articles, the patentees employ bottles, but have found reason to prefer a strong kind of earthen-ware, well glazed, to glass, as being less expensive and hazardous, either in the preparation or in carriage.

We have been thus particular in the details of this process, as we consider it an object of great importance to the health and comfort of seamen, a class of men to whom this country is so greatly indebted for its present affluence, that no pains should be spared to render their condition as comfortable as possible. The obvious advantages of the discovery are, that provisions so preserved will entirely supersede the necessity of taking out live stock to sea, which, exclusive of its own incumbrance in a ship, must be accompanied with that of its provender and fresh water. Much room, trouble, and expence will be saved, besides the loss sustained by bad weather, disease, and the wasting of the animals, which always takes place in a voyage. Being ready dressed, such meat may be eaten cold, or, if preferred, heated in a few minutes, by which fuel will be saved, and the difficulty of cooking at sea in bad weather rendered of little importance. They are well calculated for all expeditions of boats' crews, landing-parties, &c.

The salutary effects which the army and navy would derive from even an occasional supply of fresh provisions, cannot be too highly appreciated, as it would most essentially contribute to the restoration of the health and services of the sick and wounded, and eventually save to the state the valuable lives of many of our sailors and soldiers.

PROVISION, in *Traffic*, is sometimes used for the wages due to a factor. See FACTORAGE.

PROVISIONS, *Commissary of*. See COMMISSARY.

PROVISIONS, *Park of*. See PARK.

PROVISION, in the *Canon Law*, the title or instrument, by virtue of which an incumbent holds, or is provided of, a benefice, bishopric, or the like.

Ordinary collators give provision in case of vacancy by death, pure and simple demission, and permutation. See COLLATION.

The court of Rome grants provisions by resignation, devolution, and prevention.

PROVISIONS by *Prevention*, are also called *gratie expectativa*, and *mandata de providendo*; of the great abuse of which throughout England, frequent complaint was made in our ancient statutes, and a remedy was provided for the same by the statutes of premunire. See EXPECTATIVE *Graces*.

Provisions of small benefices, in the court of Rome, are

only simple signatures, which are, as it were, minutes of the bull; because the bulls themselves, dispatched on parchment, would be too expensive. The signature is no more than the petition of the impetrant answered by the pope in these words: "Concessum uti petitur in presentia D. N. papæ," wrote in the hand of the prelate who presides over the signatures.

Extraordinary provisions are signed by the pope himself in these words, "Fiat ut petitur," with the first letter of his name.

PROVISO, in *Law*, a condition inserted in a deed, upon the observance of which the validity of the deed depends.

PROVISO, in *Judicial Matters*, is where the plaintiff desists from prosecuting an action, by bringing it to trial in a due time; in which case the defendant may take out a venire facias to the sheriff, having it in these words: *Proviso quod*, &c. to the end that, if the plaintiff take out any writ to that purpose, the sheriff shall summon but one jury upon them both. In which case it is called *going to trial by proviso*. See JURY.

But this practice hath begun to be disused, since the statute 14 Geo. II. c. 17, which enacts, that if, after issue joined, the cause is not carried down to be tried according to the course of the court, the plaintiff shall be esteemed to be non-suited, and judgment shall be given for the defendant as in case of a non-suit. In case the plaintiff intends to try the cause, he is bound to give the defendant (if he lives within forty miles of London) eight days notice of trial; and if he lives at a greater distance, then fourteen days notice, in order to prevent surprise: and if the plaintiff then changes his mind, and does not countermand the notice six days before the trial, he shall be liable to pay the costs to the defendant for not proceeding to trial, by the same last-mentioned statute. The defendant, however, or plaintiff, may, upon good cause shewn to the court above, as upon absence or sickness of a material witness, obtain leave upon motion to defer the trial of the cause till the next assizes.

PROVISO, *Casu*. See CASU.

PROVISO is also a sea term. A ship is said to moor a proviso, when she has an anchor out, and also a hawser ashore; and so is moored with her head to the shore with two cables at least.

PROVISOR is generally taken for him who hath the care of providing things necessary; in which sense it coincides with purveyor.

PROVISOR *Monasterii* is used for the steward or treasurer of a religious house.

PROVISOR, in our *Statutes*, also denotes a person who sued to the court of Rome for a provision, or expectative grace. See PREMUNIRE.

"Provisores dicuntur, qui vel episcopatum, vel ecclesiasticam aliam dignitatem in Romana curia sibi ambiebant de futuro, quod ex gratia expectativa nuncuparunt, quia, usque dum vacaret, expectandum esset." Spelm.

PROVISORS, *Statutes against*. See PREMUNIRE.

PROULACH, in *Geography*, a town of the duchy of Carinthia; 11 miles S.W. of Clagenfurt.

PROVOCATIVE, in *Physic*, a medicine which strengthens nature, and stimulates or incites to venery. Such are cantharides, satyrion, &c.

PROVOCATOIRES, in *Antiquity*, a class of gladiators, supposed by Lipsius to be generally matched with the Samnites.

PROVOST, PRÆPOSITUS, an officer, of whom there are divers kinds; civil, military, &c.

PROVOST of the City, or of the Merchants, is the chief municipal magistrate in several considerable trading cities; particularly Edinburgh, Paris, and Lyons; much the same with the mayor in other places.

The provost presides at the city courts, and, together with the sheriffs, or bailiffs, decides all differences relating to trade and merchandize: he takes cognizance of the affairs of officers of policy of the city, with regard to their functions; of the delinquencies of merchants, commissioners, and factors; inspects the ports, rivers, duties, imposts, &c.

Authors attribute the institution of provost of the merchants of Paris to Philip Auguste. Du Haillan refers its epocha to the year 1190.

The provost of Edinburgh has the title of *lord*; the bailiffs are his deputies. He calls conventions of the boroughs by his own missives.

PROVOST, or Prevot Royal, also denotes a sort of inferior judge established throughout France, for the taking cognizance of all civil, personal, real, and mixt causes, among the people; but without any jurisdiction in the causes of nobles.

These, in the Bourbonnois, Auvergne, &c. are called *chatelains*; in Normandy, *vicomptes*; in Languedoc and Provence, *viguiers*.

Grand PROVOST of France, or of the Household, an officer who, in the old regime, had jurisdiction in the king's house, and over the officers in it; he looks to the policy and regulation of it, the rates of provisions following the court, &c. He was anciently called *roi des ribauds*.

Grand PROVOST of the Constable, a judge of the sword, who managed processes against the soldiers in the army, who had committed any crime.

He had four lieutenants, distributed throughout the armies, called *provosts of the army*; and particularly *provosts* in the several regiments.

PROVOST Guard. See **GUARD**.

PROVOST-Marshal of an Army, is an officer appointed to seize and secure deserters, marauders, soldiers straggling beyond the limits of the camp, and all other criminals.

The provost-marshal is to go often abroad round the army to hinder the soldiers from pillaging. It is his office to indict offenders, and to see the sentence passed upon them executed.

He likewise regulates the weights and measures, and the price of all provisions, &c. in the army, when in the field. For the discharge of his office, he has a lieutenant, a clerk, and a troop of provosts of marshals men on horseback; a serjeant's guard, and sometimes a subaltern's guard; as also an executioner. The provost-marshal, or chief provost of the army, seems to have been formerly an office of much greater rank and authority than it is now. At present, the office of provost-marshal is executed by the adjutant, whose duty it is to see all sentences of regimental courts marshal inflicted.

There is also a provost-marshal in the navy, who hath charge of the prisoners taken at sea.

The French have a *provost-general of the marines*, who is to prosecute the marines when guilty of any crime, and to make report of it to the council of war; besides a *marine provost* in every vessel, who is a kind of gaoler, and takes the prisoners into his care, and keeps the vessel clean.

PROVOSTS of the Marshals are a kind of lieutenants of the marshals of France, established for the security of the country against rogues, vagabonds, and deserters.

They take cognizance of royal causes; which, for this reason, are called *prevotal causes*. Such are all crimes com-

mitted by strollers, or people without any fixed abode; robberies on the highway, infraction of safeguard, burnings, &c. They pronounce *en dernier ressort*, or without appeal.

There are a hundred and eighty seats of these provosts in France; their chief jurisdiction regards highwaymen, footpads, housebreakers, &c. They correspond to the officers established by Augustus and Tiberius, called, as Cujas tells us, *latrunculatores*, to shew that their office was to pursue thieves.

PROVOST of the Mint is a particular judge instituted for the apprehending and prosecuting false coiners.

PROW, PRORA, in *Navigation*, denotes the head or fore-part of a ship; being that which is opposite to the poop or stern.

In front of it is the beak that cuts the water to make way for the vessel.

The prow is lower than the poop, and contains fewer stories or decks. On the beak is usually some figure or hieroglyphic, which often gives name to the vessel.

PROW, in strictness, is only that part of the fore-castle which is aloof, and not in the hold; particularly that part between the chafe and the loof.

The ancients represented beaks of birds in the prows of their ships, whence they were called *rostra*.

Prow is also a name given by seamen to the beak or pointed cut-water of a polacre, xebec, or galley. The upper part of the prow in those vessels is usually furnished with a grating platform for the convenience of the seamen, who walk out to perform whatever is necessary about the sails or rigging, or the bowsprit.

PROX, in *Natural History*, a name given by Aristotle to the *cervus platyceros*, or broad horned stag.

PROXENETA, or PROXENETES, a kind of broker or agent, who transacts between two persons. See **BROKER**, and **AGENT**.

The word is Greek, *προξενητης*, *q. d. conciliator* or *pararius, reconciler* or *mediator*. The Latins give them a more honourable appellation, calling them *interpreters*.

The term *proxeneta* is chiefly applied to those who negotiate offices, marriages, &c.

The Roman law grants the *proxenetæ* an action for recovery of their hire or wages.

These made a kind of office or college in Rome: to them the fathers addressed themselves, to sound and examine the inclinations of the young men they intended for their daughters. A commentator on the Digest accounts it a great defect in the modern policy, that there are not now any of these *proxenetæ*, or match-makers, established by public authority.

PROXIMITY, PROXIMITAS, denotes the relation or nearness either in respect of place, blood, or alliance.

PROXY, PROCURATOR, a deputy, or person who officiates in the room of another.

Princes are usually married by proxies, or representatives.

Peers are allowed to give their votes by proxies.

PROXY, Procuracy, among *Civilians*, also denotes a commission given to a proctor, by a client, to manage a cause in his behalf.

PROYART, in *Geography*, a town of France, in the department of the Somme; 10 miles W.S.W. of Péronne.

PRASN, or PRASN, a town of the duchy of Warfaw; 48 miles N. of Warfaw.

PRUAT. See **PROVAT**.

PRUCK, a town of the duchy of Stiria, on the left bank of the Muehr; 20 miles N.N.W. of Gratz. N. lat. 47° 27', E. long. 15° 8'.

PRUCK. See BRUCK.

PRUCREOS, a cape on the coast of New Spain, in the South sea.

PRUDENCE, in *Ethics*, may be defined an ability of judging what is best, in the choice both of ends and means. According to the definition of the Roman moralist, (*De Officiis*, lib. i. cap. 43.) prudence is the knowledge of what is to be desired or avoided. Accordingly, he makes *prudencia* (*De Legibus*, lib. i.) to be a contraction of *providentia*, or foresight. Plato (*De Legibus*, lib. iii.) calls this the leading virtue; and Juvenal, *Sat. x.* observes,

“Nullum numen abest si sit prudentia.”

The idea of prudence includes *εὐβουλία*, or due consultation, that is, concerning such things as demand consultation, in a right manner, and for a competent time, that the resolution taken up may be neither too precipitate nor too slow; and *συνεσις*, or a faculty of discerning proper means when they occur; and to the perfection of prudence, these three things are farther required, *viz.* *δαιμονία*, or natural sagacity; *αγχινοα*, presence of mind, or a ready turn of thought; and *αμπνηρία*, or experience. The extremes of prudence are craft or cunning on the one hand, which is the pursuit of an ill end by direct and proper though not honest means; and folly on the other, which is either a mistake, both as to the end and means, or prosecuting a good end by foreign and improper means. *Grove's Moral Philosophy*, vol. ii. chap. 2.

PRUDENCE, in *Geography*, a small island, lying N. of Canonicut in Narraganset bay, and belonging to the town of Portsmouth, in Newport county, Rhode island.

PRUDENTIUS, AURELIUS, in *Biography*, surnamed Clemens, a Latin poet of the fourth century, was born in Spain, probably at Saragossa, about the year 348. He was brought up to the bar, and became chief magistrate in two considerable cities. He also served in the army, and obtained honourable employment at the court of Honorius. This is all that is known of his personal history. He was a zealous Christian, and his poetical talents were devoted to the service of his religion. His compositions are chiefly valuable as documents of Christian antiquity, for their defects of style and versification exclude them from the list of classics even of a low order. They consist of “*Psycho-machia*,” or the soul's combat: “*Cathemerinon*,” or hymns for festivals: “*Apotheosis*,” or on the Deity, against heretics, &c. Of the editions of Prudentius, some of the best are those of Heinsius, *Lug. Bat.* 2 vols. 12mo. 1667; and the Delphin 1687.

PRUDENZA, Ital. in *Music*, a term of caution at the beginning of a difficult movement, lest in playing it at sight, a performer should begin more rapidly than he shall be able to sustain. *Con prudenza*, therefore, points out the danger. *Al suo commodo* is of the same import.

PRUINA, in *Physiology*. See HOAR FROST.

PRUM, in *Geography*, a town of France, and principal place of a district, in the department of the Sarre; 24 miles N. of Treves. The place contains 1072, and the canton 4699 inhabitants, in 42 communes.—Also, a river of France, which rises about four miles from the town of Prum, and runs into the Sour, eight miles N.W. of Treves.

PRUMBACH, a town of Bohemia, in the circle of Saatz; eight miles N. of Eger.

PRUNAY, a town of France, in the department of the Aube; 12 miles N.W. of Troyes.

PRUNE-TREE, in *Botany*. See PRUNUS.

PRUNE, *Willd.* See SLOE.

PRUNELLA, in *Botany*, a barbarous name softened down by Linnæus from *Brunella* of some authors, and so

called from the German *die Breune*, a disorder in the jaws and throat, which this plant is said to cure. Its English name *Self-heal* is of uncertain origin.—*Linn. Gen.* 301. *Schreb.* 397. *Willd. Sp. Pl.* v. 3. 176. *Mart. Mill Dict.* v. 3. *Sm. Fl. Brit.* 646. *Ait. Hort. Kew.* v. 3. 429. *Pursh.* v. 2. 402. *Brown Prodr.* 507. (*Brunella*; *Tournef. t.* 84. *Juss.* 116. *Lamarck Dict.* v. 1. 472. *Illustr. t.* 516.)—Class and order, *Didynamia Gymnospermia*. *Nat. Ord. Verticillata*, *Linn. Labiata*, *Juss.*

Gen. Ch. *Cal.* Perianth inferior, of one leaf, two-lipped, shorter than the throat, permanent; upper lip flat, rather wide, truncated, slightly three-toothed; lower lip erect, narrower, acute, cloven half way down. *Cor.* of one petal, gaping; tube short, cylindrical; throat oblong; upper lip concave, undivided, drooping; lower reflexed, obtuse, cloven into three segments, of which the middle one is broader, emarginate, serrated, concave. *Stam.* Filaments four, awl-shaped, forked at the top, two of them a little longer than the others; anthers simple, inserted into the filaments below the top, as it were on another branch. *Pist.* Germen superior, four-cleft; style thread-shaped, with the stamens incurved by the upper lip; stigma cloven. *Peric.* none, except the closed calyx, which encloses four, nearly ovate seeds.

Obj. The great peculiarity of this genus consists in its having forked filaments like *Crambe*, and the middle segment of its lower lip toothed as in *Nepeta*.

Ess. Ch. Filaments forked, one point bearing the anther. Stigma cloven.

1. *P. vulgaris*. Common Self-heal. *Linn. Sp. Pl.* 837. *Engl. Bot. t.* 961. *Curt. Lond. fasc.* 4. t. 42. *Mart. Rust. t.* 137.—“All the leaves ovate-oblong, on foot-stalks.”—Common in meadows and pastures, flowering in June and July. *Root* perennial, fibrous, somewhat creeping. *Stem* generally branched, furnished with erect, white hairs. *Leaves* ovate-oblong, rather obtuse, hairy, slightly toothed or wavy. *Spikes* terminal, solitary, cylindrical, whorled, blunt, dense, with a pair of leaves at their base; each whorl having a pair of kidney-shaped, coloured, fringed bractæas. *Flowers* of a violet hue, occasionally red and white.

2. *P. grandiflora*. Great-flowered Self-heal. *Willd. n. 2.* *Curt. Mag. t.* 337. *Jacq. Austr. t.* 377. (*P. vulgaris* β; *Linn. Sp. Pl.* 837.)—Lower leaves stalked, oblong-ovate, toothed at the base. Upper lip of the calyx trifid. *Stem* ascending.—Native of the Alps, and various other parts of Europe, flowering in July and August. This large and showy species was considered by Linnæus merely as a variety of the common one, but later authors have determined it to be distinct, its stems being constantly lower, leaves more tender, and flowers twice as large. *Stems* about six inches long, erect, slightly angular, hairy. *Leaves* entire, or slightly toothed, bright green; upper ones almost lacinated. *Spike* looser, more ovate. *Flowers* large and handsome, of a rich blue or purplish colour. Mr. Aiton in the first edition of his *Hortus Kewensis* followed Linnæus in making this species a variety of *P. vulgaris*, but in the second edition of that work he has made it a distinct species.

3. *P. laciniata*. Jagged-leaved Self-heal. *Linn. Sp. Pl.* 837. *Sm. Prodr. Fl. Græc. Sibth. v. 1.* 426. *Jacq. Austr. t.* 378. (*P. grandiflora* β; *Willd. n. 2.* *Ait. Hort. Kew. v. 3.* 430.)—Leaves ovate-oblong, stalked; the upper four or six lanceolate, toothed.—Native of mountains, and dry pastures, in various parts of Europe, frequently intermixed, as Jacquin informs us, with the last. It flowers from July to September. *Root* perennial, fibrous, creeping. *Stems* hard, small, branched, from three to six inches

inches high. *Leaves* more or less lacinated and hairy. *Flowers* larger than in *P. vulgaris*, but less than those of the last species, of a yellowish-white colour. It is subject to vary in its leaves, and the colour of its flowers. Linnæus considered this species as differing very little from the common sort.

4. *P. byssopifolia*. Hyssop-leaved Self-heal. Linn. Sp. Pl. 837. (*Brunella angustifolia integra hirsutior*; Morif. Hist. v. 3. 364. sect. 11. t. 5. f. 7.)—*Leaves* sessile, lanceolate, entire, rough. *Stem* erect.—Native of the south of France, about Montpellier, flowering from July to October.—*Stem* erect, firm and little branched. *Leaves* narrow, oblong, entire, hairy, on short stalks. *Flowers* large, generally blue, but occasionally white; the keel of the upper lip of the corolla is hairy.

5. *P. pennsylvanica*. Pennsylvanian Self-heal. Willd. Hort. Berol. 9. Ait. Hort. Kew. v. 3. 430.—*Leaves* flaked, ovate-lanceolate, toothed at the base. Lips of the calyx equal; the upper one truncated, with three awns. *Stem* ascending.—Native of Pennsylvania, received from thence by M. Thouin in 1801. It flowers from July to September.—We adopt this new species on the authority of the above quoted authors, but are not acquainted either with a specimen, figure, or description of it.

PRUNELLA, a name given by some physicians to a dryness of the tongue and throat, happening in continued fevers, especially acute ones, accompanied with a heat and redness of the throat, and a scurf covering the tongue; sometimes whitish, and sometimes blackish.

Some also give the name *prunella* to the quinzy, and others to the aphthæ.

PRUNELLÆ, *Sal*, in *Pharmacy*, is a preparation of purified saltpetre; called also *lapis prunellæ*, and crystal mineral.

It is prepared by separating and absorbing some of the more volatile parts of the saltpetre, which is done by burning upon it, when melted in a crucible over the fire, about a twenty-fourth part of its weight of flowers of brimstone. When the deflagration is over, the melted salt is poured into clean, dry, warm, brass moulds, so as to form it into little cakes.

It is given to cool, and provoke urine, in fevers and quinzies; though some think that saltpetre, purified three or four times, would be a better medicine.

The sal *prunellæ* is said to be frequently adulterated with alum; and that the deceit is known by its whiteness and glittering.

PRUNES, PRUNA, are plums dried or baked in an oven, or in the sun. See PRUNUS.

Three sorts of this fruit are ranked among the articles of the materia medica; they are all met with in our gardens; but the shops are supplied with them, moderately dried, from abroad. These are the Brignole plum, or *prunellæ*, brought from Brignole in Provence, of a reddish-yellow colour, and a very grateful, sweet, subacid taste; the common, or French prunes, called by our gardeners the little black damask plum; and damsons, the larger damask violet plum of Tours, which is seldom kept in the shops, but has been generally supplied by the common prunes. All these fruits possess the same general qualities with the other summer fruits. They are nearly inodorous; and contain chiefly mucus, saccharine matter, and malic acid. The *prunelloes*, in which the sweetness has a greater mixture of acidity than in the other sorts, are used as mild refrigerants in fevers and other hot indispositions, and are sometimes kept in the mouth for alleviating thirst in hydropic cases. The French prunes and damsons are the

most emollient, lubricative, and laxative, they are taken by themselves for gently loosening the belly in costive habits, and where there is a tendency to inflammation; decoctions of them afford an useful basis for laxative or purging mixtures, and the pulp in substance for electuaries. Lewis.

PRUNES, *Island of*, in *Geography*, a small island near the E. coast of Madagascar. S. lat. 18°. E. long. 49° 48'.

PRUNES, a river of Louisiana, which runs into the Mississippi, N. lat. 35° 33'. W. long. 90° 26'.

PRUNIFEROUS TREES, or *Sbrubs*, the plum-bearing kind, are those whose fruit are pretty large and soft, with a stone in the middle.

In this kind the flower adheres to the bottom of the base of the fruit.

PRUNING, in *Rural Economy*, the lopping or cutting out branches or boughs of trees of the fruit, timber, or other kinds. See ORCHARD and TIMBER.

It has been observed, that in timber plantations, and most other kinds of woods, it is highly proper and necessary to have an eye to the pruning and taking out the branches of the young trees occasionally as they advance in their growth, in the view of guarding against and preventing their shooting out and increasing in an irregular and improper manner, and thereby becoming too thick, and injuring each other by their rubbing, or by being drawn up weak and in too close a manner. The trees should therefore be now and then carefully looked over every year after the third from the time of their being planted, and such branches or other parts, headed down, taken out, or cut away in such other manner, as may appear suitable and proper for promoting their more perfect and beneficial growth and increase. And when this has been well effected, the only thing which remains further to be done, is that of encouraging proper leaders in the different trees, by means of shortening all the other branches which seem to contend with it, to nearly one-third of their length, in the intention of strengthening the main proper stem. All that is afterwards required is that of properly pruning out and thinning the more strong top-branches and shoots, as well as those side ones that are improperly situated, which is often done by a light kind of hand-bill; but it may be well accomplished by a small saw, or any other instrument of the strong cutting sort. These modes of pruning are applicable to forest-trees in general; but those of the fir and evergreen sort seldom require any thing more than the proper regulation of their leaders, as that of keeping them single where they throw out double, for the less the side branches are touched the better.

It may be further however noticed, that though the pruning of woods and plantations is in general considered to be much less necessary and essential than that of properly thinning of them, yet that it may notwithstanding in numerous instances be of great utility and advantage. Mr. Loudon has observed, that it equally corrects the extravagancies of the trees, takes off their redundancies, and directs their produce in the most proper methods. And that two trees of the same kind planted out in similar soils and situations, the one pruned, and the other left to nature, though they may produce in an equal length of time the same quantity or weight of timber; yet the tree that was pruned will contain the greater part of that timber in an upright clean bole or stem, while the other, which was left to nature, will have a great part of it in the arms and side branches. Hence, where the application or intention was that of ship-building, or any similar purpose, it is most likely the natural one would be preferred; but that where

PRUNING.

wainscotting or any similar use was intended, the other would unquestionably be the most profitable, and of course preferred. But even the larch, without any pruning, is supposed the best for the purpose of wainscotting; and the oak, without any pruning, the most suitable for ship-timber. These, and other cases which might be adduced, would seem to shew that trees, equally in respect to the quality of their wood, and the modes of their growth, are fitted by nature for certain particular purposes in the arts of life; and which again tends to prove that pruning is sometimes unnatural and often unnecessary. But from various and different causes and circumstances, it not unfrequently becomes necessary and proper to use trees for purposes, and intentions, which they are not designed for by nature. Anterior to the larch being introduced into this country, and in situations where it could not be obtained, it might be necessary to train the oak-tree for wainscotting uses; and where the larch alone will grow, and ship-timber is required, it may be advantageous to prune or bend it to the forms which will suit these intentions. Farther, the ash, the elm, and the beech, when planted in soils and situations which suit their different natures, are, without pruning or particular cultivation, admirably fitted for the several useful purposes to which they are applicable. But their applications and uses being reversed or intermixed, pruning then becomes necessary and essential.

In the performance of this business there are two points requisite to be particularly attended to; the first of which is the general principles of vegetation; and the second, the purposes for which the wood or timber are to be applied. In general, however, in artificial plantations, it may be a good common rule, to consider pruning as the means of throwing more timber into the trunk or principal stem, whatever direction that may have assumed by nature. Pruning, where necessary for these purposes, should commence after the trees have been five or six years planted, and continue until they are nearly full grown. In common, no tree should be divested of all its side branches; as a sufficient number of small ones should always be left in order to circulate the sap through the tree. And the branches of resinous trees never attain a timber size, which shews that their chief use is to serve this particular purpose. In the fir and pine tribe their number and importance may, it is supposed, be accounted for, from the sudden ascent of the sap, and the singular largeness of the alburnous vessels in these trees. Hence in this tribe of trees no side branches, it is thought, should be removed, until they shew some evident marks of decay, or of a tendency to be destroyed.

It is conceived that wherever the practice of pruning is much attended to, it is for the most part carried to too great a length; and that the timber is thereby very materially injured, as well as the characteristic beauty of the trees. The just and useful medium in this sort of work is but very seldom had recourse to, the trees being too frequently either wholly left to contend with whatever kinds of injuries or diseases may come in their way, or so much mutilated and deformed by the hands and tools of the forest pruner, as to be unfit to perform their proper and necessary offices or functions: the consequence of the first of which, it is supposed, is that of *unsound* timber; and that of the second, timber of a *bad quality*, as well as perpetual deformity of shape. Better proof of which cannot be afforded than in the tall, naked elms, pollard oaks, and naked fir woods, which prevail in many parts of this country, and not unfrequently disfigure whole districts of it. The timber of those sorts of trees, as is extremely well known, is, where they are treated in a proper and suitable manner, the

best and most valuable of any; but that after the above kind of management has been practised with them, both its quality and quantity are very greatly injured, impaired, and lessened; so that being rendered unfit and improper for every sort of valuable purpose, it is not unfrequently employed for use as fire-wood.

From this view of the subject, the great value and utility of moderate and judicious pruning in forest-woods and plantations is particularly evident, and the impropriety and disadvantages of carrying it too far fully pointed out and explained.

In the business of reclaiming and preserving all sorts of old woods and plantations, which have suffered from neglect and inattention, pruning in a proper manner should always accompany the various other means which are necessary for these purposes, according to the times of the growths, the dimensions, and the kinds of the trees, as well as the purposes that they are intended for.

It is supposed by Mr. Loudon, that in the management of all sorts of wood, in the view of ornament, pruning serves many important purposes. Where there are individual trees upon the lawns, or near to the houses, of heavy inelegant forms, they may often be lightened, and reduced to more desirable and agreeable shapes, either by cutting out branches, or by incisions made in the bark and outer layers of the wood, in order to force young shoots to spring out. The stems of single trees may be shewn to advantage, or be disguised where they are too formal. Small groups may also be improved in the same manner. And in connection with the knife, cords and weights may not unfrequently be had recourse to with good effects; as by these means, branches may be more gracefully and conveniently bent and directed, by hanging stones towards their extremities; or their positions may be altered, by fixing them with cords either to other branches, or the trunks of the main trees, or to posts driven into the ground for that purpose. In this way, awkward and mishapen trees, which could ill afford or admit of being thinned, may, it is asserted, be *balanced*, without cutting off any of their branches. Likewise close formal trees may be rendered irregular, by separating their boughs. And the stems of trees may be formed and moulded into more pleasing and agreeable bends or curves, in scenes of beauty and ornament; or be rift, shattered, or broken, in those of the grotesque or romantic kinds. Farther, the sky line of a plantation, too insipid from being deficient in variety, may, it is contended, be rendered interesting; or one which is composed of firs, that is displeasing from the formality of their conic tops, may be changed by taking away some trees entirely, and cutting the tops from others. Even the last of these operations may also be applied to conic trees, when they are too prevalent upon lawns, or in parks, and where they do not group well with buildings. It must, however, be allowed, that this is destroying the natural character of the trees; but the conical form of the fir is a singular character in trees, and in harmonizing scenery, general excellencies are to be chiefly attended to. It is asserted that many of these operations are executed with excellent effect at Foxley; and in some other places likewise, under the direction of the writer, where the formality of trees not pruned at all, and of others pruned only to a certain height by cattle, were equally disguised, and rendered imperceptible. See PLANTATION, PLANTING, and WOOD.

PRUNING of Trees, in Gardening, the operation of occasionally cutting out parts, in order to give them any desired form, and to retrench or reduce irregular and redundant or superfluous growths.

PRUNING.

It is particularly necessary to be practised on many sorts of fruit-trees, more especially the dwarf sorts; such as all kinds of wall and espalier fruit-trees. It is also necessary, occasionally, for standard trees, both dwarfs and half and full standards, and for some sorts annually, as all kinds of wall-trees, espaliers, and most other dwarf or trained fruit-trees; which is done in order to preserve the proper figure, and to keep them within their limited bounds, as well as to promote fruitfulness. But as to common standards, whose heads have full scope of growth every way, they require but very little pruning, except just to retrench any occasional redundancy, ill-growing branches, and dead wood. Wall-trees and espaliers require a general regulation in this way, twice every year: in summer, to retrench the evidently superfluous and ill-placed shoots of the year, and to train in a supply of the most regular ones; and in winter, to give a general regulation both for the supply of young wood left in summer, and to the old branches where necessary.

In pruning these sorts of trees, as they have their branches arranged with regularity to the right and left, one above another, in a parallel manner, four, five, or six inches asunder, and forming a regular spread, so as the branches of each tree completely cover a certain space of wall, &c.; and as the whole spread of branches constantly sends forth every year a great number of unnecessary and useless shoots, each should be limited to a certain space. An annual pruning is consequently necessary to retrench the redundancies, and all irregular and bad shoots, to give the proper bearing branches due room, as well as to confine each tree within its proper limit, consistent with its regular form.

The first pruning for wall fruit-trees, to give the head its first regular formation, is effected by pruning short, or heading down in spring all the shoots produced the first year from budding and grafting; and when a year old, being mostly pruned down in March, within four or five eyes of the bottom, to throw the sap more into the remaining lower buds; and thus, instead of running up to one stem, to push forth several strong shoots from the lower part the ensuing summer, so as to fill the necessary space of walling and espalier regularly from the bottom; which shoots being trained straight and regular in a spreading manner, each at full length all summer. And in the winter or spring following, where a supply of more principal shoots shall seem necessary to form the head more effectually, pruning short also these shoots, each to four or five eyes, when they will throw out the same number of shoots the same year, which, according as they advance in length, should be trained at regular distances at full length, during the summer; for the shoots of wall-trees should not in general be shortened in the summer season, as that would cause them to push forth many superfluous unnecessary lateral shoots; though, sometimes, in order to fill a vacancy as soon as possible, strong young shoots, by being pinched or pruned early in the season, as May or beginning of June, to four or five eyes, will throw out several proper shoots the same summer. The work of pruning short should be occasionally repeated one or two years, either in general or on particular shoots, as may seem necessary, till a proper set of branches are by that means obtained, to give the head of the tree a proper formation: afterwards it may be omitted, except occasionally to any particular shoot to fill a vacant space; but some sorts of wall-trees require almost a general shortening of their supply of shoots, such as peaches, nectarines, &c. which bear only on the young wood, have that of each year shortened, to force out a supply of shoots for future bearing. Other sorts of wall-trees and espaliers

are not, in the general course of pruning, to be shortened, such as pears, apples, plums, and cherries, which continue bearing in the same wood of from two or three to many years' growth. See *ESPALIERS*.

When the trees have been thus furnished with a proper spread of branches, trained regularly to the wall and espalier, they every year throw out many more shoots than are wanted, or can be converted to use, by some being too numerous, others ill placed, and others of a bad growth; all of which must, therefore, be regulated accordingly by proper pruning: as the regular figure of the tree, by being well furnished in every part equally from the bottom to the top of the wall or espalier with proper branches, capable of producing good fruit, is the principal object of this operation.

In performing it, the operator should be careful to free the trees of every thing that is superfluous, irregular, or hurtful, both in the summer and winter prunings. Those branches are superfluous, which though good and well placed, are more than wanted, or that can be properly laid in; and those irregular, which are so ill placed as not to be trained with regularity to the wall or espalier, such as all fore-right shoots, being such as grow immediately from the front or back of the branches in a fore-right direction; and those are hurtful, which are of bad growth, such as all very rank or singularly luxuriant rude shoots. The superfluous or redundant growths should of course be thinned, by pruning out all that seem to cause confusion; and the irregular and hurtful rank shoots be displaced, cutting all those off quite close to the place whence they proceed, only leaving a proper supply of the regular or best placed side shoots where necessary, so as to preserve every part well furnished with bearing wood, trained straight and close to the wall or espalier, at equal distances. Some sorts of wall-trees, &c. however, require a general annual supply of young wood, such as peach, and all other trees which bear only on the shoots of a year old; others require only an occasional supply of wood, such as apples, pears, &c., and all other kinds that bear on the old wood of from two or three to ten or twenty years old, or more; so that the same branches continue in bearing many years, and the trees require only a supply of young shoots now and then, to replace any worn out or dead branches. See *Summer and Winter Pruning*.

This art chiefly consists in being acquainted with the nature of bearing in the different sorts of trees, and in forming an early judgment of the future event of shoots and branches, as well as other circumstances, for which some rules may be given; but there are particular instances which cannot be judged of but upon the spot, and depend chiefly upon practice and observation.

With regard to the nature or mode of bearing of the different sorts of wall and espalier trees, &c. peaches, nectarines, apricots, &c. all produce their fruit principally upon the young wood of a year old; that is, the shoots produced this year bear fruit the year following, and the same of every year's shoots; so that in all these trees, a general supply of the best regular shoots of each year should be every where preserved, both in the summer and winter prunings, at regular distances, quite from the bottom to the extremity of the trees on every side, in such order as to seem coming up regularly one after another, and trained principally at full length during their summer's growth; but in the winter pruning generally shortened, according to the strength of the different shoots, in order to promote their throwing out more effectually a supply of young wood the ensuing summer, from the lateral eyes, in proper places for training in for the next year's bearing; the fruit-buds
being

PRUNING.

being mostly produced along their sides immediately from the eyes, as they rarely form any considerable fruit-spurs, as in the apple, pear, &c.; the same shoots producing the fruit, and a supply of shoots at the same time for the succeeding year's bearing. All these trees also bear on casual small natural spurs, sometimes arising on the two and three years' wood, one or two inches in length, which are generally well furnished with blossom buds in the proper season, and should be preserved for bearing; always, however, depending on the main young shoots as the principal bearers.

Vines also produce their fruit always upon the young wood, shoots of the same year arising from the eyes of the last year's wood only, and must therefore have a general supply of the best regular shoots of each year trained in, which in the winter pruning should be shortened to a few eyes or joints, in order to force out shoots from their lower parts only, properly situated to lay in for bearing fruit the following year.

Figs bear also only upon the young wood of a year old, a general supply of it is of course necessary every year; but these shoots should at no time be shortened, unless the ends are dead, as they always bear principally towards the extreme part of the shoots, which if shortened would take the bearing or fruitful parts away. And these trees mostly throw out naturally a sufficient supply of shoots every year for future bearing without the precaution of shortening them.

And as to apple, pear, plum, and cherry trees, they bear principally on spurs arising in the general branches, of from two or three to ten or twenty years old, the same branches and spurs continuing bearing a great number of years, as has been seen, so that having once procured a proper set of branches, in the manner already directed, to form a spreading head, no further supply of wood is wanted than only some occasional shoots now and then to supply the place of any casual worn-out or dead branch as before suggested; these spurs or fruit-buds are short, robust shoots, of from about half an inch to one or two inches long, arising naturally in these trees, first towards the once extreme parts of the branches of two or three years old; and as the branch increases in length, the number of fruit-buds increases likewise; this therefore determines, that in the general course of pruning all these kind of trees, their branches that are trained in for bearing must not be pruned or shortened, but trained at full length, as where shortened it would divest them of the parts where fruit-buds would have first appeared, and, instead thereof, would throw out a number of strong unnecessary wood-shoots from all the remaining eyes; therefore all the shoots or branches of these trees should be trained principally at full length, and as they advance still continue them entire. When however there is a vacancy, and only one shoot, where two or three may be requisite, pruning or shortening is allowable to force out the proper supply. See *DWARF-Trees*.

In these trees care is necessary to preserve all the proper fruit-buds or spurs, which are readily distinguished by their short, thick, robust growth, rarely exceeding one or two inches in length.

In the course of pruning all sorts of wall and espalier trees, all improper and ineffectual shoots and branches, necessary to be displaced, must be taken off quite close to the place whence they arise; which in the summer pruning, if attended to early, while the shoots are young and tender, may readily be rubbed off close with the thumb; but when the shoots become older and woody, as they do not readily break, it must be done with a knife, cutting them as close

as possible: all winter pruning should however be performed with a knife.

In pruning in summer, the necessary supply of regular shoots that are left for training in, should never be shortened, unless to particular shoots to fill a vacancy, or to reduce within bounds any too long extended shoots; as by a general shortening in this season, all the shoots so treated would soon push again vigorously from every eye, and run the trees into a perfect thicket of useless wood; therefore all sorts, whether they require shortening in the winter pruning or not, should in the summer dressing be laid in at full length.

Summer Pruning.—This is a necessary operation, as in spring and summer wall and espalier trees abound with a great number of young shoots that require thinning and other reforms to preserve the requisite regularity and beauty of the trees, and encourage the fruit; and the sooner it is performed the better; it is therefore advisable to begin in May or early in the following month, and disburthen the trees in time of all redundant or superfluous growth, and ill-placed and improper or bad shoots; which may be then performed with more expedition and exactness than when delayed till after the trees have shot a considerable length and run into confusion and disorder: besides, the injury of the fruit is prevented. It is therefore of importance to proceed in this operation early, when the same year's shoots are sufficiently formed to enable you to make a proper choice.

The business now is to thin and regulate the unnecessary shoots, by pruning away the superfluous ones, and all such as are ill-placed and of bad growth, retrenching the most irregular-placed, weakest, and all such as are evidently not wanted for use, and where two or more shoots any where arise from the same eye, clearing all away but one of the best, reserving a sufficiency of the moderately strong and most regular-placed side shoots, and always a leading one at the end of every branch, where it commodiously occurs; all of which should be retained to be regularly trained in to choose from in the winter pruning, leaving more or less in proportion, according to what the trees are, or the mode of bearing, though in all those trees that bear always on the young wood, at least doubly or trebly more shoots should be left in this pruning than what may appear necessary, especially of peaches, nectarines, apricots, vines, figs, &c. as it is highly requisite to reserve plenty of regular young wood in summer, to choose from in winter pruning, to lay in for next year's bearers; but as to apples, pears, plums, cherries, &c. which continue bearing many years on the same branches, only here and there some good well-placed shoots need be left towards the lower parts, or in any vacancy between the main branches till winter; and if then not wanted, be easily retrenched.

Where, however, a tree is in general inclined to luxuriance, it is proper to retain as many of the regular shoots as can be commodiously trained in with any regularity, in order to divide and exhaust the too abundant sap, which causes the luxuriance; as by humouring somewhat the natural inclination of luxuriant trees by leaving plenty of branches, and these mostly at full length, they may the most readily be reduced to a more moderate state of growth.

Great attention should always be paid to the lower parts of the trees, as it is frequently the case to find proper shoots arising in places necessary to be trained in, either to supply a present or future vacancy, or as a reserve to replace any decayed or worn-out or other bad branch, so that if moderately strong well-placed shoots arise in such parts, they are to be particularly regarded at this time; and in winter pruning,

ing,

PRUNING.

ing, such of them as are not wanted may be easily cut out and removed: but all weak trifling shoots should now be taken out.

After having summer-pruned and cleared any tree from all useless shoots, all the remaining proper shoots should be directly, or as soon as they are long enough, trained in straight and close to the wall or espaliers, at full length. When there is any great vacancy in some particular part, it may however be proper to cut or prune one or more contiguous shoots to three, four, or five eyes or buds, in order to promote an emission of laterals accordingly the same season, more effectually to supply the vacant spaces; but all the rest should be trained at full length till winter pruning, when they must undergo another regulation. Those of such trees as require it, as peach, nectarine, &c. should be shortened.

The work of training in the shoots in this season, is performed when against walls, both by nailing, by means of proper shreds and nails, and occasionally, by fastening in the smaller shoots, with little sticks or twigs stuck between the main branches and the wall; and for espaliers, by tying them with small osiers, rushes, or bafs strings.

After having thus summer-dressed and trained the trees, it will be necessary to look them occasionally over, in order to reform such branches or shoots as may have started from their places, or taken a wrong direction, and according as any fresh irregular shoots are produced, they should be displaced; and likewise, as the already trained shoots advance in length or project from the wall or espalier, be trained in close, continuing them at full length during their summer's growth; every thing being kept close and regular, by which the trees will appear beautiful to the eye, and the fruit shew itself, and attain its due perfection more effectually.

Winter Pruning.—In this pruning, a general regulation must be produced both in the mother branches, and the supply of young wood laid in the preceding summer. The proper time for this work is, in most wall-trees, any time in open weather, from the fall of the leaf in November until March. And in performing the business, it is proper to unnailed or loosen a great part of the branches, particularly of peaches, nectarines, apricots, vines, and such other trees as require an annual supply of young wood, and considerable regulation in the regular branches.

All the principal or mother branches should first be looked over, and examined, to see if any are worn out or not furnished with parts proper for bearing fruit, and such branches be cut down either to the great branch from which they proceed, or to any lower shoot or good branch they may support toward their bottom part, leaving these to supply its place; likewise examining if any branches are become too long for the allotted space either at the sides or top, and reforming them accordingly, by shortening them down to some lower shoot or branch properly situated to supply the place; being careful that every branch terminates in a young shoot of some sort for a leader, especially in all parts where room to extend them, according as the limited space admits, having the leader either placed naturally at the termination of the branch; or where too long in any particular parts of the tree, pruned conformably to some lower shoot, &c. so as that it may still terminate in a proper leader, and the extended branches not cut to naked stumpy or stubbed ends, as is often practised by inexperienced pruners. And from the principal or larger branches, pass to the young wood of the year: or, in proceeding both in the occasional reform among the principal or older branches, and more general regulation in the young wood of the year,

or shoots of the preceding summer, the above intimations relative to the principal branches should be observed in the pruning of the whole, both on the old and young wood, and be carried on regularly together at the same time; cutting out or retaining according to circumstances; as for instance, in older wood observing the above particulars, and as below, and in the general supply of young wood, cutting out close all fore-right and other irregular shoots that may have been omitted in the summer-pruning; likewise all very weak shoots, and those of very luxuriant growth, unless it be necessary to keep some to supply a vacant place; then of the remaining regular shoots, selecting a greater or smaller portion to leave either as a general supply for next year's bearing, as is requisite for peaches, nectarines, apricots, vines, and figs; or only in others some occasional shoots, such as in full trained apple, pear, plum, and cherry-trees, &c. either to furnish casual vacancies, or to supply the places of any defective or improper branches, or ineffectual bearers, as may casually occur, or that of decayed or dead wood.

But as peaches, nectarines, apricots, vines, and figs, always bear principally on the year-old wood, as already noticed, a general supply of young shoots must be left in every part, from bottom to top, at regular distances; and, at the same time, some proportional part of the most naked old wood, and of the two preceding years past bearers, be pruned out to make proper room for this requisite young successional supply of future bearers in the following summer, to be now retained in a general manner, both laterally, and as terminals to the general parent branches, which should be pruned accordingly; and mostly all the said supply of the present retained shoots, except the fig, must be more or less shortened, according to their situation and strength, to encourage their furnishing more readily a proper supply of shoots in spring and summer for the succeeding year's bearing, as noticed before, leaving the strongest shoots always the longest, as is more fully explained under each of their respective genera; but as the figs always bear towards the end of the shoots, they must not be shortened.

With respect to the apples, pears, plums, cherries, &c. as they continue to bear on the same branches of from two or three to many years standing, the said bearers must be continued accordingly; and the trees only require an occasional supply of young wood, according as any of the branches become defective, or unfit for bearing, and want removing; which should now be cut out as may seem necessary, training in here and there, in proper places, some good regular young shoots towards the lower part, and where it may seem necessary, to be coming gradually forward to a bearing state, to be ready to replace worn-out and other useless branches to be cut out, as they may occur: and of the young wood, selecting what may appear necessary of the best well-placed shoots, and the superabundance, or those not wanted for that purpose, together with all irregular-placed shoots, rank luxuriant, and other ineffectual growths, should now be cut clean out, close to whence they originate, not leaving any spur or stump, as every one would push out several strong unnecessary shoots the next spring, to the prejudice of the trees and fruit: particular regard should be paid to preserve the shoots at the termination of all the already trained branches entire, but not more than one to terminate each branch; preserving also carefully all the proper fruit-spurs, taking care that the supply of young wood be occasionally reserved, and the branches in general of these trees be trained in at full length, and continued so in future, as far as the limited space will admit: and according as any extend above the wall or espalier, or any where beyond their

PRUNING.

proper limits, they be pruned down with discretion to some convenient bud, or lateral shoot, or lower branch, which should be trimmed entire.

In this pruning, as in the summer dressing, it is of importance to have a strict eye to the lower parts of wall-trees, &c. to see if there is any present vacancy, or any that apparently will soon happen; in which cases, if any good shoot is situated contiguous, it should be trained in either at full length, or shortened to a few eyes, to force out two or more shoots, if they shall seem necessary; for precaution should ever be observed in taking care to have betimes a sufficient stock of young wood coming forward to fill up any casual vacancy, and substituting a new set of branches in place of such as are either decayed, or stand in need of retrenchment.

In wall-trees and espaliers there are sometimes many large disagreeable barren spurs, consisting both of old worn-out fruit-spurs, and of clusters of stumps of shortened shoots projecting considerably from the branches, occasioned by unskilful pruning, when retrenching the superabundant and irregular shoots, which, instead of being cut out close, are stumped off to an inch or two long, and in the course of a few years, form numerous barren stumps, and very little fruit, the trees appearing like a stumped hedge. In this season of pruning, in this case, it is proper to reform them as well as possible, by cutting all the most disagreeable stumps clean out close to the branches, leaving these at full length, especially in apples, pears, &c. and reserving an occasional supply of young wood in different parts: thus in two or three years such trees may be reduced to a regular figure and a proper state of bearing.

It is observed that bad pruning ruins many a good tree, as is observable in numerous gardens, where the wall-trees and espaliers appear as just described, pruned every year, yet never producing any tolerable crop of fruit.

Severe injudicious pruning in strong wood is greatly prejudicial to the health of some sorts of stone fruit-trees, by causing them to gum and soon decay. Plums and cherries, in particular, are often greatly damaged by a too severe discipline of the knife, these being very liable to gum by large amputations: it is therefore of importance to attend to these trees well in the summer pruning, to retrench all the superfluous and irregular shoots betimes in the summer, while quite young, and pinch others occasionally where wood is wanted to fill vacancies, so as to require but little pruning out of large wood in winter.

A general nailing, &c. must every year be performed, according as the pruning advances, as it is proper that every tree, as soon as pruned, be directly nailed to the wall, or if espaliers, tied or nailed to the trellage, being careful in the winter pruning, as the work of nailing, &c. will require to be performed more or less upon all the branches, to train them with great regularity, nailing them along horizontally, as straight and close as possible; never crossing any of the branches but training them distinctly and parallel from four to five or six inches asunder, or in proportion to the size of the leaves and fruit of the different sorts, making the opposite branches of each side arrange equally in the same manner and position.

Pruning of Standard Trees.—Standard fruit-trees require but very little pruning; for, as their branches have full scope above to extend themselves every way, they must not be shortened: besides, as the standard fruit-trees, consisting principally of apples, pears, plums, and cherries, bear fruit on natural spurs arising towards the upper parts of the branches, this determines that they must not be shortened, nor any other pruning be practised, than just to reform any

great irregularity, &c. in them. In these trees, the first occasional pruning necessary is the first two years of their growth, in order to form their heads somewhat regular, by retrenching any irregular shoots; and when designed to have them form more regular spreading heads, to prune the first shoots, when a year old, down to four or five eyes, in order to force out lateral shoots from these lower buds the following summer, to give the head a proper formation. After this, the branches should be suffered to take their natural growth, except that, if while the trees are young, any very luxuriant shoots ramble away considerably from all the others, and draw most of the nourishment, it is proper to prune them, either by retrenching entirely very irregular ones, or shortening others to some regularity, to branch out consistently with the requisite form of the head of the tree; but except in such cases of reducing irregularities, the heads of all kinds of standards always should be left to branch away as fast as possible, both in length, and laterally, agreeable to their natural mode of growing; and they will naturally furnish themselves abundantly with bearing wood.

In standard fruit-trees of some years growth, as irregularities and disorders will occasionally happen, they should be regulated a little by pruning out the most conspicuously irregular and redundant growths in the winter season.

For instance; where any considerable branches grow right across others, or in any other awkward direction, to incommode or cause confusion, or much irregularity in the head, they should be retrenched close; likewise any branch that rambles considerably from all the rest, should be reduced to order, by cutting it down to some convenient lower branch, so as to preserve some regularity. Where the head is considerably crowded with wood, let the worst of the redundancy be thinned out as regularly as possible, cutting them close to their origin; and as sometimes very vigorous shoots arise in the heart of the tree, or towards the bottom of the main branches, growing upright, and crowd the middle of the head, they should be constantly retrenched to their very bottom; cutting out also any very cankered parts, and all decayed wood; and clearing off all suckers from the root and stem. The standard trees, thus disburthened from any considerable irregularities and confusion, so as all the proper branches have full scope to spread free and easy in their natural manner, will not fail to repay the trouble in the superior quality of their future fruit. See *ORCHARD TREES*.

Pruning of Forest-trees, &c.—With respect to pruning of forest and ornamental trees, flowering shrubs, &c. it is very inconsiderable. Forest-trees, &c. must be suffered to run up as fast as possible, so that their heads should not be shortened; all that is necessary is, to prune off the lateral branches occasionally from the stems; or if, while young, any lateral shoot of the heads, which is of a very rude rambling growth; but otherwise suffering the top and general branches of the heads to remain entire, and take their own natural growth; only pruning the stragglers occasionally. It is, however, very improper to trim up the stems too high, as often practised to forest-trees, as scarce to leave any upper branches to form a head: never, therefore, trim the stem much higher than the full spread of the principal branches, as a full head is both ornamental and essentially necessary to the prosperity of the tree. See *PLANTING*.

And as to the shrub kinds, they should, for the general part, take their own growth at top; and only be pruned occasionally in any lower stragglers, from the inferior part of the stems, or any very irregular rambling shoot of the heads, and all dead wood. Except in these cases, their heads mostly should be suffered to shoot in their own way, according to their different modes of growth, in which they

will appear always the most agreeable. Where, however, it is required to keep shrubs low, they must be regulated, as convenient, with the pruning-knife, as being more proper than the garden-shears, which should never be used in that business to shrubs and trees in rural growth.

The particular method to be followed with each sort of tree has been shewn under the proper head to which it belongs.

Pruning Implements.—For the purpose of general pruning several implements are necessary, such as pruning-knives, saws, chisfels, hand-bills, hatchets, &c. Two or three different sizes of knives are requisite, in order to prune neatly; a strong one for cutting out larger branches, shoots, &c. and a small one for the more exact pruning among the smaller branches and shoots of peach and nectarine trees, &c. These knives are generally made curving at the point, and they should not be too long, broad, and clumsy, but have rather a shortish narrow blade, and but very moderately hooked at the point, for when too crooked, they are apt to hang in the wood, and not cut clean; it is also proper to be furnished with a strong thick-backed knife, to use by way of a chissel occasionally, in cutting out any hard stubborn stumps, &c. placing the edge on the wood, and with your nailing hammer striking the back of it, and it will readily cut through even and smooth. A long knife with a concave edge, and a pruning-knife with a convex edge, are also recommended by Mr. Forsyth.

Hand-pruning saws are likewise proper for cutting out any large branch too thick and stubborn for the knife: these should be of moderate sizes, one being quite small and narrow, in order to introduce it occasionally between the forks of the branches, to cut to exactness.

And as saws generally leave the cut rough, it is proper to smooth it with a knife or a pruning-chissel.

The pruning-chissels are necessary to use occasionally both to cut off any thick hard branches, and large hard knotty parts, or stumps, and to smooth cuts in large branches, &c. after a saw; they should be flat, and from about one to two inches broad: sometimes large strong chissels, fixed on a long pole, are used in pruning or lopping branches from the stems of high standard forest-trees, one man holding the chissel, while another, with a large mallet or beetle, strikes the end of the pole. A hand-bill and hatchet are also necessary to use occasionally among larger kinds of the standard trees.

All these pruning tools, in their proper different sizes, may be had at the cutlery shops, and of the ironmongers, and many of the nursery and seedsmen.

PRUNN, in *Geography*, a town of Austria; six miles S.S.W. of Vienna.

PRUNUS, in *Botany*, an ancient generic name occurring in Pliny and other Latin authors. It is called *περσύνη* by Theophrastus, and, according to Galen, is derived from *περσύνη*, an Asiatic word for the Wild Plum.—Linn. Gen. 249. Schreb. 336. Willd. Sp. Pl. v. 2. 984. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 526. Ait. Hort. Kew. v. 3. 196. Pursh. v. 1. 325. Michaux Boreal-Amer. v. 1. 284. Tournef. t. 398. Juss. Gen. 341. Lamarck Dict. v. 5. 663. Illustr. t. 432. Gært. t. 93. (Cerasus; Tournef. t. 401. Juss. 340. Armeniaca; Tournef. t. 399. Juss. 341. Lamarck Illustr. t. 431. Laurocerasus; Tournef. t. 43.—Class and order, *Icosandria Monogynia*. Nat. Ord. *Pomacea*, Linn. *Rosacea*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, bell-shaped, deciduous, cloven into five, obtuse, concave segments. *Cor.* Petals five, roundish, concave, large, spreading, in-

serted into the calyx by claws. *Stam.* Filaments from twenty to thirty, awl-shaped, nearly the length of the corolla, inserted into the calyx; anthers twin, short. *Pist.* Germen superior, roundish; style thread-shaped, the length of the stamens; stigma orbiculate. *Peric.* Drupa roundish. *Seed.* Nut roundish, compressed, even, with rather prominent sutures.

Eff. Ch. Calyx five-cleft, inferior. Petals five. Stone of the drupa even, with slightly prominent seams.

Obs. Of *Prunus*, which comprises, according to Linnæus, all the above quoted genera of Tournefort, only thirteen sorts occur in the *Species Plantarum*. Willdenow and Martyn each enumerate thirty-three species, from which the following are selected. The first five of these are British plants.

P. Padus. Bird Cherry. Linn. Sp. Pl. 677. Engl. Bot. t. 1383. Fl. Dan. t. 205.—Flowers in long pendulous clusters. Leaves deciduous, with two glands on the under side at the base.—Not unfrequent in woods and hedges in the north of England, flowering in May. The branches of this shrub, or small tree, are round and smooth. Leaves alternate, stalked, obovate, pointed, serrated, veined, smooth, rather glaucous, smelling like rue. *Stipulas* linear, slightly fringed, deciduous. *Clusters* on the newest branches, solitary, simple, pendent, composed of numerous snow-white blossoms. *Fruit* oval, dark purple or black, bitter, but very grateful to birds. The stone of the *drupa* is slightly rugged, not so smooth as in the other species of *Prunus*, which seems to confirm the opinion of Gærtner, that no solid difference exists between this genus and *Amygdalus*. Every part of *P. Padus* except its fruit is highly poisonous.

P. Cerasus. Cherry-tree. Linn. Sp. Pl. 679. Engl. Bot. t. 706.—Umbels nearly sessile. Leaves ovato-lanceolate, folded when young.—Native of woods and hedges, flowering in May. The branches of this tree are ash-coloured, polished and round. Leaves stalked, pointed, unequally serrated, veined; the younger ones folded, more or less downy beneath. *Stipulas* toothed, glandular. *Umbels* leafless, pendent, composed of but few blossoms, each on a long stalk. *Calyx* reflexed. *Fruit* red, justly celebrated for its highly agreeable and acid flavour. Dr. Smith, in his *Flora Britannica*, notices four varieties of the cherry, two of which have blackish and less acid, approaching to sweet, fruit. They also vary in size.

P. Domestica. Plum-tree. Linn. Sp. Pl. 680. Engl. Bot. t. 1783. Woodv. Med. Bot. t. 85.—Flower-stalks mostly solitary. Leaves lanceolate-ovate, convolute when young. Branches without spines.—Found frequently in hedges, bearing flowers in April or May.—A middling-sized tree, whose branches are unarmed. Leaves on short stalks, ovate, serrated, smooth; the younger ones downy. *Flowers* white, generally on solitary stalks. *Fruit* of a dark blue or purple colour, mostly elliptical or obovate. From this species proceed all the different varieties of plums which abound in our orchards and gardens. Parkinson mentions sixty sorts, “all which,” he says, “are to be had of my very good friend Master John Tradescant, who hath wonderfully laboured to obtain all the rarest fruits he can hear of in any place of Christendome, Turkey, yea, or the whole world.”

P. insititia. Bullace-tree. Linn. Sp. Pl. 680. Engl. Bot. t. 841.—Flower-stalks in pairs. Leaves lanceolate-ovate, convolute when young, downy beneath. Branches ending in a spine. Common in hedges and woody places, flowering in April.—This is rather a humble tree, whose branches usually terminate in a spine. Leaves alternate, on short stalks, attenuated at the base, serrated. *Flowers*

PRUNUS.

from different buds, in pairs, on simple, shortish stalks, large, white. *Fruit* globular, black with a blue bloom, very sour and austere, scarcely eatable in a crude state. Dr. Smith observes that the common white bullace cultivated for the table differs only from this, as the white currant or white elder differ from the common kinds of each.

P. spinosa. Sloe-tree. Black-thorn. Linn. Sp. Pl. 681. Engl. Bot. t. 842. Fl. Dan. t. 926. Woodv. Med. Bot. t. 84.—*Flower-stalks* solitary. *Leaves* lanceolate, smooth. *Branches* ending in a spine.—One of the most common British plants, flowering early in the spring. A low, bushy shrub, formed of numerous rigid, spreading, thorny branches, covered with a dark but glaucous bark. *Leaves* on stalks, lanceolate or inversely ovate, serrated, dark-green, not appearing till the plant has blossomed. *Flowers* solitary, each on a short stalk, white. *Fruit* globular, black, very austere, and only palatable when prepared with a great quantity of sugar. “Its expressed juice inspissated over a slow fire, is a substitute for the Egyptian Acacia, and not an unuseful astringent medicine. The recent fruit is one of the many articles used to adulterate port wine in England. The dried leaves are said to be a substitute for tea, and are, perhaps, often mixed with it in this country.” *Engl. Bot.*

P. prostrata. Dwarf Pink Plum. Billard. Syriac. fasc. 1. 15. t. 6. Willd. n. 33. Ait. n. 19. Sm. Fl. Græc. Sibth. t. 478, unpublished. (*P. cretica montana minima humifusa, flore suavè rubente*; Tourn. Cor. 43. Voyage v. 1. 19.)—*Flower-stalks* in pairs. *Leaves* ovate, deeply serrated, without glands; white and downy beneath. *Stem* diffuse.—Native of mount Lebanon, and of the loftiest mountains of Crete, which it enlivens with its copious pink blossoms, soon after the first melting of the snow. Dr. Sibthorp gathered it also on mount Parnassus. On its native rocks this plant is a spreading procumbent shrub, with a thick woody black stem. In our gardens it rises to the height of two feet, in a bushy form. The leaves are small, cut, and deeply serrated; bright green above; white beneath. *Flowers* small, pink, with a smooth tubular calyx. *Fruit* the size of a pea.

PRUNUS, in *Gardening*, contains plants of the fruit-tree, flowering and evergreen shrubby kind, of which the species cultivated are, the common plum tree (*P. domestica*); the bullace plum tree (*P. insititia*); the apricock or apricot tree (*P. armeniaca*); the common or cultivated cherry tree (*P. cerasus*); the small-fruited cherry tree (*P. avium*); the common bird cherry tree (*P. padus*); the Cornish bird cherry tree (*P. rubra*); the common American bird cherry tree (*P. virginiana*); the Canadian bird cherry tree (*P. canadensis*); the perfumed cherry tree (*P. mahaleb*); the evergreen bird cherry tree (*P. caroliniana*); the common laurel (*P. lauro-cerasus*); and the Portugal laurel (*P. lusitanica*).

The varieties of the first sort, or garden and orchard plums, are very numerous, differing in the form, taste, colour, and substance of the fruit; but those mostly cultivated in this country are the following, according to Mr. Forsyth, and the times at which they ripen.

The jaunhative, or white primordian, which is a small plum, of a yellow colour, and mealy; it ripens in the latter end of July, or beginning of August: one tree of this sort will be sufficient for a garden of the common size. The early damask, which is commonly called the Morocco plum, and which is middle-sized, and the flesh good; it ripens about the beginning of August, or sometimes a little later. The little black damask, which is a rich fruit, a good bearer, and becomes ripe about the latter end of August, or there-

abouts. The great damask violet of Tours, which is a fine rich plum of a blueish colour, and becomes ripe in August. The red Orleans, which is large, of a rich juice, and becomes ripe in the latter end of August. The Fotheringham, which is an excellent plum, of a dark red, and the juice rich; there is hardly any plum that excels it, according to the opinion of some. The blue perdrigon, which is of a very good taste, and ripens in August. The white perdrigon, which is a pretty good fruit, and has a sweetish taste mixed with tartness; it ripens in the beginning of September. The red imperial, or red bonum magnum, which is a great bearer, and mostly used for baking; it is ripe about the latter end of September. The white imperial bonum magnum, or egg, white Holland, or Mogul, which is a large fruit, and, like the red, mostly used for baking; it is a great bearer, and ripens about the beginning of October. The la royale, which is a fine plum, equal to the green gage, but a shy bearer; it is of a red colour, and ripens in the latter end of September. The little queen Claudia, or Dauphiny, which is a small rich fruit, becoming ripe in September. The large queen Claudia, or Dauphiny, which is an excellent plum, of a yellowish-green, and ripens about the beginning of October. The green gage, which is of an exquisite taste, and eats like a sweetmeat; its colour and size sufficiently distinguish it from any other; it ripens in August and September; it has several sub-varieties, all of which are of good qualities. The drap d'or, which is a good plum, and a plentiful bearer; it is ripe about the latter end of September. The Chester, which is rich, and a great bearer; it is ripe about the latter end of September. The apricot, which is large and sweet, is ripe in the beginning of October. The maître Claud, which is a large round whitish plum; the juice is very brisk, though sweet; it is accounted among the best white plums that we have, and ripens about the beginning of October. The myrobalanus, or cherry plum, which is a middle-sized sweet fruit, and ripens about the beginning of September: this plum is frequently planted for ornament, as it blossoms early. The la Mirabelle, which is of an amber colour, and small, but full of juice, and excellent for sweetmeats; it bears well, and becomes ripe about the beginning of September. The Brignole, which is esteemed the best plum of any for sweetmeats; the flesh is dry, but of a rich flavour; it is ripe about the latter end of September. The red diaper, which is large, and of a very high flavour; it ripens about the beginning of September. The Saint Catharine, which is one of the best, and is much used for confectionary; it is also very good for the table, having a rich sweet juice; and is a good bearer, hanging the longest of any upon the tree. Mr. Forsyth says he has had them in gathering six weeks; it ripens about the latter end of September. The imperatrice, or empress, which has an agreeable flavour, and ripens about the middle of October; it is one of the latest plums, and should not be gathered till it begins to shrivel; it will then eat like a sweetmeat; and make a great addition to the table in the latter end of October and beginning of November. Monsieur's, or the Wentworth, which is a large fruit, resembling the bonum magnum; it ripens about the beginning of October, and is good for preserving, but too sharp to be eaten raw. The winefour, or Yorkshire, which is one of the best for preserving; it is ripe in October. The damson, of which a fine large sort from Shropshire, raised from suckers or stones, is an abundant bearer, of a rich flavour, and good for baking or preserving; it ripens in the latter end of September, and continues till near the latter end of October to be good and fit for use.

To these Mr. Forsyth adds the following list: the admirable,

PRUNUS.

rable, the black damascene, the black pear, the blue matchless, the damas noir de Tours, the Don Carloses, the double-flowered, the early blue primordian, the early red primordian, the early amber, the early Tours or precoce de Tours, the early violet, the early Orleans, the fine early plum, the jacinthe or hyacinth, the Koa's imperial, the la prune Suisse, the la prune valeur Valentia, the matchless, the maugeron, the muscle, the Persian, the red queen mother, the royal pea, the royal dauphin, the St. Julian, the femina, the small white damascene, the Spanish damascene, the striped-leaved, the true prune, the verte-dock or verdock, the whitton or nutmeg, the white bullace, the white Orleans, the white pear, the white perdrigon.

The following sorts are recommended by the same writer as proper for a small garden; the jaunhative, the early damask, the Orleans, the la royale, the green gage in different sorts, the drap d'or, the Saint Catharine, and imperatrice; the magnum bonum for baking; and the winefour for preserving.

The second sort varies with black and white, or rather wax-coloured fruit; and also with a red, bitter, unpleasent fruit.

There are many varieties of the third sort; but the following are the most commonly cultivated, according to Mr. Forsyth: the masculine, which is a small roundish fruit; it is the earliest of all the apricots, ripening about the latter end of July; and is chiefly esteemed for its tart taste; when fully ripe, it is of a red colour towards the sun, and of a greenish-yellow on the other side. The orange, which is pretty large, but rather dry and insipid, and fitter for tarts than for the table; it is of a deep yellow colour when ripe, which is about the latter end of August; this is considered as the best for preserving. The Algiers, which is a flatted oval-shaped fruit, of a straw colour, juicy, and high-flavoured; it ripens about the middle of August. The Roman, which is larger than the Algiers, rounder, of a deep yellow, and not quite so juicy; it is ripe about the middle or latter end of August. The Turkey, which is larger, and of a deeper colour than the Roman; its shape more globular, and the flesh firmer and drier; it ripens about the latter end of August. The Breda, (brought from thence to England,) which is originally from Africa; it is large, round, and of a deep yellow colour; the flesh is soft and juicy; it is an excellent fruit, especially if ripened on a standard, becoming ripe about the latter end of August. The Brussels, which is held in very great esteem, on account of its bearing so well on standards, or large dwarfs; it is of a middling size, red towards the sun, with many dark spots; and of a greenish-yellow on the other side; it has a brisk flavour, is not liable to be mealy or doughy, and is preferred by many to the Breda; but when the Breda is planted as a standard, the fruit is more juicy and of a richer flavour; it ripens in August on a wall, but not before the latter end of September on standards. The Moor-park, called also Anson's, Temple's, and Dunmore's Breda, which is a fine fruit, and ripens about the latter end of August. The fruit of the peach kind, which was introduced from Paris, by his grace the duke of Northumberland, at Sion-house, in 1767, is the finest and largest of all apricots, and is generally thought to be the same as the Moor-park; but upon a minute examination, the leaves will be found to differ; it ripens in August. The black, which has been very lately introduced by sir Joseph Banks from France, in which country it is highly esteemed. It is observed, that the trees that sir Joseph planted in his gardens at Spring Grove, near Hounslow, bore fruit last season (1792) for the first time in this country; but, in consequence of the

wet and unfavourable weather, it did not arrive at perfection. It ripens about the second week in August. To the above, Mr. Forsyth has added the following; the great apricot, the Holland apricot, the Provence apricot, the alberge, the angoumoise, the blotch-leaved, the Nancy apricot, which has a fine large fruit; the Dutch apricot, the Grover's Breda, the Persian, the royal orange, the transparent, the Portugal apricot, which has a small fruit.

The following are advised as proper for small gardens, in order to have regular successions of fruit. The masculine, the Roman, the orange, the Breda, and the Moor-park.

Of the fourth sort the varieties are numerous; but the following are those most in cultivation, according to the above author; the small May cherry, which is the first ripe, and requires a good wall; one or two trees of this kind may be sufficient for a large garden; it is ripe in June. The May duke, which comes in about the same time as the former, but is larger; it is an excellent cherry, and bears well against a wall. The archduke, which, if permitted to ripen properly, is an excellent cherry; it becomes ripe in June and July. The Hertfordshire cherry, which is a sort of heart, but firmer and of a finer flavour than hearts in general; it does not ripen till the latter end of July or beginning of August, which renders it the more valuable, as it succeeds more early cherries. The bleeding heart, or Gascoign's, which is a very large cherry of a long form, and dark colour; it has a pleasant taste, and ripens in the latter end of July. The Harrison's heart, which is a fine cherry; it was introduced from the East Indies by governor Harrison, and first cultivated at his seat of Balls in Hertfordshire; some of the trees, Mr. Forsyth is informed, he presented to George I.; and they are at this time in a flourishing state, bearing fruit, in Kensington gardens; it is ripe in July and August. The black-heart, which is a fine cherry, but too well known to require any description. The Morello, or Milan, which is a very fine fruit when kept till the month of October, and makes a very great addition to the desert at that time of the year; it is the best cherry that we have for preserving, and for making cherry-brandy. The carnation, which takes its name from its colour, being red and white; it is a large round cherry, but not so sweet as the duke cherry; it ripens in the latter end of July. The yellow Spanish, which is of an oval shape and amber colour, and is a sweet pleasant fruit; it is ripe in August and September. The corone, or coron, which resembles the black-heart, and which is an excellent fruit, and a good bearer, ripening about the beginning of August. The lukeward, which comes in soon after the former, and is also a fine pleasant fruit, and a good bearer; it ripens in the beginning of August. The grassion, which is supposed by many to be the same with Harrison's heart; but, upon a close examination, Mr. Forsyth finds it to be a different cherry; its flesh is firmer and the stone flatter; it ripens in July and August. Ronalds's large black-heart, which was introduced into this country in the year 1794, from Circassia, is a fine large cherry, a great bearer, and valuable as a forcing sort; it is well worth cultivating, ripening in the beginning of July. The Frazer's black tartarian, which is a fine large fruit. The Frazer's white tartarian, which is white and transparent. These cherries are excellent bearers, but particularly the black kind; the fruit is of a fine brisk flavour, and they ripen early. The lundie gean, cultivated at lord viscount Duncan's, near Dundee, which is black, and almost as large as a black-heart cherry; Mr. Forsyth says, it is now common in the nurseries about Edinburgh; and that Messrs. Gray and Wear have had it for some years in their nursery at Brompton park. The transparent gean, which is a small
delicious

PRUNUS.

delicious fruit. To these the following list is subjoined; the amber heart; the black mazard; the Churchill's heart; the double-blossomed; the Flemish heart; the gros goblet; the Holman's duke; the Jeffrey's royal; the Kensington duke; the large Spanish cherry; the late large Morello; the Montmorency; the ox heart, the purple heart; the red heart; the Swedish black heart; the South's large black; the Spanish black; the Tradescant's; the Turkey heart; the weeping; the Wentworth heart; the white heart.

And the following are recommended as proper for a small garden. The May duke; the large duke cherry; the arch-duke cherry; the black heart; the Harrison's heart; the ox heart; the Turkey heart; and the Kensington duke cherry.

The only varieties raised by seeds from the fifth sort, are the black coroun, and the small wild cherry; of which there are two or three subvarieties, differing in the size and colour of the fruit. It is observed by the editor of Miller's Dictionary, that the wild cherries are proper to plant in parks, because they grow to a large size and make beautiful trees. In spring, when they are in flower, they are very ornamental; the fruit is good food for birds; and the wood is very useful for turners. These trees thrive in poor land better than most other sorts. The French often plant them for avenues to their houses, on poor land; they also cultivate them in their woods, to cut for hoops; and the stones are generally sown for raising stocks, to graft or bud other cherries upon, being of quicker growth and of longer duration. It is added, that the garden cherry grows only about fifteen or twenty feet high, whereas this attains forty or fifty feet in height, with a more erect and lofty head.

The sixth sort is commonly propagated in the nurseries as an ornamental tree or shrub, growing well in woods, groves, or fields, but not in a moist soil. It bears lopping, and suffers the grass to grow under it. It is sometimes called the cluster cherry tree.

Method of Culture in the Plum Kind.—It is obvious that all the varieties were first obtained by seed, or the stones of the fruit; and the approved kinds acquired in this manner were afterwards multiplied by grafting and budding, as they do not continue the same sorts from seed; for from the seed of one tree many different sorts may be produced, and probably none like the mother-tree, and very few that afford fruit worth eating: but when in possession of any approved sorts, they may be multiplied at pleasure, by ingrafting shoots or buds of them into any kind of plum-stocks. Of course the mode of increasing these trees is by grafting, budding, and occasionally by layers; but the two former are the most usual methods of practice.

The two first modes may be performed upon stocks of any sorts of the plum kind, which have been raised from the stones, sown in autumn in beds of good earth, about two inches deep; and when the plants are a year old, planted out in nursery rows two feet and a half asunder; when, after having from one to two or three years' growth, they are in a fit state for grafting or budding with the desired sorts; which is performed in the usual way, either low in the stock for dwarfs, or at several feet height for standards. See GRAFTING and INOCULATION.

These trees may be trained either as dwarf wall-trees, espaliers, or as standards and half standards.

When the first shoots from the graft or bud are one year old, those of the trees designed as dwarfs for walls, &c. should be headed down within five or six inches of the bottom, particularly the budded trees, in order to force out laterals from the lower eyes, so as to furnish a proper set of branches, proceeding regularly from the bottom of the tree,

to cover every part of the wall or espalier. With regard to the standards, their first shoots may either be suffered to run and branch in their own way, or headed to a few eyes, if it seem necessary, to force out lower laterals to give the head a more regular spreading form, afterwards letting them all take their own natural growth.

When the trees raised in either of these modes are from one to two or three years old, they are of a proper size for being finally planted out in the garden, or other proper place; though trees which are much older may be safely removed; but the younger they are planted where they are to remain, the sooner and more firmly they establish themselves, and form for bearing.

In the layer method, which is only practised occasionally, the business may be performed any time from November till March, choosing the last summer's shoots, and laying them down by *slit-laying*; when in one year they will be rooted, and must then be separated, and planted in nursery rows, being trained either for dwarf, or standards, as may be required.

And the double blossom, the striped varieties, and the stoneless kind, are all increased by budding or grafting upon any kinds of plum-stocks, either for dwarfs, or half or full standards.

The bullace kinds are capable of being increased by sowing the berries or stones an inch deep in a bed of common earth in autumn; but to continue the different varieties distinct, they must be increased by budding, grafting, or laying, as in the other sorts.

The proper season for planting all the sorts of these trees is any time, in open weather, from November until March. And trees of all the varieties will mostly succeed in any common soil, and open exposure; but some of the best sorts should always be put for walls and espaliers, those for walls generally having an east or west aspect, or even a south wall for some of the choicest sorts, and a few may also be planted against a north wall, to furnish late fruit: and those for espaliers may be planted round any of the open quarters, as also the standards.

The trees designed for walls and espaliers should be planted out at fifteen or eighteen feet distance; though where the walls, &c. are rather low, eighteen or twenty feet distance may be requisite, in order that, in default of a proper height of walling, there may be more scope to train the branches horizontally. But when the trees thus planted are quite young, as only of one year's shoot from the grafting or budding, they should in March be headed down, as above, to four or five eyes, to force out lower horizontals in the ensuing summer; which, according as they advance in length, should be trained horizontally at full length all summer, unless it be necessary to forward a further supply of lower branches as fast as possible; in which case the young shoots should be pinched off in May down to a few eyes, when each will throw out several lateral branches the same year, which should also be trained horizontally at full length during their summer's growth; and in the winter pruning, cutting out only any fore-right and back shoots, training in all the regular ones at full length; as the branches of these trees should be shortened only occasionally to procure wood to fill vacancies, as the branches always form fruit-spurs first towards their extreme parts, which would be destroyed by shortening: so that, after having shortened the first and second year's shoots occasionally, as above, and thereby procured a proper set of lower horizontals, to give the head its first form; the whole may then be trained in entire about four, five, or six inches asunder; and accordingly as the trees shoot, every summer training in a necessary supply of the regular shoots to fill the

PRUNUS.

the wall, &c. at the same time retrenching superfluities, and irregular and very rank luxuriant growths, training the supply of regular wood still at full length at the above distances; by which the trees will soon cover a large space, and the same unshortened branches continue bearing many years. See PRUNING.

The necessity of this sort of training is obvious from all the forts bearing principally upon spurs, half an inch or an inch long, arising from the sides of the branches, of from one or two to many years old, which, if shortened, would throw out a multiplicity of useless wood, and hardly any fruit-spurs.

All the forts of wall and espalier trees of this sort should be pruned twice every year, as in summer and winter, in order to retrench the superfluities of each year, and all fore-right and other irregular shoots, and bad wood, and to train in a necessary portion of young wood where wanted to fill vacancies, or to supply the place of decayed, worn-out, and other bad branches.

The standard trees should be trained as full standards and half standards, budding or grafting the former six feet high, and the latter only three or four; both kinds being worked low in the stock, training the first shoots to those heights for stems, then suffering them to branch and form heads: these may be planted out at from twenty to thirty feet distance, letting heads form naturally.

Mr. Forfyth advises, that in choosing the trees the same directions should be observed as for apricots. Clean straight plants, with single stems, should be employed, as those with two never make handsome trees on walls or standards, and the border should be managed as directed for apricots; digging the holes the same width and depth, and loosening the bottom: then fill up the holes with fine fresh loam, or the mould that was used the preceding year for melon and cucumber beds; being careful to keep the mould a proper height above the border, and the roots of the trees as near the surface as possible, spreading them horizontally. When there are any tap-roots, they should always, he says, be cut off, as should also the fine hairy roots, as they are liable to get mouldy and rot, and thereby bring on a putrefaction of the mould about the root of the tree. When the roots are not spread near the surface of the ground, it will, he says, prevent the sun and air from penetrating to them; and the fruit, of course, will not have so fine a flavour. He further advises that the stems of young plum-trees should never be cut when first planted, but be left till the buds begin to break, when they may be headed down to five or more eyes, always observing to leave an odd one for the leading shoot; always cutting sloping towards the wall, and as near to an eye as possible. Thus managed, the shoots will soon fill the wall with fine wood. When it is found that some of the shoots are too luxuriant, they may have the tops pinched off with the finger and thumb, as above, about the beginning of June in the first year after planting; by doing which plenty of wood may be obtained to fill the bottom of the wall. He adds, that a great deal depends on the first and second year's management of the trees.

With respect to the distance from each other at which plum-trees should be planted against a wall, it depends on the height of the wall. If the wall be ten feet high, which is the common height, they may be planted at eight yards distance from tree to tree; but if the wall be twelve feet high, or more, seven yards will be sufficient. For his part, he prefers a wall of ten or twelve feet, which will, he thinks, be found high enough, if the branches are trained horizontally; by which means the tree will be much more fruitful, and not grow so lux-

uriantly. He further adds, that by training an upright shoot on the plums, as directed for pears, fine kind shoots may be gotten from the sides. The leading shoot should be shortened, leaving it from one to two feet long, according to its strength. If the leading shoot be very strong, it may, he thinks, be topped twice in the summer, as for pears, and at the same time repeating the same every year till the wall is filled to the top. He would always recommend, where it is convenient, to allot one wall for plums and another for cherries, as they always thrive best by themselves, or when distinct.

As there will be plum-trees to spare, that were planted between pear-trees, when they begin to meet, these should be planted against another wall, or as dwarf standards. Those intended for standards should be prepared in the following manner. The year before they are to be planted they should be cut in the side-shoots at different lengths from one foot to three, according to the size of the trees; suffering them to grow rude all the summer, neither nailing in nor cutting the sides and fore-right shoots. And some time during the winter the ground round their roots should be opened, cutting in the strong ones, which will cause them to put forth fine young fibres; then filling in the earth. In the following autumn, or during the winter, the sooner the better, they should be transplanted out as standards. And in transplanting of the trees, especially large ones, he considers it to be of great consequence that they be placed in the same position (that is, having the same parts facing the same points of the compass) as formerly. If notice be taken when a tree is cut down, it will, he says, be found that three parts in four of the growth are on the north side. When it is intended to plant them against a wall, they should never be cut in the side shoots, but only the roots; by this method the trees will, he says, bear fruit the first year after transplanting, and there will be a great saving of time and money. He has often transplanted old plum-trees that have been headed down that have made very fine roots, which he has divided, and thereby obtained four or five trees from one, cutting them so as to form them into heads. "Some that were transplanted in 1798 were in full blossom in 1799, producing some fruit, and in 1800 bearing a full crop."

It is recommended further by the same author, that "the ground in the borders and quarters where fresh trees are to be planted should be well trenched, two spits deep at least, to give the roots room to run into the fresh-stirred ground." And he says, that when the trees are planted without stirring the mould they seldom thrive well.

He advises, that "when plum-trees are planted for standards in an orchard which is to be kept for grafts, they should be in rows at the distance of twenty yards from each other. If in the kitchen garden for standards, he would always recommend the planting of dwarfs." The tree may be trained up to have a stem of about three feet high, at the distance of seventeen yards. If the garden is laid out with cross-walks, or foot-paths, about three feet wide, the borders should be made six feet broad, planting the trees in the middle of them. "In the royal gardens at Kensington, which are very long and narrow, and where the winds are very hurtful, he has," he says, "planted two rows of apple-trees, intermixed with other fruit-trees, alternately, one row on each side of the middle walk (which runs the whole length of the garden), at the distance of seventeen yards from each other. He has also made cross-walks of three feet broad at the distance of seventy yards, with borders on each side six feet wide, having two rows of trees in each border, about twelve or fourteen feet asunder.

These

PRUNUS.

These dwarf-trees are very useful in breaking the force of high winds, and are at the same time of such a height, that a man standing on the ground may gather the fruit. As plum-trees may be planted in the same manner and for the same purpose as the above, he can have the quarters clear for crops for the kitchen, and a free air be admitted, which can never be had where espaliers are planted. Dwarf standards can," he says, "be kept to what size you please; they look much handsomer than espaliers, and produce a greater quantity of fruit."

In regard to the method of managing and restoring old decayed trees of this sort, he remarks, that he has restored "some of them which were so far decayed as to have only from one to two or three inches of bark left; they are now completely filled up with sound wood, with large heads, which at four years' growth filled a wall sixteen feet high, and are at this time full of fine fruit; some of the stems are several inches in circumference, bearing treble the crops produced by young trees that have been planted three times as long as they have been headed down. Where the trunks are become hollow, he always cuts out all the loose rotten parts, and also examines the roots, cutting off what is rotten, injured, or decayed. This method should," he says, "be pursued with all hollow and decayed trees; and, if properly executed, they may be so completely filled up, as scarcely to leave a mark behind, even where the wood is totally decayed. He has had shoots from trees of this sort which have been headed, that have grown upwards of seven feet long, and as large as a walking-stick, in one summer: this should never be suffered; but they should be pinched off with the finger and thumb, in the beginning of June, close to an eye or a bud, unless the wall be filled to the top; in which case they should never be cut while they continue to bear handsome fruit. Before they begin to cease from bearing, you must always," he says, "begin with shortening every other shoot, leaving them only from six inches to a foot long, and nail them in till the second year, taking care to rub off the superfluous and strong fore-right shoots: by that time they will begin to bear: then cut out the others that have done bearing: by this method you will," he thinks, "keep the trees in a flourishing state. When the branches are thus managed, they will frequently throw out small dugs, or fore-right shoots, about an inch or two long, which will flower next year. They should never be shortened till after the fruit is set, and become about the size of a large pea; by that time the leaves will have covered the fruit, and be able to protect it from the inclemency of the weather. You may now shorten these shoots close to the fruit, which will leave them from one to two inches long. This method he has practised with great success for several years. By leaving these short fore-right shoots, the fruit is," he says, "protected till it is out of danger of being killed by the frost, or stunted by the cold north and north-west winds that happen about the latter end of March and the beginning of April. The cold chilling rain and snow, which are also very injurious to the fruit, will be thrown off by the branches standing out from the trees. He by no means likes to see great spurs standing out from the wall; for they are always sure to be injured by the frost and cold winds. When the shoots are left naked, he has often seen the plums turn yellow, and drop after they have grown to a considerable size, from their being exposed to the cold frosty winds and rain. They should, therefore," he thinks, "in cold and frosty weather, be covered in the same manner as apricots. Plums are," he remarks, "more tender than any other sort of stone-fruit, owing to the flower-cup dropping sooner than that of

peaches, nectarines, &c. And they are very liable to decay after cutting off large limbs or branches, which always brings on the gum and canker, if it be left to nature to perform the cure. He would, therefore, recommend the application of the composition (in the same manner as directed for other sorts of fruit-trees,) to every shoot where the knife touches; as soon as the trees are cut and nailed." And with the intention of having the fruit large and fine, care must be taken to thin it where too thick; but that must not be done too soon, lest it should be pinched by the cold. The fruit ought to be of the size of a small marble, and well sheltered by the leaves, before any attempt is made to do this. He advises never to pull off the leaves that shelter the fruit, till it is full-grown and begins to turn. See AMYGDALUS.

In conclusion it is also observed, that "he has taken up several old trees from the walls, when they have grown too near each other, and planted them out as standards, at the same time shortening their branches to form handsome heads, which are now full of fine fruit." These hints and directions are highly deserving of attention, as being the result of much practical experience.

Method of Culture in the Apricot Kind.—These trees are increased by budding them upon any kind of plum-stocks, for which purpose they are raised from the stones of the fruit, sown in autumn in beds of light earth two inches deep; when they will come up the following spring, and in autumn or spring after be fit to plant out in nursery-rows; when in a year or two they will be fit to bud for dwarfs for walls, &c.; but for half standards and full standards they must have three, four, or five years' growth, and be trained up with stems from three or four to six feet high; though sometimes the budding for standards is performed low in the stock, and the first shoot trained up for a stem.

The operation of budding should be performed in August, being careful to procure shoots from which to take the buds from trees of the best sorts, performing the operation in the usual way. See INOCULATION.

The buds shoot in the following spring; at which time, before they begin to push, the stock should be headed down a little above the insertion of the bud; soon after which the buds will shoot and advance rapidly, and by autumn form a large shoot, and the trees are then proper for planting out for good, especially the dwarfs intended for wall-trees; or some may remain a year or two longer in the nursery, and be trained in a proper manner for planting against walls; and others for standards. But whether they remain in the nursery, or are planted out into the borders, the first shoot from the bud should, in the March following, be headed down to four or five eyes, to procure lower horizontal branches, as in the plum.

When those intended for wall-trees are of one year's growth with their first shoots or head entire, they are of a proper size for planting out finally where they are to remain. They may be planted out any time in open weather, from October until the beginning of March, choosing a south wall for the early and some other kinds, to come in forward; but as those exposed to the full south sun are apt to become soon mealy, it is proper to plant a principal supply against east and west walls.

Mr. Forfyth, however, thinks "the best time for planting apricots is in autumn, as soon as the leaf begins to fall. The person who goes to the nursery for the plants should," he says, "make choice of those which have the strongest and cleanest stems; and if he can procure such as have been headed down, (to use the phrase of the nurserymen,) of two

PRUNUS.

or three years' growth, they will bear and fill the walls much sooner than those which have not been so treated. He should make choice of trees with one stem; or, if they have two, one of them should be cut off; for by planting those with two stems the middle of the tree is left naked, and of course one-third of the wall remains uncovered." And though it is a practice with many to make choice of those with the smallest stems, he thinks they always make weaker shoots than the others.

These trees succeed in any common soil; they are usually planted in a range close along the wall, at eighteen feet distance, with their heads entire, which should be fastened either to the wall or to stout stakes, one to each tree, to preserve them steady until spring, when they must have their first pruning, &c.

Mr. Forfyth, however, directs, that "if the borders wherein the trees are to be planted be new, they should be made two feet and a half or three feet deep, of good light fresh loam;" and that, "if the trees are to be planted in old borders, where the earth has been injured by the roots of the former trees, it will be necessary to take out the old mould at least three feet deep, and four feet wide, filling up the hole with fresh loam, taking care to plant the trees about eight inches higher than the level of the old border, to allow for the sinking of the earth, that they may not be too deep in the ground."

After being planted, if the trees are only one year old with their first head from the bud entire, they should be headed down in the spring to four or five eyes, to force out branches below; after which the trees should have water in dry weather, and the shoots from all the remaining eyes should in summer be nailed up regularly to the wall at their full length; and if any fore-right or back shoots come out, they should be rubbed off, being careful to continue the regular shoots to the wall all summer and the following winter; and in spring each shoot should be shortened to about eight, ten, or twelve inches, according to their strength, leaving the lower ones on each side rather the longest; this pruning short being still necessary, in order to procure a further supply of lower branches, that every part of the wall may be occupied quite from the bottom; having particular attention to preserve nearly an equal number of branches arranging on each side of the tree, nailing them close to the wall horizontally, four, five, or six inches asunder. In the summer following, each horizontal branch will push out three or four, or more, new shoots, of which, if any rise fore-right and behind the branches, they should be rubbed off early in the season, nailing in all the regular side-shoots at full length during the summer, except it is necessary to pinch any particular shoot early to fill a vacancy. In the winter pruning, if there be any superfluities, or irregular growths left in summer, they should be cut out close, and all the regular-placed necessary shoots be shortened, though they should not now be pruned so short as in the two first years, only cutting each shoot according to its strength, from about eight or ten to fifteen or eighteen inches long: as the head of the tree is now tolerably well-formed, therefore pruning only so as to obtain a further supply of wood, and a production of fruit; for as these trees bear principally upon the year-old wood, it is proper to train in a general supply of young shoots, of each year, in every part; the same shoots producing at the same time both a crop of fruit and a supply of wood for next year's bearing. The annual supply of wood must always, however, be shortened in the winter pruning; for if left entire it would produce only some shoots near to the top, and leave the

bottom naked, so as in a few years the whole tree would become very thin of bearing-wood below, and bear only a little towards the extreme part of the branches. And as these trees bear also upon short spurs, arising upon the two years-old branches, it is proper to preserve them wherever they appear, only retrenching such as project considerably fore-right; leaving all those of one or two inches long, as the young shoots of one year's growth are the principal bearers: those produced one year bear fruit the next, and a general supply must be every year retained, and not shortened in summer, which would force out laterals from every eye, and spoil the shoots for next year's bearing; but in the winter pruning, a general shortening is necessary, according to the strength of the tree, and the situation and strength of the respective shoots, and the whole tree should then be regularly nailed to the wall.

