SPIRAL Vessels, in Vegetable Physiology, are found ranged concentrically round the pith in the tender branches or stalks of numerous plants, particularly the Elder, Syriuga, Cornel, Peony, and many of the Liliaceous order. If a branch be partly cut transversely, or gently broken, and the portions slowly drawn asunder, a number of fine white fibres will be perceived gradually to unroll, and these will often support a considerable piece of the divided stalk. These fibres originally formed the coat of the vessels in question. After the plant has acquired a certain firmness of texture, or has finished its growth for the season, such can no longer be unrolled. Mirbel has delineated many specimens of these vessels, in which the spiral fibre of each is more or less imperfect, shewing that, probably as they advance in age, the vessels become entire tubes.

The use of these spiral-coated vessels has been much disputed. They being commonly found on dissection to contain scarcely any fluid but air, Malpighi, Crew, and others,

have called them air-vessels, supposing they were the lungs of plants, and imbibed air from the atmosphere, through another more external set of roundish or oval air-vessels, of which leaves, petals, &c. are full. But the experiments of Darwin and Knight rather shew the spiral-coated tubes to be the true sap-vessels, in which light we have considered them in the article CIRCULATION of Sap, to which we refer the reader. No such spiral vessels are found in the bark of plants, at any period of its growth.

SPIRATION. See EXPIRATION, INSPIRATION, PER-SPIRATION, RESPIRATION, and TRANSPIRATION.

SPIRATION, in Scholastic Theology, a term used by the popish schoolmen to signify the manner in which the personality of the Holy Spirit was derived from the Father and the Son. See PROCESSION and Holy SPIRIT.

SPIRDING SEE, in Geography, a large lake of Prussia; 30 miles S. of Bartenstein.

SPIRE, in Agriculture, a term signifying to sprout, as grain in the malting process, &c. The spiring in this process should neither be carried too far nor stopped too suddenly, as in both cases the malt suffers injury. See MALT.

SPIRE, Spira, in the Ancient Architecture, is sometimes used for the base of a column, and sometimes for the atragal, or tore.

The word is formed from the Latin *spira*, the folds of a serpent, which bear some resemblance to it; or from the Greek *σπῆρα*, the coil of a rope.

SPIRE is also a pyramidal termination of the tower of a church or other building. This ornament, being the genuine offspring of the pointed arch, and not occurring in the monuments of Greece or Rome, ought to be confined to its proper style. It is an incongruity to introduce it into Grecian architecture.

SPIRE, in Geography, a city of France, and principal place of a district, in the department of Mont Tonnerre, containing 3744 inhabitants, (its canton having 7894,) in 9 communes. This was, before the French revolution, an imperial city of Germany, and the capital of a bishopric of the same name. Spire is an ancient city, said to have been founded before the commencement of the Christian era, and receives its name from the small river Spirebach, which runs into the Rhine, about 500 paces below it. It contains a cathedral, three collegiate churches, and several convents, besides two churches belonging to the Lutherans, of which class the magistrates and greater number of the inhabitants consist. The Franks took this city from the Romans, and it became one of the original imperial cities. In the year 1529, a diet was held here, in which the reformers first obtained the name of Protestants. It was destroyed by the French in 1689, and lay waste for ten years, nor was it rebuilt till after the peace of Ryfwick. Before this disaster, it was the seat of the imperial chamber. In December 1793, it surrendered to the republican troops of France. The bishopric of Spire is of considerable antiquity. Its territories were situated on the Rhine, between the Palatinate, the duchy of Wurtemberg, the margraviate of Baden, and the principality of Deux-Ponts, about 18 leagues in length, and 12 in breadth. It is mountainous, and covered with forests; nevertheless it produces corn, wine, chestnuts, and almonds. The bishop was suffragan of Mentz, and resided at Bruchsal. The territories on the left bank of the Rhine have been united to France, and in 1802, those on the right were given as indemnities to the margrave of Baden; 12 miles S.W. of Heidelberg. N. lat. 49° 18'. E. long. 8° 30'.

SPIRES,

SPIRES, in *Rural Economy*, a term provincially used to signify timber-lands.

SPIRINCHUS, in *Ichthyology*, a name by which some authors have called the smelt.

SPIRIT, **SPIRITUS**, in *Physiology*, the most subtle and volatile part, or juice of the body; by means of which its functions and operations have been supposed to be performed.

The ancients made a fourfold division of spirits; into *vital*, *animal*, *natural*, and *genital*; the first of which they placed in the heart; the second, in the brain; the third, in the stomach and liver; and the last, in the testicles: but as this division is founded on a false hypothesis, it is now deservedly set aside.

The moderns have usually divided spirits into *vital* and *animal*: the former being only the finest and most agitated parts of the blood, on which its motion and heat depend: and the latter an exceedingly thin, subtle, moveable fluid, juice, or humour, separated from the blood in the cortex of the brain, and thence received into the minute fibres of the medulla, and by them discharged into the nerves; by which it is conveyed through every part of the body, to be the instrument of sensation, muscular motion, &c. See *ANIMAL Spirits*, and *NERVOUS Fluid, Juice, and System*.

SPIRITS, *Low*, in *Medicine*. See **MELANCHOLY**.

SPIRIT, *Spiritus*, in the *Newtonian Physics*, denotes a most subtle penetrative substance, which some have supposed to pervade all, even the densest bodies, and to lie hid in them; and by the force and action of which, the particles of bodies attract each other, at very small distances, and, when contiguous, cohere; and by which electrical bodies act at greater distances, both attracting and repelling the neighbouring corpuscles; and light is emitted, reflected, and inflected, and warms bodies; and all sensation is excited, and the members of the animals move at the instance of the will, *viz.* by vibrations of this spirit, propagated through the solid capillaments of the nerves, from the external organs of sense to the brain, and from the brain to the muscles.

SPIRIT, in *Antiquated Chemistry*, is one of the hypothetical principles of natural bodies, called also *mercury*.

The chemical principle spirit was defined to be a fine, subtle, volatile, penetrating, pungent liquor, which rises, ordinarily, before the phlegm, or water, and sometimes after it.

The great properties of this liquor were imagined to be, that it penetrates and opens solid bodies; corrodes, breaks, and even dissolves certain mixed bodies; coagulates others; and produces an infinity of other effects, many of them even contrary to one another.

In the general, the early chemists gave the denomination of spirits to all the fine, subtle, not aqueous, particles raised from bodies by heat, and reduced into liquors by distillation. Such are spirit of vitriol, of nitre, of salt, &c.

They also applied the name spirits to those aqueous liquors which are drawn by liquefaction, when they are impregnated with salts or other active principles, raised, together with them, by the violence of the fire.

In this sense, the chemists were said to draw a spirit from sulphur, salt, and other bodies, when they extract the essence, or the subtlest part of them, by distillation, or otherwise. Accordingly, spirits were distributed into three principal kinds, *viz.* *inflammable* spirits, *acid* spirits, and *alkaline* spirits.

To the first class belong the most volatile and thinnest part of essential oils, the principle of smell, or *spiritus rector* of

plants, (see **AROMA**,) and *ardent* spirits, or the spirit obtained from wine, beer, and all liquors which have undergone the spirituous fermentation. See **ALCOHOL**.

The second class includes all acids obtained by distillation of minerals, vegetables, and animals; such are, 1. The acids of sulphur, vitriol, and alum, which are the same as vitriolic acid, and the acids of nitre and common salt. They are called spirit of sulphur, spirit of vitriol, spirit of nitre, &c. without specifying that they are acids. 2. The acids of vinegar, and of all liquors which have undergone the acetous fermentation, and the acids obtained in the distillation of vegetables, and of certain animals, as flies, ants, &c. These spirits are commonly called *acid* spirits, as the acid spirit of guaiacum, the acid spirit of ants, &c. because the substances which furnish them yield also spirits that are not acid. See **ACID**.

To the third class are referred liquid volatile alkalies, obtained from sal ammoniac, from all vegetable matters which have undergone a complete putrefaction, and from all animal matters. These are generally called spirits, without specifying their alkaline quality. Thus we say, volatile spirit of sal ammoniac, spirit of hartshorn, &c. As some of these substances, particularly sal ammoniac, contain also an acid which may be obtained from them, we ought, when we mention this spirit, to specify its acid quality, calling it acid spirit of sal ammoniac.

SPIRITS, *Distilled*, a general name given among distillers to those ardent liquors that are obtained from various materials, and by different processes of distillation. The nature and properties of these liquors, and the modes of obtaining them, are detailed under the articles **ALCOHOL**, **BRANDY**, **DISTILLATION**, **FERMENTATION**, &c.; but we shall here specify some particulars that more immediately relate to the common spirituous liquors that are, we lament to say it, so much in use in our own country. These are, for the most part, prepared from fermented corn of one kind or other, with certain additions, at the pleasure of the distiller, of molasses, carrots, and other saccharine vegetables. The principal ingredient, except in a season of scarcity, is one kind or other of grain. (See **ADDITION**.) The spirit thus procured is rectified for sale by being redistilled with juniper-berries, turpentine, and other substances, in order to modify and improve its flavour and appearance. The grain, when barley is used, is usually first malted, and in Scotland it is dried with peat, which gives to the spirit distilled from it, called "whisky," its peculiar flavour. It is then ground into coarse powder, and the infusion fermented with yeast in large tuns. This fermented liquor is called "wash," and in this state it is fit for distillation. Under the articles already referred to, the general process and the implements used in it are described; but previously to the operation some substances are added to the wash, for the purpose either of increasing the quantity of spirit that is afforded by it, or of keeping down the essential oil derived from the malt, which would give the liquor a nauseous flavour, or of regulating the boiling within the still, and preventing it from boiling over or "running foul," or of neutralizing the acid generated during the fermentation, which would very considerably lessen the product of spirit. For these purposes soap is considered the best addition, and accordingly it is used in large quantities. Other distillers use alkalies. At the commencement of the operation, the liquid is oily and turbid, and has a nauseous flavour, on account of the oil of the malt which accompanies it; but by degrees it becomes clear, and runs so to the last, although its strength decreases, and it becomes more watery,

SPIRITS.

and consequently of less specific gravity. (See *Specific Gravity*.) The quantity intermediately obtained, omitting the first and the last products, is then redistilled or "rectified," (see *RECTIFICATION*); and in this stage of the operation, those additions (such as juniper-berries, &c.) which give the spirit its flavour, are introduced into it. The process of distillation on a small scale is simple and easily conducted; but the large distilleries, where expensive works are carried on, require a greater degree of practical skill, both in the preparation of the apparatus, the adjustment of the materials, and the conduct of the operation. In order to expedite the process, several alterations have been made in the form of the still, particularly in Scotland, where it is an object of importance to be quick in the dispatch of the operation, on account of the mode of levying the duty; and, therefore, by gradually widening the bottom and contracting the height of the still, distillation is performed with a surprising rapidity. A still is said to have been constructed, which contains only 40 gallons in the body and three in the head, and in the use of it the whole time of its operation, from its commencement to its close, amounts only to $2\frac{3}{4}$ minutes, when the charge of wash is 16 gallons, or $\frac{2}{3}$ ths of the whole content. In rectification, which is a slower process, the charge is 24 gallons, and the time of distilling about 10 minutes.

A good spirit may be obtained without malting the grain, whether it be barley, or any other kind of corn which will answer the purpose. With us, a mixture of barley and malt is generally preferred; in Holland, the very best geneva is made from wheat and malt, though more commonly from malt and rye, the latter yielding more spirit than wheat.

The following process is that which is practised by most distillers. A quantity of rye-flour, coarsely ground, is mixed with a third or fourth part of malt, and put into the fermenting tub, with cold water, stirring it well with the hand, to prevent the meal from clotting. Water of a blood-warmth is then added, in sufficient quantity, after which the ferment, composed of the yeast of former operations, dried and kept for a certain time, is mixed with the whole. (See *FERMENT*.) When the weather is favourable, and the heat well regulated, the fermentation begins in six hours, and terminates on the third day, when the liquor becomes transparent, and assumes a hot pungent taste. The distillation is then immediately commenced, before the liquor turns sour, which should as much as possible be avoided. The distillation is conducted very slowly, to prevent the impregnation of the oil of the grain with the spirit, and of course the unpleasant flavour of the spirits. The first spirit is then rectified by a second distillation over juniper-berries, or in "double geneva," by a third process.

In some of the ordinary sorts, however, the juniper-berries are mixed with the fermenting materials, and one distillation suffices. In the common geneva or gin, vulgarly used in this country, the fine juniper flavour is coarsely imitated by turpentine. See *GENEVA*.

For the process of obtaining arrack, brandy, and rum, see *ARAC*, *BRANDY*, and *RUM*.

SPIRITS, Proof, or common saleable goods, are spirits of any kind of a determinate strength, being the same with those of good brandy, and the malt and sugar spirits of the distillery, as they are usually sold; containing equal quantities, or definite proportions, of rectified spirit and water.

The best proof spirit is that distilled from French wine; but for common use, the spirit drawn from molasses may be employed.

The common method of examining whether spirits have this due degree of strength is this:—take a long phial, fill it

half way with the common malt spirit, and give it a smart stroke by its bottom against the palm of the hand, there will then appear on the surface a chaplet, or crown of bubbles, which will go off again in a strong manner; that is, first remaining a while, and then going off by degrees, without breaking into smaller bubbles, or swelling into larger.

By this experiment all the traders in spirits judge of the strength of the goods they purchase; yet this is a mere fallacy and deception; for if only a little vinous or saccharine matter, as treacle, syrup, must, rob of fruits, or the like, be added to a quantity of highly rectified spirit of wine, this slight addition will give a brandy proof to that spirit. See *ALCOHOL*, *BRANDY*, and *BEAD Proof*.

Whether there be any secret for making weaker spirits shew this proof as well as brandies, &c. is not certainly known; but the thing is practicable, since arrack, which is but of half the strength of brandy, gives as fair a proof this way; and if a drop or two of any essential oil be added to a pint of brandy, it takes off its proof, and makes it appear much weaker than it is. The true strength may, however, always be known, by carefully burning away a measured quantity of brandy, &c. since if it leaves one half water it is right; if more or less, it is too strong, or too weak.

But beside the false method of judging of brandies by what is called *proof*, there is another not less fallacious one of judging of their goodness, though kept as a great secret in the hands of some dealers, and imagined a certain criterion to determine whether foreign brandies are mixed with corn spirits. These distillers are provided with a certain yellow liquor, a few drops of which being poured into a glass of right French brandy gives it a beautiful blue colour, and, by the strength and goodness of this colour, they judge and buy; but if common malt spirit be tinged with oak, it would give this colour equally with French brandy, and might be purchased as such. This proof tincture is expeditiously made, by dissolving a little green vitriol, first calcined to a redness, in a weak spirit of sea-salt, which thus becomes a yellow liquor, a single drop or two of which being added to a glass of any inflammable spirit, coloured yellow or brown with oak, or with long remaining in the cask, will instantly turn it of a bright and beautiful blue.

The best way of judging in these cases is by the nose and palate. Dilute a quantity of brandy considerably with water, and you will perceive the malt taste, if mixed with malt spirits; or burn a little in a spoon, and by the smell and taste of the water it leaves, you will easily judge whether there be malt in it.

Proof spirits may be distinguished into three kinds, *perfect proof*, *more than perfect proof*, and *less than perfect proof*. By *perfect proof* is usually understood that crown of bubbles, before mentioned, of a certain size, arising as a head upon a small quantity of a well-qualified spirit shook in a slender phial.

Proof more than perfect, is that in which the bubbles raised by shaking the spirits, are larger than those on the common or perfect proof, and go off more suddenly; that is, according as the spirit is higher, or approaches more to the nature of rectified spirit, or, as it is usually called, *spirit of wine*.

Proof less than perfect, is that in which the bubbles are smaller, and go off quicker and fainter than in perfect proof; the spirit in this case being mixed with more than its own quantity of phlegm, or being too poor for sale.

The surest method of judging of the strength of spirits, is by the hydrometer, water-poise, or balance; or, 2dly, by distillation, or finally, by deslagration. The specific gravity of totally inflammable spirit is so much less than that of phlegm,

phlegm, or common water, that it is easily sensible upon the balance; whence an exact hydrometer, well balanced and graduated, and furnished with a proper scale of weights, may be of great use to assign the proportions in which pure spirit and water are mixed in any given liquor. (See *Specific Gravity*, and *HYDROMETER*.) Though, perhaps, a readier way than this may be that of M. Homberg's, mentioned in the Memoirs of the Paris Academy, 1718, for determining the different gravities of different fluids, by means of a bottle with a very long and slender neck; which being filled to a certain height with any mixture of spirit, is weighed against the same bottle filled with pure water.

The most exact of all methods of determining the strength and spirit is by distillation, rectifying it up to an alcohol, or totally inflammable spirit; but this, though liable to no error, is too tedious to come into common use. And, upon the whole, the best method of all others, seems to be that of deslagration, which M. Geoffroy has been at much pains to adjust and improve.

In commerce, with regard to spirits, it would certainly be a much better method to abolish such uncertain proofs, and to make all the goods of the strength of what we call spirits of wine; that is, a totally inflammable spirit, whose purity is much greater, whose strength may always be found out with exactness, and whose bulk, stowage, carriage, and incumbrance, would be only half in regard to that of brandy, or proof spirits; and it might at all times, as occasion called for it, be mixed into a great variety of extemporaneous liquors, and the exact degree of strength would be always precisely known.

This operation, indeed, in the common way, proves so tedious and expensive, and, after all, so short of expectation, and so generally unsatisfactory, that it is not to be expected that the common distillers, till they have fallen into a better manner of working, should come into the proposal. But if, instead of the common way of rectifying by the hot-still, they would try the use of a large balneum Mariæ, made of a large rectangular boiler, and a set of tall conical vessels, they will find that little fire, and little attendance, and consequently very little expence, will, in this manner, furnish them with spirits reduced at once to this standard, and greatly superior, in all respects, to the common ones of the same strength. In this case there would be no need of any addition of salts; but the distiller may work more perfectly, and more expeditiously without them, and thus preserve the fine essential vinosity of the spirit, which, in the common way of working, they constantly lose.

The advantage of this method would be yet greater to the apothecaries, and the makers of compound cordial waters, who want only a pure spirit of such a strength, and suffer greatly in the fineness and perfection of their commodities, by the spirit they are obliged to use having in it a fulsome and nauseous oil of its own, which will always mix itself with their compositions, and the oils of the aromatics, &c. which they add to it. If spirits were brought to this standard for the market, there would be no possibility of deceit, and no farther examination need be made of it by the buyer than its burning perfectly dry in a spoon. Shaw's Essay on Distillery.

It is, however, to be observed, that though the burning of spirits away in a spoon may serve the trader in the common way, yet M. Geoffroy has observed, that they are no proofs for the philosopher, or the chemist, being not at all determinate or exact, though commonly supposed so.

From what has been said, it appears that brandy is much more inflammable than wine, and spirit of wine much more so than brandy, and ought to burn away without leaving

any remainder. Hence it is vulgarly supposed, that such spirit of wine as burns wholly away contains no phlegm, and that if two parcels of spirit both burn wholly away in this manner, they must be the same in strength, and in all other qualities; but M. Geoffroy has proved by experiment, that such spirit as burns wholly away, does yet contain a great deal of water, and two parcels both may burn thus away, and yet be very different; and that this trial is not determined by the entire absence of the phlegm, but by its proportion to the oil.

If the same spirit of wine, which in the common way of burning leaves no water, be again tried, by burning it in a hollow vessel set to float in a large quantity of cold water, it will then leave a considerable quantity of water; nay, all that is rectified only in the common way, leaves a large portion of phlegm on this experiment. The plain reason of which is, that this is the only fair trial, the other in the common way being fallacious. In this there is no more water left than was in the spirit; but in the other, the vessel becoming heated by the burning of the spirit, that heat gradually evaporates the water, as the spirit burns away; so that the one is as soon gone as the other. But keeping the vessel cool by external water, prevents that evaporation, and consequently retains and discovers all that cannot burn of the spirit.

The quantity of water thus discovered in spirit of wine is very great, and it has always been found, that in proportion as the experiment has been made more and more perfect, the spirit has always appeared proportionably less and less so.

Pure alcohol, or alcohol of a specific gravity of .796, at 60° Fahr., which is the strongest that can be procured, leaves no water; rectified spirit of moderate strength, 25 per cent.; French brandy, 56; and common malt liquor, 65.

The test for ascertaining the strength of spirits by pouring a few drops on gunpowder, is very incorrect. A more accurate test than any of these, and sufficient for common purposes, is to shake the spirit in a phial with very dry carbonate of potash, and observe the quantity of water attracted by the alkali, which indicates its strength. But the only certain mode of ascertaining the relative strength of spirits, is by determining the specific gravity of the spirit at a given temperature; thus, at 60° Fahr. the specific gravity of rectified spirit is .83599, at 65° it is .83362, and at 70° the gravity of the same spirit is .83134; while the gravity of the proof spirit of the London College, at the same degree of temperature, is .93002, .92794, and .92580, (see the table under SPIRITS, in the *Materia Medica*;) the weakest spirit having the greatest specific gravity, and this diminishing as the temperature increases. For ordinary purposes, the relative strength of spirits may be known by weighing the sample to be tried in a phial capable of holding exactly 500 grains of water. An equal bulk of rectified spirit weighs 418 grains, and of proof spirit 465; hence the number of grains above or below these sums will indicate the relative strength of the spirit.

The quality of the phlegm that is left is also of use to judge of the spirit by; if that were perfectly fine, this ought to be perfectly limpid and clear, and without taste or smell: as it wants either of these properties, it is a proof of the want of perfection of the spirit it is obtained from; but the greatest of all defects, is its having a coarse oil swimming upon it, and giving the colours of the rainbow in different lights. Mem. Acad. Par. 1718. See BRANDY.

SPIRITS, *Colouring of*, the art of giving to distilled liquors a colour, which takes off their watery appearance, and gives them a resemblance of the foreign brandies, &c.