Mr. Forfyth says, that "when the trees are planted, they should by no means be headed down till the month of April or May, when they begin to throw out fresh shoots: strong trees should be cut a foot from the ground; and those that are weak, about half that length. But in backward seasons, they should not be headed down so early; never until the buds are fairly broken: always observing to cut sloping towards the wall, and as near to an eye as possible, that the young leading shoots may cover the cut; which operation should be again performed in the next March or April: the shoots that are then thrown out must be trained horizontally, to cover the wall; the number of these to be left ought to be from three to six on each side, according to the strength of the main shoot; taking care to rub off with the finger and thumb the fore-right shoots all over the tree, except a few which may be wanted to fill up the wall, near the body of it: and in the second year the horizontal shoots must be shortened in the same manner, according to their growth; and so on every year, till the wall shall be completely covered from top to bottom."

He adds, that "it is a frequent practice with some gardeners, to head down the trees at the time of planting; which often proves fatal to them."

These trees must be pruned twice a-year, as in summer and winter.

In the summer pruning, the irregularity of the numerous shoots should be reformed, beginning in May or early in June, and rubbing or cutting off close all fore-right and back shoots, and all superfluities or very rude growths; retaining, however, in every part a full supply of the regular side-shoots, as succession-wood for the next year's bearing, training them in at full length, as above, to remain till the winter pruning; as it is of importance to leave more than a sufficiency of the well-placed shoots at this season, to have plenty in every part to choose from in the general winter pruning. See PRUNING.

In the winter pruning a general reform should be made in all the branches and shoots, retrenching all worn-out and old naked branches ill-furnished with bearing-wood; at the same time selecting and retaining, in every part, the best shoots for the next summer's bearing, cutting out close all the superfluous or unnecessary and ill-placed shoots, and reducing part of the former year's bearers and unfruitful old branches in every part of the tree, to make due room to train the necessary supply of young wood at proper distances; being careful in retrenching the old wood occasionally, to prune it down either to a young shoot, or to some convenient branch it supports, which is furnished with one or more such shoots, so as every branch may also terminate in a young shoot for its leader, cutting off all small shoots arising from the sides of the main ones, and letting the general supply

PRUNUS.

supply of young wood in every part be now shortened moderately, according to their strength: the smaller shoots may be cut to about eight or ten inches, the middling ones to twelve or fifteen, and the strong shoots to eighteen inches or two feet long, pruning them generally to a wood-bud, in order to obtain a shoot at the end for a leader. All dead wood, cankered parts, decayed spurs, and stumps should be cut out; and as soon as one tree is pruned, let it be directly nailed, which should be performed with great regularity, training all the branches, &c. horizontally, as straight and close to the wall as possible, at equal distances. See PRUNING.

When these trees are of a strong vigorous growth, the shoots should be left thicker or more abundant than in moderate shooting trees, shortening them less in proportion, that by dividing the sap among many and a greater extent of branches, the luxuriance may be restrained, as the more the strong young wood in a luxuriant tree is pruned, or the shoots shortened, the more vigorous the tree shoots, and produces little fruit. See AMYGDALUS.

The old trees should be well attended to in pruning, to continue them in a good fruitful state, by encouraging young wood in proper abundance; as by this care the trees not only more certainly produce crops, but the fruit generally ripens earlier, and has a peculiar richer vinous flavour. As these old trees are apt to run up naked below in the main branches, care should be taken, when young wood advances in these parts, as well as in all vacant spaces, to preserve it so as to continue all the parts of the tree, from bottom upwards, regularly furnished with bearing wood.

In respect to old decayed trees, Mr. Forsyth says, "it has been the general practice to train wall-trees in the form of a fan, which occasions the sap to rise too freely to the top, leaving the lower part almost naked; so that scarcely one quarter of the wall is covered with bearing wood." He says, that, "in that case, it will be necessary to cut down the whole of the tree as near to the place where it was budded as possible, always cutting it at an eye or a joint: if there should be any young shoots on the lower part of the tree, it will be proper to leave them, training them horizontally, which will check the flow of the sap, and thereby render them much more fruitful." He adds, that, "very frequently, when large branches have been cut off in a careless manner, and the wounds left to nature, the whole tree is infected with the gum and canker; which, if not checked, will in a short time totally ruin it: the best remedy in this case is," he thinks, "carefully to pare off the cankered part of the bark with a draw-knife, or other convenient instrument. You will frequently find the white inner bark infected, which must also be cut away, till no appearance of infection remains; this may be easily known by the brown or black spots, like dots made with a pen, of which not one must be suffered to remain: all the branches so cut and pared should," he says, "be immediately covered with the composition in a liquid state." And "as we sometimes see walls with all the trees infected, it will in that case be most prudent to cut every other tree, leaving the rest for a supply of fruit till those which are cut begin to bear; this will be in the second or third year. When trees are in a very bad condition, they should," he thinks, "be cut in a partial manner, taking off the worst branches first, particularly those in the middle of the tree, always cutting as near to the graft as possible; or every other branch may at first be taken out, leaving the rest to bear; by which means there will be a supply of fruit, while the other parts of the tree are renovating: it should be remembered, however, that all the cankered bark must

be cut off without loss of time; otherwise the new wood will be infected. Old trees thus headed down will," he says, "sometimes throw out very strong and vigorous shoots, which it may be necessary to top, as it will cause them to throw out side shoots, and soon fill up the wall with fine bearing wood; but they should never be suffered to have any fore-right spurs, except little dugs: the topping should be done in the beginning of June, which will cause the tree to produce fine bearing wood for the next year: those trees must be pruned in March following, shortening the shoots from fifteen to six inches, but according to their strength, always leaving the strongest shoots longest. And wherever the knife has been used, the composition must," he says, "be immediately applied."

It is also observed, that "after the fall of the leaf, it will be proper to unnailed the young shoots, leaving only a few to prevent the tree from being broken by the wind. By this method they will be more exposed to the sun and air, which will ripen and harden the wood much more speedily than if they be left nailed." He adds, that "he has a great dislike to autumnal pruning of fruit-trees, of all kinds of stone-fruit in particular; for by pruning at that season you seldom fail to bring on the canker: and no fruit-trees are more liable to this disease than the apricot: the reason is obvious,—the great acidity in these trees, the exposure of the wounds, and the dormant state of the sap, predispose to mortification; whereas, in spring, when the sap is beginning to flow, and will follow the knife, the lips will quickly grow: if the branches are small, a fresh bark and fresh wood will in one season completely cover the wound; but if large, a time proportionate to their size will be occupied: this process, however, is manifestly much accelerated by the application of the composition, which excludes the air and wet from the air and sap-vessels of the tree."

In regard to the standard trees, they sometimes in favourable seasons bear plentifully, particularly the Breda and Brussels apricot, either in half or full standards; the half standards are more out of the power of the winds and cold air.

These should be planted in a sheltered warm situation in the full sun, that they may have a greater chance of setting a good crop of fruit, and of ripening more effectually with a rich flavour: their culture is nearly the same as that of other standard fruit-trees: they require but little pruning, only just to reduce or retrench any very irregular growth or out-growing rambler, or occasionally to regulate confused crowding branches, and to cut out decayed wood; all which should be performed generally in winter.

Covering and protecting the Blossoms and young Fruit.—As trees of this kind planted against walls blossom very early, both blossom and young fruit are very liable to be injured by frosts and cutting blasts; it is therefore useful to afford occasional protection, in unfavourable seasons, to some of the forwardest and most valuable kinds, either with mats suspended over the trees, or twigs of evergreens stuck between the branches, beginning the covering as soon as the blossom begins to expand, and continuing it till the fruit is fairly set; the mats to be used only on nights and in bad weather, but the evergreens to remain constantly till all danger is past.

Mr. Forsyth remarks, that "in severe weather they ought to be covered before the flowers begin to expand; for he has often seen the blossoms drop off before they opened; and he asserts, that the best covering is old fish-nets, which should be put on three-fold; and if a few branches of dry fern are stuck in among the branches before

fore the nets are put on, they will assist greatly in breaking the force of the high winds." The common practice of covering with mats in the night, and taking them off in the day, by frequently exposing the trees to the cutting winds, does, he thinks, more harm than good. And the covering with branches of spruce-fir and yew, by being too close, he supposes, encourages a blight, and causes the leaves of the trees to curl, and the shoots to break very weak; whereas the nets admit a free circulation of the air, and at the same time break the force of the wind: when it happens to rain or snow in the fore part of the night, and freeze towards the morning, the drops are, he says, found hanging in icicles on the meshes, while the tree is almost dry; when the shoots become pretty long, and the leaves expand to cover the fruit, it will be necessary, he says, to keep the net clear from the tree, by placing forked sticks, from six inches to a foot long, between it and the wall: this will prevent the shoots and leaves from growing through the net; the forked end of the sticks should rest against the meshes of the net. See *AMYGDALUS*.

Thinning out the Fruit.—In some seasons these trees set many more fruit than can attain perfection; and as they sometimes are placed very close, or often in clusters, and sit close to the branches without any yielding footstalks, as in cherries, &c. they, in their advancing growth, must impoverish and thrust one another off; thinning becomes necessary, which in wall-trees particularly should not be omitted, and it is also proper occasionally in standards in some degree. This business should be begun when about the size of large cherries, &c. and should be done with great regularity, leaving the largest, fairest, and best situated to grow to maturity, mostly all singly, or at least never more than two at the same eye, but most commonly single in the large kinds. The fruit thinned off makes excellent tarts, and should always be saved for that purpose, and for which use they may be thinned by degrees, both in wall-trees and standards; but not in the former, so as to leave the superabundant fruit to grow large in any considerable degree, nor in great quantity, to rob the continuing crop of its proper nourishment; for this use they should always be gathered before they stone, or harden in the heart or middle.

Method of Forcing Apricots.—In this method the fruit is obtained much more early than in the natural way, and is effected by having the trees in hot-houses, or on hot-walls, or in bark hot-beds.

The proper trees for this purpose are the dwarfs, trained as wall or espalier trees, but sometimes as small low standards: they are mostly trained in the full ground till advanced to some degree of bearing, and then planted in the borders of the forcing-house and hot-wall, and trained in the manner of wall-trees, to a light open trellis; some also, as small dwarf standards, placed forward in the former, or occasionally in pots, and introduced in the same situation; in all of which, the trees, being well fresh-rooted in their places, are forced at the proper season by means either of fire-heat, or bark-bed, or sometimes both occasionally in forcing-houses, but in hot-walls mostly by the former; the forcing-houses and hot-walls have mostly flues for fire-heat, and sometimes the former have a pit for a bark-bed; but where this is not the case, the whole bottom space is formed of good earth, and the trees planted in are generally in assemblage with peaches, nectarines, plums, &c. as the same degree of heat is suitable to the whole.

The proper season to begin the work of forcing is principally in January, or early in the following month; when, or rather a little time before, the glasses are shut close; and at the proper time the fires made in the furnace moderately

every evening and morning, to heat the flues in a proper degree, to afford a moderate regular heat, to warm the internal air to a proper degree, which forwards the trees to early blossoming and fruiting; having fresh air moderately admitted in fine days, and more freely when there is a warm sun; being sometimes watered both in the earth and over the branches after the blossom is passed, and the fruit fairly set. See *FORCING-FRAME*, &c.

Culture in the Cherry Kind.—These are all increased by grafting, and budding them upon stocks of any of the cherry kind, raised from the stones of the fruit of any of the sorts; but for having larger-growing trees, for standards, walls, and espaliers, the most general stocks used are the wild black and red cherry, raised from the stones of the fruit; they, however, grow upon any sort of these stocks, and likewise take upon plums, though these stocks are not proper for general use; they are also capable of growing upon laurel-stocks; which, however, is only practised for curiosity, suffering a small part of the stock to grow up to shew the singularity of the two sorts growing upon the same root. All the varieties likewise take upon the bird-cherry stocks; but this should only be practised when it is required to dwarf any of them as much as possible; which, in this way, are proper to train for small dwarf trees, either to plant in pots, or in the open borders, and in pots for forcing, or to plant in the borders of a forcing-frame. See *FORCING-FRAME*.

But for general use, stocks either of any of the common cherry varieties; or, to have larger trees, the wild cherry-stocks, should be used, as being the freest shooters and of longest duration; though, in raising the stocks, it is from the stones of the fruit, which should be sown in autumn in beds of light earth, covering them near two inches deep; they come up in the spring, and in the autumn or spring following, if the plants are strong, plant them out in nursery rows two feet and a half asunder, to remain for grafting, &c. which, when about the size of a large goose-quill to that of a person's little finger, or little more, they are fit to work for dwarf trees; but for standards, they must have at least four years' growth, as they must be grafted at five or six feet height. And to have trees of more moderate growth either for walls, small standards, or dwarfs, the Morello and small May cherry stocks may be proper.

The grafting and budding of all the sorts is performed in the usual way, though the former is most proper for general practice, as they are not so liable to gum in the grafted part as in that of the budded trees. Though both methods may be occasionally used, and may be practised as the stocks occur in proper growth, &c. whip-grafting is the most proper, for the most part, in this method of raising them; the budding is performed in the common way; the grafting should be done in the spring, as February and March, and the budding in summer, as June or July; the dwarfs should be grafted or budded near the ground, and the half and full standards from three to six feet high; the grafted trees shoot the same year, and the budded ones the spring following.

When the first shoots from the graft or bud are a year old, those of the dwarf sorts for walls, &c. must be shortened down in March or beginning of April, to five, six, or eight inches long, according to their strength; to procure lateral shoots to form the head, and the standards may be shortened or left entire as the case requires. When wanted to form a spreading head, the first shoots should be shortened to force out lower branches; after this, the branches of the dwarfs and standards remain mostly at their full length; and while the trees continue in the nursery, those designed for walls, &c. should be trained to stakes, in a proper position, occa-

PRUNUS.

sionally pinching or pruning young shoots of the year early in summer, down to a few eyes or buds where necessary, in order to procure a production of lateral branches the same season, to train in for a further supply of young wood, to increase the expansion of the branches as soon as possible to continue entire.

When the trees have from one or two to five or six years' growth they are proper for being finally planted out; though, if planted when their heads are not more than two or three years old, they succeed much better than larger trees. Mr. Forsyth advises the same attention in choosing these trees, as for apricots, peaches, and nectarines, and that they should be headed down the first year.

The season for planting them out is any time in open weather, from the end of October or beginning of November till March.

The wall and espalier trees should be planted eighteen or twenty feet distant; and where the walls are tolerably high, a half, or a full standard may be planted in the spaces between the dwarfs, that while these cover the bottom and middle, the standards may cover the upper part of the wall.

When those planted against walls or espaliers were planted when only one year old from the grafting, &c. with the first shoot from the graft or bud entire, they should be pruned short in March or beginning of April, to furnish lateral branches; but if they were headed in the nursery, and horizontal branches obtained, they must not be shortened afterwards, except occasionally in particular shoots to fill a vacancy; as the fruit-spurs first rise towards the upper end of the branches, a general shortening would not only cut away the fruitful parts, but force out a great deal of useless wood. The necessary branches, arising every year after the first heading down, should be trained horizontally at full length, five or six inches asunder; and where wood is wanted some adjacent young shoot may be pinched in May or early in June, or shortened in the spring following, when it will push forth two or three laterals; being careful to retrench all fore-right and other irregular-placed shoots, and continue training the regular branches still at full length at equal distances, till they have filled the proper space of walling or espalier.

In these trees the bearing-wood does not want renewing annually, the same branches continuing bearing several years, and only want renewing with young wood occasionally, as any branch becomes barren or an ill bearer, except in the Morello, which generally bears the most abundantly in the year-old young wood; a general successional supply of each year's shoots should therefore be retained for successional bearers.

The trees in all the sorts should be pruned twice every year; a summer pruning being given early in the season, to retrench all the superfluous shoots soon after they are produced, likewise all fore-right and other ill-placed shoots, and rank wood, as soon as possible; and to pinch shoots where wood is wanted, so as there may be as little pruning as possible upon the older wood, which is apt to gum by much cutting; retaining, however, a general moderate supply of the regular placed shoots to choose from in the winter pruning, training the whole at full length; and in the winter pruning, examining the general branches, old and young, both in the former trained bearers, and the retained shoots of the preceding summer, retaining all the fruitful and regular placed former trained branches; and if, among these, any irregularity, disorderly or improper growths occur, the whole should be reformed by proper occasional pruning. In old trees, as well as others, it is proper to retrench any worn-out or declined naked branches, which are destitute of bear-

ing-wood, or fruitful spurs, and to cut out all decayed wood; retaining a plentiful succession of last summer's young wood, in proper places, where necessary, to supply the place of any unserviceable old wood now retrenched; and at the same time cutting out all superfluous, or over-abundant, and other unnecessary shoots reserved last summer, not now wanted, leaving only some well-placed ones, in any vacant spaces, or some in particular parts, to train in between the main branches, to be advancing for bearers, ready to supply any deficiency; and generally a terminal shoot to the general branches in all parts where the allotted space admits of extending them in proper regularity; accordingly as each tree is thus pruned and regulated, the general branches and shoots should be trained in regularity, and nailed to the wall, &c. about three, four, or five inches asunder, all at their full length, to the extent of their limited space.

Mr. Forsyth advises, in pruning these trees, never to shorten their shoots, as most of them produce the fruit at their extremities, the shortening or cutting off of which very frequently occasions the death of the shoot, at least of a great part of it. The branches, therefore, should be trained at full length. He has often seen the whole tree killed by injudicious pruning. Wherever the knife is applied, it is sure to bring on the gum, and afterwards the canker; which will inevitably kill the tree, he says, if no remedy be applied to the wounds.

The Morello, in particular, and the small early May cherry, bear both on the young wood of last summer, the fruit blossom-buds issuing immediately from the eyes of the shoots very abundantly, and upon small natural fruit-spurs arising on the two and three years' wood, and continuing on the older branches; but generally bear the most plentifully on the young wood: and, therefore, it is necessary, both in summer and winter pruning, to attend to this, and retain a general supply of the young shoots of each year, trained in plentifully in all parts of the tree in summer, of the most regular placed, as many as can be conveniently admitted with proper regularity; and in the winter pruning, making a general selection of the best well-placed shoots of last summer, to train in for successional bearers the ensuing season, cutting out the superabundant, with part of the naked former bearers occasionally, to make room for the young supply, leaving a terminal one to each mother branch, and thus train in the general branches and shoots horizontally, about three or four inches asunder at their natural length.

The standard cherry-trees should be planted twenty-one feet distance at least; but if for a whole orchard, twenty-four feet, or eight yards distant every way, will be requisite. The first shoots having been previously shortened in the nursery, if thought necessary to promote lower branches to form the head, plant them now with their heads entire, except just reducing any irregular growth, and suffer them to branch every way, and shoot in length as fast as they are able, not shortening any, and all the branches will soon form numerous fruit-spurs.

Little pruning is required for standard cherries, as too much use of the knife, in the larger wood particularly, causes them to gum and canker: all that is necessary is occasionally to retrench any very irregular growing branch, and all decayed wood.

In respect to old trees, Mr. Forsyth says, "he has headed down a great many cherry-trees, which were almost past bearing, and so eaten up with the gum and canker, that what few cherries they bore upon old cankered spurs were not fit to be sent to table;" and that "in the years 1790 and 1791 he cut, or headed down, fifty trees. The operation

PRUNUS.

operation was performed in the months of April and May, in each year. These trees made shoots from three to five feet the same summer, bore fine cherries the next year, and have continued to bear good crops ever since. To the above trees he applied the composition. At the same time he cut down twelve trees in the same row, but did not apply the composition: these twelve trees all died in the second and third years after. They now," he says, "gather more cherries from one tree where the composition was applied, than they did from the whole number formerly; being also much larger and finer fruit. When cherry-trees are very old, and much injured by large limbs having been cut off, (which will," he says, "infallibly bring on the canker and gum, and, if no remedy be applied, in a short time kill the trees,) or if there are great spurs left standing a foot perhaps from the wall, the best way to bring them to have fine heads, and to cover the wall, is to head them down as low as possible; taking care to leave some small shoots, if there be any; if not, leave a bud or two at the ends of some of the shoots. Sometimes you will have a great difficulty to find any buds. If that be the case, in the spring, before you mean to head the trees, make some incisions in the branches. This should be done on different branches, at the most convenient places for filling the wall with good wood. The size of the incisions should be from one to two inches, according to the largeness of the branches; observing to make them just above the joint where the buds should come out. If you cut just below a joint, the shoot will die as far as the next bud or joint, and of course injure the tree, if no remedy be applied." He adds, that "the time for performing this operation is in March, April, or May." But this method of making incisions is only recommended where there are no young shoots or buds, and when the tree is in the last stage of the canker. Where you have a few young shoots or buds, he advises to cut down the head as near to them as you can, and to take great care to cut out the canker, till you come to the sound bark. The canker makes its appearance in these trees in the same manner as in peaches and nectarines, and may be easily discovered by an attentive observer. "If any gum remains, it must be cut or scraped off; the best time for doing which is when it is moistened with rain: you can then scrape it off easily, without bruising the bark. This operation is very necessary; and if it be neglected, the disease will increase rapidly." And wherever the bark or branches have been cut off, the edges should be rounded, and the composition applied to them.

It is observed, that the general way of pruning these trees has been to leave great spurs, which continue to increase till they stand upwards of a foot from the wall, and become as thick as a man's arm; but it must be observed, that cutting off from year to year the shoots that are produced from the spurs, increases the canker, till large protuberances, like wens, are formed on the branches, becoming very unsightly; and these occasion them to produce only small and ill-flavoured fruit, at a great distance from each other. When this is the case, the method he pursues is to head the trees down, as before directed. And if the young shoots are properly trained, they will produce fruit the following year; and in the second year, produce more and finer fruit than a young tree that has been planted ten or twelve years. The same writer remarks, that it has been a general complaint, that heart cherries are bad bearers, when trained up as wall-trees; but by pruning them as duke cherries, he has brought them to bear in the same manner; that is, he leaves a great many fore-right shoots in summer, tucking them in with some small rods run across

under the adjoining branches, to keep them close to the wall, and prevent them from being broken by the wind, and from looking unsightly. He advises, never to make use of the knife in summer, if it be possible to avoid it, as the shoots die from the place where they are cut, leaving ugly dead stumps, which will infallibly bring on the canker. These shoots may be cut in the spring to about a couple of eyes, as duke cherries, which will form a number of flower buds.

Mr. Forsyth indeed well observes, that as cherries are a very considerable article of traffic in the London markets, and the markets of most towns throughout the kingdom, employing such a great number of people during the summer season in gathering, carrying to market, and selling them, the raising of them is certainly worth any gentleman's while, especially as the trees may be rendered ornamental, as well as profitable, by planting them in shrubberies, &c. Gentlemen of small fortunes, who are at a great expence with their gardens and plantations, may in a great measure reimburse themselves by selling their cherries, and other fruit, (for which there will be plenty of chapmen,) and thus enjoy, at an easy rate, the pleasures of a rational and useful recreation. And he adds, that in all parts of the country, there are persons employed in collecting fruit for the markets, and to hawk it about from place to place; and surely it is much better to sell it to them, than to let it rot on the ground, or be devoured by birds and insects.

It is advised, when cherry-trees begin to produce spurs, to cut out every other shoot, to make the tree throw out fresh wood. When that comes into a bearing state, which will be in the following year, to cut out the old branches that remain: by that method you will be able to keep the trees in a constant state of bearing, taking the same method as before directed with the fore-right shoots. And great care should be taken to rub off many of them in the month of May, leaving only such a number as you think will fill the tree. By so doing, your trees will continue in a fine healthy state, and not be in the least weakened by bearing a plentiful crop of fruit. The reason is obvious: the great exhalation which would be occasioned by the sun and air, in the common mode of pruning, is prevented, by the composition keeping in the sap which nourishes the branches and fruit. And further: he cut some trees, as directed above, more than twelve years ago, that are now in as good a state of bearing as they were the third year after the operation, and likely to continue so for many years. He states, that a row of dwarf cherry-trees, that stood against an old paling, with an old thorn hedge at the back of it, (which every year so infected them with a blight, accompanied by an immense number of caterpillars and other insects, that, even in a fine year, they could not gather eight baskets from the whole row,) became so fruitful, after the hedge and paling were removed, that they gathered forty-two pounds a-day for six successive weeks, besides what the birds, wasps, and flies destroyed. He mentions the fact to stimulate market-gardeners and farmers, who have large orchards and gardens, to exert themselves in trying every method, however unimportant it may at first appear, to improve and render them more fruitful; and concludes, that the duke and heart cherries from these trees were as fine as any that were produced from wall-trees. And as they are much more productive, he has been induced to take up many old renovated trees from the walls, and plant them out for dwarf standards, supplying their places with pears, plums, peaches, &c. And further: that in all old gardens and orchards throughout the kingdom, and particularly Kent, whence the London markets are chiefly supplied with cherries,

cherries, the greater part of the old trees will hardly bear fruit sufficient to pay the expence of gathering it; but if the above method of pruning, &c. were practised, the owner would soon find his account in it, and be amply repaid for his trouble: the fruit would be much finer, and he would have five times the quantity that the trees produce in their present condition; the trees would be more tightly, and always keep in a flourishing and bearing state. But when old standard cherry-trees become decayed and hollow, he would recommend heading them down, as directed for wall-trees and dwarfs; to scoop out all the rotten, loose, and decayed parts of the trunk, till you come to the solid wood, leaving the surface smooth; then use the composition.

Method of forcing of Cherries.—This sort of tree may likewise be forced by artificial heat, in houses, so as to obtain fruit at an early season, as in April and beginning of May. And for this purpose the earliest dukes and May cherry are the proper sorts, but principally the former; trained both in standards, of four, five, or six feet stems, to elevate the heads near the top-glasses of the forcing-house, which are generally pruned to a small compass for that purpose; and in dwarf standards, with short stems and low heads; both of which, for this use, should be such as are previously trained in the full ground, till the heads are of three, four, or five years' growth, or till they have commenced bearers in some tolerable degree. The forcing-houses for this use are of different constructions, according to circumstances, and the other purposes to which they are applied. They have proper flues for fire-heat, and mostly internal borders of good earth, either in the back part for the taller trees, and in the front for lower; or sometimes, where no internal bark-pit is made, for bark-bed heat: the forcing being effected wholly by fire, the whole bottom space is entirely formed into a bed of earth of proper depth, and the trees planted in it in rows from the back to the front, in some regular gradation, according to their height; sometimes with dwarfs planted between the taller standards, and towards the front; and occasionally with dwarf trees in pots. In this sort of forcing, a very slight degree of fire-heat is sufficient; therefore, when there are back flues, they need not be employed, only that in the front being used.

The author of the Scotch Forcing Gardener observes, that where the situation is dry, the bottom a kindly sand, gravel, or clay, and the soil a sandy loam to the depth of two feet; the border will require no other preparation than being well enriched with stable dung, and, if possible, a little marle, which ought to be trenched and well mixed twice or thrice during the summer before planting. But where it is wet, the bottom a cankering gravel or cold clay, and the soil either a poor sand, gravel, or stubborn clay, care must be taken to render them otherwise, by paving the border to the breadth of twelve or fourteen feet, running a drain in front to carry off the wet, and removing the bad, and bringing in good soil, so as to compose a rich sandy loam to the depth of thirty inches at the wall, and twenty-four in front, allowing three or four inches for settling. If a new building is erected for cherries, it is immaterial, he thinks, whether the building or border is completed first, (provided the latter has a sufficient time allowed for the mixing and incorporation of the soil,) as the front wall and flue stand on pillars, whose foundations ought to be at least six inches deeper (if the border is not paved) than the soil. He considers about the first of January to be a good time for planting; although a month sooner or later at this season is of little consequence, as there must be no fire-heat applied the first year. Having

provided the necessary number of healthy, well-rooted, maiden, or *one-year-trained* May dukes, (as experience shews that no other cherry deserves a place in a forcing-house,) let them be planted against the trellis at the distance of eight, nine, or ten feet, according as the length of the house will best divide; filling-in the pits with vegetable mould from decayed tree leaves, and settling all with a little water. Riders, with five or six feet boles, which have been trained two or three years against a wall, and have produced a crop or two, should be provided to fill the upper part of the trellis, where they will yield a few crops before the dwarfs require their removal. These will generally produce a few fruit the first, and be sure to produce a full crop the second year.

The surface of the border should be forked over once a year, and a little well rotted dung occasionally worked into it.

In respect to the trees, he observes, that the dwarfs or principals being the only ones intended ultimately to fill the trellis, the riders being planted solely for the purpose of obtaining a crop or two while those are making their wood and forming their fruit-spurs, and, by being checked by their removal, may not be expected to put forth much young wood while they remain there, it will be unnecessary in pruning to thin them out much, only let them be dressed regularly to the trellis, and (where not absolutely requisite) divesting them of any shoots they may make, paying respect to their fruit-spurs only; as when they have served this purpose they will be of no further use. He says, that after planting, the dwarfs, if maiden trees, should be headed down to two or three eyes, in order to make them put forth vigorous shoots, to furnish the trellis from the bottom: and, if they have been one year in training, the bottom branches should be laid well down, and the rest dressed in a regular manner to the trellis, using strings of fresh matting to tie with; and be careful to allow sufficient room in the ties, as much mischief is done to fruit, especially cherry-trees, which are so apt to gum, if not allowed a sufficiency of room in the shred, or tie, such as will at least admit another of the same size along with it.

As these trees are apt to gum, and the branches decay, from the slightest injury, it would be imprudent to train them horizontally; in which case, the loss of a branch is supplied with much more difficulty than when trained in the fan manner. This last method he therefore recommends. And when the tree has produced its shoots to the length of five or six inches, they should be gone over and thinned, so as to enable the operator to lay them in at about the distance often of twelve inches; pinching off any that are produced fore-right, and which are, from their appearance, not forming for fruit-spurs; and, as they advance, let them be neatly laid in, and divested of any laterals they may produce. If all has gone well, at the end of the first year they will have produced shoots from twelve to thirty inches long, which should then be shortened to about two-thirds of their length. In the second season they will shoot vigorously, and begin to form many fruit-spurs on the preceding year's wood, which must be encouraged, for the production of a few fruit the following year. The trees should be kept clear of all superfluous and lateral shoots, laying the leading ones at the distance of eight or nine inches; and, at the end of the season, shortening a few of the strongest alternately, so as to make them break their buds in the spring in a regular manner; as they will not require to be any more shortened. And in the third season, they will produce a few fruit, make fine spurs and moderate shoots; which as they advance to the riders, room should

PRUNUS.

should be given by lopping off their branches, or thinning away their foliage, so as to afford a free circulation of air and admission of sun. In the fourth season, they will produce a full crop of fruit; and often make such a progress towards the riders, that their presence becomes unnecessary; in which case, it will be advisable to sacrifice whatever fruit, or appearance thereof, there may be on them, to the encouragement of the principals. After the trees have filled their spaces, and have begun to produce plentiful crops of fruit, they will make little or no wood; and will require no further care, on the score of training, than to supply the place of any branch that from accident may die out or be destroyed. These trees, from their nature, bear very little artificial (especially fire) heat, on which account he would not advise the forcing of them too early, especially if there be no more than one compartment for their culture; since, in that case, there would not be a continued succession for the supply of the table, and furnishing a desert, till they came in on the open walls. He considers the first or middle of February to be an eligible time for the commencement of the forcing; but, in a new planted house, the third year ought to arrive before fire heat is applied. Were it not for the sake of other articles that may be placed or planted in the cherry-house, it would, he thinks, be better that the glasses were not put on the first season at all; but this is generally too great a sacrifice: however, if they are put on, a free circulation of fresh air, even in the night, ought to be encouraged. When, in the third year of planting, the trees have made good progress, plenty of fruit-spurs, and a reasonable hope of success is entertained, the glasses should be put on about the middle of January, plenty of air being admitted through the day, shutting them at night. On the first of February the fire may be lighted, which must be made so moderate, that, at eight at night, and eight in the morning, Fahrenheit's thermometer may not stand above 40° . In which condition it should be kept as near as possible till about the twentieth of the month; and then increased gradually to 45° : at which point endeavour to keep it till the fruit is fairly set. Afterwards increase the heat to 50° , but not more, till the stoning is over, and the fruit have begun their second swelling. Although, for the sake of the fruit, all danger is then past; yet, if too strong a fire heat is indulged in, it will have the tendency of drawing the shoots too weak: and therefore he would not advise that the air of the house, at the fore-mentioned hours, should ever pass 60° .

With regard to the admission of air, the house ought to be uncovered all the first season after planting: but, if this is not the case; and if, from the nature of what other plants are placed therein, it is imprudent to leave little air in the house in the night, it should be opened by sun-rise in the morning, having a large and free circulation all day, shutting it up at sun-set. However, when the month of May arrives, it ought, he thinks, to be entirely uncovered. In the second season, he advises, that the glasses be put on by the first of March, large portions of air being admitted, as directed above, and the glasses be removed by the first of August. From the commencement of the forcing, this article must be more particularly attended to; the first ten days after which, a very large share of air should be given, to prevent the buds from breaking too suddenly, and of consequence too weakly: besides, vegetation (in forcing) ought always to be brought on, as it were, by stealth: the juices flow more kindly; and the plant suffers the first impulse of reviving activity with more patience, than when

hurried on in a violent manner. But, after the buds begin to appear turgid, a more moderate quantity may be admitted; still having respect to the temperature of the house, and the prevention of frosty winds from hurting the bloom. At all events, advantage should be taken of sun-shine; which will allow a larger portion than at other times. Nevertheless, let no day pass (unless a severe frost) wherein less or more air is not admitted; and, in sun-shine, to the extent that the thermometer may not rise more than ten degrees above the fire-heat medium. After the crop is all gathered, if consistent with the welfare of the other articles contained in the house, the glasses should be removed, and the trees exposed to the weather till the next season.

When planted, the mould should be settled to the roots of the trees by a moderate watering; and if the house remain uncovered the first season, little attention, except in dry weather, will be required. Due attention should be paid the second year to keep the border in a moderately moist state, that the plants may grow freely; and when their growth is stopped for the season, withhold the water, that the wood may ripen perfectly before they are exposed to the weather. From the time the forcing is begun, plentiful waterings should be given to the border, until the bloom begins to open; and then in a moderate degree till the fruit is fairly set. After which, again increase the quantity till the fruit begins to colour; and then diminish the quantity by degrees till you entirely withhold it, which ought to be done sometimes previous to the fruit's being ripe. It is also observed, that washing with the hand-engine should commence with the day the fire is lighted; and, except from the time the bloom begins to appear till the fruit is fairly set, should be repeated thrice a week in the evening, and that with a considerable degree of force, till the fruit begins to ripen. And in the interval of washing, (*viz.* while in bloom, and till the fruit is set,) a little water should be poured on the flue every evening when the fire is at the strongest, which causes a fine agreeable steam to arise in the house, greatly to the benefit of the flowers and foliage. Soft and tempered water should be used at all times, and on all occasions.

With respect to the insects that infest the cherry-house, they are, the aphis, or green fly; the acarus, or red spider; the caterpillar, and the grub. The first, and least hurtful, is easily destroyed by a fumigation of tobacco; the second by the process of washing with the engine, which is indispensably necessary to the health and vigour of the trees. Therefore, when they begin to make their appearance at any time, the water, in the ordinary course of washing, should be thrown against the trees with greater force, making a point of beginning at the contrary end of the house each time; whereby, if you happen to miss any part the one way, you may strike it the other. The caterpillar and grub have given him more trouble than the preceding, or indeed any species of insect whatever; and, after trying a variety of prescriptions, being at much trouble and expence, he can venture to allure the reader, and the public, he has at last discovered a cure, which is as follows:

Take of soft soap, two pounds; flowers of sulphur, two pounds; leaf, or roll tobacco, one pound; nux vomica, two ounces; and oil of turpentine, a gill: boil them all together in eight gallons of soft or river water to six; and set the liquor aside for use. And any time in winter, at least a considerable time before the trees begin to vegetate, let them be all untied or unnailed from the trellis or wall; brush every part of the branches and buds clean with a soft

soft brush, such as is used for painting: make the liquor milk-warm; and, with a sponge, carefully anoint every part of the tree, trellis, &c. Dress the trees neatly to the trellis again; but use none of the old ties or shreds: and let this operation be repeated every winter. The first summer after anointing, there may be a few appear, whose eggs have, by being concealed, escaped the action of the liquor, which must be picked off, to prevent their breeding; but, if any, there will be very few, as it is of the most penetrating nature. But this liquor must on no account be used in summer, as it instantly destroys the foliage. Fruit-trees of all kinds should be anointed with this liquor every year; as it is equally destructive of every insect and their eggs which infest them.

In cultivating dwarf trees in pots or boxes, it is observed, that where there is an extensive variety of forcing, and a green-house or conservatory, cherries may not only be produced at an early season, but in a long succession, by removing the pots or boxes from one house to another. When there are twenty or thirty trees, they should be divided into four or five equal parts, to make as many successions; and be placed in equal rotation: first (in November or December) in the green-house, where they may remain till they are fairly set; then, in an early peach or vine-house, till they begin to colour; and lastly, in the pine or dry stove, to come to maturity. And a very rich compost, such as is used for cucumbers or melons, should be made use of, watering them frequently with the drainings of a dung-hill. They should also be washed or watered frequently over head with a hand-squirt or watering-pan; and be placed in the most airy situations.

The double-blossomed sort may likewise be increased by grafting or budding, as in the other varieties, upon any kind of cherry-stocks, and be trained both as dwarfs, half and full standards, to effect the greater variety in plantations and other places.

And the wild cherry is easily raised from seed, as the stones of the fruit; and any variety which affords large and fine fruit may be continued by grafting, &c. in which way it will bear sooner, for which a quantity of stones should be provided in autumn, when the fruit is dead ripe, and be sown in beds of light earth an inch and a half deep, when they will come up in the spring, and after having one or two years' growth may be planted out in nursery-rows, with their tops entire, training them up for standards, with stems six feet high, then letting them branch out above every way, to form heads.

They may be planted out as standards in orchards or any open grounds for the fruit, and in ornamental plantations of forest-trees, where they have a good effect.

The bird-cherry sorts may also be increased in the same manner, and likewise by layers, which will readily strike root, and be fit for planting out in one year. They will also grow well by cuttings planted in autumn.

And the last sort is capable of being raised by grafting, and sometimes by layers.

Method of Culture in the Laurel Kind.—These are readily increased by seed and cuttings: but as cuttings are the most expeditious mode, they are most commonly raised in that way.

In the first mode, the seeds should be sown in autumn, when ripe, in beds of light earth, near an inch deep, allowing them some protection in severe frosts in winter, either by hooping and matting the bed, or covering it with dry long litter; but suffering them to remain uncovered in mild weather. The plants come up in the spring, giving

occasional waterings in dry weather; and in the autumn or spring following, when the season is settled, planting them out in nursery-rows to remain two or three years, or till wanted.

The cuttings should be procured in August or September, in moist weather, from the same years' shoots, cutting them off from about eight, ten, twelve, or fifteen inches long, with about an inch of the old wood to the bottom of each, if possible, though this is not indispensably necessary: then strip off the leaves from the lower parts, and plant them in a shady border, in rows twelve inches asunder, planting each cutting half or two-thirds into the ground, giving water in dry weather, when those planted in August will be rooted the same year; and all in the following summer, shooting at top, perhaps a foot long, by the autumn; at which time, or in the spring after, they may be planted or bedded out in wide nursery-rows, to acquire strength, till wanted. In either of these methods the trees may be trained either bushy or of a shrub-like growth, or trimmed up to a single stem for standards.

These plants delight in a light loamy soil, which is not too moist.

The proper season for planting them out is in the early autumn, or spring, according to the soil. They are highly ornamental in clumps and plantations, in lawns, parks, or out-grounds.

Hedges are sometimes formed of the common laurel for ornament; but where this is practised, it should not be trimmed with garden-shears, which mangle and spoil the beauty of the large leaves: all necessary cutting should be performed with a knife, in order to preserve the leaves entire, so as to make a fine appearance.

PRURIGO, in *Medicine*, from *prurire*, to *itch*, seems to be nearly synonymous with *pruritus*, and to signify simply an *itching* sensation.

At present, however, it is commonly appropriated, after the example of Dr. Willan, to a state of disease in the skin, of which a *severe itching* is the principal characteristic, but which is also connected with an eruption of *pimples*, or *papule*. These pimples, however, as M. Long long ago remarked, are not numerous and conspicuous in proportion to the severity of the itching, but are sometimes few in number, and scarcely perceptible to the sight, while the itching is almost intolerable. "Pruritus enormes non semper densæ confertæque papulæ afferunt; paucæ vix aspectu notandæ occurrunt, quæ hominem convellant." (Long, de Morbis Cutaneis, cap. iii. art. 1. p. 2.) The papulæ are not very conspicuous, because they are of the same colour with the skin, slightly elevated, and somewhat flat; and it is only when much scratching or rubbing has been resorted to, for the relief of the itching, that they appear red and inflamed. They are less noticed, too, by an unpractised observer, on account of the appearance of a number of little dark scabs, which arrest his attention, as the most conspicuous marks of disease. These are small concretions of blood, and of a little serous fluid upon the points of those papulæ, which are excoriated by the action of the nails in scratching. These little dark scabs are, in fact, common to every eruption which is accompanied by excessive itching, where there is a papular, or even a small vesicular or pustular eruption; since they are the effect of the common operation of scratching to relieve that sensation; whence they occur in some varieties of lichen, and in scabies, or proper *itch*. With a view to the diagnosis, therefore, as the latter is a contagious disease, and the prurigo is not, an accurate examination of the *papula* in question will be requisite. In

PRURIGO.

one form of the *itch*, which has been called *scabies papuliformis*, (see SCABIES,) the resemblance of the eruption to prurigo is very considerable: but the pimples in the former are found, if carefully examined, to contain at their apex a minute portion of fluid, being in fact papuliform vesicles; they are also more acuminated, and are inflamed or red, independently of friction; and when recently abraded, they present a little shining point of humidity at their tops. The lichen is also a pimply disease, somewhat approximating to prurigo; but the pimples in lichen are acuminated and inflamed, seldom, if ever, containing any fluid, and terminating in a slight mealy desquamation; and the sensation accompanying it is often a tingling and heat, rather than mere itching: it is likewise more distinctly connected with indigestion than prurigo. See LICHEN.

The prurigo has been divided by Dr. Willan, in his classification of cutaneous diseases, into three species, (exclusive of several local forms of the disease,) to which he gave the trivial names *mitis*, *formicans*, and *senilis*. But the appearances on the skin are much the same in all cases, except as to the extent and quantity of the eruption; and the sensations differ chiefly in the degree of their severity, or in the combination of different species of irritating feelings with the itching. In young subjects of sanguine habit, the eruptions are less extensive, and the itching less severe, and the disorder is more manageable by medicine, yielding often, indeed, spontaneously with a change of season, or from slight modifications of diet: whence the epithet of *mild* (*mitis*) may be appropriated to such cases with sufficient accuracy. In persons advanced in years, universal prurigo, in a violent and unyielding degree, so as to render existence occasionally a burden, has been mentioned by medical writers, from Hippocrates downwards, as a disease of common occurrence; and the epithet *senilis*, as indicative of the period of life in which it occurs, and the severity and permanency of the malady, which that age implies, is sufficiently applicable. But, in the middle age, the disease occurs under every degree of violence; and, both in that and in the decline of life, the sensation of itching is, in some cases, combined with various other painful sensations, which aggravate the sufferings, diminish the rest, and disturb the functions of the patient. These sensations have been variously described as pricking, burning, creeping, stinging, piercing pains, such as the crawling and biting of insects, the piercing of sharp and heated points, &c. might produce. These sensations, as well as the itching, are greatly aggravated by the scratching and friction which they call for, as well as by the impression of heat, or of cool air, by the warmth of bed, of hot rooms, of the direct rays of the sun, or of a fire, and by violent exercise, and even by the exposure on undressing, or getting out of bed: they are aggravated too by internal stimulation, as by distending the stomach with food, but still more by the use of high-seasoned and strong viands, and of fermented and spirituous liquors. When the peculiar sensations, above described, are present, the epithet *formicans* is appropriated to the disease; but it may be doubted whether there is any real specific difference in these forms of the complaint.

The causes of prurigo are by no means always obvious. It is certainly often connected with that heated and irritable state of the habit, which is the result of a stimulant diet, especially in hot weather; and sometimes with other derangements of the digestive organs. In old age, however, this state of the habit seldom occurs in those affected with prurigo, and it is sometimes seen in middle age in persons of lean form, and unhealthy complexion, and in those who

are weakened by an insufficient supply of nourishment, loss of sleep, hard labour, or other sources of exhaustion.

The method of treatment, therefore, adopted for the varieties of the disease, is somewhat empirical, and often very unsuccessful. A continued use of the tepid bath is generally productive of alleviation, under all circumstances; though in the young and plethoric, it is apt to produce some increase of irritation at first. The bath of Harrogate is deemed still more efficacious, if employed with perseverance for some months, even in the most violent state of prurigo formicans; and sea-bathing has sometimes cured the disease. In the more inflammatory forms of the disease, the use of sulphur, in repeated small doses, combined with nitre or soda, contributes to diminish the cutaneous irritation, and is occasionally adequate to the removal of the disease. The sulphuric acid is also beneficial in some instances under the same circumstances; and the oxygenated muriatic acid, taken in doses of a drachm in a glass of water, is said to have effected a cure. (See Bateman's Practical Synopsis of Cutaneous Diseases, p. 19.) It is common to resort to a course of active purgation, with the view of evacuating from the habit some supposed morbid humour, which is imagined to make its way to the skin, and produce the eruption; but these purgatives appear to be actually injurious, if they are violent or often repeated. The same observation is still more decidedly applicable to the sudorific medicines that are sometimes recommended in these cases; for they seldom fail to aggravate both the eruption and the distressing sensations accompanying it. Antimonial medicines and alterative doses of mercury appear to be altogether inefficacious.

Where the eruption is so general, as is usual in these forms of prurigo, the use of local applications, whether lotions or ointments, can scarcely be resorted to; and those generally recommended, containing sulphur, hellebore, zinc, mercury, &c. are either possessed of little efficacy, or are productive of increased irritation, especially in the young and plethoric. As a temporary alleviation to the itching, in such patients, a lotion containing a considerable portion of the aqua ammoniæ acetatæ, or a little diluted spirit, has sometimes been found very beneficial. See Bateman, loc. cit.

In irritable and sanguine habits, much benefit is to be obtained by cutting off the sources of internal stimulation, *i. e.* by a careful regulation of the diet. The mere omission of wine, spirits, and fermented liquors, will sometimes occasion a cessation of the disease; and the substitution of a light and simple diet, for the strong and high-seasoned viands which are commonly used, affords a no less salutary influence. The use of whey, milk, and aqueous fluids, as drink, and of vegetable and farinaceous substances, with a little plain animal food, should be adhered to as the general regimen; and all condiments, spices, vinegar, pickles, and crude or undressed vegetables, should be avoided, as well as salted and dried meats: for all these articles have a tendency to heat the skin by sympathy with the irritated stomach, although the acids and raw vegetables are often recommended as *antiscorbutics*, in these cases, from a misinterpretation of the term *scurvy*. We have known several examples of the immediate influence of vinegar upon the skin, exciting heat and tingling very soon after it was swallowed; and Dr. Withering considered the fact so common, that he asks, "Who has not observed the full scarlet flush upon the face after eating herrings or vinegar, after drinking acetous beer or cyder?" See his Treatise on Scarlet Fever, p. 62.

When the prurigo occurs in persons much advanced in

years, or in those who are enfeebled in habit by any of the debilitating causes before-mentioned, the mode of treatment must be somewhat different. The diet, though it must be still unstimulating and void of heating qualities, should be nutritious, consisting of soups, broths, and plain animal food, jellies, and amylaceous substances. And in respect to medicine, the decoctions of sarsaparilla, cinchona, serpentaria, and other tonic vegetables, with or without the carbonate of soda, or the mineral acids, are sometimes serviceable. The warm bath, and especially the warm salt water bath, persevered in for a considerable time, affords considerable relief; and the application of a lotion, containing some active stimulant, as spirit of wine, the oxy muriate of mercury, &c. is productive of much alleviation to the distressing itching. These lotions cannot, however, be employed without exciting great irritation, where the surface is excoriated by the nails. In old people, this form of prurigo is occasionally accompanied with a great disposition to the propagation of pediculi, or body-lice, and the mercurial lotion is also useful in destroying these insects. (See PRURITIASIS.) They sometimes, however, pertinaciously continue to be produced, and aggravate the distress of the patient, notwithstanding the assiduous application of the wash. In the cases, such as we are now referring to, the popular system of purging and sweating, with a view to evacuate morbid humours, is still more unsuccessful than in the other class, as it conduces to the increase of debility, which is already too great.

Local Prurigo.—The sensation of *itching* is often very distressing in particular parts of the body, where the papular eruption, before described, does not appear, and it arises from various causes. In the *arm-pits* and *groin*, and other parts where there is a frequent attrition of surfaces, or a folding of the skin, it is occasioned by a slight inflammation, called *Intertrigo*; which see. When it affects the *pubes*, it is usually the result of the presence of morpiones, pediculi pubis, or crab-lice, which penetrate and adhere tenaciously to the skin, but which are speedily destroyed by a little common mercurial ointment, or by any essential oil or spirits of turpentine. A very troublesome itching sometimes occurs in the *urethra*, which in men is usually sympathetic of some disease about the neck of the bladder, or of the irritation of stone or gravel in that organ; but Dr. Hunter remarked, that it sometimes takes place in women without any obvious cause, and is curable by the use of a bougie. These, however, are not so frequently the objects of medical treatment as the distressing itching which affects the *pudendum* in females, and which becomes a serious malady; for the sensation is incessant and scarcely tolerable about the labia and os vaginæ, so that it is scarcely possible to refrain from perpetual attempts to obtain relief by friction, or by refrigerant lotions, or to mix in society; and sometimes even a degree of nymphomania has been the consequence of the local irritation. This formidable affection is most frequently about the period when the catamenia have finally ceased; but less degrees of it are occasionally connected with the irritation of ascarides in the rectum, and sometimes with leucorrhœa. There is generally a certain degree of inflammatory fulness about the labia in these cases, which being alleviated by refrigerant applications, the itching subsides. Simple cold water, or solutions of lead, or of the cooling salts, diluted vinegar, lime water, with calomel, or, which is the most efficacious of all, with the corrosive muriate of mercury, constitute the lotions which are usually resorted to, and certainly afford relief.

Somewhat analogous to this is the prurigo *pedicis*, or a

teazing itching about the anus, which affects men of advanced age, and especially those of sedentary habits, and that independently of ascarides in the bowel or of the piles. It generally arises from a slight inflammatory condition of the part, with some degree of increased and morbid secretion from its glands. It is sometimes also connected with a slight psoriasis of the scrotum, when the itching becomes permanent and severe, disturbing the patient night and day. The lotions, which afford much relief in the preceding affections, are inefficacious in this; but the citrine ointment, properly diluted, or the ointments of the red oxyd and white precipitate of mercury, afford much alleviation. High living and stimulant ingesta, are found very prejudicial. See Willan's Treatise on Cutaneous Diseases; and Bateman's Synopsis; also Heberden's Commentarii, cap. 76; Sennert. Pract. lib. v. part. iii. § 1. cap. 8; and Mercurialis de Morb. Curand. cap. 3.

PRURITUS, a sensation of the skin, which incites the desire of using friction to the part, and is popularly termed *itching*. It is apparently the result of a slight determination of the blood, not amounting to inflammation, to the vessels of the part affected, as from the bites of small insects, &c.; and sometimes it is so severe as to claim the character of a disease. See PRURIGO.

PRUSA, in *Geography*. See BURSA.

PRUSANA, a town of Lithuania; 36 miles N.E. of Brzesk.

PRUSATZ, a town of Bosnia; 36 miles S. of Banjaluka.

PRUSKAU. See PROSKAU.

PRUSSIA, a country of Europe, imperfectly known to the ancients, who mention various tribes that possessed it, and the amber that formed a considerable article of commerce; derives its name, as some say, from the Pruzzi, a Slavonic tribe; but, according to others, from the name of Russia, and the Slavonic word Po, signifying near or adjacent. It is bounded on the N. by Lithuania, the Baltic, Pomerania, and Mecklenburg, on the E. by Lithuania, on the S. by Saxony and Poland, and on the W. by the Baltic, Mecklenburg, Pomerania, Hildesheim, and several of the German states. But it is not easy to settle the fluctuating boundaries of this kingdom, or to ascertain the dominions which it may permanently comprehend. Besides the acquisition of Silesia, and a third part of Poland, its territories have undergone several alterations in the course of the late war, and now it is terminated, other changes will occur, upon which its extent must necessarily depend. Of the acquisitions made by Prussia, we may enumerate Hildesheim, Paderborn, Munster, Erfurt, Blankenhayn, Untergleichen, Eichsfeld, Muhlhausen, Nordhausen, Quedlinburg, Essen, Werden, Elten and Ihrford; and of its cessions we may mention Cleves, Gelders, and Moers, besides mutual cessions, which took place between Bavaria and Prussia in 1803. Exclusive of small detached territories, the kingdom of Prussia, according to the statement of Mr. Pinkerton, now extends from Hornburg and the river Oker in the country of Halberstadt, the farthest western connected district, to the river Memel, or about 600 miles. The breadth, from the southern limit of Silesia to Dantzick, exceeds 300 miles. On the E. and S., he says, Prussia now borders on the dominions of Russia and Austria, and the western limits adjoin to the bishopric of Hildesheim. Before the recent acquisitions in Poland, the number of Prussian subjects was only computed at 5,621,500, in a total extent of 56,414 square miles, that is, about 99 to the square mile. At present they probably amount to about eight millions; including

PRUSSIA.

ing the margraviate of Anspach and Bareuth, computed at 400,000; and the last acquisitions in Poland at 2,100,000 inhabitants. Prussia, however, has recently ceded the countries of Anspach and Bareuth to the French arrangements in Germany. It has also ceded Neufchatel and Vallengin, assigned, as an independent principality, to marshal Berthier. We have, however, more accurate statements from German writers. Krug (*Abriss der Neuesten Statistik des Preuss-Stock.* 1805) estimates the superficial extent of the contiguous provinces at 80,800 square miles, and that of the detached territories at 8,800. Hassel (*Statistischer Unvrifs,* 1805) gives the extent of the Prussian acquisitions in Poland, in 1793 and 1795, at 31,824 square miles. The original population of Prussia appears, from Tacitus and Pliny, to have consisted of the Peucini and Æstii, Gothic tribes bordering on the Venedi, who were Slavons. The amber of the Æstii, who seem to have been merely a tribe of the Peucini, continued to be celebrated in the time of Theodoric; but at what precise period these original inhabitants were expelled, or subdued, by the Slavonic tribes on the east, remains uncertain. It is sufficient to observe, that the Slavonic tribes, who extended widely over the north of Germany, after the old Gothic inhabitants migrated towards the fertile regions of the south, in consequence of the decline and fall of the Roman empire, were repelled by the knights of the Teutonic order in the 12th and following centuries, who destroyed great numbers of them, and in some measure restored the original Gothic population. Nevertheless, one-half of the Prussian population, as Pinkerton conceives, must still be considered as Slavonic; and to the former Pomeranians must now be added a numerous accession of Poles. One of the most singular features in the geography of these regions, during the middle ages, is the existence of Julin, a city of great extent and commerce on the right bank of the Oder in Pomerania, which was destroyed by Waldemar I., king of Denmark, so that the name hardly now exists in a place called Wollin. Farther to the east the Slavonic tribes on the Baltic continued Pagans to a late period; and the country was little known or visited, except by a species of crusaders, who went to assist the Teutonic knights in subduing the Saracens.

As a kingdom, Prussia is of recent origin; and being composed of several ancient states, its historical epochs and antiquities are complex. Without mentioning the smaller distant provinces, Prussia may be considered as comprehending four large divisions, *viz.* the electorate of Brandenburg, the kingdom of Prussia Proper, the large province of Silesia, and a third part of the ancient kingdom of Poland. The family which now rules these extensive domains was originally the electoral house of Brandenburg, which is derived from Thassilo, count of Hohenzollern, who lived about the ninth century. Brandenburg had been for some time chiefly possessed by Slavonic nations; but Sigefred, a Saxon count, who was appointed margrave A.D. 927, soon raised it to considerable distinction. In 1373 the emperor Charles IV. assigned Brandenburg to his second son Sigismund, who in 1415, being then emperor of Germany, sold this margravate and electorate to Frederic, burgrave of Nuremberg, for 400,000 ducats. Frederic, the ancestor of the present race, displayed considerable abilities. Joachim II., elector of Brandenburg, embraced the Lutheran religion in 1539, and this has ever since been the prevailing system of the state. John Sigismund became duke of Prussia in 1618. Frederic William, surnamed the great elector, succeeded his father in 1640; and in 1656 compelled the king of Poland to declare Prussia an independent state, as it had formerly been held of the Polish sovereigns. In 1688 he was suc-

ceeded by his son Frederic III., who, having supported the emperor in the contest for the Spanish succession, was by him declared king of Prussia, and proclaimed at Konigsberg on the 18th day of January 1701. Frederic William I. ascended the throne in 1713; and he was the father of that great prince Frederic II. who ascended the throne in 1740, and died in 1786, after a long and glorious reign, of which the most memorable event was the acquisition of Silesia from the house of Austria in 1742. The next important event was the completion of the Prussian acquisitions in Poland. (See POLAND.) The history of Prussia Proper will naturally occur under the article *TEUTONIC Knights*; and that of Silesia under *SILESIA*. Few ancient monuments are to be found in a country, where even a rude knowledge of the arts is comparatively so recent. Some Slavonic idols, cast in bronze, constitute almost the only pagan antiquities; and the castles and churches, erected after the introduction of the Christian religion, are not of sufficient importance to merit attention.

The following estimate of the Prussian population is compiled from the subdivisions of Hoeck, 1801;

Eastern Prussia	-	-	-	940,000
Western Prussia	-	-	-	521,625
Southern Prussia	-	-	-	1,100,000
New Eastern Prussia	-	-	-	700,000
A part of Poland incorporated with Silesia				74,000
Pomerania	-	-	-	472,957
Brandenburg	-	-	-	755,577
New Marck	-	-	-	279,584
Magdeburg	-	-	-	275,262
Halberstadt	-	-	-	111,875
Minden	-	-	-	67,952
Ravensburg	-	-	-	81,812
East Friseland	-	-	-	102,594
Cleves	-	-	-	100,000
Maers	-	-	-	17,000
Mark	-	-	-	121,984
Gelder	-	-	-	48,000
Tecklenburg	-	-	-	17,234
Lingen	-	-	-	23,432
Silesia	-	-	-	1,747,065
Anspach	-	-	-	215,256
Baireuth	-	-	-	205,440
Neufchatel and Valengin	-	-	-	42,500
				8,021,149

The same author, allowing for different territorial arrangements gained by Prussia, and other causes of augmentation that have occurred since the year 1801, reckoned the number of inhabitants at 9,500,000 in 1804. Hassel gives 9,856,000, and Krug 9,700,000. The rapid increase of population in the Prussian dominions must have rendered former accounts of the number of inhabitants in the principal towns very inaccurate. The annexed table exhibits a comparative statement of Mr. Pinkerton's estimates, with those of later German authors.

	According to Mr. P.		Hassel.		Krug.
Berlin	142,099	1803.	153,128	1803.	153,000
Breslaw	52,000	1803.	60,950	1803.	60,000
Warsaw	66,572	1801.	63,358	1803.	64,000

PRUSSIA.

Hassel reckons that of a population of 9,856,000 persons, 5,187,900 are Protestants, 4,352,000 Roman Catholics, the remaining 316,100 being Jews, Greeks, &c. And Krug, who computes the population at 9,700,000, reckons 4,800,000 Lutherans; so that the Protestants are considerably more numerous, not only than the Catholics, but than all the other sects put together. The Prussian army, according to Hoeck, amounts to 178,897 infantry, and 39,867 cavalry; forming, with artillery, &c. a total of 237,089. Another author says, that the army contains 224,144 men. Hoeck reckons the revenue at 36,000,000 dollars, or about 6,000,000/ sterling; and Hassel, who quotes him and many other writers upon the subject, computes it at from 38 to 40,000,000 dollars, or about 6½ millions.

The government of Prussia is absolute. Its military force we have already mentioned: at present it does not rank among the maritime powers. The manners of the Prussians are observed to be very different from those of the other Germans. Compared with the Saxons, who are a lively and contented people, they appear dull and gloomy, which some have ascribed in part to their military government. The ruling language of Prussia is the German. The literature of Prussia is of recent origin; nevertheless it may boast of Cluverius, an eminent geographer, Copernicus, so well known as an astronomer, Regiomontanus of Königsberg, Leibnitz, Wolfius, Ramler the poet, Nicolai, an original writer of romances, Busching, Humboldt, Klaproth, &c. &c. Prussia, however, has not yet produced any artists, painters, sculptors, or architects, of distinguished reputation. This country has several universities, such are those of Halle, which in 1802 had 634 students, of Erlangen, which in 1801 had 300 students, of Königsberg, which in 1802 had 300, and that of Frankfort on the Oder, which had 180. There is also a royal school at Posen.

The chief cities and towns of Prussia are Berlin, Königsberg, Breslaw, Warsaw, Dantzick, Brandenburg, Frankfort on the Oder, Potsdam, Magdeburg, Stettin, Elbing, Glogau, Hirschberg, and Schweidnitz; which see respectively. Although inland navigation has not been attended to in the degree which it deserves, and the most important canals are not remarkable for their extent; yet, by joining the Elbe, the Oder, and the Vistula, they form an uninterrupted line of navigation, of six or seven hundred miles in length; and the traffic upon them, though fettered by the difference of duties in different provinces, by extravagant tolls and other impediments, is nevertheless very considerable.

If we except the linens of Silesia, the manufactures of the Prussian dominions are of small importance. Yet for home consumption they afford glass, iron, brass, paper, and woollen cloth; and Frederic II. introduced a small manufacture of silk. The exports of Dantzick consist almost entirely of timber, corn, tallow, and such articles. Amber constitutes a monopoly of this country; but its commerce is become insignificant. Among the considerable exports may be reckoned excellent timber of all kinds, skins, leather, flax, and hemp; and the linens of Silesia are sent into Holland, and sold under the name of Dutch manufacture. In return Prussia receives wine, and other products of more southern and favoured countries. The exportation of amber amounts to near 200 tons annually. Brandenburg exports timber from Hamburg, to the amount of one million of dollars. In Silesia (in 1796) 40,603 persons were employed in the linen manufacture, and 13,540 in the woollen. Merd exports much timber to England.

The climate of the Prussian dominions is, upon the whole, cold and moist. That of *Brandenburg*, (which see,) the

whole of which is an extensive level of sand, and that of *Pomerania* (which see), may be regarded as less humid than that of Prussia proper, which, as Busching says, has about eight months of winter, the autumns being often deluged with rains. The northern part of *Poland*, which has fallen under the Prussian sceptre, abounds with forests and marshes, which cannot contribute to the salubrity of the air. The lower parts of *Silesia* (which see) are regarded as the most healthy and fertile provinces of the monarchy; but the southern and western parts of that duchy, bordering on elevated mountains, being covered with snow, are exposed, even in summer, to severe freezing gales. Prussia proper formerly abounded in woods, and is more fertile than Brandenburg; and this is also the case with respect to the immense plain of Prussian Poland. The soil of this latter territory is loamy and fertile. Prussia proper and the Polish provinces yield every kind of grain and esculent plant that can flourish under such a latitude. The soil of Prussia proper, however, is represented by Mr. Marshall as sandy and ill cultivated; nevertheless the peasants, though oppressed by heavy taxation, being free from the wanton extortions and capricious personal services exacted by the Polish aristocracy, displayed signs of comparative ease and prosperity. The soil being light, two oxen, or sometimes even a small horse and cow, are sufficient to draw the plough. The chief crop, according to this writer, was buck-wheat, which was found to be more profitable than barley; and this grain was generally cultivated, along with a few Swedish turnips, except in the vicinity of Dantzick, where abundance of manure assured plentiful crops of wheat.

The chief rivers of the Prussian dominions are the Elbe, the Spree, the Oder, the Vistula, the Pregel, and the Memel, forming, in part, the Prussian boundary on the east. The lakes of Prussia are numerous; especially those of the eastern part; among which may be enumerated the Spelding see; and to which class we may refer those inland sheets of water, called "Haffs," which are formed at their estuaries by the rivers Oder, Vistula, and Memel: such are that of the Oder, styled *Grass Haff*, that of the Vistula, or *Frisch Haff*, and that of the Memel, or *Curisch Haff*; which see respectively. The only mountains in the Prussian dominions are those of Silesia. (See *SUDETIC Chain*.) In the N.W. parts of Silesia are also detached mountains of considerable height, as the Spitzberg, and Gratzberg, the Ruheberg, the Georgenberg, and the Reichenbach. According to Fabri, the Silesian mountains yield some silver, tin, copper, and cobalt, with considerable quantities of calamine, lead, and iron; and there are quarries of marble, freestone, alabaster, slate, and potters' clay. Coal abounds near Schweidnitz. Woods and forests abound in Prussia proper, and in the recent Polish acquisitions. Towards Hungary, Silesia presents a continuation of thick forests, which conspire with the elevated mountains to form an impenetrable barrier.

The breeds of horses and cattle in Prussia are not deserving of particular mention, and few parts are adapted to afford any excellent breeds of sheep. The race of the urus, or large and ferocious wild cattle of Lithuania, which also appeared in Prussia proper, is almost extinct. Among the wild animals may be mentioned the marmot, a species of castor, the lynx, the bear, and the elk. In the Oder is sometimes found sturgeon of a large size. In the southern districts of Silesia were formerly mines of gold and silver, and mines of copper and lead still exist; and here are considerable founderies of iron. In the Silesian mountains are also found chryso-prase, agates, jaspers, and clear crystals of quartz, vulgarly called diamonds: coal occurs in various parts of Silesia, and the level districts present some good peat-moors. But the

most distinguished and peculiar production of Prussia is *amber*, (which see,) affording yearly to the royal revenue about 5000*l.* This is chiefly found on the Samland shore of the Baltic, near Pillau, on a neck of land formed by the Frisch Haff, which seems to have been the chief seat of this mineral from the earliest ages. Mention is made of an amber mine, in Prussia, 98 feet in depth, where the amber is found between two salbands of carbonated wood, and sometimes adherent. We ought not to omit mentioning salt, which is calculated to afford about 300,000*l.* yearly to the state. The salt springs at Halle are said to be the most productive in the known world. Silesia presents one spring of hot water at Warmbrun, near Hirschberg; and this is said to be the only mineral water worthy of notice in the Prussian dominions.

PRUSSIAN BLUE, in *Chemistry*, a colour used by artists and painters, of a fine blue. It is composed of prussiat of iron, and the earth precipitated from alum, or pure alumine.

Under the article *PRUSSIC Acid* we refer to the history of this substance. We shall here give the methods employed in the large way for manufacturing Prussian blue, as practised on the continent and in this country.

The first method employed to obtain Prussian blue, was first to calcine dried bullock's blood with potash, in a crucible at a red heat. The mixture was now poured into a quantity of water. During the heat, the animal substance afforded the prussic acid, which was caused by the potash forming the prussiat of potash. This compound dissolved in the water, constituted what was then called the Prussian lixivium. To this was added a mixture of sulphate of iron and sulphate of alumine, in a state of solution. The prussic acid takes the iron, while the potash combines with the sulphuric acid. The excess of alkali precipitates the alumine from the alum, which becomes mixed with the prussiat of iron, and forms the substance which, when separated from the liquid, washed and dried, forms a blue concrete mass, called Prussian blue. When an excess of sulphate of iron is used, the excess of alkali will precipitate the iron in the form of an oxyd, which soon becoming yellow, gives the mass a green colour, which arises from the yellow precipitate being mixed with the blue. In this case the addition of some acid will be necessary to take up the oxyd of iron, in order to produce the change from green to blue. The muriatic acid is generally employed. It is better, however, not to have to add an acid at this stage of the process, since it in common combines with the alumine which is essential in forming a body for the colour, as well as to dilute the colour.

It is now certain that the black oxyd of iron, which is that combined in green vitriol (sulphate of iron), does not form a perfect blue with prussic acid. The colour is at first green, and does not become blue but by exposure to the air, or by the addition of oxygen in some way or other. The oxyfulphate of iron, which in the state of solution is of a reddish-brown colour, contains the red oxyd of iron. When the prussiat of potash is added to this solution, a deep blue precipitate is instantly formed. Some mineral waters in the vicinity of coal-mines contain a great quantity of the oxyfulphate of iron, as well as some sulphate of alumine. Such a situation would be a desirable object for the manufacturer of Prussian blue.

A great variety of animal substances may be employed for producing the prussic acid besides blood. The horns, hoofs, and the refuse of the skins of animals, have all been employed with success for this purpose. The refuse leather of shoemakers and curriers might be used to good purpose.

PRUSSIAN Green. See *GREEN* and *PRUSSIC Acid*.

PRUSSIATS, in *Chemistry*, a class of salts formed by the prussic acid with the different alkalies, earths, and metallic oxyds. These with the latter are generally insoluble in water. Two of the earths form insoluble salts with the prussic acid; namely, yttria and zirconia. The only metallic prussiat which appears to be soluble, is that of mercury, exclusive of the metallic bases of the earths and alkalies.

For combinations of prussic acid, see the different bases, as potash, soda, iron, &c.

PRUSSIC ACID, a substance which possesses some of the properties of an acid in its combinations with earths, alkalies, and metallic oxyds, and has been classed among the acids. If, however, the doctrine of Lavoisier be correct, it is not entitled to be classed among these bodies, inasmuch as it has not been proved to contain oxygen.

This acid in its pure state is a liquid as clear as water, and extremely volatile. Its most conspicuous property is that of precipitating metallic oxyds of different colours. With oxyd of iron it forms a beautiful blue precipitate, and with the oxyd of copper it forms a pigment of an intense brown colour.

It was first discovered, in combination with potash, by a colour-maker of Berlin, of the name of Diesbach. He procured some alkali from Dippel, a celebrated chemist, for the purpose of precipitating the colouring matter from cochineal, with which alum and green vitriol were also dissolved. The alkali which he added for that purpose produced a beautiful blue precipitate. Dippel had been heating the alkali with some animal matter, for the purpose of obtaining an animal oil, for which he became celebrated. The prussic acid was formed and united to the alkali, which caused the blue precipitate in Diesbach's solution. Dippel afterwards made this blue precipitate for sale, which he kept a secret for some time. It was called Prussian blue, from the place of its discovery.

This substance, which became celebrated for its fine blue colour, was sold at a great price, and became a subject of research with other chemists. Dr. Woodward got some information of its preparation from Germany, and published an account of the process in the *Philosophical Transactions* for 1724. He recommended four ounces each of nitre and tartar to be projected into a red-hot crucible, for the purpose of procuring a tolerably pure potash; to this he added four ounces of dried bullock's blood, mixing them intimately. These were put into a covered crucible, and heated in a moderate red heat, till they ceased to give out smoke, keeping them at a low red heat for some time afterwards. The contents of the crucible were now thrown into four pounds of water, and boiled for some time. The clear liquor was now decanted, and fresh water boiled upon the residuum, for the purpose of extracting all the soluble matter. The separate clear washings being collected, the mass was evaporated to four pounds. He then dissolved one ounce of green vitriol, and eight ounces of alum, in four pounds of boiling water. He then mixed the above liquid with this solution, from which was precipitated a substance of a greenish-blue colour. To this was added muriatic acid, till the precipitate assumed a fine blue colour. This powder, being separated and dried, assumed the form of a hard blue substance, which was called Prussian blue.

It was soon found by other chemists, that almost any animal substance heated with an alkali, afforded a blue precipitate with iron. Geoffroy and Macquer conceived, that the alkali combined with the phlogiston of the animal substance, which it gave up to the iron, reducing it to its metallic form, from which they accounted for the blue colour.

PRUSSIC ACID.

The latter chemist found, that Prussian blue lost its colour by heat, leaving the iron in the state of red oxyd. He found also, that when Prussian blue was boiled with an alkali, it lost all its blue colour, and farther found, that the alkali had acquired the property of precipitating iron of a blue colour from a solution of that metal.

Little more was discovered relative to the prussic acid, till the researches made in it by the celebrated Scheele in 1782 and 1783.

The first new fact he observed in the combination of this acid with potash, which till this time had been called the phlogisticated alkali, was its losing the property of precipitating iron of a blue colour, by exposure to the air for some time. He rightly suspected, that the substance which combined with the alkali, giving it the property of producing the blue precipitate, was disengaged from the alkali by the carbonic acid of the atmosphere. To verify this conjecture, he exposed the alkali to carbonic acid gas, and soon found that it deprived the liquid of the property of producing the blue colour with iron. He further confirmed this opinion, by placing in the same vessel with the gas, over the liquid, a slip of paper which had been dipped into a solution of iron, and a little alkali dropped on the paper to precipitate some iron without leaving an excess of alkali. No sooner did the carbonic acid disengage the prussic acid, which becoming volatile, rose into the upper part of the vessel, than the paper began to assume a blue colour, arising from the volatile acid combining with the iron. That this effect was produced by the superior affinity of the carbonic acid for the alkali above the prussic acid, was proved by other acids having the property of disengaging the colouring matter.

This very ingenious experimenter, with a view to obtain the prussic acid in a separate state, mixed ten parts of Prussian blue in powder, with five parts of red oxyd of mercury, to which he added thirty parts of water. On boiling the mixture a few minutes, the blue colour disappeared, the liquid at the same time assuming a greenish-yellow colour. This liquid was separated by the filter, the residuum being washed with boiling water, and the washings added to the filtered liquid. In this process, the oxyd of mercury separated the iron in the state of red oxyd, and at the same time combined with the prussic acid, forming a soluble compound. This solution he now poured upon $2\frac{1}{2}$ parts of very clean iron filings, adding at the same time one part of strong sulphuric acid. The iron became oxydated by the mercury, and dissolved by the sulphuric acid, the mercury being reduced to its metallic form. The colouring matter of the Prussian blue was at the same time set free, and being volatile, was separated from the other substances by distillation with a gentle heat. The prussic acid he thus obtained in a liquid form. A small portion of sulphuric acid came over at the same time, which he afterwards separated by a second distillation from carbonate of lime.

By the distillation of Prussian blue, he was inclined to suppose that the colouring matter was a compound of ammonia and oil, but soon abandoned this idea, when he found it impracticable to form it of these constituents. Supposing, again, that it was a compound of ammonia and charcoal, he mixed charcoal and potash together in a crucible, and kept them in a red heat for some time. He then pushed to the bottom of the mass small pieces of sal ammoniac (muriate of ammonia.) As soon as the fumes of the salt had escaped, he poured the whole, while red-hot, into water. On examining the solution, he found that the colouring matter had been formed.

We are particularly indebted to Berthollet, for the true

analysis of prussic acid; he found that it was composed of hydrogen, azote, and carbon, forming a peculiar substance, so that although Scheele had reason to conclude it a compound of carbon and ammonia, Berthollet drew a very different conclusion, yet both agreed in its being formed of the same constituents.

The latter chemist found, that when oxymuriatic acid is mixed with prussic acid, the former loses its oxygen, assuming the form of common muriatic acid. The prussic acid, which takes the oxygen, becomes more odorous and volatile, and acquires the property of precipitating iron, not of a blue, but of a green colour. This he has denominated oxyprussic acid.

Scheele obtained the prussic acid in the form of colourless liquid. It had a strong smell, resembling peach blossom and bitter almonds. It has a sweetish acid taste, having an irritating effect upon the tongue and throat. It is said to be very poisonous. The deleterious effects of the bitter almond, and the kernels of several fruits, are said to arise from the presence of this acid.

The prussic acid has been obtained in a state of greater purity than that obtained by Scheele. For this discovery we are indebted to Gay Lussac. An account of his experiments is given in the *Annal. de Chim.* vol. lxxvii. p. 128.

He put the prussiate of mercury into a retort, and separated it in a similar way to that used by Scheele. He provided several receivers, with two necks each. The first, which was connected with the retort by one of its necks, contained a mixture of carbonate of lime and dry muriate of lime. The first was to take up any sulphuric acid which might come over, and the latter to arrest the progress of the water which might come over with the acid. The first receiver was connected with the second, that with a third, and so on to four. Each receiver was surrounded with a freezing mixture. A gentle heat being applied, the acid came over into the first receiver, where it became deprived of its water. The pure acid, which was highly volatile, was carried forwards to the next receiver, where it became condensed. When the freezing mixture was removed from the receiver containing the prussic acid, and a gentle heat applied, it passed over to the next receiver. The latter receiver, being similarly treated, caused it to pass to the next in succession, and so on to the last. By this means acid is obtained in a state of complete purity, and possesses the following properties.

It appears in the form of liquid, perfectly colourless. Its taste is first cooling, but afterwards acid and irritating; it boils at 79.7° of Fahrenheit. Its density at 44.6° Fahrenheit is .70583, water being 1. At 50° it supports 14 inches of mercury. At 68° , if it be exposed under any given volume of air, it increases the elastic volume five times, provided a sufficient quantity of the liquid be present. It becomes solid at -50° . If a drop of it be exposed at the end of a glass rod, the evaporation is so rapid that the drop freezes.

The prussic acid in its simple form is applied to no use. Its greater volatility may present some advantages in producing great cold. Combined with lime, and with potash and iron, it is employed as a sensible re-agent in detecting the presence of iron in mineral and other situations. It forms insoluble compounds with the metallic oxyds, and hence is of importance in chemical analysis. See *PRUSSIAN Blue*.

Blood appears to be the most proper substance for affording it, from the facility with which it may be obtained. The great nuisance attendant on the drying of blood may be obviated by distilling it, and burning the fetid fumes with the inflammable gas furnished at the same time. In this process a large quantity of carbonate of ammonia may be obtained. The residuum

in the retort is a shining black coal, which, when calcined with potash, will furnish the same quantity of prussic acid, which the blood would have furnished in any other state less dried.

This carbonaceous matter is pretty much the same, whether furnished from the blood or other parts of animals, perhaps with the exception of the bones.

In the large way, one hundred pounds of potash are put into a thick iron vessel, capable of bearing a brisk red heat for a length of time. The fire is to be raised till the potash is fused. Twenty-five pounds of the powdered coaly residuum above-mentioned, are now to be rapidly stirred into the fused potash. In half an hour twenty-five pounds more carbon must be added, treated as before, and at the end of a similar space of time, another twenty-five pounds. The mass is now to be constantly stirred, the heat being all the time sufficient to keep it in a soft and plastic state for several hours.

During the formation of the prussic acid, a reddish coloured flame appears upon the surface of the melted mass. The finishing of the process is marked by the flame changing from a red to a pale blueish tinge. At this period the mass is to be removed as speedily as possible into a large vessel of boiling water, and stirred, to promote the solution of the prussiat of potash. Let the dregs settle, and decant off the clear liquor. Add fresh water, and apply a boiling heat to dissolve what may remain, and decant the second liquor, and so on till the water ceases to have any considerable taste. The several decantations are now mixed together. If the liquor is not sufficiently clear, it must be filtered through flannel or linen.

The alum and green vitriol, which are now added to form the blue precipitate, are in very different proportions, from equal parts, to the proportions of two to one. The quantity of these mixed salts for the above quantity of prussiat of potash is about two hundred pounds. They are first dissolved in water and then added.

The precipitate of Prussian blue is immediately formed, and when it subsides the liquor is to be poured off. Boiling water is added from time to time, for the purpose of washing off the sulphate of potash. The pulpy mass of Prussian blue is now to be put into bags, and pressed. The mass is then exposed to the air to dry, and it assumes at the same time a deeper colour, and acquires a hard stony consistence, exhibiting a bright glossy fracture of a bronzy hue, but when ground for the use of painting, is a superb blue.

Lime and alkalies decompose Prussian acid, and hence destroy its colour, producing a dirty red. Soap which contains alkali has the same effect. See *Prussiat of Iron*, under IRON.

PRUTH, in *Geography*, a river of Poland, which rises in the S.W. part of the new kingdom of Galicia, on the borders of Hungary, passes through Moldavia, and joins the Danube near Renay in Bessarabia. In the year 1711, Peter the Great, in a war with the Turks, encamped his army on the banks of this river, not far from Jassy, in a situation so disadvantageous, that he seemed to have no hope but that of cutting his way through the enemy; with this resolution he retired to his tent, in an agony of despair, absolutely prohibiting any person from entering it under pain of death. At this important juncture, the principal officers, and the vice-chancellor Shaffirof, assembled in the presence of Catharine, and drew up certain preliminaries, in order to obtain a truce from the grand vizier. In consequence of this determination, plenipotentiaries were immediately dispatched, without the knowledge of Peter, to the grand vizier; and a peace obtained upon more reasonable

terms than could have been expected. This is called the "peace of Pruth."

PRUYM. See PRUM.

PRUYSEN DROOGTE, a rocky islet at the east entrance of the straits of Sunda. S. lat. $5^{\circ} 20'$. E. long. $106^{\circ} 48'$.

PRYCK-SPUR, in *Military Antiquities*, a sort of spur, which came into use about the time of the conquest, having only a single point, like the gaffle of a fighting cock. The knights of the three or four reigns succeeding the conquest used this kind of spur, after which the rouelle, or wheel-spur, came in fashion.

PRYGEE, in *Geography*, a town of Pegu; 38 miles N.E. of Perfain.

PRYK, a kind of service or tenure, and, according to Blount, signifies an old fashioned spur with one point only, which the tenant holding land by this tenure, was to find for the king. "Per servitium inveniendi unum equum, unum faccum, et unum pryk in Guerra Walliæ." 1 Ric. II. And in the time of king Henry VIII. light horsemen in war were called *prickers*, because they used such spurs or pryks, to make their horses go with speed.

PRYMISL, or PRSIBISLAW, in *Geography*, a town of Bohemia, in the circle of Czaclau; three miles E. of Deutsch Brod.

PRYNNE, WILLIAM, in *Biography*, a learned lawyer and antiquarian, celebrated as a leader among the Puritans in the reign of Charles I., was born at Swanwick, in Somersetshire, in the year 1600. He was educated in grammar learning at Bath, and afterwards entered at Oriel college in Oxford, where he remained till he had taken his bachelor's degree at about the age of 20. He then was entered at Lincoln's Inn for the study of the law, which he pursued with great assiduity, and became in process of time barrister, bencher, and reader of the society. By his attendance in early life on the lectures of Dr. John Preston, he became attached to the principles of Puritanism, and in 1627 he appeared as a writer. It was not, however, till the close of 1632, that he published an elaborate work, entitled "Hittorio-matrix," in which he inveighed very bitterly against theatrical exhibitions and public spectacles of all kinds. The book was regularly licensed; nevertheless, on account of some reflections against women actors, which were supposed to be levelled against the queen, who had taken a part in a pastoral performed at Somerset-house, he was prosecuted in the star-chamber, and sentenced to a fine of 5000*l.*; to be expelled the university of Oxford, and Lincoln's Inn; to be degraded and disabled to pursue the profession of the law; to stand twice in the pillory, losing an ear each time; and to remain a prisoner for life. This savage sentence, which may be taken as a sample of those cruel oppressions, that in a few years excited the people to overthrow the government which dealt in such barbarities, and brought the king himself to the block, was executed in all its rigour, chiefly at the instigation of Laud, who could never forgive Prynne's previous attacks on episcopacy, and who was steeled against every feeling of humanity. Prynne bore his sufferings like a man, supported by the consciousness of having acted in a good cause; and was so little daunted by the punishment inflicted upon him, that he continued in prison to send forth publications against prelacy. For one of these, entitled "News from Ipswich," he was again sentenced by the same court to be fined 5000*l.*, to lose the remainder of his ears in the pillory, and to be branded in both cheeks with the letters S.L., signifying "Schismatical Libeller." Such was the fate of an honest, though, perhaps, enthusiastical opposer of arbitrary power.

The

The sentence was put in execution in 1637, and he was sent for his imprisonment first to Caernarvon castle, and afterwards to the isle of Jersey. His spirit was not to be subdued by suffering; there was that elasticity in his mind, which was equal to the force of every blow, and it almost instantly recovered from the pressure. He continued to write till the meeting of the parliament of 1640, when he was chosen representative for Newport, in Cornwall, and by order of the house of commons was released. He entered London, with many other sufferers in the same cause, in a sort of triumphal procession, and presented a petition to the commons for damages against his prosecutors. He now became distinguished by his speeches and writings as an opposer of episcopacy, and when the impeachment of Laud was undertaken, he was appointed the chief manager. After the parliament had become victorious in the civil wars, he was appointed one of the visitors to the university of Oxford, and displayed great zeal for the establishment of Presbyterianism, but to his honour be it spoken, he used all his influence to promote an accommodation with the king. It was in his speech, in behalf of his majesty, that he affirmed, that in all his own services and sufferings in the cause, he had neither received redress nor reward, but that he had continued, at his own expence, to maintain by his writings the justice of the parliament's proceedings, to the conviction of great numbers at home and abroad. It is well known, by those who are acquainted with the history of that period, in what manner the army interfered to prevent an agreement with the king, and for his interference in behalf of his majesty, Prynne was with other members excluded and imprisoned. He afterwards became a bitter enemy of Cromwell and his party, the instant he saw in them enemies to the public liberties of his country; on this account he was, in 1650, thrown into prison without any particular cause being alleged in the warrant. He appealed to Magna Charta, and was liberated, and in the following year imprisoned at Taunton and Pendennis. He was still the industrious and ardent writer in the cause of liberty, civil and religious, and published between the years 1655 and 1660, no fewer than forty-six tracts. In the year 1659 he resumed his place in the house of commons, and wearied out by the tyranny of the protectorate, he became one of the most eager for the restoration of Charles II., hoping, no doubt, that he might be bound by such rules of action, as should render him a patriotic monarch. In 1660 he sat in the *healing* parliament, as it was called, and was appointed to the office of chief keeper of the records in the Tower, for which he was undoubtedly well qualified. In the following year he printed a pamphlet on a bill then depending in parliament, which drew upon him the censure of the house of commons, and he was probably convinced of his error, for he submitted to ask pardon for the offence which he had done. His latter years he occupied in writings connected with his office in the Tower. He died in 1669. He was unquestionably a man of great learning, and the most indefatigable industry. It has been said he lived solely for the purposes of writing, and Wood supposes he must have written a sheet a day from his coming to man's estate till his death. His writings, however, were the effects of his public spirit and patriotism, and he lived, not to write, but to oppose tyranny wherever he found it, and writing was the instrument he made use of to effect his purposes. He was by his contemporaries, the moderate men of his time, as well as by the governments which he opposed, looked upon as a schismatic and libeller; but without such men, all that is excellent in our constitution would long since have been lost. Prynne,

therefore, merits the regards of posterity, and ought to be treated with the reverence to which every ardent friend of the liberties of the country has a claim. His works amounted to forty volumes folio or quarto. The most valuable are, his "Collection of Records," three vols. folio. His edition of "Sir Robert Cotton's Abridgment of the Tower Records;" and his "Observations on the fourth Part of Coke's Institutes." Biog. Brit. Hume.

PRYTANEUM, *πρυτανειον*, in *Antiquity*, a considerable building in Athens, where the council of prytanes assembled, and where those who had rendered any signal services to the commonwealth, were maintained at the public expence. See ATHIENS.

PRYTANIS, or PRYTANES, the first magistrate in most of the cities of Greece.

At Athens there were fifty prytanes, at Corinth there was but one, who was the same with what the archon was at Athens.

The prytanes of Athens were the senators who composed the grand council that governed the state; and correspond to what we now call *the states general of the United Provinces*.

Fifty of these were chosen each year out of each tribe; and to these were nominated fifty more, to supply the places of the former, in cases of death, or mal-administration.

The tribes took the government by turns, each after the other, for the space of thirty-five days. This was an establishment of Solon. Scaliger is mistaken, when he says the tribes took their turns every day.

All the fifty prytanes of the tribe did not govern together during those five weeks; but in companies, ten at a time, chosen by lot; seven days each company: after which another tribe came into office, and had its five weeks after the same manner.

PRYTANITIDES, a name given to those widows who at Athens, and throughout all Greece, had the sacred fire of Vesta committed to their care. The custom of the Greeks, in this respect, differed very much from that of the Romans; who allowed none but virgins to tend this sacred fire, whence they were called Vestals.

They had the appellation Prytanitides from *πρυτανειον*, a name common to all places sacred to Vesta.

PRZEDBORS, in *Geography*, a town of Poland, in the palatinate of Sandomirz; 20 miles N.N.W. of Malogocz.

PRZELAUTSCH, a town of Bohemia, in the circle of Chrudim, on the Elbe; 12 miles N.W. of Chrudim. N. lat. 49° 58'. E. long. 15° 30'.

PRZELOM, a town of Lithuania; 22 miles N.N.W. of Grodno.

PRZEMENTZ, a town of the duchy of Warfaw; 32 miles S.W. of Posen.

PRZEMILOV, a town of Bohemia, in the circle of Chrudim; 6 miles S. of Chrudim.

PRZEMISLAU, a town of Austrian Poland, in Galicia; 20 miles E.S.E. of Lemberg.

PRZEMYSL, a town of Poland, in Austrian Galicia, defended by a castle, the see of a Greek and Roman bishop; 4 miles W. of Lemberg. N. lat. 49° 36'. E. long. 22° 45'.

PRZEROL, a town of Lithuania; 8 miles W.S.W. of Troki.

PRZEROW. See PRERAU.

PRZESTITZ, a town of Bohemia, in the circle of Pilsen; 6 miles S. of Pilsen. N. lat. 49° 33'. E. long. 13° 26'.

PRZEWAL,

PRZEWAŁ, a town of Austrian Poland, in Galicia; 38 miles E. of Chelm.

PRZEZERSKE, a town of Prussia, in the province of Pomerelia; 9 miles N. of Culm.

PRZEZLAU, a town of Austrian Poland, in Galicia; 44 miles S.W. of Sandomirz.

PRZIBOR. See FREYBERG.

PRZIBRAM, a town of Bohemia, in the circle of Beraun; 17 miles S. of Beraun. N. lat. $49^{\circ} 42'$. E. long. $15^{\circ} 5'$.

PRZINDA. See FRAUENBURG.

PRZIPCOWIUS, SAMUEL, in *Biography*, an eminent Polish knight, was born about the year 1592. He was initiated in the elements of learning in his native country, and commenced his academical course of studies at the university of Altdorf. Here he probably embraced the Unitarian doctrine, which obliged him to retire to Holland, and he pursued his studies at the university of Leyden. When he was only eighteen years of age he published anonymously "Dissertatio de Pace et Concordia Ecclesiae," which was so ably written, as to be ascribed to the pen of Episcopus. Having spent some years at Leyden, in the cultivation of science and learning, he returned to Poland, where his talents recommended him to the notice and confidence of king Uladislaus Sigismund. He was appointed to fill different posts of honour and authority; rendering his name illustrious by his valour in the field, and his wisdom in the cabinet; by his persuasive eloquence and invincible fortitude, and at the same time he was eminent for his distinguished virtues. In his leisure moments he drew up a panegyric on Uladislaus Sigismund, king of Poland, in which he extolled that prince's clemency to the Dissidents, and pointed out the important advantages which the country derived from it. Under his administration, the followers of Socinus met with wonderful success in propagating their opinions, and establishing churches in the Polish territories. Their flourishing state induced Przypcovius to compose "A History of the Unitarian Churches in Poland," but the work was lost during the storm of persecution in which they were afterwards involved.

In 1648 he experienced a sad reverse of fortune, on the breaking out of the war with the Cossacks, who plundered and laid waste the country, particularly the districts bordering on the Borysthene or Dnieper, where the possessions of Przypcovius were chiefly situated. This was soon followed by the calamities in which the Unitarians partook, in common with the rest of their countrymen, during the civil wars which overspread Poland, in which the Austrians, Muscovites, and Swedes took part, as auxiliaries, with the contending factions. After peace was restored to the country, our author and his Unitarian brethren were harassed by the incessant persecutions of the popish party, till at length, in the year 1658, a general proscription was passed against them. By this act they were, for ever, banished from their country, being allowed a year in which they might dispose of their property. Means were, however, found to deprive them of the benefit of this pretended indulgence, and the greater part of them were entirely stripped of their honours and estates, in which number was Przypcovius. After he had become an exile from his country, the reputation of his virtues and learning procured him an asylum with the elector of Brandenburg, who gave him the honourable appointment of privy-counsellor. With the salary which he derived from this office he maintained some families of his fellow sufferers in his own house, cheerfully submitting to privations, that he might be able to afford more relief to his persecuted brethren, and making no provision for the widow of his

only son, and his two grand-children by her, but trusting that a kind Providence would raise them up protectors and friends. On account of his acquaintance with theological subjects, his skill and long experience in the management of business, and because his name was in great repute among foreigners, a synod of Unitarians, held in Silesia in 1663, devolved on him the office of maintaining a correspondence with their brethren in other nations, with a view of promoting the interests and increase of the whole community. He died in 1670, at the age of 78. Besides the pieces already noticed, Przypcovius was author of "Cogitationes sacrae ad initium Matthæi et Epistolas Apostolicas:" "Vita Fausti Socini Senensis:" "Demonstratio quod neque Pater Domini nostri Jesu Christi per Metaphorem Pater, neque Filius ejus unigenitus per eandem Metaphorem Filius, dici queat aut debeat," with other pieces. It may be right to mention here that the collection entitled "Bibliotheca Fratrum Polonorum," is not complete without the works of Przypcovius.

PRZITICK, in *Geography*, a town of Poland, in the palatinate of Sandomirz; 16 miles N.W. of Radom.

PRZLARG, a town of Prussia, in Oberland; seven miles W.S.W. of Soldau.

PRZYPIECKZ, or PRYPIEC, a river that rises on the borders of Austrian Poland, and after crossing Russian Lithuania from W. to E., runs into the Dnieper, about forty miles above Kiev.

PSADURIA, in *Mineralogy*, a genus of rough stones of a plain uniform structure, not laminated, but splitting equally in all directions.

PSAGDA. See SAGDA.

PSALM, ψαλμῶν, formed from ψαλλω, *I sing*, a divine song or hymn.

The denomination psalm is now appropriated to the one hundred and fifty psalms of David; and the name canticle, or song, is given to other pieces of the same kind, composed by other prophets and patriarchs.

The ancients, as is observed by St. Augustine, made this difference between a canticle, or song, and a psalm, that the former was sung by the voice alone, but the latter accompanied with a musical instrument.

The psalms, in the ancient editions, are divided into five books; nor is David's name found at the head of more than seventy-three of them; though some, and among the rest St. Augustine and St. Chrysostom, attribute all the hundred and fifty to him without exception.

The Jews, however, were always of another opinion; and it is certain there are some few, at least, that are not his. St. Jerome observed, among the number, several that were composed a long time after David. Dupin adds, that it is difficult to ascertain the authors; all we know of the book is, that it is a collection of songs compiled by Ezra.

Gradual psalms were those anciently sung on the steps of the temple. The *penitential* psalms were not formerly the same with those now called by that name.

The psalms of David exhibit to every reader the most plain and distinguishing marks of poetical writing; the peculiar character of which has been described under the articles PARALLELISM, HEBREW Poetry, and PROPHEPIC Poetry. The book of psalms contains specimens of the various kinds of poetical composition. To the didactic, we may refer the 119th, the other alphabetical psalms, and some few others; about a seventh part of this book consists of elegies, composed on occasions of distress and mourning; the 42d psalm, in particular, is in the highest degree tender and plaintive: and the reader of it in the original, who adverts to the division of the periods, and the resolution of them

them into their constituent parts or members, will find that the periods spontaneously divide into verses of nearly equal length and measure, exactly similar to those of the four first chapters of the Lamentations of Jeremiah, which constitute the established metre of the Hebrew elegy. (See LAMENTATIONS.) The whole of the 19th psalm consists also of the same kind of verse, except the epode, which contains two long verses of the same kind, and one shorter, which last is once repeated. The 43d psalm, too, seems to be constructed upon similar principles, containing eight of the same kind of verses, with the same epode, and since it is written in the same train of sentiment, the same style, and even apparently in the same metre, it ought not perhaps to be separated from the preceding psalm, but to be considered as a part or continuation of the same composition; and if this be true, the whole poem consists of three parts, almost equal and alike, each of which is concluded by the same intercalary period or stanza. For another most beautiful poem of the elegiac kind we refer to the lamentation of David for Saul and Jonathan; 2 Sam. i. 17—27. Moreover, the whole book of psalms may be considered as a collection of sacred odes; in which we find the ode exhibited in all the varieties of its form, and supported with the highest spirit of lyric poetry; sometimes sprightly, cheerful, and triumphant; sometimes solemn and magnificent; sometimes tender and soft. As the compositions of David are of the lyric kind, there is a greater variety of style and manner in his works than in those of Job and Isaiah. The manner in which David, considered merely as a poet, excels, is the pleasing, the soft, and the tender. In his psalms, there are many lofty and sublime passages; but in strength of description he yields to Job; in sublimity, to Isaiah. It is a sort of temperate grandeur, for which David is chiefly distinguished; and to this he always soon returns, when, upon some occasions, he rises above it. The psalms, in which he touches us most, are those in which he describes the happiness of the righteous, or the goodness of God; expresses the tender breathings of a devout mind, or sends up moving and affectionate supplications to heaven. For other specimens, we refer to the article ODE. For other psalms referred to the class of Idyllions, see IDYLLION. Blair's Lectures, vol. iii. Lowth's Lectures on Heb. Poet. by Gregory, vol. ii.

PSALMANAZAR, GEORGE, in *Biography*, a literary impostor who assumed that name, was probably a native of the south of France, though he never made known either his country or family. He was supposed to be born about 1680, and educated partly at a Franciscan seminary, then at a Jesuits college, and at last at a university. He seemed to have had an uncommon facility in the attainment of languages, but was not sufficiently steady to render himself tolerably perfect in any. At an early age he left the college, in order to support himself by private tuition. But this was not at all agreeable to his disposition, and he went to Avignon, where he pretended to have left his father's house on account of ill usage through his attachment to the Roman Catholic religion. He next assumed the character of a young Irish student of theology, who had left his country for the sake of religion, and was going on a pilgrimage to Rome; and having obtained a certificate, and equipped himself with a suitable garb, he set out on his rambles. After passing through several scenes he enlisted for a soldier, and became acquainted with one Innes, chaplain to a Scotch regiment. This man soon discovered Psalmanazar to be an impostor, but instead of exposing him, immediately conceived a plan of more extensive fraud, by which he himself might reap some profit. He

engaged the young man to act the part of a convert from heathenism, and having written a letter to Dr. Compton, bishop of London, with a flattering account of his pupil, he baptized him in a public manner, procured his discharge, and in consequence of the bishop's invitation, proceeded with him to London. The learned prelate listened to his story, while he endeavoured to pass for a native of the island of Formosa, of which little was known to Europeans. Innes set him about translating the church catechism into a pretended Formosan language, which he had framed, and he next employed him in writing a "History of Formosa." Though he had no other materials than what his own invention would furnish, aided by the account of Formosa by Varenus, he drew up such a work as excited the curiosity of the public, and was regarded, at that time, as containing genuine information; though in fact, when examined with a careful and scrutinizing eye, it was found full of inconsistencies and improbabilities. A second edition was preparing, when the bishop of London sent Psalmanazar to Oxford to pursue his studies in that seminary. He remained there six months, and then returned to London, but either his patrons distrusted him, or failed to put him in any suitable way of living, for in a few years he sold his name to a manufacturer of a kind of white porcelain, which was to pass as a secret communicated by Psalmanazar, and was advertised by the name of the "curious white Formosan work." He next endeavoured to get some money as a medical empiric, and as a teacher of languages and fortification; but these resources were inadequate to his wants, and he became clerk to a regiment of dragoons, which marched to the north in the year 1715, and in that character he visited many parts of the kingdom. Without following him through all the changes of this part of his life, it may be observed that he acknowledges himself to have been dissolute, unprincipled, and void of any fixed purpose. At length he obtained some steady employment as a translator, and it is said, that Law's Serious Call, with other devotional works falling into his hands, he was awakened to a sense of his past misconduct, and formed resolutions of amendment. He entered deeply into the study of the scriptures, and of the Hebrew language, in which he soon acquired such a proficiency that he composed a dramatic piece in Hebrew verse, entitled "David and Michael." His reputation for learning caused him to be engaged as one of the writers in the Universal History, which was his principal literary labour, and employed much of his time. The history of the Jews, of the Celtes, and Scythians, of the Greeks at the early periods, the ancient Spaniards, Gauls, and Germans, were the chief parts which he contributed to this voluminous work. It does not appear when he dropt the imposture of being a Formosan convert; but in his last will, dated 1752, there is an explicit and penitential confession of his criminality in adopting that fraud, and supporting it by his pretended account of the island. After his death, in 1763, his life, written by himself, was published, from which farther information may be obtained. See *Memoirs of the Life of* * * * * commonly known by the name of George Psalmanazar.

PSALMIST, in the *Church of Rome*, one of the lesser ecclesiastical orders, the same with what among us is called *clerk, precentor, or singer*.

PSALMODIER, *Fr.*, is, in the Romish church, reciting the psalms in a particular manner, between singing and speaking; it is singing or chanting, because the voice is sustained in musical tones; it is speaking, because the words are almost always uttered in the same tone.

PSALMODY,

PSALMODY, *ψαλμοδία*, the art of singing psalms.

PSALMODY, *Metrical*. The metrical psalmody, which John Hufs, Jerom of Prague, the Bohemian Brethren, and Martin Luther, published in the German language for the use of the common people, that priests might not be wanted, was soon imitated in other countries. The celebrated poet, Clement Marot, in France, having, about the year 1540, versified and dedicated to Francis I. about thirty of the psalms, from a prose translation by the famous Hebrew professor Vatable, they soon acquired such favour at court, as to be sung, in spite of the censures of the Sorbonne, by the king, queen, and chief personages of the kingdom, to the tunes of the most favourite songs of the times. Marot, who had long been suspected by the Catholics of heresy, and once thrown into prison for his religious opinions, fearing new persecution, flew to Geneva, where he put into French verse twenty more of the psalms. These, with the thirty that had been published at Paris, were printed at Geneva in 1543, with a preface by Calvin himself, but without music. Marot dying the next year, Theodore Beza versified the rest of the psalms in the same manner, and the whole hundred and fifty were published at Strasburg in 1545. Bayle says, that during the whole sixteenth century there was no French poetry, that approached the salt and natural grace of that with which Marot furnished it. And Menage says, that the French owe the *rondeau*, the *madrigal*, and modern form of the *sonnet*, to this poet, who first confined himself to the mixture of masculine and feminine rhymes, though he did not always strictly adhere to their alternate use, as a law. The sale of his fifty psalms was so rapid, that they could not be printed fast enough to supply the public demand for them; more than ten thousand copies having been sold in a very short time. When those of Beza were added to them, their favour still continued, and they were sung not only by the Lutherans and Calvinists, but the Roman Catholics. As yet, indeed, they had never been used in the conventicles of the sectarists, but in private, merely as moral and spiritual songs, to secular tunes, such as were easy to learn, and play on viols, and other instruments.

It was not till the year 1553, when these psalms appeared in the same book as the catechism of Calvin, and the Genevan Liturgy, that the Catholics took the alarm, and prohibited the further publication and use of them. After which, to sing a psalm in France was a declaration of heretical principles, and Psalmist became another name for Reformer, Huguenot, and Calvinist. Indeed, the purposes to which this lamentable music was often applied, during the struggles and growth of Calvinism, seems to have been worse than the music itself, as, according to writers of the opposite party, it was made the signal of tumult, sedition, sacrilege, and rebellion.

The chronology of Calvinistical psalmody seems to be this: Zwinglius, the chief of the Protestants in Switzerland, before the arrival of Calvin at Geneva, had introduced among them the same kind of metrical psalmody as John Hufs and the Bohemian brethren had recommended to their followers in Germany; and this seems to have been continued till the year 1543, when the psalms of Clement Marot, with a preface by Calvin himself, were first published at Geneva, with the single melodies of Guillaume Franc, an obscure musician, if such he may be called, whose name has never had admission in any catalogue of books, or been prefixed to any musical publication, that we have been able to discover.

Among the most celebrated composers of music to Calvinistical psalms, and spiritual songs, must be ranked Claude

Goudimel, a musician of Franche-Compté, who seems to have lost his life at Lyons on the day of the massacre of Paris. See GOUDIMEL, and CLAUDE LE JEUNE, of whose psalms we have three different editions of the music, in three different forms, and in different countries: for though, according to Bayle, they have never been sung in the church of Geneva, yet, in Holland, and in France, before the revocation of the edict of Nantes, as they were universally sung in Calvinistical churches and conventicles, except at Geneva, they went through more editions perhaps than any musical work since the invention of printing.

Claude le Jeune was doubtless a great master of harmony. The manner in which he first set twelve of the psalms of Clement Marot's French translation, in four and five parts, that were dedicated to the duke de Bouillon in 1598, at that time head of the French Huguenots, very much resembled the style in which our old masters used to write upon a plain song; as one of the parts is continually singing an ancient melody, or well-known psalm-tune, while the rest are descanting, or singing in florid counterpoint. In some of these there is great merit of composition in the ingenuity and contrivance of the several parts. See CLAUDE LE JEUNE.

The establishing metrical psalmody in England, was the consequence of the reformation, and our communication with foreign Protestants.

Several of the psalms were translated into English metre during the latter end of the reign of Henry VIII. by sir Thomas Wyatt, and printed in 1549. The earl of Surrey wrote a sonnet in their praise, and translated others himself; but both his version and that of Wyatt are lost. Indeed almost all our poets, good and bad, have attempted to translate, or rather versify, the psalms; but for want of success in this, as well as in writing original hymns, or sacred songs, Dr. Johnson has admirably accounted in his *Life of Waller*.

The first edition of Sternhold's fifty-one psalms, was likewise printed in 1549, and the second in 1553, but both impressions without musical notes; and in all probability, those that were not in possession of the tunes used by the German Protestants, applied to them such ballad airs as would best suit the metre; as had been done in France, when the version of Clement Marot was in favour at the court of Francis I. Sternhold lived to write a dedication, for the first edition of his psalms, to king Edward VI. following in this the example of Marot, who had dedicated his first thirty psalms to the king of France.

The entire version of the psalms, however, was not published till 1562, when it was tacked for the first time to the Common Prayer, under the following title: "The whole Booke of Psalmes collected into English metre by T. Sternhold, J. Hopkins, and others, conferred with the *Ebrue*, with apt notes to sing them withal." Imprinted by John Day.

There was no base or other part, but the mere tunes, in this edition; which tunes are chiefly German, and still used on the continent by Lutherans and Calvinists, as appears by collation: particularly the melodies set to the 12th, 14th, 113th, 124th, 127th, and 134th psalms.

PSALMODY *Island*. The Roman Catholics, in the first ages of Christianity, had their paroxysms of psalm-singing as well as the Protestants. St. Ambrose is not only said by St. Augustine to have brought from Greece the manner of singing the hymns, and chanting the psalms, which he established at Milan, and which was afterwards called the *Ambrosian chant*, but Eusebius tells us, that a regular choir and method of singing the service were first established,

and hymns used in the church, at Antioch, the capital of Syria, during the time of Constantine; and that St. Ambrose, who had long resided there, had his melodies thence. An order of monks was established there at a very early period of the Christian era, whose discipline obliged them to preserve in their monastery a perpetual psalmody, equally perennial with the vestal fire, or perpetual lamps of antiquity. Psalmody island, in the diocese of Nismes, had its name from a monastery founded by Corbilla, a Syrian monk of this order, about the end of the fourth century. This kind of psalmody is known in the monkish writers by the name of *laus perennis*; Gregory de Tours calls it *psalterium perpetuum*.

PSALMODY, *Parochial*. Singing of this kind among the reformers and schismatics, seems in all ages of our religion to have been the favourite mode of addressing the Divinity: for not only the Arians practised it in their processions, but the Albigenses, who may be called the first Protestant martyrs; and who, according to ecclesiastical writers, when Simon Montford, their persecutor, in 1210, had lighted a pile of wood for their destruction, precipitated themselves in the flames, to the number of a hundred and forty, singing psalms.

The disciples of Wickliffe, in England, during the fourteenth century, and those of John Hufs and Jerom of Prague, in the fifteenth, were psalm-fingers; and the hymn-book of the Picards, and Bohemian brethren, printed with musical notes at Ulm, 1538, shews that the melodies used by these sects, originated from the chants to which the ancient Latin hymns of the Romish church were sung. For in this book there are translations and imitations in German metre of most of the hymns and proses still used in the Romish church: such as the "Stabat Mater dolorosa;" "Te Deum laudamus;" "O lux beata Trinitas;" "Pange lingua gloriosi," &c. Some of these melodies, indeed, are in triple time, which never is the case in canto fermo, or cathedral psalmody. But "Stabat Mater," and "O lux," in this book, are set to old Romish chants, and "Te Deum" to the same that is inserted in the preface of Meibomius to the ancient Greek musical writers, as the most ancient melody which the church has preserved.

Among the first reformers who interested themselves about the manner of performing the psalms, we have not only Wickliffe, Hufs, Jerom of Prague, and Zuingle, but Luther, Cranmer, Calvin, Beza, Buchanan, and John Knox; who, though each of them had different ideas on the subject of sacred music, yet they agreed in stripping it of all the energy and embellishments of measure and melody, as indeed the Calvinists did likewise of harmony. Nor were the original institutes of psalmody more favourable to poetry than music; for by giving to each syllable, whether long or short, a note of the same length, all prosody, rhythm, and numerical cadence, are destroyed. And however beautiful the poetical measures may be to read, when sung in this drawling and isochronous manner, they not only afford the ear no pleasure, but become unintelligible.

That metrical psalmody, in slow notes of equal length, had its origin in Germany, and was brought thence by reformers to other parts of Europe, is demonstrable: for the 28th psalm, "Beati omnes quitiment Dominum," had been translated into German verse, in order to be sung in this manner, by John Hufs, in the beginning of the fifteenth century; which translation was afterwards modernized in the same measure, and to the same tune by Luther. And the same melody, which we sing to the 100th psalm, is not only given to the 134th in all the Lutheran psalm-books, but by Goudimel and Claude le Jeune, in those of the

Calvinists; which nearly amounts to a proof that this favourite melody was not produced in England. It is said to have been the opinion of Handel, that Luther himself was its author; but of this we have been able to procure no authentic proof. Tradition, however, gives to this celebrated heresiarch, as he is called by the Roman Catholics, several of the ancient melodies, which are still used in Germany.

PSALTER, *ψαλτηριον*, the book or collection of psalms, ascribed to David. See PSALM.

There is a multitude of editions of the psalter. Augustine Justinian, a Dominican and bishop of Nebo, published a Polyglot psalter at Genoa, 1516. And Contarinus published the psalter in Hebrew, Greek, Chaldee, and Arabic, with Latin notes and glosses.

PSALTER is also used among religious for a large chaplet or rosary, consisting of one hundred and fifty beads; the number of the psalms in the psalter.

St. Dominic is said to have been the inventor of this psalter.

PSALTERIUM, in *Anatomy*, or corpus psaloides; a part of the brain, between the two posterior crura of the fornix. See BRAIN.

PSALTERY, PSALTERION, also denotes a musical instrument much in use among the ancient Hebrews, who called it *nebel*.

We know but little of the precise form of the ancient psaltery. Kircher has taken pains to prove, that it was of a square form; and from an old book in the Vatican library he has exhibited a figure of it.

That now in use is a flat instrument; in form of a trapezium, or a triangle truncated at top.

It is strung with thirteen wire cords, set to unison or octave, and mounted on two bridges on the two sides. It is struck with a plectrum, or little iron rod, or sometimes with a crooked stick, whence it is usually ranked among the instruments of percussion.

Its chest, or body, is like that of a spinet. It has its name à *psallendo*; some call it *nablum*, or *nablum*.

Papius also gives the name psaltery to a kind of flute, used in churches to accompany the singing; called in Latin *sambucus*.

PSAMMISMUS, *ψαμμισμος*, formed from *ψαμμος*, *sand*, in *Medicine*, a term sometimes used for a bath of dry and warm sand, to set the feet of dropical persons upon.

PSAMMITICUS, in *Biography*, a king of Egypt, was the son of Ecus, who was put to death by Sabbaco on the conquest of Egypt. He avoided his father's fate by flying into Syria; and after the death of king Sethon, was one of the twelve lords who assumed the government of the country, and divided it between them. His part was the sea-coast, which being the least valuable, he was induced to cultivate commerce with the Phœnicians, Greeks, and other nations, by which he acquired wealth and foreign connections. His prosperity excited the envy of his colleagues, who made war upon him, but by the assistance of foreign mercenaries or allies, he proved superior to, and finally subdued them, and then made himself sole monarch of Egypt. This event is dated B. C. 670. He rewarded his allies with lands upon the Nile, and from this era a Grecian colony subsisted in Egypt, which maintained an intercourse with their countrymen, and rendered the transactions of that kingdom a part of genuine history. Psammiticus carried on war in Syria, where he besieged the city of Azotus, which resisted his arms for the space of twenty-nine years. The preference which he gave to foreign soldiers caused a defection of a great body of his own subjects, who marched away to the confines of Ethiopia, where

where they formed a settlement. To repair this loss, he attended still more assiduously to the advancement of commerce, and opened his ports to all strangers. He also renewed his alliances with the Athenians and other Greeks. After a long and prosperous reign of 54 years Psammiticus died, and was interred in the temple of Bubastis at Sais. He was founder of several magnificent edifices, and is said to have introduced the culture of the vine in Egypt, and to have sent an expedition for discovering the sources of the Nile. Univer. Hist.

PSATYRIANS, PSATYRIANI, in *Ecclesiastical History*, a sect of Arians, who, in the council of Antioch, held in the year 360, maintained that the Son was not like the Father, as to will; that he was taken from nothing, or made of nothing; and that in God, generation was not to be distinguished from creation.

PSEDDERSHEIM, in *Geography*, a town of France, in the department of Mont Tonnerre, and chief place of a canton, in the district of Spire. The place contains 1238, and the canton 13,066 inhabitants, in 24 communes.

PSEGMA, a name given by some of the ancients to the flos æris, or flowers of brass.

PSELAPHIA, a word used by the ancient medical writers to express friction with the hands, in cases where the distempered parts require it. This was always esteemed a part of the business of a physician, and was done with his own hand.

PSELLISMUS, in *Medicine*, from $\psi\epsilon\lambda\lambda\iota\zeta\omega$, *I stammer*, comprehends not only that species of faulty articulation which is commonly called *stammering*, but every other defect in the pronunciation of words. Dr. Cullen has enumerated seven species of psellismus, and Sauvages a still greater number. Those of the former are, 1. Psellismus hæsitans, when there is a difficulty in pronouncing the first syllable or word; the *battarismus* and *ischonophonia* of authors. 2. Psellismus ringens, in which the letter R is erroneously pronounced, being always aspirated, and as it were doubled; the *rottacismus* and *blasitas* of authors. 3. Psellismus lallans, or *lamdacismus*, when the letter L is improperly sounded, or used in the place of R. 4. Psellismus emolliens, when the harder letters are pronounced too soft, and the letter S is too much used; the *traulotes* of authors. 5. Psellismus balbutiens, when, in consequence of a large or tumid tongue, the labial letters are too much heard, and are often sounded instead of others. 6. Psellismus acheilos, when the labial letters are sounded with difficulty, or cannot be pronounced at all; the *P. mogilalia* of Sauvages. 7. Psellismus lagostomatium, when, from a division in the palate, the guttural letters are not well pronounced; the *cotacismus* of authors. None of these species of psellismus is ever the object of medical practice; pronouncing carefully, under the direction of a nice ear, affords the only means of relief. See Cullen, *Nosol. Method. gen.* 113.

PSELLUS, MICHAEL, in *Biography*, a Greek writer, was preceptor to Michael, the son of the emperor Constantine Ducas. He was a very voluminous author in a variety of branches, theological, mathematical, legal, medical, political, &c. His works are frequently quoted by the Byzantine writers, and Anna Comnena has given a handsome encomium of him. He occupied an honourable station under Michael, his pupil, on whose dethronement by Nicephorus Botoniates, in 1078, he was stripped of his property, and sent to a monastery, where he died in the same year. Among his printed works are, "Compendium quatuor Artium, de quatuor Mathematicis Scientiis;" "De Sanctissima Trinitate, &c.;" "Dialogus de Energia et Operatione Dæmonum;" "Synopsis Legum versibus Græcis."

PSEN, $\Psi\eta$, the name given by naturalists to the fig-gnat, a small species of gnat bred in figs while growing on the tree, and always remaining on the leaves of the same tree, and feeding on its juices. See CAPRIFICATION.

PSENITZA, in *Geography*, a town of Bosnia; 12 miles S. of Scrajo.

PSEPHISMA, $\Psi\eta\phi\iota\sigma\mu\alpha$, among the Athenians, a decree of the senate; the same with probuleuma.

PSEPHOMANTIA, $\Psi\eta\phi\omicron\mu\alpha\tau\iota\alpha$, in *Antiquity*, a species of divination, the same with cleromancy.

PSEPHOPHORIA, the art of using the *psèphi*, $\Psi\eta\phi\omicron\iota$, or counters. This was the first arithmetic taught children of every condition. Capitolinus, in his life of Pertinax, says, "Puer literis, elementariis & calculo imbutus."

PSEPHOS, $\Psi\eta\phi\omicron$, a name given to several things, as small stones, shells, and beans, used among the Greeks in giving their suffrages, and in their computations. Their origin is, by Mr. Mahudel, ascribed to the sons of Noah, who used this kind of calculation to assist their memory in numbering their flocks. Josephus assures us, that the Egyptians borrowed this method of counting from Abraham; and Herodotus relates, that these small stones were used both by the Egyptians and Greeks, only with this difference, that the latter placed them and cyphers from left to right, and the former from right to left. The art of using them in calculations was called *psèphophoria*.

Psephi were in use too among the Romans, who called them *calculi*. Whatever materials they consisted of, they were all of the same colour when used in calculations; whereas those used in giving suffrages were partly black and partly white. Lucky days were denoted by white, and unlucky by black ones. See CALCULUS.

PSETA, in *Ichthyology*, a name given by Athenæus to the fish we call the plaice, the *passer lævis* and *plateffa* of authors. See PLEURONECTES *Plateffa*.

PSETITES, in *Natural History*, a name given by authors to a stone, having in it the figure of a turbot. There are stones found in some parts of Germany having the impressions of several kinds of fish as perfect as if drawn by a pencil, and it is not to be doubted, but that they in reality owe them to the fish themselves; which were received into beds of the matter of stone, yet unhardened, which taking its consistence while they were in it, must crush them, and retain the marks of their bodies. They are usually found in a whitish slaty stone.

PSEUDO, a term or particle, used in the composition of divers Latin and English words; in the sense of *false* or *spurious*.

The word is formed from $\psi\epsilon\upsilon\delta\omicron\varsigma$, *lie, falsehood*, of $\psi\epsilon\upsilon\delta\omega$, *I deceive*.

We say a pseudo-martyr, *q. d.* a false witness, pseudo-prophet, pseudo-apostle, pseudo-christ, &c.

PSEUDO-ACACIA, in *Botany*. See ROBINIA.

PSEUDO-ACORUS. See IRIS.

PSEUDO-APIOS, a name given by some authors to the roots of bulbocastanum, or earth-nut.

The peasants in Burgundy, and other parts of France, turn up these in great quantities with the plough, and eat them. They call them *arnottas*, and some of the writers of the adjacent places not distinguishing what they truly were, have avoided the common name, by giving them this of pseudo-apis, formed of the name of a root to which they have no alliance, and taking away a name by which they would have been much better known; *arnotta* being only a corruption of the Dutch name *erfnote*, or earth-nut, a name by which they are called almost every where. See BUNIUM.

PSEUDO-ARGYRON, in *Mineralogy*, a word used by the ancients in two very different senses; some make it the name of what Virgil calls *orichalcum album*, white brass; and others of a mineral with which the common brass was made.

It is very evident, from the joint testimony of the old Greeks and Romans both, that they had in use a kind of white metal made of copper, and they esteemed it greatly above the yellow, or brass.

Aristotle tells us of this white metal, and gives it great encomiums; he says it was very white and very bright; and that it was made by melting copper together with a certain earth; but this he does not describe, so that we are left in the dark as to what it was.

This shining white metal might very naturally be called pseudo-argyron, or bastard silver.

PSEUDO-ASPHODELUS, in *Botany*. See **ANTHERICUM**.

PSEUDO-CAPSICUM. See **SOLANUM**.

PSEUDO-CARPASUM, a name given by some authors to the plant called by the generality of writers *libanotis*.

This is a plant of a very strong smell; and the *carpasum*, or *carpasum* of the ancients, being a poisonous gum, and the smell of the *libanotis* approaching to the same odour, occasion its being called the *bastard carpasum*.

PSEUDO-CYPERUS. See **CAREX**.

PSEUDO-DICTAMNUS. See **MARRUBIUM**.

PSEUDO-DIGITALIS. See **DRACOCEPHALUM**.

PSEUDO-DIPTERE, $\psi\epsilon\upsilon\delta\omicron\delta\iota\pi\tau\epsilon\rho\omicron\varsigma$, in the *Ancient Architecture*, a temple with eight columns in front, and a single row of columns all around.

The word signifies *false* or *imperfect* diptere; and is used to distinguish this from the diptere which had two rows of columns all around.

PSEUDO-FUMARIA, in *Botany*, a name used by some for a species of fumitory.

PSEUDO-GELSEMINUM, a name given by Rivinus to a genus of plants, the same with the *bigonia* of authors.

PSEUDO-IPECACUANHA, the name by which some authors have called a poisonous kind of American apocynum, the root of which something resembles the true ipecacuanha, and has sometimes been unfortunately collected and used in its place.

PSEUDO-LOTUS, a name by which some call the guaiacana of Tournefort. See *Indian Date PLUM*.

PSEUDONYMOUS, $\psi\epsilon\upsilon\delta\omega\nu\mu\omicron\varsigma$, formed from $\psi\epsilon\upsilon\delta\omicron\varsigma$, *lie*, and $\omega\nu\mu\omicron\varsigma$, *name*, a name given by the critics to those authors who publish books under false or feigned names. As the name *cryptonimus* is given to those who publish under secret and disguised names; and *anonymous*, to those who publish without any names at all.

The Apostolical Constitutions, the greater epistles of St. Ignatius, &c. are usually supposed to be *pseudonymous*.

PSEUDOPTERUS, in *Ichthyology*, a name given by Klein to the *SCORPÆNA Volitans*; which see.

PSEUDO-PULEX ARBOREUS, in *Entomology*, the name of a genus of insects described by M. Reaumur, and somewhat approaching in their form to the *pulex arboreus*; but having their wings covered with a squamose case, which those creatures have not, and having broader and flatter bodies. These principally live upon the fig-tree and the box; they pass through a sort of metamorphosis into a hopping fly, supposed by some of the nature of a grass-hopper; but erroneously, for that animal has a case for its wings, and the other not.

PSEUDO-STELLA, in *Astronomy*, any kind of meteor or phenomenon appearing in the heavens, and resembling a star.

PSEUDO-SYPHILIS, from $\psi\epsilon\upsilon\delta\eta\varsigma$, *false*, and *sypphilis*, the venereal disease, in *Surgery*, a name given to a variety of diseases which resemble lues venerea, but are in reality of a different nature.

Sores on the glans penis, prepuce, &c. in the form of chancres, as Mr. Hunter notices, may and do arise without any venereal infection, although in general they are a consequence of former venereal sores which have been cured.

The symptoms produced by the venereal poison in the constitution, are such as are common to many other diseases. For instance, as Mr. Hunter has ably explained, blotches on the skin are common to what is called a scorbutic habit; pains are common to rheumatism; swellings of the bones, periosteum, fasciæ, &c. to many bad habits, perhaps, of the scrofulous and rheumatic kind. Thus, says this valuable observer, most of the symptoms of the venereal disease, in all its forms, are to be found in many other diseases. Hence the original cause, and many leading circumstances, such as dates, effects of the disorder upon others, from connexion, when only local, the previous and present symptoms, &c. must be considered, before we can determine absolutely what the disease truly is. All the circumstances and symptoms, taken together, may be such as will attend no other disease. However, Mr. Hunter confesses, that, with all our knowledge, and with all the application of that knowledge to suspicious symptoms of this disease, we are often mistaken, calling distempers venereal which are not so, and sometimes supposing really syphilitic affections to be of another nature.

Mr. Hunter takes notice, that in some constitutions rheumatism, in many of its symptoms, resembles the lues venerea. The nocturnal pains, swelling of the tendons, ligaments, and periosteum, and pain in those swellings, are symptoms both of the rheumatism, and also the venereal disease, when it attacks those parts. Mr. Hunter, however, did not know that he ever saw the lues venerea attack the joints, though many rheumatic complaints of such parts are cured by mercury, and therefore supposed to be venereal.

Mercury, given without caution, often produces the same symptoms as rheumatism. Mr. Hunter has seen such complaints supposed to be venereal, and the medicine continued.

This interesting author also explains, that some diseases not only resemble the venereal in appearance, but, in the mode of contamination, proving themselves to be poisons, by affecting the part of contact; then producing immediate consequences similar to buboes; and also remote consequences similar to the lues venerea.

Mr. Hunter observes, that it is nearly as dangerous, in some constitutions, to give mercury, when the disease is not venereal, as to omit it in other cases which are really syphilitic. Many of the constitutions which put on some of the venereal symptoms, when the disease is not really present, are those with which mercury seldom agrees, and commonly does harm. Mr. Hunter has seen mercury, which was exhibited for a supposed venereal ulcer of the tonsils, produce a mortification of those glands, and the patient was nearly destroyed.

PSEUDO-THECA, in *Entomology*, the name of a species of two-winged fly, approaching to the nature of a common wasp, but having no sting.

This is, according to the later distinctions in the history of insects, properly called a *wasp-fly*. There are bee-flies, as much resembling the bees as this does the wasp.

PSEUDO-TINEA, the name of a very remarkable species of insect described by M. Reaumur, approaching to the nature of the tinea, or cloth-moth, while in the worm-state; but not making themselves coats of the substance of leaves, cloth, &c. though they form a sort of cases for their defence against a very terrible enemy.

These creatures are truly of the caterpillar kind, and have in the manner of many of these insects, sixteen legs. They feed on wax, and for food enter the bee-hives; where they boldly engage the bees, and are not to be prevented by them from feeding, though at the expence of their habitations and the cells of their reservoirs of honey; so that it is no uncommon thing for a swarm of bees to be forced to change their place of habitation, and make new combs elsewhere; leaving the old ones to their contemptible victor, whom they know not how to drive out or dispossess.

Virgil and Aristotle, and all the authors who have written on bees, have complained of this destructive animal. It never eats the honey, but feeds only on the wax; attacking principally those waxy cells where the female bee deposits her eggs for the future progeny.

The bees, who are a match for most other creatures, by means of their stings, would easily destroy those weak creatures, were it not for the impervious armour they are covered with. They form themselves a coat of armour of a double matter; the first, which immediately covers the body, is a kind of silk of their own spinning; and the outer covering over this is of the bees-wax; this is laid considerably thick, and the creature just thrusting out its head to feed, goes on devouring the cells undisturbed, while a whole army of the inhabitants are in vain buzzing about him, and attempting to pierce him with their stings.

When the time of the change of this creature approaches, it contracts its body within its double covering, and there changes into the nymph state; whence, after a proper time, it comes forth in form of a moth, with granulated horns and crooked proboscis.

The bees have cunning enough to know their destructive enemy in this new form, and as this is a weak and defenceless state, they attack and destroy all the moths of this species they can meet with. They seldom are so fortunate, however, as to kill the whole race as soon as produced; and if only one escapes, it is able to lay a foundation of revenge for the death of its brethren.

The moth produced by this caterpillar flies but little, yet is very nimble in avoiding danger by running, which it does with great swiftness.

There are species of these pseudo-tineæ, or wax-eating caterpillars, which infest the subterranean hives of wasps, and other creatures which make wax: the manner of living, feeding, and defending themselves from their enemies, is the same in all the species.

The accurate author of these observations describes also a kind of pseudo-tineæ, which feed on wool, and another that eats leather; both making themselves houses also on the materials they feed on. All these creatures, whatever be their food or habitation, finally become phalænæ, or moths: and may be distinguished, even in this state, from the other species, by having granulated horns of a remarkable structure, and all of them a proboscis, or trunk, more or less incurvated.

PSEUDO-VIBURNUM, in *Botany*, the name given by Rivinus to a species of lantana.

PSIADIA, so named by Jacquin, from ψιξ, ψιξδος, a drop of dew, because of the glutinous exudation of its leaves, which often stands in drops upon their surface.—Jacq. Hort. Schonbr. v. 2. 13. Willd. Sp. Pl. v. 3. 2384.

Ait. Hort. Kew. v. 5. 180.—Class and order, *Syngenesia Polygamia-necessaria*. Nat. Ord. *Compositæ discoideæ*, Linn. *Corymbiferae*, Juss.

Gen. Ch. *Common calyx* imbricated, nearly ovate, of about ten lanceolate, bluntish, concave, unequal, erect scales, with a few smaller acute ones at their base. *Cor.* compound, radiated; florets of the disk numerous, male, tubular, funnel-shaped, with a five-cleft spreading border; those of the radius female, very numerous, in several rows, ligulate, scarcely longer than the others, each with one or two teeth. *Stam.* in the florets of the disk, filaments five, capillary, very short; anthers combined in a cylindrical tube. *Pist.* Germen only a rudiment in those florets, without style or stigma; in the others oblong; style thread-shaped; stigma divided, reflexed. *Peric.* none, except the scarcely altered calyx. *Seeds*, in the radius only, solitary, linear; down sessile, simple. *Recept.* flattish, naked, except where clothed in the centre with the firmly-fixed rudiments of germens of the male florets.

Ess. Ch. Receptacle naked. Down simple, sessile. Calyx imbricated, ovate. Florets of the radius scarcely longer than the rest, spreading.

1. Pl. *glutinosa*. Jacq. Hort. Schonbr. v. 2. 13. t. 152. (*Solidago viscosa*; Schrad. Sert. Hanov. 12. t. 6.)—Native of the island of Mauritius. It was sent to Kew by Baron Hake, from Gottingen, in 1796, and flowers there from June to August, requiring the protection of a green-house in winter. Few amateurs indeed would allow it a place there, the whole plant being far less ornamental than the meanest American *Solidago*. The stem is shrubby. Leaves alternate, stalked, ovate, acute, serrated, two or three inches long, dark green, very viscid. Flowers corymbose, terminal, small, pale yellow, without smell.

PSIDIUM, a name altered by Linnæus from ψιδίξ of the ancient Greeks.—Linn. Gen. 247. Schreb. 333. Willd. Sp. Pl. v. 2. 957. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 3. 185. Aubl. Guian. v. 1. 482. Loureir. Cochinch. 309. Juss. 324. Lamarck Illustr. t. 416. (*Guajava*; Tournef. t. 413. Gært. t. 38. *Decaspermum*; Forst. Gen. t. 37. *Nelitris*; Gært. t. 27.)—Class and order, *Icosandria Monogynia*. Nat. Ord. *Hesperideæ*, Linn. *Myrti*, Juss.

Gen. Ch. *Cal.* Perianth superior, of one leaf, bell-shaped, permanent, cloven into five, ovate, rather deep segments. *Cor.* Petals five, ovate, concave, spreading, inserted into the calyx. *Stam.* Filaments numerous, shorter than the corolla, inserted into the calyx; anthers small. *Pist.* Germen inferior, roundish; style awl-shaped, very long; stigma simple. *Peric.* Berry ovate, very large, crowned with the calyx, of one or occasionally more cells. *Seeds* numerous, small, kidney-shaped, imbedded in pulp.

Ess. Ch. Calyx five-cleft, superior. Petals five. Berry with very numerous seeds.

Obs. This genus seems but ill distinguished from *Myrtus*.

1. *P. pyrifcrum*. White Guava. Linn. Sp. Pl. 672. *P. fruticosum*; Brown Jam. 238. (*Guajaba foliorum angulis quadrangulis, fructu oblongo*; Trew. Ehret. t. 43. Merian Surin. t. 19.)—Leaves elliptical, downy beneath. Stalks single-flowered.—Very common in Jamaica and others of the West Indian islands, also in Cochinchina and the southern provinces of China. It flowers at Kew in June and July. This handsome tree varies from about six to twelve feet in height; its trunk being about a foot and half in diameter. Bark yellowish-brown, with large ash-coloured dots. Leaves opposite, on short stalks, blunt, entire, smoothish. Flower-stalks solitary, short, each sup-

PSIDIUM.

porting a white, sweet smelling blossom. *Fruit* smooth, roundish, whitish or yellow on the outside. *Seeds* enveloped by a firm, flesh-coloured, sweet, aromatic pulp. The fruit of the White Guava is much esteemed both by the natives and Europeans either in its crude state, or when made into jellies. The *wood* is very tough, frequently used for bows and yokes.

2. *P. pumilum*. Dwarf Guava. Willd. n. 2. Vahl. Symb. v. 2. 56. (Cujavillus; Rumph. Amboin. v. 1. 145. t. 49.)—Leaves lanceolate, acute, downy beneath. Stalks single-flowered.—Native of Ceylon. In habit and appearance this is exactly similar to the first species, but only a fifth of the size in all its parts, being a *shrub* about two feet high, whose *branches* are covered with a villous, ash-coloured bark. *Leaves* opposite, entire, smooth above, hairy beneath. *Fruit* the size of a hazel-nut, villous.

3. *P. aromaticum*. Aromatic Guava. Willd. n. 3. Aubl. Guian. 485. t. 191.—Leaves oblong, pointed, smooth. Stalks single-flowered.—Native of woods in Cayenne and Guiana, flowering in October and bearing fruit in February. This *tree* is about five feet in height, branched at the summit in a scattered manner. *Leaves* opposite, on short stalks, entire; when bruised smelling like Balm. *Flowers* white, occasionally with only four petals. *Berry* globular, like a cherry, yellow, esculent.

4. *P. grandiflorum*. Great-flowered Guava. Willd. n. 4. Aubl. Guian. 483. t. 190.—Leaves ovate, pointed, smooth. Stalks single-flowered, with bractæas.—Found in the woods of Cayenne, flowering and fruiting rather later than the last. The *trunk* of this is about ten feet high, branching irregularly from the summit. *Leaves* opposite, on short stalks. *Flowers* axillary, rather large and showy, white, fragrant. *Fruit* yellow, austere, not eatable.

5. *P. Decaspermum*. Linn. Suppl. 252. Willd. n. 5. (*Decaspermum fruticosum*; Forst. Gen. 37.)—Leaves ovate, pointed, downy. Stalks single-flowered, with bractæas.—Native of Otaheite, and the other Society Isles. This *shrub* is for the most part smooth. *Leaves* on stalks, small, entire, veined, not marked with lines. *Flowers* small, white, on short, silky stalks. *Fruit* small, globular, rugged. *Seeds* placed in a double row, oblong, convex on one side, compressed on the other. Jussieu well observes that the *seeds* of this plant being solitary, in each of the ten cells of the *berry*, the genus of Forster ought perhaps to be retained.

6. *P. pomiferum*. Red Guava. Linn. Sp. Pl. 672. (Malacka pela; Rheed. Hort. Malabar. v. 3. 33. t. 35.)—Leaves oblong-lanceolate, downy beneath. Stalks three-flowered.—Native of the West Indies, and introduced at Kew in 1692, where it flowers in June and July. The *stem* or *trunk* of this species is thick, about twenty feet high, much branched at its summit. *Leaves* on short stalks, with a strong midrib, and much veined, of a light green colour. *Flowers* showy, large, and white. *Fruit* resembling a pomegranate, having an agreeable fragrance.

Jacquin remarks that the Red Guava is nearly allied to the first species, but not so common, and scarcely ever eaten. In Martinico the first is called *Goyavier de Cayenne*; the latter *Goyavier du pays*. *P. pomiferum* of Loureiro appears to be a much smaller shrub, for he describes it as only four feet in height.

7. *P. guineense*. African Guava. Willd. n. 7. Swartz Prodr. 77. Ind. Occ. v. 2. 381.—Leaves ovate, entire, downy beneath. Stalks three-flowered.—Native of Prince's Island on the coast of Guinea, and cultivated in Hispaniola. A small *tree*, whose trunk is smooth and branched. *Leaves* opposite, stalked, elliptical, nerved, thick, coriaceous.

Flowers three together, the middle one sessile, the others on stalks, often deciduous. *Fruit* small, roundish, tawny without, of a deep red within, having a most grateful and exquisitely sweet taste.

8. *P. montanum*. Mountain Guava. Willd. n. 8. Swartz Prodr. 77. Ind. Occ. v. 2. 879. (*P. arboreum maximum, foliis ovatis nitidis, ligno fusco, fibris undulatis*; Brown Jam. 239.)—Leaves oblong, pointed, crenulated, shining. Stalks many-flowered.—Native of woods in Jamaica. This is one of the largest *trees* in the island, frequently reaching to sixty, seventy, or even a hundred feet, and of a proportionate thickness, covered with smooth, spreading *branches*. *Leaves* opposite, stalked, undulated at the margin. *Flowers* white, fragrant, resembling those of the White Guava. *Fruit* acid.—Brown tells us “it is an excellent timber-wood, of a dark colour and curled grain; works easily, and takes a fine polish. It makes very beautiful walking-sticks.”

9. *P. caninum*. Loureir. Cochinch. v. 1. 310.—Leaves slightly serrated, downy on both sides. Stalks many-flowered, axillary, and terminal.—Found in fields near Canton. This shrub is about two feet high, much branched, diffuse. *Leaves* alternate, on short stalks, veined. *Flowers* white, in smallish oblong clusters. Loureiro called this species *canina*, because “dogs frisk round it with the same delight as cats do about Valerian.” Willdenow suspects this not to be different from *P. pumilum*, n. 2.

10. *P. nigrum*. Loureir. Cochinch. v. 1. 311.—Leaves slightly serrated. Stalks terminal, branched.—Native of woods in Cochinchina. A middle-sized *tree*, with tortuous, spreading branches. *Leaves* ovato-lanceolate, dark-green, shining. *Flowers* white, on terminal stalks. *Fruit* small, round, black.

11. *P. rubrum*. Loureir. Cochinch. v. 1. 311.—Leaves oblong, entire. *Flowers* sessile, crowded together, axillary. Found with the last, being, like that, a *tree*, of a middling size, with spreading *branches*. *Leaves* obtuse, smooth. *Flowers* white, axillary. *Fruit* small, oblong, red, esculent, having a sharpish yet sweet flavour.

Loureiro properly retains this species in *Psidium*, although its *calyx* and *corolla* have only four instead of five parts.

PSIDIUM, in *Gardening*, contains plants of the exotic tree kind, of which the species cultivated are the white guava (*P. pyriferum*), and the red guava (*P. pomiferum*).

Method of Culture.—These plants are increased by seeds, which must be procured from the countries where they grow naturally; and when these are brought over in the entire fruit, gathered full ripe, they succeed with greater certainty. They should be sown in pots filled with rich kitchen-garden earth, plunging them into a hot-bed of tanners' bark, giving them water from time to time, as the earth dries. When the plants come up, they must have free air admitted to them, in proportion to the warmth of the season; and when they have attained strength enough to be removed, be each planted out in a small pot, filled with the same sort of earth, and be plunged into a fresh hot-bed, shading them from the sun until they have taken new root, when they should have a large share of free air admitted to them every day in warm weather, to prevent their drawing up weak: they must also be frequently refreshed with water in summer.

When they have filled these small pots with their roots, they should be shaken out, and their roots pared, putting them into larger pots, filled with the same sort of earth, and replunged into the hot-bed, where they should remain till autumn, when they must be plunged into the tan-bed

in the stove. During the winter, they should have moderate warmth, and not too much water; and in summer, have plenty of moisture, and in hot weather a great share of air.

They afford ornament among other stove-plants.

PSILOCITHARISTA, among the *Ancients*, one who plays on the cithara, without singing in concert to it.

PSILOTHRON, $\psi\iota\lambda\omega\theta\rho\omega\nu$, formed from $\psi\iota\lambda\omega\varsigma$, *deglabro*, I make bald, or bare, and $\theta\rho\iota\zeta$, hair, in *Medicine*, depilatory; an external form of medicine proper to take off the hair.

Such are the strong lixiviums, quick-lime, ants' eggs, sandarac, orpiment, and arsenic.

PSILOTUM, in *Botany*, received that name from Professor Swartz, in allusion to the slender, apparently leafless, habit of the original species, in which it differs from *Lycopodium*, though previously confounded with that genus under the appellation of *L. nudum*. The above word is derived from $\psi\iota\lambda\omega\varsigma$, slender and naked.—Swartz Syn. Fil. 187. Brown Prodr. Nov. Holl. v. 1. 164. Ait. Hort. Kew. v. 5. 495. (Bernhardia; Willd. Sp. Pl. v. 5. 56. Timeopteris; Bernh. in Schrad. Journ. for 1800. part 2. 131. Swartz Syn. Fil. 187. Billard. Nov. Holl. v. 2. 105. Willd. Sp. Pl. v. 5. 56.)—Class and order, *Cryptogamia Filices*. Nat. Ord. *Filices exannulatae*.

Ess. Ch. Capsules of two or three cells, and two or three valves, coriaceous, opaque, with many seeds. *Brown*.

1. Pf. *triquetrum*. Triangular Naked-fern. Swartz n. 1. Brown n. 1. Ait. n. 1. (*Lycopodium nudum*; Linn. Sp. Pl. 1564. *Lycopodioides frutescens*, spicis laxis nudis; Dill. Musc. 468. t. 64. f. 4.)—Branches triangular in every part.—Native of the West Indies, the isles of Mauritius and Bourbon, and New South Wales.—*Stem* about a foot high, repeatedly forked, slender, spreading, triangular, smooth, green. *Leaves* minute, so as scarcely to be observed, acute, entire, scattered, sessile; the floral ones divided. Structure of the *flowers*, and mode of impregnation, not yet detected. *Capsules* numerous, sessile, solitary, at the division of each floral leaf, appearing reticulated under a magnifier, three-lobed, the size of a large pin's head.

2. Pf. *complanatum*. Flat Naked-fern. Swartz n. 2. t. 4. f. 5. (Bernhardia complanata; Willd. Sp. Pl. v. 5. 57.)—Branches two-edged, compressed.—Native of Jamaica, on the trunk and branches of trees. Like the foregoing in habit, but flat, and bearing much fewer capsules, situated at the very summits of the branches.

3. Pf. *truncatum*. Abrupt-leaved Naked-fern. Brown n. 2. (Timeopteris tannensis; Bernh. in Schrad. Journ. for 1800. part 2. 131. t. 2. f. 5. Billard. Nov. Holl. v. 2. 105. t. 252.)—Leaves dilated, abrupt, with a bristly point. Capsule of two cells.—Found by Forster in the island of Tanna. Mr. Brown and M. Labillardiere have observed it in various parts of New Holland. We have specimens from Port Jackson. This is a leafy fern, about a span high, unbranched. *Leaves* imperfectly two-ranked, alternate, somewhat stalked, oblong, oblique, abrupt, single-ribbed, smooth, about an inch long, each tipped with a small bristle; the floral ones divided to the very base. *Capsules* oblong, of two horizontally divaricated acute lobes.

Mr. Brown has made a very curious observation on the seeds of this genus; or at least on what are supposed such. These are oval bodies, appearing white in a mass, but semitransparent when separate, each exploding by a very minute orifice when put into water.

PSINIA, in *Geography*, a river of European Turkey, which runs into the Vardar, four miles S. of Krupulik.

PSITTACULA, in *Ornithology*, a species of *Alca*.

PSITTACUS, the Parrot, a genus of birds of the order Picæ, of which the generic character is, bill hooked; upper mandible moveable, and mostly covered with a cere; the nostrils are rounded, and placed in the base of the bill; the tongue is fleshy, obtuse, entire; feet formed for climbing.

This splendid and numerous genus is chiefly confined to the warmer regions of the ancient and new continent, or within the limits of the tropics; none being natives of Europe. Some few are found in latitudes far beyond what was supposed by Buffon, and even as far as 40° or 45° on each side of the equator. They are remarkable for their active and imitative disposition. From the peculiar form of their tongue, which, in most species, is thick, flattish, rounded, and fleshy, they are enabled to articulate with greater distinctness than other birds. The upper mandible is, as we have seen, moveable; and the feet formed for climbing, with a power of bringing forward at pleasure one of the hind toes. They are frugivorous and monogamous, depositing their eggs, which are generally two, sometimes three, in the holes of decayed trees. Though usually observed in pairs, they sometimes assemble in vast flocks. The whole genus, which, according to Gmelin, comprehends about 170 species, is divided into two sections, according to the shape of their tails.

A. Tail long, and wedge-shaped.

Species.

MACAO; Red and Blue Maccaw. Red; quill-feathers above blue, beneath rufous; feathers of the shoulders variegated blue and green; cheeks naked, wrinkled. This being by far the most magnificent of the whole parrot tribe, we shall give a pretty full description of it. It is a native of South America, where it resides chiefly in the palm woods, and feeds, like the rest of the birds of this genus, on various kinds of fruit. It has been more accurately described and figured by Edwards than by any other naturalist. He says, "it is undoubtedly the first of the parrot kind, if we consider either its magnitude, or the great variety and beauty of the colours with which its plumage is adorned. It is the biggest of all the kinds I have met with: when the tail is perfect, I have found some of them to measure more than three feet from bill-point to tail-end; the arch of the upper mandible, from the forehead to the point of the bill, is nearly three inches; the leg, from the knee downwards, is not an inch and half long; the longest toe, with the claw, is two inches and a half long; the upper mandible of the bill is whitish, except on each side next the head, where it is dusky; the lower mandible is black or dusky; it has no bare skin covering the bill; the nostrils are placed in the upper part of the bill, just within the feathers; the bill is great and strong; the tongue roundish and soft; the sides of the head, from the bill backwards, for a good broad space, are bare of feathers, and covered with a whitish, wrinkled, rough skin; in the upper parts of these spaces are placed the eyes, whose irids are yellow; the head, neck, breast, belly, thighs, upper part of the back, and lesser covert-feathers of the wings, are of a fine bright red or scarlet colour; the quill-feathers of the wings are of a very fine blue on their outsides, and a faint red on their under side; the first feathers next above the quills are of a fine yellow colour, some of the feathers being tipped with green; the blue quills which fall next the back are tinged with

PSITTACUS.

with green; the hinder part of the thigh has some green intermixed with the red; the lower part of the belly, and coverts under the tail, as also the lower part of the back, and coverts on the upper side of the tail, are of a very fine blue colour; the tail-feathers gradually shorten towards the sides; some of the longest or middle feathers are wholly red; the shorter or side feathers are partly red, and partly blue, their tips being blue, and their bottoms red; the legs and feet are covered with blackish or dusky scales; the toes are disposed two forwards and two backwards, as in other parrots; they are all armed with strong claws." This noble bird, says Dr. Shaw, at its first introduction into Europe, was considered as a present fit for royal personages, and was one of the principal ornaments in the halls of palaces. In a state of nature, these, of all the species of parrots, fly the best; and they always perch on the summits of trees, or on the highest branch. During the day they wander to the distance of two or three miles from their favourite spot, or home, but always return in the evening. They build in the holes of trees, which they enlarge when too narrow, and line the inside with feathers. They have two hatches annually, like all American parrots, and each consists of two eggs. The males and females sit alternately on the eggs, or cherish the young, and both equally carry the food: they never desert their charge so long as their assistance is required, and always perch near their nest. The young are said to be easily tamed; and in many parts of South America these birds are never taken but in the nest, the grown birds being educated with great difficulty. In a state of captivity, like many other birds, they are subject to epileptic fits, which, however, do not prevent them from arriving at a very considerable age, sometimes not less than thirty years.

ARACANGO; Red and yellow Maccaw. Pale scarlet; scapular feathers yellow, tipped with green; quill-feathers above blue, beneath rufous; cheeks naked, wrinkled. It inhabits Guiana, Brazil, and Jamaica, and is the size of the last. The tail-feathers above are scarlet, mixed with violet, beneath dusky red, two middle ones both sides dusky red on the upper half.

MILITARIS; Military Maccaw. Green; wings blue; front and tail red; cheeks mostly naked, with feathered lines. The bill is black; the rump and tips of the tail-feathers blue.

ARARAUNA; Blue and yellow Maccaw. Above blue, beneath yellow; cheeks naked, with feathered lines. There is a variety of this species, which has a long tail and naked cheeks. It is found in Jamaica, Guiana, Brazil, and Surinam. The tail of the female is yellow, that of the male red.

HYACINTHUS; Hyacinthine Maccaw. Violet blue; head and neck paler; chin and orbits yellow, naked.

MAKAWANNA; Parrot Maccaw. Above dusky green; head green mixed with blue; chin, throat, and upper part of the breast, reddish; lower part of the breast and belly green; rump red-brown. It inhabits Cayenne and Guiana; is eighteen inches long, and migrates.

ATER; Black Maccaw. Black, with a green tinge; bill and eyes red; legs yellow. It inhabits the interior parts of Guiana, on the sterile tops of rocks and dry mountains.

OBSCURUS; Obscure Parrot. Brown; cheeks red, naked; crown varied with blackish and ash; tail cinereous. It inhabits Africa, and is about the size of a magpie.

NOBILIS; Noble Parrot. Green; cheeks naked; shoulders scarlet. It inhabits Surinam, and is the size of a turtle-dove.

SEVERUS; Brazil green Maccaw. Green, cheeks naked; quill and tail-feathers blue, beneath purplish. A variety is

of a dusky green; with the front brown, and the crown greenish-blue. It is found in Jamaica, Guiana, and Brazil.

EUPATRIA; Gingi Parrot. Green; cheeks naked; shoulders scarlet; bill purplish. It inhabits Gingi in India.

JAPONICUS; Japanese Parrot. Green; beneath and lateral tail-feathers red; quill-feathers blue. It is found in the southern parts of Japan.

AMBOINENSIS; Amboina Parrot. Scarlet; back blue; wings with a green spot. It is about fifteen or sixteen inches long.

CYANOCEPHALUS; Blue-headed Parrot. Head green, chin blue. It is about a foot long, and inhabits India.

HÆMATOTUS; Red-breasted Parrot. Body above green; throat and breast orange; the feathers edged with blue, belly and tail green. There are three other varieties of this species, *viz.* 1. Breast red, varied with blue; head, chin, and middle of the belly, blue. 2. This resembles the last, except that the whole belly is blue. 3. Scapulars spotted with red and yellow. Found in New Holland and Amboina.

ATRICAPILLUS; Black-crowned Parrot. Above blue; chin, throat, and breast red; belly and vent green; crown black; collar green and red. It inhabits the Molucca isles, and is fourteen inches long.

TABUENSIS; Tabuan Parrot. Head, neck, breast, and belly, purple; back and wing-coverts green; crown terminated by a lunular blue mark; first quill-feathers and greater part of the tail blue. It inhabits the Friendly islands. There is a variety of this species, which is green, head, neck, breast, and belly scarlet; neck terminated by a lunular blue mark; wings green; rump blue; tail deep blue. This is found in New South Wales.

PAPUENSIS; Papuan Parrot. Head, neck, and breast red; hind head with a blue spot and two black crescents; wings and part of the back green; rest of the back, belly, and tip of the tail, red: three varieties are, 1. Belly crossed by a black stripe edged with green, breast purplish. 2. Scarlet; tail shorter, hinder part of the back blueish-black; a yellow spot between the wings. 3. Middle of the belly green. It inhabits Papua, and is sixteen inches long.

BORNEUS; Borneo Parrot. Red; quill and tail-feathers green at the tips; wings with a blue spot; orbits brown. It is an Indian parrot, and nine inches and a half long.

INDICUS; Indian Parrot. Scarlet varied with brown and violet; upper part of the head and neck, breast and stripe behind the eyes, violet; greater quill-feathers tipped with pale brown; lesser and tail-feathers violet brown. It is a native of Amboina, and nearly a foot in length.

ELEGANS; Beautiful Parrot. Head, neck, and body beneath red, above brown; interscapulars pale blue, mixed with red; tail greenish-brown, tipped with white. A variety has its wings, tail and body above green. It inhabits the Molucca islands: the first is about fifteen inches long, and the second twelve: in the former the bill is of a yellowish-brown; in the latter it is a lead-colour, and yellow at the tip.

GUEBIENSIS; Gueby Parrot. Bright red; quill-feathers black, with a transverse red band; tail brownish-red. It is about nine or ten inches long.

JANTHINUS; Violet Parrot. Head and body above brown, beneath violet; shoulders blue; tail and wings green and red. It is found near the river Amazons.

VARIEGATUS; Variegated Parrot. Scarlet; nape, beginning of the back, breast and belly, purple or blue; wings above

PSITTACUS.

above red, beneath yellow; tail green. It inhabits India, and is from ten to eleven inches long.

PENNANTII; Pennant's Parrot. Scarlet; fore part of the back black, waved with scarlet, sides and throat blue; quill-feathers each with a white spot. It is fifteen inches long, and inhabits New South Wales. There is a variety, having the middle of each wing with a pale band.

EXIMIUS; Nonpareil Parrot. Head, throat, breast, and vent crimson; back black, waved with yellow-green; wings and tail blue. It inhabits New Holland.

GLORIOSUS; Splendid Parrot. Bright blood-red; back-feathers edged with black; chin, wings, and tail blue. It is a native of New Holland, and is sixteen inches long.

NOVÆ GUINÆÆ; New Guinea Parrot. Black, with a bright blue tinge; tail beneath red; orbits naked, brown.

JAVANICUS; Javan Parrot. Scarlet; orbits naked, silvery; head crested, chin grey; throat and breast rosy; shoulders and wings mixed red and green; two middle tail-feathers scarlet, the rest rosy, mixed with green, tipped with blue. It is about the size of a lark, and is a native of Java.

JANDAYA; Yellow-headed Parrot. Above green, beneath yellow; head and neck yellow. It is a native of Brazil.

SOLSTITIALIS; Angola Parrot. Yellow; wing-coverts green; orbits red; lateral tail-feathers blue without. It inhabits Angola, and is nearly a foot long.

PALLIDUS; Pale Parrakeet. Yellow; wings whitish, slightly tinged, and a cast of greenish, according to the direction of the light. It inhabits Andalusia, and is about seven inches long.

GUAROUBA; Brazil Yellow Parrot. Yellow; greater quill-feathers green. It is found in Brazil, and is eleven inches long. There is a variety that is yellow; head reddish; neck orange; wings green. It inhabits New Spain.

CAROLINENSIS; Carolina Parrot. Green; head, neck, and knees yellow. It is a native of Guiana, and migrates into Carolina in the mulberry season; it is very destructive to orchards; builds in hollow trees in swampy places; does not easily learn to speak.

ALEXANDRI; Alexandrine Parrot. Green; collar and crest red; chin black. There are of this species the following varieties. 1. Collar rosy; hind-head violet; legs ash. 2. Collar purple, throat and breast pale rosy. 3. Collar double. 4. Head, chin, and tail blue. 5. Head mixed blue and yellow; temples black; throat and breast reddish; tail yellowish.

PERTINAX, Yellow-faced Parrakeet. Green; cheeks tawny; quill and tail-feathers rather hoary. This species is a native of America, and it migrates in flocks to the North: it feeds on seeds and fruits, and builds in large ant-hills, and is about thirteen inches long.

LEVERIANUS; Leverian Parrot. Pale green; head and neck yellow; quill-feathers, and tips of the tail-feathers, blue; rump crimson. It is found in the southern parts of Asia.

SMARAGDINUS; Emerald Parrot. Shining green; hind part of the belly, rump, and tail rusty chestnut. Inhabits near the Straits of Magellan, and is thirteen inches long.

CANICULARIS; Red-fronted Parrot. Green, with a red front; hind-head and outer quill-feathers blue; orbits tawny. It inhabits South America.

ÆRUGINOSUS; Brown-throated Parrakeet. Green, crown and first quill-feathers blue; orbits ash. It is a native of America, and is ten inches long.

RUFIROSTRIS; Red-billed Parrot. Green; bill and legs red; tail-feathers bluish at the tips; the orbits are of a flesh

colour. There is a variety whose bill, legs, and claws are whitish-red; the orbits are cinereous. It inhabits South America, is twelve inches long, and is easily taught to speak.

ORNATUS; Orange-billed Parrot. Yellow-green, hind-head, chin, and breast red; crown and auricles blue; orbits cinereous. This is a native of India.

JAQUILMA. Green; quill-feathers brown at the tip; orbits tawny. It inhabits Chili, lives in flocks, and feeds on buds of trees and plants; the flesh is very savoury.

GUIANENSIS; Pavouane Parrot. Green; cheeks spotted with red; the lesser wing-coverts are scarlet, the greater are yellow; quill-feathers beneath pale yellow, with a blackish margin towards the tip. It is found in Guiana and the Caribbee islands.

MARGINATUS; Varied-winged Parrot. Green; wing-coverts black; the lesser edged with yellowish-brown, the greater with blue. Found in Luzonia, as is the next.

SONNERATI; Blue-collared Parrot. Green; collar blue; spot on the origin of the wings red.

PONDICHERIANUS; Mustachio Parrakeet. Green; front and stripe from the mandible each side to the chin black; face white and blueish; breast purplish-blue; tail beneath straw-colour. A variety has its head from the base of the bill to the eyes chestnut; a brown line from the nostrils to the eyes; chin black, extending back like a beard; the nape is red. This species is found in Pondicherry.

ERYTHROCEPHALUS; Blossom-headed Parrakeet. Green; head red mixed with blue; chin black; collar black and pale green. There are three other varieties; 1. Crown and cheeks rosy; hind-head and two middle quill-feathers blue above, the rest blue at the edge. 2. Head, chin, throat, breast, and fore-part of the belly, peach-blossom colour. 3. Colour verging to yellow; area of the eyes and hind-head rosy. This species is a native of India.

BIMACULATUS; Spot-necked Parrot. Green, with two oblong black spots on the neck, and a large sulphur-coloured spot on each wing.

PLUMBEUS; Brown-fronted Parrakeet. Green; bill, legs, and orbits of a lead-colour; front, cheeks, and chin brown; edges and tips of the tail-feathers blue. This is nearly a foot long, and inhabits the tropical regions of America.

BUBALINUS; Buff-fronted Parrakeet. Green above, yellowish-green beneath; the front is buff. This is a native of Cayenne.

OLIVACEUS; Lace-winged Parrakeet. Olive; hind-head with a blueish spot; wings varying with blue, green, and orange. It is found in Luzonia, and is eleven inches long.

DUBIUS; Dubious Parrot. Green; neck reddish; orbits yellow, naked.

CHRYSOGASTER; Orange-bellied Parrot. Green, belly orange, bill greenish.

VIRESCENS; Yellow-winged Parrakeet. Greenish; lesser wing-coverts at the base, and within, white; without, and at the tip, yellow: the first seven quill-feathers within black, edged with white; the next seven are white, edged and tipped with yellow. This is a native of Cayenne, and it is eight inches long. It is a very numerous species, docile, and not shy; it feeds on the flowers of the erythrina corallidendron.

VERSICOLOR; Waved Parrakeet. Green; head and chin brown, the latter waved with tawny; wings blue, with a flame-coloured bar; belly pale blueish-purple, with brown waved lines. It inhabits Cayenne and Surinam.

SQUAMMOSUS; Scaly Parrakeet. Green; feathers of the head, neck, and breast, edged with orange. A native

PSITTACUS.

of Cayenne, and is only about eight inches and a half long.

INCARNATUS; Red-winged Parrakeet. Green; bill, legs, and claws, carnation; cere and orbits whitish; chin and wing-coverts red. It inhabits India.

MURINUS; Grey-breasted Parrakeet. Olive; face, chin, and breast mouse-colour; quill-feathers green. Inhabits Montevideo; it is about ten inches long, and is easily tamed.

CORNUTUS; Horned Parrot. Green; head scarlet, with two long feathers standing out like horns; the collar and rump are straw-colour; the outer edge of the quill and tail-feathers blue. It inhabits New Caledonia, as does the next.

CALEDONICUS; Caledonian Parrot. Olive; crown greenish-yellow; tail-feathers whitish at the tip, the outer edges of the four outermost pale blue.

NOVÆ-SEELANDIÆ; Red-rumped Parrot. Green; front purple; crown greenish-tawny; a red stripe from the base of the bill through the eyes; tail-feathers blueish, the two middle ones edged with green; the rump is red. It inhabits New Zealand, and is 15 inches long.

NOVÆ HOLLANDIÆ; Crested Parrakeet. Olive; crested head and chin yellow; behind the eyes there is a red spot, and an oblique band across the wings. It is a native of New Holland, and is a foot long.

FORMOSUS; New Wales Parrot; and sometimes it is denominated the black-spotted parrakeet of Van Diemen's Land. This species is green; the four middle tail-feathers barred with green and black, the rest with black and yellow; the bill and legs are black, and the tail much wedged. This is a most beautiful and elegant species, about a foot long, inhabiting New South Wales, and other parts of New Holland. It is rarely seen, except on the ground, particularly in moist places. It is not known to perch on trees like other parrots, but rises from among the grass, and immediately alights in it again. The legs and toes are more slender than usual in this genus, and the claws more straight.

ULIETANUS; Society Parrot. Olive; head black-brown; rump dusky-red; wings and tail dusky. It inhabits Ulietea, and is 10 or 11 inches long.

MULTICOLOR; White-collared Parrot. Green; head, chin, and belly blue; fore-part of the breast red, hind-part and tail beneath yellow; collar white. It inhabits India; the bill is red, and the head is ornamented with a white crescent.

AUREUS; Golden-crowned Parrakeet. Green; cere and orbits blueish-carnation; crown golden; wing-coverts with an oblique blue stripe. It is a native of Brazil.

LINEATUS. Green; quill-feathers beneath brown, the inner edge pale. This is about the size of a turtle-dove.

CONCINNUS; Crimson-fronted Parrakeet. Green; spot behind the eyes and front crimson; the crown is blueish. It inhabits New Holland, and is the size of a turtle-dove.

PACIFICUS; Pacific Parrakeet. Green; spot behind the eyes and each side of the rump red; front red; outer edge of the wings blue; tail beneath ash. There are five other varieties; 1. No spots on the rump; quill-feathers blue. 2. Rump and temples red. 3. Crown yellow. 4. Hind-head, spot below the eyes, and sides of the belly, scarlet. 5. Crown blue; hind-head spotted with yellowish-green, the shoulders are edged with yellow. This species, in all its varieties, inhabits the islands in the Pacific ocean.

PALMARUM; Palm Parrot. Green; bill and legs red; quill-feathers tipped and edged with black. It is found among the palm trees in Tanna island.

AUSTRALIS; Blue-crested Parrakeet. Green; crown blue, crested with long feathers; chin and middle of the belly red, thighs purple. It is found in the Sandwich islands, and is six or seven inches long.

PEREGRINUS; Peregrine Parrakeet. Green; on each wing there is a longitudinal brown spot. It inhabits the islands in the Pacific ocean, and is about eight inches long.

TAITIANUS; Otaheite Parrakeet. Blue; feathers of the head long; chin and throat white, bill and legs red. This is a native of Otaheite; it is five inches long; feeds on the fruits of the banana; the tongue is fringed at the end; the body is often white beneath.

CYANEUS; Blue Parrakeet. Body entirely of splendid full blue. This also is found in Otaheite, and has been thought to be a variety of the last.

PUSILLUS; Timid Parrakeet. Olive brown; frontlet scarlet; tail-feathers within, near the base, scarlet. This inhabits New South Wales, and is seven inches long.

PYGMÆUS; Pigmy Parrakeet. Green; feathers tipped with greenish-yellow; quill-feathers within dusky. It inhabits the islands in the Pacific ocean, and is six inches long.

AGILIS; Agile Parrot. Green; primary quill-feathers blueish, with tawny coverts; tail hardly lengthened, beneath red; orbits cinereous. It inhabits America, and is 10 or 11 inches long.

SANGUIOLENTUS; Red-shouldered Parrot. Green; frontlet crimson; crown, and outer edge of the wings, deep blue; shoulders, and wings beneath, blood-red. This is found in New South Wales.

B. *Tails short, equal at the end.*

CORONATUS; Crowned Cockatoo. Green; crest plicatiled red, tipped with blue. This is about 18 inches long, and inhabits Guiana and Surinam.

ATERRIMUS; Black Cockatoo. Black; crest large, paler; cheeks red, naked. This is three feet long, and found in New Holland.

FUNEREUS; Funereal Cockatoo. Black; middle of the tail straw-colour freckled with black. This likewise is a native of New Holland, and is nearly as large as the last.

BANKSI; Banksian Cockatoo. Splendid black; crest small; head and wing-coverts dotted with buff; outer tail-feathers scarlet in the middle, barred and tipped with black. This is about three feet long, and found in New Holland. There are two varieties; *viz.* 1. Sides of the neck, chin, and throat yellow; this is about 22 inches long. 2. Dusky-brown inclining to olive; tail, except the two middle feathers, crossed with a broad red bar. The size of the former.

SULPHUREUS; White Cockatoo. White; crest folding pointed, and with the spot beneath, the eyes sulphur-yellow. It is about 14 or 15 inches long, and inhabits the Molucca islands.

GALERATUS; New Wales Cockatoo. White; crest long, folding, pointed, sulphur; base of the tail sulphur. It inhabits New South Wales, and is twenty-seven inches long.

PHILIPPINARUM; Red-vented Cockatoo. White; crest folding, sulphurous, white at the tip; orbits yellowish-red; the lower tail-coverts are red, dotted with white. This is a native of the Philippine islands.

MOLUCCENSIS; Molucca Cockatoo. White, inclining to pale rosy; crest beneath red; lateral feathers within from the base to the middle sulphurous. This species and the next inhabit the Molucca islands, and are about seventeen inches long.

CRISTATUS; Great white, or yellow-crested Cockatoo. White; crest folding and yellow; the feathers of the neck are loosely flowing; the crest is five inches long, and capable of being erected. It is about eighteen inches in length, and the size of a domestic ordinary fowl. This and several

PSITTACUS.

several others of the species frequently repeat the word *cockatoo*.

ERYTHROLEUCUS; Red and white Parrot. Cinereous; rump, quill and tail-feathers scarlet.

ERYTHACUS; Hoary Parrot. Hoary; temples naked, white; tail cochineal or scarlet. There are three varieties: *viz.* 1. Wings red. 2. Variegated with red. 3. Red; head cinereous; cheeks naked; primary quill-feathers brown-ash. They all are natives of Africa, and about twenty inches long. This species is very loquacious, modulating its voice in various tones, and easily repeating whatever it hears. It is sometimes called Jaco, from one of its most frequent sounds.

CINEREUS; Cinereous Parrot. This is entirely of a blueish-ash colour. It inhabits Guinea, and is larger than the last species.

MERIDIONALIS; Southern Parrot. Above greenish-ash, beneath bright bay; orbits, crown, hind-head, and neck cinereous; the feathers are tipped with brown. It inhabits New Zealand, and is about sixteen inches long.

MASCARINUS; Mascarine Parrot. Cinereous; frontlet beneath black; orbits naked, reddish; lateral tail-feathers whitish at the base.

FUSCUS; Brown Parrot. This is entirely of a brown-ash, and thirteen inches long.

GARRULUS; Ceram Lory, or Ceram purple Parrot. Red; orbits ash; cheeks and wings green; latter half of the tail-feathers blue. There are three varieties: 1. Scarlet coloured; wings green and black; tail-feathers yellow, the latter half greenish. 2. Shoulders spotted with yellow. 3. Most of the wing-coverts dotted with blue. It inhabits the Molucca islands.

DOMICELLA; Blue-cap Lory. Red; cap violet; wings green; shoulders and cheeks blue; orbits brown. There is a variety with a blue cap, black orbits, and yellow collar: but, according to some writers, these are male and female. They inhabit the East Indies, and are remarkable for speaking distinctly, and very quickly learning their lessons. They are very scarce birds, and fetch a high price.

LORY; Violet-cap Lory. Purple; cap violet; wings green; breast, cheeks, and tail blue; the orbits are of a pale flesh colour. It is a native of the Philippine islands.

PUNICEUS; Crimson Lory. This is of a deep scarlet colour, but beneath it is violet; lesser and under wing-coverts, quill-feathers within and underneath, blackish-brown. It inhabits Amboina.

RUBER; Molucca Lory. Red; area of the eyes and quill-feathers black; spot on the wing and under tail-coverts blue; tail chestnut at the tip. A variety has its shoulders, belly, vent, tips of the secondary quill-feathers, and greater wing-coverts, blue. It inhabits the Molucca isles and New Guinea.

GRANDIS; Grand Lory. Red; beneath mixed red, blue, violet, and green; nape violet; wings blue; tail tipped with yellow. A variety is varied above with brown and green; beneath it is blue; the edge of the wings and their under-coverts blue; the tail is chestnut colour. It inhabits Ceylon.

COCHINCHINENSIS; Cochinchina Parrot. Blue; front, nape, lower part of the neck, breast, and middle of the belly, scarlet. It inhabits, as its name imports, Cochinchina.

GUINEENSIS; Yellow-breasted Lory. Head and neck scarlet; eye-brows and breast yellowish; wings yellow-green, tipped with blue; belly, vent, and under part of the tail, hoary, tipped with scarlet. It inhabits Guinea.

PARAGUANUS; Paraguan Lory. Scarlet; head, neck,

vent, tail, shoulders, and wings, black. It is thought to be a native of Brasil.

NIGER; Black Parrot. Tail long and equal; the body is of a blueish-black; the bill and orbits are white. It inhabits Madagascar, and is thirteen inches and a half long.

CÆRULOCEPHALUS; Blue-headed Parrot. Blue; belly, rump, and tail green; crown yellow; quill and tail-feathers red. It inhabits Guinea.

VARIUS; Variegated Parrot. This species is varied with brown and blue; cheeks, chin, and throat whitish; quill and tail-feathers dusky-brown, the outer webs blue. It inhabits South America.

VIOLACEUS; Ruff-necked Parrot. This is of a violet colour, varied with mixed black and green; back dusky-green; greater quill-feathers black, the rest varied with yellow-green and red, with a rosy spot on their coverts. It is a native of America, and the size of a hen.

FRINGILLACEUS; Finch Parrot. Green; head blue; cheeks, chin, throat, and spot on the belly white, with a sort of bloody hue; the belly is of a violet colour. It is a native of South America, and is rather more than six inches long.

CHORÆUS; Chili Parrot. Green; beneath ash; orbits carnation. It inhabits Chili.

SINENSIS; Chinese Parrot. Green; under wing-coverts red, some of the greater and edge blue; tail beneath brown. It inhabits the southern parts of China, Amboina, and New Guinea, and is of the size of a hen.

MACRORHYNCHOS; Great-billed Parrot. Green; beneath inclining to yellow; wings mixed blue and green, with black coverts. It inhabits New Guinea, and is fourteen inches long.

NASUTUS; Gristled Parrot. Green; head and breast greenish-grey; wing-coverts yellow. It is a native of China, and is twelve inches long.

GRAMINEUS; Grass-green Parrot. Green; beneath olive; front and crown blue; tail beneath yellow. It is sixteen inches long, and a native of Amboina.

LEUCOCEPHALUS; White-fronted Parrot. Green; quill-feathers blue; front white; orbits snowy. There are the following varieties: 1. Throat red; the feathers edged with white; belly purple; quill-feathers blue on the outer webs. 2. Head from the front to the neck white, the rest pale blue; orbits and spurious wings red. 3. Crown blueish-ash; belly spotted with red. These are found in Martinico, Jamaica, and New Spain.

GERINI; Gerin's Parrot. Green; head white; shoulders, some of the middle quill-feathers, and tail-feathers within at the base, red. This is a native of Brasil.

OCHROPTERUS; Yellow-winged Parrot. Green; front and orbits whitish; crown, cheeks, chin, throat, and remoter wing-coverts, yellow. It is thirteen inches long, and is found in South America. A friend of Buffon possessed one of this species, which shewed a strong attachment to his master, but was yet of a very capricious temper, expecting a full return for every demonstration of its civility. It would, in play, sometimes bite a little too hard, and laugh heartily at the act; but if chastised, it became refractory, and could only be reclaimed by gentle and kind treatment. It took much delight in tearing every thing to pieces; was dull and silent, if confined in its cage; but when set at liberty, it chattered incessantly, and repeated every thing that was said. It was very fond of children, which is contrary to the usual disposition of parrots. During the moulting season, it appeared dejected and uneasy for three months together. It subsisted chiefly on hemp-seed, nuts, fruits of all kinds, and bread soaked in wine, but preferred

PSITTACUS.

flesh, when it could get at it: when, however, it was indulged much in this latter article, it became dull and heavy, and shortly after began to lose its feathers. It was also observed to make use of a sort of rumination.

OCHROCEPHALUS; Yellow-headed Parrot. Green; crown yellow; wing-coverts red; quill-feathers variegated with green, black, violet, and red; the two outer tail-feathers within red at the base. There are two varieties of this species: 1. Crown with a yellow spot; bill ruddy. 2. Upper mandible blueish-green, with yellow sides, and a black spot at the tip; lower of a lead-colour, yellow in the middle. This species is from sixteen to eighteen inches long. It inhabits South America.

BARBADENSIS; Ash-fronted Parrot. Green; orbits and front cinereous; crown, cheeks, chin, throat, and lesser wing-coverts yellow, the greater blue; many of the primary quill-feathers without violet, the rest from the base to the middle red, and afterwards blue. Inhabits Barbadoes, and is the size of a pigeon.

LUCIONENSIS; Manilla Parrot. Green; hind-head and rump blue; wings marked with black, blue, and red. It is found in Luzonia, and is more than a foot long.

ÆSTIVUS; Amazon Parrot. Green, slightly spotted with yellow; the front is blue; shoulders blood-red; orbits carnation. There are eight varieties of this species, viz. 1. Head and breast yellow; front and chin blueish; edges of the wings and vent red. 2. Lesser wing-coverts red. 3. Cap blue, variegated with black; a yellow spot on the crown, and each side below the eyes; chin blue. 4. Crown, cheeks, and chin yellow. 5. Pale green; front pale yellow; temples tawny. 6. Green; front blue; crown, cheeks, chin, and middle of the belly, yellow. 7. Green; head and neck yellow; shoulders red. 8. Green, variegated with yellow; front blue; shoulders red. These are all natives of South America, excepting the first variety, which is a Jamaica bird.

LUTEUS; Yellow-shouldered Parrot. Green; crown blue; shoulders yellow; great wing-coverts with an orange spot. It inhabits South America.

PULVERULENTUS; Mealy Parrot. Green; above mealy; spot on the head yellow, on the wings red. It is found in Cayenne, is very large, and speaks distinctly.

HAVANENSIS; Blue-fronted Parrot. Green; the front, the chin, and throat, are of an ashy-blue; on the breast is a large red spot; the orbits are cinereous. It inhabits Havannah, and is a foot long.

PARADISI; Paradise Parrot. Yellow; chin, belly, and base of the tail-feathers red. This is rather longer than the last, and inhabits Cuba.

AURORA; Aurora Parrot. Yellow; arm-pits, edges of the wings, and greater quill-feathers without in the middle red. It inhabits Brasil.

PASSERINUS; Passerine Parrot, or blue and green Parakeet. Yellowish-green; spot on the wings, and wings beneath blue. It inhabits Brasil and Guiana, and is about the size of a common house-sparrow.

CYANOLYSEOS; Blue-collared Parrot. Yellowish-green; collar blue; rump red. This species is something larger than a pigeon. It inhabits Chili, where it is called *thecau*, and where it does a deal of mischief to the corn, flying always in flocks. When the troop is about to fettle, one of them acts as sentinel on a tree, and gives the alarm if any person approaches, on which account it is very difficult to shoot them. This species breeds in the holes of rocks, laying two white eggs in the most inaccessible and craggy parts. From the tops of the cliffs the inhabitants in pursuit of them let themselves down by ropes. Both the eggs and

young birds are reckoned very delicate eating. If robbed of its young, this bird will lay a second time, and sometimes even a third. It is easily tamed, and learns to speak well.

SORDIDUS; Dusky Parrot. Brownish; chin blue; wings and tail green; bill and vent red. It is about the size of a pigeon, and inhabits New Spain.

DOMINICENSIS; Red-banded Pigeon. Green; band on the forehead red; lunules on the neck and back black; quill-feathers blue. It is a native of St. Domingo.

ERYTHROPTERUS; Crimson-winged Parrot. Green; orbits blackish; middle of the back black, lower part blue; wing-coverts red. It inhabits New South Wales.

FESTIVUS; Festive Parrot. Front purplish, eye-brows and chin blue; back blood-red. It inhabits Guiana; is eleven inches long, very active, but fierce and untractable.

ROBUSTUS; Robust Parrot. Green; head somewhat ash; wing-coverts dirty black, edged with green; spot on the wings red. It is the size of a pigeon.

MAGNUS; New Guinea Parrot. Green; greater quill-feathers blue, lesser beneath red. It inhabits New Guinea.

ORIENTALIS; Eastern Parrot. Green; outer edge of the wings and primary quill-feathers blueish; tail yellow at the tip. It inhabits India.

ADSCITUS; Blue-cheeked Parrot. Green; cheeks and wings blue; back on the fore-part black, with yellow streaks, hind-part yellowish.

BATAVENSIS; Batavian Parrot. Green, with yellow streaks; hinder part and nape blackish; face and thighs scarlet. It is a native of Batavia.

TARABA; Tarabe Parrot. Green; head, chin, throat, breast, and lesser wing-coverts red. It inhabits Brasil, and is ten inches long.

BRASILIENSIS; Brasil green Parrot. Green; face red; temples blue; orbits ash. This also is a native of Brasil, and is thought to be a variety of the next.

AUTUMNALIS; Autumnal Parrot. Green; front and spot on the quill-feathers scarlet; crown and primary quill-feathers blue. There are two varieties: 1. Front and chin blue. 2. Head variegated with red and whitish. It inhabits Guiana, and is the size of the last.

COCCINOCEPHALUS; Scarlet-headed Parrot. Green; crown and front scarlet; rump greenish-yellow; quill and tail-feathers blue without. Size of the mistle thrush.

ACCIPITRINUS; Hawk-headed Parrot. Green; head grey; neck and breast varied with blueish; quill and tail-feathers tipped with blue. There is a variety, of which the feathers of the head are white, long, and narrow, streaked with black. The former is a native of India; the latter of Guiana, where it is domesticated. When angry it erects its crest.

MENSTRUUS; Blue-headed Parrot. Green; head blueish; vent red. This species is found in Guiana; it is not very docile, and has the voice of a jack-daw. It is the size of a turtle dove.

PURPUREUS; Purple-bellied Parrot. Above black-brown, beneath purple; crown and cheeks black; orbits blue; collar with dirty spots; quill and tail feathers blue. It inhabits Surinam.

MELANOCEPHALUS; White-breasted Parrot. Green, yellow beneath; cap black; breast white, orbits flesh-colour. Its length is nine inches and a half. It inhabits Mexico, Guiana, and the Caraccas in South America. It frequents woods, and is rarely seen in inhabited districts. Its call is a shrill whistle, which it often repeats in its flight, and it does not learn to talk like other birds of this genus. According

PSITTACUS.

to Mr. Latham, the white-breasted parrots fly in small numbers together, but are perpetually quarrelling with one another; and if any one is taken, it refuses all food, till at length it is starved to death. Parrots of the most stubborn nature are often subdued by means of the smoke of tobacco; but this bird is only put into bad humour by the attempt. Buffon has observed that "it is thicker and shorter necked than most parrots; that its feathers are more stiffly set on, and that it is of a more dull and sluggish disposition."

PILEATUS; Hood Parrot. Green; head black; orbits white; spot on the shoulders blue; tail tipped with blue. It inhabits Cayenne, is about eight or nine inches long, and migrates.

LUDOVICANUS; Orange-headed Parrot. Sea-green; head tawny, inclining to red towards the bill. This species inhabits Louisiana; it feeds on the seeds of the *Bromelia* and *Liriodendron*, which see; it flies in large flocks, making a great noise; is not easily taught to speak, and is about thirteen inches long.

COLLARIUS; Red-throated Parrot. Green; chin reddish; throat red. It is a native of Jamaica, and about the size of a pigeon.

SENEGALLUS; Senegal Parrot. Green; beneath yellow; head cinereous; orbits black and naked. This, as its name imports, is found on the sandy shores of Senegal; its voice is harsh and unpleasing; it flies in flocks of six or seven, and rests on the top branches of trees.

TUIPARA; Red-fronted Parrot. Pale-green; lunule on the front red; spot on the middle of the wings yellow. It inhabits Brazil.

CHRYSOPTERUS; Golden-winged Parrot. Green; spot on the wings blue and tawny; orbits naked and white. It inhabits India.

PULLARIUS; Ethiopian Parrot. Green; front red; tail tawny, with a black band; the orbits are cinereous. This is not six inches long. It inhabits Guiana, Ethiopia, India, and Java; it imitates the manners of other birds, but does not easily learn to speak, and is fond of its own tribe.