The colouring is not only necessary on this account, but as we usually esteem the spirits by the proof of the crown of bubbles, it is found that the clean rectified spirit will not afford this proof till it has received its dose of the colour. The distillers dispense this colour in any proportion that they find convenient or necessary; it is always yellow, but, according to the degree, differs extremely in deepness, from the palest straw-colour to the deepest orange. This art of colouring was first introduced, from observing that all the fine and soft foreign brandies, that had the mellowness necessary to their perfection to the taste, had also a yellow colour. The colour, in this case, has indeed nothing to do with the flavour; but that being kept in casks the same age that was necessary to give them this mellowness, would also give them a colour from the wood. It was hence supposed, that the particular excellence of the foreign brandies depended on the woody colour, and accordingly pains have been taken to give the same colour to our spirits by various methods.

The way of obtaining it, by many years standing in the cask, proved too tedious for our hasty workmen, and accordingly they provided means of giving it extempore by strong tinctures of several ingredients; the chief of which are logwood, saffron, Japan earth, treacle, burnt sugar, and oak-chips; the three former of these have but little to recommend them, but the others are found very ready, and very proper for the use.

Treacle gives a fine colour not much unlike that of the foreign brandies, and being necessarily used in a large quantity, as its colour is but dilute, it not only mends the bubble, or bead-proof, impaired by the rectification, but also gives it a fulness in the mouth; both which properties are very agreeable to the vulgar, who are the chief retail consumers of these coarse goods.

Burnt sugar, that is, sugar dissolved in a little water, and scorched over the fire till it turns black, goes much farther in the colouring than treacle, and at the same time gives no sweetness, but rather an agreeable bitterness; and thus recommends itself to the nicer palates, that are not for a luscious spirit. Indeed sugar, thus treated, tinges to a great perfection, and that without loss of time, and with as much cheapness as can well be desired.

The last article mentioned, namely oak-chips, is of all others the most natural for imitating the dye of foreign spirits, as it is the very wood of which the casks they come over in are made, and from which they take that colour of which we are so fond. The colouring with oak has also this farther advantage in spirits meant as sophistications of the foreign ones, that it will stand some tests usually had recourse to on the occasion, which the others will not stand.

Common spirit poured on oak-chips, and digested in a moderate heat, easily fetches out the resinous part of the wood on which the colouring depends; but then it does not go near so far as the burnt sugar; a large quantity of oak being required to colour a small parcel of brandy, or spirits. It is adviseable not to make the tincture every time, but to have recourse to an extract of this wood in a liquid form: this extract is best made in two menstrua, alcohol and water, and may be evaporated to any strength, so that a very small dose of it will tinge a great quantity of liquor. The two liquid extracts will be mixed together, and as they will be apt to separate in standing, it will be proper to add to them, when newly made, a quantity of fine sugar; this will give a body to the whole, and it will keep better from mouldiness than it would without it. Shaw's Essay on Distillery.

SPIRITS, Convertibility of. This is a doctrine that has obtained among many of the most curious experimenters, and, indeed, the most intelligent of our chemists have always allowed, that provided proper care were taken in the getting together of the material, one spirit may always be changed into another, as brandy into rum, malt-spirit into brandy and brandy into malt-spirit. The principles on which this is believed are these.

All simple spirits (as they are called) consist of four parts, water, oil, phlegm, and alcohol; the last of these is the essential part, and is what constitutes the whole a spirit. In reducing spirits, therefore, to their utmost degree of simplicity and purity, it is evident that the three superfluous parts are to be got rid of, and the fourth left alone; by this means the alcohol is procured distinct, and is a liquor *sui generis* of many peculiar qualities, not to be found in any other fluid.

Among others, it has these remarkable properties: 1. When absolutely purified, it is an uniform and homogeneous liquor, capable of no farther separation, without loss or destruction of some of its homogeneous parts. 2. It is totally inflammable, leaving no foot nor any moisture behind. 3. It has no peculiar taste or flavour, any more than pure water, except what is owing to its nature as alcohol, or perfectly pure spirit. 4. It is an unctuous and crispy fluid, running veiny in the distillation, and its drops rolling on the surface of any other fluid, like pease upon a table, before they unite. 5. It appears to be the essential oil of the body it is obtained from, broken very fine, and intimately and strongly mixed with an aqueous fluid, which is assimilated, or changed in its nature in the operation. 6. And lastly, it seems to be a kind of universal fluid, producible with the same properties from every vegetable subject; but to produce it thus requires some care in the operation. See ALCOHOL.

On these principles is founded the opinion, that all spirits may be reduced to a perfect similarity, or sameness, from whatever subject they were procured, and on this depends their convertibility into one another; for when once they are brought to this standard of simplicity, there needs nothing more than to add the oil of such of the finer spirits as is required to convert the spirit into that particular kind. By this means the same tasteless spirit, whether obtained from malt, sugar, or grapes, may be made either into malt-spirit, brandy, or rum, by adding the essential oil of the grape, sugar, or malt; and thus, what was once malt-spirit, shall become brandy, or whatever else the operator pleases.

Many methods have been attempted to obtain the first point, that is, the reducing of the spirit to perfect and pure alcohol. The most practicable means seem to be long digestion, and the repeated distillation from water into water, where the essential oil will at once be left upon two surfaces, and the acid imbibed. The shorter ways are those by rectifying from neutral absorbent salts and earths; such as sugar, chalk, and the like. And lastly, the use of fixed alkalies may be tried, for these very forcibly keep down both the phlegm and oil; inasmuch that this last method promises to be the shortest of all, if the art were known of utterly abolishing the alkaline flavour, which the alcohol is apt to acquire in this operation, and which, for this purpose, is by no means suitable, as absolutely destroying all vinosity, which universally consists in a fine volatile pungent acidity. The distillers are the only people whose business would lead them to make the experiment. This method of converting one spirit into another, would be of immense

profit to them if they could perfectly succeed in it; but as it would require time and slow processes to bring it about, there is but little hope of its ever being brought to bear among them, while they are in their present scheme of doing every thing with dispatch and hurry.

Dr. Shaw has said a vast deal in the praise of a tasteless spirit, which is producible from a vegetable substance, only overlooked, as he tells us, because it is too common, with which all the foreign spirits might be imitated to the utmost perfection by means of their essential oils, all thin fine wines raised to any due degree of strength, without giving them the brandy flavour, and many other things of great use performed; but he has not told us what the vegetable substance is from which we are to obtain this. Shaw's Essay on Distillery.

SPIRIT, *Ardent*, called also *spirit of wine*, because it can only be obtained from substances which have undergone the vinous fermentation, is a very light, very volatile, very fluid liquor, perfectly white and limpid, and of a strong, penetrating, agreeable taste and smell. See **ALCOHOL**.

Spirits drawn from wine, such as French brandy, may, in a great measure, be purified or rectified by simple distillation, in tall vessels with a gentle heat, the pure spirituous parts rising before the phlegm: if French brandy be thus distilled to one-half, the distilled spirit proves tolerably pure. See **BRANDY**.

But wine or brandy being in this country too dear an article for distillation, this purification is chiefly practised on the cheaper spirits of molasses and malt-liquors. To separate the offensive oil with which these abound, after they have been freed by distillation from the greatest part of their phlegm, they are mixed with an equal quantity of spring-water, and the spirit drawn off again by a gentle heat: a considerable portion of the oil is thus left behind in the water, which now proves turbid and milky, and very nauseous both in smell and taste. The first produce is the strongest and purest, and when it has come over to the amount of $\frac{1}{4}$ th of the whole contents of the still, forms the rectified spirit. By repeating this ablution with fresh quantities of water, the foulest and most offensive spirits may be purified from all ill flavour. To complete the purification, or free them from their remaining phlegm or oil, or the watery vapour which is raised even by the gentlest heat in which they can be distilled, a little fixed alkaline salt, thoroughly dried and powdered, or lime, or some other article of a like kind, is added; which, imbibing the phlegm, is thereby dissolved into a ponderous liquid, that does not mingle with the spirit, but settles at the bottom. If the spirit is very phlegmatic, four pints will require a pound of the alkali; if the distillation has been performed with due care, half this quantity, or less, will be sufficient: in either case, if all the salt dissolves, the spirit is to be digested with a little more, till at least a part remains undissolved. The spirit now poured off is to be again distilled, in order to separate from it a portion of the salt which has united with it, and which, though extremely minute, may in some respects change its qualities. As some particles of the alkali are apt to be carried up with it, even in the distillation, so as to communicate an ill flavour, or an urinous taste, it is advisable previously to add a small portion of calcined vitriol, or burnt alum and charcoal, which will completely absorb the alkali, without giving any new impregnation to the spirit. Malt-spirits, when properly rectified, yield as pure and as strong rectified spirit as brandy. Lewis's Mat. Med. See **DISTILLATION**, and **SPIRITS**, in the *Materia Medica*, infra.

When only a small quantity of spirit of wine is to be rectified, the usual operation for this purpose, by means of distillations of the spirit called *aqua vitæ*, obtained from the first distillations of liquors that have undergone the spirituous fermentation, and which are overcharged with a large quantity of phlegm and light oil, is difficult. These distillations being slowly conducted with a gentle fire and water-bath, yield but a small quantity of that liquor, which, being the most volatile, rises first with the least heat, and which is the true or rectified spirit of wine. Several chemists, therefore, in order to obtain a larger quantity of the first spirit, propose to mix with the spirit of wine some intermediate substances, to absorb and retain its phlegm and oil, such as dried and calcined salts, very dry chalk, &c. Kunckel proposes to separate more effectually the oil, by adding to the spirit a large quantity of water, and by distilling this diluted spirit with a very gentle heat. But the trouble and inconvenience of depriving the spirit of wine of the water with which it was diluted in this process, may be avoided, by rectifying at once a large quantity of *aqua vitæ*. Nothing more is required to obtain at once a considerable quantity of pure spirit of wine, than to set aside the twelve or fifteen pints first drawn over from a large quantity, *e. g.* from three hundred pints of *aqua vitæ*, distilled with a very gentle fire in a large alembic. As the most spirituous, least aqueous, and least oily part of it always rises first, these twelve or fifteen pints are perfectly rectified spirit of wine, especially when the heat has been well conducted.

By thus keeping apart portions of the spirit obtained, at different times, we may have spirit of wine of the several degrees of strength and purity. The weaker spirit may, by another distillation, be again rectified; and the spirit of moderate strength may be preserved for many uses. The method is followed by M. Beaumé in the rectification of spirit of wine, and is certainly the most convenient and the best.

A perfectly rectified spirit of wine, or such as is entirely freed from water, is undoubtedly a thing of frequent and necessary use in the nice operations of chemistry.

It had used to be prepared, either by often distilling the spirit, and every time drawing over only half of it, and repeating this till the half remaining in the cucurbit appeared as strong as that drawn over; or else by raising it to a great height from the body of the vessel, and this in a very gentle heat, so that spirit alone could rise, the water not being capable of being driven so far by that degree of heat.

But the accurate Boerhaave always found upon trial, that there was still remaining some water in these spirits, whether prepared by the first or second process, or both. Boerhaave's Chem. part ii. p. 124.