MALACCENSIS; Malacca Parrot. Green; front and rump blue; under wing-coverts red.

CERVICALIS; Red-naped Parrot. Green; front and semilunar spot on the nape, under part of the throat, and breast scarlet.

INDICUS; Indian Parrot. Green; orbits pale flesh-colour; crown red or orange; hind part of the rump red; quill-feathers within and tail without blueish-green. It is a native of India, and about the size of a lark.

VERNALIS; Vernal Parrot. Bright green; wings paler; throat, rump, and tail blood-red.

GALGULUS; Sapphire Parrot. Green; rump and breast scarlet; the crown of the male bird is blue. There is a variety that has a yellowish-blue head, with a transverse orange bar behind; the front, the under part of the throat, and tail-coverts red. This species is about five inches long, and inhabits the Philippine islands. It sleeps suspended by one foot, and is very fond of the fresh juice of the cocoa-nut tree. If this is confined in a cage it seldom whistles, and grows fullen. It suspends itself by its feet, so that the back is turned towards the earth, and seldom changes this situation. Its favourite food is boiled rice. The nests are remarkable for the fineness of their texture. "If," says a traveller, "they had a different construction, the monkeys would be very mischievous to them; but now, before they can get to the opening, the lowest part, being the weakest, breaks in pieces, and the depredator falls to the ground, without in the least annoying the birds."

ANACA; Chestnut Parrot. Green; beneath tawny-brown; crown bay; spot on the back and tail pale-brown; wings edged with red. It inhabits Brazil, and is the size of a lark.

PURPURATUS; Purple-tailed Parrot. Green; crown and neck cinereous; rump, edge of the wings, and tips of the spurious wings, blue; tail purple, edged with black. It inhabits Cayenne, and is eight inches long.

CANUS; Grey-headed Parrot. Green; head, chin, and throat grey-green; tail rounded, with a broad black band. It inhabits Madagascar.

MELANOPTERUS; Black-winged Parrot. Pale-green; back, wing-coverts, band on the tail, and primary quill-feathers black; the secondary yellowish, dotted with blue. It inhabits Java and Luzonia, and is six inches long.

CAPENSIS; Cape Parrot. Green; some of the quill-feathers blue; bill and legs reddish. Inhabits the Cape, and is four and a half inches long.

TORQUATUS. Green; hind-head with a yellow transverse band streaked with black. This species inhabits the Philippine isles, and is five and a half inches long, and does not talk.

MINOR; Lesser Parrot. Green; crown scarlet; breast blue; greater quill-feathers black. It inhabits Luzonia, and is smaller than the last.

TOVI. Green; throat with a pale-orange spot; wings with a broad chestnut band, of a gold-green hue; about seven inches long, and is supposed to inhabit America.

TIRICA. Green; bill flesh-colour; legs and claws blueish. It is a native of Brazil and Jamaica, and the size of a lark.

SOSOVE; Cayenne Parrakeet. Green; a pale yellow spot on the wings and tail-coverts. This is a native of Guiana; is easily tamed, and is very talkative.

TUI; Gold-headed Parrakeet. Green; front orange; orbits yellow. It inhabits Brazil, and is the size of a starling.

ERYTHROCHLORUS; Red-tailed Parrot. Green; head crested; wings and tail red. It is the size of a black-bird; the crest of this bird consists of six feathers, three of which are longer and moveable at pleasure.

MEXICANUS; Mexican Parrot. Green; front crested; wing-coverts and tail purple; orbits blue; chin yellow; neck red. This is a native of New Spain, and is about seven inches long.

Among the many parrots that have been imported into this country, the one whose imitative talent was reckoned most extraordinary, belonged to colonel O'Kelly, which he purchased for 100 guineas. This bird not only repeated a great number of sentences, and answered questions, but was able to whistle many tunes. It appeared to have an accurate ear for music, and would beat time while it whistled; and if by chance it mistook a note, it would revert to the bar where the mistake occurred, and finish the tune with great accuracy. The writer of this article is at the moment within hearing of a bird, that will imitate the whistling of a black-bird and thrush, with a vast degree of accuracy. Colonel O'Kelly's parrot could express her wants articulately, and give her orders in a manner nearly approaching to rationality; she could sing a number of songs in perfect time and tune.

PSKOV, or **PLESKOW**, in *Geography*, a city of Russia, capital of a government, situated on the river Velika, where it discharges itself into the Tchudskoe lake; the see of an archbishop,

archbishop, and an university; 136 miles S.S.W. of Peterburg. N. lat. $57^{\circ} 50'$. E. long. $28^{\circ} 14'$.

PSKOVSKOI, a government of Russia, so called from its capital Pskov; bounded on the N. by the governments of Petersburg and Novgorod, on the E. by the government of Tver, on the S. E. by that of Smolensk, on the S.W. by that of Polotsk, and on the W. by that of Riga; about 200 miles long, and 96 broad. N. lat. $54^{\circ} 40'$ to $57^{\circ} 12'$. E. long. $27^{\circ} 24'$ to $32^{\circ} 34'$.

PSOAS, in *Anatomy*, the name of two muscles situated in the lumbar region.

The *psoas magnus* (prélombo-trocantinien) is placed at the lateral and inferior part of the vertebral column, at the side of the upper aperture of the pelvis, and in the upper part of the thigh. It extends from the side and lower part of the last dorsal vertebra to the apex of the trochanter minor. It is elongated, and larger in the middle than at the two extremities; so that it resembles two triangular pyramids joined at their bases. The external surface of the psoas slants backwards: it is covered above by the diaphragm, lower down by the kidney, the peritoneum, and the psoas parvus: still lower it becomes anterior, and is covered by the artery of the lower extremity. The posterior surface covers the quadratus lumborum, from which it is separated by the anterior branches of the lumbar nerves and the anterior layer of the aponeurosis of the transversus; it also covers the transverse processes of the lumbar vertebra, to the basis of which it is attached, excepting the fifth. About the middle of the psoas its posterior surface covers the ilio-lumbar ligament, and the iliacus internus muscle; it is at first separated from the latter by cellular tissue, by the lumbar nerves, and the ilio-lumbar vessels: the two muscles then become inseparably united. The tendon of the psoas, with the fleshy fibres of the iliacus internus coming to join it, covers the excavation on the front of the os innominatum from the anterior superior spine of the ilium to the linea ilio-pectinea. Lower down it covers the orbicular ligament of the hip-joint. Between the latter and the os innominatum on one side, and the tendon on the other, a bursa mucosa is placed, which communicates sometimes with the cavity of the joint. The internal surface of the muscle covers the side of the bodies of the lumbar vertebræ, and of their fibro-cartilages, to which parts it is attached, but only at the upper and lower part; for, at the middle of the bodies, it is separated from them by the lumbar vessels, and by the communicating filaments between the lumbar nerves and the great sympathetic. Between this internal surface, and the last lumbar vertebra, there is an interval filled by cellular substance: the surface then becomes narrower, and descends along the side of the upper aperture of the pelvis, covered by the external iliac vein and the tendon of the psoas parvus. Below the crural arch, the internal surface of the psoas grows still narrower, and is converted into an edge, which is parallel to the pectinalis, and separated from it by the internal circumflex vessels.

The upper extremity of the psoas is thin and pointed, and attached to the inferior and lateral part of the last lumbar vertebra, and sometimes to the posterior extremity of the last rib. Thence it descends along the side of the vertebral column, growing larger. It runs along the upper aperture of the pelvis, diminishing again in bulk, and directed a little outwards. Confounded with the iliacus internus, it passes out of the pelvis behind the crural arch, then descends on the upper and front part of the thigh, directed obliquely backwards and outwards, to the tro-

chanter minor, in the apex and anterior part of which it terminates.

The inferior extremity of the psoas magnus is formed by a strong tendon, common to it with the iliacus internus, and continued into the body of the muscle, as far as its middle, increasing in breadth. The fleshy fibres arise by short aponeuroses from the bodies of the last dorsal, and four upper lumbar vertebræ, their fibro-cartilages, and the transverse processes of the four first lumbar vertebræ; they terminate on all sides of the tendon, which they accompany very low, particularly on the inside.

The psoas magnus carries the thigh forwards on the pelvis, and rotates it outwards. If the thigh is fixed, it will bring the pelvis forwards on it, as in stooping to bring the hand to the ground. It may also bring the loins forwards on the pelvis. When the trunk is inclined backwards, it will restore it to the erect attitude; in the latter posture, it maintains the pelvis in equilibrio on the thigh, and prevents it from yielding backwards. It is much employed both in standing and walking.

The *psoas parvus* (prélombo-pubien), which does not always exist, is a long, thin, and flat muscle, situated on the outer and anterior part of the psoas magnus, and extending from the body of the last lumbar vertebra to the ilio-pectineal eminence. It is covered on the outside by the diaphragm, the renal artery and vein, the peritoneum, and the external iliac artery. Its internal surface covers the psoas magnus, and is united to it by loose cellular tissue. The upper extremity is fixed to the lower and lateral part of the body of the last dorsal vertebra, and to the fibro-cartilage between it and the first lumbar. It passes obliquely downwards and outwards, and soon forms a flattened tendon, which increases in breadth as it descends, covers the lower and anterior part of the psoas magnus, and terminates by an insertion in the ileo-pectineal eminence, and in the crista of the pubes. This tendon is continued, on the outside, into a fascia, which covers the iliacus internus, and joins the fascia lata (see FASCIA): the upper third of the psoas is fleshy; the two lower are tendinous. It will bend the pelvis on the loins, or the loins on the pelvis, according as the one or other of these is the fixed point.

PSOAS *Abscess*, in the language of *Surgery*, denotes a collection of purulent matter, which sometimes takes place in the course of the psoas muscle, and is a disease that is frequently attended with considerable danger. It is often called a *lumbar abscess*. It is occasionally the consequence of an acute inflammation of the cellular substance which lies about the psoas muscle; but, in by far the majority of examples, the inflammation which precedes it is entirely chronic. The inflammation of this last kind is merely accompanied with a pain about the loins, extending up the back, and down towards the thigh. Such pain is increased when the thigh is raised, or extended backward, or when the patient holds himself quite erect. Hence it is observable, that the patient, whether standing or walking, is obliged to incline his trunk forwards. When the inflammation is acute, the pain is severe; but when it is chronic, the uneasiness which the patient experiences is duller, and alternately subsides and recurs, and may easily be mistaken for sciatica, the pain arising from hemorrhoids, or that proceeding from disease of the kidney. The acute inflammation is usually attended with evident febrile symptoms; the chronic is seldom accompanied with them. The first falls into a state of suppuration with all the ordinary symptoms; the second suppurates for the most part slowly and imperceptibly, and often not till after a period of several months.

PSOAS ABSCESS.

The inflammation may be produced by a variety of causes. It may arise from a violent strain of the psoas muscle in leaping, raising a heavy weight, or in some other forcible bodily exertion. Sometimes it is brought on by exposure to cold, or by a blow or fall on the lower part of the back. In the latter case, it often does not occur till long after the occurrence of the injury, so that its cause is already quite forgotten. In numerous examples, the psoas abscess appears also to originate from internal causes; at least, it is remarked, that the disease happens with particular frequency in unhealthy subjects. In such cases, the commencement of the disorder is in general very obscure and imperceptible. All experienced surgeons have noticed how many of the patients with psoas abscesses are manifestly of a scrofulous habit. It has been supposed that the disease is commonly occasioned by a caries of the vertebræ, which are situated close to the origin of the psoas muscle. (Ford on Diseases of the Hip-joint.) Possibly this may sometimes be the real cause; but it is not invariably so; for in psoas abscesses it often happens that no caries whatever exists; and when it does, it may, with equal probability, be regarded as an effect of the abscess. Richter's *Anfangsgr. der Wundarzneykunst*, band 5. kap. 5.

The original situation of the abscess is generally in front of the psoas muscle, and very near to it; but it is also, in many instances, behind this part. By degrees the matter makes its way outward, though a long period often elapses ere this happens. Abscesses which follow acute inflammation usually point much earlier than those which are the consequence of chronic inflammation. In the former cases the cellular substance is apt to be extensively affected, and it falls into a state of suppuration; besides, acute inflammations much more quickly suppurate than those of the chronic kind.

While the abscess does not present itself externally, the diagnosis is attended with considerable difficulty and uncertainty. After the usual symptoms of inflammation, the patient is indeed conscious of several particular local sensations. For instance, he is sensible of weakness in the loins, which are also exquisitely tender on being touched, or when the thigh is moved, and the lower extremity is remarkably weak. Frequently some general signs of suppuration likewise occur, such as hectic fever, nocturnal sweats, diarrhœa, cough, &c. But all the local symptoms may be considered by the surgeon as proceeding from rheumatism, disease of the kidney, or hemorrhoidal complaints. In the early stage of the psoas abscess, the general symptoms of suppuration are hardly ever very obvious. The previous signs of inflammation are mostly so mild, and precede the formation of matter so long, that they often pass unnoticed. Besides, all conjectures respecting the nature of the disorder avail nothing, as the practitioner can adopt no effectual measures before the abscess presents itself externally.

The psoas, or lumbar abscess, presents itself in a variety of situations. In common cases, the matter descends, by its own weight, in the course of the psoas muscle, passes under Poupart's ligament, and occasions a fluctuating tumour in the soft part of the abdomen. The tumour is free from pain and inflammation; a circumstance which indicates that the matter is not formed in the situation of the swelling itself. The diminution of the local complaints about the lumbar region after the swelling has occurred; the manner in which the tumour is increased when the patient holds his breath or coughs; its sub-

sidence in an horizontal position, and under external pressure, together with other symptoms already noticed, are sufficient to prove that the matter in the swelling arises from a psoas abscess. There is a possibility of mistaking the tumour for a femoral hernia, as it is diminished when it is compressed, or the patient is in the recumbent posture. Such a mistake, however, cannot easily be made, because all other signs of a hernia are absent; the reduction and recurrence of the tumour are not proportioned to each other; a distinct fluctuation may be felt; and the general and local symptoms of a psoas abscess have prevailed. Sometimes also the swelling subsides so much, that betwixt it and Poupart's ligament, the surgeon can feel an interspace, which is entirely free from tumour.

The swelling in the bend of the thigh seldom attains a considerable size, for the matter commonly soon makes its way under the fascia of the thigh. In this circumstance it sometimes descends close to the knee, where it occasions a large external tumour, as in the groin. In some instances the matter collects itself into an abscess, near the insertion of the psoas muscle, at the inside of the thigh. Sometimes it passes down into the pelvis, and causes a swelling in the vicinity of the anus. In particular examples, it makes its way towards the loins and buttocks, and the swelling presents itself just where abscesses, arising from disease of the hip joint, frequently occur. In such cases, the sacrum and os coccygis are frequently carious. In less common examples, and probably when the matter is originally formed in the cellular substance, behind the psoas muscle, the abscess makes its way backwards, and occasions a swelling somewhere in the back. In still more unusual cases, the matter perforates the abdominal muscles, and produces a tumour in the belly. In all these instances, the previous general and local complaints; the subsidence of the latter, as soon as the swelling presents itself externally; the increase of the tumour, when the patient is erect, holds his breath, or coughs; and the diminution of it under external pressure, or by change of posture; are circumstances fully indicating the source of the matter.

An inflammation of the psoas muscle and adjacent cellular substance, not attended with any material degree of suppuration, would not be of itself a dangerous disorder, and no doubt might, in the generality of cases, admit of a curative plan adapted to the nature of the cause. General and local bleeding, blisters, cold applications, the exhibition of calomel, opium, and other antiphlogistic medicines; and the observance of rest, a horizontal posture, and, more especially, the avoidance of all motion of the thigh, by which the pain is always increased; seem well calculated to put a stop to the complaint, when its real character is discovered, at an early period of its progress. The pain in the loins, which is the principal symptom of such inflammation, is for the most part so moderate, that it is disregarded, and, as it may proceed from numerous causes, its true cause is generally not understood. The inflammation is only paid much attention to when it is acute, and hence this case is, in fact, the least serious, though the most uncommon.

When the inflammation has already terminated in suppuration, the abscess ought to be opened as soon as possible, that is to say, immediately it presents itself in some external situation; for, prior to this occurrence, no surgical operation is at all proper or practicable. As it is constantly advantageous to open the abscess early, and the collection of matter is generally late in presenting itself outwardly, it would be desirable, if the surgeon had any means by which he could promote the progress of the matter to the surface of the body; but, unfortunately, no such means have hitherto been devised.

PSOAS ABSCESS.

devised. The source of the matter lies so deeply, that no effect can reasonably be expected from the employment of external emollient applications.

Experience has clearly proved, however, that when the abscess is opened in the common manner, death generally takes place sooner than if no opening at all were made. A fever, accompanied with nocturnal sweats and diarrhoea, commonly soon comes on after the abscess has been punctured; the matter becomes thin, fetid, and acrid, and is incessantly discharged in large quantity; so that the patient at length dies debilitated and exhausted. This fatal event has been ascribed by surgical writers to a variety of causes; some dwell upon the entrance of the external atmospheric air into the cavity of the abscess; some build conjectures on the great distance of the source of the matter from the surface of the body, and from the reach of the practitioner; while others take more into consideration the ample extent of the cyst of the abscess.

The following circumstances seem to prove, says Richter, that the external air which enters the cavity of the abscess after the operation, has a material share in producing the bad and fatal symptoms. The fever and pain always become more violent after the opening has been made than they were previously. The whole cavity of the abscess appears to be in an inflamed state, in consequence of the irritation arising from the atmospheric air. When the abscess is first opened, the matter is usually observed to be of a tolerably good quality; but, very soon afterwards, it becomes fetid, thin, and acrid. This sudden change in the matter is also imputed to the effect of the air. It is remarked, likewise, that the larger the opening is which the surgeon makes, the greater is the degree in which the preceding circumstances occur; while, on the contrary, the smaller the aperture is the milder they are, and the result of the operation is in proportion more successful. Hence, it is better to let the abscess break of itself, than make a large opening; for the aperture which is formed by ulceration is mostly a small one. Such lumbar abscesses as make their way through the abdominal muscles, and present themselves at the belly, are found to be less dangerous than others, perhaps (adds Richter) because the passage of the matter through the muscles towards the surface of the body is so crooked, that the opening of the tumour does not readily give admission to the air into the original cavity of the abscess, so as to excite inflammation and other bad consequences. Lastly, the observations of Mr. Abernethy prove, that the operation may be frequently repeated with the greatest success, provided it be done so as not to let the air enter the cyst of the abscess.

But, notwithstanding the preceding observations, it is now the opinion of the most accurate surgeons, that the bad effects of the air on abscesses have been exaggerated beyond all moderation. In the first place, it is almost certain that when a lumbar abscess is opened, no air at all can insinuate itself into the cyst, which is so strongly compressed by all the surrounding parts, that its capacity is diminished immediately the matter escapes from it. Secondly, even if air were injected into it, the consequences would not be so terrible as has been commonly represented. It is more probable that the irritation which a large opening itself produces in the extensive cyst, and the consequent inflammation of the whole of its surface, are the real cause of the violent fever which is so apt to arise, and of the changes in the quality of the matter afterwards secreted. We can believe with Hunter, that, were it possible to make a large opening in a lumbar abscess, even in a vacuum, the same dangerous conse-

quences would be just as likely to follow, as when such an opening is made while the surface of the body is exposed to the air.

The apprehension entertained by many practitioners in regard to mischief caused by the entrance of the air into the cysts of lumbar abscesses, has led to the almost universal advice to take the precaution of making the opening in such a way, that no opportunity will be afforded for the air to enter into the cavity from which the matter is discharged. It has also been the usual aim of practitioners to lessen the cyst of the matter, and bring it so near the surface of the body, that the case may be opened and treated like other abscesses, without any risk of dangerous consequences. Both these indications are fulfilled in the mode of treatment recommended by Mr. Abernethy, who opens the collection of matter with an abscess lancet, and as soon as the pus is discharged, brings the sides of the puncture together with sticking plaster, and heals the aperture by the first intention. Immediately the tumour rises again, it is emptied again in the same manner, and the operation may be repeated, if necessary, three or four several times, or even still more frequently.

In this plan of treatment, regularly as the matter is formed again after each operation, it descends, by its own weight, to the lower part of the cyst of the abscess under Poupart's ligament, where it occasions a return of the swelling. But before the upper part of the cyst is filled with matter again, the surgeon takes a proper opportunity of repeating the operation. Thus the highest portion of the cyst is continually kept empty, and, consequently, by degrees contracts itself, and is obliterated. The lower external part of the cyst, situated under Poupart's ligament, is all that remains, and an immense psoas abscess is in this manner converted into a small superficial abscess, which may now be safely opened, and treated like any ordinary case.

But in order to succeed in effecting this desirable alteration of the cyst of the abscess, the surgeon should not defer the second operation too long. Immediately the swelling is sufficiently prominent to admit of being opened with safety, the operation ought to be repeated. We may conclude, that the upper and deeper part of the cyst is obliterated, and that the psoas abscess is changed into one of a superficial kind, when, in the last operation, the quantity of matter discharged is small; when no more can be got out either by pressure, or making the patient stand up and cough; when no material impulse is communicated to the tumour by coughing; and when the swelling is no longer capable of being lessened by pressure, or the horizontal position. As soon as these changes are remarked, the radical operation may be undertaken, which consists in making an incision into the tumour, and healing it like any common abscess.

It is advantageous in puncturing a psoas abscess to let the opening have a perpendicular direction; for a transverse wound may easily be forced open again from violent coughing, or forcible extension of the thigh. When the external swelling is small, care must be taken not to injure the large crural vessels with the lancet. On this account, the opening ought to be made as much as possible towards the side of the tumour. During the operation the patient should stand up, and be directed to hold his breath, and cough frequently, so that all the matter may be discharged. When the surgeon entertains the slightest doubt concerning the nature of the swelling, he acts prudently in making the opening cautiously, with a bistoury, and not of too large a size. After the contents of the abscess have been let out, the opening ought always to be accurately closed with sticking plaster. The patient,

patient, throughout the treatment, must abstain from all exercise, and especially avoid moving the thigh, taking care, however, to be as much as he conveniently can in an erect posture.

In general, it will be proper to make the second puncture about a fortnight after the first. But if the swelling becomes very prominent earlier, and, particularly, if the first puncture puts on an inflamed appearance, the second opening ought to be made sooner. In every repetition of the operation, the quantity of matter will be found to be diminished, a sufficient proof that the cavity of the abscess is lessened. For instance, if in the first operation three pints of matter are discharged; in the second the surgeon will let out only about twelve ounces; in the third, six; in the fourth, four; and so on. After the abscess has been emptied three or four times, the upper portion of the cavity is usually obliterated, so that the radical operation for the cure of the lower and superficial remains of the abscess may now be attempted.

Candour urges us to confess, however, that there are cases in which the preceding mode of treatment proves ineffectual. Such are the examples, in which, notwithstanding every precaution, the cyst of the abscess inflames; the puncture ulcerates; where the disorder has originated from internal causes, which yet continue to influence and keep up the disease; where caries exists; and where the abscess has been the consequence of acute inflammation. It is particularly to chronic abscesses that the foregoing plan of treatment is adapted. When this treatment fails, two things may happen; the discharge may continue to be so profuse, that the patient is exhausted; or the abscess may end in a fistula, with which the patient may live a great while. The surgeon, however, is not to abandon all hope in the above description of cases. When the puncture inflames, the bad consequences may often be averted by speedily letting out the newly collected matter through another puncture, at some distance from the other, the antiphlogistic treatment being strictly observed. When some internal cause has a share in keeping up the disease, its removal is obviously indicated. Lastly, experience proves, that, though caries may exist, the termination of most cases is favourable. When the bones are suspected of being diseased, issues in the vicinity of them is a measure which should never be neglected.

Some writers and practitioners prefer opening lumbar abscesses with a seton; while others are advocates for the bold practice of letting out the matter with a trocar, the cannula of which they recommend to be left in the part, and closed with a stopper, which may be taken out as often as necessary, for the purpose of discharging the matter.

PSOL, in *Geography*, a river of Russia, which rises near Oboian, in the government of Kursk, and runs into the Dnieper, near Kremenzug, in the government of Ekaterinoflav.

PSOPHIA, *Trumpeter*, in *Ornithology*, a genus of birds of the order Grallæ: the generic character is, bill cylindrical, conic, convex, somewhat pointed, the upper mandible the longer; nostrils are oval, pervious; tongue cartilaginous, flat, fringed at the tip; feet four-toed, cleft. There are two

Species.

CREPITANS; Gold-breasted Trumpeter. Black; back grey; breast shining blue-green; orbits naked and red. The bill is yellowish-green; legs strong, tall, brownish-ash or green; beneath the back-toe is a round protuberance, at a little distance from the ground; the tail is very short; feathers of the head downy, of the lower part of the neck

squamiform, of the shoulders ferruginous, lax, pendulous, silky; scapulars long, pendent. This is the *agami* mentioned by voyagers: it is nearly twenty-two inches long, and about the size of a full-grown domestic fowl. It inhabits South America, particularly the interior parts of Guiana, in considerable troops. In its native haunts, it is not distrustful of man, and is susceptible of domestication in an eminent degree, acquiring many of the social habitudes of the dog. It emits from the lungs a harsh and uncommon noise, not unlike that of a child's trumpet, hence its trivial name. It stands on one leg, and sleeps with its neck drawn in between the shoulders; the eggs are blue-green.

UNDULATA; Undulated or African Trumpeter. Crest of the hind-head short and whitish; of the breast long, black, pendent. It is a native of Africa, and is the size of a goose.

PSORA, in *Botany*, $\Psi\omega\sigma\alpha$, *scurf of any kind*, and among others *that of trees*. Hence the name is employed to designate a supposed genus of *Lichenes*, established by Hoffmann, whose habit is crustaceous or scurfy. See LICHEN and LICHENES.

PSORA, $\Psi\omega\sigma\alpha$, in *Medicine*, a term which has been very generally, but incorrectly, applied to the contagious eruption of the skin, called *itch*.

The appellation, *psora*, was universally employed by the Greek physicians to designate a scaly or scurfy disorder of the skin, and not the vesicular or pustular itch. Occasionally, indeed, they conjoined the epithet $\epsilon\lambda\kappa\omega\delta\eta\iota\varsigma$, *ulcerating*, with the term *psora*; thus obviously distinguishing the ulcerating or pustular disease (which appears to have been *impetigo*), from the *psora* simply, which always signified the dry, scaly, or scurfy tetter, mentioned below under the appellation of *psoriasis*. Hippocrates classes the *psora* with lepra, alphas, and lichenes, considering them as blemishes, rather than diseases. And the Greek writers, who followed him, looked upon the prurigo, lichen, *psora*, and lepra, as progressive degrees of the same affection;—the prurigo being a simple itching,—the lichen, itching combined with roughness of the skin,—the *psora*, itching with branny exfoliations,—and the lepra, itching with actual scales. (See Actuarius, *Math. Med. lib. ii. cap. 11.*) The misapplication of the term to *itch*, seems to have originated with some of the early translators of the Greek writings, who considered *scabies* (quasi *scabrities*) as synonymous with $\Psi\omega\sigma\alpha$, or a roughness of the skin; whence the true scabies, or itch, was subsequently confounded with *psora*. (See ITCU.) Sir John Pringle remarks, that the general opinion, that the *psora* mentioned by the Greeks is the itch, is so far from being evident from their writings, that he is rather disposed to conclude, that the itch was either altogether unknown, or at least uncommon among the ancients. On *Diseases of the Army*, p. iii. chap. 8. See also Bateman's *Pract. Synopsis of Cutan. Diseases*. pp. 6 and 186, *notes*.

PSORALEA, in *Botany*, from $\Psi\omega\sigma\alpha\lambda\epsilon\iota\sigma\varsigma$, *scabby*, because the calyx, and other parts of the plant, are more or less besprinkled with glandular dots, giving a scurfy roughness. Linn. *Gen.* 386. Schreb. 508. Willd. *Sp. Pl.* v. 3. 1342. Mart. *Mill. Dict.* v. 3. Ait. *Hort. Kew.* v. 4. 374. Juss. 355. Lamarck *Illustr. t.* 614. Gært. *t.* 145.—Class and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, dotted with tubercles, in five acute, permanent, equal segments, the lowermost only twice as long as the rest. *Cor.* papilionaceous, of five petals, with coloured veins; standard roundish, emarginate, directed upwards; wings crescent-shaped, obtuse, small; keel crescent-shaped, obtuse, of two petals.

petals. *Stam.* Filaments in two distinct sets, one simple and setaceous, nine combined, all ascending; anthers roundish. *Pist.* Germen superior, linear; style awl-shaped, ascending, the length of the stamens; stigma obtuse. *Peric.* Legume the length of the calyx, without valves, compressed, ascending, pointed. *Seed* one, kidney-shaped.

Eff. Ch. Calyx the length of the legume. Stamens in two distinct sets. Legume single-seeded, somewhat beaked, without valves.

The plants of this genus are chiefly shrubby, and the greater part natives of the Cape of Good Hope. A few are found in the south of Europe, and still fewer in America. The *leaves* are either pinnate, ternate, or simple. *Flowers* spiked or solitary, of a dull blue or dirty white. Linnæus has fourteen *Pforalea* in his *Sp. Pl.* two of which now enter the restored genus of *Dalea*. Willdenow has twenty-nine. Nineteen are mentioned in the new edition of *Hortus Kevenfis*, all green-house plants, except the last, *corylifolia*, which is an East Indian biennial species.

Pf. pinnata. Wing-leaved Pforalea. Linn. *Sp. Pl.* 1074. Willd. n. 1. Ait. n. 1. Andr. *Repos.* t. 474. (*Spartium africanum*; Riv. *Tetrap. Irr.* t. 5.)—Leaves pinnate, of two or three pair of linear leaflets, with an odd one. Stalks axillary, single-flowered.—Native of the Cape; an old inhabitant of our green-houses, where it flowers in summer. The *stem* shrubby, much branched. *Leaves* alternate, stalked, dark-green, smooth; *leaflets* about an inch long, narrow. *Stipulas* in pairs, ovate, pointed. *Flowers* the size of the laburnum, blue, with white claws.

Pf. bracteata. Oval-spiked Pforalea. Linn. *Mant.* 264. Willd. n. 6. Ait. n. 5. Jacq. *Hort. Schoenbr.* v. 2. 52. t. 224. Curt. *Mag.* t. 446.—Leaves ternate; leaflets obovate, with a recurved point, and besprinkled with pellucid dots. Spike terminal, capitate. Bractæas fringed.—From the same country, and likewise a common green-house shrub, flowering in summer.—Linnæus once made it a *Trifolium*, as Commelin had done before him. The *flowers* are numerous at the ends of the branches. *Standard* violet. *Wings* and *keel* white.

Pf. aphylla. Leafless Pforalea. Linn. *Sp. Pl.* 1074. *Mant.* 450. Willd. n. 9. Ait. n. 7. Jacq. *Hort. Schoenbr.* v. 2. 51. t. 223.—Stem-leaves ternate or simple. Branches leafless. *Stipulas* somewhat imbricated.—From the same country, introduced at Kew by Mr. Masson in 1790. It flowers in June and July. The long leafless scaly *branches* terminate in a longish cluster of several *flowers*, whose *standard* is blue, the other *petals* white.

Pf. bituminosa. Bituminous Pforalea. Linn. *Sp. Pl.* 1075. Willd. n. 21. Ait. n. 14. Sm. *Prodr. Fl. Græc. Sibth.* v. 2. 92. *Fl. Græc.* t. 738, unpublished. (*Trifolium bituminosum*; Riv. *Tetrap. Irr.* t. 14. Dod. *Pempt.* 556. Ger. *Em.* 1187.)—Leaves ternate; leaflets ovato-lanceolate. Footstalks downy, without glands. Spikes capitate, stalked, axillary.—Native of the south of Europe, in stony ground; frequent in Greece and its neighbouring islands. It is one of our oldest and most common green-house shrubs, though not remarkable for beauty. The whole plant when rubbed has a strong bituminous smell. The *flowers* are of a dull blue, with a dark-coloured *calyx*. Their common *stalks* are usually much longer than the *leaves*. This plant appears evidently, by the precise description in Dioscorides, to be his *τριφυλλον*, or Trefoil.

Pf. corylifolia. Hazel-leaved Pforalea. Linn. *Sp. Pl.* 1075. Willd. n. 27. Ait. n. 19. Curt. *Mag.* t. 665. Burm. *Ind.* t. 49. f. 2.—Leaves simple, ovate, somewhat toothed. Spikes ovate.—Native of the coast of Coromandel, hence it requires to be treated as a tender annual, or

biennial, flowering in summer, and readily ripening seed. The habit is herbaceous. *Leaves* two or three inches broad. *Flowers* small and inconspicuous, with a pale purplish *standard*, and darker *wings*, as well as *keel*, forming small, long-stalked, axillary heads or spikes. Dr. Sims, in Curt. *Mag.*, judiciously indicates the great generic affinity of this plant and *Trifolium caruleum*, or Blue Melilot.

PSORALEA, in *Gardening*, comprises plants of the shrubby exotic kind for the green-house and stove, of which the species cultivated are, the winged-leaved pforalea (*P. pinnata*); the prickly pforalea (*P. aculeata*); the oval-spiked pforalea (*P. bracteata*); the hairy pforalea (*P. hirta*); the bituminous pforalea (*P. bituminosa*); the American pforalea (*P. americana*); the hazel-nut-leaved pforalea (*P. corylifolia*); and the annual pforalea (*P. dalea*).

Method of Culture.—These plants are increased by sowing the seeds in the early spring months, on a moderate hot-bed, or in pots, plunging them in it. When the plants have attained three or four inches in growth, they should be planted out into small pots separately, gradually hardening them to the open air, so as to be placed out in it in the beginning of the summer. They are likewise capable of being increased by planting cuttings of the young shoots in the summer months, in pots filled with light earth, plunging them in a moderate hot-bed and covering them close with glasses, watering and shading them well till they have stricken root.

They afford variety among other potted green-house plants.

PSORAS, in *Ichthyology*, a name by which some authors have called a fish of the turdus kind, remarkable for the variety and beauty of its spots, and more usually known by the name lepras.

PSORIASIS, in *Medicine*, *ψωριασις*, a term used by the ancients to express a scaldness and roughness of the eyelids and corners of the eyes, and also a rough and scaly state of the scrotum, attended with great itching. (See Galen de Oculo, cap. 7, and *Definit. Med.*) Dr. Willan, however, in his classification of cutaneous diseases, thought proper to extend the signification of the word to the more general eruptions of a scaly nature, namely, to the dry or scaly tetter, (the *psora* of the same writers,) for the purpose of avoiding the confusion, which the double signification of this term among the ancients, and the misapplication of it to scabies by the moderns, was likely to produce. (See PSORA.) Whence, in the nomenclature of our contemporaries, the

PSORIASIS, or *Scaly Tetter*, is a disease of the skin, “characterized by a rough and scaly state of the cuticle, sometimes continuous, sometimes in separate patches of various sizes, but of an irregular figure, and for the most part accompanied with rhagades, or fissures in the skin.” (Willan on Cutan. Diseases, p. 149.) This tetter is, therefore, very analogous to lepra, and in some cases, indeed, the two diseases run into each other. The lepra differs, however, in general, by its oval or circular figure, its elevated border, and large scales; whilst the psoriasis has no regularity of form, is more scurfy, is often intermixed with chaps, and usually attended with some disorder of the constitution. Similar distinctions were pointed out by the Greek writers between the lepra and psora. Paul of Ægina says, “*Lepra* affects the skin deeply, in circular patches (*κυκλωσεως*), and throws off scales like those of fishes; but *psora* is more superficial, and variously figured, and throws off bran-like substances.” (Lib. iv. cap. 2.) Actuarius gives a similar statement of the characteristics of the two diseases. The older writers among the moderns have comprised the psoriasis under

PSORIASIS.

under the appellations of *psora sicca*, *scabies sicca*, and *impetigo*. See Etmüller, Hoffmann, Mercurialis, &c.

In the first edition of his work, Dr. Willan described eight varieties of the psoriasis, which, in his second edition, he extended to eleven, by the addition of some local varieties, affecting the prepuce, eye-lids, &c.

1. The psoriasis *guttata*, in which the eruption appears in very small, separate patches, of an irregular form, seldom exceeding two or three lines in diameter, may be deemed a sort of connecting link between this genus and lepra. The little patches have not the regular oval or circular margin of lepra, nor the elevated border of that disease, and the scales which form upon them are thinner, and separate in smaller fragments, and, when detached, they leave a less inflammatory, though somewhat red and polished, base. There is scarcely any part of the body on which the patches do not appear, not excepting even the face, which is rarely the seat of lepra; but in the latter situation, they exhibit only a redness and roughness, without any actual scales. In children, the eruption often appears suddenly, accompanied by some degree of febrile irritation, and spreads rapidly over the body: but in adults its progress is gradual and slow, and it is apt to return in the spring season for several successive years, preceded by head-ache, and pains in the stomach and limbs.

2. The psoriasis *diffusa* presents a considerable variety of appearances. In most cases it consists of large patches, which are irregularly circumscribed, and exhibit a rough, red, and chapped superficies, with very slight scaliness interspersed. This surface is often exceedingly tender and irritable, and is attended with a sensation of burning and intense itching, both of which are much augmented by approaching a fire, on becoming warm in bed, or even on exposure to the direct rays of the sun; but they are relieved by the impression of cool air. As the disorder proceeds, the redness increases, and the skin appears thickened and elevated, with deep intersecting lines or furrows, which contain a powdery substance, or very minute scurf. The heat and painful sensations are much aggravated by the least friction, which also produces excoriation, and multiplies the sore and painful rhagades. This form of the disease is most frequent about the face and ears, and the back of the hands; but occasionally occurs on other parts of the body, either at the same time or in succession, as in the forehead and scalp, the shoulders, back, loins, and abdomen, on the fleshy parts of the lower extremities, the outside of the fore-arm, and the instep. When the scales are removed by frequent washing, or by the application of ointments, the surface, though raised or uneven, appears smooth and shining, and crossed with deep furrows. Should any portion of the diseased surface be forcibly excoriated, a thin lymph issues out, mixed with some drops of blood, which slightly stains and stiffens the linen, but soon concretes into a thin dry scab: this is again succeeded by a white scaliness, gradually increasing, and spreading in various directions. As the eruption declines, the roughness, chaps, scales, &c. disappear, and a new cuticle is formed, at first red, dry, and shrivelled, but which, in two or three weeks, acquires the proper texture. The whole duration of the complaint is from one to four months, and in some cases much longer.

On the first appearance of psoriasis *diffusa*, the constitution is usually somewhat disordered; there is a feeling of universal languor and debility, with loss of appetite, head-ache, pain or sickness at the stomach, and pains in the limbs. During the progress of the eruption these symptoms are diminished, or cease altogether; but the eruption is apt to return at particular seasons, and each return is usually pre-

ceded by the same symptoms. The disease is often confined to a solitary patch, of an irregular form, red, scaly, chapped, and itching, situated on the face, the breast, calf of the legs, about the wrist or elbow, and especially about the lower part of the thigh behind. In any of these situations, it continues several months with little alteration. The eruption called the *baker's itch*, which occurs on the back of the hand in bread-bakers, is the psoriasis *diffusa*, and consists at first of one or two small, rough, scaly patches, which extend and coalesce, reaching from the knuckles to the wrist. Washerwomen are also subject to a peculiarly severe form of this psoriasis, on the hands, wrists, and fore-arms, apparently from the irritation of soap. From the whole of the surface, which is highly inflamed, the scaly and brittle cuticle separates in large irregular flakes in rapid succession.

3. Psoriasis *gyrata*. In this form of the disease, the tetter is distributed in narrow patches or stripes, of various figures; some of them are nearly straight, some circular, or semicircular, with worm-like extremities, and some are tortuous or serpentine, resembling earth-worms or leeches. The arrangement of these patches is singular, often regularly corresponding on both sides of the chest or spine. A slighter variety of this tetter affects delicate young women and children, in small scaly circles, slightly discoloured, on the cheeks, neck, and upper part of the breast, which are sometimes called ringworms.

4. The psoriasis *palmaria*, a very obstinate species of tetter, is nearly confined to the palm of the hand. It commences with a small, harsh, or scaly patch, which gradually spreads over the whole palm, and sometimes appears in a slighter degree on the inside of the fingers and wrist. Its colour often changes to a dirty hue, which the most diligent washing does not alter. The cuticular furrows are deep, and cleft at the bottom in various places, so as to bleed on stretching the fingers. There is usually a sensation of heat, pain, and stiffness in the motion of the hands, and often a troublesome itching, especially on the returns or aggravations of the eruption. It is most troublesome in the winter and spring; in summer and autumn it sometimes disappears, leaving a soft dark red cuticle; but many persons have it for a series of years, with only very slight remissions. Shoemakers are subject to this complaint from the irritation of the wax which they constantly employ; and braziers, tinmen, silversmiths, &c. seem to suffer by it from handling cold metals. But it is often produced without any very obvious irritation; and a scaliness of the soles of the feet, but without chaps, occasionally concurs with the affection of the hands.

5. Psoriasis *labialis*. The lips are sometimes affected with scaliness, intermixed with chaps and fissures of the cuticle, when the other parts of the body are free from psoriasis. The scales that form on the lips are of a considerable magnitude, so that their edges are often loose while the central points are attached: a new cuticle gradually forms beneath the scales, but it is not durable; in the course of a few hours it becomes dry, shrivelled, and broken, and while it exfoliates, gives way to another layer of tender cuticle, which soon, in like manner, perishes. These appearances should be distinguished from the slight chaps and roughness of the lips, produced by very cold or frosty weather, and which are easily removed. The psoriasis *labialis* may be a little aggravated by frost or sharp winds, yet it receives no material alleviation in warm weather: it continues in many cases, indeed, through all seasons. The under lip always suffers more than the upper; and the disease especially affects persons whose lips are full and prominent.

6. Psoriasis *ophthalmica*. This affection begins about the
4 X 2 external

PSORIASIS.

external angles of the eyes, producing a bright redness of the skin, with a smooth, shining, and somewhat moist surface; and the edges of the eye-lids near the angles become thickened and rigid, and somewhat inflamed, with considerable itching.

7. The psoriasis *præputii* often accompanies the psoriasis *palmaria*. It is characterised by a scaldiness, with painful fissures and thickening of the prepuce. These symptoms, being usually attended with a phymosis, render connubial intercourse difficult, or even impracticable. In some cases, both internal medicines and external applications disappoint our expectation, and the patient can only be relieved by circumcision. This complaint should be carefully distinguished from the venereal phymosis, in which scales and fissures of the skin do not occur.

8. Psoriasis *scrotalis*. Sometimes the skin of the scrotum is affected with roughness and scaldiness, together with much heat, itching, tension, and redness, independently of any similar affection in other parts of the body. The symptoms are succeeded by a hard, thickened, brittle texture of the skin, and by painful chaps or excoriations, which are not easily healed. The itching and irritation are much increased by changes of temperature, especially on undressing, or getting into bed. The disease sometimes appears to be the sequel of the prurigo scroti.

9. Although the nails are generally affected only in conjunction with the tetter of the hands and arms, yet occasionally a psoriasis *unguium* occurs alone, when the nails are bent either upwards or downwards at their extremities, and are either rough and ragged, or thickened and deeply furrowed, and of a brown or yellowish hue.

10. The psoriasis *infantilis*, which occurs under the age of two years, does not differ materially in its appearances from the psoriasis *diffusa*, but Dr. Willan marked it as a variety, because it is sometimes succeeded by inflamed and suppurating pustules, and because it is not easily distinguishable from the scaly disease which occurs in infants from venereal infection. The nature of it can only be determined by taking into consideration the collateral circumstances.

11. The last variety described by Dr. Willan is the psoriasis *inveterata*, the most severe modification of the complaint, beginning in separate irregular patches, which multiply and become confluent, until they extend over all the surface of the body, except a part of the face, or sometimes the palms of the hands and soles of the feet, producing at length an almost universal scaldiness, interspersed with deep furrows, and a harsh and thickened state of the skin, which is red, stiff, and rigid, impeding the motion of the joints. The production and separation of scales is so rapid, that large quantities are found in the bed in which the patient has slept. Sometimes the eruption becomes extensively inflamed, and even excoriated, discharging lymph, after which a dry, hard, and horny cuticle is formed, which separates, not in scales, but in large pieces. The nails, both of the fingers and toes, become thickened, convex, and opaque, and are at intervals renewed, but the new ones soon assume the same morbid form. The disease often continues, with indeterminate remissions and exacerbations, for a long period of time, especially in old people, but sometimes even occurs in the young. It results occasionally from repeated attacks of the psoriasis *diffusa*; and has sometimes followed the prurigo *senilis*.

The causes of psoriasis are by no means obvious in general. It is not contagious, as asserted by some of the older writers, unless the appearance of the small circles in children of the same family or school, can be considered as a proof of contagion in these cases. The other forms of the disease were never seen to spread by contagion. A strong hereditary

disposition to it is certainly manifest in some individuals. Dr. Falconer, in his paper on the lepra græcorum, in which he includes also the scaly tetter (see Memoirs of the Med. Society of London, vol. iii.), ascribes it, in many instances, to sudden chills, from drinking cold water after being violently heated by exercise, a cause to which many other eruptive diseases have been imputed. Women, and especially those of a sanguineo-melancholic temperament, are most liable to it, having a dry skin and languid circulation; and it affects them more particularly after parturition, or during a state of chlorosis. Dr. Willan had observed it occasionally in both sexes, connected or alternating with gouty rheumatic affections; and we have sometimes seen it occur under a state of great mental anxiety, grief, or apprehension. In those who are constitutionally predisposed to this eruption, indeed, slight occasional causes seem to be capable of producing it; such as being overheated by exercise, the unseasonable use of the cold-bath, a copious use of acid fruits, vinegar, or crude vegetables, and some incongruous mixtures of food.

Treatment of Psoriasis.—The same general mode of treatment is applicable to the different modifications of the disease, but especially to the three first species, which are not limited to particular parts. The popular practice, which is much the same as that which was recommended by Willis above a century ago, is founded upon the old humoral pathology, and consists chiefly in attempts to expel imaginary humours by evacuants, or to correct them by what are called antiscorbutics. But experience has proved, that a system of blood-letting and of repeated purging is injurious, and that the vegetable juices and acids are not merely void of all efficacy, but absolutely prejudicial. In fact, the erroneous notion, that these tetter, and most other cutaneous affections, are of a *scorbutic* nature, seems alone to have led to the use of these medicines. A more recent empiricism, which resorts to mercury in all diseases of a chronic nature, and of some obscurity of character, is not more successful; for from the time of Willis (de Med. Operat. p. 292.) the inefficacy of a mercurial course, whether internal or by external friction, has been acknowledged by all observing practitioners. Dr. Willan says, that, from many experiments cautiously made, he was well assured that strong mercurial preparations are of no advantage in the scaly tetter, but eventually rather aggravate the complaint. Chalybeate waters, such as those of Scarborough and Tunbridge, and chalybeate medicines generally, appear to have no direct remedial operation in this disease, but are sometimes secondarily useful by improving the constitution.

In the commencement of psoriasis, especially under the three first varieties, and when it appears suddenly in connection with febrile symptoms, a moderate antiphlogistic treatment must be pursued. A gentle purgative should be administered, and the diet made light, by abstracting every thing stimulant. This regimen is, indeed, necessary throughout the course of the disease, which is immediately aggravated in sympathy with irritation of the stomach, whether by spices, fermented and vinous liquors, pickles, &c. But when the constitutional disturbance has subsided, the use of the fixed alkali, with sulphur lotum, together with tepid washing with simple water, or milk and water, will be beneficial. If the scaly patches have extended over a considerable part of the body, or the disease have assumed the inveterate form, it must be considered in a similar light with the lepra vulgaris, and treated by the medicines recommended for that disease. (See LEPROSY of the Greeks.) It is very difficult by any local applications to give the patient relief from the shooting and burning pain and itching, which he anxiously

looks for : he is mortified to find that even the mildest substances often prove irritants, and aggravate his distress. A decoction of bran, a little cream, or oil of almonds, sometimes produce ease.

But the more local and less inflammatory eruptions of psoriasis not only bear, but require local expedients. In the psoriasis *palmaria*, the same internal medicines are proper, as in the other forms of the disease : but the heat, dryness, and itching of the palms, are relieved by holding them for some time every night in the vapour of hot water, and afterwards putting on gloves made of oiled silk, and by applying the unguentum hydrargyri nitrati, diluted with some mild ointment, according to the degree of irritation in the skin. Sea-bathing, continued for many weeks, is generally an effectual remedy.

In the psoriasis *labialis*, the same temperate regimen is particularly necessary, and remedies for the correction of disordered stomach should likewise be prescribed. All acrid applications should be avoided, as uniformly detrimental to the lips, which should be kept almost constantly covered with some mild ointment or plaister, that they may not be influenced either by heat or cold. To the psoriasis *ophthalmica* and *scrotales*, the diluted ointment just mentioned may be applied with advantage ; but in the latter complaint, besides this application and the use of general remedies, great care is requisite to keep the parts clean by frequent ablution with warm water, gruel, &c., and to prevent attrition by the constant use of the ointment. In the psoriasis *unguium*, the nails may be immersed from time to time in warm water, and cut smooth. The complaint, however, is more likely to be removed by sea-bathing, and other remedies which act on the constitution, than by any local application. See Willan on Cutaneous Diseases, p. 149, &c. ; Bateman's Practical Synopsis of Cutan. Diseases, p. 36.

PSORICA, ψωριζα, medicines good against the itch, scabs, and other cutaneous eruptions, especially those of the eye-lids.

PSORICE, or PSORICE-Ροα, a name given by the botanical writers among the ancient Greeks to the plant we call *scabiosa*, or *scabious*.

PSOROPHTHALMIA, ψωροφθαλμια, from ψωρος, and οφθαλμια ; *scabies oculi* ; *lippitudo scabra* ; *oculi psoriasis*. Psorophthalmia, in *Surgery*, means a disease of the eye-lids, which consists of an inflammation and ulceration of their internal membrane near their edges, attended with a discharge of acrid purulent matter. In order to have an accurate idea of psorophthalmia, one must recollect, that both the tarfi have on their inner surfaces several perpendicular rows of sebaceous glands, the excretory ducts of which terminate just within the internal margin of each cartilage, where they pour out an unctuous kind of secretion, commonly known by the name of the humour of Meibomius. It is these glands which are particularly affected in psorophthalmia ; the matter which they are accustomed to secrete, instead of being soft and bland, becomes acrid and adhesive, producing a substance which is usually called gum, and which irritates the eye and eye-lids, causes ulceration of the edges of the latter parts, and thus keeps up the disease for a very long time. Monsieur St. Yves, in treating of the ophthalmia, which is occasioned by the small-pox, has drawn up one of the most correct descriptions of psorophthalmia, which is any where extant.

Psorophthalmia frequently follows inflammation of the eye, and sometimes accompanies all its stages. This is very common in scrofulous subjects, and patients troubled with herpetic disorders. But, occasionally, psorophthalmia is the consequence of that purulent affection of the eye-lids,

to which the Greeks have given the name of σ'ιον. In psorophthalmia, the ulceration is ordinarily confined to the edge of the eye-lids ; but, in particular instances, it extends much further over their outer surface, and even over the cheeks, which are excoriated, and have an erysipelatous appearance. It is also sometimes accompanied with an eversion, or true ectropium of the lower eye-lid, in which circumstance the case proves exceedingly obstinate. The ancients, and even several of the moderns, have detailed different affections, which bear considerable resemblance to those which have just now been mentioned ; but they have regarded them as depending upon some constitutional disease, which requires removal, and which, being cured, is always followed by the relief of the symptomatic complaint of the eyes. Where other symptoms exist, shewing a foundation for the suspected disease of the habit, the previous doctrine may be really true ; but when no symptoms of this kind prevail, it may lead to very erroneous practice. The ulceration of the ciliary glands in psorophthalmia, may be seen not only with a magnifying glass, but even with the unassisted eye, when the eye-lids are everted. The matter poured out from them is of an irritating quality, and, when dry, forms gummy incrustations, which glue the eye-lids together. When psorophthalmia is accompanied with symptoms, evincing that the disorder is combined with disorder of the system, the first indication is to endeavour to amend the state of the constitution.

Scrofula is the disease with which psorophthalmia is most apt to be conjoined, and, in this case, it is necessary to prescribe such general remedies as are found to be most effectual for scrofula, at the same time that topical applications are employed. Baron Stork spoke highly of the extract of cicuta ; in confirmation of its efficacy, he relates twenty cases, in which this medicine was at first exhibited in the dose of two grains twice a-day, which dose was afterwards increased to three grains, administered three times every twenty-four hours. In the third volume of the Medical Observations and Inquiries, Dr. Fothergill published some remarks on the effects of cicuta, which, while it is described as being an useful medicine, is acknowledged to be sometimes unavailing. This practitioner had already extolled the efficacy of bark in cases of inveterate ophthalmia, and he has betrayed a partiality to it ; for it was his common practice invariably to prescribe it, in conjunction with calomel pills. In certain cases, mercurials and purgatives bring the constitution into a state, in which the disease of the eye-lids may readily be cured by means of suitable applications.

Before the true character of psorophthalmia was well understood, the generality of oculists applied emollient substances, as mucilage of quince-seeds, cream, fresh butter, &c., or mildly astringent ointments, which were put on the edges of the eye-lids, in order to prevent them from becoming adherent together. In this manner, they succeeded in softening the scabs and making them fall off ; but others soon formed, and thus the disorder went on. Some of the old practitioners, however, ventured to make use of stronger applications. Rhazes recommends a stimulating collyrium to be applied to the ulcerated eye-lids ; and the celebrated oculist, St. Yves, was an advocate for touching the fore part of the eye-lids with the lapis infernalis. "J'ai trouvé (says he) qu'en touchant ces ulcères avec la pierre infernale, ils se cicatrisoient aisément. Il faut en ôter l'ardeur aussitôt qu'elle les a touché en faisant baigner l'œil plusieurs fois dans un petit verre d'eau ; et il faut surtout prendre garde que l'endroit de la paupière sur lequel on a appliqué la pierre ne pose point sur le globe de l'œil, que la cuisson qu'elle

qu'elle a caufée, n'en foit paffée. On les touchera une ou deux fois la femaine, jufqu'à ce qu'on juge que ce foit affez, et on met fur ces endroits foir et matin de la tuthie en poudre très fine, qui achenera de les cicatrifer."

The application of cauftic, in the manner advifed by St. Yves, is liable to objections, and the practice, when inconfiderately adopted, has done mischief. A fafer topical application, for fulfilling the fame indication, confifts of an ointment, compofed of twenty-four grains of red precipitate, incorporated with two drachms of white falve. Some of this is to be tenderly put on the edges of the difeafed eye-lids.

But of all the topical remedies for pforophthalmy, none have gained fo much repute as the unguentum hydrargyri nitrati, which was brought into notice in this cafe by the eminent Mr. Ware. He direfts a little of this ointment to be melted, and rubbed with the end of the fore-finger, or the point of a fmall camel's-hair brush, into the edges of the affected eye-lids, every night, at bed-time. A plafter of ceratum album is then to be put over the eye-lids, in order to prevent them from sticking together. If, notwithstanding this method, they fhould yet be found to adhere to each other in the morning, Mr. Ware advifes cleaning them with milk and butter well mixed together. In a few examples, where the fmall-pox has occafioned ulcers on the edges of the eye-lids, it is neceffary to have recourfe to the argentum nitratum. When the inflammation extends to the globe of the eye, the thebaic tincture is to be employed as a topical application, as mentioned in the article OPTHALMY.

Pforophthalmy is a complaint that is particularly apt to recur; and hence it is frequently indifpenfible to obferve, for fome time after the cure, a proper regimen, and to continue a courfe of alterative medicines. See L'Encyclopédie Méthodique, Partie Chirurgicale, art. Pforophthalmie; Ware on Ophthalmy, &c. &c.

PSUCHAGOGICA, formed of $\psi\upsilon\chi\eta$, *anima*, and $\alpha\gamma\omega$, *duco*, a word ufed by the ancients to exprefs fuch medicines as were ufed in apoplexies and faintings, to recall life.

PSUCHROTROPHON, in the *Materia Medica of the Ancients*, a name given to a plant often recommended, but not perfectly underftood as to what fpecies it means. It is the fame plant called *cestrum* by the Greeks, and has this firft name only becaufe of its growing in moift places; the word being formed of the Greek $\psi\upsilon\chi\epsilon\sigma$, *moift*, and $\tau\epsilon\sigma\epsilon\iota\upsilon\upsilon$, *to nourifh*, or *caufe to grow*.

PSYCHOLOGY, $\Psi\upsilon\chi\omicron\lambda\omicron\gamma\iota\alpha$, formed from $\psi\upsilon\chi\eta$, *soul*, and $\lambda\omicron\gamma\omicron\varsigma$, *discourfe*, the doctrine of the foul.

Anthropology, or the fcience which confiders man, confifts of two parts: the firft treating of the body, and the parts belonging to it, called *anatomy*; and the fecond of the foul, called *psychology*.

PSYCHOMANCY, formed of $\psi\upsilon\chi\eta$, *soul*, and $\mu\alpha\upsilon\tau\epsilon\iota\alpha$, *divination*, a kind of magic or divination, performed by raifing the fouls of perfons deceafed.

PSYCHOTRIA, in *Botany*, a name altered by Linnæus from the *Psychotrophum* of Browne, which alludes to the fhady place of growth of moft of the fpecies. $\Psi\upsilon\chi\omicron\tau\omicron\phi\omicron\nu$ is an ancient name for an herb loving fhade.—Linn. Gen. 92. Schreb. 125. Willd. Sp. Pl. v. 1. 961. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 1. 373. Swartz Ind. Occ. v. 1. 390. Juff. 204. Lamarck Illuftr. t. 161. Gærtn. t. 25. (Psychotrophum; Browne Jam. 160. t. 13. f. 1.)—Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Stellate*, Linn. *Rubiaceæ*, Juff.

Gen. Ch. *Cal.* Perianth fuperior, very fmall, five-toothed, permanent. *Cor.* of one petal, falver-shaped; tube long; limb fhort, in five, nearly ovate, acute fegments.

Stam. Filaments five, capillary; anthers linear, erect, not rifing above the mouth of the tube. *Pift.* Germen inferior, roundifh; ftyle thread-fhaped; ftigma in two rather thick blunt fegments. *Peric.* Berry globular, of two cells, crowned with the calyx. *Seeds* folitary in each cell, hemifpherical; flat on the inner fide; convex, with five furrows, on the outer.

Eff. Ch. Calyx five-toothed, crowning the globular berry. Seeds two, hemifpherical, furrowed. Corolla tubular.

An extenfive genus of, chiefly Weft Indian, shrubby plants, with fimple oppofite leaves, fheathing intrafoliaceous membranous ftipulas, and copious, fmall, whitifh, paniced or corymbofe, axillary or terminal, flowers. They are generally fmooth, growing in dry bufhy hilly places. Their qualities have not been much investigated, though the not very remote affinity of the genus to *Cinchona*, and its nearer approach to *Coffea*, might induce a fuppofition of their not being altogether unimportant. Only two fpecies, the *afiatica* and *herbacea*, are mentioned in the *Species Plantarum* of Linnæus, but the difcoveries of Aublet and Swartz have greatly enriched this genus, fo that thirty-nine fpecies occur in Willdenow. Four of them are cultivated at Kew, but fcarcely known in other collections. The following examples may fuffice.

Pf. *citrifolia*. Citron-leaved Psychotria. Swartz Ind. Occ. 398. Willd. n. 8. Ait. n. 1.—Stipulas ovate, permanent. Leaves elliptical, pointed, fomewhat coriaceous, very fmooth. Panicles fhorter than the adjoining leaves. Berries oblong, ribbed.—Found by Mr. Alexander Anderfon, in the Weft Indies; introduced at Kew by Capt. Bligh in 1793. It is kept in the ftove, but has not yet flowered. A fmall tree, with a fmooth bark; the branches oppofite, flightly compressed. Leaves ftalked, contracted at the bafe, from three to fix inches long, ribbed, veiny, of a fine fhining green. Stipulas ovate, pointed, rigid, permanent. Flowers rather large, whitifh, in repeatedly three-forked panicles. Segments of the corolla villous. Berry furrowed, crowned with the fmall obtufe calyx. Seeds enveloped in a tunic.

Pf. *nitida*. Wild-cows' Psychotria. Willd. n. 9. (Mapouria guianensis; Aubl. Guian. v. 1. 175. t. 67.)—Stipulas roundifh-ovate, deciduous. Leaves broadly elliptical, pointed. Panicle terminal. Limb of the corolla longer than its tube.—Found by Aublet about rivers in Guiana, flowering in September. The stems are shrubby, brittle, full of pith, feven or eight feet high. Leaves fometimes eight inches long and four broad, of a fhining green, pliable, with large deciduous ftipulas. Flowers fmall, white, in terminal panicles. The inhabitants call the plant *Maypouricrabri*, becaufe the *Mapouris*, or Wild Cows, are very fond of feeding on its leaves and branches. Hence Aublet, who thought it a new genus, conftituted the name of *Mapouria*.

Pf. *parasitica*. Parasitical Psychotria. Swartz Ind. Occ. 408. Willd. n. 16. Ait. n. 2. (Viscoides pendulum; Jacq. Amer. 73. t. 51. f. 1.)—Stipulas abrupt, clafping the item. Leaves ovate, pointed, veinlefs, rather fucculent. Clusters compound; terminal and axillary.—Native of mountainous woods, in feveral of the Weft Indian iflands, where it grows for the moft part parasitically, on the trunks of aged trees. The stem climbs, throwing out feveral pendulous leafy branches. Leaves ftalked, about an inch and a half long, rather curved, bright green, fmooth; paler beneath. Flowers few, fmall, white. Corolla downy at the orifice.

Pf. *involutrata*. Athma Psychotria. Swartz Ind. Occ. 413. Willd. n. 20. (Nonatelia officinalis; Aubl. Guian.

Guian. 182. t. 70. f. 1.)—Stipulas with two teeth.—Leaves ovato-lanceolate, polished. Clusters terminal, corymbose; their partial stalks three-flowered. Bractees of three linear leaves.—Native of barren places, by way sides, in Guiana and Cayenne, flowering and fruiting in August. *Aublet*. It is said also to be found in Jamaica. The shrubby stem is two or three feet high, with smooth knotty branches. Leaves about two inches long, tapering at each end. Stipulas with a pair of awl-shaped teeth at each side. Flowers small, white. Berry black, the size of a red currant, with ten furrows. Aublet says it has five cells, with a seed in each, and hence he established his genus *Nonatelia*; but Swartz, from an examination of original specimens, assures us this is a mistake, the *Nonatelia* of Aublet being true *Psychotria*. The species of which we are speaking is said to be in some degree aromatic, when dried or bruised. An infusion of the leaves is esteemed useful in the asthma.

Pf. *herbacea*. Herbaceous Psychotria. Linn. Sp. Pl. 245. Willd. n. 29. Ait. n. 4. Jacq. Amer. 66. t. 46.—Stem herbaceous, creeping. Leaves roundish-heart-shaped, stalked, obtuse.—Native of the West Indies; said to blossom in the stove at Kew, from April to June. The stem is thread-shaped, creeping close to the ground, sending down many tufts of fibrous radicles, and throwing up, here and there, a simple, erect, herbaceous stem, three or four inches high, bearing two pair of opposite long-stalked leaves, and a few terminal, corymbose, bracteated, white flowers. Berries globose, even, red.—Jacquin says this species grows abundantly in moist shady parts of Martinico, bearing flowers, as well as plenty of ripe fruit, in December.

Pf. *emetica*. Emetic Psychotria. Linn. Suppl. 144. Willd. n. 30. (Ipecacuanha; Pif. Bras. 101? Marcgr. Bras. 17?)—"Stem herbaceous, procumbent. Leaves lanceolate, smooth. Stipulas awl-shaped, extrafoliaceous. Heads axillary, stalked, of few flowers."—Native of the province of Girona, in the hottest part of North America, by the governor of which it was sent to Mutis, who communicated a description, but as far as we can discover, no specimen, of the plant to Linnæus, supposing it one kind at least of Ipecacuanha. The root is perpendicular, roundish, somewhat branched. Leaves crowded. Stipulas deciduous. Flowers axillary, white, stalked, from two to five on each stalk. Berry nearly ovate. We have never seen this species.

PSYCHOTROPHUM, Browne Jam. 160. t. 13. f. 1. See PSYCHOTRIA.

PSYCHROLUSIA, formed of ψυχρός, cold, and λουω, I wash, a word used by medical writers to express cold bathing.

PSYCHROMETER, formed from ψυχρός, cold, and μέτρον, measure, an instrument for measuring the degree of coldness of the air; more usually called a thermometer.

PSYCTICA, formed of ψυχρός, I cool, a term used by medical writers to express cooling remedies.

PSYDRACIA, in Medicine, ψυδρακία, pustules mentioned by the ancient writers, which, according to Gorræus, were of a cold nature, "quasi ψυδρα ιδρακία, id est, frigida seu frigefactæ guttula." Whence Dr. Willan, in the definitions prefixed to his treatise on "Cutaneous Diseases," adopted the term in opposition to phlyzacia, or hot pustules, to designate the minute pustules, which produce but a slight elevation of the cuticle, and have little inflammation at their base. The psydracia were enumerated among the eruptions peculiar to the head by Alexander and Paul, and some other Greek physicians; but Galen and others mention them as common to other parts of the

body. See Gorræus, Definit. Med.; and Bateman's Synopsis of Cutan. Diseases, p. 21.

PSYGMATA, derived from ψυχρός, I cool, a name given by physicians to all refrigerating medicines, external and internal.

PSYLLI, in Ancient Geography, inhabitants of Cyrene, and other parts of Cyrenaica (which see), situated between the Nafanones and the Gætuli. Their territory abounded with serpents, against the bite of which they were provided, according to Strabo, with a secret antidote, by the use of which, as well as by eating the serpents, they amused the credulity of observers. Savary (Letters in Egypt, vol. i.) informs us, that these serpent-eaters still exist in our days. In a procession at Rosetta, which drew together a large concourse of people, the chiefs, or priests of the country, were followed by a band of seeming madmen, with their arms bare, and a wild look, holding in their hands enormous serpents, which were twisted round their bodies, and were endeavouring to make their escape. These Pfylli griping them forcibly by the neck, avoided their bite, and notwithstanding their hissing, tore them with their teeth, and ate them up alive, the blood streaming down from their polluted mouths. Others of the Pfylli were striving to tear from them their prey; so that it seemed to be a struggle among them who should devour a serpent. The populace followed them with amazement, and believed their performance to be miraculous. Accordingly they pass for persons inspired, and possessed by a spirit who destroys the effect of the serpent.

PSYLLIUM, or PSYLLA, a town of Asia Minor, in Bithynia, on the northern coast, according to Ptolemy, between Heraclea Pontæ and Tion.

PSYLLIUM, in Botany, ψύλλιον of the ancient Greeks, so denominated from ψύλλα, a flea, in allusion to the appearance of its little brown, shining, and slippery seeds. See PLANTAGO.

PSYLON, in Ichthyology, a name given by Aristotle, and many others of the old Greek writers, to the tench, or cyprinus niger.

PSYRA, in Ancient Geography, an island of the Ægean sea; N.W. of and near the promontory Melæna, in the isle of Chios.

PSYRA, in Geography, a small island in the Grecian Archipelago, situated W.N.W. of the island of Scio. N. lat. 28° 36'. E. long. 25° 39'.

PSYTALIA, in Ancient Geography, an island of the Saronic gulf, S.E. of Salamine. After the battle of Salamine the Greeks made a descent on this island, and massacred several bodies of Persian troops. In the time of Pausanias, this island contained several statues of Pan.

PTARMICA, Πταρμικα, formed of πταρμός, sneezing, medicines proper to promote sneezing; more usually called *errhines* and *sternutatories*.

PTARMICA, in Botany, πταρμικη of the Greeks, so called from πταρμός, sneezing, because of its effects. (See ACHILLEA.) Both *A. Ptarmica*, and the much more common *A. Millefolium*, have a power of causing sneezing, by means of the minute prickles which border their leaves, and which irritate the nostrils when introduced therein with a slight degree of violence. If a blow be given externally while the nostril is thus stuffed, these prickles are found sufficient to wound the small blood-vessels, and to cause a bleeding at the nose.

PTARMIGAN, the lagopus of Pliny, and the tetrao lagopus of Linnæus, in Ornithology, is also called the *white game*, and erroneously the white partridge. This bird is of a pale brown or ash-colour, elegantly crossed or mottled with

with small dusky spots, and bars, the head and neck with broad bars of black, rust-colour, and white; the wings are white, but the shafts of the greater quill-feathers black; and the belly white. In the male, the grey colour predominates, except on the head and neck, where there is a great mixture of red, with bars of white. The females and young birds have a great deal of rust-colour. Both agree in their winter-dress, being entirely white: except that in the male a black line occurs between the bill and the eyes: the shaft of the seven first quill-feathers is black; the tail consists of sixteen feathers; the black feathers being covered by two upper ones, which in summer are brown, and in winter white.

These birds are called by Pliny *lagopi*, because their feet are clothed with feathers to the claws, as the hare's are with fur, which serves to guard them from the rigour of the winter: the nails are long, broad and hollow, scooped off at the end exactly like a writing-pen, without the slit, which enables them to form a lodgment under the snow, where they lie in heaps to protect themselves from the cold. Their length is near fifteen inches, the extent twenty-three; and the weight nineteen ounces. They are found in these kingdoms only on the summits of the highest hills of the Highlands of Scotland and of the Hebrides; and some few are found on the lofty hills near Keswick, in Cumberland. They resemble the grouse in taste, and, like them, keep in small packs, but never, like those birds, take shelter in the heath, but beneath loose stones.

In Hudson's Bay, this bird is called the willow partridge: they gather together in large flocks in the beginning of October, harbouring among the willows, the tops of which are their principal food. They then change to their winter dress; change again in March; and have their complete summer dress by the latter end of June. They make their nest in the ground in dry ridges, and are so plentiful, that ten thousand have been killed in the three forts in one winter. Pennant's Brit. Zool. vol. i. p. 272, &c. Phil. Transf. vol. lxxiii. part ii. art. 28. See GORCOCK.

PTELEA, in *Botany*, πτελεα, the Greek name for an Elm, is adopted by Linnæus for a new American genus, whose fruit bears a considerable resemblance to that of *Ulmus*.—Linn. Gen. 60. Schreb. 680. Willd. Sp. Pl. v. 1. 670. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 1. 264. Pursh 107. Juss. 375. Lamarck Illustr. t. 84. Gært. t. 49.—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Tribilata*, Linn. *Terebintaceæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, small, in four deep acute segments, deciduous. *Cor.* Petals four, ovato-lanceolate, spreading, flat, coriaceous, larger than the calyx. *Stam.* Filaments four, awl-shaped, erect, hairy, when perfect nearly as long as the corolla; anthers roundish. *Pist.* Germen superior, orbicular, compressed; style short, compressed; stigmas two, divaricated, bluntish. *Peric.* Drupa dry, membranous, veiny, orbicular, compressed, with a dilated margin of two cells. *Seeds* solitary, oblong, tapering upward.

Eff. Ch. Petals four. Calyx inferior, in four deep segments. Stigmas two. Drupa roundish, compressed, dry, membranous, of two cells. Seeds solitary.

Obs. Linnæus originally confounded with this genus what he afterwards called *Dodonæa*. His son referred to it Forster's *Blackburnia*. Some curious observers in Germany, having found the stamens imperfect on one tree and the pistil on another, removed *Ptelea* to *Dioecia*; but Willdenow more correctly says the genus is polygamous, being merely liable to occasional imperfection in one or

other of the organs of impregnation, the rudiments, at least, of both sexes being found in every flower.—One species only is now admitted.

P. trifoliata. Shrubby Trefoil. Linn. Sp. Pl. 173. Mill. Ic. t. 211. (*Dodonæa trifoliata*; Trew Rar. 12. t. 9. *Frutex virginianus trifolius, ulmi samaris*; Dill. Elth. 147. t. 122. f. 148.)—Native of shady moist hedges, and the edges of woods among rocks, from New York to Carolina, according to Mr. Pursh; flowering in June. It appears to have been known in the beginning of the last century to the British cultivators of curious shrubs, and still keeps its place in shrubberies, rather for the sake of variety than beauty, flowering about Midsummer and afterwards. It often forms a small tree, with spreading branches. The leaves are deciduous, alternate, stalked, each of three, rarely five, ovate irregularly serrated leaflets, about two inches long. Flowers terminal, small, corymbose, copious, of a greenish-white. They are often five-cleft and pentandrous.

Blackburnia, Forst. Gen. t. 6, is supposed to differ generically in having a simple stigma, as well as a single-seeded berry. Its ripe fruit however has not been observed.

PTELEA, in *Gardening*, contains a plant of the shrubby kind, of which the species is the three-leaved ptelea, or shrubby trefoil (*P. trifoliata*.)

There is a variety of this with five leaves.

Method of Culture.—This plant may be increased by seeds, cuttings, and layers.

The seeds should be sown in the early spring months, as March, in pots filled with light rich mould, plunging them in a moderate hot-bed to bring up the plants, giving them occasional waterings during the summer season, and protecting them during the winter from severe frost, planting them out in the following spring in nursery-rows, to get strong for being finally planted out.

The cuttings should be made from the young shoots, and planted in pots filled with light earth in March, plunging them in a hot-bed to strike them, but they should not have much heat, due shade being given. They readily strike root, and may be planted out the following autumn.

The layers may be laid down in the autumn, choosing the young shoots for the purpose, giving them a slit underneath, and then placing them in the soil. They are mostly rooted in the course of a twelvemonth.

These plants are proper for shrubberies, and other places in pleasure-grounds, where they have a very ornamental effect.

PTELEUM, in *Ancient Geography*, a town of Theffaly, in the Phthiotide, at the entrance of the Pelagic gulf, and very near it. Homer says that the territory of this town abounded with pasturage. It existed in the time of the war of Perseus. At the approach of the consul P. Licinius, 171 years B. C., the inhabitants fled and abandoned their town, which the consul took possession of and totally destroyed.

PTERANTHUS, in *Botany*, so called by Forskall, from πτερον, a wing, and ανθος, a flower, because, either of the dilated calyx-leaves, or of the broad compressed flower-stalks. See LOUCHEA, and CAMPHOROSMA.

PTERARIA, in *Natural History*, a class of insects, according to the distribution of Dr. Hill.

PTERIA, in *Ancient Geography*, a province of Asia Minor, situated, according to Herodotus, in Cappadocia, near Sinope.

PTERIDION, in *Botany*, a name used by some authors for

for a small kind of fern common in damp places. Ger. Emac. Ind. 2.

PTERIGYNANDRUM. See PTEROGONIUM.

PTERIS, a name borrowed from the ancient Greeks, whose πτερις; appears to have been some kind of fern, so called on account of its wing-like figure.—Linn. Gen. 559. Schreb. 757. Willd. Sp. Pl. v. 5. 355. Mart. Mill. Dict. v. 3. Swartz Fil. 94. Sm. Act. Taurin. v. 5. 412. Brown Prodr. Nov. Holl. v. 1. 153. Ait. Hort. Kew. v. 5. 519. Juss. 15. Lamarek Illustr. t. 869.—Class and order, *Cryptogamia Filices*. Nat. Ord. *Filices annulatae*.

Ess. Ch. Fructification in an uninterrupted marginal line. Involucrum from the inflexed margin of the frond, bursting inwardly.

The original type of this genus is the common English Brake, or *Filix femina* of old writers. Linnæus founded its character on the continued line of capsules, running along the edge of the leaf beneath. The writer of the present article, in his Essay on the Genera of Dorsiferous Ferns, first adverted to the involucrum, and particularly to its direction, or the manner in which it finally separates. In many species that membrane becomes reflexed or revolute, being pushed back, and usually quite concealed by the abundant capsules. See *FILICES*.

Linnæus describes but nineteen species of *Pteris* in his *Sp. Plantarum*. Willdenow, our latest guide, has 108, to which Mr. Brown has added five or six from New Holland. Mention of others, not yet sufficiently ascertained, may be found at the end of the genus, in Swartz's *Synopsis Filicum* 107, from Thunberg, Lourcuro and others. The genus is divided into numerous sections, according to the division of the frond. The habit of the whole is firm and rather coriaceous; the form and aspect agreeable. In some the stalk is pale and opaque; in others blackish and highly polished.

Section 1. *Frond simple*. Six species in Willdenow.

P. piloselloides. Linn. Sp. Pl. 1530. Willd. n. 1. Banks Ic. Kæmpf. t. 31. Swartz n. 1. t. 2. f. 3.—Barren fronds roundish or obovate; fertile ones linear, elongated, obtuse. Common stalk creeping.—Native of Africa and the East Indies.—The long, branched, slender, scaly stalk creeps to a great extent over the stems and branches of trees, throwing up numerous, alternate, stalked, simple, blunt, entire leaves, or rather fronds, of a thick leathery texture; convex and smooth above; concave, paler, and opaque beneath. Of these the barren ones are hardly an inch long; the rest twice that length, but not so broad as the former, bordered with a broad, dense, hairy line of tawny-brown capsules.

The five remaining species have much the same habit and appearance.

Section 2. *Frond palmate*. Three species.

P. pedata. Linn. Sp. Pl. 1532. Willd. n. 8. Swartz n. 70. (Hemionitis; Plum. Fil. t. 152.)—Fronds very deeply palmate, five-lobed, pinnatifid; their segments linear-lanceolate, acute, partly unequally pinnatifid.—Native of the West Indies and of Virginia.—The whole frond is a foot or more in height, erect, with a dark-coloured polished stalk. The upper surface is deep green; the under paler, but not powdery as in the following species.

Section 3. *Frond ternate*. Four species.

P. argentea. Swartz Syn. n. 71. 105. and 301. Willd. n. 11. Gmel. in Nov. Comm. Petrop. v. 12. 519. t. 12. f. 1. (*P. pedatæ* varietas Sibirica; Linn. Sp. Pl. 1533.)—Fronds white and powdery beneath; the barren ones twice three-lobed; fertile ones ternate, pinnatifid, crenate.—Native of Siberia, in rocky places. An elegant fern three or four

inches high, with a dark purplish polished stalk, and a pentagonal frond, whose under side is clothed with fine dense white powder, not easily rubbed off. Nothing can be more distinct than this and the *pedata*, which last is a much larger fern.

Section 4. *Frond quinate*. One species.

P. pentaphylla. Willd. n. 14.—Frond of five nearly sessile, lanceolate, pointed, sharply serrated leaflets.—Native of rocks in the isle of Bourbon.—Stalk six inches high, square, channelled, green, Leaflets five; the central one three or four inches long, nearly sessile, with very fine parallel veins; the two next about two inches in length, and the two outermost only one inch. Willdenow, from whose account alone we know any thing of this species, never saw the fructification; but he describes the consistence, colour, and appearance, of the barren fronds, as exactly like *P. cretica*.

Section 5. *Frond pinnatifid*. One species.

P. pilosula. Lamarek Dict. v. 5. 717. Swartz n. 60. Willd. n. 15.—“Frond pinnatifid, coriaceous; segments dotted with white, undivided or bluntly lobed. Stalk, as well as the ribs beneath, hairy.”—Native of the island of Mauritius. Lamarek.

Section 6. *Frond pinnate*. Twenty species.

P. trichomanoides. Linn. Sp. Pl. 1532. Willd. n. 17. Swartz n. 49. (*Trichomanes majus*, pinnis sinuatis subtus niveis; Sloane Jam. v. 1. 80. t. 35. f. 1. *T. argenteum*, ad oras nigrum; Plum. Fil. 57. t. 75.)—Frond pinnate. Leaflets ovate-oblong, obtuse, wavy; hairy at the edge; white and powdery beneath.—Not uncommon in dry rocky places in the West Indies. The numerous fronds form a tuft, and are each about a foot high, composed of many short, crowded, bluntish, undulated, sessile leaflets; of a fine green above; white and mealy beneath, having a marginal line of dark capsules, interspersed with golden hairs, such as clothe the common stalk. We see no reason to doubt the identity of Sloane's and Plumier's plants.

P. longifolia. Long-leaved Brake. Linn. Sp. Pl. 1531. Willd. n. 31. Ait. n. 1. Swartz n. 8. Jacq. Hort. Schoenbr. v. 3. 78. t. 399, 400. (*Lonchitis non ramosa*, longis angustis et ad basin auriculatis foliis; Plum. Fil. 52. t. 69.)—Frond pinnate. Leaflets linear, acute, finely serrated; somewhat auricled and heart-shaped at the base. Stalk and main rib rough with scales.—Native of the West Indies. Supposed to have been first introduced into the English stoves by Mr. James Gordon, the celebrated nurseryman of Mile End, about the year 1770.—The fronds grow in tufts, and are, when at their full size, three or four feet high. Leaflets numerous, parallel, narrow, smooth, of a fine green, with three ribs and innumerable transverse veins; the largest near a span long; all are more or less elongated at the base, into a pair of lobes or auricles. Line of fructification pale brown, very dense. Although Jacquin, in his splendid work above cited, devotes two plates to this species, nothing is there shewn in detail of the capsules or involucrum, which in such expensive plates ought not to be omitted.

Section 7. *Frond either pinnatifid or pinnate; the lower divisions compound*. Sixteen species.

P. cretica. Linn. Mant. 130; excluding all the synonyms, except that of Tournefort. Willd. n. 44. Swartz n. 14. (*Lingua cervina*, foliis costæ innascentibus; Tourn. Inst. 545. t. 321.)—Frond pinnate. Leaflets lanceolate, pointed, on short stalks; contracted and serrated at the base; the lowermost in two or three deep divisions.—A native of various parts of the south of Europe, rarely bearing fructification further north than Naples. The

PTERIS.

root bears several pale *fronds* about eighteen inches high, whose *leaflets* are of a rigid, but delicate and transparent texture, with fine parallel veins; the edges more or less partially, and rather acutely, serrated. *Capsules* of a light brown.

P. atropurpurea. Purple Brake. Linn. Sp. Pl. 1534. Willd. n. 46. Ait. n. 4. Swartz n. 76. Schkuhr Crypt. 93. t. 101. (*Filicula faxatilis, osmundæ facie, foliis variis marginè non ferratis*; Pluk. Mant. 81. t. 349. f. 2, 3.)—Fronn pinnate. Lower leaflets ternate or pinnate, lanceolate, obtuse; abrupt or somewhat heart-shaped at the base.—Found in various parts of North America, from whence living plants were brought to Kew garden in 1770. The dark purplish-black of the polished *stalk*, as well as the deep green of the *leaflets*, give this species the habit of an *Adiantum*; but the elongated figure of each *leaflet*, as well as of the whole *frond*, agrees with *Pteris*, as does the *fructification* entirely.

Section 8. *Fronn doubly pinnatifid*. Fifteen species.

P. thalictroides. Swartz n. 23. Willd. n. 52. (*Acrostichum thalictroides*; Linn. Sp. Pl. 1527. A. n. 377; Fl. Zeyl. 179. t. 4. A. n. 17; Amoen. Acad. v. 1. 275. A. filiquosum; Sp. Pl. 1527. A. n. 376; Fl. Zeyl. 179. A. n. 7; Amoen. Acad. v. 1. 270. t. 12. f. 3. *Millefolium aquaticum*; Rumph. Amboin. v. 6. 176. t. 74. f. 1.)—Fronns doubly pinnatifid; segments of the barren ones dilated, irregularly sinuated, obtuse; those of the fertile ones linear, acute, often deeply divided. Native of Ceylon, Amboyna, and Tranquebar. Rumphius informs us of what the fleshy pellucid habit of this singular fern might well lead us to suspect, that it grows in stagnant waters and slow rivulets, flourishing in the dry season, when the water is low. The *root* consists of a dense tuft of very long, mostly simple, pale fibres. *Stalks* thick, succulent, weak and tender. *Barren fronds* broad, very succulent, flaccid when dry, of numerous, irregularly dilated and sinuated, obtuse leaflets; *fertile ones* more compound, with very numerous, narrow, awl-shaped, pale segments, about an inch long, under whose reflexed margins are situated the large, pale-yellowish, rather sparingly dispersed *capsules*, partly imbedded in the succulent *frond*, which they seem so entirely to cover, that we cannot wonder at Linnæus for having referred the plant to his genus *Acrostichum*. That he divided it into two species is less easily to be accounted for.

P. macroura. Willd. n. 56. (*Filix latifolia caudata, pinnulis lonchitidis dentatis*; Plum. Fil. 11. t. 13.)—"Fronn pinnate. Leaflets ovate-oblong, pinnatifid; segments lanceolate, serrated towards the point; the terminal one very long, tapering, deeply serrated."—Found near the sides of rivers in Martinico and Hispaniola, by Plumier, the only writer who has given an original account of this species. Willdenow is the only systematic author who has adopted it from him, though it seems a handsome well-defined species, very distinct from all others. The *stalks* are two feet high, slender, brown, smooth and naked, every one bearing three or four pair, besides a terminal odd one, of elliptic, or ovate-oblong, *leaflets*, each deeply and copiously pinnatifid, and ending in a long narrow serrated point. The segments are also serrated towards the extremity, bearing a marginal row of chestnut-coloured *capsules* lower down.

Section 9. *Fronn doubly pinnatifid, doubly or triply pinnate, the lowermost division deeply divided*. Eleven species.

P. baurita. Linn. Sp. Pl. 1534. Willd. n. 67. Swartz n. 25. (*Filix pinnulis lonchitidis obtusis non dentatis, ad oras pulverulentis*; Plum. Fil. 13. t. 15.)—Fronn pinnate. Leaflets pinnatifid; their segments linear, obtuse, toothed

at the end; the lowest leaflets deeply divided.—Found in various parts of the West Indies. The *fronds* are two or three feet high, of a bright green, and very conspicuous for the deep division of each of their two lowest branches or *leaflets*, which are, in a manner, a pair of twin *leaflets* at each side.

Section 10. *Fronn doubly or triply pinnate*. Twenty-three species.

P. crispa. Curled Stone Fern, or Rock Brake. Linn. MSS. in Sp. Pl. 1522. Sm. Fl. Brit. 1137. Engl. Bot. t. 1160. Willd. n. 89. Swartz n. 101. Ait. n. 6. (*Osmunda crispa*; Linn. Sp. Pl. 1522. Bolt. Fil. 10. t. 7. Fl. Dan. t. 496. *Adiantum album floridum*; Pluk. Phyt. t. 3. f. 2.)—Fronns repeatedly compound. Leaflets of the barren ones wedge-shaped, cut at the extremity; those of the fertile ones elliptical, obtuse, convex.—This pretty species is found on the mountains of Lapland, Norway, Germany, Switzerland, and the Pyrenees, as well as in Britain. In Westmoreland it occurs plentifully on dry stony open ground, about the sides of lofty hills, being in perfection from June to September.—The *fronds* grow many together, in tufts, from six to twelve inches high, of a pale but pleasant green. Each consists of a long smooth *stalk*, supporting an ovate, or somewhat triangular *leaf*, which is twice or thrice compound in an alternate manner. The *leaflets* of the shorter *fronds* are barren, dilated, wedge-shaped, sometimes pinnatifid, all cut or toothed at the extremities; those of the taller ones all fertile, longer and narrower than the former, their margins pale, membranous, crenate, so strongly inflexed as nearly to meet over the dense lines of tawny *capsules*.

P. nigricans. Willd. n. 90. (*Filix crenis rotundis, et nigricante limbo præcinctis*; Plum. Fil. 32. t. 42. Swartz Fil. 108.)—Fronn doubly pinnate. Leaflets ovate-oblong, obtuse, strongly crenate. Partial stalks zigzag.—Found by Plumier in abundance by the sides of rivulets, in the moist woods of Hispaniola. No other botanist appears to have met with this fern, nor did Swartz venture to refer it to any genus, he having merely indicated it as a probable species of *Pteris*. Willdenow has been less scrupulous, and perhaps justly. The creeping *root* throws up many *fronds*, a foot or more in height; their outline of a broad lanceolate figure; their *stalks* smooth and slender. Each is doubly, alternately, and copiously pinnate, their partial *stalks* remarkably zigzag. *Leaflets* so strongly crenate as to seem almost pinnatifid, but very obtusely; their upper surface of a fine shining green; the lower pale, ribbed, and downy. *Fructification* in a blackish uninterrupted line, along the obtuse edge of each segment.

P. aculeata. Prickly-stemmed Brake. Swartz n. 40. Ind. Occ. v. 3. 1601. Willd. n. 98. Ait. n. 7. (*Filix arborescens, ramosa et aculeata*; Plum. Fil. 6. t. 5 and 11.)—Fronn doubly pinnate. Leaflets oblong, pointed, pinnatifid; segments lanceolate, acute, serrated. Stalk arborescent, thorny.—Native of the forests of Martinico, where Plumier observed it in plenty. Swartz says it grows in the rather mountainous woods of Jamaica. Living plants were brought to the stoves at Kew in 1793, but we know not how they have succeeded there. Plumier describes the main *stem* as thick as a man's body, but low, and beset with black spines. This *stem* however appears to be produced in very aged plants only, the generality merely throwing out a number of no less spinous *stalks*, from one very thick tufted *root*. Each stalk is almost three inches in diameter at its origin, and the whole *frond*, of a fan-like figure, and subsequently twice pinnate, is as tall as a man. The segments of the *leaflets*, when barren, as in Plumier's t. 11, are serrated through-

throughout; otherwise at the point only, the sides being each occupied by a dense line of *capsules*, not continued or united along the sinus at the bottom. *Polypodium spinosum*, Linn. Sp. Pl. 1554, figured in Sloane's Jamaica v. 1. t. 56, though cited by Swartz and Willdenow, is evidently a totally different plant, and perhaps a *Cyathea*. Whether Swartz intended this only as a native of Jamaica, or whether he found there the genuine *Pteris aculeata*, we have no certain information.

Section 11. *Fronde in three deep divisions, or pedate with doubly pinnate branches.* Seven species.

Perhaps, if we may judge by Plumier's description, the last-described species ought rather to be placed in this section.

P. esculenta. Eatable-rooted Brake. Forst. Prodr. n. 418. Swartz n. 43. Willd. n. 103. Billard. Nov. Holl. v. 2. 95. t. 244.—Fronde in three deep divisions. Branches doubly pinnate. Leaflets pinnatifid, with linear, obtuse, decurrent segments; the upper ones elongated and undivided.—Native of the Society islands, and of Van Diemen's land. The natives feed on the *root*, which is creeping, thick, knotty and brittle, full of a starch-like pith. The *fronds* are two or three feet high, much resembling our Common Brake, *P. aquilina*, but more coriaceous, much less uniformly pinnatifid in their ultimate divisions, and remarkable for the simple elongations of the extremities.

P. aquilina. Common Brake. Linn. Sp. Pl. 1533. Sm. Fl. Brit. 1136. Engl. Bot. t. 1679. Willd. n. 105. Swartz n. 41. Ait. n. 9. Bolt. Fil. 16. t. 10, bad. (Felix fœmina; Ger. Em. 1128. Matth. Valgr. v. 2. 627.)—Fronde in three deep divisions. Branches doubly pinnate. Leaflets crowded, lanceolate, acute; the upper ones confluent.—Native of dry barren woods and heaths in all parts of Europe, as well as the north of Asia and America. With us it is the most common fern, and well known for its uses for packing, firing, and shelter, of various kinds. It is sometimes killed in very hard winters. The *fronds* are annual, originating from a perennial, creeping, scaly *root*, and rise to the height of from two to five feet, according to the soil. They are rigid and harsh, cutting the hands if incautiously drawn through them. Their colour is a light green, and they spread in a handsome, partly horizontal posture, being regularly compounded in an almost pectinate manner. The upper part of each branch is simple, as in *P. esculenta*, but not elongated, or enlarged, so conspicuously as in that species.

Section 12. *Fronde repeatedly forked.* One species.

P. cornuta. Beauvois Oware, 63. t. 37. Willd. n. 108.—Fronde repeatedly forked; segments awl-shaped, alternate. Capsules in simple rows.—An aquatic species, found by M. Palissot de Beauvois, in salt ditches or pools, near the sea, at Oware on the coast of Guinea. This plant is evidently, as its discoverer remarks, akin to *P. thalictroides*, see sect. 8. It bears tufts of a parasitical plant, perhaps a *Marfilea*, which might easily be taken for barren *fronds*, or *leaflets*, of its own.

PTERIUM, in *Ancient Geography*, a town of Asia, in Media. Steph. Byz.

PTEROCARPUS, in *Botany*, so named by Loeffling and Linnæus, from πτερον, a wing, and καρπος, fruit, the margin of the legume being dilated into a flat wing-like expansion.—Linn. Gen. 366. Schreb. 484. Willd. Sp. Pl. v. 3. 904. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 4. 248. Juss. 364. Lamarek Illustr. t. 602. Gært. t. 156.—Class and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, of a tu-

bular bell-shape, with five acute teeth. *Cor.* papilionaceous; standard roundish-heartshaped, spreading, convex, with a long claw; wings lanceolate, shorter; keel short. *Stam.* Filaments ten, all connected; anthers roundish. *Pist.* Germen stalked, oblong, compressed; style awl-shaped; stigma simple. *Peric.* Legume roundish-falcate, compressed, with a leaf-like edge, veiny at the sides, woody within, not bursting, the cell, or cells, longitudinally disposed. *Seeds* solitary; kidney-shaped, thickest at the base.

Ess. Ch. Calyx five-toothed. Stamens all united. Legume falcate, leafy, with tumid veins, bordered with a wing, not bursting. Seeds solitary.

1. *P. Draco*. Dragon's-blood Pterocarpus. Linn. Sp. Pl. 1662. Willd. n. 1. (*P. officinalis*; Jacq. Amer. 283. t. 183. f. 92. Moutouchi suberosa; Aubl. Guian. v. 2. 748. t. 299. Draco arbor indica filiquosa, populi folio; Commel. Hort. v. 1. 213. t. 109.)—Leaves pinnate, ovate, pointed. Stipulas oblong, obtuse. Legume rounded at the extremity.—Native of South America.—A tree thirty feet high, yielding a red pellucid resin, which had formerly the reputation of stopping hæmorrhages, but is now out of use. *Leaves* of two or three pair of shining leaflets, with a larger odd one. *Flowers* yellow, in compound axillary clusters. *Legume* an inch and a half broad, obtuse, marked with strong elevated lateral veins. Gærtner's *P. hemiptera* seems, notwithstanding his opinion, to be the same with this. It is a stranger to our gardens, though formerly raised from seed at Amsterdam.

2. *P. indicus*. East Indian Pterocarpus. Willd. n. 2. (Lingoum, anxana; Rumph. Amb. v. 2. 205. t. 70.)—Leaves pinnate, oblong, pointed. Stipulas none. Legume sharp-pointed.—Native of the East Indies. Willdenow has distinguished it from the foregoing, by the figure of Rumphius only, but perhaps justly. The wood is said to be valuable for the finer kinds of cabinet work, being beautiful and fragrant. *Flowers* of a fine deep yellow, smelling like Wall-flowers.

3. *P. Marsupium*. Pouch Pterocarpus. Roxb. Coromand. v. 2. 9. t. 116. Willd. n. 3.—Leaves pinnate, elliptical, emarginate. Stipulas none. Clusters terminal, thrice compound.—Native of the Circar mountains of Coromandel, flowering in the rainy season. Dr. Roxburgh describes it as a very large tree, whose wood, of a yellowish-orange colour, and hard, but not heavy, is much esteemed by the natives, and used for various purposes. The *flowers* are copious, white with a tinge of yellow. *Legume* with an oblique acute wing.

4. *P. Robrii*. Guiana Pterocarpus. Vahl. Symb. v. 2. 79, excluding the synonyms.—Leaves pinnate, oblong-lanceolate, pointed. Stipulas none. Clusters simple, axillary. Legume orbicular.—Native of South America.—A tree, with smooth, round, greyish branches. *Leaves* of three or four pair of ovate-oblong, pointed, smooth, shining leaflets, with an odd one. *Clusters* half the length of the leaves. *Flowers* drooping. *Legume* membranous, smooth, nearly orbicular, an inch and a half long. *Seed* one. Mr. König, in Ann. of Bot. v. 1. 358, has corrected Vahl and Willdenow, who cite under this species Aublet's *Apalatoa spicata*, Guian. v. 1. 382. t. 147, a plant differing from it in genus.

5. *P. lunatus*. Crescent-podded Pterocarpus. Linn. Suppl. 317. Willd. n. 5. Ait. n. 1. (*P. aptera*; Gært. v. 2. 351. t. 156. Medicago leguminibus lunatis; Plum. Ic. t. 201. f. 2.)—Leaves pinnate. Stipulas spinous. Legume crescent-shaped, thick-edged.—Native of Surinam, from whence specimens in spirits were sent to Linnæus by Dalberg. Living plants were introduced at Kew in 1792,

by Mr. Alexander Anderfon, but never flowered there. This is a rigid *shrub*, or *tree*, with a pair of strong hooked spines, at the base of each leaf, in the place of *stipulas*. *Leaves* of from five to seven alternate, oblong, obtuse *leaflets*, about an inch long, one of them terminal. *Panicle* terminal, downy, its branches spiked, incurved. *Flowers* white. *Legume* full an inch broad, thick, woody, and smooth, curved so completely round that the point folds over the base; the edge is thick and even, without any wing. *Seed* one, large.

6. *P. santalinus*. Three-leaved Pterocarpus. Linn. Suppl. 318, excluding the reference to Aublet. Willd. n. 6. Ait. n. 2. — *Leaves* ternate, roundish, abrupt, very smooth. *Petals* crenate, wavy. — Native of mountainous precipices in the East Indies, where it was observed by Koenig and Roxburgh. Sir Joseph Banks procured it for the stoves at Kew in 1800, but the plant has not yet flowered there. A very lofty *tree*, with a *bark* like Alder, and alternate *branches*. *Leaves* rarely pinnate, mostly ternate, hoary beneath. *Stipulas* none. *Clusters* axillary; simple or branched. *Flowers* yellow, streaked with red. *Legume* curved upwards, with a membranous wing along the lower edge. This was sent to Linnæus as a kind of *Santalum rubrum*, or Red Sanders Wood, having been ascertained as such by Koenig. It is described as hard and heavy, deep red with black veins, and taking a fine polish. The finely perfumed wood, commonly called Sandal wood, and used for fans, necklaces, &c. is very different. See SIRIUM *myrtifolium*.

7. *P. Ecastaphyllum*. Oval-leaved Pterocarpus. Linn. Syst. Nat. ed. 12. v. 2. 439. Swartz Obs. 275. Willd. n. 7. Ait. n. 3. Bergius in Act. Holm. for 1769. 117. t. 4. (Hedyfarum Ecastaphyllum; Linn. Sp. Pl. 1052. Ecastaphyllum; Browne Jam. 299. t. 32. f. 1. Spartium scandens, citri foliis, floribus albis ad nodos confertim nascentibus; Plum. Ic. 244. t. 246. f. 2.) — *Leaves* simple, ovate, pointed; silky beneath. — Native of the West Indies. Found by Browne, in low swampy places, about Kingston in Jamaica. Houlton sent seeds of this species to Miller, but it seems not to have survived in our gardens. The *stem* is shrubby, spreading obliquely to the extent of six or seven feet. *Leaves* all simple, three or four inches long, and one and a half broad, downy all over when young. *Stipulas* oblong. *Flowers* few together, in short axillary clusters.

PTEROCEPHALUS. See SCABIOSA.

PTEROCOCCUS, from πτερον, a wing, and κοκκος, a berry, a name given by Pallas to the plant which Linnæus called PALLASIA, but which was rightly referred by L'Heritier to CALLIGONUM; see those articles.

PTEROGONIUM, altered by Swartz from Hedwig's *Pterigynandrum*, a name designed to express that the male and female flowers, in this genus of Mosses, are both axillary, or lateral, on a pinnate stem. — Swartz Musc. Suec. 26. Sm. Fl. Brit. 1270. Turn. Musc. Hib. 32. Schwaegr. Hedw. Sp. Musc. Suppl. 1. 100. (Pterigynandrum; Hedw. Sp. Musc. 80.) — Class and order, *Cryptogamia Musci*. Nat. Ord. *Musci*.

Eff. Ch. Capsule oblong, from a lateral scaly sheath. Fringe simple, of 16 linear upright teeth. Veil generally hairy.

The simple *peristomium*, or fringe, distinguishes this genus from *Hypnum* and *Neckera*, without adverting to the upright hairs of its veil, which, though usual, are not invariably present. Hedwig describes nine certain species in his *Species Muscorum*, to which four are added by his editor and continuator Dr. Schwaegrichen, in a Supplement published at Leipzig in 1811. To these 13, are added three others by

the writer of the present article, one of them the Linnæan *Hypnum sciuroides*, or *Dicranum sciuroides*, Fl. Brit. 1215. We shall confine our remarks to the six British species.

P. gracile. Slender Wing-moss. Fl. Brit. n. 1. Engl. Bot. t. 1085. Hedw. Sp. Musc. Suppl. 1. n. 7. (Pterigynandrum gracile; Hedw. Crypt. v. 4. 16. t. 6. Hypnum gracile; Linn. Mant. 310. H. gracile ornithopodioides; Dill. Musc. 320. t. 41. f. 55.) — *Stem* creeping. *Branches* clustered, cylindrical, recurved. *Leaves* ovate, finely serrated. — Native of the trunks of trees, and mountainous rocks, in Britain, Switzerland, Portugal, Carinthia and Carniola, bearing capsules in spring and summer, but rarely with us. This plant forms broad, dense, cushion-like tufts, composed of wiry, creeping, much divided *stems*, throwing up innumerable recurved, slender, leafy *branches*, about an inch high. The *leaves* are every way closely imbricated, deep green; yellowish and shining in exposed situations; their form broad-ovate, ribless, minutely toothed or serrated. *Sheaths* lateral, small, pale. *Fruit-stalks* solitary, hardly an inch long, red. *Capsule* cylindrical, nearly erect. *Lid* conical, bluntish, rather curved. *Veil* pale, slender, clothed with upright deciduous hairs.

P. filiforme. Capillary Wing-moss. Hedw. Sp. Musc. Suppl. 1. n. 2. Engl. Bot. t. 2297. (Pterigynandrum filiforme; Hedw. Crypt. fasc. 4. 18. t. 7. Hypnum filiforme; Timm. Megapolit. 225.) — *Stem* decumbent, weak, irregularly branched, creeping. *Leaves* ovate, serrated, closely imbricated. *Capsules* ovate-oblong, erect. — Native of mountainous rather shady rocks, in the middle of Europe, but not common, bearing fruit in summer. This species was detected, since the publication of *Fl. Brit.*, on Ben Lawers in Scotland, by the late Mr. Geo. Don, and in Ireland, by Mr. J. T. Mackay. The *stems* and *branches* are prostrate, in dense entangled patches, and clothed with very small, closely imbricated, slightly oblique *leaves*, of a deep, scarcely shining, green, without rib or furrows; their upper half serrated. *Sheaths* pale, with long, taper-pointed, serrated scales. *Stalks* tawny. *Capsule* shorter, and more ovate, than in the preceding. *Lid* conical, with a blunt point. The *veil* has not been observed.

P. sciuroides. Squirrel-tail Wing-moss. Turn. Musc. Hib. 32. Engl. Bot. t. 1903. (Dicranum sciuroides; Fl. Brit. 1215. Swartz Musc. Suec. 32. Hypnum sciuroides; Linn. Sp. Pl. 1596. H. arboreum sciuroides; Dill. Musc. 319. t. 41. f. 54.) — *Stems* creeping, branched. *Branches* cylindrical, incurved by drying. *Leaves* ovato-lanceolate, striated, entire. *Veil* smooth. *Teeth* of the fringe deeply cloven. Found on the trunks of trees abundantly, in most parts of Europe, though rarely bearing capsules in Britain. The habit of the plant is perhaps most akin to *P. gracile*, but the whole is of larger dimensions. The *leaves* are of a rich green, entire, with three longitudinal plaits, but no ribs. They are sometimes, in Norfolk, accompanied by axillary branching tufted buds. *Sheaths* axillary, long and taper. *Stalks* tawny, hardly thrice as long. *Capsule* erect, ovate, smooth. *Lid* conical, red. *Veil* slender, naked. *Fringe* small, tender, pale, its teeth deeply divided, but resembling the internal fringe of *Hypnum* in texture, not the firm teeth of a true *Dicranum*. This circumstance, and especially the lateral situation of the female, as well as male, *flowers*, first induced Mr. D. Turner to remove the plant in question to the genus where we now retain it. The male *flowers* are red.

P. Smithii. Curling Wing-moss. Swartz in Schrad. Journ. v. 2. 173. Fl. Brit. 1271. Engl. Bot. t. 1326. Schwaegr. in Hedw. Sp. Musc. Suppl. 1. 105. (Hypnum Smithii; Dickf. Crypt. fasc. 2. 10. t. 5. f. 4. Dr. Pl.

n. 19. Hedw. Sp. Musc. 264. t. 68. f. 5-7. Muscus squamosus filicinus repens atro-virens, &c.; Mich. Gen. 114. n. 98.)—Stems creeping, much branched. Branches pinnate, incurved by drying. Leaves entire. Sheath nearly as long as the fruit-stalk. Found on the trunks of trees in Italy; very plentifully in the old gardens of Florence, Rome, Genoa, &c., bearing abundance of fruit in the winter and spring. The writer of this, whose name, by the friendship of Mr. Dickson, has been given to the present curious species, had the good luck to discover it, the day after he landed in England from the continent, near a small inn on Barham downs, Kent, where, and in other places, it has since been found by several English botanists. The stems are depressed and creeping, much divided, throwing up many triply pinnate branches, about two inches high, which are well compared by Micheli, in their moist state, to spruce firs in miniature, laden with cones. When dry, they speedily become incurved, or curled, in every part. The leaves are closely imbricated, roundish, obtuse, entire, deep green, opaque, with one rib at the base only. Sheaths long, pale, their inner scales taper-pointed. Stalks yellowish, scarcely exceeding the sheaths, twisted at the apex. Capsule cylindrical, inclining to ovate, with a narrow mouth, smooth, brown. Fringe small, pale, deciduous, of 16 undivided teeth. Lid conical, oblique. Veil yellow, shining, clothed with copious erect hairs.

P. rotundifolium. Round-leaved Wing-moss. Turn. MSS. Engl. Bot. t. 2525.—Stems ascending, tufted, scarcely branched. Leaves closely imbricated, roundish-ovate, obtuse, entire. Discovered by Mr. Mackay in the south of Ireland, but without fructification, so that it is presumptively only, by its habit, referred to *Pterogonium*, like the next-described species. The stems are ascending, or nearly erect, hardly an inch high, in dense tufts; each of them generally simple, leafy, swelling upwards, and obtuse. Leaves closely imbricated every way, broad, of a pale but dull green, minutely reticulated, with little or no appearance of any rib.

P. caespitosum. Matted Wing-moss. Engl. Bot. t. 2526.—Stems branched, entangled, prostrate, slender. Ultimate branches ascending, obtuse. Leaves ovate, concave; revolute at the base; minutely serrated at the summit. Gathered by Mr. W. Borrer, on rocks by the river at Dulzie bridge, Scotland. The wiry much-divided stems throw up many short, simple, obtuse, ascending branches, clothed with larger and paler leaves than those on the main stems. As no fructification has been found, we cannot be certain of the genus, though the habit is such as to leave no scruple in our minds on that subject.

PTERON, in *Ancient Geography*, a promontory of Lower Mysia, between the mouth of the Danube, called Sacrum Ostium, and the town Istropolis, according to Ptolemy.

PTERONIA, in *Botany*, from πτερον, a wing; altered by Linnæus from the *Pterophorus* of Vaillant, a word which seems to allude to the feathery scales of the receptacle.—Linn. Gen. 414. Schreb. 542. Willd. Sp. Pl. v. 3. 1776. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 4. 511. Juss. 174. Lamarck Illustr. t. 667. Gært. t. 167.—Class and order, *Syngenesia Polygamia-aqualis*. Nat. Ord. *Compositæ discoideæ*, Linn. *Cinaroccephala*, Juss.

Gen. Ch. Common calyx imbricated, with lanceolate, keeled, pointed scales. Cor. compound, uniform, the florets numerous, equal, all perfect, tubular, funnel-shaped, with a five-cleft acute limb. Stam. Filaments five, capillary, very short; anthers united into a cylindrical tube. Pyl. Germen oblong; style thread-shaped, the length of the

stamens; stigma cloven. Peric. none, except the unchanged calyx. Seeds solitary to each floret, oblong, compressed. Down sessile, rather feathery, its rays somewhat hairy. Recept. bristly, flattish, its scales cut into numerous segments, whose bristly points are shorter than the seeds.

Obs. Jussieu says that in some species, if not in all, at least those with opposite leaves, the receptacle is certainly naked; though the seeds, being not only crowned with down, but clothed with villous hairs, give an appearance of a bristly receptacle. This account does not agree with Gærtner, nor with what we have observed.

Ess. Ch. Receptacle clothed with many-cleft scales. Down somewhat feathery. Calyx imbricated, with keeled scales.

A genus of rather humble rigid shrubs, of which Linnæus has only one species, *camphorata*, in his *Sp. Pl.* but which the discoveries of Thunberg chiefly have so greatly enriched, that Willdenow admits 27, all natives of the Cape of Good Hope, except the last, a very doubtful *Pteronia*, from Mexico. We select a few examples.

P. spinosa. Thorny Pteronia. Linn. Suppl. 357. Willd. n. 1. Thunb. Prodr. 113.—Leaves awl-shaped, becoming pungent spines. The stem is woody, round, much branched. Leaves remote, alternate, sessile, spreading widely, awl-shaped, rigid, with a sharp spinous termination, permanent and finally much hardened. Flowers about four, sessile, axillary, near the tops of the branches.

P. camphorata. Aromatic Pteronia. Linn. Sp. Pl. 1176. Willd. n. 2. Ait. n. 1. (*Conyza aromatica frutescens mauritanica, camphorata foliis, &c.*; Pluk. Mant. 56. t. 345. f. 2.)—Leaves scattered or fasciculate, thread-shaped, ciliated. Calyx-scales finely serrated. Hairs of the receptacle somewhat tufted. Introduced from the Cape by Mr. Masson in 1774. It blossoms from June to September, and is sheltered in the green-house in winter. Stem much branched, about a yard high. Leaves very narrow, flat, spreading. Flowers terminal, yellow, solitary, larger than those of *Santolina maritima*. It appears, from Mr. Masson's communications to Sir Joseph Banks, that he gathered this species in sandy ground, near Swartland.

P. oppositifolia. Forked Pteronia. Thunb. Prodr. 143. Willd. n. 18. Ait. n. 3. (*Cyanus centauroides frutescens, lavandulæ folio*; Breyn. Ic. 28. t. 17. f. 3.)—Leaves ovate, clothed with powdery down. Calyx-scales ovate, entire.—Sent by Mr. Masson from the Cape in 1774. It flowers with us in July. A small shrub, hardly six inches high, with opposite forked branches. Leaves small, ovato-lanceolate, hoary. Flowers terminal, sessile, yellow.

P. Porophyllum. Dotted-leaved Pteronia. Cavan. Ic. v. 3. 13. t. 225. Willd. n. 27.—Leaves pinnatifid, obtuse, with fringe-like teeth.—Native of Mexico. It flowered in the garden at Madrid in November, being an annual herbaceous plant, about two feet high. Leaves scattered, about two inches long, pinnatifid, lyrate, obtuse, their serratures tipped with long hairs. Flowers terminal, solitary, yellow, with pinnatifid, almost capillary, bracteas.

PTEROPHÆNICUS INDIARUM, in *Ornithology*, a name under which Nieremberg has described a bird, which he says is called by the Spaniards there *commendadoza*, remarkable for the redness of the upper part of its wings. It is of the shape and size of the starling, and not unlike it in colour, but for the singularity of the upper part of their wings, which, in one part of their lives, are of a yellowish or orange colour, and in the rest red. They are kept in cages, and learn to imitate the human voice; they feed on vegetables, principally Indian corn, and are common as well in the colder as in the hotter climates; flying in large flocks, and often doing

doing great damage to the people. They build in trees and are eaten there; but are no very valuable bird. See *ORIOBUS Phanicus*.

PTEROPHORES, in *Ancient Geography*, a country of Scythia, towards the Riphæan mountains, according to Pliny.

PTEROPHORI, Πτεροφοροι, in *Antiquity*, a name given to such of the Roman couriers as brought tidings of any declaration of war, a battle lost, or any mishap befallen the Roman armies.

They were so called, because they bore wings on the points of their pikes; from the Greek πτερον, *wing*, and φερω, *I bear*.

PTEROPHORUS, in *Botany*. See *PTERONIA*.

PTEROPUS, in *Zoology*. See *VESPERTILIO*.

PTEROSPERMADENDRON, in *Botany*. See *PENTAPETES* and *PTEROSPERMUM*.

PTEROSPERMUM, a very superb East Indian genus, whose name is derived from πτερον, *a wing*, and σπέρμα, *seed*. It was originally placed under *Pentapetes*, by Linnæus in the *Flora Zeylanica*.—Schreb. 461. Willd. Sp. Pl. v. 3. 728. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 4. 194. Lamarck Illustr. t. 576. (*Pterospermadendron*; Amman. in Act. Petrop. v. 8. 215. *Pentapetes*; Linn. Zeylan. 113.)—Class and order, *Monadelphia Dodecandria*. Nat. Ord. *Columnifera*, Linn. *Malvaceæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, deeply cloven into five, coriaceous, oblong, reflexed segments. *Cor.* Petals five, oblong, spreading. *Stam.* Filaments fifteen, linear, combined at the base into a tube; anthers oblong, erect, twisted. At every third stamen is a long, coloured, erect body, as long as the petals, resembling a barren stamen, but without any anther. *Pist.* Germen superior, roundish, (stalked?); style cylindrical, the length of the stamens; stigma thickish. *Peric.* Capsule stalked, woody, ovate, five-celled, each cell two-valved. *Seeds* numerous, oblong, compressed, with a membranous wing.

Ess. Ch. Calyx simple, five-cleft. Petals five. Stamens twenty; five of them barren. Style cylindrical. Stigma thickish. Capsule woody, five-celled. Seeds winged.

1. *P. suberifolium*. Various-leaved *Pterospermum*. Willd. n. 1. (*Pentapetes suberifolia*; Linn. Sp. Pl. 959. Cavan. Diff. 3. 130. t. 43. f. 2.)—Leaves oblong, pointed; slightly toothed at their tips.—Native of the East Indies. It flowers in September and October. The branches of this handsome plant are erect, and covered with a rusty down. Leaves alternate, on short stalks, thick, green above, whitish beneath, with a strong, longitudinal rib. Flowers axillary, at the summits of the branches, one, two, or three together, white. Linnæus remarked that the leaves of this plant resembled those of the *Ilex*, or Holm Oak, in substance; and that its flowers had the appearance of *Michelia* and *Grewia*.

2. *P. acerifolium*. Maple-leaved *Pterospermum*. Willd. n. 2. Bot. Mag. t. 620. (*Pentapetes acerifolia*; Linn. Sp. Pl. 959. Cavan. Diff. 3. 131. t. 44.)—Leaves oblong, heart-shaped, obtuse, nearly entire.—Native of the East Indies, and introduced by Messrs. Lee and Kennedy about 1790. It flowers from July to September. This very superb species, considerably larger than the preceding in all its parts, but exceedingly similar to that in habit, has its bark covered with a white wool, like the underside of its leaves, which are peltate, and supported on long footstalks thickened at both ends. Flowers terminal, white, fragrant. Calyx like thick buff leather, externally dotted, like the stem, with red and brown.

PTEROSTYLIS, from πτερον, *a wing*, and στυλο:, *a*

column, because of the winged style, or column of the fructification.—Brown Prodr. Nov. Holl. v. 1. 326. Ait. Hort. Kew. v. 5. 204.—Class and order, *Gynandria Monandria*. Nat. Ord. *Orchideæ*.

Gen. Ch. *Cal.* Perianth superior, ringent, of two lanceolate pointed leaves; the lowermost deeply divided, or rather composed of two, combined in their lower part. *Cor.* Petals two, oblong, converging with the upper calyx-leaf. Nectary a lanceolate stalked lip, shorter than the petals, with an appendage, or swelling, at the base; its claw connected below with the lower calyx-leaf. *Stam.* Column united at its base with the petals and upper calyx-leaf; winged on each side at the upper part; anther a terminal, moveable, permanent lid, its cells close together; masses of pollen powdery, compressed, two in each cell. *Pist.* Germen inferior, oblong, with six furrows; style, column as above described; stigma tumid, attached to the middle of the column. *Peric.* Capsule of one cell and three valves. *Seeds* numerous, minute, attached to three longitudinal receptacles.

Ess. Ch. Lip stalked, with an appendage at the base. Two lower calyx-leaves combined, and united to the claw of the lip. Column winged in the upper part. Anther a terminal lid. Pollen powdery.

Of this curious and very distinct genus of New Holland *Orchideæ*, Mr. Brown enumerates nineteen species, in three sections. They all grow on the ground, and are smooth herbs, with a pair of naked, undivided, round bulbs. Leaves sometimes radical, stellated, ribbed, membranous, the flower-stalk being, in that case, leafless, though furnished with bractæas; sometimes cauline, alternate, none radical. Flowers solitary, rarely in clusters, of a pale yellowish-white; their size, for the most part, rather considerable.

SECT. 1. *Appendage to the lip divided, and tufted, at the tip. Leaves radical, stellated. Stalk bracteated, leafless.* Eight species.

P. concinna. Elegant *Pterostylis*.—“Leaves radical, stellated. Stalk with one bractea near the middle. Lip emarginate, within the flower, the length of the column.”—Gathered by Mr. Brown, and Mr. Caley, near Port Jackson. Leaves three or four, heart-shaped, stalked, reticulated, about half an inch long. Stalk four or five inches high, with one bractea near the base, and another more than half way up. Flower solitary, rather large, striped with green and white; the lower calyx-leaf with two very long, slender, divaricated points.

P. ophioglossa. Cloven-tongued *Pterostylis*. Br. n. 2.—“Leaves radical, stellated. Stalk naked in the middle. Lip emarginate, longer than the column, protruding at the summit.”—Observed by Mr. Brown about Port Jackson, as well as in the tropical part of New Holland.

SECT. 2. *Appendage divided, mostly tufted. Radical leaves none when the plant is in flower. Stem leafy.* Five species.

P. obtusa. Blunt-lipped *Pterostylis*. Br. n. 9. Ait. n. 1.—“Stem leafy, single-flowered. Lip obtuse, not contracted towards the end; appendage tufted.”—Gathered by Mr. Brown near Port Jackson, and sent by Mr. George Caley, in 1800, to Kew, where it is said to be a green-house plant, flowering in July and August.

P. reflexa. Br. n. 10. (*Disperis alata*; Labill. Nov. Holl. v. 2. 59. t. 210.)—Stem leafy, single-flowered. Lip tapering, acute; appendage tufted. Petals with an angular entire dilatation at their inner margin. Found by Dr. White and Mr. Brown near Port Jackson; by M. Labillardiere at Van Diemen's land. The stem is a span high, straight, erect. Leaves rather distant, lanceolate, sheathing,

sheathing, acute, about an inch and half long. *Flower* erect, about the same length, exclusive of the *germen*, white striped with green.

SECT. 3. *Appendage obtuse, undivided.* Five species.

P. gibbosa. Br. n. 17.—“Leaves radical, stellated. Bractæas distant. Calyx pointed. Lip thickish, naked above, with a bristle on each side at the base.”—Gathered by Mr. Brown, near Port Jackson.

P. mutica. Br. n. 18.—“Leaves radical, stellated. Calyx rather obtuse. Lip membranous.”—From the same country.

SECT. 4. *Character of foliage uncertain.* One species.

P. dubia. Br. n. 19.—“Radical leaves . . . ? those on the stem two; the upper one shorter than the flower-stalk. Calyx slightly downy. Lip undivided, with a tufted appendage.”—Native, as Mr. Brown informs us, of Van Diemen's land. It is suspected to be but a variety of *P. cucullata*, his sixth species.

Mr. Brown has shewn us another species of this genus, found by sir Joseph Banks in New Zealand; and he informs us that the late colonel Paterfon has discovered two more in the neighbourhood of port Dalrymple, Van Diemen's land, where he established a colony.

PTEROTRACHEA, in *Ichthyology*. Body detached, gelatinous, with a moveable fin at the abdomen or tail; two eyes, placed within the head. There are four species, of which the first has been pretty fully described, as follows:

Species.

CORONATA. Abdomen and tail furnished with fins; head with a round perpendicular proboscis, and a coronet of ten spines on the front. It inhabits the Mediterranean and Archipelago. The body is subcylindrical, about a span long, and an inch in diameter; the head is rounded on the fore-part, and furnished in front with a coronet of ten spines; beneath the coronet is the proboscis, two inches long, with a whitish middle nerve, and thick hyaline tip, and terminal mouth; the eyes are seated on each side the back of the neck internally, and remote; trunk near the fin beneath spotted with white; abdomen rough beneath, with an ovate pendulous pouch before the fin; vent near the ligament of the tail; the tail is vertical, an inch long, and triangular, with four prickly lines on each side; the fin is situated beyond the middle of the body; it is orbicular, compressed, and fixed to the white laminæ of the trunk, which are crenate on each side; beneath in the margin is another pinnule, which is bell-shaped, hyaline, and affixed by a middle point.

HYALINA. Head elongated, projecting, smooth; the fin is central.

PULMONATA. Head obtuse, hyaline; intestine respiratory and ciliate, with plumes.

ACULEATA. Abdomen without fin; tail longer than the trunk, with prickly lines, and a terminal horizontal fin. This, as well as the first, is found in the Archipelago. The habitation of the others is not known.

PTERYGIUM, or **PTERYGION**, dim. of πτερύξ, a wing. By the term pterygium, surgeons universally imply that preternatural, reddish, ash-coloured, triangular, little membrane, which most frequently grows from the internal angle of the eye, near the caruncula lachrymalis, and gradually extends over the cornea, so as to cause a serious impediment to vision.

Of this disease the celebrated Scarpa has recently published a description, which may be regarded as the most

perfect one extant, and which we therefore feel it to be our duty to incorporate in this comprehensive dictionary.

Though, says Scarpa, the pterygium generally originates from the internal angle of the eye, it is sometimes observed to proceed from the external one, and, in some instances, from the superior or inferior hemisphere of the eye-ball. But whatever be its origin, its figure is invariably that of a triangle, with its base on the white of the eye, and its apex more or less advanced over the cornea, towards the centre of this membrane and of the pupil. Indeed, there are a few cases, in which two or three pterygia of different sizes take place on the same eye, and are arranged round its circumference at interspaces of various breadths. Their points are directed towards the centre of the cornea; and if they should unfortunately conjoin there, the whole of that transparent membrane becomes covered with an opaque veil, and a total loss of sight is the consequence. It seems to Scarpa, that the term *pannus* was applied by the ancients to exactly this sort of complication.

Strictly speaking, chronic varicous ophthalmia, with relaxation, and thickening of the conjunctiva, opacity of the cornea, and the pterygium, only differ in the degree of the disease. In reality, all the three complaints consist of a more or less extensive varicous state of the vessels of the conjunctiva, combined with a degree of preternatural relaxation, and thickening, of that membrane.

In chronic varicous ophthalmia, the extraordinary amplitude and knottiness of the vessels, the flaccidity and thickening of the conjunctiva, are limited to the white of the eye. In opacity of the cornea, certain veins even dilate, and become knotty, for some way, over that delicate layer of the conjunctiva, which is continued over the surface of the cornea. In the pterygium, an extraordinary swelling of this subtle membranous expansion is added to the varicous state of its veins. Hence, the pterygium seems at first like a new membrane formed on the cornea, while it is really nothing more than the delicate continuation of the conjunctiva just mentioned, deprived of its transparency, and degenerated, in consequence of chronic ophthalmia, into a thick, opaque membrane, on which there is a plexus of varicous blood-vessels: consequently, in the case of pterygium, there is no new production on the eye, but only an alteration of one of the thin, transparent membranes, which naturally cover it. The following circumstance, as will be more fully explained presently, illustrates, says Scarpa, the veracity of the preceding statement. The incipient pterygium may be cured in the same manner as opacity of the cornea, viz. by merely cutting off that portion of it, which is situated at the junction of the cornea with the sclerotica, without detaching the whole of it from the surface of the former membrane; just as is practised in opacity of the cornea, in order to destroy the communication of the varicous veins of the conjunctiva with their trunks, the ramifications of which produce and maintain the disease.

Scarpa observes, that the pterygium would be as common a complaint as the varicous chronic ophthalmia, so often occupying the white of the eye, if the delicate continuation of the conjunctiva, over the surface of the cornea, were not naturally of a denser and more compact texture than the rest of the membrane, from which it is produced, and if its vessels were not very minute, and delicate, and not so dilatable as those of the other part of the conjunctiva. This is the reason why the pterygium is comparatively a rare case, in respect to the great frequency of varicous, chronic ophthalmies. But should the vessels of the transparent layer of the conjunctiva once yield to the impulse of the fluid propelled into them; should they once become varicous; the cellular

PTERYGIUM.

cellular texture, in which they are enveloped, never fails to swell gradually, and thus the delicate, diaphanous membrane in question changes into a pulpy, reddish tunic, precisely similar to the pterygium.

That the pterygium is truly nothing else, but the natural, delicate, transparent expansion of the conjunctiva on the cornea, converted, for a certain extent, into a pulpy, flaccid, varicous membrane, may be inferred (continues Scarpa) from the folds which the pterygium and conjunctiva form at the same time, when the morbid eye is turned towards the origin of the disease. The same inference is equally deducible from the tension occasioned in both these parts, whenever the eye is moved in the opposite direction. We become still more convinced of the fact on observing, that in the first position of the eye, both the pterygium, and the corresponding portion of the conjunctiva (which is equally relaxed, varicous, and reddish), may be easily taken hold of with a small pair of forceps, and raised together in the form of a fold.

When the pterygium is met with in the dead subject, on carefully cutting off, and detaching that flaccid and thickened portion of the conjunctiva in the white of the eye, which corresponded to the part of the cornea in the state of opacity, from the pterygium, Scarpa has constantly found, that the pterygium might be separated, with equal facility, both on the white of the eye, and the cornea. The latter membrane was evidently denuded at the seat of the disease, being no longer covered with the transparent continuation of the conjunctiva. But Scarpa has never been able to deprive the cornea of its natural covering, beyond the limits of the pterygium. Also, when several pterygia occur on the same eye, with interspaces between them, as many flaccid, varicous, pulpy places appear in the conjunctiva on the bulb, and constitute the basis of the pterygia; while the rest of this membrane, covering the white of the eye, continues smoothly spread over the ball, and no varicous blood-vessel is perceptible on the anterior hemisphere of the eye, except where the relaxation of the conjunctiva, and the knottiness of the vessels, have implanted, as it were, the distant roots and rudiments of the pterygium.

The pterygium, whether large or small, and whatever its situation may be at the circumference of the eye-ball, constantly retains its triangular shape, with its base on the white of the eye, and its apex on the cornea. The constancy of this fact seems to Scarpa attributable to the increasing degree of firmness, with which the subtile, transparent layer of the conjunctiva adheres to the surface of the cornea, as it proceeds from the circumference to the centre of that membrane. The following consequences must necessarily result from this sort of structure, and the different degree of cohesion actually existing in healthy eyes. 1. The progress of the pterygium must be slower in every instance on the cornea, than on the white of the eye. 2. As the pterygium always meets with augmented resistance, in proportion as it endeavours to approach the centre of the cornea, it must from mechanical necessity assume the form of a triangle, with its base on the white of the eye, and its apex directed towards the centre of the cornea. Forestitus (*Oper. Med.*) has accurately noticed the circumstances of this appearance, and, he continues, "non cooperit oculum nisi in formâ sagittæ."

From this invariable appearance, and figure of the pterygium, one of its principal diagnostic characters results, by which the true disease may be discriminated from false instances, and from every other soft, fungous, reddish excrescence that obscures the cornea. For on this membrane excrescences sometimes form, which, from having the colour and consistence of a soft membrane, bear a very great re-

semblance to the pterygium, though they are really widely different, and, strictly speaking, consist of the texture of the cornea itself, degenerated into a soft, fungous substance. Such pellicles, however, not only almost always create a greater prominence on the cornea, than what accompanies the pterygium, but they are constantly of an irregular tuberous form, and never represent a triangle, with the apex pointing towards the centre of the cornea, like the genuine pterygium.

Another distinguishing character of the pterygium (continues Scarpa) consists in the facility with which the whole of it may be taken hold of with a pair of forceps, and raised into a fold on the cornea. Every other kind of excrescence, attached to this membrane, continues firmly adherent to it, and cannot be folded, and raised from the surface of the cornea, in any manner whatever. This particularity is of the highest importance in the treatment of the disease; for the genuine pterygium may be cured by simple means, while fungous excrescences of the cornea can only be radically removed, and perfectly cicatrized with the utmost difficulty. Plenck very properly observes, on this head: "Pterygia, quæ filamentis solummodò adhærent, facillè abscinduntur, difficillimè quæ ubique accreta sunt corneæ, ac in plicam non possunt." If this excrescence should adhere firmly to the cornea, be of a deep red colour, easily bleed on being touched, and cause shooting pains in the whole eye and temple, though it be of a triangular figure, and constitute the true pterygium, it now threatens to assume a malignant cancerous nature, or has done so already. Hence, in the treatment, it is necessary only to adopt a palliative plan, or else extirpate the whole eye-ball.

The true benign pterygium, says Scarpa, which has a triangular figure, is ash-coloured, or pale-red, is free from pain, and admits of being raised in the form of a fold on the surface of the cornea, may be cured by cutting the opaque triangular little membrane accurately from the surface of the cornea, which is in part covered by it. But as it appears, from what has been said, that the pterygium is nothing but a portion of the delicate, transparent layer of the conjunctiva, converted by chronic varicous ophthalmia into a thick, opaque tunic, it follows, that the pterygium cannot be removed in any way, without the spot, which it occupies on the cornea, being bereft of its natural external covering. Also, as this denudation of the cornea renders a cicatrix unavoidable at the place, it equally follows, that the knife cannot be employed in the cure of the disease, without the cornea being rendered more or less opaque at the part where the pterygium was before situated. Hence, Scarpa cautions young surgeons not to allow themselves to be deceived by the specious accounts of authors, who assert, that they have removed pterygia with the scalpel, and entirely restored to the cornea its former natural transparency. It is true (he says) that, after the removal, and cure, of the pterygium, the cornea at the part affected becomes less opaque than it was before; but the place always continues dim, and clouded with an indelible, though a superficial cicatrix. The amendment derived from the operation cannot but be considerable; by means of the incision, and firm cicatrix, a stop is put to the progress of the complaint, or rather to the increase of the varicous affection, and swelling, of the thin, transparent layer of the conjunctiva, situated on the cornea; the local cause of irritation, and inflammation of the eye, is entirely obviated; and, thus, complete opacity of the cornea is prevented. But should it ever have happened after the resection of a large pterygium, that the patient regained his sight, we are to understand a certain degree of vision; in that proportion (Scarpa wishes to signify) which exists between

PTERYGIUM.

tween a dense membrane, which entirely obstructs the passage of the light, and a slight, superficial cicatrix of the cornea, which does not intercept it altogether.

Scarpa's experience enables him to state, however, that the superficial, indelible speck remaining in the cornea after the recision of the pterygium, is always less extensive than the space previously occupied by the disease. This fact, says he, is a constant one, and, in the vast number of pterygia for which he has operated, some had advanced over the cornea two lines, others two and a half, towards its centre. In all, the scar, and opacity of the cornea, diminished after the cure was perfected, and never exceeded a line and a half, or a little more, in cases in which the pterygia had been two lines in length.

The recision of the pterygium is a very easy operation. For this purpose there is no occasion for a needle threaded with silk, which most surgeons recommend to be passed through the little membrane, in order to make a noose for raising the pellicle, which must be divided at its base. The plan is disadvantageous, as it prolongs the operation considerably, and, particularly, as the bleeding from the punctures prevents the operator from distinguishing, with the necessary clearness, the margin of the parts designed for removal. A pair of dissecting forceps, and a pair of sharp scissars, suffice for this operation.

It is customary (continues Scarpa) to remove the pterygium by making the incision on the cornea, and extending it over the white of the eye, as far as the base of the disease reaches on the conjunctiva; so that when the pterygium grows from the internal angle of the eye, most surgeons continue the section as far as the caruncle. This practice is disadvantageous, first, because it denudes too much of the white of the eye; secondly, because, in consequence of the large portion of the conjunctiva removed at the base of the pterygium, and, in consequence of the direction of the wound, the cicatrix in the white of the eye forms an elevated frænum, which, like a little cord, keeps the eye-ball approximated to the caruncula lachrymalis, and destroys the freedom of its motions, particularly towards the external angle.

To avoid this inconvenience, Scarpa says, he has found it useful, in the treatment of pterygia with bases extending far in the white of the eye, to detach them at their apex, as far as the junction of the cornea with the sclerotica, and then to separate them at their base by a semi-circular incision, comprehending one line in breadth of the substance of the conjunctiva, and made in a direction concentric with the edge of the cornea. Scarpa has observed, that, in this mode of operating, the subsequent cure takes place sooner than when the common method is adopted; the cicatrix occasions no sort of frænum, and the conjunctiva, circularly stretched by the cicatrix, lies smoothly over the white of the eye, and loses that relaxation and varicous state, which are the ground-work of the pterygium. Such attention, however, is not requisite when the pterygium is small, and its base does not extend far in the white of the eye.

Scarpa describes the operation as follows: The patient being seated, an assistant behind him is to elevate the upper eye-lid with the index and middle fingers of one hand, while he depresses the lower eye-lid with the corresponding one of the other. Supposing it the right eye, the operator is to stand, or sit down, just as he prefers, in front of the patient; and the former, after directing the latter to move his eye-ball towards the part corresponding to the base of the pterygium, is to seize the morbid membrane with a pair of forceps held in his left hand, and pinch it into a fold, at about one line from its apex. The duplicature is now to be

raised, and drawn out gently, until a sensation of something giving way is felt, which indicates the detachment of the pterygium from the delicate cellular texture, by which it is connected with the subjacent cornea. Next, by means of a pair of scissars in the right hand, the surgeon must dissect this fold, as closely as possible, from the cornea, proceeding from the apex towards the base of the pterygium. The section being completed to where the cornea and sclerotica meet, the fold is to be again elevated still more, and, with one stroke of the scissars, the pterygium, and the relaxed portion of the conjunctiva, forming its base, are to be detached, as concentrically and closely to the cornea as possible. This second incision will have a semilunar shape, the horns of which ought to extend two lines beyond the relaxed part of the conjunctiva in following the curvature of the eye-ball.

When the operation is finished, the surgeon must promote the hemorrhage, by washing the part with warm water, and then cover the eye that has been operated on, with a pledget of dry lint, or lint moistened in the aqua vegeto-mineralis, supported by a bandage, that does not make too much pressure on the part.

If no particular symptoms arise (continues Scarpa), such as pain, tension of the eye, considerable tumefaction of the eye-lids, it is sufficient to wash the eye, and inside of the eye-lids, three or four times a day with a warm lotion of mallows, and carefully keep these parts from being exposed to the air without compressing them. If the symptoms just mentioned should afterwards occur, the antiphlogistic treatment must be adopted in its full extent, &c.

On the fifth or sixth day, at latest, after the operation, all the surface from which the pterygium was cut appears yellowish, and covered with a fluid, like mucus. This is a mode of suppuration (says Scarpa) peculiar to membranes in general, and particularly to those of the eye. The edges of the wound, and the adjoining part of the conjunctiva, assume a reddish colour. Afterwards the surface of the wound contracts more and more daily, so that at length it completely closes, and the cicatrix forms.

During the whole treatment, subsequent to the operation, there is no occasion to employ any other topical applications but the warm lotion of mallows, three or four times a day. Numerous cases have convinced Scarpa that astringent collyria, and the boasted powders of the Florentine iris and alum, cause great irritation to the eye operated on, and give rise to tumefaction, and a fungus-like state of the conjunctiva, which are impediments to the cure. What is still more inconvenient is, that such means produce fungous excrescences on the middle of the wound itself, which only admit of being repressed and cicatrized with difficulty. Scarpa has seen all these inconveniences arise from one single unnecessary application of the argentum nitratum. On the other hand, when a mere lotion of mallows is the only remedy employed in the treatment, the cure proceeds regularly; the yellowish surface of the incision diminishes daily, and in three, or, at most, four weeks, the wound is quite healed. The vitriolic collyrium, containing a few drops of camphorated spirit of wine, can only be prudently intilled three or four times a day into the eye, for the purpose of strengthening the conjunctiva and its vessels, after the wound is perfectly cicatrized.

We have already repeated Scarpa's sentiment, that the incipient pterygium, strictly speaking, is nothing more than an opacity of the cornea, in which the venous vessels of the conjunctiva covering that part of the cornea, which is the seat of the disease, are somewhat more dilated, than in the case to which the term *opacity* is usually assigned; and, also, that the density and opacity of the delicate layer of

the conjunctiva are much more considerable at the part affected in the instance of pterygium, than in that of simple opacity of the cornea.

The incipient pterygium (adds this author) is not a dense, opaque membrane, but a pellicle as fine as a cobweb, interwoven in different places with varicous blood-vessels, the iris containing tolerably visible behind it. In this early state of the pterygium, it is unnecessary to deprive the cornea of its natural covering; it is quite enough to cut off a portion of it, in order to intercept all communication between the dilated venous ramifications of the pterygium, and the varicous trunks in the white of the eye.

The recision, says Scarpa, is accomplished by cutting out, with a pair of forceps and scissors, a semilunar piece of the conjunctiva, at the point where the cornea and sclerotic conjoin, and exactly at the base of the incipient pterygium, just as is practised for opacity of the cornea. The recent pterygium is observed to disappear gradually after the operation, or to change into a slight dimness of the cornea, extending over a part of the space previously occupied by the disease. This opacity is commonly much more trivial than what follows a cicatrix. Acrell, in his Surgical Observations, mentions having successfully treated an incipient pterygium in this manner. Scarpa has also tried the plan several times with success. Scarpa Sulle Malattie degli Occhi, cap. 11.

PTERYGODIUM, in *Botany*, from *πτερυγιδες*, winged; or *broad-shouldered*; a name expressive of the wing-like aspect of the broad, spreading petals.—Swartz in *Act. Stockh.* for 1800. 217. t. 3. f. E. and in Schrader's *New Journal*, v. 1. 35. t. 1. f. E. Willd. *Sp. Pl.* v. 4. 56. Ait. *Hort. Kew.* v. 5. 197.—Class and order, *Gynandria Monogynia*. Nat. Ord. *Orchideæ*

Gen. Ch. *Cal.* Perianth superior, ringent, of three lanceolate, equal, concave, spreading leaves. *Cor.* Petals two, roundish-obovate, nearly as long as the calyx, spreading, approaching the upper calyx-leaf so as to form a hood. Nectary a lip, various in shape, inserted into the column between the lobes of the anther, reflexed and spreading. *Stam.* Column erect, short, either blunt or pointed; anther of two roundish separate lobes, one at each side of the column, bursting laterally. *Pist.* Germen inferior, oblong, furrowed; style column as above; stigma convex, posterior, at the base of the back of the anther. *Peric.* Capsule of one cell, with three valves. *Seeds* numerous, minute.

Ess. Ch. Lip inserted into the middle of the column, between the lobes of the anther. Petals rounded. Two lower calyx-leaves divaricated, concave. Stigma posterior.

Willdenow, after Swartz, reckons up six species.

1. *P. alatum*. Winged Pterygodium. (*Ophrys alata*; Linn. *Suppl.* 404.)—"Stem leafy. Leaves lanceolate. Lip in three segments; the middle one very short."—Found by Thunberg at the Cape of Good Hope. A small plant, three or four inches high.

2. *P. catholicum*. Inflated Pterygodium. (*Ophrys catholica*; Linn. *Sp. Pl.* 1344. *O. alaris*; Linn. *Suppl.* 404. *Orchidi affinis*, flore luteo; Buxb. *Cent.* 3. 13. t. 21.)—"Stem with two or three oblong pointed leaves. Lip spatulate, pointed, wavy." Native of the Cape. A span, or more, in height, with a few large, concave, yellow flowers.

3. *P. Volucris*. Arrow-lipped Pterygodium. (*Ophrys Volucris*; Linn. *Suppl.* 403. *O. triphylla*; Thunb. *Prodr.* 2.)—"Stem with three ovate leaves. Lip hastate."—Gathered by Sparrmann and Thunberg at the Cape. Introduced at Kew in 1797, by sir Joseph Banks. It flowered in the green-house in June and July. This species is a foot

high. *Leaves* three on the stem, ovate or oblong, pointed, ribbed. *Spike* of many, distant, rather small flowers.

4. *P. caffrum*. Caffre Pterygodium. (*Ophrys caffra*; Linn. *Sp. Pl.* 1344. Thunb. *Prodr.* 2.)—"Stem with about five oblong leaves. Lip very large, two-lobed."—Gathered by Thunberg and others at the Cape. A foot high. *Cluster* of three or four yellow flowers, whose lip is very broad, kidney-shaped and emarginate.

5. *P. inversum*. Cloven-spiked Pterygodium. (*Ophrys inversa*; Thunb. *Prodr.* 2.)—"Stem clothed with sword-shaped two-ranked leaves. Lip lanceolate, divided at the base."—From the same country. *Spike* dense, of many flowers.

6. *P. atratum*. Blackened Pterygodium. (*Ophrys atrata*; Linn. *Mant.* 121.)—"Stem with several linear-setaceous leaves. Lip spatulate, somewhat heart-shaped." Native of sandy ground at the Cape. *Stem* three or four inches high. *Leaves* numerous, distant; the lowermost broadest; the upper longest and narrowest. *Spike* lax, of several distant flowers. The whole plant when dried turns as black as ink, whence the name; but this circumstance is common to many of the *Orchis* family.

PTERYGOID, in *Anatomy*, the name of a process and of a foramen of the sphenoid bone, and of some other parts situated near them. See **CRANIUM**.

The pterygoid nerve is a branch of the superior maxillary going through the pterygoid foramen. See **NERVE**.

PTERYGOIDEUS EXTERNUS, and **PTERYGOIDEUS INTERNUS**, two muscles of the lower jaw, arising from the pterygoid process of the sphenoid bone. See **DEGLUTITION**.

PTERYGO-PALATINE CANAL, is formed between the palate and sphenoid bones, and terminates at the posterior palatine foramen. It transmits the palatine nerve.

PTERYGO-PHARYNGÆUS, a name given to some of the fibres of the constrictor pharyngis superior.

PTERYGO-STAPHYLINUS INTERNUS, the levator palati muscle.

PTERYGO-STAPHYLINUS Externus, the circumflexus palati.

PTILOISIS, from *πίλος*, bald, a loss of the eye-lashes, from disease of the eye-lids.

PTILOTUS, in *Botany, from *πίλωτος*, winged, especially with a dry membranous expansion; alluding to the shining, scariose, permanent bractæas.—Brown *Prodr. Nov. Holl.* v. 1. 415.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Amaranthaceæ*, Juss. Brown.*

Ess. Ch. Calyx in five deep lanceolate segments. Stamens connected at their base, without teeth. Anthers of two cells. Stigma capitate. Capsule without valves, single-seeded, inclosed in the three inner segments of the calyx, which are connected by wool half way up, but naked and spreading above.

This genus consists of annual smooth herbs, with narrow alternate leaves. The flowers are terminal, somewhat capitate, accompanied by three membranous shining bractæas, which remain after the calyx is gone. It is said by its learned author to be very nearly akin to his **TRICHINIUM**; see that article hereafter.

1. *P. conicus*.—Heads solitary, roundish, somewhat conical. Stamens inversely heart-shaped at the summit, contracted in the middle. Leaves linear.

2. *P. corymbosus*.—Heads corymbose. Stamens thread-shaped. Lower leaves lanceolate; upper linear.

Both species were gathered by Mr. Brown in the tropical part of New Holland.

PTINUS, in *Entomology*, a genus of insects of the order *Coleoptera*: antennæ filiform, the last joints larger; thorax

nearly round, not margined, receiving the head. There are thirty-nine species, divided into two sections, depending upon the form of the feelers and lip.

The genus *Ptinus*, like that of *Dermestes* (which see), consists of small insects, which, in general, have similar habits, living both in their larva and complete state among dry animal substances, and some species of dry wood, committing much havoc among the older articles of furniture, which they pierce with innumerable holes, thus causing a slow but gradual destruction.

A. *Feelers clavated.*

Species.

* **TESSELLATUS.** Brown; thorax even; shells slightly tessellate. It is a native of England.

STRIATUS. Brown; thorax uneven, with two ferruginous dots at the base. It is a native of Kiel.

RUFIPES. Black; thorax roundish; shells striate; legs ferruginous. This is found in different parts of Germany.

CASTANEUS. Downy, chestnut; shells striate. It inhabits France.

* **PERTINAX.** Brown, immaculate; thorax compressed. This is found in divers parts of Europe, and is very destructive to wooden furniture and books. When caught it contracts itself and counterfeits death, nor can it be put into motion again by any stimulating means but by the application of great heat.

BOLETI. Brown, opaque; legs testaceous. Inhabits Germany, is on fungi. The body is rarely testaceous.

* **MOLLIS.** Testaceous; eyes black; shells naked. It is of a brick-colour, with dark-coloured eyes. It is found in this country and various parts of Europe, among rubbish; it is extremely destructive to collections of plants, and not to be got rid of but by the heat of an oven. The larva is white, and capable of enduring great cold.

PANICEUS. Downy, ferruginous; shells striate. Found in stale decayed bread.

ABIETIS. Brown, naked; shells testaceous. It inhabits Germany, and is found in the fir-tree.

PLANUS. Brown; thorax plain; shells with crenate striæ. It is a native of Kiel.

CAPENSIS. Ferruginous; shells striate, paler. Found at the Cape of Good Hope.

MINUTUS. Testaceous; thorax rounded; shells sub-striate and pubescent. Found in dried plants brought from Italy.

MICANS. Smooth, brown; shells naked; legs testaceous. Found in some parts of Germany, as is the next.

NITIDUS. Naked, black, polished; legs testaceous.

* **PULSATOR,** or Death-watch. Subvillous, dusky, with irregular grey brown spots. There seems a considerable degree of doubt where to place the death-watch; some will have it to be a species of the *Termes*. Fabricius appears to have supposed it the *dermestes tessellatus*, and Dr. Shaw describes it as the *ptinus fatidicus*: for its curious habits and manners; see our article *DEATH-watch*.

FAGI. Black; antennæ tawny; shells grooved and punctured. It is a native of Berlin.

FERRUGINEUS. Ferruginous; eyes black; shells obsoletely striate. A native of some parts of Germany.

TESTACEUS. Ferruginous, eyes black; shells smooth. A native of Berlin.

FUSCUS. Brown; body speckled with grey; scutellum grey; antennæ ferruginous. Inhabits divers parts of Europe, as do the four following.

RUFUS. Rufous, with a yellow gloss; thorax with a yellow spot on each side behind; the shells are striate and punctured.

FERRUGINOSUS. This also is of a ferruginous colour; the thorax is uneven; shell punctured striate; antennæ reddish.

STRIATULUS. Testaceous; shells lightly striate; the three last joints of the antennæ much larger.

BRUNNEUS. Brown; shells slightly striate, pubescent.

B. *Feelers filiform; lip bifid.*

PUBESCENS. Pubescent, black; shells striate, testaceous. It inhabits France.

GERMANUS. Brown; thorax four-toothed; antennæ and legs ferruginous.

LONGICORNIS. Black, polished; legs yellowish. Found in Germany.

* **FUR.** Testaceous; thorax four-toothed; shells with two white bands. This is a very destructive species to museums, books, furniture, preserved subjects of natural history, and dry seeds. It is finely figured in Shaw's *General Zoology*. It is more than the tenth of an inch long; its colour is pale chestnut-brown, sometimes marked on the wing-coverts by a pair of greyish bands; the antennæ are rather long and slender; the body remarkably convex, and the thorax, when magnified, appears to have a projecting point on each side. It delights in cold and moisture, and is best kept off by heat, but is destroyed most effectually by corrosive sublimate. The female is without wings. The larva has six feet; is soft, thick and hairy. The pupa is inclosed in a glutinous spherical covering.

* **IMPERIALIS.** Brown; the thorax somewhat crenated; the elytra marked with a white blotch, divided into lobes. It inhabits many parts of the north of Europe, as well as this country, and to be found in trees. It is about the size of a grain of wheat. The antennæ are of the same length with the body; the legs are of a rusty colour; the scutellum white; the elytra marked with a white spot, resembling the eagle worn on the imperial standard; whence it has obtained its specific name.

CRENATUS. Brown; thorax gibbous; shells with crenate striæ, immaculate. It is a native of Germany, and less than the *P. fur*.

LATRO. Testaceous, immaculate; thorax two-toothed. Found at Strasburg.

DENTICORNIS. Black; shells striate; antennæ serrate. Native of Paris.

SERRICORNIS. Thorax gibbous, deflected; body testaceous; antennæ serrate. Found among the dried herbs from America.

SPINICORNIS. Oblong, two lower joints of the antennæ longer and spinous. Found in the Sandwich islands.

SULCATUS. Whitish; thorax downy, with four grooves; shells connected, brown testaceous, polished. Found in dried plants brought from the Canary islands.

SCOTIUS. Thorax naked, pitchy; shells connected, brown testaceous, polished. It is found on the birch in different parts of Europe.

STRIATUS. Thorax gibbous, with two tubercles; shells globular, striate. It inhabits Saxony.

UPSALIENSIS. Testaceous; eyes black; shells striate; thorax plano-convex. Found at Upsal.

FABER. Dull testaceous; shells naked, waved with cinereous. A native of Holland.

APTERUS. Head brown; front channelled; shells, legs, and antennæ rufous; thighs clavate; shanks ciliate.

PTISAN, **PTISANA,** πτισαν, in the *Materia Medica*, a cooling potion usually made of barley boiled in water, and sweetened with liquorice, &c.

To these are sometimes added the roots of quick-grass, and

and sometimes senna, to render it laxative. Most of the decoctions of physicians are called *ptisans*. Feverish patients are prohibited wine, &c. and reduced to ptisans.

PTISCIANA, in *Ancient Geography*, a town of Africa, in the interior of Mauritania Tingitana. Ptol.

PTOLEMAIC SYSTEM, or *Hypothesis*. See SYSTEM.

PTOLEMAIC Sphere. See SPHERE.

PTOLEMAIS, in *Ancient Geography*, one of the towns of Phœnicia, situated 32 miles from Tyre, according to the Itinerary of Antonine. Its ancient name was Acco or Aco. See ACRE.—Also, a town of Egypt, in the Thebaid, according to Strabo, who says that its government was formed after the model of the republics of Greece. Ptolemy calls it Hermii, and says that it was the capital of the Thinite nome.—Also, a town of Africa, in Cyrenaica, according to Strabo, Pliny, and Steph. Byz.—Also, a town of Ethiopia, upon the Arabic gulf, according to Pomponius Mela. Pliny names it Epitheras, and places it on the borders of the lake Monoleus, adding, that it was built by Philadelphus, at the distance of 4820 stadia from Berenice, on the coast of the Red sea.—Also, a town of Asia Minor, in Pamphylia. Strabo.—Also, a port of the town of Arsinoe, in the Arsinoite nome, in Egypt, according to Ptolemy.

PTOLEMAITES, in *Ecclesiastical History*, a branch of the ancient Gnostics, so called from their leader Ptolemy, a man of considerable learning, who improved greatly on the system of the Gnostics his predecessors, and enlarged it with a number of notions and visions of his own.

The Ptolemites were properly a branch of the sect of the Valentinians, which sprung up towards the close of the second century, under Ptolemy, who differed in opinion from his master Valentine, with respect both to the number and nature of the æons.

St. Epiphanius is very full on the subject of the Ptolemites, and produces a letter of Ptolemy to Flora, in which that heretic lays down his doctrine. He maintained, that in the law of Moses there were three things to be considered, inasmuch as it did not all come from the same hand; but part of it, said he, from God, part of it from Moses, and part of it from neither of them, but from the pure traditions of the ancient doctors: on which last part it was that he founded his dreams.

PTOLEMY, surnamed *Lagus*, and *Soter*, in *Biography*, king of Egypt, was a native of Eordæa, in Macedonia; he was probably a natural son of king Philip, who gave his mother, Arsinoe, when pregnant by him, in marriage to Lagus, a Macedonian of mean descent. He passed for the real son of Lagus, from whom that dynasty of Ptolemies were called Lagides. He was brought up to arms, and became one of the most celebrated officers of Alexander the Great, whom he accompanied in all his expeditions. He particularly distinguished himself in the war against the nations on the Indian border, and had a great share in the successes of his sovereign. On the division of the Macedonian empire at the death of Alexander, the government of Egypt, with part of Arabia and Lybia, were assigned to Ptolemy. His administration of that province was so wise and equitable, that many resorted to it from Europe and Asia, and by the honours which he paid to the remains of Alexander, when conveyed to Egypt for interment, he attached to himself many of the veteran soldiers of that conqueror. When Perdiccas began to manifest his ambitious designs, Ptolemy joined in a league with Antipater and Craterus to keep him within bounds; and when Antipater made a new division of the provinces, Ptolemy was confirmed in the government which he possessed, and which in-

deed could not be taken from him. He afterwards possessed himself of Syria and Phœnicia. He met with very little opposition in this attempt, except from the Jews, whose resistance obliged him to lay siege to their capital, Jerusalem. This city he took by storm on the sabbath-day, the religion of the inhabitants not permitting them, on that day, to make use of the means of self-defence. He sent a number of Jews as captives into Egypt, of whom he selected those fitted to his purpose to serve in his garrisons, and placed the rest in the conquered countries of Lybia and Cyrene. He afterwards, together with Lyfimachus and Cassander, formed a confederacy to support Seleucus against the power of Antigonus, who took Syria from Ptolemy, and laid siege to the Phœnician sea-ports, which he reduced. Being obliged, however, to carry his arms elsewhere, Ptolemy marched into Syria, and defeated Demetrius, the son of Antigonus, and recovered all that he had lost. A defeat, given by Demetrius to a general of Ptolemy's, produced another change of fortune, and Ptolemy retreated to Egypt, with a great quantity of spoil, and a numerous body of people who were desirous of living under his protection. Peace was restored, and soon after broken: Ptolemy now made incursions into Cilicia, and conquered the greater part of the island of Cyprus. He then obtained various successes in Lesser Asia and the Archipelago, and attempted to gain the hand of Cleopatra, the sister of Alexander; but upon the bare suspicion of the princess's intentions in his favour, she was put to death by order of Antigonus. His career was stopt by the activity of Demetrius, who defeated him in a sea-fight, and reduced the isle of Cyprus. On this occasion the conqueror assumed the title of king, and conferred the same on his son, and his example was followed by Ptolemy, and the other Macedonian chiefs. This happened in the year 306. Antigonus and Demetrius now resolved to attempt the entire conquest of Ptolemy's dominions, and accordingly invaded Egypt with a powerful armament by sea and land; but Ptolemy was too prudent and skilful to allow them to carry their plans into effect. They turned their arms against Rhodes, but by the assistance of Ptolemy that city was saved, and the inhabitants, for his services, honoured him with the appellation of *saviour*. Ptolemy, in his turn, became the aggressor, and Antigonus was killed in battle, while Demetrius underwent a total defeat. Ptolemy now recovered the isle of Cyprus, and captured in Salamis the mother and family of Demetrius, whom he dismissed with magnificent presents. He regained likewise part of Syria and Phœnicia. At length, having arrived at an advanced age, he devolved the cares of government upon his son Ptolemy Philadelphus, associating him in the throne, and declaring him his successor, to the prejudice of an elder son by another wife. He survived two years longer, and died in the year 283 B.C. in the 84th year of his age, having reigned more than forty years. Ptolemy Soter, says the historian, was one of the greatest of Alexander's successors, and the best prince of the line which he founded. His reign, on the whole, was highly prosperous, and at his death his kingdom was very extensive; besides Egypt and its dependencies, he held Phœnicia and Cœlo-Syria, Lybia, Pamphylia, Cilicia, Syria, Caria, and some of the Cyclades. The seat of his kingdom was the new city of Alexandria, which he rendered populous by inviting inhabitants from various countries, and bestowing on them great privileges. He built the famous Pharos, or light-house, at the entrance of its port, and founded an academy or society of men of letters, for whose use he began that collection of books, which afterwards became celebrated through the world as the Alexandrian library. He was himself a man of un-

questionable

questionable learning, and composed a history of the conquests of Alexander, which was regarded by Arrian as the best authority for the events of that splendid period. While on the throne he retained the simplicity of manners and familiarity which had distinguished him as a soldier. His government was mild, prudent, and equitable, so that his dominions were the refuge of numbers who fled from the disorders, and oppressions prevailing in other parts of the Macedonian empire. He had been four times married; his two last wives were Eurydice, the daughter of Antipater, and mother of Ptolemy Ceraunus; and Berenice, by whose charms he was so captivated in advanced life, that he consulted her on all occasions, and made her son his heir. Univer. Hist.

PTOLEMY PHILADELPHUS, king of Egypt, son of Berenice, began to reign, as we have just observed, during the life-time of his father, and in 281 B.C. succeeded him as sole monarch. Soon after his succession he banished the philosopher Demetrius Phalereus, a miserable act of revenge, whom he suspected of having advised his father to nominate as his successor, his eldest son Ptolemy Ceraunus. The name Philadelphus appears to have been assumed by this king in compliment to his brother Ceraunus, after the latter had sent him an embassy expressing his desire to live on friendly terms with him, notwithstanding his disappointment in the succession. Philadelphus had, as has been seen, received a powerful and opulent kingdom, which placed him among the greatest sovereigns of the times. He had married, as his first wife, Arsinoe, the daughter of Lyfimachus, whom he repudiated, and then married his own sister, who was the widow of their half-brother Ceraunus; such was the custom of the royal families of the Macedonian race. He now formed an alliance with the Romans, the Athenians, and Lacedæmonians, and sent a fleet to the relief of Athens when besieged by Antigonus Gonatus. The general tranquillity of his reign was interrupted by the revolt of his maternal brother Magas, whom Ptolemy Soter had made governor of Lybia and Cyrene. Magas, with a numerous army, advanced towards Alexandria with a view to dethrone Ptolemy, but was recalled to his own government by a revolt of the Marmarides. Afterwards, in conjunction with his father-in-law, Antiochus Soter, king of Syria, he renewed his design; but Ptolemy was before-hand with him, and defeated all his plans. It was chiefly through the policy of Philadelphus that Alexandria became so celebrated for its commerce. He founded a city on the Red sea, near the frontier of Ethiopia, which he named, after his mother, Berenice, but finding its harbour inconvenient, he removed the trading station to Myos-Hormos, on the same sea. To this port were brought the commodities of the East, whence they were transferred on camels to Coptos on the Nile, and thence to Alexandria; and, in order to facilitate the passage across the desert, he carried a canal into it from the Nile for the supply of water, and built houses of accommodation at proper intervals. He likewise, for the protection of trade, kept two strong fleets, one on the Red sea, the other in the Mediterranean, in the last of which were some vessels of extraordinary magnitude. By these prudent measures, he rendered his kingdom flourishing, his people happy, and he filled the country with a number of populous towns and cities. Upon the death of Magas, his widow excited a war between her brother Antiochus Theos and Ptolemy, which produced a formidable invasion of Egypt by the Syrian king.

This war did not prevent Ptolemy from pursuing those plans of liberal munificence which have rendered his name illustrious. He employed learned men to collect books from all quarters for his great library, and it is said to have been

in consequence of his literary curiosity that the SEPTUAGINT (which see) was made; though the manifest fables with which the narrative of this transaction is mingled, have thrown doubts upon the whole. His generosity as a man and patron of letters, drew to his court many eminent persons in various branches, among whom were seven Greek poets, from their number popularly called the Pleiades. He was also the greatest collector, in his age, of the productions of the fine arts, which he purchased by means of his agents throughout Greece. After the death of his sister-wife, his affliction was unabating, and he perpetuated her memory by giving her name to several cities, and raising sumptuous monuments to her honour, nor did he long survive her loss. Ptolemy died in the year 246 B.C. leaving two sons and a daughter by the first wife. He was not of an amiable temper or character, though splendid in all his acts as a public man. He was indolent, luxurious, and effeminate; though he adopted the surname of Philadelphus, he put to death two of his brothers on suspicion of conspiracies, whence some writers have supposed the application of the name to be irony. His reign forms a kind of era in letters and the arts, and few monarchs have established a more lasting reputation arising from their encouragement. Univer. Hist.

PTOLEMY EUERGETES, son of the preceding, succeeded to the throne of Egypt in the year B.C. 246. Soon after his accession, his sister Berenice, widow of Antiochus Theos, king of Syria, being, with her infant son, reduced to the most imminent danger by Laodice, the first wife of that king, Ptolemy marched with an army to her succour, but before his arrival, they were taken and put to death. In revenge, he not only seized and put to death Laodice, but made himself master of Syria, Cilicia, and all the country to the Euphrates. He then passed that river, and reduced Mesopotamia, Babylonia, and, it is said, the whole tract as far as Bactria and the confines of India. Being called by a revolt in Egypt, he brought back an immense booty in gold and silver, and also a vast number of Egyptian idols which had been carried away by Cambyfes. These he replaced in their temples, and hence he acquired, among his superstitious subjects, the surname of Euergetes, or the Benefactor. When Ptolemy set out on this expedition, his queen Berenice made a vow to consecrate her beautiful hair to the gods in case he should be returned to her in safety. She fulfilled her vow, but through the negligence of the priests it was soon lost. To avert the king's wrath, Conon, the celebrated mathematician, feigned that the locks had been transported into the heavens, and formed a group of stars near the tail of the lion. To this new constellation, as he called it, he gave the name of *Berenice's Hair*, by which it is still known. After this Ptolemy made an expedition southwards, which in the end gave him possession of all the coasts of the Red sea on the Arabian and Ethiopic sides, down to the straits of Babelmandel. He died in the year 221 B.C. This king, says the historian, inherited the love of learning which distinguished his progenitors, and employed much care and expence in augmenting the Alexandrian library. He entertained men of literary eminence at his court, and having been a pupil of the celebrated Aristarchus, was himself eminent in letters, particularly in historical composition. Univer. Hist.

PTOLEMY PHILOPATOR, king of Egypt, succeeded his father Euergetes, assuming his name, *lover of his father*, for reasons that cannot now be ascertained. He was a vicious, dissolute, and cruel prince: one of his first acts, after his accession, was to put his brother Magas to death, because he was supposed to be too much loved by the army. Ptolemy was soon involved in a war with Antiochus the Great, king

PTOLEMY.

of Syria, who attempted, but unsuccessfully, to recover the provinces of Cælo-Syria and Palestine, which had been detached from the Syrian crown by Euergetes. A peace soon followed, in which the contended provinces devolved to Ptolemy, and on this important occasion he visited all their principal cities, and among the rest Jerusalem, where he offered sacrifices, and made rich presents to the temple. Being resisted by the priests in his attempt to enter the Holy of Holies, he returned to Alexandria so much exasperated against the Jewish nation, that he determined to deprive them of their privileges. A rebellion which broke out in Egypt was the cause of the destruction of a number of Jews, which Eusebius records about this period, representing them as fighting on the royal side. Philopator, in the ninth year of his reign, made an alliance between Egypt and Rome: his queen brought a son, after having been childless a great number of years. In joy for this event he gave himself up to all sorts of debaucheries; his queen remonstrated, and to prevent her interference, he caused her to be assassinated. He is also represented as having put his own mother to death: and according to history, he was unquestionably a most detestable sovereign. But he was not, however, without some good qualities: the love of learning, which was hereditary in his house, was eminently displayed in his character, and he gave some meritorious instances of munificence. He died in the year 204 B.C., after a reign of about seventeen years.

PTOLEMY EPIPHANES, king of Egypt, son of the preceding, was only in his fifth year when he succeeded to the throne. During his minority, Antiochus the Great having formed an alliance with Philip, king of Macedon, for the partition of the Egyptian dominions, invaded and took Cælo-Syria and Palestine. Ptolemy's guardians thereupon sent an embassy to Rome, imploring the protection of the republic, and M. Lepidus was deputed by the senate to go to Egypt, and assume the direction of affairs. When the young king assumed the reins of government, he fell under the government of courtiers, who ministered to his vicious inclinations, and subverted the influence of Aristomenes, who had been in the habit of giving him faithful advice. This he continued, which Ptolemy so much resented, that he caused him to be put to death. His administration became so odious and tyrannical, that a conspiracy was formed among his subjects, which had nearly effected his deposition. By means of another able minister, Polycrates, he was extricated from the danger, but he manifested his treacherous disposition, by cruelly executing the conspirators, after they had submitted upon the promise of a pardon. He cultivated a strict friendship with the Romans, to whom he offered succours in their war with Antiochus, although he had married Cleopatra, the daughter of that king. He also maintained a strict connection with the Achaian republic, and one of his last acts was to send an embassy, inviting it to a league, offensive and defensive. As he was preparing to make war against Seleucus, king of Syria, he was poisoned by his nobles and principal officers, who suspected that he meant to defray the expences of the war with their fortunes. This occurred in the year B.C. 180, in the 24th year of his reign. Univ. Hist.

PTOLEMY PHILOMETER, and PTOLEMY PHYSCON, kings of Egypt, sons of the preceding, both minors at their father's decease. Philometer, at the age of six, was declared successor to the crown, under the guardianship of his mother Cleopatra. She had the conduct of the regency during eight years, but after her death the young king was dethroned, and his brother Physcon was declared sovereign. Physcon, who assumed the name of Euergetes II., was expelled by Antiochus, who replaced Philometer on the

throne. The two brothers were then persuaded to reign in conjunction. They did not, however, live in concord, and Physcon dethroned his brother. The latter proceeded to Rome in a mean garb, and with a few attendants, in order to excite compassion; and representing his wrongs before the senate, they deputed two of their body to conduct him back and restore him. They accommodated the difference by decreeing the possession of Egypt to Philometer, and that of Libya and Cyrene to Physcon. The latter, afterwards, by a journey to Rome, obtained a decree for the addition of Cyprus to his share, which island had before been common to the brothers. Philometer, not choosing to acquiesce in the decree which deprived him of his share of Cyprus, opposed his brother with an armed force in the island, and took him prisoner: in this case he displayed a truly fraternal spirit, and not only pardoned the hostility, but restored to him Libya and Cyrene, which he had lost, and added some territories in lieu of Cyprus. After this, Philometer was engaged in a contest with ALEXANDER BALAS, (see his article,) in which he lost his life, in the year B.C. 145. He is highly extolled by historians, as well for his benevolence as clemency. By his wife and sister Cleopatra, he left a son and two daughters. Upon the death of Philometer, Physcon prepared to assert his claim to the succession. By the mediation of the Roman ambassador, an accommodation was effected, on condition that Physcon should marry Cleopatra, and reign jointly with her, while her son should be considered as heir to the throne. Physcon, however, murdered the son on the very day of the nuptials; and the remainder of his reign is represented by historians as one of the most sanguinary that ever afflicted the human race. He so depopulated Alexandria by his bloody executions, that he was obliged to invite strangers from all parts to re-people it. It would disgust the reader to mention but a small portion of the cruel acts which he perpetrated. He lived the scourge of the human race, and the curse of his own people, till the year 117 B.C. Tyrant as he was, he had the reputation of being a great patron and promoter of learning, and even such a proficient in letters, as to have obtained the title of Ptolemy the Philologist. He enriched the Alexandrian library with a great number of books, collected at a vast expence; and himself composed a historical work, regarded as a commentary on Homer. There were other Ptolemies of Egypt, but they do not seem worthy of record. Univ. Hist.—We shall, however, on account of his attachment to music, mention

PTOLEMY AULETES, the father of Cleopatra, and the last of the Ptolemies who reigned over Egypt. This musical prince derived his cognomen of Auletes, the flute-player, from his excessive attachment to that instrument.

Strabo (lib. xvii.) says of him, that besides his debaucheries, he applied himself in a particular manner to playing the flute. He had such an opinion of his own abilities, as to institute musical contests at his palaces, and had there the courage to dispute the prize, publicly, with the first musicians of his time; and as the dress of players on the flute among the ancients was peculiar to that profession, this prince submitted to wear the robe, the buskins, the crown, and even the bandage and veil of a tibicen, as may be seen on a beautiful anethyst in the king of France's possession, of inestimable value, which is supposed to have been engraved by command of this prince, and worn by him to gratify his vanity on account of his musical excellence. Indeed the surname of Auletes is seriously given to him by Cicero, and by Strabo. The first in his defence of Rabirius Posthumus; and the second, who was likewise his contemporary, never mentions him but by the title of Auletes. He had likewise an opprobrious appellation given to him, by his own subjects,

in the Egyptian language, of the same import, being called *Phothingos*, or *Phothingios*, from *Phothinx*, *Monaulos*, or single flute. His violent passion for music, and for the company of musicians, gained him the name of ΝΕΟΣ ΔΙΟΝΥΣΟΣ, *the new Bacchus*.

A melancholy truth forces itself upon the mind in reading the history of this prince, and that of the emperor Nero, whom he very much resembled, which is, that, if the heart is depraved, music has not the power to correct it. And though these musical princes obtained prizes in the public games, they acquired no honour to themselves, nor did they reflect any upon the profession of music. A musician is so distant in character and dignity from a sovereign prince, that the one must stoop too low, or the other mount too high, before they can approximate; and the public suffers with equal impatience, a sovereign who degrades himself, or an artist who aspires at a rank above his station in the community.

An inordinate love of fame, or a rapacious desire of monopolizing all the glory as well as goods of this world to themselves, must have incited these princes to enter the lists in competition with persons so much their inferiors: a passion that should always be distinguished from the love of music, which they might have gratified, either from their own performance, or from that of others, in private, much more commodiously than on a public stage.

PTOLEMY, CLAUDIUS, a celebrated Egyptian geographer, astronomer, and mathematician, was born at Pelusium, about the year 70 of the Christian era. He taught astronomy at Alexandria, where he flourished under the reigns of the emperors Marcus Antoninus and Adrian. Many of his observations were made between the years 125 and 140. He has always been regarded as the prince of astronomers among the ancients, and in his works he has left us an entire body of science. We are indebted to him for preserving and transmitting to us the observations and principal discoveries of the ancients, enriched and augmented by his own. He corrected Hipparchus' catalogue of the fixed stars, and he formed tables, by which the motions of the sun, moon, and planets might be calculated and regulated. He digested the observations of the ancients into a system entitled Μεγάλη Σύστασις, or *Great Construction*. In this he has adopted and exhibited the ancient system of the world, which placed the earth in the centre of the universe, and this has been called, after him, the Ptolemaic system, to distinguish it from those of Copernicus and Tycho Brahe. By order of the kings of Arabia, in 827 this work was translated into Arabic, in which language it was called *Almagestum*, and from the Arabic it was translated into Latin about the year 1230, under the patronage of the emperor Frederic II. There were also other versions of it from the Arabic into Latin. The Greek text was first printed at Basil in 1538, and accompanied with eleven books of commentaries by Theon, who flourished at Alexandria in the reign of the elder Theodosius. In 1541 it was reprinted at the same place, and again in 1551, with other works of Ptolemy. An abridgment of it was made by Purbach, and John Muller, with valuable commentaries by the latter, and published at Basil in 1543, in folio. (See *ALMAGEST*, and *PTOLEMAIC System*.) Another important work of Ptolemy was his "*Geographiæ, libri vii.*" in which he informs us that he followed the geography of Marinus of Tyre, but with numerous additions and corrections, with respect to the longitudes and latitudes of places, as well as the boundaries of countries and provinces in different quarters of the world. Ptolemy was the first who searched out and marked the situations of places according to their latitudes and longitudes: and though, for want

of observations, it is far from being perfect, yet it has been found very useful to modern geographers. There are other works of Ptolemy still extant, such as "*Quatuor Libri de Apotelesmatibus et Judiciis Astrorum:*" "*Fructus Librorum suorum, centum Aphorismis Astrologicis,*" which was a sort of supplement to the preceding; "*Recensio chronologica Regum a Nabonassoro Assyriorum, Medorum, Persarum, Græcorum, et Romanorum usque ad Antoninum Pium:*" "*De Apparentiis et Significationibus Stellarum inerrantium;*" "*De Analemate:*" "*De Hypothesi Planetarum Liber;*" "*Planisphærium;*" "*Elementorum Harmonicorum,*" of which the best edition in Greek and Latin, accompanied with the commentaries of Porphyry, was first published at Oxford, by Dr. John Wallis; and "*De iudicandi Facultate et Animi Principatu,*" published at Paris, in Greek and Latin, in 1603.

Ptolemy ranks as high amongst the great writers of antiquity for his Harmonics, or theory of sound, as for his *Almagest* and Geography.

Every writer on the subject of music, till the time of Ptolemy, regarded the fourth as the *first* concord, and dividing all the fifteen modes into tetrachords, regulated the scale in all the genera by that interval. But Ptolemy, about the year one hundred and thirty of the Christian era, and four hundred and fifty years from the time in which Aristoxenus flourished, proposed a new doctrine and reform in the ancient musical system; in which he reduced the fifteen modes to seven, and made the diapason, or octave, the regulator of his scales, not by abandoning the tetrachords, for he regulated the genera by those intervals in the same manner as his predecessors; but in his reduction of the modes he kept them within the bounds of the octave, and made their number equal to the species of diapason. The ancient names of Dorian, Hypodorian, Lydian, Hypolydian, Phrygian, Hypophrygian, and Mixolydian, he retained, as well as their relative places or distances from each other; but it has been misrepresented as his intention to alter the pitch of all the modes, by raising the proslambanomenos of each a fifth higher. The only ground for this opinion is in the eleventh chapter of his second book, where having occasion to exemplify, in *some one* octave, the manner in which the *meses* of his seven modes would occupy all its notes, he chose that octave between e and E, as he says himself, preferably to any other part of the Greek scale, on account of its convenience; as it was situated in the middle of the scale and voice. But there is not the least reason to conclude that he meant to propose any *reform*, or to disturb, in *this* respect, the established doctrine and practice.

Dr. Wallis, who has translated into Latin the Harmonics of Ptolemy, and reduced his modes to modern notation, makes them all consist of transpositions of the Dorian mode, which Ptolemy calls the first, and which Dr. Wallis, after him, has written in the minor key of A natural, placing it in the part of the scale which in *practice* belonged to the hypodorian.

Dorian Hypod. Phrygian Hypophrygian
1 5 6 7

By this disposition of Ptolemy's modes, it seems as if his design had been to establish a more easy and obvious relation and connection between them, than had been hitherto practised; for though the modes placed above and below the five principal ones might have been originally intended as their adjuncts, yet from the multiplicity and promiscuous arrangement of the modes at the distance only of a semitone above each other, their intimate relation and union had not been sufficiently attended to. He therefore included all his seven modes in the compass of an octave, "making," says Dr. Wallis, "the Dorian the centre or mean; after which he placed the mixolydian a fourth above the Dorian; the hypolydian a fifth below the mixolydian; and the Lydian a fourth higher than the hypolydian. Then, beginning again at the Dorian, he placed the hypodorian a fourth below it; the Phrygian a fifth above the hypodorian, and the hypophrygian a fourth below that." But this round-about order of the modes is not that of Ptolemy; for in his tenth book, chap. ii. the title of which is, *How to adjust accurately the Distances of the Modes*, he gives his method of taking them by fourths and fifths in the only direct and warrantable way in which they can be taken, according to modern modulation, by beginning at the mixolydian: D, A, E, B, F*, C*, G*. Now if each of these modes produced seven species of diapason or octave, the seven modes of Ptolemy would furnish seven times seven, or forty-nine species of octave; not indeed all of different kinds, but of different pitch in the scale. To each of these modes he assigned the compass of a diadiapason, or double octave, as was the practice in the ancient modes; with this difference, that the first and characteristic sound in the fifteen modes was proslambanomenos, but in those of Ptolemy mese is made the key note, and the centre of the scale; which may be supposed to extend an octave above, and an octave below the sound given in the table.

We know not, indeed, what was the success of Ptolemy's reformation during his life: a reformation, it must be owned, that had something Calvinistical in it; a zeal for tearing; and yet, strange to tell! all the traces to be found of it are in the modes of the Romish church, established long after, but which resemble those of Ptolemy in nothing except their number and names. Ptolemy's modes are manifestly transpositions of the scale into *different* keys: the ecclesiastical, only different species of octave, in *one* and the same key.

This great astronomer, geographer, and musician, whose peculiar use of the species of octave, and reformation of the modes which we have just given, appears to have been less shackled by authority, and a more bold and original thinker on the subject, than most of his predecessors; indeed he was not insensible of his own force and superiority, for he treats all former musical writers and their systems with little ceremony. Some parts of his disputes and doctrines are now become unintelligible, notwithstanding all the pains that our learned countryman Dr. Wallis bestowed on him near 120 years ago, particularly his third book, which forms a very striking contrast with the scientific solidity and precision of the two first. The instant he sets foot within his beloved circle, the magic of it transforms him at once from a philosopher to a dotard. He passes suddenly from accurate reasoning and demonstration, to dreams, analogies, and all the fanciful resemblances of the Pythagorean and Platonic schools: discovers music in the human soul, and the celestial motions: compares the rational, irascible, and concupiscent parts of the soul, to the 8th, 5th, and 4th: makes the sciences, and the virtues, some diatonic, some chromatic, and some enharmonic: turns the zodiac into a lyre, making the equinoctial the key-note of the Dorian

mode: sends the mixolydian to Greenland, and the hypodorian to the Hottentots!

He seems to have been possessed with an unbounded rage for constructing new scales, and correcting those of former times. He gives us no less than eight different forms of the diatonic scale, three of which were his own; the other five went under the names of more ancient musicians of great renown; such as Archytas of Tarentum, Aristoxenus, Eratosthenes, and Didymus. Most of these scales seem but to differ in deformity, according to our present ideas of harmony and temperament. Indeed there is only one of them which modern ears could suffer, and concerning that it is necessary to be somewhat explicit.

Euclid, who first discovered that six major tones in the ratio of $\frac{9}{8}$ were more than sufficient to fill up the octave, gave two major tones and a limma to his tetrachord; which made the major thirds intolerable. Didymus was the first who discovered that whole tones were of two kinds, major and minor; and, giving to his minor tone the ratio of $\frac{16}{15}$, divided his tetrachord into major semitone $\frac{1}{2}$, minor tone $\frac{16}{15}$, and major tone $\frac{9}{8}$, including the whole series in the usual bounds of a true fourth $\frac{4}{3}$. This arrangement has been censured by Padre Martini, and with reason, if a major key and counterpoint had been in question; but, as the abbé Roullier justly observes, a minor key, and simple melody, were alone considered at that time. The minor tone, from C to D, therefore had this convenience, that it rendered D a true 5th below mese, the central string of the lyre, which regulated the whole system, and to which all the other strings were tuned, as well as the octave above proslambanomenos, the fundamental note of every mode. (See Dissert. p. 9.) When the major tone is from C to D, and the minor from D to E, as in Ptolemy's arrangement, this cannot be the case; for then the 5th from D to a, will contain only two minor tones, one major, and a major semitone, instead of two major tones, one minor, and a major semitone, of which every perfect 5th, in the ratio $\frac{3}{2}$, is composed.

Ptolemy, nearly two centuries after Didymus had suggested the major semitone, and minor tone, adopted them in one of his divisions of the diatonic 4th, but changed the place of the minor tone, arranging his intervals, suppose them to be these, B C D E, in the following order and proportions: major semitone $\frac{1}{2}$, major tone $\frac{9}{8}$, minor tone $\frac{16}{15}$, which, together, completed the fourth in the usual, perfect, constant, and true ratio of $\frac{4}{3}$; and these are the famous proportions of the intervals proposed in that system of Ptolemy which is known to theorists by the name of *diatonium intensum*, or sharp diatonic; and which, long after his time, was received in our counterpoint, and is pronounced by Dr. Wallis, Dr. Smith, and the most eminent writers on harmonics, to be *the best division of the musical scale*. The intervals of our C natural, when made perfect, are in the following proportions, ascending: 1, $\frac{9}{8}$, $\frac{7}{6}$, $\frac{5}{4}$, $\frac{4}{3}$, $\frac{3}{2}$, $\frac{2}{1}$; that is, giving to the octave three major tones, two minor tones, and two major semitones, arranged in this order: from the key-note to the 2d of the key, a major tone; from the 2d to the 3d of the key, a minor tone; from the 3d to the 4th, a major semitone; from the 4th to the 5th, a major tone; from the 5th to the 6th, a minor tone; from the 6th to the 7th, a major tone; and from the 7th to the octave, or 8th, a major semitone. And no sharp key can be perfect, but by being tuned in the same manner; and yet, where to place the minor tone has occasioned endless disputes among writers on temperament. De Moivre, in his *Doctrine of Chances*, gives 210 permutations to these intervals T, T, T, t, t, H, H.

This arrangement of Ptolemy has been considered by some

some writers as a temperament, on account of his departing from the just proportion of some of the 5ths, in order to give perfection to 3ds and 6ths. This temperament, however, if it may be so called, is become to us the standard of perfection, and every deviation from it, in the modern sense of the word, is now called temperament. If temperament implies *imperfection*, and the alteration of intervals from those proportions which best satisfy the ear; and if those scales are the *most*, though not the *best* tempered, which most offend the ear, the word is in that sense chiefly applicable to the old Pythagorean diatonic, adopted by Euclid, and to the other numerous divisions above mentioned.