The method he therefore invented is this: fill a still half full of the spirit prepared for alcohol in one or other of these ways, and add to it half a pound of pure decrepitated, and perfectly dried sea-salt; put this in hot, then place on the head, and carefully lute the junctures; leave this for twelve hours in a heat so small, as not to make the alcohol boil, then distil off the spirit; keep the first two ounces apart, because some aqueous vapour may have happened to lodge in the head or worm of the still, which this certainly washes off; after this receive two-thirds of the following alcohol into a pure dry glass vessel, and keep it perfectly stopped; then draw off the remainder, and keep that by itself: there will remain a moist salt in the still, which has attracted the aqueous matter of the alcohol, and held it so down, that it could not rise by the heat of boiling water, which

SPIRITS.

which is all that must be used in this distillation; and the salt having been first decrepitated, never makes any change in the alcohol by adding any thing to it. By this means an alcohol is prepared perfectly pure, and fit for all the uses of chemistry.

For the tests and properties of pure alcohol, see **ALCOHOL**.

M. Reaumur discovered, that a mixture of spirit of wine and water acquired a specific gravity greater than that which would arithmetically result from the proportions employed of each of these liquors. Thus, fifty measures of spirit of wine, and fifty measures of water, mixed together, were found to make only ninety-eight measures; but in what progression the density is increased by mixing various proportions of the two liquors, had not been determined till M. Brisson made a set of experiments with that view; an account of which is given in the Memoirs of the Academy of Sciences of Paris, for the year 1769.

From his experiments he has constructed the following table, which shews this progression, and also enables us to discover the proportion of spirit of wine and water, in any given mixture of these (as brandies, rums, &c.), the specific gravity of which is found to correspond with any of the specific gravities in the table. Thus, for instance, if we find upon accurate trial, that the specific gravity of the rum, brandy, or other mixture, whose strength is required to be known, be to that of water as $942\frac{1}{2}$ to 1000, we learn, by inspection of the table, that this spirituous mixture consists of equal parts of water and spirit of wine, of which spirit the strength is such, that its density is to that of the water as 837 to 1000. The first column shews the proportion of well rectified spirit of wine in the mixture; the second column shews the proportion of the water in the mixture; the third column shews the specific gravity of the mixture; the fourth column shews the difference between the specific gravity of the mixture and that of the preceding mixture; and the fifth column shews the proportion which the several augmentations of density, caused by penetration of the two liquors, have to each other, that is their progression.

Spirit of Wine.	Water.	Specific Gravity.	Differences.	Proportionable Augmentations of Density from Penetration.

Spirit of wine is used in dyeing, as a non-colouring drug, and though it gives no colour itself, it serves to prepare the stuffs to receive other colours. Its consumption is also very

considerable in several other works and manufactures, particularly the making of varnish.

Proof-spirit cannot be used for burning in lamps, for dissolving resins, and for making varnish; and there is also a great number of tinctures, solutions, and mixtures, for which it cannot serve; but rectified spirit, or alcohol, besides its ready use for medicinal purposes, may, when the spirit is of a proper kind, be made into punch, and all other mixtures, with greater purity, and much greater certainty and exactness in point of strength. See next article and **ALCOHOL**.

SPIRITS, in the *Materia Medica*, "rectified spirit" of the London Pharmacopœia; "alcohol," "spiritus vinosus rectificatus five purissimus," Edinb.; "spiritus vinosus rectificatus," Dub.; is alcohol nearly in the highest state of concentration in which it can be easily prepared in the large way for the purposes of trade. The London and Edinburgh colleges state its specific gravity to be to that of water as 835 to 1000, while the Dublin college states it at 840. The Edinburgh college names this spirit alcohol; but directions being given both by the London and Dublin colleges, for the preparation of a still stronger spirit, the name of alcohol, in their pharmacopœias, is judiciously retained for the stronger spirit, while that of rectified spirit is applied to the present preparation.

The alcohol of the Lond. Ph. is prepared by taking of rectified spirit a gallon, and of subcarbonate of potash, three pounds: add a pound of the subcarbonate, previously heated to 300 degrees, to the spirit, and macerate for 24 hours, frequently shaking the mixture; then pour off the spirit, and add the remainder of the subcarbonate, heated to the same degree; and lastly, distil the alcohol from a water-bath, and preserve it in a well-closed vessel. The specific gravity of this alcohol is to that of distilled water as 315 to 1,000.

The alcohol of the Dub. Ph. is prepared by taking of rectified spirit of wine, a gallon; pearl-ashes, dried at a heat of 300°, and still hot, a pound; caustic kali, in powder, an ounce; muriate of lime, dried, half a pound. Mix the spirit and the kali; add the pearl-ashes, previously reduced to powder, and digest the mixture for three days in a closed vessel, frequently shaking it; then pour off the spirit; mix with it the muriate of lime; and lastly, distil with a moderate heat, until the residue begins to thicken. The specific gravity of this spirit is to that of distilled water as 315 to 1000.

Rectified spirit of the specific gravity of 835, contains about 15 per cent. of water; and to free it from this is the intention of the above processes. The Edinburgh college has no process for the preparation of pure alcohol, which may be easily dispensed with; but it has very improperly given this title to the rectified spirit of the other pharmacopœias. The theory of the operation is sufficiently obvious. The affinity of the alkali and the muriate of lime for water is much greater than that of the spirit: it is, therefore, attracted by these substances, and prevented from rising with the spirit during the distillation, by which means the alcohol comes over in a very highly concentrated state. Of the two processes, that of the Dublin college is to be preferred; muriate of lime being a much more powerful agent for separating the water, which is the object in both, than subcarbonate of potash.

Dr. Black thus obtained alcohol of the sp. gr. of 800°, and Richter procured it so low as 0.792, in the temperature of 68° Fahr. at which degree of concentration it may be regarded almost as pure alcohol, or alcohol perfectly free from water, though more than sufficiently concentrated for all the purposes of pharmacy.

SPIRITS.

The following Table, drawn up by Lowitz, with an additional column by Dr. Thomson, shews the specific gravity of different mixtures of pure alcohol, of a specific gravity .791, and distilled water, at the temperatures of 60° and 68° of Fahrenheit.

100 Parts by Weight.		Sp. Gravity.		100 Parts by Weight.		Sp. Gravity.

* Alcohol of the London and the Dublin Pharmacopœias. † Ditto (Edinburgh); rectified spirit (London). ‡ Rectified spirit (Dublin). § Proof spirit (Lond. Dub.) || Ditto (Edinburgh).

In the extract from Mr. Gilpin's table (see *Specific Gravity*), the standard spirit was of the specific gravity of 0.825, or contained 89 pure alcohol, and 11 water, in 100 parts.

Pure rectified spirit has a fragrant odour, and a hot highly pungent taste. It is colourless; always fluid; cannot be congealed at any known degree of cold; evaporates speedily at the ordinary temperature of the atmosphere; boils at 163° Fahrenheit; and is extremely inflammable, burning with a blue lambent flame, without any sensible smoke. Like alcohol, it combines with water in every proportion; and, on account of its affinity for water, precipitates many of the neutral salts from their aqueous solutions. It is capable of dissolving many saline bodies, and is the proper solvent of the greater number of the proximate principles of vegetables. Its constituents are 85 of pure alcohol and 15 of water, in 100 parts, when its specific gravity is 835, at a temperature of 60° of Fahrenheit; but 83 only of pure alcohol, and 17 of water, when it is 840, as designated by the Dublin college.

Rectified spirit is a very powerful stimulant. In its undiluted state it is never exhibited as a remedy; and is merely employed for forming the diluted spirit, and as a pharmaceutical agent.

The "spiritus tenuior," or "weaker spirit," of the Lond. Ph.; the "diluted alcohol," the "spiritus vinosus tenuior five dilutus" of Edinb. Ph.; and "spiritus vinosus tenuior" of Dub. Ph., or "proof spirit," is merely rectified spirit diluted with a certain proportion of water. According to the London and Dublin colleges, its specific gravity should be to that of distilled water, as 930 to 1000; while the Edinburgh college orders it of the gravity of 935. The former may be formed by mixing four parts by measure of rectified spirit with three of water, and contains 44 parts of pure alcohol, and 55 of water, in 100 parts; the latter is obtained from equal parts of rectified spirit and water, and contains 42 of pure alcohol, and 58 of water, in 100 parts. Alcohol, diluted to the degree of proof-spirit, is still a very powerful diffusible stimulant, and too strong for internal use. Externally applied, it is recommended in burns; to restrain bleeding in passive hæmorrhagies; and as a friction or fomentation to relieve muscular pains; and in a more diluted state it forms a good collyrium in the latter stage of ophthalmia. Proof-spirit diluted with water is employed as a remedy in the form of tinctures and spirits; and the ardent spirits in common use may be regarded as nearly of the same nature. These taken in moderation, increase the general excitement, communicate additional energy to the muscular fibres, strengthen the stomach, and exhilarate the mind. Hence they are often and advantageously used in cases of debility and low typhoid fevers, in which the use of wine is indicated; and in habits disposed to create acidity, they are even preferable to wine; some of them, particularly brandy, proving gratefully stomachic, when wine is nauseated and rejected. As an article, however, of daily or dietetical use, particularly if taken in immoderate doses, or long continued, ardent spirits, besides being the source of much moral evil, and debasing the human character nearly to a level with that of brutes, are apt to occasion disease, and are commonly the origin of dyspepsia, hypochondriasis, and hepatic and visceral obstructions. The hurtful effects of ardent spirits, however, are obviated in a considerable degree by diluting them with water, and adding lemon-juice and sugar to the mixture, so as to form what is generally known by the name of punch. Although all the varieties of ardent spirits may be regarded as diluted alcohol, yet each has a peculiar operation: thus, brandy

SPIRITS.

brandy is simply cordial and stomachic; rum, heating and fudorific; gin and whisky, diuretic; and arrack, styptic, heating and narcotic, and ill adapted to European constitutions.

Vinous spirits, therefore, in small quantity, and properly diluted, may be applied to useful purposes in the relieving of some disorders; whilst in larger ones, or imprudently continued, they act as a poison of a particular kind. The moderate use of them is most serviceable to those who are exposed to heat and moisture, to corrupted air, or to other causes of colliquative and putrid diseases; and they are the most pernicious in opposite circumstances, and to those who are afflicted with hysterical and hypochondriacal complaints: for whatever temporary relief these spirituous cordials may afford in the lownesses to which hysterical and hypochondriacal persons are subject, there are none, as Dr. Pemberton observes, who feel so soon the ill effects arising from the habitual use of them. Lewis's Mat. Med.

The power of brandy, or any thing of this kind, in killing worms, is evident from this, that the children of the people in the northern islands of Scotland, who are accustomed from their infancy to drink that coarse sort of brandy which they call aqua vitæ, never are troubled with worms. It is a dangerous practice to use brandy in this general manner, but on some occasions it may be very serviceable. Philof. Tranf. N^o 233.

SPIRITS, Laws relating to Foreign and British. By a variety of statutes, which it would be too tedious here to enumerate, duties both permanent and temporary, of the customs and the excise, have been imposed on brandy, rum, arquebuse, geneva, arrack, and spirits, the amount of which is very considerable in proportion to the original price. By 43 Geo. III. c. 69. (sched. A), and 43 Geo. III. c. 81. several duties are imposed upon spirits imported; but by 49 Geo. III. c. 98. several duties of customs are imposed: the said duties are payable by the importer, before landing. If any person shall land any French brandy, before the duty be paid or secured, or without licence from the proper officer, and conceal the same when landed, he and his aider shall not only forfeit the same, but also double value; and if any officer of the customs or excise shall connive at it, he shall forfeit 500*l.*, and be incapable of holding any office in the revenue. (1 Ann. stat. 2. c. 14.) The officers of excise may go on board any ship and search, as officers of the customs may do, for any exciseable liquors, and seize such as shall be forfeited, and such as shall be unshipped before entry and payment of the duties, together with the casks and other package. (11 Geo. I. c. 30.) Any officer of the excise may search for concealed foreign spirits, and seize, &c.; and the penalty of obstruction is a forfeiture of 100*l.* By a general clause in 8 Geo. I. c. 18. all brandy, arrack, rum, spirits, and strong waters, and all foreign exciseable liquors, forfeited, together with the casks and package, may be seized by any officer of the customs or excise, or persons deputed from the lord treasurer, or undertreasurer, or by special commission under the great or privy seal, and no other person; and the penalty of obstruction is 40*l.* If any foreign brandy, arrack, rum, or strong waters, or spirits of any kind, shall be imported in any vessel of 100 tons burden, or under, (except for the use of seamen, not exceeding two gallons each,) such vessel, with its tackle, and also the spirits, shall be forfeited (5 Geo. III. c. 43.): except rum or other spirits of the growth and manufacture of the British sugar plantations, which may be imported in any vessel of not less burden than 70 tons. (6 Geo. III. c. 46.) If any vessel of 50 tons, or under, partly or fully laden with brandy, be at anchor or within two leagues of the

shore, and not proceeding on her voyage, if wind and weather permit, such vessel may be compelled by the commander of any man of war, or armed sloop appointed to guard the coast, or the commander of any vessel in the service of the customs, to come into port; and the case is the same with ships hovering near the coasts. (6 Geo. I. c. 21.) If any vessel come from foreign parts, and have on board any foreign brandy or spirits, in casks under six gallons, (except for the use of seamen, not exceeding two gallons each,) shall be found at anchor, &c. as in the former case, all such spirits, with the casks and package, or value, shall be forfeited, and the same may be seized, or value sued for by the officers; and if the vessel do not exceed 50 tons in burden, the said vessel, with her tackle and furniture, shall be forfeited: and if any person, having charge of the vessel, shall suffer any brandy to be put into lighters or boats, in order to be landed, he shall, besides other penalties, suffer six months' imprisonment. No brandy shall be imported in any vessel not containing 60 gallons at the least, on pain of forfeiting the same, or value. (4 W. c. 5.) And no geneva or rum shall be imported in any vessel or cask, not containing 60 gallons at least, (except for the use of seamen, not exceeding two gallons each,) on pain of forfeiture. (5 Geo. III. c. 43.) If any officer shall find any increase of rum or spirits, (except such as have been imported and lodged in a warehouse, according to law,) above the quantity found on the last survey, or any decrease, (beyond the quantity legally delivered or allowed for leakage,) the proprietor or importer shall forfeit 500*l.*; and opening the warehouse, except in the presence of the warehouse-keeper or excise officer, incurs a forfeiture of 500*l.* If any rum or spirits remain in the warehouse above twelve calendar months (6 Geo. III. c. 47.), without paying the duty, the commissioners of excise may sell them by auction, and pay the duty and charges, transferring the overplus to the proprietor or importer. A permit shall be obtained for removal of the quantity sold; nor shall any liquor, exceeding one gallon, be carried away without such permit, on pain of forfeiting the same, with the casks and vessels. If the liquor be not removed, and the permit not returned, the person that took it out shall forfeit treble value. No person shall receive a permit, without direction in writing of the person (or his servant) from whose stock the goods are to be removed, on pain of 50*l.*; and in default of payment, three months' imprisonment. No foreign spirits, although under one gallon, shall be received into the custody of any retailer, without a permit, signifying that the duties were paid, or that they had been condemned, on pain of forfeiting the same. (8 Geo. I. c. 18.) No feller or dealer shall be allowed to take out more than one permit in one day; provided that several permits may be taken out, and casks containing foreign spirituous liquors sent to the same persons the same day, so that each cask may be sent under different permits, and by different conveyances; and provided dealers shall not be prevented from sending with one permit by one and the same conveyance any number of casks, containing 60 gallons each, or upwards, of the same kind. Foreign spirits, not being casks of 60 gallons, or upwards, shall not be removed, unless at the following times; that is, from September 29th to March 25th, yearly, between the hours of seven in the morning and five in the evening; and from March 25th to September 29th, between the hours of five and seven, (except the same is carrying by a known common stage-coach, waggon, or other stage carriage, usually travelling out of these hours,) on pain of forfeiture, with or without a permit. (23 Geo. III. c. 70.) No foreign spirits more than 60 gallons shall be brought to London by

one permit, or one conveyance, at the same time, from any part of England by land or water, (except by Gravesend, in the ordinary course of commerce,) on pain of being seized and forfeited. (26 Geo. III. c. 73.) If any person shall counterfeit a permit, or give or receive any false permit, or alter any granted by the proper officer, he shall forfeit 500*l.* 23 Geo. III. c. 70.

For the conditions, regulations, and restrictions, under which rum imported from the West Indies may be secured in warehouses, without payment of duty, see 43 Geo. III. c. 132. 45 Geo. III. c. 87. 46 Geo. III. c. 137. and 48 Geo. III. c. 126; and for those under which brandy, geneva, and other spirits, may be secured in warehouses, without payment of duty, see 43 Geo. III. c. 132. 45 Geo. III. c. 87. 46 Geo. III. c. 137. and 48 Geo. III. c. 126. For other laws and regulations, see CUSTOMS, DISTILLER, EXCISE, SMUGGLING, and WINE.

SPIRIT of Ammonia, in the *Materia Medica*, is prepared, according to the directions of the Lond. Ph., by mixing two pints of rectified spirit with a pint of solution of ammonia. The "ammoniated alcohol," formerly *spirit of ammonia*, of the Ed. Ph., consists of 32 oz. of alcohol (835), 12 oz. of lime recently burnt, and 8 oz. of muriate of ammonia; and is prepared in the same manner as water of ammonia. (See AMMONIA.) The *spirit of ammonia* of the Dub. Ph. is prepared by mixing three pints of proof-spirit, 4 oz. of muriate of ammonia, and 6 oz. of potashes; and distilling, with a moderate heat, two pints. This spirit, properly prepared, has the pungent odour and acrid taste of ammonia, with which it coincides in its medicinal properties. (See AMMONIACAL Preparations.) It is chiefly used for pharmaceutical purposes. The official preparations are "spiritus ammoniæ compositus," "spiritus ammoniæ fetidus," "tinctura castorei composita," "tinctura guaiaci composita," and "tinctura opii composita."

SPIRIT of Ammonia, Aromatic, is prepared, according to the Lond. Ph., by mixing two pints of spirit of ammonia with oil of lemon and oil of cloves, of each two fluid-drachms. The "aromatic ammoniated alcohol," formerly *aromatic spirit of ammonia*, of the Edinb. Ph., is composed of 8 oz. of ammoniated alcohol, 1½ drachm of volatile oil of rosemary, and a drachm of volatile oil of lemons, which are mixed so as to dissolve the oils. The *aromatic spirit of ammonia* of the Dub. Ph. is formed by digesting two pints of spirit of ammonia, two drachms of essential oil of lemons, and half an ounce of bruised nutmegs, in a covered vessel for three days, frequently shaking the vessel; and then distilling a pound and a half. This spirit is an useful stimulant in languors, and flatulent colic; and the oils render it more grateful to the stomach than the simple spirit of ammonia. The dose is from fʒss to fʒj, in any convenient vehicle. The officinal preparations are "tinctura guaiaci ammoniata," and "tinctura valerianæ ammoniata."

SPIRIT of Ammonia, Fetid, is prepared, according to the Lond. and Dub. Ph., by macerating two pints of spirit of ammonia, and 2 oz. of assafœtida (1½ oz. Dub.), for 12 hours (for three days, in a covered vessel, with frequent agitation, Dub.); and then by a gentle fire distilling a pint and a half into a cold receiver. The "fetid ammoniated alcohol," formerly *fetid spirit of ammonia*, of the Edinb. Ph., is prepared by digesting 8 oz. of ammoniated alcohol, and ½ oz. of assafœtida, in a close vessel for 12 hours, and then distilling 8 oz. by the heat of boiling water. The medicinal properties of this spirit, and the dose, are the same with those of the preceding. It acquires colour from age.

SPIRIT of Ammonia, Succinated, of the Lond. Ph., is prepared by macerating three drachms of mastic in nine fluid-drachms of alcohol, so that it may be dissolved, and pouring off the clear tincture; then adding fourteen minims of oil of lavender, four minims of oil of amber, and ten fluid-ounces of solution of ammonia, and mixing them by agitation. This spirit is employed as a stimulant and antispasmodic, in the same cases as the oil of amber, and has been used with success in India against the bite of the rattlesnake. The dose is from ℥ʒx to fʒss, in any convenient vehicle. See AMBER.

SPIRIT of Anise-seed of the Lond. Ph. is formed by macerating for 24 hours half a pound of anise-seeds bruised, a gallon of proof-spirit, and a sufficient quantity of water to prevent empyreuma, and distilling by a gentle fire. The *compound spirit of anise-seed* of the Dub. Ph. is obtained by distilling one gallon from anise-seeds and angelica seeds bruised, of each half a pound, a gallon of proof-spirit, and water sufficient to prevent empyreuma. In flatulent colic, and similar affections, these are pleasant carminatives. The dose is from fʒss to fʒiv, in water.

SPIRIT of Horse-radish, Compound, "spiritus armoraciæ compositus," of the Lond. Ph., is prepared by macerating fresh horse-radish sliced and orange-peel dried, of each a pound, half an ounce of nutmegs bruised, a gallon of proof-spirit, and water sufficient to prevent empyreuma, for 24 hours, and distilling a gallon by a gentle fire. (See COCHLEARIA.) The "compositus spiritus raphani," of the Dub. Ph., is formed by distilling two gallons from horse-radish dried and peel of Seville oranges, of each two pounds, four pounds of fresh garden scurvy-grass, one ounce of nutmegs bruised, two gallons of proof-spirit, and water sufficient to prevent empyreuma. These spirits, which were formerly used as antiscorbutics, are now held in little estimation in that intention. They are chiefly used in dropfies, attended with much debility. The dose is from fʒj to fʒiv, combined with infusion of fox-glove or juniper-berries.

SPIRIT of Camphor of the Lond. Ph. is prepared by mixing four ounces of camphor with two pints of rectified spirit, that the camphor may be dissolved. The "tincture of camphor," commonly called the "camphorated vinous spirit," is obtained by mixing one ounce of camphor with one pound of alcohol (sp. gr. 835), so that the camphor may be dissolved. It may be also made with double or triple the quantity of camphor. This spirit is too strong to be given internally; and if water be mixed with it, the camphor is separated. It is an useful stimulant and discutient application to chilblains, and in chronic rheumatism, paralytic numbness, and gangrene. See CAMPHOR.

SPIRIT of Carraway of the Lond. and Dub. Ph. is obtained by macerating a pound and a half (half a pound, Dub.) of carraway seeds bruised in a gallon of proof-spirit, and water sufficient to prevent empyreuma, for 24 hours, and distilling a gallon by a gentle fire. The *spirit of carraway* of the Edinb. Ph. is prepared by macerating half a pound of carraway seeds bruised in nine pounds of proof-spirit, for two days in a close vessel, adding water enough to prevent empyreuma, and distilling nine pounds. This spirit is an useful carminative, and an adjunct to griping purgatives. See CARUM.