The scale of the Pythagoreans was indeed founded upon some principle; being, as the abbe Rouffier has shewn, produced by a series of perfect 5ths; but the other divisions seem to have been the produce of random experiment, and unmusical calculation, and were as various and unfit for use, as want of principle could make them. Scarce any rule seems to have been observed, but that of keeping the *soni stantes*, the boundaries of the tetrachords, unmoved from their just ratio of $\frac{4}{3}$. The ancient theorists revenged themselves, however, for this confinement by every kind of licence in the disposition of the two remaining sounds: the various tunings of which constituted what they called the *χρῶμα*, the colours or shades of the three genera. In these, all kinds of intervals seem to have been admitted, provided they were but *rational*, that is, *expressible by numbers*.

Aristoxenus did not confine himself even to this rule; for his equal divisions were neither reducible to rational numbers, nor were the vibrations of his intervals, if they could have been put in practice, commensurable. Music, however, was more obliged to him for the invention of a method which it must be allowed left every thing to the guidance of the ear, uncertain as it may be, than to those mathematical speculators who furnished it with so many accurate and demonstrable rules for being infallibly out of tune. Indeed, it is probable, that among the ancients, as well as the moderns, many such untuneable divisions, served more to amuse theorists, than to guide practical musicians.

Ptolemy having a facility, and perhaps a pleasure, in calculating, seems to have sported with the scale, and wantonly to have tried confusions, by dissecting and torturing it in all possible ways; and though one of his many systems suits our present practice, it is not to be imagined that it was designedly calculated for the use of counterpoint, which was far from his thoughts. It seems, however, as if music in parts was first suggested by this arrangement of the intervals; for the 3ds and 6ths, which were before so harsh and crude as to be deservedly ranked among the discords, were now softened and sweetened into that grateful coincidence with which modern ears are so much delighted. It was impossible, after hearing them, for lovers of music not to feel the charms arising from the combination and succession of these consonances; and it was from this time that the seeds of that harmony which may be said, in a less mysterious sense than that of Pythagoras, to be implanted in our nature, began to spring up. They were certainly of slow growth, as no good fruit was produced from them for more than 1000 years after: but arts, like animals to whom great longevity is allowed, have a long infancy and childhood, before adolescence and maturity come on.

PTOLEMY of Lucca, an ecclesiastical historian in the fourteenth century, was descended from a noble family, from whom he derived the name of "Bartholomew Fiadoni." He entered young into the order of St. Dominic, and upon his profession he took the name of Ptolemy. He ranked

among the most celebrated Italian divines of his time, and was the first of his countrymen who employed his pen on ecclesiastical history. He was superior of the monastery at Lucca, and in 1301 and 1302 he filled the same post at Florence. He was afterwards selected by pope John XXII. as his confessor, and in 1318 he was made bishop of Torcello, under the patriarchate of Venice. This prelate died in the year 1327. He was author of "Annales," extending from the year 1060 to 1303, which was published at Lyons in 1619. But his largest work was "Historiæ Ecclesiasticæ," in twenty-four books, commencing with the birth of Jesus Christ, and brought down to the year 1313. This work remained in MS. in the Vatican, Barberini, and other libraries, till it was published at Milan in 1727, by Muratori, in his grand collection, entitled "Rerum Italicarum Scriptores." Moreri.

PTOSIS, from *πτῶσις*, to fall, signifies, in *Surgery*, a disorder of the upper eye-lid, which the patient either cannot elevate at all, or not in a proper degree. In the first case, sight is entirely impeded, unless the eye-lid be raised with the finger; and in the second, although the patient can see a little when he turns his eye downwards, he soon gets into the habit of squinting. The disease also in this state gives him a particularly drowsy appearance. Of ptoſis, surgical authors reckon three species, which originate from three different kinds of causes. The first species proceeds from a preternatural lengthening of the external skin of the eye-lid; the second from weakness, or total paralysis of the levator muscle; and the third from a spasmodic contraction of the orbicularis palpebrarum.

The first is the most frequent case. The preternatural elongation of the skin may be known partly by the appearance of the affected eye-lid, and partly by the circumstance of the patient being able to raise his eye-lid immediately the skin of the part is pinched up into a transverse fold. Sometimes likewise it may be known by adverting to the causes from which the disorder had its origin. Transverse wounds of the lower part of the forehead, or of the eye-lid itself, when their edges are not skilfully brought together, are frequently followed by such an elongation of the skin, the consequent cicatrix being very wide. It often happens, too, that no cause whatsoever can be assigned for this lengthening of the skin. In some instances the complaint is transient and of short duration, as when it depends upon an inflamed or œdematous state of the eye-lids; a case of which we need say nothing more in the present article. Nor need we here dwell upon the example in which the eye-lid is preternaturally distended by an incysted tumour under it, the only indication being that of cutting out the swelling. In the treatment of the first species of ptoſis, the object which the surgeon must have in view is to cut away the superfluous portion of the skin of the eye-lid. A transverse fold of it is to be raised up with the fingers, or a pair of forceps, and removed with scissars. The practitioner must be careful, however, neither to cut away too little nor too much. In the first circumstance, the disease is not effectually cured, but merely lessened; and in the second, an opposite complaint is brought on, namely, a preternatural shortness of the eye-lid. If, while the skin is pinched up into a transverse fold, the patient is capable of raising the eye-lid completely, all is managed rightly, and such fold is to be removed. But if he cannot perfectly raise the eye-lid, a sufficient portion of the skin is not pinched up, and the fold must be larger. Lastly, if he can raise the eye-lid well, but not shut the eye completely, too much of the skin is pinched up, and some of it

must be let loose again. As soon as the requisite quantity of the skin has been cut away, the edges of the wound are to be brought together with adhesive plaster, or a future. The cure is generally accomplished in a few days, and the cicatrix is afterwards scarcely discernible.

Sometimes this species of ptosis may be cured without any operation. In one instance, where the usual operation was about to be performed, and the skin had already been pinched up into a fold, the patient, through fear, suddenly drew back his head, by which means the eye-lid was violently pulled and stretched. This happened three times successively, on which account the operation was deferred. The next day the patient had regained the complete power of moving the eye-lid. (See Janin's Observations sur l'Œil.) The same event has been frequently remarked. Probably, says Richter, the mechanical irritation, and the inflammation thence arising, increased the tone of the levator muscle of the eye-lid, and he takes the opportunity of suggesting that benefit might perhaps be expected (at least in cases in which the eye-lid is not very much lengthened) from cauterizing the eye-lid, or applying to it the tinctura lyttæ, cold water, or a weak solution of the lapis infernalis.

The second species of ptosis, or that proceeding from loss of tone, or paralysis of the muscles of the eye, is more uncommon. It is most frequently met with in old persons, when it is very difficult of cure, if it can be cured at all. Sometimes it precedes apoplexy, or is a remaining effect of that alarming disease. It occasionally proceeds from internal causes, and in this circumstance the treatment comes within the province of the physician, who should endeavour to detect and remove these causes. This second species of ptosis has been known to occur as a symptom of chlorosis. (Müller, Diff. de Palpebrarum affectibus, Halæ 1772.) Sometimes the complaint is caused by irritation in the stomach, in which case a cure may be effected by emetic medicines. In some examples, worms seem to act as a cause; not to mention several other causes of an analogous description. Sometimes the complaint is altogether local, and it is only then that it is to be classed with surgical diseases. Although a patient with this kind of ptosis, can lift up the eye-lid with his finger, he can never do it in any other manner: when the integuments are pinched up into a transverse fold, the levator muscle continues quite incapable of doing its office.

Besides the means already recommended, the following have been resorted to: the shower-bath on the hinder part of the head (Cantwell, in Phil. Trans. N^o 449. p. 33. Guerin, des Maladies des Yeux); the external use of cold water (Warner on the Eye); and, at the same time, the internal exhibition of bark (Alix, Observata Chirurgica, fasc. 2.); a plaster of wax and fetid oil of tartar put on the eye-lid (Chandler on the Eye); a salve of the tinctura mari syriac, honey, and camphor. Lastly, it deserves notice, that this species of ptosis is often periodical.

The third case of ptosis originates from a spasmodic contraction of the orbicularis palpebrarum muscle. It is a most rare form of the complaint, and never lasts. The attack occurs at certain or uncertain periods, and varies in its duration. During the paroxysm one can plainly see that the eye-lids are forcibly closed, and that a great and extraordinary resistance is made whenever an attempt is made to separate them. Such spasm of the eye-lids, says Richter, is always the effect of some idiopathic, or sympathetic irritation. In some instances the affection is confined to the eye-lids; in others it extends to the muscle of

the face, which distorts the countenance in various directions. The sympathetic irritation, which is productive of the spasm, is of different kinds. The complaint often occurs as a symptom of hysteria, hypochondriasis, worms, obstructed menses, &c. and the treatment falls to the duty of the physician. In these examples local means avail little or nothing. The applications recommended, however, are luke-warm milk, in which a small quantity of saffron is mixed; a decoction of white poppy-heads, or of hemlock.

Amongst the local causes which may give rise to this species of ptosis, we have to enumerate such irritating substances as are accidentally introduced under the eye-lid from without. These should be removed, or washed away as soon as possible. Some cases of acute ophthalmia are accompanied with a spasmodic closure of the eye. No cause whatsoever is occasionally assignable for the complaint. In this circumstance, external anodyne applications must be tried, and if they are insufficient, internal medicines of the same class must also be administered. The warm bath, and bathing the eye with warm water, are mentioned as particularly deserving of trial. See Richter's Anfangsgr. der Wundarzneykunst, band ii. kap. 16.

PTYALAGOGA, formed of πτυλλον, *spittle*, and αγω, *I draw*, a word used by physicians to express such medicines as promote a copious discharge of the saliva, such as pellicitory-root, and the like. See SIALAGOGUES.

PTYALISM, PTYALISMUS, Πτυαλισμος, formed from πτυω, *spuo*, *exspuo*, *I spit*, in *Medicine*, a spitting, or a discharge of saliva by the glands of the mouth; whether it amount to an absolute salivation or not. See SALIVATION.

PTYCHIA, in *Ancient Geography*, an island of the Ionian sea, near the isle of Conyra. Some have represented it as a town of this island.

PTYSMA, a word used to express whatever is brought up from the lungs by spitting.

PTYSMAGOGA, medicines which promote a copious discharge by spitting.

PUAGORA, in *Geography*, a town of the island of Sardinia; 15 miles E.N.E. of Sassari.

PUANTE, a river of Canada, which runs into the St. Laurence, N. lat. 46° 24'. W. long. 72° 21'.

PUARAY, a town of New Mexico; 60 miles S. of Santa Fé.

PUBBLE, in *Agriculture*, a term provincially signifying plump or full-bodied, when spoken of grain.

PUBEGA, or PIUBEGA, in *Geography*, a town of Italy, in the department of the Mincio; 14 miles W.N.W. of Mantua.

PUBELA, a town of Bengal; 28 miles S.S.E. of Islamabad.

PUBERTY, in *Physiology*. The Latin word *pubertas* means the growth of the hair about the organs of generation: at the same time that this appears, various important changes occur in the whole economy, which have been included altogether under the term puberty. See GENERATION.

PUBERTY, *Pubertas*, in the *Civil Law*, a natural majority, or the age in which a person is allowed to contract marriage. See MAJORITY.

Boys arrive at puberty at fourteen years of age, maids at twelve. *Full* puberty is accounted at eighteen. See AGE.

Dr. Kramer observes, that all boys at the time of puberty, between twelve and fourteen years of age, complain of uneasiness

uneasiness at their breasts, which are swelled and itchy, the nipples and areolæ round them inflaming with pain, and sometimes excoriation and exulceration of some of the lactiferous ducts. The best remedy for which, he says, is to press out the white serum then contained in them, after which they are cured with a bit of plaster.

By the law of Scotland, persons under puberty, or under the years of discretion, are capable of committing the higher crimes, which being contrary to the law of nature, are obvious. But they are not chargeable with smaller offences arising from positive law or statute.

PUBERTY of *Plants*, the period in which they arrive at their full growth, and are capable of producing blossoms and fruit. It varies very much according to the nature and habits of growth of the particular plants, some arriving early at this state, while others are extremely slow in coming to it.

PUBES, in *Anatomy*, that part of the abdomen adjoining the generative organs, which is more or less covered with hair in both sexes.

PUBESCENCE, **PUBESCENTIA**, in *Botany* and *Vegetable Physiology*, comprehends all the various hairy, downy, or woolly clothing of plants, which Linnæus, under the denomination of *pilus*, a hair, reckons the seventh and last among their *fulera*, or appendages. He defines the *pilus* as an excretory duct, of a tapering or bristle-like form. Such it seems to be in numerous plants, whose hairy coats exude a viscid moisture, like the Garden Clary, *Salvia Sclarea*, and some others of that genus; as well as, possibly, in *Phlomis* and *Verbascum*, some species of which exhale from their dense woolly covering, when slightly touched, a peculiar odour, depending on an exudation, otherwise hardly perceptible; but which can only be conveyed through their pubescence. Such is the soapy odour of *Phlomis fruticosæ*, and the light transient fragrance of various herbs, which vanishes, and is replaced by a different scent, when they are bruised. Odours that reside in glands, or cells, in the surface of the leaf itself, are more durable, if not at first more powerful.—The stinging Nettles, *Urtica*, of which three species are natives of Britain, are unquestionably furnished with a tubular bristly pubescence, each hair of which is pervious, and has at its base a bag of liquid poison, so contrived that when the perforated point of the hair receives a slight touch, the contents of the bag are pressed upwards through the tube, and discharged into any thing, as the human skin, that may be wounded by such minute but formidable weapons. The poison of a viper is conveyed, through its perforated teeth, in the same manner. When that animal is not excited to attack or vengeance, its fangs are recumbent and harmless. So when the pubescence of a nettle is forcibly depressed, by a rude or fearless grasp, these delicate points cannot insinuate themselves so as to take effect.

The hair or pubescence of plants, though generally tubular, is not always pervious, being very frequently found, with the assistance of a slight magnifier, to consist of numerous joints, distinguished by transverse partitions. Fluids cannot readily be supposed to pass along a tubular body beset with such impediments. Yet, if we mistake not, such a jointed structure exists in the pubescence of several glutinous plants.

The external configuration of the pubescence of vegetables is very different in different species and tribes. The hairs are sometimes hooked, as on the calyx of *Myosotis*, and the herbage of some Syngenesious plants. In the genus *Hedypnois* of Fl. Brit. now adopted in Willdenow

and other writers by the name of *Apargia*, the hairs of the leaves and other parts vary in having one, or occasionally more, forked terminations. In *Croton*, *Solanum*, and *Lavatera*, they often assume an elegant starry figure, being in the last mentioned genus, and several of its allies, densely entangled, and occasionally endowed with a stinging or pungent, if not venomous, quality. The pubescence of *Hippophaë*, and some species of *Croton*, is partly starry, but on the whole so depressed as to become scaly, nor does it seem capable of conveying any fluid through its own substance.

The pubescence of some plants is exquisitely delicate, whether it consists of erect or depressed hairs. Of the former kind the *Pelargonium odoratissimum*, *Geranium rotundifolium*, and *Althæa officinalis*, are instances, infinitely transcending the pile of the finest velvet, in softness and minuteness. Of depressed pubescence, no more beautiful example can be found than in the White Willow, the Silver Tree of the Cape, *Protea argentea*, or the Silver-leaved Ladies' Mantle, *Alchemilla alpina*. A more dense, woolly, and impenetrable covering attracts our notice in various oriental plants, natives of the arid and scorching soil of the Archipelago. These seem to require such a protection against a burning sun, by which all their moisture might otherwise be dried up. It is far more difficult to account for the abundance of such a woolly coating, on the under sides of the leaves in so many Mexican plants, whose smooth upper surfaces are exposed to the hot sun of that climate. Possibly, after all, some chemical operations may be performed in the wool itself, where the necessary agents of moisture, air, and exhaled effluvia, are present, as well as the greatest possible quantity of light that the position of the leaves will admit of, the wool being always white, and its substance pellucid.

Whatever other purposes the pubescence of plants may answer, its mechanical use, in abundance of instances, cannot be overlooked. We can be at no loss to understand how the appropriate covering of each particular species, or of the several parts of any one herb, may be effectual in repelling or moderating the attacks, or the accidental injuries, of insects, or the atmosphere. It is one, amongst many, means, by which rain, in quantity, is studiously prevented from lodging on the foliage of plants, for any length of time. Leaves require a more continual intercourse with air, and even with light, than with wet; by which last, if superabundant, their predominant functions are impeded, and their constitution finally injured; except their nature be such that, like fishes, they cannot exist out of the water.

The envenomed armour of the Stinging Nettles seems so powerful a defence against the attacks of caterpillars, that it is difficult to conceive how any of them can trust their delicate skins within its reach. Yet nothing is more certain than that the plants in question afford nourishment to a greater variety of such insects than most others. Possibly the copious prominent bristles, or tufts of hairs, with which many of them are covered, being longer than the pubescence of the nettle, may sufficiently protect them, and enable them to range with impunity over the leaves, on which they feed.

Few appendages to the herbage of plants are more variable than their pubescence, at least with respect to quantity, and even structure. Young shoots and leaves are often very downy or hairy, though subsequently they become quite smooth. The purpose of protection against heat and cold, or too much wet, is well answered by such a clothing in their first tender state, and at an unfavourable or unsettled season. It either drops off, or becomes more scattered, by the expansion of their surface. Circumstances, with which

we are but little acquainted, act in some way or other on the constitution of many plants, so as greatly to influence the quantity of their pubescence. Thus we have seen several mints, hairy or smooth in their native situations, becoming very much if not entirely the reverse, the next season, on being transplanted into a garden. Nor does this change always appear to depend on any sudden transition with regard to moisture. In general, however, it is found, that bog or aquatic herbs, become more hairy on removal into a dry soil or situation; and also that a change from shade and moisture, to an open, airy, or sunny exposure, produces the same effect. The rich dense woolly, cottony, or silky clothing, of many rock or alpine plants, becomes starved, mean, and unsightly, in our gardens, as their whole form and constitution assume an enfeebled laxity or meagreness. Even in a state of nature, as we have remarked above, the hairs of the same species are occasionally simple or variously forked. The hooks or curvatures of such appendages are usually more permanent in every case; but always most decided or vigorous in proportion as the plant is most healthy.

The direction of the hairs or bristles, composing the pubescence of plants, proves, on a careful examination, to be more invariable than any circumstance attending such appendages. This was first remarked by the writer of the present article, in the progress of his investigation of the British *Mentha*. The direction of the pubescence, as well indeed as its absence or presence, on the calyx and flower-stalks of these plants, is found to indicate more certain specific distinctions than any other. By attending to its position, their innumerable and ever fluctuating varieties are reducible to a determinate number of certain and well-defined species. Dr. Roth, an able German botanist, has since applied the same test to the genus of *Myosotis*; in which, on the contrary, several species, readily distinguishable by the pubescence of their calyx, had been huddled together as varieties. (See MENTHA and MYOSOTIS.) In *Galium* the direction of the minute prickles on their leaves, or on the different parts of their leaves, stands us in equal stead, for the determination of some otherwise obscure and difficult species. It would be well if botanists would pursue these observations, and by that means perhaps elucidate the specific characters of other disputed or intricate plants. We have derived some benefit from this principle in *Salix*, but we lament its insufficiency, not its failure, in the more perplexing family of *Saxifraga*. In *Ranunculus* it confirms rather than leads the character. In the class *Tetradynamia* it solves some difficulties, but does not serve us throughout. There is, however, no instance, that has fallen under our observation, of any variation in the direction of the pubescence of any plants, in the same species, that could cause the least perplexity, where it serves at all to distinguish one species from another.

PUBIS Os, in *Anatomy*, the anterior part of the os innominatum. See EXTREMITIES.

PUBIS *Symphysis*, the union of the right and left ossa pubis, by which the pelvis is completed in front. See EXTREMITIES.

PUBLIC ACCOUNTS. Commissioners are to enquire of the accounts of sheriffs, customs, and other the king's officers, after having been passed in the exchequer, and if detected of any fraud they shall pay treble damages, by stat. 6 Hen. IV. cap. 3. And all the lands, tenements, and hereditaments, which any accountant hath, shall for the payment of debts to the crown, be liable and put in execution in like manner as if he had stood bound by writing obligatory, having the effect of a statute staple, &c. stat. 13 Eliz. cap. 4; and there have been several statutes for tak-

ing the public accounts of the kingdom, and examining and determining the debts due to the army and navy; also corruptions in the management of the king's treasure, &c. empowering commissioners for that purpose, who were to give an account of their proceedings to the king and parliament, stat. 2 W. & M. 1 Ann. 2 Geo. I. &c. See PUBLIC ACCOUNTS.

PUBLIC Verdict. See VERDICT.

PUBLICAN, PUBLICANUS, among the Romans, a person who farmed the imposts, taxes, and public revenues.

This function was usually exercised by the Roman knights, who constituted an order of great consideration at Rome, and a kind of middle rank between the senators and the people. Their institution was as early as Romulus. They did not attain the great offices, nor enter the senate, as long as they continued in the order of knights; and thus they were the more capable of employing themselves in collecting the revenues of the Roman people.

The publicans are distinguished by Sigonius into three sorts or degrees: the farmers of the revenues, their partners, and their securities; in which he follows Polybius. These are called the Mancipes, Socii, and Prædes, who were all under the Quæstores Ærarii, that presided over the finances at Rome. But there were properly only two sorts of publicans, the Mancipes and the Socii. The former, called by the Greeks ἀρχιμελωναι, were much superior to the common publicans in dignity, being mostly of the equestrian order; so they were generally in their moral character. Cicero mentions them with great respect and honour: "flos," says he, "equitum Romanorum, ornamentum civitatis, firmamentum reipublicæ, publicanorum ordine continetur." Orat. pro Plancio, apud Opera, vol. v. sect. 9. p. 544. Olivet edit. He likewise calls them "ordinem mihi commendatissimum." Epist. Fam. lib. xiii. epist. 10. Oper. vol. vii. p. 442. epist. 9, and epist. ad Attic. lib. i. ep. 17. vol. viii. p. 80.

But as for the common publicans, the collectors or receivers, as many of the Socii were, they are spoken of with great contempt, by Heathens as well as Jews; and particularly by Theocritus, who said, that among the beasts of the wilderness, bears and lions are the most cruel; among the beasts of the city, the publican and parasite.

The reason of this general hatred was, without doubt, their rapine and extortion: for having a share in the farm of the tribute, at a certain rate, they were apt to oppress the people with illegal exactions, to raise as large a fortune as they could for themselves. Besides, publicans were particularly odious to the Jews, who looked upon them to be the instruments of their subjection to the Roman emperors; to which they generally held it sinful for them to submit. So that paying tribute to the Roman emperor they looked upon to be a virtual acknowledgment of his sovereignty. This was, therefore, a peculiar grievance, and created an aversion to the collectors, as the instruments of illegal oppression, apart from all consideration of their rapacious practices. Moreover, the Jews, who accepted the office of publicans, were on that account hated of their own nation equally with heathens: and according to the rabbies it was a maxim; a religious

religious man, who becomes a publican, is to be driven out of the society of religion.

Nevertheless, some of the publicans in Judea were honest persons, and respected on account of both their character and substance. Such a one was Levi or Matthew. (See Luke, v. 29. Matt. ix. 10. Mark, ii. 14.) No hint occurs of any unjust practices which Levi had been guilty of, in the post which he had occupied; and from the great openness and impartiality with which the evangelists have written their history, it is reasonable to conclude, there was no exception against Matthew's character, besides his employment, which undoubtedly was not reputable. Publicans, who were Jews, are so often mentioned in the gospels, that Dr. Lardner seems almost inclined to think that the Roman tribute was collected for the most part by Jews. The Romans might make choice of this method. The Jews that were thus employed became odious, but the Roman government was relieved. In most provinces our author conceives that natives were employed in the towns as under-collectors, and that the receivers-general, or other superior officers, were only Romans. The publicans were far from being beloved in any province; the Romans might, therefore, judge it prudent to employ some natives in collecting taxes; and it is probable, that in all places some would be found, who were willing to make an advantage of the subjection of their country, and accept places under the Romans their masters.

PUBLICANS was also a name given to the Arnoldists and Albigenfes.

PUBLICANDIS, *Regula de*. See RULE.

PUBLICATION, PUBLICATIO, the act of promulgating, or making a thing known to the world.

By the canons, publication is to be made of the banns of marriage three times before the ceremony can be solemnized; without especial licence to the contrary. See MARRIAGE.

PUBLICATION, in *Law*, is used of depositions of witnesses in a cause in chancery, in order to the hearing; and rules may be given to pass publication, which is a power to shew the depositions openly, and to give out copies of them, &c. The cause is then ripe to be set down for hearing, which may be done at the procurement of the plaintiff, or defendant, before either the chancellor or the master of the rolls, according to the discretion of the clerk in court, regulated by the nature and importance of the suit, and the arrear of causes depending before each of them respectively.

There is also a publication of a will, which is a solemnity requisite to the making thereof, by declaring it to be the last will of the testator, in the presence of a number of witnesses; and a will, which hath been made many years, may be new published, with additions, and that makes it equivalent to a new will. 3 Nels. Abr. 27.

PUBLICATION of *Libels*. See LIBEL.

PUBLIUS, SYRUS, in *Biography*, a celebrated composer of the dramatic pieces called *Mimes*, was a native of Syria, and was brought, while young, in the condition of a slave, to the Roman capital. He had the happiness to fall into good hands, and his master afforded him an excellent education, and then liberated him. He became distinguished in the time of Julius Cæsar; and after the death of Laberius, succeeded him with still greater applause on the mimetic theatre. His writings, of which fragments only remain, were held in high estimation by Julius Cæsar, Cassius Severus, and Seneca. These fragments have been published, with those of Laberius, and other writers, illustrated by the notes of various critics. The best edition is said to be that of Havercamp and Preyger, 1708.

PUBNA, in *Geography*, a town of Bengal, in the circar of Bettooriah; 28 miles S.S.E. of Nattore. N. lat. 24° 2'. E. long. 89° 23'.

PUC, a lake of Mexico, in the south part of the province of Yucatan; 30 miles in length, and 10 in its greatest breadth; communicating by a river with the bay of Honduras.

PUCARA, a town of Peru, in the diocese of La Plata; 65 miles W. of Caravaya.

PUCCA, in *Commerce*. See MAUND.

PUCASERAI, in *Geography*, a town of Bengal; 25 miles E.S.E. of Biffumpour.

PUCCOON, in *Botany*. See SANGUINARIA.

PUCULOE, in *Geography*, a town of Bengal, capital of the circar of Attyah; 94 miles E. of Moorshedabad. N. lat. 24° 10'. E. long. 90° 7'.

PUCELAGE, in *Natural History*, a name by which some authors among the French have called the porcelain-shells.

PUCELLAGE, PUCELLAGIUM, in an ancient manuscript written *puellagium*, denotes the state of virginity, or maidenhead.

PUCERON, the name given by naturalists to a small insect of a peculiar nature, frequently found on the young branches of trees and plants, often in such clusters as wholly to cover them.

The puceron is a small animal, but very numerous in the several genera and species; inasmuch that Reaumur has observed that there is scarcely a vegetable to be found, either in the fields or gardens, that has not its peculiar species of puceron to feed on its juices. M. de la Hire, of the Paris Academy, has left many curious particulars in regard to these animals, in the Memoirs of the year 1703; and M. Leeuwenhoeck, and others since, have given figures and descriptions of several of the species.

Pucerons are all viviparous animals, and that after a very singular manner. It is to be observed, that the name is scarcely more expressive of the creature, than some of the others given of late to insects; that of the polype to a creature which has no legs or feet at all, is very improper; as that of the puceron hardly less so, as it would naturally lead us to imagine, that the creature thus called was able to hop like a flea, whereas, in reality, it is very slow in its motion, and seldom so much as walks.

These creatures have six legs, which are extremely small and slender; and which, when the animal is at its full growth, are loaded with a weight so large, that they seem scarcely able to support it. Some of the species arrive at a tolerable bigness from common observation; but the greater number are too small to be accurately seen without the assistance of glasses. Among these insects there are great numbers that in their full perfection have wings, and become a sort of little flies: these are distinguished from the others by the name of *alated* pucerons.

Those species which never become winged, have nothing of the appearance of the caterpillar kind; having not long but short bodies, and much resembling flies whose wings had been taken off. All the species have antennæ or horns; but these in the several kinds are very different from one another, some being very short, and others as remarkably long; and of these last kinds, some carry them straight before the head, as is the usual custom, and others carry them laid along over their backs; in some of these the horns are longer than the body. But beside these antennæ, the greater number of these creatures have two other horns or spines placed in a very singular manner behind them near the tail. They are placed at some distance at their origin, but they

PUCERON.

they become more distant as they go out from the body. These are much thicker and much shorter than the antennæ; and there are among the various kinds of them, some which actually want them, and others which appear to want them, though they have them in reality; and others have in the places of them certain round spots, which stand just where they should, and seem destined to perform their functions.

The several kinds of pucerons differ greatly in colour. The greater number of them are green; but many are brown, some yellow, and some are black. In August the rose-trees afford a vast number of them of a pale red, and some exactly of the colour of the damask rose; in some other months of the year we find green ones on the rose-trees. The sycamore and several other plants afford green ones in the summer, and red ones in November; and there seems no doubt, but that these are the same individual animals which change colour, the leaves and juices of the plants being not capable of affording them the same sort of nourishment at some times that they do at others. Some of them also are of a dusky colour, and others bright and shining, as if varnished over. Those of the willow, of the poppy, and some other plants, are of a cloth-like appearance, and some resemble velvet; others, as those of the apricot, and of the catch-fly, are shining, as if covered with the finest lacquer. Some appear of the colour of bronze metal, when it has its highest polish; such are those of the tanfy, and some other plants. The largest kind are found on the oak and other trees. The gooseberry-bush affords a species that are of the colour of mother-of-pearl; and, in general, the skin or covering of those species which are thus bright and shining, is much harder and firmer than that of the others. The more usual species are all over of one colour, but there are some others which are spotted; that of the common wormwood is prettily speckled with black and brown; those of the sorrel are green in the middle, and black at each extremity; and there are several others, as of the willow, &c. that are variegated with these two colours.

It is not certain, however, that all the species are peculiar to the plants upon which they are found; for it has been observed, that when a plant of the common wormwood has been full of them, by some accident they all have left it to fix themselves upon plants in the neighbourhood, which had juices of a less disagreeable taste. These creatures always live in companies; we never find them singly on plants; and very seldom otherwise than in extremely great numbers. In plants they fasten themselves on every part; but in trees they only seize upon the leaves and young shoots, and they usually cover these entirely, leaving no part to be seen.

The elder is the tree on which they are of all others the most plentifully produced, and on which they are observed in their several stages with the greatest accuracy and ease. They often cover the thick green roots of this tree for many inches together, and sometimes for many feet; and they are always placed so close together, that they touch in every part, and sometimes they lie in two beds, one over another. These are of a greenish-black. If they are observed on the branches undisturbed, they are always found to be perfectly quiet, and seem to pass their whole lives in inaction; but they are all this time doing the most necessary business of life, that is, sucking in their own nourishment from the juices of the tree. They do this by means of a fine slender trunk, which easily escapes the naked eye; but it is always found by the microscope, and it is by means of this that they pierce the bark of the tender parts of the vegetables, and get at their juices. The trunk is usually of two-thirds

of the length of the body; but when they are moving on, it is always applied so closely under the belly, that it is not seen.

When there are two series of these insects placed one over another, they are always more loosely placed in the upper series, and these are usually the larger, and the nimbler in all their motions. In this case they have no power of sucking the plant; for beside that it is close covered with the other series, their trunks are not long enough to reach and penetrate it from the height at which they stand above it. These, therefore, are such as have no farther need of nourishment, but are employed in propagating their species.

M. Reaumur saw them brought forth; and indeed Mr. Leeuwenhoek long before saw, by the help of microscopes, the young animals perfectly formed, though extremely minute, in the bodies of the full-grown females.

They are a sort of animal which propagates so quickly, that usually there are many females on the same leaf or branch of a plant in labour at the same time; and their fecundity is so great, that when they have once begun to bring forth young ones, they seem to continue it incessantly for a long time together. They will often bring forth fifteen or twenty successively, and if their bodies be a little squeezed afterwards, there are forced out of them a vast number of others less mature.

These little insects are extremely plentiful on many different trees, and are very easily observed in their several stages and progressions by a curious searcher after them; but if at any time they are not so easily found, the person who seeks after them may be conducted to them by the ants, which he will find moving in great numbers on the trees and plants where they are, and pointing out the way to them.

M. Leeuwenhoek, Hartsoeker, and others, have observed this, and have supposed that the ants fed on them, by their frequenting the places where they are found; but that is far from being the case, the ants, on the contrary, seem to love them as friends. We may easily find out the reason of the ants following the clusters of pucerons, without doing them any injury, when we consider that the ants love sugar and all sweet things, and the places about which the pucerons are, have usually the cavities filled with a thick saccharine matter, and this the ants feed upon.

The most natural opinion would seem, that this was the juice of the tree simply extravasated; but experience shews that it has another origin: it is really the excrement of these pucerons; they receive no solid food into their bodies, all that is conveyed into them coming through their trunk, which is an extremely fine pipe; and as none but a very thin and pure juice can be received through such an organ, it is no wonder that the creature, which lives wholly upon it, should void no solid excrements. The drops of this liquor are not so frequently found on the leaves of plants as might be expected, and that because many of them are immediately devoured by the ants, and many others are dried up by the sun; but they may always be found collected in some quantity in the bladders of the elm, and other trees inhabited by these creatures, as there the liquor is defended from the heat of the sun, and is safe from being devoured.

The puceron, like most other insects, changes its skin three or four times before it arrives at its full growth. These exuviae perfectly resemble the animal in its natural state, the legs and other parts being all in their proper places; but whatever is the colour of the species of puceron, these skins which it casts are whitish.

The male and female pucerons, as they are usually supposed

posed to be, differ greatly from one another in form, even in their time of growing, but much more eminently at the time of their maturity, the male having then wings, which the females never have. Læwenhoek and others, who have treated of these animals, have supposed that they all became at length little flies, that is, were winged; but this is a great error.

Notwithstanding, however, the general opinion, that the winged pucerons are all males, and the unwinged ones females, it appears that their manner of generation is yet unknown to us. This opinion was formed too hastily by some from a supposed analogy of these and other insects; but later observations prove that this is not strictly the case: for that the winged ones, as well as the others, bring forth young ones. Some have supposed, that these winged and naked pucerons were the offspring of different families of several species living together; but the contrary is proved by this, that the winged ones are found to produce some winged and some naked ones; and the naked to produce both kinds in the same manner. Some have imagined, that they found the male pucerons among the others, observing some of a flatter shape, in whose bodies there were never found any young ones, as there always were in the others, even when they were very young; but these have been since found to be only such females as had already brought forth their offspring.

The young pucerons being themselves filled with embryos, and that in every individual, so that all that have been ever examined appear mothers, has given many strange ideas of the manner of their generation: many have imagined them all to be hermaphrodites: and as no copulation has ever been observed among them, they are by some supposed to be able to impregnate each itself. The later opinion, however, is, that when a female is once impregnated by a male, she will bring forth young ones already impregnated with others, and thus to the third or fourth succession; so that copulation is only necessary to these animals once in three or four generations, and the children and children's children of an old puceron that has had congress with a male, will bring forth young ones without having ever had any such congress. Reaumur's Hist. Inf. vol. vi. p. 9, &c. See *WOOD-Puceron*, *OAK-Puceron*, &c.

PUCERON, Bladder, a sort of puceron that lives in bladders on the leaves of trees. See *PUCERON*, *supra*.

We often observe on the leaves of different trees, a sort of roundish bladders, which only adhere to the leaf by a short pedicle: these are a sort of small galls, and their figure varies much in the different kinds; some are less round than others, and many are very rough on the surface, and sometimes they are long, terminating in a point, and being broader at the base than in any other part, and sustained by no pedicle, but fixed immediately to the leaves.

The elm and ash affords us more frequent instances of these than any other trees, and very often on the first of these they grow to the bigness of a nut, and sometimes much larger; and when they are grown to their full size, they often take up the whole surface of the leaf. When these bladders are opened, they are found to contain a large number of pucerons.

If these bladders are examined at the time when they are but newly risen, which usually is the beginning of June, on opening them there is usually found in them only one puceron, and that always a female big with young; and in others more advanced, the parent insect is found surrounded with different numbers of her young ones. These bladders have all of them at first only one female puceron; but after-

wards they have more, as they become larger; and the largest of all are usually found filled with a prodigious number of young ones. The newly risen bladders are always found close and firm in every part; the aperture, at which the female puceron had entered, being usually neatly and closely stopped up. The question is, how this bladder was formed?

The method of the formation of them seems to be this: as soon as the female puceron is produced, she fixes her trunk into the leaf to suck its juices; the consequence of this in all the pucerons is, that the surface of the leaf separates a little from the nervous part. In the common cases, the creature takes no advantage of this, but only continues sucking the juices; but in this kind, the female, as soon as she has made the separation between the parts of the leaf, gets into the cavity that is formed there, by enlarging the orifice first made by the trunk, till it will admit her body. When once in, she works forward in a straight line, and the hole behind her soon closes up, as there was no rupture, but only a stretching open of the parts of the leaf. The female thus finds herself in a secure place, and the elevation she makes in the leaf is scarcely perceivable, only appearing as an oblong small species of gall. The mark of the aperture, at which she made her way in, is always to be seen at some distance behind her, though usually very neatly closed up: thus the whole continues till the creature produces her young. But then the scene is quite altered; the young ones begin to suck as soon as produced, and as they usually seize upon the sides of the small gall, already formed for that purpose, this derives more juices than otherwise would flow into it; and it begins to elevate itself much higher, and forms a tubercle of the shape of a nut or pear.

Its growth, in this case, is entirely analogous to that of the common galls on the branches of trees, &c. and all the difference in the shape of the several bladders is owing to the manner of the young puceron sucking; for if they suck much at its base, that enlarges and becomes the broadest part, as is the case in the conic and pointed ones; but if they let this alone, and suck only the sides and upper part, they swell while this does not, and consequently this forms a sort of pedicle to the growing bladder.

PUCERON, Bassard. See *FIG-Infest*, and *GRUB of the Box*.

PUCERON, Earth. See *EARTH*.

PUCERON, Grub. See *GRUB*.

PUCERON-Eater, or *Lion-Puceron*. See *LION-Puceron*.

PUCERON, Oak. See *OAK*.

PUCERON, Ver. See *VER Puceron*.

PUCERON, Wood. See *WOOD*.

PUCHATUI, in *Geography*, a town of Russia, near the sea which separates the continent of Asia from America. N. lat. 65° 50'. E. long. 188° 34'.

PUCHELBACH, a town of Tyrol; 8 miles S.E. of Reuten.

PUCHENSTAIN, a town of the duchy of Stiria; 6 miles N. of Windisch Gratz.

PUCHINGONG, a town of Bengal; 48 miles S.E. of Dacca.

PUCHLACHTA, a town of Russia, in the government of Archangel, near the White sea; 56 miles N.N.W. of Oneg.

PUCKARPOUR, a town of Hindoostan, in Oude; 8 miles S. of Bahraitch.

PUCKARYA, a town of Bengal; 23 miles N. of Goragot.

PUCKASTER COVE, a creek or bay in the English Channel,

Channel, on the south coast of the Isle of Wignt, a little east of Rocken End.

PUCKAUN BEADY, in *Natural History*, a name given by the people of the East Indies to a peculiar species of opiment, which they use in medicine.

They find it on the hills and on the banks of rivers. It is prepared by several tedious processes, and then is given with success in a diabetes.

PUCKBALL, a common name of a species of mushroom, full of dust.

PUCKER, in *Geography*, a river of Hindoostan, one of the arms of the Indus, which runs into the sea.

PUCKHOLI, a town of Asia, and capital of a district, in the country of Lahore, situated at a considerable distance on the east of the Indus; and therefore it cannot occupy the site of the "Peucelaotis" of Alexander, since that lay on the west bank of the Indus: but as Alexander advanced to this place, from the neighbouring district of Bazira, and the country of the Affacani, (*i. e.* Bijore and Ashenagur, which was the name of Sewad only a few centuries ago,) major Rennell very much suspects that Peucelaotis was the ancient name of Puckholi, and that an alteration of boundary, which has frequently taken place in other provinces, may have confined its limits to the east side of the Indus, in the present times; although it might anciently have extended further to the west. The district called Puckholi, Sewad (or Sowhad), and Bijore, were the scene of Alexander's warfare on the west of the Indus; all of which were subjected to regular authority, during the long and vigorous reign of Acbar. Rennell supposes Puckholi to have been the "Pactya" of Herodotus, (as well as the "Peucelaotis" of Arrian,) from whence Scylax set out to explore the course of the Indus, under the orders of Darius Hystaspes; for it lies towards the upper part of the navigable course of that river, being the frontier province of Hindoostan, east of the Indus. The Ayin Acbaree gives its dimensions at 35 cosses by 25; and says, that it is bounded on the south by the districts of Attock. Its eastern limit is the river Kishengonga; and the Indus takes its general course between the provinces of Puckholi and Sewad. Few particulars are known concerning it, except that the northern, and by far the greater part of it, is mountainous. Puckholi, its capital, is 85 miles S.W. of Cashmere. N. lat. $33^{\circ} 45'$. E. long $72^{\circ} 5'$.

PUCKLE-NEEDLE, in *Agriculture*, the common name of a troublesome weed in hard tilled lands, among the wheat, injuring the sample in a high degree. It is with difficulty separated from the grain. It is often known by the names of shepherd's needle and beggar's needle. See WEED.

PUCKO, in *Geography*. See PAUSK.

PUDAGERI. See PONDICHERRY.

PUDAGUL, a town of South America, in Chili; 16 miles W. of St. Yago de la Nouvelle Estremadura.

PUDAMPOUR, a town of Bengal; 37 miles W.N.W. of Rangur.

PUDASJARVI, a town of Sweden, in the government of Ulea; 44 miles N.E. of Ulea.

PUDDAMBALLY, a town of Hindoostan, in the province of Cattaek; 35 miles W.S.W. of Cattaek.

PUDDAMPOUR, a town of Hindoostan, in the province of Cattaek; 8 miles E. of Cattaek.

PUDDAMTOLA, a town of Hindoostan, in Orissa; 35 miles S.E. of Boad.

PUDDANGARDE, a town of Hindoostan, on the coast of Malabar; 10 miles N. of Paniany.

PUDDAR, or PADDAR, a river of Hindoostan, which rises in the country of Agimere, and discharges itself

through several openings into the gulf of Cutch, 30 miles S.W. of Janagur. Some have supposed that the word "Puddar" may be merely an appellative, and that the proper name of the river is Butlefs. This river periodically overflows a tract of low fenny land, on the west of Amedabad.

PUDDENING, in a *Ship*, a thick wreath or circle of cordage, tapering from the middle towards the end, and fastened about the main-mast and fore-mast of a ship, to prevent their yards from falling down, when the ropes by which they are usually suspended are shot away in battle. The puddening is generally formed in the following manner: a small piece of rope, whose length is twice the diameter of the mast, is spliced together at the two ends; and being thus doubled and extended, a thimble is seized into each of the extremities. After this a large quantity of parcelling is firmly wound about its surface, in such a manner as to make it gradually larger from the two ends towards the middle. It is afterwards once or twice sewed with spun-yarn throughout the whole length, to bind the parcelling more closely, and render it more compact; and the whole is completed by pointing it on the surface. Being then fitted with the laniard at one of the eyes, it is fixed about the mast by passing the laniard alternately through both eyes or thimbles on the fore side of the mast. Falconer. See DOLPHIN.

Puddenings are also ropes nailed to the arms of the main and fore-yards near the ends, and then three or four at due distances inwards one from another, in order to keep the robbins from galling or wearing asunder upon the yards, when the top-sail sheets are haled home.

They call also those ropes which are wound about the rings of anchors, to save the clinch of the table from being galled with the iron, by this name; so that when the ring is so served, it is called the *puddening of the anchor*.

PUDDING-FISH, in *Ichthyology*. See SPARUS *Radiatus*.

PUDDING-Grass, in *Botany*. See MENTHA *Pulegium*.

PUDDING-Pipe-Tree, the English name of a genus of plants, called by botanical writers *caffia*.

PUDDING-Stone, in *Mineralogy*, a term applied by English lapidaries to an aggregate of oblong and rounded pebbles of flint, about the size of almonds, and usually black, imbedded in a hard siliceous cement, of a light yellowish-brown. This mineral substance is capable of receiving a very high degree of polish, and was formerly much used in inlaying, and other ornamental works. It is chiefly procured from the county of Essex. See OCULATUS *Lapis*.

PUDDLE, a small hollow full of water, especially of that which is of the more dirty kind, as in roads or fields.

PUDDLE also denotes loamy earth mixed up with water, to the consistence of thin mortar, for securing the bottom and sides of a canal or reservoir from leaking.

PUDDLE-Gutter, or *Puddle-Ditch*, is a ditch filled up with puddle, so as to form a wall of that substance within any bank that is to retain a head of water; as *aefb*, *Plate I. Canals*, *fig. 14*.

PUDDLING-BOOTS are strong leathern boots, provided for the men who perform the operation of puddling.

PUDDOCK, in *Agriculture*, a term used to signify a small inclosure. See PADDOCK.

PUDDY, in *Commerce*, a measure of capacity at Madras. The puddy by which oil, milk, and some other liquids are sold, is the same as that used for grain; and therefore 77 such puddies are = 125 quarts.

PUDENDA, in *Anatomy*, the external organs of genera-

tion in both sexes. The singular word pudendum is often applied to the female.

PUDENDAL ARTERY, a branch of the internal iliac distributed principally to the organs of generation. See **ARTERY**.

PUDENDUM denotes a thing to be ashamed of. Hence, *pudendum virile*, and *pudendum muliebra*. See **GENITAL**.

It is remarkable, that among the fish-tribe, all that are oviparous have no pudenda, properly speaking; that is, they have no penis or vulva, unless the ovaria of the females, and the vesiculæ feminales of the males, may be called by that name.

The viviparous fish, on the other hand, as the cetaceous fish in particular, and many kinds of the cartilaginous, have the penis and vulva, distinctly and properly so called. *Arctedi Ichthyolog.*

PUDENDUM Regale. See **APHRODITA**.

PUDGDARGONG, in *Geography*, a town of Hindoostan, in Goondwana; 38 miles N. of Nangpour.

PUDGLA, a town of Anterior Pomerania, and island of Ufedom, the principal place of a bailiwick; 6 miles N.E. of Ufedom.

PUDIANO, in *Ichthyology*, called also *pediano*, and by others *vermelho*, *apaimixira*, and *tetimixira*, a fish of the size of a middling perch, but not so broad as that fish. Its whole body is of a gold yellow; but that the upper part of its head, and its back, to the end of the back-fin, are of a very beautiful purple; the rim or edge of the belly-fin is also purple, and the rest of a gold yellow. It is a wholesome and well-tasted fish.

PUDIANO Verde, the name of an American fish of a very remarkable colour, and very well-tasted and wholesome.

It is of an oblong shape, and its usual size is about ten fingers long, and three broad in the broadest part; for towards the tail it is but about half that breadth.

PUDICA INTERNA, in *Anatomy*, the same as the pudendal artery. The pudicæ externæ arteries come from the femoral.

PUDICA Planta, in *Botany*. See **MIMOSA**.

PUDICOTTA, in *Geography*, a town of Hindoostan, in Coimbatore; 12 miles N.W. of Caroor.—Also, a town of Hindoostan, in Marawar; 10 miles N.N.E. of Trumian.

PUDIMO, a small island on the east side of the gulf of Bothnia. N. lat. $63^{\circ} 18'$. E. long. $21^{\circ} 42'$.

PUDMAH, a town of Bengal; 20 miles N.N.E. of Palamow.

PUDMOUL, a town of Hindoostan, in Bahar; 18 miles N.N.E. of Hajipour.

PUDOGA, a town of Russia, in the government of Olonetz, on the east coast of the lake Onezskoe; 108 miles E. of Olonetz. N. lat. $61^{\circ} 36'$. E. long. $36^{\circ} 30'$.

PUDOL, a town of Russia, in the province of Usting; 124 miles N. of Usting.

PUDSER, a town of Bengal; 13 miles N. of Natore.

PUDSEY, a large township and chapelry, in the parish of Calverley, and wapentake of Morley, west riding of Yorkshire, is situated at the distance of 4 miles E. from the town of Bradford, and 197 N. from London. This township consists of Middle, Nether, and Over Pudsey, which together contain, according to the population returns of 1811, 997 houses and 4697 inhabitants. It is indebted for its origin to a society of Moravians, chiefly emigrants from Germany, who settled here in 1748; and for its progressive improvement to the increase of its manufactures. The Mo-

ravians have here a chapel, refectory, dormitory, school, and chair-houses, upon the plans generally adopted by that very peculiar, but sober and industrious, sect of Christians.

PUEBLO, a town of Spain, in Galicia, near the Atlantic; 25 miles S.S.W. of Santiago. N. lat. $42^{\circ} 32'$. W. long. $8^{\circ} 51'$.—Also, a town of Spain, in the province of Grenada; 5 miles N.N.E. of Huesca.—Also, a town of Spain, in Aragon; 16 miles S. of Saragossa.

PUEBLO d'Alcocer, a town of Spain, in Estremadura; 39 miles E. of Merida.

PUEBLO de los Angelos, a town of Mexico, and capital of the province of Tlascala. The buildings, generally of stone, are lofty and elegant; the streets are broad, clean, and regular, intersecting one another at right angles: in the centre of the city is a large square, said to be equal, if not superior, to that of Mexico. On three sides it is adorned with uniform porticoes, occupied by shops full of all kinds of rich commodities; and on the other side is the grand cathedral, with a beautiful front and two lofty towers, all of stone, in the modern taste. It is now the see of a bishop, translated hither from Tlascala. It has several churches, besides the cathedral, and also convents, well built and richly adorned: the best felts in the country are made in this city, besides which it has also a mint and a glass-house. The number of houses is estimated at sixteen or seventeen hundred. A small river runs through the town, and the adjacent valley produces vines, and all sorts of European fruits. In its vicinity are several sorts of mineral waters; 7 miles E.S.E. of Mexico. N. lat. $29^{\circ} 35'$. W. long. $99^{\circ} 40'$.

PUEBLO Cordova, a town of South America, in the province of St. Martha, on the coast of the Spanish Main; 20 miles S. of St. Martha.

PUEBLO de los Infantes, La, a town of Spain, in the province of Seville; 13 miles N. of Carmona.

PUEBLO Moro, a town of South America, in the province of Chocos; 20 miles E.S.E. of Zittara.

PUEBLO Nuevo, a town of Mexico, in the province of Veragua, near the Pacific ocean.—Also, a bay on the coast of Catalonia. N. lat. $42^{\circ} 24'$. E. long. $3^{\circ} 6'$.—Also, a town of South America, in the province of St. Martha; 62 miles S. of St. Martha.—Also, a town of South America, in the province of Caraccas; 10 miles N.N.W. of Varinas.—Also, a town of South America, in the government of Caraccas; 20 miles N.E. of Segovia Nueva.

PUEBLO de Sanabria, a town of Spain, in the province of Leon; 37 miles S.W. of Astorga.

PUEBLO Viejo, a town of Mexico, in the province of Nicaragua; 40 miles N.W. of Leon.

PUECHBERG, a town of Austria; 8 miles S. of Kirchschlag.

PUEGOS, or **SQUIOR**, one of the Philippine islands, small, but well-peopled with brave and warlike inhabitants; 50 miles N. from the W. part of Mindanao.

PUELCHES, inhabitants of the mountains of Chili, in South America, now united with the state of Araucana, who are more rude and savage than the others. Their name signifies Eastern men. They are of a tall stature, and fond of the chase, so that they often change their habitations, and even detach colonies to the eastern sides of the Andes, as far as the lake Naguelgapi, and the shores of the Atlantic, in the wide plains of Patagonia. The Araucans highly esteem these mountaineers for their bold services in war, and their lasting fidelity to the confederacy.

PUENTE de Arcobispo, a town of Spain, in New Castile, on the Tagus; 50 miles W.S.W. of Toledo.

PUENTE del Congostor, a town of Spain, in Old Castile; 37 miles W.N.W. of Avila.

PUENTE *d' Eume*, a town of Spain, in Galicia ; 8 miles N. of Betanzos.

PUENTE *de Gonzalo*, a town of Spain, in the province of Cordova ; 13 miles W. of Lucena.

PUENTE *de la Reyna*, a town of Spain, in Navarre ; two miles S.S.W. of Pamplona.

PUERCO, an island in the bay of Panama, behind which vessels may anchor with safety.

PUERCO. See GREEN KEY.

PUERIALIMENTARIUM. See ALIMENTARIUM.

PUERILE STYLE. See STYLE.

PUERILITY, in *Discourse*, is by Longinus defined to be a thought, which, by being too far fetched, becomes flat and insipid. Puerility, he adds, is the common fault of those who affect to say nothing but what is brilliant and extraordinary.

PUERITIA, or CHILDHOOD, in the *Civil Law*, denotes the age of minors from seven to fourteen, which was divided into two equal parts ; from seven to ten and a half, which was *etas infantie proxima* ; and from ten and a half to fourteen, which was *etas pubertati proxima* ; during which stage they were punishable, if found to be *doli capaces*, or capable of mischief ; but with many mitigations, and not with the utmost rigour of the law. See AGE.

PUERO, in *Geography*, a town of the province of Darien ; 32 miles E.N.E. of St. Maria de Darien.

PUERORUM EPISCOPUS. See EPISCOPUS and BOY-BISHOP.

PUERPERAL CONVULSIONS, in *Medicine*, convulsions occurring during, or immediately previous to the act of parturition.

Under the article CONVULSIONS we mentioned briefly, that, in the puerperal state, women are liable to a severe and dangerous modification of these affections, which requires a prompt and decided practice. The importance and peculiarity of the convulsive paroxysms, under these circumstances, as well as the prevalence of some difference of opinion among respectable authors on the subject, render a more particular notice of them necessary. Without repeating, therefore, any of the general doctrines before detailed, we shall briefly state the circumstances peculiar to convulsions occurring in the puerperal state.

The great general sympathy of the whole habit, with the uterine system in females, is a subject of common observation ; and the mobility of the nervous system is considerably increased in connection with the changes that take place in the uterus during the progress of pregnancy ; whence the constitution is unusually liable to suffer, during this period, from any inordinate causes of irritation. This increased irritability of the habit, then, may be considered as the principal *predisposing* cause of puerperal convulsions : but the predisposition is farther increased by the existence of a sanguine temperament, and an habitual tendency to nervous and hysterical complaints, as well as by a plethoric condition. In constitutions of this nature, therefore, the occurrence of convulsions should be more actively anticipated, when the following premonitory symptoms are observed.

If, at the beginning or during the progress of labour, the patient complains of giddiness, dimness of sight, of a ringing noise in the ears, and violent piercing head-ache, and more especially if she sighs deeply, and exhibits signs of incoherence of ideas, or slight delirium, the probability of approaching convulsions may be foreboded. This foreboding will be strengthened, if there is at the same time a fullness of the neck, with an enlargement of the features of the face, and a staring or protrusion of the eyes, implying a considerable determination of the fluids to the head. Sometimes also

acute pains at the stomach, and vomiting, are among the precursors of the fits, and sometimes there are rigors or shiverings at the return of the pain. These symptoms usually continue for some hours, and occasionally days, before the accession of the convulsive paroxysms : but at length some slight twitches are observed about the mouth and eye-lids, which terminate in the complete and universal convulsion of the body.

The paroxysm of puerperal convulsions is commonly considered as in all respects analogous to that of epilepsy, occurring in other circumstances. (See EPILEPSY.) And in a great measure this view is correct : both Dr. Denman and Dr. Bland, however, have pointed out a strong analogy to apoplexy, which usually characterises the puerperal disease, and which, therefore, demonstrates the peculiar practice which it requires. This is marked by the presence of *stertor*, or snoring, and a comatose condition, in the intervals, usually deemed peculiar to apoplexy ; and together with the frothing of the mouth, which is common to this convulsion and epilepsy, Dr. Denman remarks, " there is also a sharp hissing noise, produced by fixing the teeth, and by the sudden motion of the under lip, as if attempts were made to retract the saliva back into the mouth ; and by this noise," he adds, " I have generally been able to discover the state of the patient, though she was in another room." (Introduction to Midwifery, vol. ii. p. 202. See also Bland's Observations on human and comparative Parturition, p. 138.) Sometimes, however, the comatose state does not continue through the intervals between the paroxysms, but the patient recovers more or less completely the use of her senses.

The fits continue to recur at longer or shorter intervals, if remedies are not employed, according to the state of the system in general, and to the action of the uterus in particular, with which they are much connected : and they will thus return repeatedly, in some cases, until the delivery is accomplished, in which they assist like ordinary pains ; and then they generally cease spontaneously, for they rarely occur after delivery. In some cases, the proper remedies have had the effect of preventing a second paroxysm : but in others, the first fit has terminated the life of the patient, or, after repeated paroxysms and recoveries, death has at length occurred in the fit. The prognosis, indeed, is at the best extremely uncertain : for such is the dangerous nature of the paroxysm, that, although the symptoms seem to wear the most favourable aspect, any single accession may produce death. Yet Dr. Denman has justly remarked, that the danger is not exactly to be estimated by the frequency of the returns ; since this chiefly depends upon the frequency of the action of the uterus, and not upon an increase of the cause of the convulsions. Mauriceau deduces his prognosis more particularly from the condition of the patient in the intervals of the accessions : if she lies in a state of total insensibility between the fits, the danger, he believes, is much greater than when she returns to her usual sensibility. *Traité des Maladies des Femmes grosses*, liv. ii. p. 335.

Under the state of morbid irritability already noticed, several exciting causes appear to produce the convulsions in different instances. The painful distension of the uterine passages, and particularly of the *os uteri*, which is the seat of much irritability, is the most general source of the convulsive actions ; whence these convulsions are much more common in a first labour, than in subsequent parturitions, when the relaxation is more easily accomplished ; and it has been frequently remarked, that any attempt to assist the dilatation of the *os uteri* has brought on, continued, or increased the convulsions. Violent mental emotions have also been observed to produce these attacks. A severe fit of anger,

for instance, has been known to induce them. But the depressing passions appear to be more frequently the origin of them, such as grief, and the apprehension of future misery. "Unmarried women," Dr. Denman observes, "whose unfortunate situations render pregnancy an evil instead of a blessing," are peculiarly liable to be attacked by convulsions during labour, and to become maniacal after it. Sudden terror has also operated as an exciting cause. Blows, falls, and even less violent corporeal agitations, such as dancing, or other considerable muscular exertions, have occasionally given rise to convulsions about the period of delivery: and internal irritations, such as indigestible food, or flatulent congestions in the alimentary canal, or even distension of the urinary bladder, have proved the cause of puerperal convulsions in those predisposed in the way above-mentioned.

The immediate or *proximate cause* of these convulsions, however, is, without doubt, an over-excitement of the brain, from a great determination of blood to that organ. Dissection after death, according to Dr. Denman, has usually exhibited a general turgidity of the vessels of the brain, and of the membranes surrounding it; and Mr. Hewson, in one case, found a small effusion of blood on its surface.

The foregoing view of the symptoms, causes, and nature of the disease, seems to lead, then, distinctly to three indications, with a view to the prevention and cure of puerperal convulsions; *viz.* 1. To obviate the great determination of blood to the head; 2. To remove all sources of irritation, external and internal, as far as is practicable: and 3. To diminish the morbid irritability of the system.

The *first* indication, and, indeed, the first great object of practice in this formidable disease, is the removal of the over-distension of the vessels of the brain. This end is obtained by *blood-letting*, which is to be employed freely, according to the obvious marks of determination to the head. It may be performed either in the arm, or from the jugular vein; but, on the whole, the latter is preferable. One copious bleeding has often entirely removed the convulsions, especially from the vessels in the immediate vicinity of the brain; and accident has sometimes effected, what art had been too timid to accomplish. Dr. Denman mentions a case which was related to him by Dr. Bromfield, in which, after a bleeding from the arm had been employed with little benefit, the orifice of the vein was re-opened during a subsequent convulsion, and a considerable quantity of blood lost; from which time the convulsions ceased. This evacuation should, therefore, be repeated, when the first operation has not produced adequate relief, unless some unusual state of the constitution absolutely interdict it.

The *second* indication may be fulfilled at the same time, and the means will consist in the free ventilation of the room, by which the irritation of heat and foul air will be removed; in the free evacuation of the bowels by purgatives and glysters; in the use of the catheter, where the bladder appears to be distended with urine; in the application of fomentations to the abdomen, or the use of the warm-bath, where there are cramps or pains in the belly; and in the endeavour to tranquillize the mind, by removing all causes of anger, and opposing the tendency to grief, fear, or despondency, by inspiring hope and confidence.

The *third* indication, with a view to relieve the morbid irritability of the whole frame of the patient, can only be attempted with success, or even with safety, after a sufficient evacuation by blood-letting has been accomplished. The administration of opiates or other anodynes, previous to the reduction of the morbid fullness of the brain, can only be

expected to increase the evil, by the stimulation which is combined with their narcotic power. When the first object has been effected, however, a full dose of laudanum, *i. e.* from twenty-five to forty drops, may be administered with considerable advantage. Perhaps, however, the hyoscyamus, which is possessed of less stimulant power, and has no tendency to confine the bowels, would be preferable to the preparations of opium in such cases. Dr. Hamilton, the present professor of midwifery at Edinburgh, is in the habit of uniting camphor with the opium, under these circumstances, or of giving camphor alone, which he conceives to be less stimulating and equally soothing. The warm-bath may be resorted to if convenient, for the purpose of calming the general irritability, and warm fomentations are sometimes useful for the same purpose; but in truth, after the immediate source of the convulsions is removed by blood-letting, these secondary expedients are of minor importance.

It may be proper to observe, before we conclude, that some practitioners have asserted the propriety of assisting the delivery immediately, without waiting till the os uteri is sufficiently dilated by the natural efforts to admit of a ready extraction of the child. But both reason and experience have decided on the propriety of desisting from any attempt to dilate the os uteri, since the very attempt is liable to excite the paroxysms. If the first stage of labour be past, indeed, before the convulsions come on, the passage will be so much dilated as to admit of turning (especially if the membranes be not broken), or of delivery by the forceps or vectis. The comparative advantages of waiting have been clearly stated by Drs. Bland and Denman, in the works to which we have referred in the course of this article.

PUERPERAL Fever, in *Midwifery*, a fever incident to lying-in-women, and attacking them during or soon after labour. For its history and treatment, see *LABOUR, Natural*.

The puerperal fever is, in fact, connected with an inflammation of the peritoneum, or membrane lining the abdomen and surrounding the intestines, and differs from ordinary peritoneal inflammation only in the circumstances peculiar to the puerperal state, which increase the danger of the disease. The term *puerperal fever* should, therefore, be changed for that of *puerperal peritonitis*, or *peritonitis puerperarum*, which conveys a more correct notion of the nature of the disease. See *PERITONITIS*.

PUERS, in *Geography*, a town of France, in the department of the Two Nethes, and chief place of a canton, in the district of Malines. The place contains 3664, and the canton 15,067 inhabitants, on a territory of 85 kilometres, in nine communes.

PUERTO de Acazut, La, a harbour on the coast of Peru. N. lat. 14°.—*P. de los Angeles*, a harbour of the Pacific ocean, on the coast of Mexico. N. lat. 15° 30'.—*P. del Baylio Bucareli*, a large bay on the W. coast of the Prince of Wales's Archipelago, discovered in 1775 by signor Quadra, in which is a great number of small islands. N. lat. 55° 14' to 55° 40'. E. long. 226° 12' to 227° 5'.—*P. de Bazan*, a bay on the S.W. coast of the Prince of Wales's Archipelago. N. lat. 54° 49'. E. long. 227° 16'.—*P. de Cabanas*, a harbour on the N. coast of the island of Cuba. N. lat. 23° 4'. W. long. 83° 6'.—*P. del Canaveral*, a harbour on the S. coast of Pitt's Archipelago, in the Canal de Principe. N. lat. 53° 32'. E. long. 230° 16'.—*P. Cabello*. See *PORT Cavallo*.—*P. Calvo*, a harbour on the coast of Brasil. S. lat. 9° 10'. W. long. 34° 50'.—*P. Carnero de Tucape*, a harbour on the coast of Chili. S. lat. 37° 40'.—*P. Claro*, a bay of the Pacific ocean, on the coast of Darien. N. lat. 6° 52'.—*P. del*

Coral, a harbour on the coast of Chili, a little N. of Valdivia.—*P. Cordova y Cordova*, a large bay of the North Pacific ocean, on the S. side of the Prince of Wales's Archipelago. N. lat. $54^{\circ} 42'$ to $55^{\circ} 6'$. E. long. $227^{\circ} 28'$ to 228° .—*P. Cordova*, a bay on the E. coast of Prince William's Sound, between Hawkins's island and the W. coast of America. Entrance N. lat. $60^{\circ} 37'$. E. long. $214^{\circ} 13'$.—*P. Deseada*. See *PORT Desire*.—*P. Falso*, a bay of the Pacific ocean, on the coast of New Albion. N. lat. $32^{\circ} 45'$. E. long. $243^{\circ} 6'$.—*P. Escondido*, a harbour in the Pacific ocean, on the coast of Mexico. N. lat. $16^{\circ} 12'$.—*P. Gravina*, a bay or inlet of the Pacific ocean, on the W. coast of N. America, and E. side of Prince William's Sound. Entrance N. lat. $60^{\circ} 41'$. E. long. $214^{\circ} 11'$.—*P. del Governador*, a harbour on the coast of Chili, at the mouth of the Longotoma. S. lat. $31^{\circ} 30'$.—*P. del Ingles*, a harbour of the Pacific ocean, on the coast of Mexico. N. lat. $8^{\circ} 56'$.—*Alfo*, a harbour on the coast of Chili, N. of the Caldera. S. lat. $26^{\circ} 50'$.—*P. de los Inocentes*, a harbour on the W. coast of the island of Madre de Dios, in the Pacific ocean. S. lat. $50^{\circ} 44'$.—*P. de Machala*, a harbour on the coast of Peru. S. lat. $1^{\circ} 20'$.—*P. Magno*, a small sea-port on the W. coast of the island of Iviça, seven miles N. of Iviça. N. lat. $38^{\circ} 58'$. E. long. $1^{\circ} 22'$.—*P. de Malamacor*, a narrow pass in the mountains of Spain, N. of Valencia.—*P. Maria*, a sea-port on the S. coast of Jamaica. N. lat. $18^{\circ} 26'$. W. long. $76^{\circ} 40'$.—*P. Marin*, a town of Spain, in Galicia, on the Minho; 12 miles S. of Lugo.—*P. de Margues*, a bay of the Pacific ocean, on the coast of Mexico. N. lat. $17^{\circ} 10'$.—*P. de Mota*, a harbour on the S. coast of the island of Cuba. N. lat. 20° . W. long. $77^{\circ} 23'$.—*P. de Monte Moreno*, a harbour on the W. coast of America. S. lat. $23^{\circ} 8'$.—*P. de la Natividad*, a harbour on the coast of Chili, at the mouth of the Lora. S. lat. $34^{\circ} 44'$.—*P. Natividad*, a harbour on the W. coast of America, in the province of Xalisco. N. lat. $19^{\circ} 44'$.—*P. de Ocana*, a town of South America, in the province of St. Martha, on the river Madalena; 30 miles W.N.W. of Ocana.—*P. Papudo*, a harbour on the coast of Chili. S. lat. $32^{\circ} 20'$.—*P. de la Posseñion*, or *Realijo*, a bay of the Pacific ocean, on the coast of Mexico. N. lat. $12^{\circ} 36'$.—*P. del Principe*. See *VILLE del Principe*.—*P. de Pinas*, a harbour on the Pacific ocean, on the coast of Darien. N. lat. $7^{\circ} 30'$.—*P. Quemado*, a harbour on the coast of Darien, in the Pacific ocean. N. lat. $7^{\circ} 10'$.—*P. Quintero*, a harbour on the coast of Chili. S. lat. $32^{\circ} 42'$.—*P. Real*, a sea-port town of Spain, in the province of Seville, near the mouth of the Guadalete; six miles E. of Cadiz. N. lat. $36^{\circ} 32'$. W. long. $6^{\circ} 30'$.—*P. Revilla Gigedo*, a bay on the N.W. part of Prince William's Sound, on the W. coast of N. America. N. lat. $60^{\circ} 56'$. E. long. $213^{\circ} 25'$.—*P. de St. Antonio*, a bay on the coast of Darien, in the Pacific ocean. N. lat. $6^{\circ} 28'$.—*P. de St. Antonio*, a harbour on the coast of Mexico. N. lat. $19^{\circ} 55'$.—*Alfo*, a harbour on the coast of Chili. S. lat. $53^{\circ} 8'$.—*P. St. Juan*, a harbour on the Pacific ocean, on the coast of Mexico. N. lat. $11^{\circ} 32'$.—*P. St. Martin*, a harbour in the gulf of California, on the coast of Mexico. N. lat. $28^{\circ} 15'$.—*P. Salinas*, a bay of the Pacific ocean, on the coast of Mexico. N. lat. $16^{\circ} 36'$.—*P. St. Pedro*, a large bay on the Atlantic, on the coast of Brasil, at the mouth of Rio Grande. S. lat. $31^{\circ} 40'$.—*P. St. Yago*, a sea-port on the W. coast of Mexico, in the province of Xalisco; 25 miles S. of Purification. N. lat. $19^{\circ} 30'$. W. long. $105^{\circ} 46'$.—*P. de Santa Maria, El*, a sea-port town of Spain, situated in the bay of Cadiz, containing one parish, a hospital, five convents, and from 8000 to

10,000 inhabitants; whose chief trade is salt; seven miles N. of Cadiz. N. lat. $36^{\circ} 38'$. W. long. $6^{\circ} 25'$.—*P. de St. Vicente*, a bay on the coast of Chili, S. of Concepcion.—*P. de Tintoque*, a harbour in the Pacific ocean, on the coast of Mexico. N. lat. $21^{\circ} 3'$.—*P. de Topocalma*, a harbour on the coast of Chili. S. lat. $34^{\circ} 8'$.—*P. de Touro*, a harbour on the coast of Brasil. S. lat. $5^{\circ} 1'$. W. long. $35^{\circ} 20'$.—*P. de Valdes*, a bay on the N. part of Prince William's Sound, about 14 miles long and two broad.—*P. Vermejo*, a harbour on the coast of Peru. S. lat. $9^{\circ} 42'$.—*P. Velho*, a port on the coast of Brasil. S. lat. $16^{\circ} 10'$.—*P. Viejo*, a harbour on the coast of Peru; 10 miles E.N.E. of Monte Christi. S. lat. $9^{\circ} 42'$.—*P. de la Velas*, a harbour in the Pacific, on the coast of Mexico. N. lat. $10^{\circ} 35'$.—*Alfo*, a harbour on the coast of Peru. S. lat. $25^{\circ} 30'$.

PUERTOLAS, a town of Spain, in Aragon; eight miles N. of Ainsa.

PUERTOS, Los, a town of South America, in the province of Venezuela, E. of the river, which forms a communication between the gulf of Venezuela and lake Maracaybo; 15 miles N.N.E. of Maracaybo.

PUFF-BALL, the common English name for the fungus pulveris lentus, or lycoperdon. See **LYCOPERDON**.

The dust contained within this body, (which, when it is crushed, flies out in an inconceivably fine powder, in form of a cloud of smok,) when examined by the microscope, appears to be a multitude of regularly figured, though extremely small bodies. These require the most powerful magnifiers to distinguish them, and are found to be little globules of an orange colour, and somewhat transparent; and so small, that the cube of the diameter of a hair would be equal to a hundred and twenty-five thousand of them. In other species of this mushroom, the globules are evidently seen to be so many puff-balls, being of a darker colour, and having each a little stalk or tail; by means of these stalks they penetrate into the ground, when shed from their parent plant.

The dust of these mushrooms is very hurtful to the eyes, and we have had instances of persons being blinded for a long time by it, with violent pain, swelling and inflammation; and this is probably owing to the sharpness of these almost inconceivably minute stalks or tails. Baker's Microscope, p. 255.

PUFFENDORFF, SAMUEL, in *Biography*, a learned historian and jurist, was born in 1631 at Flåh, a village of Misnia, near Chemnitz, where his father was a Lutheran minister. He received the early part of his education under his father, and was sent to Leipzig to study divinity, which he soon abandoned for the law. After residing some time at this university he removed to Jena, and pursued the mathematics under the celebrated Weigel, and then applied himself to the law of nations, and the politics of the German empire, in which he became thoroughly versed. In 1658 he was appointed governor to the sons of Coyer, ambassador of the court of Sweden to that of Denmark, whom he accompanied first to Leyden, and then to Copenhagen. When war broke out between the two kingdoms, all the household of the Swedish ambassador was put under an arrest. Puffendorff, during the eight months of his confinement, employed himself in commenting on the work of Grotius "On the Rights of War and Peace," and the political writings of Hobbes, and having arranged his observations, he published them in 1660 with the title of "Elements of Universal Jurisprudence." By this essay he acquired so much reputation, that the elector palatine founded, in his favour, a professorship of natural law in the university of Heidelberg.

Heidelberg. In 1670 Charles XI., king of Sweden, conferred upon him the same office in the university of Lunden. While he was in that situation, the publication of his great work on the law of nations, brought upon him an attack from professor Beckmann, who printed a libel against him, for which he was banished the kingdom. Enraged at this punishment, he sent Puffendorff a challenge, of which he wisely took no notice. When Schonon became the seat of war, he quitted Lunden, and went to Stockholm, where he was appointed royal historiographer and counsellor of state, with the title of baron, and was engaged in writing on Swedish history. He finally accepted the invitation of the elector of Brandenburg to reside at his court as counsellor of state, with the charge of writing the history of the great elector, Frederic-William. Baron Puffendorff died at Berlin in 1694, leaving behind him a character of great integrity and honour. His historical works are as follow: "An Introduction to the History of the principal States at present in Europe," with a "Continuation." "History of Sweden from the Expedition of Gustavus Adolphus into Germany to the Abdication of Christiana." "History of Charles Gustavus." "History of Frederic-William II., the great Elector of Brandenburg." This was published in two vols. fol. in 1696; it was drawn from the archives of the house of Brandenburg, underwent many retrenchments in the course of printing, and complete copies are now rarely to be met with. Of his works on law are "Elementorum Jurisprudentiæ Universalis:" "A Treatise on the Law of Nature and Nations." This work maintains a place among the leading publications on the subject, and it is allowed, that the author has rectified and extended the principles of Grotius. An abridgment of this work was published under the title of "Duties of a Man and a Citizen."

PUFFENDORFF, ISAAH, brother of the preceding, born in 1628, was educated at Leipzig, where he distinguished himself, and took the degree of M.A. After various changes of fortune, he was made governor of the young count of Koningmark, and was afterwards chancellor of the duchy of Bremen. In 1686 he was appointed ambassador of the king of Denmark to the diet of Ratisbon, and died there in 1689. He is the author of a satirical work, entitled "Anecdotes of Sweden, or Secret History of Charles XI." Moreri.

PUFFIN, in *Ornithology*, a name by which some call the *Anas arctica Clusii*, or the northern duck, or *Alca arctica* of Linnæus.

This bird weighs about twelve ounces; its length is twelve inches, and the breadth from tip to tip of the wings extended, twenty-one inches; the bill is short, broad at the base, compressed on the sides, and running up to a ridge, triangular, and ending in a sharp point; the base of the upper mandible is strengthened with a white, narrow, prominent rim, full of small holes; the bill near the head is of a blueish-grey, and the lower part red; in the former is one transverse furrow, in the latter three furrows; and the size of the bill varies in different birds; the nostrils are long and narrow; the irides are grey, and the edges of the eyelids of a fine crimson; on the upper eye-lid is a singular callous substance, grey, and of a triangular form; on the lower is another of an oblong form; the crown of the head, whole upper part of the body, tail and covert-feathers of the wing, are black; the quill-feathers are of a dusky hue; the cheeks are white, and full of feathers; the chin of the same colour, bounded on each side by a broad bed of grey; from the corner of each eye is a small separation of the feathers, terminating at the back of the head; the neck is

encircled with a broad collar of black, but the whole lower part of the body is white; the tail is composed of sixteen feathers, and black; the legs small, of an orange colour, and placed so far behind as to render it incapable of standing otherwise than in an erect position, resting not only on the foot but the whole length of the leg, which circumstance makes the rise of the puffin from the ground very difficult; but when it gets on the wing, few birds fly longer or stronger.

These birds frequent the coast of several parts of Great Britain and Ireland, but are most numerous in Priestholm isle, off the coast of Anglesea. They are birds of passage, resorting there annually about the fifth or tenth of April; quit the place, and return twice or thrice before they settle to burrow the first week in May; but some dislodge the rabbits, and make use of their holes. The task of burrowing falls chiefly to the males, which also assist in incubation. The first young are hatched in the beginning of July, to which the old ones discover a very strong affection, which ceases at the stated time of migration, taking place punctually about the eleventh of August, when they leave such young as cannot fly to the mercy of the peregrine falcon. They lay only one egg, and the eggs are of very different forms. The flesh of these birds is exceedingly rank, as they feed on weeds and fish, especially sprats; but when pickled and preserved in spices, they are admired by those who love high eating. Dr. Caius tells us, that in his time the church allowed them in Lent instead of fish. They are taken by digging them out, or drawing them from their burrows with a hooked stick. Their noise, when taken, is very disagreeable, being like the effort of a dumb person to speak. The winter residence of this genus is but imperfectly known; it is probable they live at sea, in some more temperate climate, remote from land, forming those multitudes of birds which navigators observe in many parts of the ocean; they are always found there at certain seasons, retiring only at breeding time: repairing to the northern latitudes; and during that period are found as near the pole as navigators have penetrated. Pennant.

PUFFIN *Manks*, or *Shear-water*. See PROCELLARIA *Puffinus*.

PUFFIN'S *Island*, in *Geography*, a small island near the W. coast of Ireland; 4 miles S. of Brea Head.

PUFFINET, in *Ornithology*, the name of a bird known among authors by that of the *columba Groenlandica*, or the Greenland or sea turtle-dove. See COLUMBA.

It is common on the northern coasts, and is black all over, except two small spots on its head; but it is pretended by some, that in winter it turns white.

PUG-Piling, is the same with *dove-tailed* or *pile-planking*; which see.

PUGANORE, in *Geography*, a town of Hindoostan, in Myfore; 58 miles N.W. of Arcot.

PUGET'S ISLAND, a narrow island about five miles in length, discovered by Capt. Vancouver in Columbia river, about 24 miles from its mouth.

PUGET'S *Sound*, an inlet of several branches, and containing many islands, S. of Admiralty inlet, within Georgia Sound. N. lat. 47° 10'. E. long. 237° 25'.

PUGET-THENIERS, a town of France, and chief place of a district, in the department of the Maritime Alps. The place contains 914, and the canton 2133 inhabitants, on a territory of 142½ kilometres, in 6 communes.

PUGGAR, a town of Bengal; 30 miles W.N.W. of Ramgur.

PUGIL, from *pugillus*, *little hand*, among *Physicians*, &c. a measure of flowers, seeds, or the like matters, containing

so much as may be taken up between the thumb and two fore-fingers.

The pugil is esteemed the eighth part of the *manipule* (which see), or handful; though some confound pugil with manipulus, and use it for a handful. The French frequently call it *pincée*, a *pinch*.

PUGLIENZA, in *Geography*. See POLLENZA.

PUGNANI, GAETANO, in *Biography*, chamber musician and first violin to the court of Turin. He was of the Tartini school, and formed many great scholars upon his instrument, among whom we need only mention fig. Viotti as an illustrious example.

Pugnani went to Paris in 1754, and pleased and astonished extremely at the Concert Spirituel, both as a composer and performer of his own pieces.

In 1763 he published at Amsterdam three quartets, opera prima. In 1765 six duos for two violins, opera secunda; and six trios for two violins and a base, opera terza. A second set afterwards of six duets, opera quarta. His opera quinta was six sonatas for the harpsichord, with a violin accompaniment. Six symphonies, opera sexta. In 1770 six violin solos, opera septima. Three quintets for two violins, two flutes, and a base, opera octava. Six solos, opera nona, for the violin, besides a great number of solo concertos for his own performance, which still remain in manuscript.

In 1768 he came to England, and led some time at the Opera. His manner of playing there is not yet forgotten. He was very near-sighted; but grasped a whole page generally by a single glance, which gave him full leisure to look around him for admiration: and with a nose long enough for a *Muso*, he either thought himself or wished others to think him an Adonis. But he had here at this time a most powerful rival in talents and personal appearance in Giardini. It appeared to us in his solos and concertos that Pugnani had not that great and firm command of the finger-board, which Giardini and some other eminent performers on the violin have since manifested. In his shifts he was never sudden nor frequent; but having attained a new position, he never quitted it till he had played all the notes within his reach, which kept his hand stationary sometimes for a whole page.

While at the head of our Opera band, he composed a comic opera called "Nanette e Lubino." But though an able professor and writer for his own instrument, he seemed to have begun writing for the voice too late in life to arrive at great excellence in vocal compositions. He since that time has, however, composed several serious operas for different parts of Italy; among the rest "Demofonte" for Turin, in 1788. We have heard nothing of him since the revolution and dethroning of his sovereign.

PUGNAX AVIS, in *Ornithology*, the name of the bird called in English the *ruff*, and the female of which is the *reeve*. It has its Latin name from its quarrelsome disposition, the males being always fighting. See TRINGA *Pugnax*.

PUGNO CHIUSO, in *Geography*, a town of Naples, in the province of Capitanata; 5 miles S. of Vicste.

PUICELEY, a town of France, in the department of the Tarn; 10 miles N.W. of Gaillac.

PUJET, LE, a town of France, in the department of the Var; 9 miles S. of Brignoles.

PUIGUILLIEN, a town of France, in the department of the Dordogne; 10 miles S.W. of Bergerac.

PUINORMAND, a town of France, in the department of the Gironde; 12 miles N.E. of Libourne.

PUJOLS, a town of France, in the department of the Gironde, and chief place of a canton, in the district of Libourne; 12 miles N.E. of Libourne. The place contains

1012, and the canton 10,473 inhabitants, on a territory of 122½ kilometres, in 16 communes.—Also, a town of France in the department of the Lot; 10 miles N. of Agen.

PUIS *Darrein Continuance*, *q. d.* since the last adjournment, in *Law*, a plea which the defendant may plead even after issue or demurrer joined, when some new matter arises, at the day given for his next appearance. Pleas of this kind, when brought to a demurrer in law, or issue of fact, shall be determined in like manner as other pleas.

PUISEAUX, in *Geography*, a town of France, in the department of the Loiret, and chief place of a canton, in the district of Pithiviers; 9 miles E. of Pithiviers. The place contains 1926, and the canton 7085 inhabitants, on a territory of 105 kilometres, in 14 communes.

PUISNE, PUNY, in *Law*, a younger-born; or a child born after another.

The word is French, in which language it bears the same signification.

Puisne is not only applied to the second, third, fourth, &c. with regard to the first; but to the third with regard to the second, &c. The last of all is called absolutely *cadet*.

In the like sense we say a puisne judge, a puisne counsellor. Three of the judges of the court of common pleas are called puisne justices; and also three of the barons of the court of exchequer are distinguished by the same appellation.

PUISSERGUIER, in *Geography*, a town of France, in the department of the Herault; 9 miles W.N.W. of Beziers.

PUKER, a town of Bengal; 25 miles N.W. of Moorshedabad.—Also, a town of Hindoostan, in the circar of Bickaneer; 35 miles N. of Bickaneer.

PUKING, a cant word for a nausea, or disposition to vomit. See VOMITING.

PUKIS, in *Geography*, a town of Sweden, in the government of Abo; 7 miles E. of Abo.

PUKKILA, a town of Sweden, in the province of Nyland; 16 miles N. of Borgo. N. lat. 16° 20'. E. long. 25° 32'.

PUKOGNO, a town of Russia, in the government of Olonetz; 68 miles E.N.E. of Pudoga.

PUL, in *Commerce*, a general name which the Persians give to all the copper monies current in that empire.

Olearius, who was at Ispahan in 1637, in the retinue of the ambassador of Holstein, assures us, that each city in Persia has its several copper money, marked with its particular badge, which is only current in that district, and is changed every year. At the beginning of each year, which is at the vernal equinox, all the old money is cried down, and the new appears in its place.

Both the emperor and the state find their interest in this frequent change: the first, in that he only gives at the rate of 17*d.* sterling *per* pound for copper; yet delivers it out coined in kabesqui and demi-kabesqui, at about 2*s.* *per* pound: the second, in that the copper money is by this means less abundant, being reduced each year to nearly the same quantity.

PULAHA, the name of one of the personages often mentioned in Hindoo sacred writings, as the "ten lords of created beings," sometimes called Bramadikas, or sons of Brahma, and Prajapatis, or lords of creatures. On other occasions seven only are mentioned, and they have been reasonably considered as the same personages as those called Menus, Munis, and Rishis. See MENU, MUNI, and RISHI.

PULANSA, in *Geography*, a town of Hindoostan, in Guzerat; 44 miles N. of Radimpour.

PULASHI, a county of Kentucky, containing in 1800,

3361, and in 1810, 6897 inhabitants.—Also, a county of Georgia, containing in 1810, 2093 inhabitants.

PULASTYA, in *Mythology*, the name of one of the earliest created beings, according to the sacred books of the Hindoos, hence called Bramadikas, or children of Brahma. They are ten in number, and their names are enumerated under the article **MUNI**. See also **PULAHIA** and **PAULASTYA**.

PULBAIT, in *Geography*, a town of Hindoostan, in Oude; 32 miles N. of Kairabad.

PULCHER PISCIS, in *Ichthyology*, a name given by Gaza to the fish commonly known by the name of the *uranoscope*, or star-gazer. See **URANOSCOPIUS**.

It is a species of the trachinus, and distinguished by Artedi by the name of the trachinus with many beards on the lower jaw.

PULCHERIA, in *Biography*, a Roman empress, was a daughter of Arcadius, emperor of the East. In the year 414, being then only 16 years of age, she was declared Augusta, or empress, by her brother Theodosius II., who was two years younger than herself, and immediately took the lead in the government. To this elevated station she was entitled by talents, which were rarely found, at that period of the declining empire, in the possessors of the throne, and which rendered her the only worthy descendant of the Great Theodosius. She was elegantly skilled in the Greek and Latin languages, spoke and wrote with facility, was indefatigable in business, and by her vigilance and prudence maintained the public tranquillity during a long administration. She was likewise very devout, and, with her two sisters, early took a vow of perpetual virginity. She superintended the education of her brother, and wished to render him worthy of the high dignity to which he was born. At his death, in 450, Pulcheria was unanimously proclaimed empress of the East; but as a female reign was yet unknown to the Romans, she chose, after exercising her authority, by putting to death the unworthy Chrysaphius, to admit as a partner on the throne the senator Marcianus, whom at the same time she made her husband, though he was so only in title. By her authority the general council of Chalcedon was assembled in 451, the fathers of which conferred on her the epithets of guardian of the faith, and a new Helena. She died in 454, at the age of 56, leaving her vast wealth to the church and the poor. On this account, and for her zeal for orthodoxy, a place was assigned her among the faints of both the Greek and Latin churches. *Univer. Hist.* Gibbon.

PULCI, LUIGI, an Italian poet, was the youngest of three brothers of a noble Florentine family, all of whom cultivated polite literature. Luigi was born in 1431. Little is known of his life, except that he lived on intimate terms with Lorenzo de Medici and Angelo Poliziano. It was at the desire of Lucretia, mother of Lorenzo, that he undertook the composition of his principal poem entitled "*Morgante Maggiore*." This was first printed at Venice in 1488. It is said to display much invention and poetical imagination, with a purity of style with respect to Tuscan proverbial phrases, of which it has great abundance. The best edition is that of Paris, with the date of London 1768. There are other poems of Luigi Pulci in print, and among them, sonnets in conjunction with Matteo Franco, another Florentine poet in the burlesque style. Of the two brothers, **BERNARDO** wrote an elegy on the death of Cosmo de Medici, and another on the beautiful Simonetta, a translation of Virgil's *Eclogues*, and a poem of Christ's passion. **LUCA** wrote stanzas on the tournament of Lorenzo de Medici; heroic epistles; a pastoral romance entitled "*Driadeo d'Amore*,"

and an epic romance, probably the first of the kind that appeared in Italy, entitled "*Il Ciriffo Calvanco*."

PULE, LE, in *Geography*, a bay on the W. coast of the island of Jersey.

PULECA, a town of Bengal; 13 miles S. of Kishenagur.

PULEGIUM, in *Botany*. See **PENNY-ROYAL**.

PULENTE, LA, a bay on the W. coast of the island of Jersey; 3 miles W. of St. Aubin.

PULEX,—the *Flea*, in *Entomology*, a genus of insects of the order Apteræ, of which there are only two species. The generic character is as follows: Mouth without jaws or feelers, with a long inflected proboscis, covered at the base with two ovate laminæ; the sheath is two-valved, five-jointed, and concealing a single bristle; lip rounded, and fringed with reflected prickles; antennæ projecting, moniliform; it has two eyes; the abdomen is compressed; it has six legs, formed for leaping.

Species.

* **IRRITANS**. Proboscis shorter than the body. For a full account of this insect, see our article **FLEA**.

PENETRANS; the Chigoe. Proboscis as long as the body. It inhabits South America. This insect is extremely troublesome in the sugar colonies, penetrating into the skin of the inhabitants, where it lodges its eggs, and causes malignant and often fatal ulcers. The body is reddish-brown; abdomen of the female, when gravid, orbicular, and swollen to near a hundred times its usual size.

PULEX Aquaticus. See **Water BEETLE**, and **MILLEPEDES**.

PULEX-Eaters, a name given by naturalists to a sort of worms frequently found on the leaves of trees, where they devour the animals called *pulices arborei*.

Of these there are several species, which owe their origin to the eggs of different creatures; for they are none of them in their ultimate state in this their time of feeding. According to the different animals whose eggs they are hatched from, these are of different form and structure: some are hexapodes, or furnished with six feet; these belong to the beetle tribe, and finally change into beetles like the parent animals from whose eggs they sprung; others have no legs, and are produced from the eggs of flies of various kinds; and finally, others are genuine caterpillars, though small; but these are the most rare of all. The two general kinds are the hexapodes or beetle-worms, and the apodes, or fly-worms. The fly which gives origin to the last of these is a four-winged one, and takes care always to deposit her eggs in a place where there is plenty of the pulices, usually on the stalk or young branches of a tree in the midst of large families of them. The worm, as soon as hatched, finds itself in the midst of abundance of food, preying at pleasure on these animals, which are wholly defenceless. The stalks of the elder and woodbine are frequently found covered over with these pulices, and among them there may usually be found one or more of these destroyers feeding at will, sucking in the juices from their bodies, and then throwing away the dry skins. Besides the worms of this four-winged-fly, there is one of a two-winged wasp-fly, very destructive of these animals. *Reaumur's Hist. Inf. tom. i.*

PULEX-Arboreus, in *Natural History*, the name given by M. Reaumur to a very large genus of small animals. They are a kind of half-winged creatures; they have granulated antennæ, and some of them, in their most perfect state, have complete wings. These are distinguished from the others by the name of *musca pulex*, or the winged pulex.