SPIRIT of Cinnamon of the Lond. and Dub. Ph. is prepared by macerating one pound of cinnamon bark bruised in a gallon of proof-spirit, and water sufficient to prevent empyreuma, for 24 hours, and distilling a gallon by a gentle fire. The *spirit of cinnamon*, "spiritus corticis lauri cinnamomi," of the Edinb. Ph., is prepared with a pound of cinnamon bark, in the same manner as the spirit of carraway.

This

SPIRITS.

This spirit is an agreeable cordial in diseases attended with much languor and debility. The dose is from fʒj to fʒiv, in any suitable vehicle. The official preparation is “infesum digitalis.” See CINNAMON.

SPIRIT, Coal. See COAL.

SPIRIT of Sulphuric Ether of the Lond. Ph. is obtained by mixing half a pint of sulphuric ether (see ETHER) with a pint of rectified spirit. The “sulphuric ether with alcohol,” of the Edinb. Ph., is prepared by mixing one part of sulphuric ether with two parts of alcohol. The specific gravity of this mixture is .816. It may be used for the same purposes as the ether, but it is much less active. The dose is from fʒj to fʒiij. An useful gargle for slight inflammation of the fauces is prepared by adding fʒj of this spirit to fʒvi of boiling water, sweetened with fʒiv of syrup of marsh-mallows. The sulphuric ether, of which this is an official preparation, is stimulant, narcotic, and antispasmodic. In its operation it resembles alcohol, but is more diffusible, and its effects are less permanent. It is beneficially employed as a cordial in typhoid and low fevers, particularly when nausea, subsultus tendinum, and other spasmodic symptoms are present. As an antispasmodic, it relieves the paroxysm of spasmodic asthma, whether it be taken into the stomach, or its vapour only be inhaled into the lungs; in which latter form it is also useful in simple dyspnoea and in catarrh. It is employed with advantage in hysteria, tetanus, cramp of the stomach, hiccough, and in cholera morbus to check the vomiting; and also allays the violence of sea-sickness. The usual dose of sulphuric ether is from fʒss to fʒij; but it has been given in much larger doses with the most beneficial effects; and in all cases, the dose must be repeated at short intervals, to produce the full effect of the remedy. As an external application, ether acts either as a stimulant or a refrigerant, according to the mode in which it is applied. The first takes place when it is prevented from evaporating, by being confined over the spot to which it is applied; in which case it often proves useful in relieving head-ache, and other muscular pains: and from its refrigerant effect produced by its rapid evaporation, it is applied to burns, and to assist in the reduction of strangulated hernia. It has produced, says Thomson (Lond. Disp.), almost immediate relief in ear-ache, when dropped into the external meatus.

SPIRIT of Ether, Aromatic, of the Lond. Ph., is obtained by macerating three drachms of cinnamon bark bruised, a drachm and a half of cardamom seeds powdered, long pepper powdered and ginger-root sliced, of each a drachm, in a pint of spirit of sulphuric ether, for 14 days, in a stoppered glass-bottle, and straining. The “aromatic sulphuric ether with alcohol,” of the Edinb. Ph., is made with the same aromatics, and in the same manner as the compound tincture of cinnamon, except that sulphuric ether with alcohol is employed instead of proof-spirit. The medicinal properties of these preparations are the same with those of the former; the aromatics rendering them in a slight degree more grateful.

SPIRIT, Ethereal, of Frobenius, Spiritus Etherius Frobenii, a name given by Frobenius, and others, to a liquor famous for its extreme volatility, and many other qualities; for which see Sulphuric ETHER.

The use of this liquor in medicine is now well known: as a very thin and volatile inflammable matter, it acts powerfully on the nervous system. Frederic Hoffman was one of the first who employed it as a sedative and antispasmodic. See LIQUOR Mineralis Anodynus, and SPIRIT of Ether, infra.

It is now often prescribed singly, in the dose of seven or

eight drops upon a bit of sugar, which is to be eat, or to be dissolved in some proper liquor, and drank. It is given in flatulent colics, obstinate hiccoughs, convulsive hysterical affections, and other disorders of this kind. This ether is said to take spots of grease from silk, without affecting their colours.

We have several curious observations on this ether of Frobenius by Mr. Grosse, who has described three different methods of making it in the Memoirs of the Academy of Sciences, for the year 1734.

SPIRIT of Ether, Compound, of the Lond. Ph., is prepared by mixing a pint of spirit of sulphuric ether with two fluid-drachms of ethereal oil. (See Sulphuric ETHER.) This is intended as a substitute for the anodyne liquor of Hoffman (see the preceding article); for, besides being stimulant and antispasmodic, it is supposed to possess anodyne properties. It is an useful addition to tincture of opium, when given for the purpose of procuring sleep; and it often prevents the opium from exciting the nausea which it is apt to produce in some habits. The dose is from fʒss to fʒij, in any appropriate vehicle.

SPIRIT of Juniper, Compound, of the Lond., Dub., and Edinb. Ph., is prepared by macerating one pound of juniper-berries bruised, carraway seeds and fennel seeds bruised, of each an ounce and a half, in a gallon (nine pounds, Edinb.) of proof-spirit, for 24 hours (two days, Edinb. and Dub.); and then distilling a gallon (nine pounds, Edinb.) by a gentle heat. This spirit is a grateful and useful addition to infusions of fox-glove, and other diuretics, in dropsy. See JUNIPERUS.

SPIRIT of Lavender. See LAVANDULA.

SPIRIT of Libanus, Smoking. See LIQUOR.

SPIRIT of Malt. See MALT-Distillery.

SPIRIT of Mindereus. See ACETITE of Ammonia, LIQUOR, and VINEGAR.

SPIRIT, Molasses. See MOLOSSRS-Spirit.

SPIRIT of Nitre. See NITRIC Acid, and Nitrat POTASSÆ.

SPIRIT of Nitric Ether of the Lond. Ph. is obtained by taking two pints of rectified spirit, and three ounces (by weight) of nitric acid. Add the acid gradually to the spirit, and mix them, taking care that the temperature, during the mixture, does not exceed 120°; then distil, by a gentle heat, 26 fluid-ounces. *Spirit of nitrous ether* of the Edinb. Ph. is prepared by pouring three pounds of alcohol into a large phial placed in a vessel full of cold water, and adding one pound of nitrous acid gradually, with frequent agitation. Slightly cork the phial, and place it in a cool place for seven days; then distil the liquor, by the heat of boiling water, into a receiver kept cool with snow or water, as long as any spirit comes over. The *nitrous ethereal spirit* of the Dub. Ph. is prepared in the following manner: Add to the matter which remains after the distillation of nitrous ether, the rectified spirit of wine, employed in that operation for condensing the elastic vapour, and distil to dryness, with the greater heat of a water-bath. Mix the distilled liquor with the alkaline liquor which remains after the separation of the nitrous ether, and also add as much dry sub-carbonate of kali as shall be sufficient to saturate the predominant acid; which is to be determined by the test of litmus. Lastly, distil by the medium heat of a water-bath, as long as any fluid comes over. The specific gravity of this liquor is to that of distilled water, as 850 to 1000. The spirit of nitric ether, as procured by the London or Edinburgh process, has an extremely fragrant odour, and a pungent acidulous taste. It is very volatile and inflammable, soluble in water and alcohol, and strikes a deep
olive

olive with solution of green sulphate of iron. See *Nitrous ETHER*.

Spirit of nitric ether is refrigerant, diuretic, and antispasmodic. It has been long known and used, under the title of "sweet spirit of nitre," as a grateful refrigerant, and for quenching thirst in febrile affections; for which purpose the dose is from ℥xx to ℥xl, given in a cupful of water, or any other appropriate vehicle. In larger doses it acts as a gentle stimulant to the stomach, relieving nausea and flatulence; and also determines to the kidneys, increasing the flow of urine; on which account it is advantageously prescribed as an auxiliary to other diuretics in dropical complaints. The dulcified spirit of nitre is added by drops to potions and juleps, till it has given them an agreeable acidity.

It is also much used by our distillers to give a vinosity to those spirits, whose natural flavour of that kind they have destroyed by the improper use of alkaline salts in the rectifications. Nothing can be more proper for this purpose than this spirit, as it really gives the brandy-flavour, and is not at all prejudicial to health, but very well falls in with the nature of the spirit, and promotes its medicinal properties as a diuretic, deobstruent, and lithontriptic.

It has been suggested, that the method of making it for this purpose is improveable, by using in the preparation a spirit of wine impregnated with some fine flavoured ingredient, which has not much oil, for acids do not readily mix where there is much oil.

In the preparation of this dulcified spirit of nitre, the longer it stands in digestion with the spirit of wine, the milder it grows; and by the same means also, the violently corrosive oil of vitriol may be so blunted, as to be rendered scarcely perceptible to the taste. In fine, it has been said that a *spiritus nitri dulcis* may be made, by a slow digestion, greatly superior to that commonly used, and of so fixed a nature, that it will not be subject to have its flavour fly off from the spirit with which it is mixed, any sooner than the native vinosity of brandy will of itself fly off from that spirit, as it always will in time. A proper care in the preparation of this acid might free the distillers from that troublesome necessity they are under of adding their spirit of nitre, just before they send their goods away, for fear the flavour should be lost before the spirit is wholly used, and so the sophistication be found out. There is no fixing any certain proportion in which the acid is to be mixed with the spirit, but in general it is best not to over-do it; for though it will give an agreeable vinosity to any tolerable clean spirit, the person will be much deceived who attempts to draw the bad flavour of a foul one by it. Shaw's Essay on Distillery.

Mr. Woulfe describes an apparatus by which *nitrous ether* (in the article under *ETHER*) may be expeditiously obtained by distillation, with the heat only occasioned by mixing together the nitrous acid and the spirit of wine. This distillation is performed in a matras with a high neck, to which is fitted a head with a spout, communicating with the receiver by means of a long tube. The vapours that are not condensed in this receiver, or in a bottle joined to a spout in its bottom, are conveyed from the receiver through a bent tube into spirit of wine contained in a bottle. If any vapours pass uncondensed through this spirit of wine, they are conveyed through another bent tube into more spirit of wine contained in another bottle. The liquor collected in the bottle annexed to the receiver, being slowly rectified with slaked lime, furnishes very fine ether. The spirit of wine in which the vapours were condensed, contains so much ether, that this fluid may be separated from the spirit by

adding water. This spirit of wine is by the operation changed into good dulcified spirit of nitre. Phil. Trans. vol. lvii. art. 59.

SPIRIT of Sal Ammoniac. See *AMMONIACAL Preparations*.

SPIRIT of Salt. See *MURIATIC Acid*.

SPIRIT of Sulphur, or of Vitriol. See *SULPHURIC Acid*.

SPIRIT of Turpentine. See *TURPENTINE*.

SPIRIT of Venus. See *ACETIC Acid*.

SPIRIT of Vinegar. See *ACETOUS Acid, and VINEGAR*.

SPIRIT of Vitriol. See *SULPHURIC Acid, and VITRIOL*.

SPIRIT of Wine. See *ALCOHOL and WINE*.

SPIRIT is also used for any incorporeal being, or intelligence. In which sense God is said to be a spirit, angels are spirits; and the devil is an evil spirit.

In this sense the human soul is also called a spirit, from its thinking and reflecting powers, which cannot be conceived to reside in any thing material. See *SOUL*.

F. Malebranche observes, it is extremely difficult to conceive what it is that should make the communication between the body and the spirit; for if the spirit have no material parts, it cannot move the body. But the argument must be false somehow or other; for we believe that God can move bodies, and yet do we not attribute any material parts to him.

SPIRIT, in *Theology*, is used, by way of eminence, for the third person in the Holy Trinity, called *the Spirit, the Holy Spirit, or Holy Ghost*.

Concerning the nature and even the personality of the Holy Spirit, very different opinions have been entertained by theological writers, both ancient and modern. It has been said, indeed, that no mention occurs of any difference of opinion on this subject, that attracted any notice, till after the commencement of the Arian controversy, and even till after the council of Nice. It has been also asserted, that even after the rise of the Arian controversy, many persons expressed themselves concerning the Spirit as if it had no proper divinity, at least of a personal nature, without censure; and that this could not have been the case, if it had been the uniform doctrine of the orthodox, that the Holy Spirit was a proper *divine person*, equal to the Son, or the Father. Clement, one of the apostolical fathers, makes no particular mention of the Holy Spirit. Ignatius, allowing his epistle to the Ephesians to be genuine, seems to have considered the Holy Spirit rather as a "power" than as a "person." Justin Martyr says but little concerning the Holy Spirit; nor is it easy to conclude what was his real opinion. But some have imagined that he regarded him as a created being, since he represents him as inferior to Christ. Irenæus seems to have considered the Holy Spirit as a divine influence, and no proper person; calling him, in reference to the words of Isaiah (ch. lxi. 1.), the unction. Athenagoras considered the Holy Spirit as an efflux from the Deity. Tertullian seems to have thought, that the Holy Spirit was derived from Christ, in the same manner as Christ was derived from God, that is, by a kind of prolation. Novatian, who was as orthodox in his notions with regard to the Trinity as any person in his age, could not believe in the divinity of the Holy Spirit, whom he represents as inferior to the Son, whom he also makes inferior to the Father. Lactantius is complained of for not mentioning the Holy Spirit, and for denying his personality. Dionysius of Alexandria is censured by Basil for not admitting the divinity of the Holy Spirit, and reducing him to the rank of a created being. Hilary also seems to have considered the Spirit as a divine influence. After the council of Nice, the sentiments and language of the fathers appear to have undergone a material change.

change. Athanasius contended strenuously and effectually, not only for the divinity of Christ, and his consubstantiality with the Father, but also in behalf of that of the Holy Spirit, whose divinity was denied by Macedonius. Being in Egypt when this heresy prevailed, he procured a synod to be called, at which he attended, and where the Holy Spirit was, for the first time, decreed to be consubstantial with the Father and the Son. Soon after this, the divinity of the Holy Spirit was more solemnly determined at a council held in Constantinople, and from that time it was decreed no less heretical to deny the divinity of the Spirit, than that of the Son.

At this time the doctrine of the perfect equality of the Spirit and the Son, as well as that of the Son and the Father, was fully established; and it was not long before the forms of public worship were accommodated to this opinion; for instead of the customary doxology of "Gloria Patri," Flavianus of Antioch made an alteration, for which purpose he is said to have assembled a number of monks, and to have first chanted out "Glory to the Father, to the Son, and to the Holy Ghost." Whereas, before his time, some had said "Glory to the Father through the Son, in the Holy Spirit," which was the most customary form; and others, "Glory to the Father in the Son, and the Holy Spirit."

The doctrine avowed and maintained by Athanasius, was supported by the influence of Basil, the two Gregories, Chrysostom, and Cyril of Alexandria. The latter says, "the Holy Spirit is the Spirit of the unbegotten God, and comes forth from him, has personality and life, and always exists, being from that which exists." At this time the doctrine of the inferiority of the Spirit to the Son, and of his having been created by him, was severely reprobated. Basil maintained, that to deny the divinity of the Holy Spirit, is to be guilty of blasphemy against the Holy Spirit; and Chrysostom observes, "it cannot be that he who halts with respect to the Spirit, can walk upright with respect to the Son." However, though it was admitted, that the Spirit was a divine person as well as the Son, and yet, like the Son, not absolutely underived, there was some difficulty in settling the mode of his derivation. At length, the term "proceeding" was adopted, as expressing the manner of the emission of the Spirit from the fountain of Deity, and was deemed to be different from that of "generation," which had been appropriated to the Son: nevertheless, the difference between the two terms could not be easily adjusted. Austin says that the Holy Spirit, being the Spirit both of the Father and the Son, proceeds from them both; and this he makes to be the difference between the generation of the Son and the procession of the Spirit. Cyril of Alexandria thought that he had some idea of the nature of the procession of the Spirit from the substance of God, when he says, that "Christ breathed upon his disciples, to shew that the Holy Spirit proceeds from the divine substance, as the breath of man proceeds from him."

In proof of the divinity of the Holy Spirit it has been alleged, that divine names, titles, attributes, works and worship, are or seem to be ascribed, in various passages of scripture, to the Holy Spirit. Many plead that the Holy Spirit is called Jehovah in the Old Testament, by comparing Acts, xxviii. 25. with Isaiah, vi. 9; and Heb. iii. 7—9. with Exod. xvii. 7; Jer. xxxi. 31—34. with Heb. x. 15, 16. In adverting to the first of these cited passages, in which the words spoken by God to Isaiah are by St. Paul said to be spoken by the Holy Ghost, it has been concluded, that God and the Holy Ghost are one and the same individual person. But in Rev. xi. 43, an inferior angel is introduced as speaking in the person of God, and therefore this mode of

reasoning has not been allowed by the opposers of this doctrine. It is alleged further, that the Holy Spirit is, probably, called God v. 4, to which passages some add 1 Cor. iii. 16. vi. 19. 2 Cor. iii. 17. Moreover, divine perfections are said to be ascribed to the Spirit of God; particularly omniscience, 1 Cor. ii. 10, 11. Is. xl. 13, 14; to which some add 1 John, ii. 20; — omnipresence, Pf. cxxxix. 7. Eph. ii. 17, 18. Rom. viii. 26, 27; — omnipotence, Luke, i. 35. 1 Cor. xii. 11; — eternity, Heb. ix. 14. Again; divine works are ascribed to the Spirit, Gen. i. 2. Job, xxvi. 13. xxxiii. 4. Pf. xxxiii. 6. civ. 30, &c. Some persons likewise add those texts in which miracles, inspiration, and saving operations upon the heart of man, are ascribed to the Spirit. The chief texts produced to prove that divine worship is given to the Spirit are, Is. vi. 3. compared with v. 9, and Acts, xxviii. 25, &c. Rom. ix. 1. Rev. i. 4. 2 Cor. xiii. 14; and above all, Matth. xxviii. 19. Upon the whole it is alleged, that the blessed Spirit is spoken of in such a manner, as it cannot be imagined would be used in speaking of a mere creature, and, consequently, must be possessed of a nature properly divine. On the other hand it is maintained, that the proofs taken from the attributes and operations of the Spirit are of no more force than in the case of the Son's supreme deity; both Son and Spirit, being agents under God at his will, are concerned in his glorious works, and partakers of his power and wisdom; so that it is no wonder if most of these be ascribed to the Spirit, but still as to one sent of God. Moreover, these arguments bear less evidence in relation to the Holy Spirit, because of the different ideas which the word Spirit stands for. The Spirit, and Holy Spirit, very often signify not a personal Spirit, but the attributes and operative efficacious virtue of God, the energy of his power, wisdom, and holiness, exerted in powerful operations, afflatus, and inspiration. The name of God is never once given to the Spirit, nor is direct worship or invocation, prayer or praise, glory or dominion, once given to him, in precept or practice, in the New Testament; though his communications are wished and prayed for to Christians, 2 Cor. xiii. 14.

The chief controversy on this head is, whether the spirit of God be a person in the *philosophical sense*, or merely a divine power or energy. That he is a person, is argued from his being described as having understanding, 1 Cor. ii. 10, 11; willing, 1 Cor. xii. 11; speaking and sending messengers, Is. vi. 8, compared with Acts, xxviii. 25. viii. 19. x. 19, 20. xiii. 1—4. 1 Tim. iv. 1; as Dr. Barrow interprets it, sending Christ, Is. xlvi. 16; as pleading, Rom. viii. 26; as being grieved, Is. lxiii. 10. Eph. iv. 30; as teaching and reminding, John, xiv. 26; as testifying, John, xv. 26; as reproving, John, xvi. 8, &c.; as executing a commission received from God, John, xvi. 13, 14.

Among those who grant the Spirit to be a person, it is debated whether he be the same philosophical person with the Father, or another distinct from him; to suppose the latter (supposing him at the same time equal with the Father) is making him *another God*. Some, therefore, have represented him as a created Spirit, in his own nature inferior both to Father and Son; against which the passages above enumerated have been strongly urged; as it has also been, that the Spirit is never mentioned as a creature called upon to praise God, when a large enumeration of such is made. Others consider him as a created Spirit, (called as one thinks Michael the archangel), so united to God, and so actuated by him, as by virtue of this union to become capable of such representations and regards as the Son is, though acting in some subordination to him in the economy

of our redemption;—while many others have contented themselves with asserting, that there is only a *political, modal, or economical* distinction, in the personality of the Father, Son, and Spirit. Others again have maintained, that the Spirit is a third distinction in the Deity; and when he is called a *person*, the word is to be taken in such a sense below the philosophical and above the modal; though what determination is to be affixed to it, they do not more particularly say.

Those, and they form a numerous class, who assert the Spirit to be a divine *power*, plead chiefly the sense of the word in the Old Testament, where they say it has generally that signification: and that it would be absurd to suppose, that the idea should be so greatly changed, when Christ and his apostles addressed those who had been bred up in the Jewish religion, and must, therefore, have been used to conceive of the Spirit according to the representation made in their sacred oracles. It is also pleaded, that the *pouring out one person on another*, is both unscriptural and unintelligible language, but not so, if it relates to a divine *power*, influence, or operation. They urge in favour of the explication of the doctrine, Luke, i. 35; and reply to the passages of scripture above cited, by observing, that nothing was more common among the ancients, and more especially the Eastern nations, than to represent powers, properties, and attributes, by personal characters; thus, wisdom is represented as contriving, rejoicing, inviting, pleading, reproving, &c. Prov. i. 20, &c. iii. 13, &c. iv. 6, &c. viii. 1. ix. 1, &c.; charity, as believing, rejoicing, &c. 1 Cor. xiii.; and death, as being plagued, Hof. xiii. 4; the scripture, as foreseeing and preaching, Gal. iii. 8; the sun, as rejoicing, Ps. xix. 5; a famine, as coming at God's call, 2 Kings, viii. 1; righteousness, as walking before him, compare Ps. lxxxv. 10—13; and the wind, as willing, John, iii. 6. To those who allege these passages, it is replied, that none of them come up to the preceding texts; more especially considering how frequently the personal term *εἶδος* is used, when spoken of the Spirit, and that not merely in poetical, but most plain and simple discourses, which, indeed, as it might be argued, is necessary to render the personification complete; but the strongest objection against this opinion is said to arise from the form of baptism, and the fore-mentioned John, xvi. 13, 14.