The several species of these creatures are of different colours;

lours; some are brown, others yellow; but the most frequent are green. They all feed upon the leaves of trees, which become withered and curled up on their eroding them; and they are so common, that wherever a leaf of a tree is found curled up, or of a different form from the others, it is highly probable these animals are on it, or that it is their work. Among trees, the willow and the rose are most infected by them; and among plants, the bean and the poppy. They live a social life, multitudes of males and females being found together. The females are easily distinguished from the males, by their being thicker in the body, and having larger bellies.

It is very wonderful, that of all the known animals of the winged kind, these are the only ones which are viviparous. This is easily seen beyond a possibility of doubt; for, on examining a cluster of them together, it is a common thing to see, by the help of a small magnifier, a female in the act of parturition; and the author of this account frequently saw the young pulex protruded out, from a passage near the anus of the female, perfectly formed. He had suspected this from the total want of eggs among so numerous a tribe of animals, and from their remarkably speedy propagation, and was thus convinced of it by ocular demonstration. Reaumur's Hist. Insects, tom. i.

PULGAR, FERNANDO DE, in *Biography*, secretary, counsellor, and chronicler to Fernando and Isabel. He was a native either of the city or kingdom of Toledo. He wrote the chronicle of the Catholic kings up to 1492. This was published in 1565 as the work of Antonio de Nebrija, by his grandson, who finding it among his grandfather's papers supposed it to be his own work, and that the more readily, as Antonio had published a Latin translation. The *Claros Varones* of Pulgar have been more frequently printed. Gen. Biog.

PULICA, or PULHA, in *Geography*, a town of Austria. See BULCKAU.

PULISCHIAH, a town of Persia, in the province of Irak; 66 miles S.W. of Hamadan.

PULK, in *Rural Economy*, a provincial word signifying a puddle.

PULKA, in *Geography*, a town of Hindoostan, in the circar of Surgooja; 65 miles S.W. of Surgooja.

PULKELA, a town of Sweden, in East Bothnia; 38 miles S.E. of Brahestad.

PULLECOIL, a town of Hindoostan, in the Carnatic; eight miles E. of Tanjore.

PULLENDORF, a town of Austria; four miles E. of Mistlebach.

PULLEY, in *Mechanics*, one of the five MECHANICAL powers (see the article); consisting of a little wheel, or rundle, having a channel around it, and turning on an axis, serving, by means of a rope which slides in its channel, for the raising of weights.

The Latins call it *trochlea*; and the seamen, when fitted with a rope, a *tackle*. An assemblage of several pulleys is called a system of pulleys, or *polyspaston*: some of which are in a block or case, which is fixed; and others in a block which is moveable, and rises with the weight. The moveable wheel or rundle, is called the *sheave* or *shiver*; the axis on which it turns, the *gudgeon*; and the fixed piece of wood or iron, into which it is put, the *block*.

PULLEY, *Doctrine of the*. 1. If the equal weights W and P (*Plate XXXVI. Mechanics, fig. 11.*) hang by the cord BB upon the pulley A, whose block *b* is fixed to the beam HI, they will counterpoise each other, just in the same manner as if the cord were cut in the middle, and its two ends hung upon the hooks fixed in the pulley, at A and

A, equally distant from its centre. See MECHANICAL powers.

Hence a single pulley, if the lines of direction of the power and the weight be tangents to the periphery, neither assists nor impedes the power, but only changes its direction.

The use of the pulley, therefore, is when the vertical direction of a power is to be changed into an horizontal one; or an ascending direction into a descending one; and on the contrary.

This is found a good provision for the safety of the workmen employed in drawing with the pulley.

This change of direction by the means of a pulley has this farther advantage; that if any power can exert more force in one direction than another, we are here able to employ it in its greatest force.

Thus, *e. gr.* a horse cannot draw in a vertical direction, but draws with all its advantage in a horizontal one. By changing the vertical draught, therefore, into a horizontal one, a horse becomes qualified to raise a weight.

But the grand use of the pulley is, where several of them are combined; thus forming what Vitruvius, and others after him, call *polyspasta*; the advantages of which are, that the machine takes up but little room, is easily removed, and raises a very great weight with a moderate force.

2. If a weight W hangs at the lower end of the moveable block *p* of the pulley D (*fig. 11.*), and the cord GF goes under the pulley, it is plain that the half G of the cord bears one half of the weight W, and the half F the other; for they bear the whole between them. Therefore, whatever holds the upper end of either rope, sustains one half of the weight; and if the cord at F be drawn up so as to raise the pulley D to C, the cord will then be extended to its whole length, except that part which goes under the pulley; and consequently, the power that draws the cord will have moved twice as far as the pulley D with its weight W rises; on which account, a power whose intensity is equal to one half of the weight, will be able to support it, because if the power moves (by means of a small addition), its velocity will be double the velocity of the weight; as may be seen by putting the cord over the fixed pulley C (which only changes the direction of the power, without giving any advantage to it), and hanging on the weight P, which is equal only to one half of the weight W; in which case there will be an equilibrium, and a little addition to P will cause it to descend, and raise W through a space equal to one half of that through which P descends. Hence, the advantage gained will be always equal to twice the number of pulleys in the moveable or undermost block. So that, when the upper or fixed block *u* contains two pulleys, which only turn on their axes, and the lower or moveable block *U* contains two pulleys, which not only turn upon their axes, but also rise with the block and weight, the advantage gained by this is as four to the working power. Thus, if one end of the rope KMOQ be fixed to a hook at I, and the rope passes over the pulleys N and R, and under the pulleys L and P, and has a weight T of one pound hung to its other end at T, this weight will balance and support a weight W of four pounds, hanging by a hook at the moveable block U, allowing the said block as a part of the weight. And if as much more power be added, as is sufficient to overcome the friction of the pulleys, the power will descend with four times as much velocity as the weight rises, and consequently through four times as much space. The two pulleys in the fixed block X, and the two in the moveable block Y, are in the same case with those last mentioned; and those in the lower block give the same advantage to the power. See POLYSPASTON.

It is necessary to observe, that if the lower pulleys do not rise all together in one block with the weight, as in the cases just recited, but act upon one another, and the weight is only fastened to the lowest of them, the force of the power is very much increased, each pulley doubling it. *E. gr.* A power whose intensity is equal to 8 lb. applied at *a*, (*fig.* 12.) will, by means of the lower pulley A, sustain 16 lb.; a power equal to 4 lb. at *b*, will, by means of a lower pulley B, sustain the power of 8 lb. acting at *a*; a third power equal to 2 lb. at *c*, will, by means of the pulley C, sustain the power of 4 lb. at *b*; a fourth power of 1 lb. at *d*, will, by means of the pulley D, sustain the power of 2 lb. at *c*; and this is not altered by having its rope carried over the upper pulley or roller E. In the former cases, the force of the power is augmented in an arithmetical proportion of the number of ropes or pulleys; but in this, in a geometrical proportion.

3. If a power move a weight by means of several pulleys, the space passed over by the power will be to the space passed over by the weight, as the weight to the power.

Hence, the smaller the force that sustains a weight by means of pulleys is, the slower is the weight raised; so that what is saved in force, is spent in time.

The common methods of arranging pulleys in their blocks, may be reduced to two. The first consists in placing them one by the side of another, upon the same pin; the other, in placing them directly under one another, upon separate pins. Each of these methods is liable to inconvenience. Mr. Smeaton, in order to avoid the impediments to which these combinations are subject, proposes to combine these two methods in one. Accordingly, the pulleys are placed in each block in two tiers; several being upon the same pin, as in the first method, and every one having another under it, as in the second; and so that, when the tackle is in use, the two tiers that are the remotest from one another, are so much larger in diameter than those that are nearest, as to allow the lines of the former to go over the lines of the latter without rubbing. From this construction arises a new method of reeving the line upon the shieves; for here, whatever be the number of shieves, the fall of the tackle will be always upon the middle shieve, or on that next to the middle, according as the number of pulleys in each pin is odd or even. To do this, the line is fixed to some convenient part of the upper block, and brought round the middle shieve of the larger tier of the under block, from thence round one of the same sort next the centre one of the upper block, and so on, till the line comes to the outside shieve, where the last line of the larger tier falls upon the first shieve of the smaller, and being reeved round those, till it comes at the opposite side, the line from the last shieve of the smaller tier again rises to the first of the larger, whence it is conducted round, till it ends on the middle shieve of the upper block on the larger tier. See *fig.* 13. *Phil. Trans.* vol. *xlvi.* art. 82. p. 494, &c.

As a system of pulleys has no great weight, and lies in a small compass, it is easily carried about, and can be applied, in a great many cases, for raising weights, where other engines cannot be used. But they have a great deal of friction on these accounts; 1. Because the diameters of their axes bear a very considerable proportion to their own diameters; 2. Because in working they are apt to rub against one another, or against the sides of the block; 3. Because of the stiffness of the rope that goes over and under them. *Ferguson's Mechan.* p. 37, 4to. See FRICTION.

PULLICATE, in *Geography*, a town of Hindoostan, on the coast of Coromandel, near a large lake to which it gives name. This lake, called by d'Anville *Ericans*, seems to owe its existence to the same cause as the Chilka

lake; that is, to the sea's breaking through a low sandy beach, and overflowing the lands within; for its communications with the sea are extremely narrow, like the *embouchures* of small rivers. This lake is in extent thirty-three British miles, from N. to S., and eleven over, in the broadest part, and contains some large islands within it: one of these is named *Ircum*, in Mr. Bernard's map of the Jaghire, published by Mr. Dalrymple; and as M. d'Anville names this island, as well as the lake, *Ericans*, Major Rennell concludes it to be a corruption, or misconception, of *Ircum*. In the year 1609 the Dutch established themselves, and built a fort which they called *Geldria*. After the loss of *Negapatam*, the chief government on the coast of *Coromandel* was removed to this town; 22 miles N. of *Madras*. N. lat. $13^{\circ} 24'$. E. long. $80^{\circ} 27'$.

PULLICH, a town of France, in the department of the Rhone and Moselle; 6 miles E. of *Kayserch*.

PULLING, in *Sea Language*, denotes the act of rowing with the oars.

PULLINGI, in *Geography*, a town of Sweden, in West Bothnia, on the *Tornea*; 48 miles N. of *Tornea*.

PULLS, in *Agriculture*, the chaffy pods of rape or cole.

PULLUMNAIRE, in *Geography*, a town of Hindoostan, in the Carnatic; 94 miles W. of *Madras*. N. lat. $13^{\circ} 10'$. E. long. $78^{\circ} 50'$.

PULLUS, or PALLEN, ROBERT, in *Biography*, an English cardinal who flourished in the 12th century, was distinguished as a zealous friend to the interests of literature. He pursued his studies at Paris, and about the year 1130 he returned to England, where he had the mortification of seeing the university of Oxford ravaged and nearly ruined by the ignorant and ferocious Danes, under the reign of Harold I. He was one of those able men, to whose indefatigable exertions this seat of learning was indebted for its revival and restoration. To this object he devoted his advice, his fortune, his personal labours, and his learning. For some years he taught daily in the schools: for this and other eminent services, he was rewarded with the archdeaconry of Rochester. After this he returned to Paris, where he filled the chair of professor of divinity. He was, however, recalled by his metropolitan, and the revenues of his benefice sequestered till he obeyed the summons. The archdeacon appealed to the see of Rome, and sentence was given in his favour. The fame of his learning induced pope Innocent II. to invite him to Rome, where he was received with great marks of honour; and in the year 1144 was created cardinal by Celestine II., and afterwards chancellor of the Roman church, by pope Lucius II. He died in the year 1150. He was author of several works; but the only one of them now extant is his "*Sententiarum Liber*," which was published at Paris in 1655.

PULLYVELLUM, in *Geography*, a town of Hindoostan, in the Carnatic; 8 miles S. of *Terriore*.

PULMANN, THEODORE, in *Biography*, a philologist, born, about 1570, at *Cranenburg*, in the duchy of *Cleves*, was brought up to mechanical pursuits, and for some years exercised the trade of a fuller at *Antwerp*. By hard study in the intervals of his business, he became a proficient in classical literature, and an able grammatical critic. He was employed for sixteen years as a corrector of the press, and gave good editions of several Latin writers, from the press of *Plantin* at *Antwerp*: for which purpose he revised the text by ancient MSS. He died at *Salamanca*. He gave editions of *Virgil*, *Horace*, *Lucan*, *Juvenal*, *Æsop*, *Terence*, *Suetonius*, and several others. *Moreri*.

PULMO, in *Anatomy*. See LUNGS.

PULMO *Marinus*, *Sea-Lungs*, among *Naturalists*, a light spongy

spongy body, of a shining colour, like crystal, intermixed with blue, and usually of a figure resembling the human lungs; whence its name. It is also called *Urtica marina*, (which see) or the sea-nettle.

It swims on the surface of the water, and is popularly reputed to presage a storm. It is commonly supposed to be only a viscous excrement of the sea, hardened by the sun; but Sir Robert Sibbald and Dr. Merret rank it among the zoophytes. It shines in the night time, and communicates its luminous property to a stick rubbed with it. Being applied to the skin, it raises an itching, and takes off the hair.

PULMONALIS, in *Anatomy*, pulmonary, a term applied to the artery, veins, and nerves of the lungs. See **LUNGS**.

PULMONARIA, in *Botany*, so called by ancient writers, because the leaves were thought to resemble the speckled surface of the human lungs. Hence the plant was supposed, by one set of physicians, to possess certain virtues, indicated by that resemblance; which caused it to be used in coughs and phthical complaints. The mucilaginous qualities of the herbs rendered it rather favourable than otherwise, in allaying irritation of the throat.—Linn. Gen. 75. Schreb. 101. Willd. Sp. Pl. v. 1. 768. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 217. Ait. Hort. Kew. v. 1. 292. Juss. 130. Lamarck Illustr. t. 93.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Asperifoliae*, Linn. *Borragineæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, with five angles, and five teeth, permanent. *Cor.* of one petal, funnel-shaped; tube cylindrical, the length of the calyx; limb cut half way down into five obtuse ascending segments; throat pervious. *Stam.* Filaments five, very short, in the throat; anthers erect, converging. *Pist.* Germens four; style thread-shaped, shorter than the calyx; stigma obtuse, notched. *Peric.* none, the permanent unchanged calyx containing the seeds in its lower part. *Seeds* four, roundish, obtuse.

Ess. Ch. Corolla funnel-shaped, pervious. Calyx with five acute angles and flat sides.

Section 1. *Calyx about the length of the tube of the corolla.*

1. *P. angustifolia*. Narrow-leaved Lungwort. Linn. Sp. Pl. 194. Ait. n. 1. Engl. Bot. t. 1628. Fl. Dan. t. 483. Park. Parad. 251. f. 2. (*P. foliis echii*; Raii Syn. 226. *P. maculosa*; Ger. Em. 808.)—Calyx nearly as long as the tube. Leaves all lanceolate, rough.—Native of woods in Sweden, Siberia, Germany, Switzerland, and England, flowering in May or June. Mr. Turner and Mr. W. Borrer gathered this species wild in a wood between Newport and Ride, in the Isle of Wight, so that all doubts respecting the British plant are removed. (See Fl. Brit. 218, and Engl. Bot. p. 1628.) The root is perennial, tuberous, dark, with thick fibres. Stems a foot high, mostly simple, leafy, round, hairy. Leaves all lanceolate, acute, wavy, rough, slightly if at all spotted; the radical ones four or five inches long, tapering at the base into longish footstalks. Spikes terminal, in pairs, short. Corolla of a deep purplish-blue; red in the bud. Calyx hairy.

2. *P. officinalis*. Common Lungwort. Linn. Sp. Pl. 194. Fl. Brit. n. 1. Engl. Bot. t. 118, excluding the uncoloured leaves, which belong to the first species. Fl. Dan. t. 482. Woody. Suppl. t. 212. (*P. foliis echii*; Ger. Em. 808.)—Calyx nearly as long as the tube. Radical leaves ovate or heart-shaped, rough.—Native of shady places in various parts of Europe; rare in England, except in gardens, where it frequently occurs, flowering in May. This differs from the foregoing chiefly in its much broader, shorter, and more spotted leaves, whose surface is besprinkled

with pale, whitish, round blotches, most remarkable at an early stage of growth.—The flowers are occasionally white in this as well as the *angustifolia*.

Sect. 2. *Calyx but half so long as the tube of the corolla.*

3. *P. suffruticosa*. Shrubby Lungwort. Linn. Sp. Pl. 1667. Willd. n. 3. (*Lithospermum angustifolium umbellatum*; Boec. Sic. 77. t. 41. f. 2. Pluk. Phyt. t. 42. f. 7.)—Leaves linear, rough. Segments of the calyx deep, awl-shaped.—Native of mountains in Italy and Sicily. A species but little known, entirely a stranger to our gardens. Its stem is short, but perennial and rather woody, clothed with the permanent foliage of the last year. Leaves copious, long and narrow. Flowers blue, with more of the character of a *Lithospermum* than of a *Pulmonaria*.

4. *P. paniculata*. Panicked Lungwort. Ait. Hort. Kew. ed. 1. v. 1. 181. ed. 2. v. 1. 293. Willd. n. 4.—Calyx short, hispid, with deep segments. Leaves ovate-oblong, pointed, rather hairy.—Native of Hudson's Bay. Dr. Solander is recorded as its introducer at Kew, in 1778. This is a hardy species, flowering in May and June, of which no figure has appeared, nor have we seen a specimen.

5. *P. virginica*. Virginian Lungwort. Linn. Sp. Pl. 194. Ait. n. 4. Curt. Mag. t. 160. Mill. Ic. t. 212. (*P. foliis ovatis glabris, scapo laxo*; Trew Ehret. 11. t. 42. Symphytum, five *Pulmonaria non maculata, foliis glabris, americana, flore patulo cæruleo*; Pluk. Alm. 359. t. 227. f. 6.)—Calyx short, very smooth. Leaves lanceolate, bluntish.—Native of North America; from Pennsylvania to Carolina according to Mr. Pursh, growing on the gravelly shores of rivers, and flowering from March to May. With us it is a hardy perennial, of great beauty, but not so generally cultivated as it deserves. The whole herb is very glaucous, and so nearly smooth as almost to form an objection to the name of its natural order. The flowers are drooping, of a fine sky blue, and shaped like those of an *Onosma*; their tube and buds purple.

6. *P. sibirica*. Siberian Lungwort. Linn. Sp. Pl. 194. Ait. n. 5. (*Anchusa*; Gmel. Sib. v. 4. 75. n. 15. t. 39.)—Calyx short. Radical leaves heart-shaped.—Native of Siberia, and North America. Nearly akin to the last. Mr. Masson introduced it at Kew, in 1801. It is perennial, flowering in June and July.

7. *P. maritima*. Sea Lungwort. Linn. Sp. Pl. 195. Fl. Brit. n. 2. Engl. Bot. t. 368. Curt. Lond. fasc. 6. t. 18. Fl. Dan. t. 25.—(*Cerithe maritima procumbens, foliis et floribus cæruleis*; Dill. Elth. 75. t. 65.)—Calyx short. Leaves ovate, glaucous. Stem branched, procumbent.—Native of sandy sea-shores in Iceland, Norway, Scotland, and the north of England, flowering in July. This is most akin to the two last, but differs in being smaller, with a procumbent, much branched, and widely spreading stem. The whole herb is very glaucous. Leaves ovate, tapering at the base, rough with minute scattered tubercles. When chewed, in a recent state, their flavour is somewhat like a raw oyster; but by no means the more pleasant on that account, even to oyster-eaters. The flowers are racemose, terminal, of a very beautiful purplish-blue, pink in the bud. This is one of the most strikingly elegant of our native plants, at least in its native situations. The late Mr. John Mackay observed a variety, whose herbage was entirely green, not glaucous.

PULMONARIA, in *Gardening*, furnishes plants of the hardy, perennial, fibrous-rooted kind, of which the species cultivated are the common lungwort (*P. officinalis*); the narrow-leaved lungwort (*P. angustifolia*); and the Virginian lungwort (*P. virginica*).

The second species varies with white flowers.

Method of Culture.—These plants are increased by seeds, and parting the roots.

The seeds should be sown in the spring, in a bed or border of common earth, raking them in. They soon come up; and the latter end of summer they should be put out, either where they are to remain, or in nursery-beds, till October, when they should be planted out finally.

The roots should be parted in the autumn, as about August or September; but the sooner after they have done flowering, the better. They should not be divided too small, and be planted directly; when they flower strong in the following spring. They afford ornament in shady situations.

PULMONARY CONSUMPTION, in *Medicine*, *Phtthisis pulmonaris*, or consumption of the lungs. See CONSUMPTION.

PULMONES, in *Anatomy*. See LUNGS.

PULMONES *Marinae*. See PULMO, and URTICA *Marina*.

PULMONIC MACHINE, is a machine contrived for drawing fresh air, or medicated steams, into the lungs or throat, &c. Some have recommended for this purpose an inverted funnel: others have contrived machines for infusing herbs, &c. and annexed to them tubes for inspiring the steam or volatile parts thus obtained for them. A machine of this kind was contrived some years ago by Mr. Arden of Derby, which is described in the Gentleman's Magazine for 1748, vol. xviii. p. 486. A machine of this kind was contrived by Dr. Hales, for meliorating the air passing through the lungs of miners, &c. and is described in his "Vegetable Statics," vol. i. p. 264, &c. An instrument designed for similar purposes, and called an inhaler, was lately invented by Mr. Mudge. See INHALER.

PULMONUM ANIMA. See ANIMA.

PULO AKAT, in *Geography*, a small island in the East Indian sea, near the N.E. coast of Ceram. S. lat. $3^{\circ} 6'$. E. long. $131^{\circ} 3'$.—P. *Ampal*, a small island in the East Indian sea, on the W. coast of Sumatra. S. lat. $0^{\circ} 44'$. E. long. $99^{\circ} 29'$.—P. *Anam*, a small island in the East Indian sea, near the W. coast of Sumatra. S. lat. $0^{\circ} 40'$. E. long. $99^{\circ} 27'$.—P. *Anna*, a small island in the Pacific ocean, seen by captain Carteret in 1767, who called it Current island. N. lat. $4^{\circ} 38'$. E. long. $131^{\circ} 46'$.—P. *Aru*, a small island in the straits of Malacca. N. lat. $2^{\circ} 57'$. E. long. $100^{\circ} 24'$.—P. *Auro*, a small island in the Chinese sea, near the E. coast of Malacca. N. lat. $2^{\circ} 30'$. E. long. $104^{\circ} 40'$.—P. *Ayer*, a small island near the W. coast of Sumatra. S. lat. $1^{\circ} 11'$. E. long. $100^{\circ} 12'$.—P. *Babee*, a small island near the W. coast of Sumatra. S. lat. $5^{\circ} 45'$. E. long. $100^{\circ} 3'$.—P. *Alfo*, a small island in the straits of Sunda. S. lat. $5^{\circ} 45'$. E. long. $106^{\circ} 10'$.—P. *Baby*, a small island in the East Indian sea, near the N. coast of the island of Nyas. N. lat. $1^{\circ} 27'$. E. long. 97° .—P. *Batoa*, an island in the East Indian sea, near the W. coast of Sumatra, about 40 miles in circumference. N. lat. $0^{\circ} 20'$. E. long. $98^{\circ} 5'$.—P. *Bava*, a small island in the East Indian sea, near the S. coast of Nyas. N. lat. $0^{\circ} 52'$. E. long. $97^{\circ} 18'$.—P. *Bin-tango*, a small island near the W. coast of Sumatra. S. lat. $0^{\circ} 58'$. E. long. $99^{\circ} 47'$.—P. *Brasse*, an island in the East Indian sea, of a triangular form, about 20 miles in circumference, near the N. coast of Sumatra. N. lat. $5^{\circ} 24'$. E. long. $95^{\circ} 18'$.—P. *Brata*, a small island near the E. coast of Malacca. N. lat. $4^{\circ} 55'$. E. long. $103^{\circ} 40'$.—P. *Bringen*, a small island near the W. coast of Sumatra. S. lat. $1^{\circ} 58'$. E. long. $100^{\circ} 21'$.—P. *Canton*, or *Pulo Ratan*, an island in the Chinese sea, near the coast of Cochinchina. At some distance it bears the resemblance of two islands, being high at both extremes, and low in the middle. N. lat. $15^{\circ} 10'$.

E. long. $109^{\circ} 35'$.—P. *Capas*, a small island near the E. coast of Malacca. N. lat. $5^{\circ} 18'$. E. long. $103^{\circ} 20'$.—P. *Casse*, a small island near the W. coast of Sumatra. S. lat. $0^{\circ} 20'$. E. long. $99^{\circ} 28'$.—P. *Cava*, a small lofty island in the gulf of Siam, near the W. coast. N. lat. $8^{\circ} 28'$. E. long. $101^{\circ} 20'$.—P. *Condore*. See CONDORE.—P. *Dammer*, an island in the East Indian sea, about 20 miles in circumference, near the S. coast of Gilolo. S. lat. $0^{\circ} 58'$. E. long. $128^{\circ} 22'$.—P. *Datte*, a small island in the East Indian sea, near the W. coast of Borneo. N. lat. $0^{\circ} 8'$. E. long. $108^{\circ} 59'$.—P. *Ding-Ding*, a small island on the coast of Malacca, at the mouth of the river Pera.—P. *Doa*, a small island near the W. coast of Sumatra. N. lat. $1^{\circ} 18'$. E. long. $97^{\circ} 33'$.—P. *Docan*, a small island in the East Indian sea. S. lat. $1^{\circ} 2'$. E. long. $105^{\circ} 39'$.—P. *Dua*, a small island near the W. coast of Sumatra. N. lat. $2^{\circ} 46'$. E. long. 97° .—P. *Een*, a small island in the Pacific ocean, near the N.W. coast of the island of Waygoo. N. lat. $0^{\circ} 12'$. E. long. $130^{\circ} 37'$.—P. *Ely*, a small island near the W. coast of Sumatra. N. lat. $1^{\circ} 6'$. E. long. $98^{\circ} 11'$.—P. *Gasseb*, a small island in the East Indian sea, near the S.E. coast of the island of Ceram. S. lat. $3^{\circ} 29'$. E. long. $131^{\circ} 13'$.—P. *Gasses*, a small island in the East Indian sea, near the E. coast of the island of Oby. S. lat. $1^{\circ} 37'$. E. long. $128^{\circ} 20'$.—P. *Goere*, a small island in the East Indian sea, near the N. coast of Sumatra. N. lat. $4^{\circ} 42'$. E. long. $97^{\circ} 42'$.—P. *Gontei*, a small island in the East Indian sea, near the coast of Sumatra. N. lat. $5^{\circ} 15'$. E. long. $95^{\circ} 23'$.—P. *Gunton*, a small island in the straits of Malacca. N. lat. $1^{\circ} 22'$. E. long. $101^{\circ} 38'$.—P. *Lalang*, an island in the straits of Malacca, about 50 miles in circumference. N. lat. $2^{\circ} 25'$. E. long. $100^{\circ} 9'$.—P. *Laut*, an island in the East Indian sea, at the S. entrance of the straits of Macassar, near the S.E. coast of the island of Borneo, of a triangular form, about 100 miles in circumference, producing chiefly rice, and thinly inhabited. The channel between the island of Pulo Laut and Borneo is about two miles broad, and from seven to eight fathom deep. It affords a good harbour for shipping. S. lat. $3^{\circ} 45'$. E. long. $116^{\circ} 24'$.—P. *Laut, Little*, a group of small islands in the East Indian sea; 18 miles S. of Pulo Laut. S. lat. $4^{\circ} 54'$. E. long. $115^{\circ} 55'$.—P. *Lawn*, a small island in the East Indian sea. S. lat. $1^{\circ} 33'$. E. long. $128^{\circ} 48'$.—P. *Leat*, a small island in the East Indian sea. S. lat. $2^{\circ} 51'$. E. long. $107^{\circ} 5'$.—P. *Majo*, a small island in the East Indian sea, near the N. coast of Cumbava. S. lat. $8^{\circ} 11'$. E. long. $117^{\circ} 20'$.—P. *Malora*, a small island near the N. coast of Sumatra. N. lat. $5^{\circ} 24'$. E. long. $95^{\circ} 39'$.—P. *Mariore*, a small island in the Pacific ocean. N. lat. $4^{\circ} 17'$. E. long. $131^{\circ} 57'$.—P. *Marra*, a small island near the W. coast of Sumatra. S. lat. $1^{\circ} 22'$. E. long. $99^{\circ} 48'$.—P. *Mintaon*, an island in the East Indian sea, about 40 miles long and 12 broad, nearly on the equinoctial line; about 40 miles from the W. coast of Sumatra. E. long. $97^{\circ} 50'$.—P. *Moar*, a small island in the East Indian sea, near the E. coast of Gilolo. N. lat. $0^{\circ} 6'$. E. long. $128^{\circ} 58'$.—P. *Nancy*, an island near the N. coast of Sumatra, of a triangular form, about 20 miles in circumference. N. lat. $5^{\circ} 18'$. E. long. $95^{\circ} 21'$.—P. *Niamo*, or *Ausquitto*, a small island near the W. coast of Sumatra. S. lat. $1^{\circ} 8'$. E. long. $99^{\circ} 45'$.—P. *Nye*, a small island in the East Indian sea, near the W. coast of the island of Poggy. S. lat. $2^{\circ} 48'$. E. long. $99^{\circ} 32'$.—P. *Padum*, an island in the straits of Malacca, of a triangular form, and about 30 miles in circumference. N. lat. $1^{\circ} 21'$. E. long. $101^{\circ} 58'$.—P. *Pabang*, a small island near the coast of Malacca; about five miles from the town of Pahang.—P. *Panca*, a small island near the W. coast of Sumatra. N.

lat. $0^{\circ} 18'$. E. long. $98^{\circ} 35'$.—P. *Pandan*, a small island in the straits of Malacca, near the N. coast of the island of Sumatra. N. lat. $3^{\circ} 30'$. E. long. $98^{\circ} 57'$.—P. *Panjang*, a small island in the East Indian sea, near the E. coast of the island of Bintang. S. lat. $1^{\circ} 3'$. E. long. $104^{\circ} 55'$.—P. *Panjoor*, an island in the straits of Malacca, near the coast of Sumatra, about 150 miles in circumference. N. lat. $1^{\circ} 6'$. E. long. $102^{\circ} 28'$.—P. *Pec*, a small island in the straits of Malacca; about 5 miles W. from the city of Malacca. N. lat. $2^{\circ} 12'$. E. long. $102^{\circ} 6'$.—P. *Penneu*, or *Orange island*, a small island near the W. coast of Sumatra. S. lat. $1^{\circ} 28'$. E. long. $100^{\circ} 2'$.—P. *Pinang*. See PRINCE OF WALES'S ISLAND.—P. *Pifang*, a small island in the East Indian sea, near the W. coast of Sumatra, where the Dutch keep a quarter-master and some slaves. On the E. side of the island is a stone wharf. S. lat. $5^{\circ} 10'$. E. long. $105^{\circ} 33'$.—Also, a small island in the East Indian sea. S. lat. $1^{\circ} 25'$. E. long. $128^{\circ} 58'$.—Also, a small island near the E. coast of Malacca. N. lat. $2^{\circ} 40'$. E. long. $104^{\circ} 32'$.—P. *Poggy*. See POGGY.—P. *Prompton*, one of the Banda islands. S. lat. $4^{\circ} 2'$. E. long. $130^{\circ} 38'$.—P. *Rhun*. See POOLARON.—P. *Rocket*, a small island near the N. coast of Java. S. lat. $5^{\circ} 57'$. E. long. $108^{\circ} 17'$.—P. *Ron*, a small island in the East Indian sea, near the S.E. coast of Gilolo. S. lat. $0^{\circ} 48'$. E. long. $128^{\circ} 30'$.—P. *Rondo*, a cluster of small islands in the East Indian sea, N. of Sumatra. N. lat. $5^{\circ} 45'$. E. long. $95^{\circ} 22'$.—P. *Roopat*, an island in the straits of Malacca, about 120 miles in circumference, separated by a narrow channel from the island of Sumatra. N. lat. $1^{\circ} 58'$. E. long. $101^{\circ} 9'$.—P. *Rou*, a small island near the coast of Malacca. N. lat. 7° . E. long. $102^{\circ} 12'$.—P. *Sabadda*, a small island near the W. coast of Sumatra.—P. *Sabuda*, a small island in the East Indian sea; about 30 miles W. from New Guinea. S. lat. $2^{\circ} 35'$. E. long. $131^{\circ} 48'$.—P. *Salanama*, a small island in the straits of Malacca, near the N. coast of the island of Sumatra. N. lat. $3^{\circ} 27'$. E. long. $98^{\circ} 51'$.—P. *Salier*, a small island in the East Indian sea. S. lat. $5^{\circ} 50'$. E. long. $105^{\circ} 56'$.—P. *Sambolong*, i. e. *Nine Islands*, a cluster of islands in the East Indian sea, at the entrance of the river Pera, on the coast of Malacca.—P. *See Booro*, a small island in the East Indian sea, near the N. coast of the island of Pera. S. lat. $1^{\circ} 52'$. E. long. $99^{\circ} 9'$.—P. *See Geere*, a small island in the East Indian sea, near the N. coast of the island of Pera. S. lat. $1^{\circ} 55'$. E. long. $99^{\circ} 10'$.—P. *Selan*. See PRINCE'S ISLAND.—P. *Seyer*, a cluster of islands in the East Indian sea. N. lat. $8^{\circ} 40'$. E. long. $97^{\circ} 15'$.—P. *Sonaro*, a small island near the W. coast of Sumatra. S. lat. $0^{\circ} 53'$. E. long. $99^{\circ} 42'$.—P. *Suarjee*, one of the Banda islands. S. lat. $4^{\circ} 6'$. E. long. $130^{\circ} 20'$.—P. *Tamong*, a small island near the W. coast of Sumatra. N. lat. $0^{\circ} 27'$. E. long. $98^{\circ} 24'$.—P. *Taya*, a small island in the East Indian sea. S. lat. $0^{\circ} 42'$. E. long. $104^{\circ} 57'$.—P. *Teega*, a small island near the W. coast of Sumatra. S. lat. $0^{\circ} 52'$. E. long. $99^{\circ} 40'$.—P. *Tellore*, a small island near the W. coast of Sumatra. S. lat. $1^{\circ} 42'$. E. long. $100^{\circ} 15'$.—P. *Timoan*, an island in the East Indian sea, inhabited by Malays, found to be surly and insolent by commodore Byron, who touched at the island in 1765. The commodore, notwithstanding their hostile appearance, armed with a long knife in one hand, an iron-headed spear in the other, and a dagger by their side, went on shore, and commencing a treaty with them, could merely obtain about twelve fowls, and a goat and kid. His offers of knives, hatchets, bill-hooks, and similar articles, were contemptuously rejected, and they demanded rupees; but the commodore having none, tendered for payment of what he had purchased, pocket-handkerchiefs, which they condescended to accept,

selecting the best of them. The stature of these people was small; but they were well made, and of a dark copper colour. The island is mountainous and woody: its productions are rice, and the cabbage and cocoa-nut tree, in great abundance. N. lat. 3° . E. long. $104^{\circ} 25'$.—P. *Timpalis*, a small island in the straits of Malacca, near the N.E. coast of Sumatra. N. lat. $4^{\circ} 27'$. E. long. $97^{\circ} 45'$.—P. *Toobooyan*, a small island in Keyser's bay, on the S. coast of Sumatra. S. lat. $5^{\circ} 46'$. E. long. $104^{\circ} 42'$.—P. *Toty*, a small island in the East Indian sea. S. lat. $0^{\circ} 58'$. E. long. $105^{\circ} 50'$.—P. *Troofan*, a small island near the W. coast of Sumatra. S. lat. $1^{\circ} 6'$. E. long. $99^{\circ} 58'$.—P. *Tullong*, a small island in the straits of Malacca. N. lat. $4^{\circ} 27'$. E. long. $100^{\circ} 33'$.—P. *Varella*, a small island in the straits of Malacca, near the N.E. coast of Sumatra. N. lat. $3^{\circ} 51'$. E. long. $98^{\circ} 42'$.—P. *Ubi*, a small island in the Chinese sea, near the N.W. coast of Cambodia. N. lat. $8^{\circ} 33'$. E. long. $104^{\circ} 10'$.—P. *Ubi, False*, a small island in the Chinese sea, near the coast of Cambodia. N. lat. $8^{\circ} 52'$. E. long. $103^{\circ} 53'$.—P. *Way*, a small island in the gulf of Siam, near the gulf of Cambodia. N. lat. $10^{\circ} 8'$. E. long. 103° .—Also, an island about 30 miles in circumference, near the N. coast of Sumatra; 27 miles N. of Acheen. N. lat. $5^{\circ} 33'$. E. long. $95^{\circ} 33'$.—Also, one of the Spice islands, in the East Indian ocean. S. lat. $4^{\circ} 9'$. E. long. $130^{\circ} 26'$.

PULP, PULPA, in fruits, the *flesh*; or that soft and succulent part between the rind and the nucleus or seed.

The pulp of a tree or plant is the parenchyma, which grows and swells by means of a juice, at first very coarse and disagreeable; at length sweeter, and more delicate.

PULP, in *Pharmacy*, denotes the soft part of fruits, roots, or other bodies, extracted by infusion or boiling, and passed through a sieve.

PULP, in *Physiology*, denotes the fattest, fullest, and most solid part of the flesh.

Some people apply the word particularly to the upper part of the belly, because fleshy; and because it is here that they feel animals, to examine whether they be fat. This part the Latins call *pulpa*, from *pulpare*, *to feel, handle*.

PULPIT, PULPITUM, a term now restrained to an elevation, or apartment in a church, whence sermons are delivered.

Some authors derive the word from *publicum*, because people are there exposed to open view.

To the observations on pulpit eloquence, which the reader will find under ELOCUTION *of the Pulpit*, and under other heads to which we shall refer at the close of this article, we shall here introduce some reflections that may not be thought unappropriate to the subject, nor altogether uninteresting and uninteresting.

Pulpit eloquence has its advantages and also its disadvantages. It derives advantages from the dignity and importance of its subjects, which, duly considered, must be acknowledged superior to every other. They are in themselves highly interesting, as addressed both to the understanding and the heart; and they admit, at the same time, both the highest embellishment in describing, and the greatest vehemence and warmth in enforcing them. A preacher likewise, in treating these subjects, has often the advantage of addressing a large assembly, of proceeding without interruption, and of being under no necessity of making any extemporaneous replies. He may also previously chuse the theme of his discourse, and make every kind of necessary preparation. To counterbalance these advantages, the pulpit orator, though he has no adversary with whom he is called upon to contend, is not raised and enlivened by debate: and though he chuses his subjects, which are in themselves important and interesting, they are trite and familiar;

miliar; they have often been discussed by others; they have frequently recurred to himself in the exercise of his office; and they do not admit of much novelty and variety in the mode of treating them. It should also be considered, that the preacher is very much restricted to abstract qualities, such as virtues and vices; whereas other popular speakers present persons as well as characters to the view of their hearers, and hence derive peculiar advantage for interesting their attention. Accordingly Bruyere, in his "Mœurs de Siècle," closes his comparison of the eloquence of the pulpit with that of the bar by observing, "that it is more easy to preach than to plead; but that it is more difficult to preach well than to plead well." Nevertheless, though the art of preaching well is of difficult and rare attainment, Dr. Campbell (Rhetoric, b. i. c. 10.) candidly remarks, that considering how rare the talent of eloquence is among men, and considering all the disadvantages under which preachers labour, particularly from the frequency of this exercise, joined with the other duties of their office, to which fixed pastors are obliged, there is more reason to wonder that we have so many instructive and even eloquent sermons, than that we hear so few. Some indeed have unjustly argued, that preaching is no proper subject of the art of eloquence. But true eloquence, which is the art of placing truth in the most advantageous point of view for conviction and persuasion, cannot in any department of oratory be more suitably employed. A regard to this object is most intimately connected with the successful execution of the preacher's office; and if any further reasoning were necessary in so plain a case, we might refer to the discourses of the prophets and apostles, as models of the most sublime and persuasive eloquence, adapted both to the imagination and passions of men. "With regard to the pulpit," says Dr. Blair (Lect. vol. ii.), "it certainly has been a great disadvantage, that the practice of reading sermons, instead of repeating them from memory, has prevailed in England. This may, indeed, have introduced accuracy, but it has done great prejudice to eloquence; for a discourse read is far inferior to an oration spoken. It leads to a different sort of composition, as well as of delivery; and can never have an equal effect upon any audience." We much doubt, however, whether compositions, delivered from memory, are likely to be more truly eloquent and more impressive on the auditors, than those that are properly read. Perhaps the most advantageous mode of preaching, with regard to present effect, though very few excel in it, is that which is wholly extemporaneous: the preacher having previously formed the general plan of his discourse, and trusting for enlargement, on mere hints committed to paper, to the invention of the moment. But this is a mode of preaching which one could hardly venture to recommend to young divines, lest by acquiring an habitual self-command and a facility of *off-hand* speaking, they neglect to furnish themselves with ample materials for judiciously varied discourses. A few subjects, recurred to again and again, have usually formed the whole stock of popular extemporary preachers.

"Another circumstance," Dr. Blair observes, "has been unfortunate. The sectaries and fanatics, before the Restoration, adopted a warm, zealous, and popular manner of preaching, and those who adhered to them in after-times, continued to distinguish themselves by somewhat of the same manner. The odium of these sects drove the established church from that warmth which they were judged to have carried too far, into the opposite extreme of a studied coolness and composure of manner. Hence, from the art of persuasion, which preaching ought always to be, it has

passed in England, into mere reasoning and instruction; which not only has brought down the eloquence of the pulpit to a lower tone than it might justly assume; but has produced this farther effect, that, by accustoming the public ear to such cool and dispassionate discourses, it has tended to fashion other kinds of public speaking upon the same model." See ELOCUTION, ELOQUENCE, ORATION, PREACHING, *Public SERMON*, and *Public SPEAKING*.

PULPITUM, among the Romans, was a part of the theatre, called also *proscenium*, or what we now call the *stage*, on which the actors trod. Though some say it was properly an eminence on the stage for the music, or a *gestum* whence declamations, &c. were spoken.

The French use the word pulpit, *pupitre*, for a reading-desk in a church, library, or the like: those large ones in churches they properly called *lutrins*.

PULSATILLA, in *Botany*, from *pulsare*, to beat; because its flowers, in their open elevated native stations, are beaten about by the wind. Hence the name of Wind-flower. See ANEMONE.

PULSATION, PULSATIO, in *Medicine*, the motion of the pulse, or the beating of an artery. See PULSE.

PULSATOR, a name given by some writers to that species of beetle commonly known among us by the name of the death-watch, and about which so many superstitious fancies prevail.

PULSE, in *Anatomy*, the beating of the arteries, perceptible to the touch, and eye, produced by the influx of a fresh quantity of blood from the heart. See HEART, and CIRCULATION.

PULSE, in *Medicine*. As the pulse is well known to consist of the successive dilatations and contractions of the arteries, in consequence of the successive impulses given to the blood through them by the repeated contractions of the heart, and by their own muscular and elastic powers, it might be supposed, that this phenomenon would excite little attention among pathologists, prior to the discovery of the circulation of the blood. This supposition, however, would be the very reverse of truth; for, in fact, the variations of the pulse, as an index both of health and disease, have been attended to from the earliest ages of medicine, being frequently mentioned by Hippocrates, and described at great length by Galen and Cælius Aurelianus. Celsus has likewise noticed the pulse, as an indication of disease, adding, with his usual sagacity, that it is a very uncertain guide, "*fallacissima res*," and stating some rational rules for the mode of investigating its actual condition. In truth, though the cultivation of anatomy has enabled us to explain the nature of the pulse, and of some other functions of the living body, yet it has scarcely opened any new source of knowledge respecting the *prognosis* to be derived from the pulse in particular diseases; a knowledge which is the result of observation alone, or of a comparison of different cases of disease, in which the pulse is variously modified, and which, therefore, like many other doctrines in medical science, was equally open to the ancients, though ignorant of anatomy, and successfully cultivated by some of them. The ingenuity and imagination of Galen led him, indeed, to make a great many subtle distinctions respecting the varieties of the pulse, which were echoed by medical writers even down to the last century, but which are now pretty generally exploded as frivolous and impracticable; it would, therefore, be superfluous to enter into a minute detail on the subject. On the other hand, however, we are not disposed to agree with Dr. Falconer, in commending the opposite extreme, into which we conceive a very able and estimable physician of our own country has fallen, of reducing

all the cognizable variations of the pulse to two, *viz.* *quick* and *slow*. (See Dr. Heberden's excellent paper, entitled "Remarks on the Pulse," in the second volume of the Medical Transactions of the College of Physicians; and Dr. Falconer's "Observations on the Pulse," Lond. 1796.) For in the first place, the uncertainty of the healthy standard in individuals, which induced Dr. Falconer to take the trouble of calculating a long series of tables of comparative rates in different persons, necessarily renders the celerity of the pulse a point of considerable uncertainty; not to mention the numerous sources of variety in this respect, from age, strength, time of day, &c. which we shall presently describe; and in the second place, we think, every attentive practitioner, with a very moderate tact, is able to distinguish several other varieties, which occasionally direct his decision as to the mode of practice which he pursues. The distinctions, for instance, of strong and weak, full and small, hard and soft, equal and unequal, regular and irregular or intermittent, are surely very perceptible in many cases of disease; and not unfrequently serve to modify both the diagnosis and the prognosis, as well as the direction of remedies. The degree of *celerity* of the pulse is, however, the most obvious quality, and is capable of being measured without any of the tact of experience; and it is moreover the most variable quality under every variation of the condition of the body; it becomes, therefore, the principal object of our consideration.

It is not above a century since the pulse was first counted, or a standard of its natural frequency was attempted to be accurately established. Sir John Floyer appears to have been the first who applied a portable instrument to the purpose, beginning with a minute-glass, (see his work entitled "The Physician's Pulse Watch," 1707,) and it was only during the present age that the general introduction of such instruments among professional men took place. With respect to the natural standard, to which the comparative terms *quick* and *slow* must be referred, there has indeed been considerable difference in the statements of different physicians. This standard has been attempted to be inferred from the examination of the pulse in a number of persons in health, by taking the mean of the numbers collectively. The natural pulse of individuals varies considerably, however, from so many circumstances, that there is some difficulty in adjusting this standard. These circumstances have been methodically detailed by Dr. Falconer, and require to be taken into the consideration of all, who would properly estimate the signs and indications afforded by the pulse: they are as follows.

First, such circumstances as arise from *bodily organization*; and these are, 1. That of *sex*. The average number of the pulsations in an adult man, in good health, between 30 and 40 years of age, is estimated at about 73 in a minute; but the pulse of women of the same age and condition is somewhat quicker. Kepler, who estimated the mean pulses of men at 70 in a minute, estimated those of women at 80, or at one-seventh more; and Dr. Falconer considers the difference to be in about the same proportion, calculating the ordinary pulse of men at 75, and that of women at 84. 2. The *temperament*. The same causes which produce a quicker pulse in women than in men, probably operate in different temperaments; for those persons, who bear marks of the sanguine habit (which approximates to the female constitution), namely, who have a fair and florid complexion, light-coloured and soft hair, blue eyes, soft and succulent flesh, with considerable sensibility of mind and disposition, have generally a quicker pulse than persons with dark hair and eyes, pale or fallow complexion, firmness of the mus-

cular parts, and, in the mental qualifications, resolution, and steadiness of temper. 3. The *stature*. It may be questioned whether the difference of stature occasions so much difference in the velocity of the pulse, as the mechanical physicians maintained, though it probably has some influence. Dr. Bryan Robinson has given a table of pulses, according to stature, taking six feet as the standard, at which height he found the pulse to be 65, and computing upon this rule, which he says was founded upon a great number of observations, that the mean pulses of well-proportioned bodies were to one another, inversely, as the biquadrate roots of the cubes of the lengths of the bodies. Senac held a similar opinion, but his computation was somewhat different. He states the following proportion; namely, at 2 feet, pulse 90; at 4 feet, pulse 80; at 5 feet, pulse 70; and at 6 feet, pulse 60; the last number of which he says was deduced from observation of one hundred men of the royal guards, who were selected for that office on account of their tallness of stature. Haller, however, pays little regard to this opinion, and brings as instances the Swiss people, who are in general tall of stature, and their pulses more numerous than this standard. He himself, he tells us, was six feet high, and his own pulse beat 78 in a minute.

Secondly, the pulse is varied by the *period of life*. The variations of the pulse during the progress of life have been minutely investigated by the late Dr. Heberden, who has stated the following inferences. "The pulse of a healthy infant asleep on the day of its birth is between 130 and 140 in one minute; and the mean rate for the first month is 120; for during this time the artery often beats as frequently as it does the first day, and I have never found it beat slower than 108. During the first year the limits may be fixed at 108 and 120. For the second year at 90 and 100. For the third year at 80 and 108. The same will very nearly serve for the fourth, fifth, and sixth years. In the seventh year, the pulsations will be sometimes so few as 72, though generally more." From the twelfth year, then, except that the pulsations are much more easily quickened by illness or any other cause, they differ but little from those of a healthy adult, the range of which Dr. Heberden states to be from a little below 60 to a little above 80 in a minute. From an average of five and twenty boys, observed by Floyer, between the ages of twelve and sixteen, the pulse was about 83; in all of them above 80. In stating the average of the pulse of adults, most authors have taken a less extensive range than Dr. Heberden. Sir John Floyer, who employed considerable industry in the investigation of this matter, found the average of eight healthy persons, from twenty to forty years of age, to be somewhat more than 73 in a minute; and he observes, (Physician's Pulse-Watch, p. 40, and 74), "the most natural pulse will have from 70 to 75 beats in a minute in perfect health." Senac also estimates it at the same rate exactly (see his *Traité du Cœur*); and Dr. Bryan Robinson found, after an accurate examination of two healthy persons for many weeks together, and at no less than sixteen intervals, of an hour each, daily, that the average number of the pulse of one of them was 73, and of the other $74\frac{1}{2}$ in a minute. Dr. Falconer, after comparing all the authorities with his own observations, is inclined to consider 75 as the average of an adult healthy pulse. It is not satisfactorily ascertained, whether any material alteration is produced in the pulse by advanced age. Haller thinks that the pulse in old persons is slower than in the middle age; but Dr. Falconer points out some strange mistakes which he has committed, in quoting his authorities. Floyer has given a list of thirteen old persons, in whom the pulse on an average was exactly 76 in a minute.

Dr. Fal-

Dr. Falconer is disposed to believe, though not very confident in his opinion, "that the pulse in a healthy person becomes gradually slower from about forty-five years of age to about sixty, after which period it begins again to grow quicker, and to become, as several other circumstances in the system do also, more resembling that of children. But to this," he adds, "there are undoubtedly many exceptions." P. 23.

Thirdly, the pulse is varied by the *time of day*. The variation of the pulse at different times of the day, even in perfect health, is well known. Whether this variation be the effect of the excitement, produced by the food and drink, exercise, and employment of mind, in the course of the day, or from whatever causes it may arise, it is generally observable, that the pulse is slower in the morning, and somewhat accelerated in the afternoon and evening. This change is particularly obvious in persons of feeble habit and delicate health, in whom a slight tendency even to feverishness is often present in the afternoon; and, in febrile complaints, notwithstanding the utmost care is taken to prevent the access of every irritating cause, the acceleration of the pulse is very commonly aggravated in the evening. Sir John Floyer observed, that his own pulse in the morning falling beat 76 times in a minute, a little before dinner 77, and after dinner 95 times. Senac, in his *Traité du Cœur*, has left a few observations on the same subject; according to him, the pulse which was 62 in the morning, rose to 86 after dinner. Haller also found, that the pulse, which in the morning beat 75, in the evening, towards the time of rest, beat 82. (*Opera Minora*, vol. i. p. 186.) Dr. Bryan Robinson, after stating some very accurate observations on this subject, drew this inference, "that the pulse is slower in the morning than at any other time of the day; that it grows somewhat quicker before breakfast, and a little more so after it; that it grows slower again before dinner, and quicker immediately after dinner, and that the quickness acquired by this meal continues for about three or four hours, and then abates a little, and continues in that state without any considerable change, in bodies which eat and drink little at night, till they go to rest." Robinson's *Animal Economy*, p. 148.

Fourthly. This, however, leads us to the consideration of the effects of *food* and *abstinence* on the pulse, to which the variations at different times of the day may perhaps be partly attributed. It is universally acknowledged, indeed, that taking food accelerates the pulse, while fasting retards it; and many facts in proof of this are recorded by Floyer, Robinson, Haller, and others; but the degree of acceleration produced, is very different in different individuals, being the greatest in persons of delicate and irritable habits.

Fifthly. The pulse is varied by the state of the system, with respect to *rest* or *activity*. Observations have been sufficiently numerous to prove, that during *sleep* the pulse is usually slower than when a person is awake, as might indeed have been anticipated from the consideration, that various causes of excitement, both mental and corporeal, cease to operate during that condition. Dr. Falconer says, "I have repeatedly found the pulse at first waking, not to exceed 61, 62, or 63 beats in a minute, which in a short time, without any alteration of posture, rose to 66, 67, or 68." This slowness, however, will not be observed, if a person has taken plentifully of food or stimulating liquor, a little time before going to sleep, or if he sleeps in a close and hot room, or under a great load of bed-clothes; but it will invariably occur, if the stomach is not loaded, the air pure and cool, and the bed-clothes not more than sufficient to preserve a comfortable warmth.

Motion and *exertion* of every kind is found to quicken the pulse; even the little effort that is made to preserve the body in a standing posture is sufficient to produce a very perceptible increase of the pulse above what it was in a sitting or recumbent posture. Dr. Bryan Robinson has given a proportion of relative increase upon change of position and motion, as follows: lying down, pulse 64, sitting 68, standing 78, walking at the rate of two miles an hour 78, at the rate of four miles an hour 100, running raised it to 140, 150, or more. Speaking is a kind of exercise which has a considerable effect upon the pulse. Every physician must have observed the pulse quickened during his examination of it several beats in a minute by a few words spoken at that time, more especially in a febrile state; hence they generally recommend silence to their patients during such examination.

Mental agitation of every kind appears to accelerate the pulse, but with this difference, according to the observations of Dr. Falconer, that the depressing passions, as fear, anxiety, and grief, tend at the same time to render it weaker, while the stimulating passions, as joy and anger, make it more full and strong. Floyer mentions an instance of the pulse being excited to 104 beats in a minute by anger, and that it did not return to the natural standard in three or four days.

Lastly. The pulse is varied with the *temperature* of the body. The application of heat, exceeding the natural temperature of the body, accelerates the pulse. A very hot room, or sitting near a fire, will increase the number of its beats. In physiological experiments, indeed, it has been ascertained that the application of heat will renew the motion of the heart (or *punctum saliens*) in an egg, after it had ceased for a considerable time. On the other hand, the gradual influence of cold air upon a body that has been over-heated diminishes the number of the pulse. The sudden shock of the cold bath, indeed, quickens the pulse considerably; but in this case the *sensation* becomes a stimulus to the system, and excites both quickness of pulse and an actual glow or evolution of heat. Sir John Floyer has given a table of the pulses of men in different latitudes, making them 120 in a minute under the equator, and 30 at the north pole; but the data upon which this table is formed appear to be questionable. See his *Physician's Pulse-Watch*, vol. i. p. 298.

Before we could derive any information from the pulse, relative to the degrees and nature of diseases, it was absolutely necessary to be acquainted with the foregoing observations in respect to the common standard, and the common causes of variation in health; otherwise we should be liable to many errors in investigating the state of the pulse. Against these ordinary causes of the fluctuation of the pulse, indeed, the physician must be always upon his guard even in disease. The advice of Celsus upon this subject must be followed as long as the pulse is an object of medical attention. After enumerating many causes of its variation, he mentions apprehension, anxiety, and other mental emotions. Therefore, he says, "when the physician first enters the room, if he be a skilful man, he will not immediately apply his fingers to the patient's wrist, but he will first sit down with a cheerful countenance, and make some general inquiries; and if he observes any alarm in the patient, will relieve him by encouraging remarks, and then will proceed to examine the pulse. Now if the sight of the physician is sufficient to quicken the pulse, how easily may a thousand other circumstances disturb it!" (Celsus, de *Medicinâ*, lib. iii. cap. 6.) In feeling the pulse, the two principal qualities to be ascertained are the *quickness* or *frequency* (which we deem synonymous), and the *strength* of the pulsations.

tions. The former, of course, is easily determined by a stop-watch; but the latter requires somewhat of tact and experience; for the degree of strength in the pulse is very different in individuals of different sex, temperament, and vigour, in health. In order to ascertain the force of arterial pulsation, the vessel should first be pressed gently; and, if any doubt arise, it should be strongly compressed by two or three fingers, until no pulsation is felt, and then the fingers should be gradually relaxed until the comparative force with which the pulsation returns may be estimated; the degree of *compressibility* of the pulse, or the facility with which the pulsation may be entirely stopped, affording a tolerably good comparative notion of its strength. The degree of obesity of a patient should be attended to in estimating the strength of the pulse; for very fat persons have naturally a feeble pulse, and the pulsation is felt less distinctly through a layer of fat. A strong firm pulse is consistent with high health; for the heart contracts with vigour, when filled with healthy blood; but the strongest pulse, though scarcely compressible under the finger, has some degree of *softness*, if healthy. If there is a *hardness* in its beat, if it strikes the finger like a tense cord or wire, it shews a tendency to inflammatory disease, a phlogistic diathesis, as it has been called, consisting of a morbid fullness and tone of the arterial system. When with this *hardness* there is increased frequency, and some local pain, inflammatory fever is present. Some writers, indeed, carrying their dread of refinement in the discrimination of pulses too far, make light of all the distinctions, save of frequency; but we are persuaded that those who question the distinction between the soft, fluent, and undulating impression of a healthy pulsation, and the smart stroke, even when feeble, of an inflammatory pulse, must be somewhat deficient in the sensibility of their digital nerves, or in the attention which they bestow upon the subject.

The principal practical use that is made of this distinction between a *hard* and *soft* pulse, which is at the same time *quick*, is its indication of the propriety of blood-letting, or the contrary, in acute diseases. And if those who have denied the existence of the distinction, only intended to assert that such a distinction is not a sufficient guide in practice, they were in a great measure correct. For after all that can be observed of the pulse, we must accede to the statement of Celsus, that it is extremely deceptive, "*fallacissima res*;" and that it is only when taken into consideration in conjunction with the other symptoms of a disease, and with the general state of the constitution of a patient, that it can be relied on implicitly as a guide in the administration of remedies. But in conjunction with the other symptoms, the continuance or cessation of that smartness and cord-like tension in each pulsation will be an important index, as to the continuance or cessation of inflammatory action in acute disease, and therefore as to the extent to which evacuations ought to be carried.

In all diseases accompanied by *pain*, and especially when the pain is extremely severe, the state of the pulse is commonly the chief, sometimes the only index, by which the nature of the pain, whether it be *inflammatory* or *spasmodic*, is to be ascertained. (See PAIN.) This is sometimes of extreme importance; because a large dose of opium, which will speedily remove a spasmodic pain, will not only not alleviate, but will often greatly augment an inflammatory pain, and leave the disease to itself, at the only time when the active remedy, blood-letting, was likely to be beneficial. Mere pain, however violent, does not always quicken the pulse, and never produces that hardness in its beats which we have above alluded to. An able observer, the late Dr.

Heberden, has remarked; "it is often supposed that great pain will quicken the pulse; I am more sure that mere pain will not always do it, than I am, that it ever will. The violent pain occasioned by a stone passing from the kidneys to the bladder is often unattended with any quickness of the pulse; and the excessive and almost intolerable torture produced by a gall-stone passing through the gall-ducts never once quickened the pulse beyond its natural pace, as far as I have ever observed, though it be a disorder which occurs so very frequently; and this natural state of the pulse, joined with the vehement pain about the pit of the stomach, affords the most certain diagnostic of this illness. I have seen a man of patience and courage rolling upon the floor and crying out through the violence of this pain, which I was hardly able to lull into a tolerable state with nine grains of opium given within twenty-four hours, to which he had never been accustomed, and yet his pulse was all the time as perfectly quiet and natural, as it could have been in the sweetest sleep of perfect health." (Med. Transact. vol. ii. p. 32.) In such cases, without examining the pulse, a careless practitioner might proceed to a copious blood-letting, which might be injurious to a feeble habit, and would be productive of no relief; whence, on the other hand, if a violent inflammatory pain in the bowels were supposed (from not attending to the pulse, which would, in this case, be quickened,) to be merely spasmodic, as in colic, and no bleeding were employed, but a large dose of opium administered and repeated, no relief would be procured, and the inflammatory disease would probably pass on rapidly to a fatal suppuration or gangrene.

When gangrene has commenced, there is commonly a sudden cessation of the pain, and patients themselves and their attendants imagine that the pulse at this time will generally explain the real condition of the patients; for it will be found either quick and extremely feeble in its beats, or tremulous rather than pulsating, or probably altogether imperceptible at the wrist, implying that the powers of life are sinking, and that death, and not recovery, is impending.

With respect to the degree of disease and of danger, indicated by increased celerity in the pulse, we cannot do better than quote some of the observations of the late experienced Dr. Heberden. He says, "if the pulse either of a child or of an adult be quickened so as to exceed the utmost healthy limit by ten in a minute, it is an indication of some little disorder. But a child is so irritable, that during the first year a very slight fever will make the artery beat 140 times, and it will beat even 160 without danger; and as there begins to be some difficulty in counting the pulse when the motion is so rapid, the thirst, quickness of breathing, averseness from food, and above all the want of sleep, enable us better than the pulse to judge of the degree of fever in infants." Indeed, to shew how little can be determined by the state of the pulse in infants, Dr. Heberden adds, "a child of two years will die of an inflammatory fever, though the artery beats only 144 times in a minute; and I have seen a child of four years recover from a fever, in which it beat 156 times; and one of nine, where it beat 152.

"In adults ill of an inflammatory fever, the danger is generally not very great, where the beats are fewer than 100; 120 shew the beginning of danger, and they seldom exceed this number unattended with deliriousness, and where the patient does not die. There are two exceptions to this observation: the first is, that before some critical swelling or deposit of matter begins to shew itself in fevers, the pulse will be so rapid and indistinct as hardly to admit of being counted

counted; but I have known it certainly not less than 150, and yet the patient has recovered. Acute rheumatism affords a second exception, in which the artery will often beat above 120 times without any sort of danger; and in both these cases we may remark, that the appetite and senses and sleep and strength are put less out of their natural state, than where the life of the patient is in immediate danger.

"Though it may be difficult to count above 140 strokes in a minute, if they be unequal in time or in strength, yet where they have been very distinct, I have been able to count 180." Some authors have denied that the pulse can be distinctly counted when it exceeds 160; and in common fevers, before it reaches that degree of celerity, it is generally so feeble that its beats are very indistinct; there is one disease, however, in the latter stage of which the pulse retains a sharpness combined with extreme velocity, which renders it perfectly countable, even above the number stated by Dr. Heberden. We have distinctly counted 190 beats in the last stage of hydrocephalus; and Dr. Whytt, who observes that no patient dies of this disease, while his pulse remains under 130, in one case counted it at 210 on the day of death.

On the other hand, disease and danger are likewise indicated by a preternatural *slowness* of the pulse, which is usually connected with some degree of compression of the brain. Even in children, as Dr. Heberden remarks, "if the pulse be 15 or 20 below the natural standard, and if there be at the same time signs of considerable illness, it is a certain indication that the brain is affected, and consequently such a quiet pulse, instead of giving us hope, should alarm us with the probability of imminent danger." In adults, whenever the pulse is reduced to 50, or lower, if there be also a lethargic disposition, or stupor, danger of an apoplectic or paralytic attack is to be apprehended. During an attack of apoplexy, the continuance of the slowness of the pulse, together with the insensibility, heavy, slow, and stertorous breathing, and coma, is in the highest degree unfavourable, as indicating the great extent of the compression of the brain. The pulse, in these cases, is often under 40, and sometimes less than 30 in a minute. The operation of large doses of digitalis, and some other narcotic vegetable substances, also renders the pulse remarkably slow. The sudden change from quick to slow in the pulse, when it occurs in disease, is therefore to be considered as indicative of an unfavourable termination, if the other bad symptoms continue at the same time unalleviated: it is a proof not of the decrease of the disorder, but of the diminished irritability of the patient, the disease being transferred to the brain, and coma, palsy, apoplexy, or death, is to be apprehended.

Of the many fanciful variations of the pulse, which many writers a century or two ago indulged themselves with describing and naming, and with pointing out the indications to be deduced from them, as they are altogether incomprehensible to ordinary observers, we shall say nothing, referring those who have any desire to investigate the subject to the works of Bordeu, Nihel, Bellini, Massaria, and if they please to the various treatises of Galen.

We must observe, however, with Dr. Heberden, that though in many cases an useful index of the state of the health, yet the pulse is by no means a certain guide in all, and without a due consideration of concomitant symptoms may greatly mislead; for there are many anomalies observable respecting it. A good pulse, as that author observes, (which is sometimes found in comatose fevers,) with delirium, rapid loss of appetite and strength, sleeplessness, quickness of breathing, and great thirst, would afford very little hope; and a bad one without any of these might be

harmless. "I remember two young women," Dr. Heberden says, "ill together with others in the same house of the same infectious fever; the pulse of one of which was never above 84, and the pulse of the other was always extremely quick, and I once counted it when I thought her dying 180. Both of them recovered, and the latter quite beyond my expectation.

"Some books," Dr. Heberden remarks, "speak of *intermitting* pulses as dangerous signs, but I think without reason; for such trivial causes will occasion them, that they are not worth regarding in any illness, unless joined with other bad signs of more moment. They are not uncommon in health, and are perceived by a peculiar feel at the heart by the persons themselves every time the pulse intermits." We have generally considered these intermitting pulses as of dyspeptic origin, and have seen them removed, in fevers, by a purge. Where the pulse intermits, and is very unequal in its beats, and there is at the same time palpitation of the heart, oppression of the breathing, lividity of countenance, or other serious symptoms, then the intermission is probably one among the signs of some affection of the heart; but in ordinary cases, occurring with symptoms of indigestion, or slight feverishness, it is perfectly void of danger. It is curious, indeed, that irregularities of the pulse are sometimes habitual, and disappear only with good health. Dr. Heberden says, "many persons will likewise have unequal pulses without any other sign of ill health. I have met with two who, in their best health, always had pulses very unequal, both in their strength and the spaces between them; and upon their growing ill, their pulses constantly became regular; and it was a never-failing sign of their recovery, when their arteries began again to beat in their usual irregular manner." Med. Transf.

PULSE is also used for the stroke with which any medium is affected by the motion of light, sound, &c. through it.

Sir Isaac Newton demonstrates, lib. ii. prop. 48. Princip. that the velocities of the pulses in an elastic fluid medium (whose elasticity is proportionable to its density) are in a ratio compounded of half the ratio of the elastic force directly, and half the ratio of the density inversely: so that in a medium whose elasticity is equal to its density, all pulses will be equally swift.

PULSE, in *Agriculture*, a term applied to all leguminous plants, as pease, beans, tares, vetches, lupins, &c. Many of these are highly valuable as food, and for being made into hay.

And all the species and varieties of pulse afford great abundance of excellent manure when turned into the soil, in the state in which nature presents them. The custom of ploughing in green succulent plants of this kind is very ancient. All the Roman writers commend it highly. Columella, particularly, advises lupins as a manure, which, if cut down and turned in while green, will have as good effect as the best and strongest dunging whatever. They may be sown upon poor land about the middle of September, and be ploughed in before they attain their full growth. In gravelly soils they should be cut down after they have put forth their second flower; and in strong lands, when a little more advanced. In the former of these grounds they are turned in while young and tender, that they may quickly rot; and in the latter, are let stand till they grow stronger, that they may produce a better effect on the stiff clods of earth, and render them more mellow and friable. Pease, beans, lupins, vetches, and other succulent plants, have also been strongly recommended by the older writers on husbandry, as excellent manures, especially for sandy ground. These plants en-

rich the earth greatly if ploughed in either green, or when in bloom. In strong land they are advised not to be turned down till the pods begin to harden.

PULSE Crops, any of those crops which have been just noticed. In improved husbandry they are now seldom cultivated with the view of being turned in as manure, but as a row or green crop, for the purpose of cleaning and improving the land, being mostly interposed between those of the white corn kind, so as to prevent the necessity of having so frequent recourse to the more uneconomical practice of naked fallowing. In this way they are found highly beneficial. And Lister has recommended for the improvement of sandy, light ground, or any clay well fanded, all plants of the pulse or pea kind, and particularly, upon experience, the wood vetch, which, besides its being perennial, (at least with respect to its roots,) and its thriving even in woods and among bushes in almost every country, has these qualifications, that it shoots out a thousand roots far and wide, and spreads itself under ground, like quick-grass; whilst it is so rampant above ground, that it will climb a fathom and a half upon measure, and preserve itself in spite of weeds or drought. It may be set as well as sown, in furrows. For the former of these purposes the roots may be dug up in September, which is also the time for gathering the ripe seed. The growth of the plants will be greatly advanced by setting their roots; for the older they are, the stronger, more numerous, and fuller of buds their shoots will be. He sowed in the latter end of March the seed which he had gathered in September, and had that year a very great increase, the bed being thick covered over with grass above two feet high: but it did not flower that year. He reckoned that one pea had put forth above thirty shoots in August of the first year. In the second year it flowered by the middle of June, and bore a wonderful crop, the roots being innumerable. He has observed this pea very common in all the mountains as well as plains of this country where bushes or hedges are. Both the pea and grass are very sweet, and very agreeable to cattle, as he has found on trial. See **VETCH**.

But buck-wheat and vetches are the two plants most commonly sown in this country for being turned in as manure. The best time for ploughing them in is when they are coming into bloom; being then in their most succulent state. Some farmers turn down their second crop of clover to enrich the land for wheat in the autumn. This should be done early enough to give the plants sufficient time to putrify thoroughly before the grain is sowed; otherwise it might prove prejudicial.

However Mr. Elliot, of America, prefers millet to every other plant for green dressing of land, on account of the cheapness of the seed, and the largeness of the stalks and leaves, which must afford a good coat to turn in when ploughed. An old farmer who had long been in the practice of green dressing, assured him that he had increased the strength of his land to a great degree, in a few years, by the following method: After his oats were harvested, he added a little seed to the scattered grains, and then ploughed them in. Towards the end of September, he ploughed in the green oats, and sowed rye; and the next summer, when the rye was well grown and full of sap, he ploughed that in at the usual sowing season, then sowed wheat, and always had a large crop. See **BEANS**, **BUCK-Wheat**, **PEASE**, &c.

PULSE-Glass, a well-known instrument invented by Dr. Franklin, and serving to shew the quick evaporation which would take place if we had no atmosphere. This is a small tube with a bulb at each end, exhausted of its air, and con-

taining a small quantity of spirits of wine. If this instrument be held sloping, with one end in the palm of the hand, the heat of the hand will quickly cause the spirit to boil, but the vapour rising to the other end becomes condensed as soon as it is in contact with the cold glass. This shews that a very small degree of heat would be sufficient to evaporate most fluids, if we had no atmosphere. It also shews, that evaporation produces cold; for at the instant when the spirit begins to boil, a sensation of sudden cold is felt on that part of the hand where the bulb rests.

PULSILOGIUM, a name given by authors to a pulse-watch, or instrument to measure the celerity of the pulse. Sanctorius was the first inventor of this machine; but several have since spoken very largely in favour of it, and sir John Floyer wrote a treatise on this subject.

PULSION, formed from *pello*, *I drive*, the act of driving or impelling a thing forwards.

PULSLATER BAY, in *Geography*, a bay on the S. coast of Wales, and county of Pembroke; two miles N. of St. Gwen's Head.

PULSNITZ, or **POLSNIZA**, a town of Lusatia, on a river of the same name, with a citadel; 15 miles N.E. of Dresden. N. lat. $51^{\circ} 10'$. E. long. $13^{\circ} 59'$.

PULST, a town of Bavaria, in the bishopric of Bamberg; two miles S.W. of Mark Schorgast.

PULSUS LATUS. See **LATUS Pulsus**.

PULTAVA, in *Geography*. See **POLTAVA**.

PULTENÆA, in *Botany*, received that appellation from the writer of the present article, in honour of his friend Dr. Richard Pulteney; (see that article.)—Sm. Bot. of New Holland, 35. Ann. of Bot. v. 1. 502. Willd. Sp. Pl. v. 2. 506. Ait. Hort. Kew. v. 3. 17.—Class and order, *Decandria Monogynia*. Nat. Ord. *Papilionacea*, Linn. *Leguminosæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, permanent, bell-shaped, two-lipped; the upper lip in two deeply separated, broadish segments; lower in three narrower ones, about the same length; with a lanceolate appendage at each side, between the two lips, sometimes at the base of the tube. *Cor.* papilionaceous, of five petals, with claws; standard obovate, emarginate, ascending; wings two, half-obovate, shorter than the standard, with an angle at the upper edge; keel as long as the wings, of two obovate petals, cohering by their lower edge, with an angle, toward the base, above. *Stam.* Filaments ten, separate, awl-shaped, nearly equal, declining, rather shorter than the keel, anthers small, roundish, two-lobed. *Pist.* Germen superior, sessile, ovate, with rudiments of two seeds; style awl-shaped, ascending; stigma simple, acute. *Peric.* Legume a little longer than the calyx, ovate, acute, turgid, of one cell and two valves. *Seeds* two, roundish-kidney-shaped, on short stalks, inserted into the upper edge of each valve, near the base, "with a lobed notched appendage." *Brown*.

Ess. Ch. Calyx five-cleft, two-lipped, with an appendage at each side. Corolla papilionaceous; wings shorter than the standard. Germen sessile. Style awl-shaped. Stigma acute. Legume of one cell, with two seeds; their appendages lobed and notched.

1. *P. stipularis*. Scaly Pultenæa. Sm. Bot. of N. Holl. 35. t. 12. Tr. of Linn. Soc. v. 9. 245. Curt. Mag. t. 435. Willd. n. 1. Ait. n. 6.—Leaves linear, pointed, flat, somewhat fringed, straight. Stipulas solitary, divided, two-ribbed, torn, rather spreading. Heads many-flowered. Native of New South Wales. First raised from seed, in 1792, in the garden of Benjamin Robertson, esq. at Stockwell. It is a green-house shrub, flowering from April to July. The stem is determinately branched; the branches clothed

clothed with crowded, rather spreading *leaves*, an inch long, narrow, deep green, most fringed in an early state, on short flat *stalks*, with intrafoliaceous, solitary, deeply cloven, acute, chaffy *stipulas*. *Flowers* of a golden yellow, in large, terminal, solitary heads; their standard marked with a purple ring. *Calyx* reddish; its appendages inserted about the middle of the tube. *Legume* brown, invested below with the withered *calyx*, and crowned with the recurved *style*.

2. *P. vestita*. Awned Pultenæa. Brown in Ait. Hort. Kew. n. 7.—“Leaves linear-lanceolate, pointed, smooth; their edges inflexed. *Stipulas* fringed. *Flowers* axillary. *Calyx*-teeth and appendages awned.”—Gathered by Mr. Brown on the south coast of New Holland. Introduced at Kew, in 1803, by Mr. Peter Good. It flowers, in the green-house, from April to July.

3. *P. paleacea*. Chaffy Pultenæa. Sm. Tr. of Linn. Soc. v. 9. 246. Willd. n. 2.—Leaves linear, pointed, revolute; recurved at the point. *Stipulas* solitary, two-ribbed, sheathing, membranous, torn. Heads of few flowers.—Gathered in New South Wales, by John White, M. D. This *shrub* is much smaller, and more branched, than *P. stipularis*; with small, but very numerous, heads of yellow *flowers*, whose long pointed *bractæas* rise much above them. *Leaves* silky beneath, with close-pressed hairs, but not fringed. *Stipulas* dilated, thin, membranous, white, with two brown ribs; they embrace the stem, and are very conspicuous, though liable to be injured, and partly obliterated, by time and weather.

4. *P. elliptica*. Elliptical Pultenæa. Sm. Tr. of Linn. Soc. v. 9. 246.—Leaves elliptical, concave, rather hairy. *Stipulas* solitary, two-ribbed, villous, imbricated. *Flowers* axillary.—Native of Port Jackson, New South Wales. The *leaves* differ from all other known *Pultenææ*, with simple *stipulas*, in their elliptical form. They are concave above; convex, and rough with prominent points, beneath; their margin now and then furnished with long loose white hairs. *Stipulas* intrafoliaceous, simple, closely pressed to the branches, and so long as to lap over each other; their shape likewise is elliptical, with two ribs and an intermediate furrow, and they are shaggy with white hairs. *Flowers* deep yellow, axillary, but so crowded about the tops of the branches as often to seem terminal and capitate, at least till the *fruit* advances. Appendages attached to the base of the *calyx*, whose teeth are long, slender, and hairy.

5. *P. linophylla*. Flax-leaved Pultenæa. Schrad. Sert. Hannov. 28. t. 18. Willd. n. 3. Sm. Tr. of Linn. Soc. v. 9. 247. Ait. n. 5.—Leaves linear, abrupt with a small point, hairy. *Stipulas* minute, in pairs. *Bractæas* ovate, shorter than the *calyx*. *Flowers* capitate.—From the same country. It first flowered at Kew, in January 1791, and was given us by Mr. Aiton. Its habit is more upright and wand-like than *P. paleacea*, n. 3; the *leaves* somewhat angular and dilated at their apex, as well as slightly pointed. The minute separate *stipulas*, shorter than the *footstalks*, and the ovate blunt *bractæas*, which, instead of rising above the *flowers*, are shorter than the *calyx*, abundantly distinguish this species from all the foregoing.

6. *P. retusa*. Obtuse-leaved Pultenæa. Sm. in Ann. of Bot. v. 1. 502. Tr. of Linn. Soc. v. 9. 247. Ait. n. 4.—Leaves linear, abrupt, pointless, smooth. *Stipulas* minute, in pairs. *Bractæas* ovate. *Flowers* capitate.—Native of New South Wales. Said to have been introduced at Kew, by Sir J. Banks, in 1789. It flowers in the green-house in April and May. This is very like the last in habit, but the *leaves* are quite smooth, and moreover not dilated at their apex. We have found the *bractæas* shorter than the *flower-*

stalks; but Mr. Brown characterizes them as rather longer than the *calyx*; so that it appears they are variable in this respect.

7. *P. scabra*. Rough-leaved Pultenæa. Brown in Ait. n. 3.—Leaves wedge-shaped, revolute, abrupt, with a bristly point; rough above; villous beneath. *Stipulas* in pairs, setaceous, recurved. *Flowers* capitate.—Found in New South Wales, by Dr. Brown, and sent to Kew, in 1805, by Mr. G. Caley. It blooms from May to July. There are said to be but few *flowers* in each head.

8. *P. obcordata*. Heart-leaved Pultenæa. Andr. Repof. t. 574. Brown in Ait. n. 2.—Leaves inversely heart-shaped, abrupt, smooth, with a spinous point. *Stipulas* minute, in pairs. *Flowers* capitate.—Gathered in Van Diemen’s island by Mr. Brown. Sent to Mr. Lambert from thence by Mr. Littlejohn, in 1808. It is a green-house plant, flowering in summer, and differs from the following chiefly in the obcordate shape of its *leaves*, which are nearly half as broad as they are long. The *flowers* are large and handsome, yellow, variegated with purple. Their appendages stand about the middle of the *calyx*.

9. *P. daphnoides*. Daphne-like Pultenæa. Sm. in Ann. of Bot. v. 1. 502. Tr. of Linn. Soc. v. 9. 247. Andr. Repof. t. 98. Curt. Mag. t. 1399. Willd. n. 6. Ait. n. 1.—Leaves obovate, smooth, with a spinous point. *Stipulas* minute, in pairs. *Flowers* capitate. *Bractæas* ovate, shorter than the *calyx*.—This was among the first plants received from New South Wales; we had specimens from Dr. White in 1789. It was also raised from seed in the gardens soon afterwards, and has attracted general notice by its size and beauty, vying in those particulars with *P. stipularis*, n. 1. The *leaves* are about thrice as long as broad, obovate; not obcordate like the last. *Stipulas* separate, very small. *Flowers* large, yellow, with a purple keel, and purplish-brown hairy *calyx*, forming large heads at the tops of the branches.

10. *P. flexilis*. Shining-leaved Pultenæa. Sm. in Ann. of Bot. v. 1. 502. Tr. of Linn. Soc. v. 9. 248. Ait. n. 9.—Leaves linear, somewhat obovate, flat, with a small point, quite smooth, as well as the *calyx*. *Stipulas* longer than the *footstalks*. *Flowers* axillary.—Native of New South Wales, where the late Col. Paterson is said to have first discovered it. Sir Joseph Banks sent seeds to Kew, about the year 1801. It flowers in the green-house in spring, and is an elegant, slender, rather drooping *shrub*, quite smooth in every part, with shining *leaves*, of a dark green, and copper-coloured *branches*. The foliage which usually attends the *flowers* is sometimes deficient, so that the latter become in appearance racemose, but the *stipulas* are always present. The perfectly smooth-sided *calyx* distinguishes this species from all the rest.

11. *P. villosa*. Villous Pultenæa. Sm. in Willd. n. 5. Ann. of Bot. v. 1. 503. Tr. of Linn. Soc. v. 9. 248. Ait. n. 8. Sims in Curt. Mag. t. 967.—Leaves elliptical, concave, hairy, as well as the stem and *calyx*. *Flowers* axillary.—From the same country; sent by Dr. White among his earliest communications. This is a dense bushy *shrub*, with numerous short leafy *branches*, and copious axillary solitary yellow *flowers*. The *leaves* are scarcely half an inch long, oval, concave, pointless, clothed with prominent hairs; and the *branches* are more densely villous. *Stipulas* longer than the *footstalks*, often connate. No *bractæas* are observable. The appendages of the *calyx* originate from near its base, and are longer than its tubular part, having a more leafy appearance than in any other species of *Pultenæa*. Mr. Andrews has published under the name of *P. villosa*, t. 309,

a very different shrub from the above, constituting a new and distinct genus, which the writer of the present article has named *Aotus villosa*, in Ann. of Bot. v. 1. 504, and which is figured under that appellation in Curt. Mag. t. 949.

PULTENEY, RICHARD, in *Biography*, a distinguished literary botanist and practical conchologist, as well as an able physician, was born at Loughborough, Feb. 17, 1730. He first settled as a surgeon and apothecary at Leicester; but having been educated as a Calvinistic dissenter, the good Christians of that town, who chanced to have different prejudices, of course gave him but little support. He struggled against pecuniary difficulties with economy, and shielded his peace of mind against bigotry, in himself or others, by looking "through Nature, up to Nature's God." His remarks and discoveries were communicated first to the Gentleman's Magazine, in 1750, as well as several subsequent years; and he intermixed antiquarian studies with his other pursuits. His botanical papers printed by the Royal Society, on the Sleep of Plants, and the Rare Plants of Leicestershire, procured him the honour of election into that learned body in 1762. In 1764 he obtained a diploma of Doctor of Physic from Edinburgh, even without accomplishing that period of residence, then usually required, and now indispensable; and his thesis on the *Cinchona officinalis* amply justified the indulgence of the university.

Soon afterwards, Dr. Pulteney was acknowledged as a relation by the earl of Bath, who had moreover imbibed a favourable opinion of his talents; which circumstances induced him to attach himself to that nobleman, as travelling physician. His lordship unfortunately died soon after, on which the subject of our memoir, becoming at a loss for a situation, hesitated whether to settle at London or elsewhere; but he soon decided in favour of Blandford in Dorsetshire, where there happened to be a vacancy. Here he continued in great reputation, and extensive practice, till his death, which happened on the 13th of October 1801, to the deep regret of all who knew him, in the 72d year of his age. His disease was an inflammation in the lungs, of only a week's duration.

Dr. Pulteney married, in 1779, Miss Elizabeth Galton, of Blandford, a lady who bore him no children, but whose society and attainments contributed very essentially to his happiness, and who has in every respect proved herself worthy of her amiable and distinguished husband. His remains were interred at Langton, near Blandford, a tablet to his memory having been placed, by his widow, in the church of the last-mentioned town. This monument is decorated with a sprig of the *PULTENÆA stipularis*, see that article; but in obedience to the strict commands of the deceased, the inscription is of the simplest kind.

As an author, Dr. Pulteney was conspicuously distinguished, by his General View of the Writings of Linnæus, and his Sketches of the Progress of Botany in England. The former, published in 1782, in one volume 8vo., has contributed more than any work, except perhaps the Tracts of Stillingfleet, to diffuse a taste for Linnæan knowledge in this country. It proved a very popular book, and a new edition was soon called for. This however did not appear during the author's life; but has been published by his learned and much-valued friend Dr. Maton, who has prefixed, to this handsome quarto, portraits of Linnæus and his biographer, with a life of the latter, to which we are principally indebted for the above particulars. A translation of Linnæus's celebrated manuscript diary of his own life is subjoined. Of this we have spoken in its proper place. See LINNÆUS.

The "Sketches of the Progress of Botany," making two octavo volumes, appeared in 1790, but did not become so popular as the Account of Linnæus. These volumes, nevertheless, abound with original and valuable information; nor is it any reproach to the memory of their intelligent author, that they do not contain, as he was well aware, all that might have been collected on every subject. Their most learned readers will ever be more sensible of their merits than their defects.

Dr. Pulteney had been associated with the Linnæan Society, soon after its first institution, and he ever retained a great attachment to that body, as well as to its founder. Several of his papers appear in the Transactions of the Society; and he gave a final proof of his regard, in the bequest of his valuable museum of natural history. He stipulated that his collections should always be kept separate from any others which the Society might possess; and he provided that it should be at the option of the members, either to keep this museum entire, or to dispose of it, in order to raise a fund, whose interest should be expended annually in a medal, for the best botanical paper read before the Society in the course of the year. It was without hesitation determined, that these treasures should be preserved entire, as the best and most useful memorial of a benefactor to science, to whom a large portion of this corporate body were individually and strongly attached. Few men have enjoyed more entirely the respect and affection of his acquaintance than Dr. Pulteney. An air of urbanity and gaiety was diffused over his countenance and manners, which bespoke the simplicity, candour, and liberality of his mind. His ardour for science was unbounded; and as lively at the close of his life, as at the beginning of his literary career. His religion was unaffected, and devoid of bigotry or intolerance; the only feelings which he contemplated without sympathy or indulgence. His conversation, like his morals, was spotless; and his cheerfulness flowed from the never-failing spring of a benevolent and honest heart. Pulteney's Works. Maton's Memoirs of Dr. Pulteney, prefixed to his View of the Writings of Linnæus.

PULTENEY'S *Island*, in *Geography*, an island in the Mergui archipelago, of an oval form, about eight miles in circumference. N. lat. 10° 46'.

PULTURA, formed from *pulsare*, to knock, to ask, in our *Old Law Books*, denotes a previous demand or examination: on account of the monks, who, before they were admitted into the monasteries, *pulsabant ad fores*, knocked at the doors for several days. "Et volo, ut sint quieti de omnibus causis, et querelis, et placitis ballivorum et præpositorum hundredi, et a pultura serjanorum," *i. e.* from the examination of serjeants; "et de rewardo forestarum," *i. e.* the visitation of the forests.

PULTUSK, in *Geography*, a town of the duchy of Warsaw, late in Masovia, on the Narew; 25 miles N.N.E. of Warsaw. N. lat. 52° 36'. E. long. 21° 10'.

PULVERARIA, in *Botany*, so named from its powdery habit, a genus of *Lichenes* in the *Methodus* of professor Acharius, subsequently sunk in his *Lepraria*. See LICHENES.

PULVERATICUM, in *Roman Antiquity*, the fee paid to surveyors for their trouble; also a sum exacted from the provincial cities by their garrison.

PULVERIZATION, PULVERIZATIO, the art of pulverizing, or reducing a dry body into a fine powder.

This is performed, in friable bodies, by pounding or beating in a mortar: but to pulverize malleable ones, other methods must be taken.

To pulverize lead, or tin, the method is this: rub a round wooden box all over the inside with chalk; pour a little of the melted metal nimbly into the box, when, shutting the lid, and shaking the box briskly, the metal will be reduced into powder.

PULVERIZATION, in *Agriculture*, the separation of the earthy particles of soils, in such a manner, as to render them of a fine mellow mouldy quality, or to partake of the nature of powder. This state of mould is obtained in different ways, as by frequent ploughing and harrowing in the less stiff sorts of land; and in those of the more heavy and retentive descriptions, by the same means, and the frequent exposure of them to the influence and effects of the atmosphere, with the growth of such sorts of crops as produce a close thick shade upon them. This state of the soil, when produced in lands, has various advantages, the roots of plants penetrate it with more readiness and greater facility. It admits of the particles of moisture more equally, and in a more extensive manner, by which the fibrous roots of the crops are more fully supplied with nourishment. It likewise produces a more equal and regular mixture of the different materials of which the soils are constituted or composed, so as to yield the nutrition of plants in a more extensive and abundant manner. The rains in the vernal months are also, by this means, more abundantly drank up and retained, in consequence of their sinking to a greater depth, as well as more equally diffused through the different parts, from which much advantage is derived in the support of the crops. By this fineness in the particles of the soils, the manures, or other ameliorating substances, are also more extensively and more perfectly blended and incorporated with them, and of course a more equal and abundant supply of nutritious materials provided for the growth and increase of the crops, of whatever kind they may be. And the air of the atmosphere is more intimately and abundantly received and blended with them. These are a few of the various advantages that may be derived from the pulverization of land; but there are many others noticed by writers on agriculture and rural economy. See **FALLOWING**.

In consequence of these beneficial effects, it is evidently a state of tillage that ought as much as possible to be aimed at by the intelligent cultivator, by the judicious ploughing, harrowing, and laying up of his lands, at those seasons when they can be the most acted upon and influenced by the extensive operation of atmospherical and other agents. See **PLOUGHING** and **TILLAGE**.

PULVILLUS, in *Surgery*, a term used to express a little pledget-bolster, or compress.

PULVINARIA, in *Roman Antiquity*, cushions upon which the statues of the gods were laid in the temples, at the time that thanks were given for some signal victory.

PULVINATED, **PULVINATUS**, in the *Ancient Architecture*, a term applied to a frieze, which swells, or bulges out, in manner of a pillow, *pulvinus*: whence the name.

PULVIS, in *Chemistry* and *Medicine*. See **POWDER**.

PULVIS Antilyssus, was originally composed of equal parts of the lichen cinereus terrestris, or ash-coloured ground liverwort, and black pepper; but this quantity of pepper rendering the medicine too hot, only one part of the pepper is now used to two of the lichen. See **ANTILYSSUS Pulvis**, and **LICHEN**.

PULVIS Fecundans, in *Natural History*, a name given by late writers to that fine powder, which is contained in capsules upon the stamina or threads in the flowers of plants, and is called by some English writers the *male-dust*, and in

general the farina of flowers. See **FARINA**, and **FECUNDATION of Plants**.

PULVIS Fulminans, or the thundering powder. See **FULMINANS**.

PULVIS Patrum, the Jesuit's powder. See **CORTEX Peruvianus**.

PULVIS Puteolanus, in *Natural History*, the name of a fossil substance, found in form of powder, and famous for its consolidating under water. The accounts of it seem, however, to be a little erroneous. See **POZZOLANA**.

PUMICE-STONE, Lat. *Pumex*, Fr. *Pierre Pome*, in *Mineralogy*, a light, spongy, vitreous stone, found in the neighbourhood of certain volcanoes, and used for polishing metals and marble, and smoothing the surface of wood and pasteboard. It is said to form a good glaze for pottery. The specific gravity of the lighter pumice-stones does not exceed 0.914; they swim on water. The constituent parts of pumice from Lipari, according to Klaproth, are,

Silex	-	-	-	-	-	75.5
Alumine	-	-	-	-	-	17.5
Oxyd of iron, and a trace of manganese						1.75

The characters of the different kinds of pumice, and the situation from which they are chiefly procured, are perspicuously described by Dolomieu, in his "Voyages aux Isles de Lipari."

The island of Lipari, he says, is an immense magazine of pumice-stones for all Europe; notwithstanding the quantity which has been taken away, they do not appear diminished. Whole mountains are entirely formed of pumice. Quarries of vast extent have been dug in this stone at the feet of the mountains, and in the vallies the whole island appears to have a base of this singular substance. The essential characters of the pumice-stones of Lipari are a white or greyish-white colour, a coarse grain, and a fibrous texture. The pores are long; they have a glassy or silky lustre. Pumice-stones are generally lighter than common solid lavas, and are less hard. They are nearly free from admixture with iron, and to the absence of this metal part of their qualities is to be attributed. Pumice-stones may be divided into five species.

The first are grey, and have a compact grain, the pores and fibres being scarcely discernible: they have a considerable degree of weight and solidity: the fracture presents a surface somewhat vitreous. These stones are easily worked, and much used in the island for masonry. The city of Lipari is almost entirely built of this variety of pumice.

The second kind of pumice is equally grey, but much lighter and more porous; the fibrous texture is more strongly marked than in the preceding species, but these stones will not float on water. They are used in the construction of cellars, and are exported in great quantities into the maritime towns of Naples and Sicily. The third kind are light, porous, and fibrous, they have a silky lustre when broken, they swim on water, and unite a coarse grain with a certain degree of consistence, which fits them for the purpose of polishing marbles and metals. These are the only kind of pumice-stones known in foreign countries. The fourth species is a very white and extremely light stone, of a loose texture, and a slight degree of consistence. It appears to have arrived at the extreme degree of rarefaction which a substance can attain, and preserve a union of its parts. It is not used for any purpose. When it falls into the sea, it swims on the surface, and is carried to a great distance, being commonly found on the coasts of Sicily, Calabria, and the kingdom of Naples. A fifth species of pumice might be added, which is formed of the latter species, rarefied by heat, so as to have the affinity of aggregation of the particles destroyed,

destroyed, and is pulverized by a kind of volatilization. Pumice-stones appear to have flowed in the manner of lavas, and like them to have formed great currents, which are found at different depths over each other round the group of mountains in the centre of Lipari. They are thus piled in great homogeneous masses, in which quarries are opened for building stone. The heavy pumice occupies the lower part of these currents or masses; the light pumice-stones are above. This arrangement is conformable to that of common currents of lavas, of which the porous lavas always occupy the upper part. This position proves the identity of the nature of the heavy solid pumice with that which is light and porous, and shews that this great lightness is not an essential character of these stones. The elongated fibre of pumice-stones is always in the direction of the volcanic currents, and appears to have depended on the semifluid state of the lava, which draws out in threads, like melted glass.

When pieces of pumice-stone have the fibres bent in every direction, we may be assured, says Dolomieu, that they have been ejected in detached masses, and have never been part of the current. The silky threads of pumice are almost a perfect glass. Spallanzani, who visited Lipari after Dolomieu, describes the Campo Bianci, from whence most of the pumice-stones are procured, as a lofty and extensive mountain, formed wholly of white pumice-stones. When seen at a distance, it excites the idea that it is composed entirely of pure snow, from the summit to the foot. This prodigious mass of pumice is not one solid whole, but an aggregation of numerous beds of pumice successively placed on each other; which beds are distinguishable by their colour, and in many places project from the mountain. They are almost always disposed horizontally, and their position is not dissimilar to stratification. Each bed of pumice does not form a distinct whole, but it consists of an aggregate of globular masses of pumice united together, but without adhesion. Hence Spallanzani is led to infer that these pumices were thrown out of the volcano in a state of fusion, and took a globular form in the air, which they preserved at the time of their sudden congelation. We have, however, many instances, in the mineral kingdom, of substances assuming a globular form, which we cannot suppose to have been thrown out of volcanoes in detached masses; as in mountains of basalt and granite, and even in some lime-stone. In the process of glass-making, various phenomena are frequently presented, which, if properly attended to, would elucidate the formation of many volcanic products, and particularly of their tendency to assume a globular form. "Glass vessels are well known to be convertible into Reaumur's porcelain, by the internal arrangement of their particles, without losing their external form, and consequently at a temperature much below that requisite for fusion. The change of glass into Reaumur's porcelain does not arise from an evaporation of the alkali, as has been asserted, but from a regular arrangement of the molecules of the glass. It commences by the formation of fibres perpendicularly to the surface of the glass, and penetrating into it. At nearly the same time, smaller radiated globules are formed in the interior of the glass, and the re-union of these with the fibres by their mutual increase, forms the whole into a new substance." See Experiments of G. Watt, Phil. Transf. 1804.

The globes of pumice on the mountains of Lipari were probably formed by a similar arrangement of the particles during the cooling of the lava. A great quantity of these globular pumices, which Spallanzani observed on the sea-shore near Campo Bianci, were probably detached from the mountain by gradual disintegration, for it scarcely seems possible, for balls of a substance so light and frangible to

have preserved their form in falling; or if we suppose them to have been in a semifluid state, they must have been flattened by the fall. It is a singular fact, that the islands of Lipari and Vulcano are almost the only volcanoes in Europe that produce pumice-stones in considerable quantities. Dolomieu suggests that this may be owing to the nature of the mountains in which the volcanoes break out, and to the great degree of heat which has been in action. From the similarity of the constituent parts of felspar and pumice, it may be inferred that felspar, or granitic rocks containing a large portion of felspar, have been the substances from which pumice was formed, but a more than common degree of heat appears to have been requisite. The immense bed of lava which burst from the sides of Etna in 1669, and traversed Catania, has, according to Dolomieu, a base of granite, the constituent parts of which are not changed. When this lava is exposed to a strong heat in a furnace, it vitrifies, and is changed into an opaque porous frit, resembling pumice, a certain proof, adds Dolomieu, that this vast bed, by a more active heat, would have been converted into stones similar to those of Lipari.

By a long continued heat, pumice-stone melts into a vitreous, semi-transparent mass, in which a number of small crystals of white felspar are discernible. By intense heat, common glass is in some instances so rarefied as to resemble pumice. Brongniart describes a red pumice found on Vesuvius, and a greenish pumice from the external volcanoes of Auvergne. Ferrara also mentions a stone ejected from Etna in 1802, of which one half was lava and the other half pumice. Probably this was formed from a rock composed of hornblende and felspar. Some geologists have carried their attachment to theory so far, as to deny the volcanic origin of pumice, because it is sometimes associated with rocks, which they assert were not of igneous formation. To this opinion it will scarcely be thought necessary to reply, further than to observe that pumice is sometimes seen floating on the sea, at a vast distance from land, which appearance can only be accounted for by the action of submarine volcanoes. Mr. Dove, captain of an Indiaman, observed immense quantities of pumice on the Atlantic ocean, in S. lat. $35^{\circ} 36'$ W. long. 9° ; the shoals of it continued floating over the surface of the sea for several days, and extended 317 miles. Phil. Transf. vol. xxxv. p. 444.

The volcanoes of the Molucca islands are said to eject such prodigious quantities of pumice, that the ocean sometimes appears covered with it for many leagues.

Though Dolomieu describes a white or greyish-white colour as a distinguishing character of the pumice-stones of the Lipari islands, it would appear, from the description of Brongniart and Ferrara, above referred to, that pumice may be of various colours, according to the nature of the stone which has been fused; but rocks which melt into a colourless glass, and are composed principally of felspar, seem to be the base from which most pumice-stones have been formed. See VOLCANO.

PUMMEL. See POMMEL.

PUMP, ANTLIA, in *Hydraulics*, a machine formed on the model of a syringe, for raising of water.

Vitruvius ascribes the first invention of pumps to Ctesibius the Athenian; whence the Latins call it *machina Ctesibiana*, or *organum Ctesibicum*.

Pumps are distinguished into several kinds, with regard to the several modes of their acting. As the

Common sucking-pump, which consists of a pipe open at both ends, in which is a moveable piston, bucket, or sucker, as big as the bore of the pipe in that part in which it works, and leathered round so as to fit the bore exactly; and may be

PUMP.

be moved up and down, without admitting any air to come between it and the pipe or pump barrel. There are several kinds of buckets: the most simple of all, which is commonly used for ordinary pumps, consists of a cylindric piece of wood, whose diameter is somewhat less than the bore of the barrel, that it may move in it freely, having a hole quite through the middle of it. Upon the top of this there is an iron piece fastened to a rod of iron or wood, which goes quite to the top of the pump, and by means of which the motion is given to the bucket. Near the top of the cylindric wood, there is a leather ring fastened round it, which goes a little higher than its top: the hole in the wood is stopped by a valve, made of a round piece of leather, fastened in one part of the wood with nails. Upon this there is an iron plate, a little larger than the bore of the hole, and another iron plate under it, a little less than the same bore; and the plates and leather are fastened together by means of a rivet or screw in the middle of them. When the bucket is put into the barrel, and the leather becomes wet, it will apply itself to the sides of the barrel, and prevent the passage of the air. The use of the two iron plates is to sustain the pressure of the water which would otherwise bend the leathers. For larger pumps, the bucket is made in the following manner: there is a hollow piece of brass, almost equal at top to the bore of the barrel, but small at the bottom, having at its top a brass bar, and at the bottom two notches to receive the ends of another brass bar, of the same figure as that at the top. Round the brass piece there goes a leathern ring, fastened to it at its lower part by means of an iron ring, which, being almost at the bottom of the brass piece, is not so large as its top, and consequently does not touch the sides of the barrel: this leathern ring should go a little higher than the cross-piece at bottom. The valve consists of a piece of leather almost equal to the top of the brass piece, covered by two iron plates of the same size as the leather, and having under it two plates somewhat smaller than the bore of the brass piece at its top; these iron plates and leathers are fastened together with screws. This valve must be applied to the top of the brass piece or box, so that the brass bar upon it may be between the two iron plates under the leather. The whole is fastened together by means of an iron piece, whose lower part goes through the holes in the middle of the valve, and the two brass rods, so that its upper part getting between the two upper iron plates of the valve, presses upon the leather, and makes it apply itself close to the upper brass bar. This iron piece or rod ought to have two holes, one at the bottom, just under the lower brass rod, to hold it close by means of a pin or key; and another at its top, to fasten it to another iron rod, which is continued quite to the top of the pump, in order to give motion to the bucket. The chief advantages of this kind of buckets are, that they give the freest passage to the water, having the least friction possible, as they touch the barrel only at the upper end of the brass box; and that the sand or gravel, which is commonly mixed with the water, cannot get between the bucket and the barrel, because the leathern ring is higher than the brass tube; besides, if by any accident the motion of one side of the valve were hindered, the other would serve till it were mended. See VALVE.

The construction of pumps is usually explained by glass models, in which the action both of the pistons and valves may be seen. In order to understand the structure and operation of the common pump, let the model DCBL (*Plate XIV. Hydraulics, fig. 4.*) be placed upright in the vessel of water K, the water being deep enough to rise at least as high as from A to L. The valve *a* on the

moveable bucket G, and the valve *b* on the fixed box H, (which box quite fills the bore of the pipe or barrel at H,) will each lie close, by its own weight, upon the hole in the bucket and box, until the engine begins to work. The valves are made of brass, and covered underneath with leather for closing the holes the more exactly: and the bucket G is raised and depressed alternately by the handle E and rod D*d*, the bucket being supposed at B before the working begins.

Take hold of the handle E, and thereby draw up the bucket from B to C, which will make room for the air in the pump all the way below the bucket to dilate itself, by which its spring is weakened, and then its force is not equivalent to the weight or pressure of the outward air upon the water in the vessel K: and, therefore, at the first stroke, the outward air will press up the water through the notched foot A, into the lower pipe, about as far as *e*: this will condense the rarefied air in the pipe between *e* and C to the same state it was in before; and then, as its spring within the pipe is equal to the force or pressure of the outward air, the water will rise no higher by the first stroke; and the valve *b*, which was raised a little by the dilatation of the air in the pipe, will fall, and stop the hole in the box H; and the surface of the water will stand at *e*. Then depress the piston or bucket from C to B, and as the air in the part B cannot get back again through the valve *b*, it will (as the bucket descends) raise the valve *a*, and so make its way through the upper part of the barrel *d* into the open air. But upon raising the bucket G a second time, the air between it and the water in the lower pipe at *e* will be again left at liberty to fill a larger space; and so its spring being again weakened, the pressure of the outward air on the water in the vessel K will force more water up into the lower pipe from *e* to *f*; and when the bucket is at its greatest height C, the lower valve *b* will fall, and stop the hole in the box H, as before. At the next stroke of the bucket or piston, the water will rise through the box H towards B, and then the valve *b*, which was raised by it, will fall when the bucket G is at its greatest height. Upon depressing the bucket again, the water cannot be pushed back through the valve *b*, which keeps close upon the hole whilst the piston descends. And upon raising the piston again, the outward pressure of the air will force the water up through H, where it will raise the valve, and follow the bucket to C. Upon the next depression of the bucket G, it will go down into the water in the barrel B; and as the water cannot be driven back through the now, close valve *b*, it will raise the valve *a* as the bucket descends, and will be lifted up by the bucket when it is next raised. And now, the whole space below the bucket being full, the water above it cannot sink when it is next depressed; but upon its depression, the valve *a* will rise to let the bucket go down; and when it is quite down, the valve *a* will fall by its weight, and stop the hole in the bucket. When the bucket is next raised, all the water above it will be lifted up, and begin to run off by the pipe F. And thus, by raising and depressing the bucket alternately, there is still more water raised by it; which getting above the pipe F, into the wide top I, will supply the pipe, and make it run with a continued stream.

So, at every time the bucket is raised, the valve *b* rises, and the valve *a* falls; and at every time the bucket is depressed, the valve *b* falls, and *a* rises.

As it is the pressure of the air or atmosphere which causes the water to rise, and follow the piston or bucket G as it is drawn up: and since a column of water 32 feet high is of equal weight with as thick a column of the atmosphere, from

PUMP.

from the earth to the very top of the air; therefore the perpendicular height of the piston or bucket from the surface of the water in the well must always be less than 32 feet; otherwise the water will never get above the bucket. But when the height is less, the pressure of the atmosphere will be greater than the weight of the water in the pump, and will therefore raise it above the bucket: and when the water has once got above the bucket, it may be lifted by it to any height, if the rod D be made long enough, and a sufficient degree of strength be employed, to raise it with the weight of the water above the bucket, without ever lengthening the stroke.

The force required to work a pump, will be as the height to which the water is raised, and as the square of the diameter of the pump-bore, in that part where the piston works. So that, if two pumps be of equal heights, and one of them be twice as wide in the bore as the other, the widest will raise four times as much water as the narrowest; and will therefore require four times as much strength to work it.

The wideness or narrowness of the pump, in any other part besides that in which the piston works, does not make the pump either more or less difficult to work; except what difference may arise from the friction of the water in the bore, which is always greater in a narrow bore than in a wide one, because of the great velocity of the water.

The pump-rod is never raised directly by such a handle as E at the top, but by means of a lever, whose longer arm (at the end of which the power is applied) generally exceeds the length of the shorter arm five or six times; and, by that means, gives five or six times as much advantage to the power. Upon these principles, it will be easy to find the dimensions of a pump that shall work with a given force, and draw water from any given depth.

The quantity of water raised by each stroke of the pump-handle, is just as much as fills that part of the bore in which the piston works, be the size of the rest of the bore above and below the piston what it will. The pressure of the atmosphere will raise the water 32 feet in a pipe exhausted of air; but it is advisable never to have the piston more than 20 or 24 feet above the level of the surface of the water in which the lower end of the pump is placed: and the power required to work the pump will be the same, whether the piston goes down to be on a level with the surface of the well, or whether it works 30 feet above that surface; because the weight of the column of air that the piston lifts, is equal to the weight or pressure of the column of water raised by the pressure of the air to the piston. And although the pressure of the air on the surface of the well will not raise or force up the water in the pump-bore more than 32 feet, yet when the piston goes down into the column so raised, the water gets above it, and may then be raised to any height whatever, above the piston, according to the quantity of power applied to the handle of the pump for that purpose.

Pumps ought to be made so (says Mr. Ferguson) as to work with equal ease in raising the water to any given height above the surface of the well. And this may be done by duly proportioning the diameter of the bore (in that part where the piston works) to the height the water is to be raised, as that the column of water may be no heavier in a long pump than a short one; or indeed equally heavy in all pumps from the shortest to the longest, on a supposition that the diameter of the bore is of the same size from top to bottom: and whatever the size of the bore be, above or below that part in which the piston works, the power required to work the pump will be just the same as if the bore was of the same size throughout.

In order that a man of common strength may raise water by pumps with the same ease, to any height not less than 10 feet, or more than 100 feet, above the surface of the well, Mr. Ferguson has calculated the annexed table, in which the diameter of the bore is duly proportioned to the height; and in these calculations he supposes the pump handle to be a lever increasing the power five times.

Height of the Pump, in Feet, above the Surface of the Well.	Diameter of the Bore.		Water discharged in a Minute, in Wine Measure.	
	Inches.	100 Parts of an Inch.	Gallons.	Pints.
10	6	.93	81	6
15	5	.66	54	4
20	4	.90	40	7
25	4	.38	32	6
30	4	.00	27	2
35	3	.70	23	3
40	3	.46	20	3
45	3	.27	18	1
50	3	.10	16	3
55	2	.95	14	7
60	2	.84	13	5
65	2	.72	12	4
70	2	.62	11	5
75	2	.53	10	7
80	2	.45	10	2
85	2	.38	9	5
90	2	.31	9	1
95	2	.25	8	5
100	2	.19	8	1

In the first column, look for the number of feet the water is to be raised; then, in the second column you have the diameter of that part of the bore in which the piston or bucket works; and in the third column, the quantity of water which a man of ordinary strength can raise in a minute by the pump to the given height.

The quantity of water contained in a pipe of either of those heights in the table, supposing the diameter of the bore to be the same from top to bottom of the pipe, is 4523.2 cubic inches, or 19.58 gallons in wine measure, as near as the hundredth part of an inch in the diameter of the bore can make it.

Mr. Ferguson has calculated the following table, by which the quantity and weight of water in a cylindrical bore of any given diameter and perpendicular height may be very readily found.

Diameter of the cylindrical Bore one Inch.			
Feet high.	Quantity of Water in cubic Inches.	Weight of Water in Troy Ounces.	In Avoirdupois Ounces.
1	9.4247781	4.9712340	5.4541539
2	18.8495562	9.9424680	10.9083078
3	28.2743343	14.9137020	16.3624617
4	37.6991124	19.8849360	21.8166156
5	47.1238905	24.8561700	27.2707695
6	56.5486686	29.8274040	32.7249234
7	65.9734467	34.7986380	38.1790773
8	75.3982248	39.7698720	43.6332312
9	84.8230029	44.7411060	49.0873851

PUMP.

For tens of feet high, remove the decimal points one place towards the right hand; for hundreds of feet, two places; for thousands, three places; and so on. Then multiply each sum by the square of the diameter of the given bore, and the products will be the answer.

Example.

Qu. *What is the quantity and weight of water in an upright pipe 85 feet high, and 10 inches in diameter of bore? The square of 10 is 100.*

Feet high.	Cubic Inches.	Troy Ounces.	Avoirdupois Ounces.
80	753.982248	397.698720	436.332312
5	47.1238905	24.8561700	27.2707695
85	801.1061385	422.5548900	463.6030815
Multiply by	100	100	100
Anf.	80110.6138500	42255.4890000	46360.3081500

Which number (80110.61) of cubic inches being divided by 231, the number of cubic inches in a wine gallon, gives 342.6 for the number of gallons in the pipe: and 42255.489 troy ounces being divided by 12, gives 3521.29 for the weight of the water in troy pounds: and lastly, 46360.3 avoirdupois ounces being divided by 16, gives 2897.5 for the weight in avoirdupois pounds.

The power required to work a pump, or any other hydraulic engine, must not only be equal to the weight of the whole column of water in the pump bore, but as much superior to it as will overcome all the friction of the working parts of the engine.

PUMP, the Forcing, raises water through the box H (*fig. 5.*) not in the same manner as the sucking-pump does, when the plunger or piston *g* is lifted up by the rod *Dd*. But this plunger or forcer (see **FORCER**) has no hole through it, to let the water in the barrel *BC* get above it, when it is depressed to *B*; and the valve *b* (which rose by the ascent of the water through the box *H* when the plunger *g* was drawn up) falls down and stops the hole in *H*, the moment that the plunger is raised to its greatest height. Therefore, as the water between the plunger *g* and box *H* can neither get through the plunger upon its descent, nor back again into the lower part of the pump *Lc*, but has a free passage by the cavity around *H* into the pipe *MM*, which opens into the air-vessel *KK* at *P*; the water is forced through the pipe *MM* by the descent of the plunger, and driven into the air-vessel; and in running up through the pipe at *P*, it opens the valve *a*; which shuts at the moment the plunger begins to be raised, because the action of the water against the under side of the valve then ceases.

The water being thus forced into the air-vessel *KK* by repeated strokes of the plunger, gets above the lower end of the pipe *GHI*, and then begins to condense the air in the vessel *KK*. For as the pipe *GH* is fixed air-tight into the vessel below *F*, and the air has no way to get out of the vessel but through the mouth of the pipe at *I*, and cannot get out when the mouth *I* is covered with water, and is more and more condensed as the water rises upon the pipe, the air then begins to act forcibly by its spring against the surface of the water at *H*: and this action drives the water up through the pipe *IHG*, from whence it spouts in a jet *S* to a great height; and

is supplied by alternately raising and depressing of the plunger *g*, which constantly forces the water that it raises through the valve *H*, along the pipe *MM*, into the air-vessel *KK*.

The higher the surface of the water *H* is raised in the air-vessel, the less space will the air be condensed into, which before filled that vessel; and therefore the force of its spring will be so much the stronger upon the water, and will drive it with the greater force through the pipe at *F*: and as the spring of the air continues whilst the plunger *g* is rising, the stream or jet *S* will be uniform, as long as the action of the plunger continues: and when the valve *b* opens, to let the water follow the plunger upward, the valve *a* shuts, to hinder the water, which is forced into the air-vessel, from running back by the pipe *MM* into the barrel of the pump.

If there was no air-vessel to this engine, the pipe *GHI* would be joined to the pipe *MMN* at *P*; and then the jet *S* would stop every time the plunger is raised, and run only when the plunger is depressed.

Mr. Newsham's water engine, for extinguishing fire (see **FIRE-Engine**), consists of two forcing-pumps, which alternately drive water into a close vessel of air; and by forcing the water into that vessel, the air in it is thereby condensed, and compresses the water so strongly, that it rushes out with great impetuosity and force through a pipe that comes down into it; and makes a continued uniform stream by the condensation of the air upon its surface in the vessel.

By means of forcing-pumps, water may be raised to any height above the level of a river or spring; and machines may be contrived to work these pumps, either by a running stream, a fall of water, by horses, or by steam. See **WATER Works**.

The rod of the bucket in a sucking-pump is sometimes made to work through a collar of oiled leathers and brass plates connected with the barrel of the pump by screws, and kept moist by water contained in a vessel at the top: it prevents the water issuing from the top of the pump, and therefore, by a pipe, it will rise to any height. This is called in the North, a *jack-head*. Defaguliers's Exp. Phil. vol. ii. p. 152, &c. Ferguson's Lectures, p. 73, &c. 4to.

PUMP, the Lifting, differs from the sucking-pump only in the disposition of its valves, and the form of its piston frame. This kind of pump is represented in *fig. 6.* *AB* is a barrel fixed in a frame *IKLM*, which is immoveable, with its lower part communicating with the water. *GEQHO* is a frame with two strong iron rods, moveable through holes in the upper and lower parts of the pumps *IK* and *LM*; in the bottom of this frame *OQH*, is fixed an inverted piston *BD*, with its bucket and valve upon the top at *D*. Upon the top of the barrel there goes off a part *FR*, either fixed to the barrel, or moveable by a ball and socket; but in either case water and air-tight. In this part, at *C*, is fixed a valve opening upwards. It is evident, that when the piston frame is thrust down into the water, the piston *D* descends, and the water below will rush up through the valve *D*, and get above the piston; and that, when the frame is lifted up, the piston will force the water through the valve *C* up into the cistern *P*, there to run off by the spout. The piston of this pump plays below the surface of the water. Mr. Martin has described a mercurial pump, which works by quicksilver, invented by Mr. Hofkins, and perfected by Defaguliers; and another pump of the lifting sort, invented by Messrs. Gosset and De la Denille, and set up in the king of France's garden at Paris, the piston

of which works without friction. Phil. Brit. vol. ii. p. 57, &c. ed. 3.

PUMP, *Ctesebes's*, the first of all the kinds, acts both by suction and pulsion. Its structure and action are as follow: —A brass cylinder A B C D (*fig. 7.*), furnished with a valve in L, is placed in the water. 2. In this is fitted the embolus M K, made of green wood, which will not swell in the water, and adjusted to the aperture of the cylinder with a covering of leather, but without any valve. In H is fitted on another tube N H, with a valve that opens upwards in I.

Now, the embolus E K being raised, the water opens the valve in L, and rises into the cavity of the cylinder: and when the same embolus is again depressed, the valve I is opened, and the water driven up through the tube H N.

This is the pump used among the ancients, and that from which both the others are deduced. Sir S. Morland has endeavoured to increase its force by lessening the friction; which he has done to good effect, inasmuch as to make it work without almost any friction at all.

PUMPS for draining *Mines* are worked by horses, or water, but more than either by the steam-engine, which, had it produced no other advantage than the facilities it offers in mining, would have been of more real value than any philosophical discovery ever made. The pumps for this purpose are generally sucking-pumps of the common construction, made of cast-iron, except that they have an opening at the lower part of the barrel, to give access to the valve or bucket when they require repair or renewal of the leathers, and this is closed by a door or lid, fastened on with screws. The pump rod is suspended by chains from the arched end of a lever situated over the pit, and put in motion by the piston of the steam-engine acting at the opposite end, or by a crank turned from a horse-wheel or water-wheel. When the depth is considerable, the pit is divided into two or three lifts, and as many different pumps used; the lowest to raise the water from the bottom of the mine into a cistern at the first lift, in which the second pump stands, and raises the water to a second cistern, from which the third or upper pump raises it to the surface, or to the level or subterranean passage, at which it can run off to some lower land than that on which the engine is erected. The rods of the three pumps are brought into one by bolting them together at the top, and are suspended from the beam or lever, as before-mentioned. They are made of wood, the lengths being united together by iron joints; but even these in deep mines are of such great weight as to require a second beam or lever, placed on the opposite side of the pit to the engine, and having a balance weight at the outer end; because it would be too great a weight for any beam to bear, if a sufficient balance were put upon the opposite end of the same working beam that bears the strain of working the pumps: if they are of light wood, a considerable portion of their weight is taken off, by their being immersed in the water which the pumps contain.

A plan which is common in the mines of Cornwall, obviates the necessity of thus balancing the pump rods; it is by employing forcing-pumps instead of lift or suction-pumps. In these the engine is employed to lift the weight of the rods, and their descent is the power that raises the water in the pump, by pressing down the piston or forcer, and expelling the water from the barrel at the bottom through a valve into a pipe, which ascends the pit. The construction of the pump is varied from that in common use, though its principle is the same. Instead of the barrel

being bored correctly within, and fitted with the leathered forcer, the forcer is made rather longer than the stroke of the pump, and being made true and smooth on the outside, it is fitted in a collar of leather at the top of the barrel of the pump. By this means, when the piston is raised up and down, it increases and diminishes the capacity of the barrel, which being provided with valves at the bottom and at the foot of the pipe, it will raise or force up the water, in the same manner as the force-pump before described.

The suction-pumps before mentioned, used in mining, are always made of cast-iron, in lengths of six or eight feet, screwed together at the flanches, forming a long tube, which is called the pile or pillar of pumps.

The working barrel of each lift of pumps, or that length of pipe in which the bucket moves, is usually fourteen to twenty feet above the bottom, and has at its upper end a wider part, and a cover, which, like that above-mentioned, takes off by screws to new leather, or to repair the bucket. The bottom length of mine-pumps is called the wind-bore, usually enlarged at two or three feet from the bottom, and diminishing thence to a point like that of an egg, which part is full of rows of holes three quarters or an inch in diameter. The upper row of these holes is plugged up with deal plugs, which the miners can open or stop as the water increases, or otherwise, and according to the going of the engine. When a pit or mine is first sinking, it becomes necessary to contrive the means of drawing the water completely from the bottom, that they may not have to stand in the water to work, which, besides its inconvenience, prevents them using gunpowder if the bottom is rocky. Sometimes, instead of the plugs of wood, the holes of the wind-bore are surrounded by a circular apron of strong leather, made fast and tight above to the pipe; which apron the miners can from time to time turn up or down like the cuff of a coat, so as to regulate the access of water, and prevent, as much as possible, the drawing of air by the pumps, as this deranges the motion of the engine. In sinking pits, the lower lift of pumps should stand in the deepest hole which has been made in the bottom of the pit, and for this purpose, when a new hole has been made, either by picking, or blasting, near to the pumps, they are levered towards, and let to sink into such new hole. In long lifts and heavy pumps, this lowest and moveable length of the pump is wholly or in part suspended by strong ropes attached to the great windlafs, which is, in all such cases, provided near the shaft for drawing the pump rods, or the pumps themselves, in cases of need. As the shaft is deepened, new lengths of pump barrels are added at the top of the lower lift, generally about a yard at a time, and the pump rods are lengthened as the pump requires. This, which is the common mode of working in sinking pits, has many inconveniences: 1. As it is necessary for the pumps, whilst sinking, to keep the water very low in the pit, the engine frequently goes too fast, in consequence of the pump drawing up air, and carries up by the violence of the current small pieces of stone, coal, or other substances, and lodges them above the bucket upon the valves, which must considerably retard the working of the pump, and wear the leather. 2. When the engine is set to work, (after having been stopped whilst working upon air, and consequently a quantity of air remaining in the pump-barrel, with the small stones, &c. deposited on the valves of the bucket,) it often happens that the compression of the air by the descent of the bucket, is not sufficient to overcome the weight of the bucket valves so loaded with rubbish, and the column of water in the stand-pipes: the pump is hereby prevented from catching

catching its water. The usual remedy for this is to draw the bucket out of the working barrel, until a quantity of water has escaped by its sides to displace the air: this evil often arises from the unnecessary magnitude of the space between the bucket and clack. 3. The pumps being suspended in the pit by capstan ropes for the purpose of being readily lowered as the pit is sunk, the stretching of the ropes, (especially when sinking in soft strata,) occasions much trouble, by suffering the pumps to rest on the bottom and choke; but the most serious evil is, that the miners, in shifting the pump from one place to another, that they may dig in all parts of the pit, throw them very far out of the perpendicular, thereby causing immense friction and wearing in all parts, besides endangering the whole apparatus, by breaking the bolts and stays, and straining the joints of the pipes.

Mr. William Brunton, of Butterly iron-works in Derbyshire, has presented to the Society of Arts an improved pump for mining, which obviates all the above difficulties. To avoid the pump drawing air, he has introduced a side pipe, connecting the parts of the working barrel which are above and below the bucket, which pipe has a stop-valve, that the miner can regulate with the greatest ease, so as to keep the engine to its full stroke, without drawing air, by letting down the water from the upper part of the barrel into the lower, so that it is working again in its own water. Instead of having the whole weight of the lower lift of pumps standing on the bottom, it is fixed in the pit by cross beams, and the miner has only to lift and move an additional pipe or wind-bore, which slides upon the lower length of the pump like a telescope, to lengthen down, and this additional wind-bore is besides crooked, and turned aside like a short crank, which, by the facility with which it turns round in the leathered collar above the nose of it, can easily be removed into every fresh hole which is made in the bottom by the miners. The pumps are supported in the pit by beams placed across at proper distances, so as to suit the lengths of the pipes, or lengths of the pump, which are nine feet. Short pieces are laid across these, with half circular holes in them, which being put round the pump, just beneath the flanches, firmly sustain its weight, but may quickly be removed when it is required to lower the pumps in the pit; and as they are not fastened by any bolt, they do not prevent the pumps being drawn upwards, if it becomes necessary to take out the pumps when the pit is full of water. The pumps by these means remain stationary and the suction-pipe lengthens as the pit is sunk, until it is drawn out to its full extent; the whole column is then lowered to the next flanches, and another pipe is added to the top. The pumps being thus kept stationary till nine feet are sunk, the pipe at the top will of course deliver the water at the same level at all times, and instead of being obliged to lengthen the column every yard sunk, it will only be necessary every nine feet.

Fig. 4. of Plate XV. Hydraulics, explains the construction of Mr. Brunton's pump, being a section through the centre of the working barrel and suction piece. A is the door which unscrews to get at the clack of the pump; B is the working barrel, with the bucket D working in it; E is the clack, also shewn enlarged in *figs. 5 and 6*; F is the suction-pipe, and G G a moveable lengthening piece: this slides over, and includes the other when the pump is first fixed; but as the pit is sunk, it slides down over the pipe F, to reach the bottom. The outside of the inner pipe, F, is turned truly cylindrical and smooth, and the inside of the outer pipe G, at the upper end, for about six inches down, is made to fit it. The junction is made perfect, by leathers being placed in the bottom of the cup *aa*, which holds water and wet clay over

them, to keep them wet and pliable, and consequently air-tight. The lower extremity of the suction-pipe G terminates in a nose R, pierced with a number of small holes, that it may not take up dirt. This nose is not placed in a line with the pipe, but curved to one side of it, like a crank, so as to describe a circle when turned round. By this means the miners, by turning it round upon the pipe F, can always place the nose R in the deepest part of the pit; and when they dig or blast a deeper part, they turn the nose about into it, the sliding tube lengthening down to reach the bottom of the hole, as shewn in the figure. By this means there is never a necessity to set a shot for blasting, so near the pump-foot as to put it in any danger of being injured by the explosion, as is the case in the common pump, in which this danger can only be avoided by moving the pump-foot to one side of the pit, which necessarily throws the whole column of pumps out of the perpendicular.

The construction of the clack is explained by *figs. 5 and 6*, the former being a section, and the latter a plan. L L is a cast-iron ring, fitting into a conical seat in the bottom of the chamber of the pump, as shewn in *fig. 4*; it has two stems, *l, l*, rising from it, to support a second iron ring M M; just beneath this, a bar, *m*, extends across from one stem to another, and has two screws tapped through it; these press down a second cross-bar *n*, which holds the leather of the valves down upon the cross-bar of the ring L, and this makes it fast, forming the hinge on which the double valves open, without the necessity of making any holes through the leather, as is common: but the chief advantage is, that by this means the clack can be repaired, and a new leather put in, with far less loss of time than at present, an object of the greatest importance; for in many situations the water gathers so fast in the pit, that if the clack fails, and cannot be quickly repaired, the water rises above the clack door, so as to prevent any access to it, and there is no remedy in the common pump but drawing up the whole pile of pumps, which is a most tedious and expensive operation. In Mr. Brunton's pump, the clack can at any time be drawn out of it, by first drawing out the bucket, and letting down an iron prong Z, which has hooks on the outside of its two points: this, when dropped down, will fall into the ring M, and its prongs springing out will catch the under side, and hold it fast enough to draw it up. Another part of Mr. Brunton's improvement consists in the addition of a pipe H, (*fig. 4.*) which is cast at the same time with the barrel, and communicates with it at the top and bottom, just above the clack: at the upper end the pipe is covered by a flat sliding plate, which can be moved by a small rod *b*, passing through a collar of leather; the rod has a communication by a lever, so that the valve can be opened or shut by the men in the bottom of the pit. The object of this side pipe is to let down such a proportion of the water which the pump draws, as will prevent it drawing air, though, of course, the motion of the engine will be so adapted as not to require a great proportion of the water to be thus returned through the side pipe, yet it will not be possible to work the engine so correctly as not to draw some without this contrivance, and if it does, it draws up much dirt and pieces of stone into the pump, besides causing the engine to work very irregular, in consequence of partially losing its load every time the air enters the pump. Another use of the side pipe is to let down water into the chamber of the clack to fill it, when the engine is first set to work, after the pumps have been standing still, and the lower part of the barrel and chamber empty.

Figs. 7 and 8, of Plate XV. are a section and elevation of a three-barrelled force-pump, of a very good construction,

PUMP.

construction, which was used by Mr. Smeaton in the numerous water-engines which he erected at London bridge, Stratford, and other places for the supply of towns with water. It has the advantage of the valves being very accessible, and the water-way may be kept to the full size of the barrel without contractions, which, as they occasion great resistance to the motion of the water, are a waste of power. It acts on the same principle as the ordinary forcing-pump, only that three barrels are connected together, for the advantage of raising a constant stream of water. *A, A,* are the barrels, which are bored out truly cylindrical. If the pump is small, the barrels are usually made of brass, but for larger work cast iron is used. From one side, near the bottom of each, proceeds a curved pipe *B*, turning up, and ending with a flaunch, to screw to the under side of the forcing chamber *L*. There is also, near the bottom, at the opposite side of the barrel, a projecting neck or short pipe, *D*, covered at the end by a door screwed on, that it may be removed to give access to the valve, *m*, in the bottom of the barrel. The barrels have projecting rings or flaunches, by which they are screwed down upon the suction chamber *H*, which is common to all three barrels; it has a pipe from each of its ends terminating in a flaunch *b*, to screw on the pipes which bring water to the pump. The upper flaunch, or top of the suction chamber *H*, has three holes in it, one under each barrel, and each is covered by a valve shutting downwards, as is shewn in the section, *fig. 7*. These valves are made of iron, to shut down upon hinges like a door, and are covered with leather at the lower side. Mr. Smeaton made his valves with the centre pin of the hinge removed backwards from the hole which the valve covers, and it is also raised above the surface of the under side of the valve, by which means the valve opens in some degree on that side where the hinge is, as well as on the other, and any obstruction getting into the valve, will be less liable to be detained, and will not have such a great leverage to break the hinge of the valve when the force of the water shuts it down, as it would if the hinge was on a level, and close to the edge of the hole, because the obstacle will not be so near the centre. The hinge is fastened to the pump by a screw, *w*, passing through the metal, and screwing into the hinge; this being withdrawn, and the door, *D*, opened, the valve is quite loose, and may be taken out to renew the leather. To give facility to this, the doors, *D*, are made oval, as shewn in *fig. 8*. Another similar valve, *n*, is fitted at the top of each of the pipes, *B*, to cover their apertures; they are all covered by a common forcing chamber, *L*, which is exactly similar to the suction chamber, except that it has nozzles, *R*, in the top over each valve, and covered with doors to give access to them. The conducting pipes are carried away from either end of the forcing chamber, flaunches being provided to unite them. Each barrel is fitted with a piston or forcer *M*, which consists of three metallic plates, secured to the rod: the middle plate is turned true, and fitted as accurately as possible to the barrel; the upper and lower plates are somewhat smaller. Two round pieces of leather, larger than the barrel, are placed above and below the middle plate, being held fast between it and the upper and lower plates. When forced into the barrels, these leathers turn up and down round the upper and lower plates, forming two cups of leather, which accurately fit the barrel, and will not permit any fluid to pass by them. The parts of the pump are fastened together by screws and nuts, as will be understood by inspection of the figures. The whole pump is supported on two ground-cills, and by means of two iron flaunches of the suction chamber, *H*, the whole pump is bolted down upon the ground-cills. The action of this pump is simply

this; when the piston or forcer of one barrel is raised, it causes a vacuum in it, and the pressure of the atmosphere forces the water up the suction pipe *H*, (if not more than 30 or 33 feet,) opens the valve, *m*, in the bottom of the barrel, and fills it with water: on the descent of the forcer the lower valve shuts, and the forcing valve, *n*, opens by the water the barrel contained being driven through it into the forcing chamber, *L*, and thence to any place whither the forcing-pipe is carried. On the re-ascent of the forcer, the lower valve, *m*, opens, and the shutting of the forcing valve, *n*, prevents the water returning into the barrel. The three forcers work up and down alternately, so that while one barrel is sending water up the force pipe, the others are lifting it up the suction pipe, and the third continues the action in the interval, when the change of motion takes place between the two. In this manner, the pump will raise a very constant stream of water, if the forcers are worked in a proper manner, which is best done by means of cranks, placed at such an angle to each other, upon the same axis, that they will act in due succession.

PUMPS for Ships.—Among the perils of a sea-faring life, a leaking ship may be reckoned the most dreadful and fatal of all others: here not only one man, or a few men, perish, but every living creature on board. When a ship strikes against a rock, and is wrecked, some lives may be saved by floating planks and rigging; if the magazine takes fire, death comes instantaneously, and kills, perhaps, in the most gentle manner; but in the desperate case of a leak, how slowly does the awful monarch advance, attended by all the terrors of anxious suspense.

In such a melancholy situation, all their hopes and expectations for help and safety must be placed in the pumps, and this consideration renders those machines of vast estimation and consequence; it highly imports every commander of a ship (to whom the lives of his men are committed) to take the utmost care that his ship be supplied with such pumps as will best provide against, and ward off, these impending dangers. By any negligence in this respect, he may become guilty of destroying his own life, the lives of his men, and of the ruin and misery of many families; it therefore becomes his duty to be furnished with the best pump that can be procured for evacuating the hold from the water that may, at any time, get in, with the least force, and in the shortest time.

At different times, almost every description of pump has been employed in ship service; but custom has at length decided in favour of the chain-pump, although, from the friction naturally attending its construction, it takes somewhat more power to raise a certain quantity of water than some other kind of pump when well made. Yet on the whole, from being so little liable to choke up or be deranged by violent use, it has gained the preference with the seamen. Constant attempts have been made to produce a pump that would raise a greater quantity of water than the chain-pump with the same power, and still to preserve the other advantages of that machine.

These inventions have been offered to the public one after another, with pompous recommendations by their respective projectors, who have never failed to report their effects as considerably superior to that of other pumps with which they have been tried. It is, however, much to be regretted, that in these sorts of trials there is not always a scrupulous attention to what may be called mechanical justice. The artist who wishes to introduce a new piece of mechanism, has generally sufficient address to compare its effects with one of the former machines which is crazy, or out of repair: a report of this kind, indeed, favours strongly

PUMP.

of the evidence of a false witness; but this finess is not always discovered. The persons appointed to superintend the comparative effect of the different pumps, have not always a competent knowledge of hydraulics to detect these artifices, or to remark, with precision, the defects and advantages of those machines, as opposed to each other. Thus, the several inventions proposed to supplant the chain-pumps which are now generally used in the British navy, have hitherto proved ineffectual, and are no longer remembered.

In many instances, for want of a proper knowledge of mechanics and hydraulics, these inventions have proceeded upon a mistaken principle, supposing it possible to make some contrivance or other, by which a pump should raise more water with a certain power than has ever been done before. This is a mistaken idea, for pumps, in point of the quantity of water they will raise, have long ago been brought to as great a degree of perfection as it is perhaps possible; and to raise a greater weight of water than the power applied is equal to, is an impossibility, as no power or effort can really be increased by any kind of machinery, it can only be modified; and what is gained in the magnitude of the effect the machine produces, is lost in the time expended to accomplish it: in truth, rather more is lost, because of the friction of the machine, and the power expended in working its parts; we should, therefore, ascertain the quantity of water that can be raised in a given time by the force of one or more men, without deductions for friction; and when a ship's, or other pump is to be considered, if its produce comes near to this standard, we should be satisfied as to its performance, and look for improvements in the conveniences of its construction.

Desaguliers, in the second volume of his *Experimental Philosophy*, has taken much pains to find out an average of the quantity of water which can be raised in a given time by any number of men; and this will serve to guide us in these pursuits, and to enable us to value the pretensions of projectors in the art of raising water. He found, that the mean strength of a man, when applied to the best kind of pump that had been in his time in use, amounts to no more than the raising of one hoghead of water in a minute, to the height of ten feet. Mr. Smeaton says, he made a variety of machines, and many observations of this kind, but never found the value of men's strength at a medium quite equal to what is set down by Desaguliers, unless they are supposed to work in haste or distress for a few minutes.

The improvements which are desirable in pumps for a ship's use, are, 1st, that as little power as possible should be lost in friction and resistance of the water passing through the valves and pipes; 2dly, that no water be lost by leakage, and that the pump be not liable to choke up by chips or other extraneous matters getting into the pump; 3dly, it should not be obliged to raise its water to a greater height than is necessary for it to run off, namely, to the load-water line of a ship; lastly, that it should be so adapted, that the united efforts of a great number of men can be applied, without any of them working to a disadvantage. The pumps which are at present in use in the navy are of two kinds, the chain-pump, and the hand-pump; the chief dependence of pumping the ship, in emergency, being placed upon the former, the latter being used in ordinary occasions, to clear the hold from that trifling leakage which would injure the cargo, though it puts the ship in no danger.

English ships of war carry four chain-pumps and three hand-pumps, all being fixed in the same well, which also includes the main-mast. (See *Plates IV. and VI. of Naval*

Architecture.) One of the hand-pumps is called the wash-deck pump, being used to raise water from a cistern in the hold to the upper deck, for washing the ship; but in emergency, it assists to pump the ship. The chain-pump (*Plate XIV. fig. 8.*) is no other than a long chain, A, with a sufficient number of pistons, *a*, called buckets or saucers, fixed upon it at proper distances: it passes downwards through a wooden tube, B, and returns upwards, in the same manner, on the other side, D; the ends being united together. The chain is extended over two wheels, E and F, called sprocket wheels: one is placed over the tubes, B and D, of the pump, and the other at the bottom, in the space between the two tubes through which the chain ascends and descends. By turning the upper wheel, E, the chain of buckets is put in motion; and the lower part of the wooden tube, in which the chain ascends, is lined with a brass barrel, in which the saucers are fitted. As they are continually ascending in this tube, they raise a constant stream of water, which runs off from the top of the ascending trunk, and is carried by a trunk through the ship's side into the sea. The pump is worked by a crank, or winch, G, fixed on the axis of the upper wheel, whereon several men may be employed at once; and thus it discharges, in a limited time, a much greater quantity of water than the common pump, and that with less inconvenience to the labourers.

The chain-pump now in use in the navy is of a very improved construction, compared with original chain-pumps. It was introduced by Mr. Cole, under the direction of captain Bentinek. The chain of this machine is simple, and not much exposed to damage. It is exactly similar to that of the fire-engine, and appears to have been first applied to the pump by Mr. Mylne, to exhaust the water from the caissons at Blackfriars bridge. It has thence been transferred to the marine by captain Bentinek, after having received some material additions to answer that service. The links of the chain (*fig. 9.*) are each formed of two long plates of iron, *e, e*, with a hole at each end, and fixed together by two bolts, serving as pins for the joints. The buckets or saucers fixed upon it are two circular plates of brass, *g*, with a piece of leather between them. The sprocket wheels for the chain are formed in the same manner as the trundles used in mills, by two iron wheels fixed at eight inches distance upon the axle, and united by several round iron bolts, forming a rest for the chain; and its links have hooks, *b*, which are taken by these bolts; and thus the chain is secured upon the wheel, to prevent it from jerking back, when charged with a column of water.

This pump was a great improvement upon the old chain-pumps, used in ships before, in which the chain was of too complicated a fabric, and the sprocket wheels used to work it were deficient, in wanting some contrivance to prevent the chain from sliding or jerking back upon the surface of the wheel, which frequently happened when the buckets were charged with a considerable weight of water, or when the pumps were violently worked. The links were too short, and the awkward manner in which they were connected exposed them to a great friction in passing round the wheels: hence they were sometimes apt to break, or burst asunder, in very dangerous situations, when it was extremely difficult or impracticable to repair the chain. Mr. Cole's pump is so constructed, that the chain may be easily taken up and repaired, when broken, or choaked with ballast; and it discharges a much greater quantity of water with an inferior number of men, as appears from a trial of this machine with the old chain-pump aboard the *Seaford* frigate; where it was found that its effects, when compared with the latter, were as follows: the new pump with four men

PUMP.

men raised one ton of water in $43\frac{1}{2}$ seconds, while the old pump required seven men to raise the same quantity of water in 76 seconds. In this experiment, the chain of the new pump was purposely broken, and dropped into the well, and afterwards taken up and repaired, and set to work again in two minutes and a half: then the lower wheel of the pump was taken up, to shew how readily it might be cleared and refitted for action, after being choaked with sand or gravel, which could be performed in four or five minutes. These are advantages which, with a seaman, have a superior consideration to that of increasing the quantity of water which the machine will raise, unless it was in a considerable degree; and indeed the very best pumps will not raise a much greater proportion with the same power. The only alteration which has been made on Mr. Cole's pump, since its first introduction near 30 years ago, is that they now omit the lower sprocket wheel altogether, the ascending and descending pipes being so united by a curved metal tube, that the chain passes better than if a wheel was used. The cranks are made to take off, and apply when wanted, that they may not be in the way: they are long enough for 30 men to work at once. Of late it has been proposed to add fly-wheels to them: this would be attended with but slight advantage, and several inconveniences, from occupying that room where the men should stand to work, it being an object to employ as many as possible; but if they are crowded, they only incommode each other, instead of assisting.

Hand-pumps for ships, are those which act with a barrel and bucket, worked by a lever or brake. Those in common use are sucking-pumps, made in the rudest manner, with a wooden bucket and valves; but several improved constructions have been proposed, and are now adopted in the navy. Mr. Cole made great numbers of hand-pumps, which had brass chambers, or barrels, fitted into the wood where the bucket worked. The valves were made of brass, and fitted into a conical seat, and a door was provided in the lower part of the pump, to give access to the lower valve when requisite; it was closed by a hoop surrounding the pump, and wedged tight. The brake, or lever of the pump, had a cross handle at the end, of sufficient length to allow several men to work together, and on occasion other men could apply their strength, by standing on the deck below, and having a rope descending through the upper deck from the end of the brake.

Mr. Smeaton, in 1765, invented a hand-pump for the sea service, in which, besides the advantage that he expected to obtain from better mechanism and proportion of the parts, he had the following objects in view. The common ship's pump, in general, delivers its water upon the main deck, which, according to the size and construction of the ship, is four, five, or six feet above the surface of the sea, or load-water line, at the same time that this line is not above from 14 to 18 feet above the ship's bottom; it therefore appears that the ordinary pumps lift the water from $\frac{3}{4}$ d to $\frac{1}{4}$ th higher than the level at which the water might be delivered, and thereby require $\frac{3}{4}$ d or $\frac{1}{4}$ th more power to do the same work, or with the same power they do less work than they might do by $\frac{3}{4}$ d or $\frac{1}{4}$ th, in case the water was delivered at or just above the water line. For this purpose he used wooden trunks or pipes, proceeding horizontally from the upright trunk of the pump, to carry off the water through the ship's side, being fitted at the other ends into boxes, or short wooden tubes, let in through the ship's side, and caulked just above the load-water line. These side pipes were closely jointed with the boxes in the ship's side at one end, and at the other end into strong planks, which were bolted against the

sides of the pump, in order that the side pipes might be got out and in without disturbing the pump, which was a sucking-pump, with its bucket worked by a lever or brake, upon the deck over the pump. From the top of the pump a stand pipe was carried up to the main deck, or as high as was thought necessary, to prevent the water reverting and running back into the ship over the top of the pump, when the sea rose above the orifices of the side pipe, or when, from the ship being in distress, they were under her load-water line. By this, even when both boxes and pipes were wholly under water, it would no ways interrupt the action of the pump, for whenever the water in the stand pipe rose above the level of the water without, the pressure of the column in the stand pipe would cause it to make its way through the side pipes, so that in this case no level was lost, and though the pump was at rest no water could revert down the pump, because there were the valves of both bucket and fixed box or clack which prevented it. The working barrel was of brass, and very truly bored, the bucket and fixed box being of the same construction as those used in the steam-engines, and the pump rod was made of greater bulk than was necessary, merely for strength, but by way of weight, that when the brake was lifted up, the pump rod should readily descend by its own weight. The brake of the pump had a branch fixed on, rather obliquely at each side, so as to form three handles, for four men to work at once; they stood one on each side the middle stem of the brake, and one on the outside of each of the branches, and every quarter of an hour they could relieve themselves by changing hands, which was done by changing places. They were intended to make no more than 25 strokes *per* minute, moving the pump rod $17\frac{3}{4}$ inches, up and down, at each stroke, the barrel being a nine-inch bore; this was much better than making shorter strokes and quicker, as they usually do. Their hands moved up and down about four feet six inches, and by working with this stroke at a moderate rate, so as to hold it an hour, four men would in that time deliver 20 tons at a height of 22 feet. This was upon a supposition of raising the water to the usual height, but when by the application of the maxim before described, this perpendicular was shortened to 16 or 17 feet, then nearly the same delivery could be made by three men, or proportionably more by four men, that is, as $17:22::20:26$ tons at 17 feet. The foot of the pump was let through the ship's inner planking or ceiling, betwixt two of the floor timbers, and did not touch the bottom or outside planking, within $2\frac{1}{2}$ inches, the lower end being rounded within like a trumpet mouth, it being a bad plan to have the pump standing upon its lower extremity, with holes bored to let in the water, as it is thus very liable to be choaked by dirt. A plank of the ceiling was made to lift up near the pump's foot, that a man could occasionally get in his arm, to clear away any chips, sand, dirt, or other matter, that should happen to be drawn thither.

Mr. Noble has furnished a great number of hand-pumps for the navy, which have two buckets, working one below the other in the same barrel: they rise and fall alternately, so as to produce a constant stream, like the chain-pump. This is effected by causing the rod for the lower of the two buckets to pass down through the upper bucket in a collar of leathers: the rods of the two buckets are united to the brake or lever, upon opposite sides of its centre or fulcrum, so that the descent of one produces the elevation of the other; thus one is always raising a stream of water, whilst the other is descending for a fresh supply. Such a pump requires no lower valve, unless by way of precaution, in case either bucket should fail, in which case it would become a single pump. The idea is ingenious; but the

complication of the stuffing-box in the upper bucket prevents them being readily taken out, if the pump chokes up, as all ships' pumps are liable to do from chips or loose ballast; and hence it has never been in favour with the seamen, although it acts very well when in order.

The ingenious Benjamin Martin invented a ship's pump with two barrels drawing from one suction-pump, so as to raise a constant stream. This has so much merit, that we have given a section of it in *Plate XV. fig. 9.* Here A is the suction pipe, conducting the water from the ship's hold up to the pump, where it is enlarged, to communicate with both barrels D, D, through the valves C, C, in the bottom; E, E, are the pistons of the barrels, with double valves in them; they are not, like other pistons, fitted to slide in the barrels, but are simply brass rings, in which the valves are fitted, and being smaller than the barrels, have large circular pieces of leather fixed on them, the outside edges of which are attached to the insides of the pump barrels; hence when the pistons are moved up and down, the leather folds sufficiently to admit the motion, as is shewn in the figure; but being close all round, these pistons can have no leakage or friction, and only a small resistance from the stiffness of the leather. To fasten the edges of the leather piston to the barrels, they are made in two lengths, an upper and a lower, and the leather is introduced in the joint between them, being held fast, and the pump kept together by bars, I, I, fixed over the barrels, and bolts to press the upper length of the barrels down upon the lower. Both the barrels are included within a box or cistern, B B, fixed upon the ship's deck, with trunks L, L, which carry off the water as it runs over the tops of the barrels into the cistern. The pump is worked by the piston-rods, H, H, being united by chains to a wheel K, the axle of which is supported by standards from the sides of the cistern B B, and is put in motion by the double lever M, at the ends of which cross handles are fixed for several men to work at once. Mr. Martin's pump acts extremely well; the constant stream raised by the alternate action of the two barrels upon one pipe produces an advantage that was shewn by experiment, for the water not only rises while the piston rises, but continues to do so even after the piston begins to descend; and therefore the pump was found to deliver more water than was expected from calculation of the contents of the barrel, and the number of strokes made.

To account for this, it must be considered that as this pump has both its large pistons working (alternately ascending and descending), at the same time there must be produced a constant rising column of water in the pipe, whose velocity through a bore of five inches, to supply the barrels of twelve inches diameter each, must be so great, that it cannot be checked or stopped at once, or upon the first descent of the piston; and therefore a surplus of water is produced. Notwithstanding these advantages of Mr. Martin's pump, it has objections which are serious obstacles to its use on board ships, though in other situations it is a good machine: these are the shortness of its stroke, which renders it very fatiguing for men to work for a long time; but another more serious objection is, that the leathers would, in general, remain dry, and thus become liable to harden and grow stiff, so as to break into holes when used at first, before they become soaked, and to fill the cistern first with water would be very troublesome.

Mr. Robert Clarke, of Sunderland, has proposed an improvement in the mode of applying men's force to pumping, which is worthy the consideration of seamen. It is to change the posture of standing to sitting, and making the action the

same as that of rowing, which, besides that it is by philosophers considered as the most efficacious application of a man's force, is to seamen most particularly so from their habitual practice of it. He objects to the ordinary action of pumping with a brake, as the posture is weak, and requires much force to preserve it. It oppresses the man by overstretching his loins on one side, and incommodes respiration, by the flexure of the body on the other side. Too much motion of the shoulder-joint is required, as the muscles which act on the arm-bone at this joint are disproportionate to the effort they must make, when the arm vibrates on the shoulder-joint as a centre, for the force to be communicated by the hand. Besides this, the arms themselves are at one instant enfeebled, by being thrown above the head, and requiring a pull, and the next instant require a pushing effort, which changes of direction in the exertion and sustaining force, are too continual and rapid for long continuance; in standing, the body is a continued dead weight upon the legs.

The action of rowing is powerful to a surprising degree, and so well adapted to a man's ease, that he can continue it a greater length of time without fatigue, than any other mode of exertion; for though the motion is large, it is made up of easy motions in several joints; the velocity and resistance of which suit the muscles employed. Very little sustaining force is required, for the body is supported, and returns unloaded to its charge: the breathing is free. The manner of carrying this into effect is very simple, the lever or brake being bent at right angles at a centre pin, so that it hangs straight down when it is at rest, instead of being horizontal; then to the lower extremity a rod is jointed, which is carried rather in an inclined direction upwards to the seamen, who is seated before the pump with a rest for his feet. The rod has a cross handle, to hold by both hands, and in some cases it may be made long enough for two men to sit side by side upon the same seat; and by drawing and pushing it, in the same manner as rowing, the perpendicular lever is caused to vibrate, and the horizontal arm, or bended part, which suspends the pump spear, partakes of the motion sufficiently for pumping.

The latest improvements in hand-pumps, are by Capt. Jekyll, R. N. This gentleman has invented an addition to the pump of an air-vessel, and stuffing-box for the rod to pass through, by which it will raise the water to a greater height than the head of the pump, and a hose being attached to the pump spout, by very simple means, the water is conveyed to any desired part of the ship, and thrown in a jet through a nose pipe with great force, to extinguish fire, if such a calamity should befall a ship, and thus the pump is rendered of twofold service. The idea of converting the pump to a fire-engine is not new, having been attempted in many different ways by forcing-pumps, but these having pipes proceeding from the lower part of the barrels and valves, which are not very accessible, are always liable to choke up by obstructions, and have not succeeded in general use. The air-vessel has always been in the way, if made of a sufficient size, to answer the purpose of equalising the stream. Capt. Jekyll has obviated these objections, and, without altering the material parts of the hand-pump, has rendered it as complete a fire-engine as can be wished. This is explained by *fig. 1. Plate XV.* which is a section of the pump through its whole length. A B C is the iron brake or lever to work it; it is branched at the extreme end, and has a wooden pole, C, fixed in it, for several men to hold at once; D is the iron staunchion or fulcrum of the brake; it is fixed to the pump head by means of strong iron hoops at E E and F F, which at the same time strengthen the work of the pump. The centre pin is to be at a height of two feet

feet six inches above the ship's deck. H are the slings of the pump, united by a forelock or pin to the end of the brake, and suspending the pump-spear I, by means of the joint-piece g. I K is the pump-spear, made of copper in the upper part, I, and the lower length, K, of iron; the latter has the bucket, M, attached to it. The valve of the bucket is made in a very simple and effective manner, the valve being merely a round plate of brass, with a hole through the centre, to receive the rod, upon which it rises and falls, and covers the aperture in the bucket. The bucket is a ring of brass, with a cross-bar to fix the rod in; it is made in two thicknesses, one above the other, and a cup of leather is held in between them, projecting all round the upper part of the bucket, and turning up, to make a tight fitting in the barrel. The two rings of the bucket are held together by the piston-rod passing through both, and a cross-wedge beneath. L is the brass chamber in which the bucket works; it is well fitted into the wood of the pump-tree, so that the water cannot leak by it, and is bored smooth withinside. N is the lower box, fitted into the lower part of the pump-tree, beneath the chamber; it has a groove round it, into which oakum is placed, and when it is put down, makes a tight joint: its valve is of the same construction as that of the bucket, with the addition of a ring or eye on the top of the pin, on which the valve rises and falls. By this eye the box can be drawn up when it needs repair, by first drawing up the bucket of the pump, and putting an iron hook down into this eye. O O P is the air-vessel; this is a cylinder of sheet copper, soldered to a cover of brass; within the centre of it is a tube, likewise soldered to the cover, through which the copper pump-spear passes, and is fitted round at top with a collar of leather and stuffing. To prevent the escape of the water, it is packed with hemp, and two rings of leather. R shews the place of two iron bars, fitted through the head of the pump, and confining the cover, O O, of the air-vessel; they are fastened by the wedges d: it is by these only that the air-vessel is held down: a circle of leather is first put round the air-vessel, just beneath its lid, and this being pressed upon the recess in the wood, makes the joint tight. T is the pump nozzle, which delivers the water. When it is used as a fire-engine, a hose is fixed on by its link-joints, and keys or wedges: the nozzle is fixed to the pump by four screw-bolts going through the thickness of the pump, and it is fixed in such a direction as will most conveniently lead to a receiver, *fig. 2*, which unites the hoses from all three of the ship's pumps.

Fig. 3. is the link-joint of the hose, T representing the pump-spout made of cast iron, and screwed to the pump-tree; *ee* is the collar or socket, made of brass, with the hose X bound upon it: this has two trunnions, on which a link, *f*, is fitted, one on each side; these links pass through grooves, in the cast-iron piece T, and a key *g*, put down through the link behind it, draws the joint tight, without any screwing or further trouble. The socket, *ee*, is fitted into the nozzle, and has a leather ring to make it tight. The outside of the pump is to be hooped at every three feet, to prevent it from bursting by the pressure of the water. The disposition of the three hand-pumps in a ship's well, renders their connection with a common receiver very convenient to bring all the water into one stream, which will then be very powerful, and more capable of extinguishing a fire than any moveable engine. Two hand-pumps are always placed on the starboard side of the main-mast, in the well, and one of them being the cistern pump used for washing decks, its foot stands in a small cistern fixed upon the step of the main-mast, and supplied with water by a pipe through the ship's side, with a cock to admit it at pleasure; there is one pump on the larboard side of the mast, three separate hoses being

united with each of the pumps by a link-joint, like *fig. 3*, at one end, and with three necks, *k, k, k*, of a receiver, *fig. 2*, by similar joints at the other, brings all the water into one, and a hose being joined by a link-joint, *l*, to the opposite end of the receiver, conveys the whole water to any part of the ship. The receiver has the three nozzles, *k, k, k*, at one end made in a divergent direction, agreeable to the directions in which the hoses came from the three different pumps, and a valve is placed withinside, before each nose, to open inwards, in order that the receiver may be used for one or two pumps, whilst the others are repairing, or getting ready, or that if any of the hoses burst, the water may not escape from the receiver at that nozzle. There are two handles fixed to the receiver, to lift and carry it, as it is to be moveable, and when in use, is proposed to be laid on the grating of the main hatchway, as the most central situation, from which the hose may be carried in any direction. Z is a branch pipe, or jet, screwed at the end of the great hose, X; and it also unscrews at the extreme end, to fit on jets of different bores, in the same manner as all other fire-engines. In working, the pressure of the water condenses the air contained in the receiver, O O P, into a small space, and its reaction to resume its former bulk equalizes the efflux of water from the nozzle of the pump.

In some experiments which we have witnessed upon this pump, it performed as well as could be desired, a single pump forming a very effective engine; but when the three were combined, it was superior in force to any we have ever seen, and would throw a stream, of an inch in diameter, over the main-top-mast head of a 74-gun ship. Besides, the length of the handle, C, admitting several men to work at once, an accession of force is gained by a rope, *n*, made fast to the brake A B, and conducted through a single block, hooked to the deck at *m*, and thence along the ship's deck. At this any number of men may be applied very advantageously, to produce the stroke, leaving those at the handle only to return it by lifting the handle. If the ship proves leaky, and the stuffing-box is thought to be an obstruction to the working of the pump, the air-vessel may be taken out, by drawing the wedges *d*, and taking out the bars R, which confine it; then after taking out the key which connects the joint-piece, *g*, with the copper rod, also removing the brake, lift out the air-vessel by the two screws of the stuffing-box, and fix on the joint piece again, but fix the guide-eye, H, in the lowest pair of holes, so that it will receive the top of the copper rod, and prevent the pump-spear having any play in the slings. In this state it acts as a common hand-pump, but the air-vessel can be restored to its place, and be ready for work in two minutes. To prevent any of the work being neglected from carelessness, the inventor proposes that one of the pumps shall be always used to wash the ship by the hose and jet in the morning, which it would do much more effectively than by the present mode of raising the water into buckets; and the force with which the jet of water is thrown would very completely wash into every recess of the gun carriages, and other places, where a brush cannot reach; while, by this constant exercise the pumps would always be ready at a moment's notice on an alarm of fire.

PUMP, *Air*, in *Pneumatics*, is a machine, by means of which the air is emptied out of vessels, and a sort of vacuum produced in them. For the invention, structure, and use of this pump, see *AIR-pump*; and for Smeaton's improved gage, see *GAGE*.

PUMPS, *Bare*, are small ones made of cane, or a piece of wood bored through, used in lieu of cocks, &c. to pump beer or water out of the casks.

PUMPS, *Bur*, called also *bilge-pumps*, are chiefly used by the Dutch, who have them by their ship's sides. In these is a long staff, with a bur at the end like a gunner's sponge, to pump up the bilge-water.

PUMP-Cisterns, cisterns of wood fixed over the heads of chain-pumps, to receive the water until it is conveyed through the sides of the ship by the pump-*dales*.

PUMP-Dales, a large tube or pipe, generally made of fir, fitted to the cisterns, with a large scupper hole through the side, through which the water is conveyed from the pumps overboard.

PUMP, *Fetching the*. See **FETCHING**.

PUMP, *Rotatory*. See **ROTATORY Pump**.

PUMP, *Spiral*. See **Archimedes' SCREW**, and **SPIRAL**.

PUMPELMOES, a name used by some for a species of orange.

PUMPING at Sea, is usually done by spells, that is, by relieving the men with fresh ones, and counting how many strokes they pump each watch. By this means they know if the ship be staunch, or how her leaks increase.

When all the water is drawn up, and there comes up nothing but wind and froth, they say the *pump sucks*.

PUMPKIN, **CUCURBITA**, in *Botany*. See **CUCURBITA**. The pumpkin is frequently cultivated by the country people in England, who plant them upon their dunghills, where the plants run over them, and spread to a great distance; and when the seasons are favourable, they will produce plenty of large fruit; these they usually allow to grow to maturity, then they cut open a hole on one side, and take the seeds out of the pulp as clean as possible, after which they fill the shells with apples sliced, which they mix with the pulp of the fruit, and some add a little sugar and spice to it; then bake it in an oven, and eat it in the same manner as baked apples; but this is a strong food, and only fit for those who labour hard, and can easily digest it.

For the Method of propagating them, see **CUCURBITA**.

PUMPLITZ, in *Geography*, a town of Switzerland, in the canton of Berne; four miles S. of Berne.

PUN, or **PUNN**, a *lusus verborum*, the wit of which depends on a resemblance between the sounds and syllables of two words, which have different, and, perhaps, contrary significations. See **PARONOMASIA**.

Such are,—*Cane, de cane, cane.*—*Far mole mole mola.*—*Lex Dei, lux diei.*—All houses are turned to ale-houses.—Matrimony is become matter of money.—Some men's paradise is a pair of dice.—Was it so in the time of Noah? Ah no.—*L'ordre tiré du disordre, ou disordre ordonne*, is the title of a French book.

Puns, when they come easily, and are very ingenious, poignant, and apposite, are allowed of in conversation, letters, epigrams, madrigals, and the like compositions; but they are absolutely banished out of the grave, serious, and sublime, because they weaken its force, and diminish its beauty, which consists in something great and elevated. The Greeks and Romans, it is true, sometimes indulged themselves in the practice, and used puns as ornaments in the most serious discourses: but the most severe and philosophical genius of our age, is by no means satisfied with such an outside of wit. Devices, symbols, rebuses, mottoes, &c. are their proper sphere, where they shine to most advantage.

PUNA, in *Geography*, an island in the Pacific ocean, near the W. coast of America, in the bay of Guayaquil, about 60 miles in circuit. The land is flat and low, and on account of its numerous rivers and strong divergent tides, it is encompassed by many dangerous sand-banks. Its capital is Puna, which is situated at the head of the har-

bour, in the N.E. part of the island: it consists of about 50 small houses and a church: the houses are erected upon posts ten or twelve feet high, and ascended by ladders on the outside, on account of the inundation to which the river Guayaquil is subject; they are thatched with palmetto leaves, and their chambers are well boarded. Tradition reports, that the inhabitants formerly amounted to between 12 and 14,000; but at present they do not exceed 300, consisting of Casts and Spaniards, the Indians being very few. The large ships, which cannot lie at Guayaquil, on account of the sand-banks, load and unload here; the anchorage against the middle of the town being very good, with five fathoms of water within a cable's length of the shore. S. lat. 45'. W. long. 79° 46'.

PUNAGRI, in *Hindoo Romance*, is the name of a mythological animal composed of man and bird, on which their god Vishnu is conveyed. Another of its names is *Superna*; which see.

PUNARU, in *Ichthyology*, the name of a small fish of the alauda kind. It has an oblong body, and a thick head, obtuse at the snout. The mouth is small, and in the lower jaw there are only two oblong teeth, which are sharp and pointed like needles. The eyes stand high in the head, the pupil is black, and the iris yellow; and over these there are two short red filaments. The gills are large, and have two oblong fins placed behind them. The back-fin reaches from the head to the tail, and is prickly at the edge. The belly-fin reaches from the anus to the tail. The skin and fins are all brown.

Besides this, there is another species, variegated on its sides with lines of a dusky purple; its jaws beset with very small teeth, and its fins not prickly. Both kinds are found among the rocks about Brasil, and sometimes get into the shells of the larger shell-fish. Marggrave Hist. of Brasil.

PUNAY, in *Ornithology*, a name given by the people of the Philippine islands to a very beautiful species of turtle, common in their woods.

It is of the size of a small parrot, and is of a fine green colour, but the extreme feathers of its wings are tipped with white, and the lower part of its belly is of a saffron colour. Its beak is yellow.

PUNCATEEAH, in *Geography*, a river of Bengal, which runs into the Hooringottah. N. lat. 22° 4'. E. long. 90°.

PUNCH, an instrument of iron or steel, used in several arts, for the piercing and stamping of holes in plates of metals, &c. being so contrived, as not only to perforate but to cut out and take away the piece; whence the French call it, *emporte-pièce*, *q. d.* take-off piece.

The punch is a principal instrument of the metal-button-makers, wafer-makers, patch-makers, shoe-makers, &c. The punch of the makers of plate-buttons serves to cut and parcel out the plates of gold and silver with which they cover their moulds. It is large, round, four or five inches high, the bottom hollow for about half an inch, well fleeced, and the edge very sharp.

To use it, they extend the plate of metal on a leaden table or block, and with a pretty heavy hammer strike the head of the punch, &c. See **BUTTON-making**.

PUNCH Horse, in the *Manege*, is a well-set, well-knit horse, short-backed and thick-shouldered, with a broad neck, and well lined with flesh. Thus, we have the Suffolk punch horse, &c.

PUNCH is also a name of a sort of compound drink, frequent in England, and particularly about the maritime parts of the country.

Its basis is spring water, which being rendered cooler, brisker, and more acid, with lemon-juice, and sweetened again to the palate with fine sugar, makes what they call *sherbet*; to which a proper quantity of a spirituous liquor, as brandy, rum, or arrack, being superadded, the liquor becomes *punch*.

Several authors condemn the use of punch, as prejudicial to the brain, and nervous system. Dr. Cheyne insists, that there is but one wholesome ingredient in it; *viz.* the mere water.

The proportions of the ingredients are various. Some, instead of lemon-juice, use lime-juice, which makes what they call *punch-royal*; this is found less liable to affect the head, as well as more grateful to the stomach.

Some also make milk-punch, by adding nearly as much milk to the sherbet as there is water, which tempers the acrimony of the lemon. Others prefer tea-punch, made of green tea instead of water, and drank hot.

Lastly, What they call punch for chamber-maids, is made without any water, of lime-juice, sharpened with a little orange and lemon-juice; twice as much white wine as lime-juice, and four times as much brandy, with sugar.

PUNCHEEE, in *Geography*, a town of Morung; 75 miles E. of Amerpour.

PUNCHEON. See PUNCHION.

PUNCHIN, or PUNCHION, in *Building*. See PUNCHION.

PUNCHION, or PUNCHEON, a little block or piece of steel, on one end of which is some figure, letter, or mark, engraven either in creux, or in relievō; impressions of which are taken in metal, or some other matter, by striking it with a hammer.

There are various kinds of these punchions used in the mechanical arts. Such, for instance, are those of the goldsmiths, cutlers, pewterers, &c.

PUNCHION, in *Coining*, is a piece of iron steeled, on which the engraver has cut, in relievō, the several figures, arms, effigy, inscription, &c. that are to be in the matrices with which the species are to be marked.

Minters distinguish three kinds of punchions, according to the three kinds of matrices to be made; that of the effigy, that of the cross or arms, and that of the legend or inscription.

The first includes the whole portrait in relievō. The second are small, each only containing a piece of the cross or arms, *v. gr.* a fleur-de-lys, a harp, a coronet, &c. by the assemblage of all which the entire matrix is formed. The punchions of the legend only contain each one letter, and serve equally for the legend on the effigy-side, and the cross-side. See COINING.

For the manner of engraving, tempering, and stamping, these punchions, to form the matrices, see ENGRAVING on steel, MATRICE, &c.

PUNCHIONS, in *Printing*, are those used in stamping the matrices, in which the types of printing characters are cast. See LETTER FOUNDERY.

PUNCHION is also used for several iron tools of various sizes and figures, used by the engravers in creux on metals. Seal-gravers particularly use a great number, for the several pieces of arms, &c. to be engraven; and many stamp the whole seal from a single punchion.

PUNCHION is also a common name for all the iron instruments used by the stone cutters, sculptors, locksmiths, &c. for the cutting, incising, or piercing their several matters.

Those of sculptors and statuaries serve for the repairing statues, when they are taken out of the moulds.

The locksmiths use the greatest variety of punchions;

some for piercing hot, others for piercing cold; some flat, some square, some round, others oval; each to pierce holes of its respective figure in several parts of locks.

PUNCHION, or *Punchin*, in *Carpentry*, is a piece of timber placed upright between two posts, whose bearing is too great, serving together with them to sustain some large weight.

The punchion is usually lower and slighter than either prick-posts or principal posts, and is joined by a brace, or the like, of iron. See POST. Those on each side of a door, are called *door punchions*.

PUNCHION is also a piece of timber raised upright under the ridge of a building, in which the little forces, &c. are jointed. Vitruvius calls the punchion *columnen*.

PUNCHION is also used for the arbor or principal part of a machine, on which it turns vertically; as that of a crane, &c.

PUNCHION is also a measure for liquids, containing a hoghead and a third, or 84 gallons, or one-third of a tun.

The Paris punchion is the same with their demiqueue; at Rouen it is three bushels, &c. See MEASURE.

PUNCRACK, in *Geography*, a town of Hindoostan, in Bahar; 22 miles N.E. of Bahar.

PUNCTA LACRYMALIA, in *Anatomy*, the two small round openings at the inner ends of the eye-lids, by which the lacrymal canals, conveying the tears to the lacrymal bag from the surface of the eye, begin. They are distinguished by the epithets *superius* and *inferius*. See EYE.

PUNCTATED HYPERBOLA, in the *Higher Geometry*, an hyperbola whose oval conjugate is infinitely small, *i. e.* a point.

PUNCTICULARIS FEBRIS, in *Medicine*, a name given by some authors to fever, when accompanied with an eruption of purple spots, or *petechiæ*; these spots being sometimes called *puncticula*. See PETECHIÆ.

PUNCTION, or PUNCTURE, in *Surgery*, an aperture made in the lower belly, in dropical persons, to discharge the water, called also *paracentesis*.

PUNCTUATION, in *Grammar*, the art of pointing; or dividing a discourse into periods, and members of periods, by points expressing the pauses to be made in the reading of it; and necessary both for understanding and pronouncing it.

The points that are used are four; *viz.* the *period*, *colon*, *semicolon*, and *comma*. See the particular use of each under its proper article.

Punctuation is a modern art; the ancients were entirely unacquainted with the use of our commas, colons, &c. and wrote not only without any distinction of members and periods, but also without distinction of words; which custom, Lipsius observes, continued till the 104th Olympiad; during which time the sense alone divided the discourse.

The antiquity of pointing, however, has had its advocates; some have ascribed the invention of it to Thrasymachus, who was contemporary with Plato; others to Isocrates, who flourished about the same time; and others to Nicanor, in the time of Adrian. A late writer observes, that pointing was not unknown in the time of Alexander the Great. Aloysii Antonii Verneii, &c. de Orthog. Lat. Rom. 1747.

Cicero's expressions, *verborum et sententiarum interpunctas clausulas in orationibus*, lib. iii. de Orat. and *clausulus atque interpuncta verborum*, &c. in his Orat. pro Muræna, have been alleged by some as evidences of the antiquity of this practice; but others have referred the former words to speaking, and not to writing; the latter, to those points which were formerly placed after each word, in order to distinguish

tinguish word from word, when the whole was written in large capitals, at equal distances from one another; which is a very different thing from that sort of punctuation which divides the sense and subject matter into members and sentences, and parts of sentences, in such proportions as either the sense or the construction may require. The words of Seneca in his 40th Ep. *Nos etiam cum scribimus interpungere solemus*, are more applicable to this latter sort of pointing than those of Cicero; and yet these have been understood to refer to the distinctions of words. See an Essay on the Use of Pointing, by Sir James Burrow, F.R.S. and F.A.S. 4to. p. 6.

There is much more difficulty in pointing than people are generally aware of. In effect, there is scarcely any thing in the province of the grammarian so little fixed and ascertained as this. The rules usually laid down are impertinent, dark, and deficient; and the practice, at present, is perfectly capricious, authors varying not only from one another, but from themselves too.

Dr. Lowth observes, that few precise rules can be given which will hold without exception, in all cases; they must be laid down with as much exactness as the nature of the subject will admit; and they may serve for a general direction, to be accommodated to different occasions, and to be supplied, when deficient, by the taste and judgment of the writer. *Introd. to Eng. Gram. Ed. 1772, p. 194.*

Indeed, F. Buffier, and since him Dr. Ward, and bishop Lowth, have done something towards a fixed and precise system of pointing, from the reason and analogy of things. Their doctrine the reader will find under the articles COMMA, COLON, SENTENCE, &c.

In the general, we shall only here observe, that the comma is to distinguish nouns from nouns, verbs from verbs, and such other parts of a period as are not necessarily joined together. The semicolon serves to suspend and sustain the period when too long; the colon, to add some new, super-numerary reason, or consequence, to what is already said; and the period, to close the sense and construction, and to release the voice. For the proportional quantity, or time of the points, with respect to one another, see COMMA.

PUNCTUM, in *Geometry*, &c. See POINT. In the schools they have their

PUNCTUM *Terminans*, which is the indivisible extreme of a line, beyond which no part of the line extends.

PUNCTUM *Continuans*, an indivisible magnitude between contiguous points of a line, by which they are connected, and from whence arises a continuity.

PUNCTUM *Initians*, an indivisible point, from which the line begins.

PUNCTUM *Formatum*, or *Generatum*, in *Conics*, is a point determined by the intersection of a right line drawn through the vertex of a cone to a point in the plane of the base that constitutes the conic section.

PUNCTUM *ex comparatione* denotes either of the foci of an ellipsis and hyperbola; thus called by Apollonius, because the rectangles under the segment of the transverse diameter in the ellipsis, and under that and the distance between the vertex and the focus in the hyperbola, are equal to one fourth part of what he calls the *figure* of it.

PUNCTUM *Lineans*, in *Geometry*, is a term used by some authors for that point of the generating circle of a cycloid, or epicycloid, which in the genesis produces any part of the cycloidal line.

PUNCTUM *Saliens*, in *Anatomy*, the heart of the incubated chicken, at the time when it first displays motion. See INCUBATION.

PUNCTUM *Aureum*, an old mode of operating with a view

of accomplishing the radical cure of hernia, or ruptures. An incision was made down to the neck of the hernial sac, under which a golden wire was drawn and tightened, after the bowels had been reduced. The dangerous consequences which have occasionally followed this method, and particularly its insufficiency to protect the patient from a future descent of the bowels, are the reasons which have led the generality of modern practitioners to abandon the practice altogether.

PUNCTURE, PUNCTURA, in *Surgery*, &c. any wound made by a pointed instrument.

PUNCTURED WOUNDS. See WOUNDS.

PUND-BRECH, or POUND-BREACH, compounded of the Saxon, *pund*, *pound*, and *brech*, *fracture*, *breaking*, denotes the illegal taking of cattle out of the pound; either by breaking the pound, picking the lock, or otherwise.

“Si pund-brech fiat in curia regis, plena wyta fit: alibi quinquin manæ.” *Leg. Hen. I.* See POUND.

PUNDFULDA, a pound for cattle, or pinfold. “Placita inter abbat.” *Glaston. et Hen. de Hamel, anno 1236.*

PUNDIPOUR, in *Geography*, a town of Hindoostan, in Oude; 20 miles S.S.W. of Fyzabad.

PUNDIT, in the *History of Eastern Literature*, the name given to the interpreter of the Hindu law.

PUNDNA, in *Geography*, a town of Affam; 20 miles W. of Gentiah.

PUNGANORE, a town of Hindoostan, in Myfore; 60 miles W.N.W. of Arcot. N. lat. 13° 12'. E. long. 78° 32'.

PUNGITIUS, in *Ichthyology*, the ten-spined stickleback of the British Zoology, a species of *Gasterosteus*; which see.

PUNGNAN, in *Geography*, a town of Meckley; 58 miles W. of Munnypour.

PUNGO ISLANDS, a cluster of small islands, at the mouth of the river Gabon, near the coast of Benin; the principal island being about six miles in circumference and governed by a king.

PUNHETE, a town of Portugal, in Estramadura, at the conflux of the Zezere with the Tagus; 8 miles W.N.W. of Abrantes.

PUNICA, in *Botany*, *malum punicum* of the ancients, so called, as it is presumed, because the Romans obtained this fruit from the north of Africa. Sometimes it was called *malum granatum*, in allusion to its internal granulations; whence the English name, Pomegranate.—*Linn. Gen. 248. Schreb. 335. Willd. Sp. Pl. v. 2. 981. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. v. 3. 194. Sm. Prodr. Fl. Græc. Sibth. v. 1. 336. Juss. 325. Tourn. t. 407. Lamarck Illustr. t. 415. Gærtn. t. 38.—Class and order, Icosandria Monogynia. Nat. Ord. Pomaceæ, Linn. Myrti, Juss.*

Gen. Ch. Cal. Perianth superior, of one leaf, bell-shaped, coloured, permanent, in five acute segments. Cor. Petals five, roundish, rather spreading, inserted into the calyx. Stam. Filaments numerous, capillary, inserted into the tube of the calyx, without any order, and shorter than its segments; anthers oblong. Pist. Germen inferior, roundish; style simple, the length of the stamens; stigma capitate. Peric. Apple nearly globose, large, crowned with the calyx, separated into two internal divisions by a transverse partition, the uppermost of them subdivided into about nine cells, the lowermost into about three, with membranous partitions. Seeds very numerous, angular, each with a pulpy coat. Receptacle fleshy, pitted, dividing each cell into two parts.

Ess. Ch. Calyx superior, in five segments. Petals five. Apple with many cells. Seeds numerous, pulpy.

1. P. *Granatum*. Common Pomegranate Tree. *Linn. Sp.*

Sp. Pl. 676. Willd. n. 1. Ait. n. 1. Sm. Fl. Græc. Sibth. t. 476, unpublished. Trew Ehret. 36. t. 71, 72. Mill. Illustr. t. 41. Woodv. Med. Bot. t. 58. Andr. Repof. t. 96, with white flowers. (*Malus granata*; Ger. Em. 1450.)—Leaves lanceolate. Stem arboreous.—Native of the south of Europe and north of Africa. Dr. Sibthorp found it plentiful in Greece, both wild and cultivated. The inhabitants know it by its ancient name *ῥόζον*. This tree is one of the oldest exotics in our gardens, but scarcely perfects its fruit, except, now and then, against a warm wall. The beautiful blossoms are produced from June to September, and in a double state are particularly admired and valued. The leaves are opposite or ternate, sessile, wavy, entire, of a fine green, deciduous. *Flowers* sessile. *Calyx* thick and coriaceous. *Petals* membranous and wavy. *Fruit* as big as an orange, of a tawny brown, with a thick astringent coat, containing abundance of seeds, each enveloped in a distinct, very juicy, crimson coat, whose flavour, in a wild state, is a pure very strong acid, but in the cultivated plant sweet and highly grateful.

2. *P. nana*. Dwarf Pomegranate Tree. Linn. Sp. Pl. 676. Curt. Mag. t. 634.—Leaves linear. Stem shrubby.—Native of the West Indies. Said to have been cultivated in Sherard's garden at Eltham in 1723. At present it is a rare green-house shrub, of humble size, flowering in summer, and having all the appearance of a dwarf variety of the foregoing.

PUNICA, in *Gardening*, contains plants of the tree and shrub kinds, of which the species cultivated are, the common pomegranate (*P. granatum*); and the dwarf pomegranate (*P. nana*).

Of the first there are several varieties; as the large double-flowered, and the striped-flowered.

Method of Culture.—The first sort and varieties are readily increased by layers, which should be laid in autumn, chusing the young branches for the purpose, giving a little slit underneath at a bud, and laying them in the usual way, giving occasional waterings in summer; and by the following autumn they will be well rooted, and fit to be planted in nursery-rows for two or three years, to get strength, and then planted where they are to remain.

Those of the common sort and varieties may be trained as half or full standards, or as dwarfs; but those designed for walls should be managed as directed for peaches, &c. This sort may be planted against warm walls, and be pruned and trained as other fruit-trees.

Of this sort, the double-flowering kind is much more esteemed than the other in this country, for the sake of its large, fine, double flowers, which are of a most beautiful scarlet colour; and, if the trees are supplied with due nourishment, continue to produce flowers for two months successively; which renders it one of the most valuable flower-

ing trees. This sort may be rendered more productive of flowers by grafting it upon stocks of the single kind, which check the luxuriance of the trees, and cause them to produce flowers upon almost every shoot.

The second sort may be raised also by layers, as the former, but must be planted in pots filled with rich earth, and preserved in a green-house. In the summer, when the flowers begin to appear, if the plants are exposed to the open air, the buds will fall off without opening; they should therefore be placed in an airy glass case, and a large share of air should be given them every day in warm weather. By this treatment the plants may be continued in flower upwards of three months, and make a fine appearance.

These are very ornamental trees for shrubberies and other places.

PUNICUS LAPIS, in *Natural History*, a name given by the writers of the middle ages to a stone of a spongy texture, the powder of which was good in diseases of the eyes.

This seems to have been no other than the pumice, the writers of these times having been strangely incorrect in their orthography; and all the virtues ascribed to this stone, as also the places where it was found, which are the Æolian islands, &c. seeming to have been copied from Pliny's account of the pumice.

PUNIE, in *Geography*, a town of Lithuania, in the palatinate of Troki; 5 miles N. of Olita.

PUNJE, a town of Hindoostan, in the circle of Ellichpour; 5 miles E. of Akoat.

PUNJEREE, a town of Hindoostan, in Bahar; 20 miles N.W. of Palamow.

PUNJGOOR, or *PUNGER*, the name of a small but fertile district of Persia, lying about ten days' journey N.N.E. from Kej, the capital or chief town of all Mekran. It is celebrated for the quality and quantity of the dates it produces, and contains 13 well-peopled villages, all of which are abundantly supplied with water from the bed of the river Burdoo, a few miles N. of them. These villages, two of which are larger and more respectable than the others, are governed by an independent chief. Punjgoor is 15 days' journey from Kelat, by the route of Khozelar, and at the same distance from Nooshley by that of Kharan. It is spoken of as a very mountainous tract, producing in some of its villages grain, sufficient for the consumption of the few wandering shepherds who inhabit them. The people are rather a small delicate race; their arms are a match-lock, sword and shield, and each village has its own chief, who settles the disputes which occur among the inhabitants. This district has plenty of water, except in the months of April, May, and June, when it becomes scarce; it produces dates, and furnishes camels, sheep, and goats, but not in great numbers.