Dr. Lardner examines the different senses in which the words Spirit, Spirit of God, and Holy Ghost, are used in the Old and New Testament; and he finds, 1. That Spirit is in many places equivalent to God himself. 2. That it often means the power or wisdom of God, or his will and command. 3. That it often means an extraordinary gift from God of power, wisdom, knowledge, and understanding. In Heb. ii. 14. gifts of the Holy Ghost should be distributions of the Holy Ghost; an expression plainly declaring, that by the Holy Ghost or Holy Spirit were meant those spiritual gifts, which came down upon men from heaven immediately, or were communicated in great variety by laying on the hands of the apostles. 4. In the epistles of the New Testament, there are at the beginning and elsewhere wishes of peace from God the Father and the Lord Jesus Christ, but none from the Spirit distinctly; nor are there any doxologies or ascriptions of glory to the Spirit distinctly, though there are several such ascriptions to God and Christ, or to God through Christ.

But it may be said, as our learned and impartial author states the objections of those who maintain a different opinion, that the Spirit or the Holy Ghost is oftentimes spoken of as a person, and especially in St. John's gospel. To which he replies, 1. It is not uncommon in the language of

scripture, as we have already stated at large, to personize many things to which we do not ascribe intelligence; thus, *e. g.* wisdom is personified in the book of Proverbs, and sin and death in the New Testament. 2. There is not in the Acts of the Apostles, or in any other book of the New Testament, any account of the appearance and manifestation of a great agent or person after our Saviour's ascension; therefore no such thing was promised or intended by our Saviour, nor expected by his apostles, who could not but know his meaning. 3. In other texts of scripture, and particularly in St. John's gospel, by the Spirit or Holy Ghost is meant a gift, or plentiful effusion of spiritual gifts. 4. Our Saviour himself explains what he meant by the Comforter, *i. e.* the divine influence or effusion of spiritual gifts. 5. Our blessed Lord, in speaking of this matter, has made use of a variety of expressions, by attending to which we may clearly discern his true meaning, in what he says of the Comforter. All which seem to shew, that by the Spirit is to be understood that special influence, which, in different measures and proportions, God vouchsafes to men through Jesus Christ for their own comfort and establishment, and for spreading the great truths of religion in the world. This power or divine influence, this effusion of knowledge and other spiritual gifts, our Lord calls the Comforter or the Advocate, *παρακλητος*, as thereby their cause would be pleaded with men, and they would be justified in preaching boldly in the name of Jesus Christ. This gift, this divine influence, he calls also the spirit of truth, because by this wonderful influence on their minds, the apostles would be led into the knowledge of all the truths of the Gospel, and would be enabled to teach them to others with perspicuity. And our Lord speaks of the Spirit's bringing to their remembrance the things which he had said, and of his receiving of his and shewing it unto them; because by his miraculous influence upon their minds, those prejudices would be removed, which had obstructed their clear discernment of what Christ had said unto them, when he was with them. By the Holy Ghost in Matth. xxviii. 19, where we have the form of baptism, we are to understand the miracles of our Saviour's ministry, and likewise the miracles wrought by his apostles, and the spiritual gifts bestowed upon the apostles and other disciples of Jesus, and all believers in general, soon after our Lord's ascension, and all the miraculous attestations of the truth, and divine origin of the doctrine taught by Jesus Christ. On the subject of this article, we refer our theological readers to Calamy on the Trinity, Sermon vi. Emlin's Tracts, vol. ii. Burnet on the Art.—Script. Doctr. of the Trin. Diss. v. Watts on the Trin.—Also, Christ. Doctr. of Trin. Barrow's Works, vol. ii. Clarke on the Trin. part i. ch. 3. part ii. § 3, 4. 19, 20, 21, 22. 28—32. 40—42. 45, 46. 53. Taylor on the Trin. part iii. Owen on the Spirit, l. i. c. 3. Pearson on the Creed. Dr. Scott's Ess. towards a Demonstr. of the Script. Trin. prop. iii. Lardner's First Posit. to the Letter on the Logos, apud Works, vol. xi. Priestley's Hist. of Early Opinions, vol. ii.—Corruptions, vol. i. Doddridge's Lectures.

SPIRIT, Order of the. See *HOLY Ghost*.

SPIRIT is also used, among *Divines*, for the divine power and virtue, and the communication of it to men.

In this sense, the spirit is said to have gone out on the face of the deep (Gen. i. 2.), and the prophets to have been possessed with the spirit of God. Providence, in this sense, is that universal spirit by which God makes all nature to act.

Thus, the holy Virgin is said to have conceived of the Spirit.

SPIRIT, *Private*, is a term that made a great figure in the controversies of the two last centuries. It signifies the particular sense or notion each person has of the dogmata of faith, and the truths of religion, as suggested by his own thoughts, and the persuasion he is under with regard to them.

The first reformers denying strenuously any infallible interpreter of the scripture, or any settled judge of controversies, maintained, that every person was to interpret and judge of revealed truths by his own light, assisted by the grace of God; and this was what they called *private spirit* or *judgment*.

Against this, the arguments used by the Romanists are, that revealed truths being one and the same for all believers; the rule God has given us for judging of them, ought to represent them to us uniformly, and the same; but the private spirit informs Luther one way, and Zuinglius another. It divides Oecolampadius, Bucer, Osiander, &c. And the doctrine it discovers to the Confessionites, is quite different from that it shews the Anabaptists and Menonites, in the very same passage of scripture.

SPIRIT, *Spiritus*, is also used, in *Prosody*, to signify the greater or less degree of breath employed in the pronunciation of the initial Greek vowels, and of the letter ρ.

In sounding the vowels, we may observe every vowel has its sound by a simple conformation of the mouth, in which the breath has little or no concern, as being confined in the arteria aspera: the spirits, or breaths, which are placed on the initial vowels in words, are to denote the force this initial vowel is to have from the breath, when the word is pronounced. If the sound of this vowel be smooth, as all the sounds of the vowels naturally are, this is termed *spiritus lenis*, a mild breath; but if this vowel be to be pronounced with a more vehement expulsion of the air, this is termed *spiritus asper*, or a rough breath, or aspirate: and when the aspirate and acute are in the same syllable, the mark of the breath, in this initial vowel, only signifies, that the vowel is to be pronounced with a stronger breath than the initial mild vowels; for aspirates do not alter the tone of any syllable, but only strengthen, increase, and swell the tone.

SPIRIT-LEVEL. See **LEVEL**.

SPIRIT-ROOM, in *Ship-Building*, a secure apartment built next abaft the after-hold, to contain the spirits. See **SHIP-BUILDING**.

SPIRITOSO, *con Spirito*, Ital., in *Music*, severally imply animation, spirit, and fire, in the performance of the movements to which either of these terms is prefixed.

SPIRITU SANTO, or *Espiritu Santo*, (which see,) in *Geography*, a sea-port of Brazil, in the government of Rio Janeiro, situated on the south side of a large bay, about three leagues from the ocean, but having neither walls nor fortifications, except a small ruined castle; so that its defence consists in the bravery of its inhabitants, who amount to about 900. The port is a small bay, opening to the east, and intersected with many small islands. At the top of a mountain, at some distance from the town, is a large white tower, which the Portuguese call Nossa Senhora de Pena, and near it a small church, surrounded with a wall. At the foot of the mountain are still to be seen a few old houses, the melancholy remains of a place once called Villa Veja, or the Old City. S. lat. 20° 8'.—Also, a town of the island of Cuba; 155 miles E.S.E. of Havannah. N. lat. 22° 15'. W. long. 79° 47'.—Also, a town of Peru; 8 miles W. of Potosi.—Also, a town of Chili; 60 miles from Coquimbo.—Also, a river of Mexico, which runs into the Pacific ocean, N. lat. 23°. W. long. 106° 40'.—Also, a town of Mexico, in the province of Mechoacan;

65 miles E.N.E. of Zacatula.—Also, a river of Brazil, which runs into the Atlantic, S. lat. 20° 10'.—Also, a lake of East Florida, near the southern extremity.

SPIRITU SANTO Bay, called also Tampay bay, and Hillborough bay, a large bay on the west coast of East Florida. N. lat. 28°. W. long. 82° 45'.

SPIRITU SANTO Islands, or *Andros*, a chain of islands, situated to the south-west of the Bahamas; the largest about 40 miles in length, and eight in breadth. N. lat. 24° to 25° 12'. W. long. 77° to 78° 15'.

SPIRITUAL FRIARS. See **FRANCISCANS**.

SPIRITUALITIES of a bishop, are such profits as arise to him from the benefit of his jurisdiction in his diocese, and not as a baron of parliament.

Such are those of his visitations, institutions, ordinations, presentation-money, &c.

SPIRITUALITIES, *Guardian of the*. See **GUARDIAN**.

SPIRITUALIUM CUSTOS. See **CUSTOS**.

SPIRITUALIZATION, in *Chemistry*, the action of extracting spirits from natural bodies. See **SPIRIT**.

Spiritualization is an operation that belongs principally to fermented salts, and then to fermented juices and liquors; the fermentation rendering the spirits volatile and inflammable.

Spirit of wine is sometimes spiritualized to that degree, that upon throwing a quantity into the air, not a drop shall fall down; but the whole evaporate, and be lost.

SPIRITUS. See **SPIRIT**.

SPIRKET, in *Rural Economy*, a term applied to a hook to hang any thing upon, as the cart-geer, &c. in stables and other places.

SPIRKETTING, in *Ship-Building*, a thick strake, or strakes, wrought withinside upon the ends of the beams or water-ways. Spirkettings under ports reach from the water-ways to the upper side of the lower fill, which is generally of two strakes, wrought top and butt.

SPIRTING CUCUMBER, in *Botany*, a species of *momordica*; which see.

SPISE, in *Geography*, a town of Africa, in the kingdom of Ningo, in the interior part of the Gold Coast.

SPISSUM, in the *Ancient Music*, was used to signify those two smaller conjunct intervals of a tetrachord, which, taken together, were less than the third.

The Greek term for this was *σπυρισμ*. This happened in the enharmonic, and the three chromatic genera; in each of which, the interval between the hypate and the lichanos, was less than the interval between the lichanos and the nete. To the spissum was opposed the non-spissum, *ἀσπυρισμ*, or *rarum*, as Martianus Capella translates it. The *σπυρισμ* happened in the two diatonic genera, where the two smallest intervals were equal to, or greater than the third. They were supposed equal in the diatonicum molle, and greater in the intenfum. See **GENUS**.

SPIT, *The*, in *Geography*, a shoal of the Atlantic, near the coast of South Carolina; 15 miles S. of Cape Fear. N. lat. 33° 34'. W. long. 78° 10'.

SPIT, in *Agriculture* and *Gardening*, the quantity or depth of earth or mould which the spade takes up at once in digging or delving over ground. Thus, this sort of work is performed to one, two, or more spits deep, according to circumstances, and the nature of the soil and crops.

SPIT-DUNG, that sort of dung manure which has undergone complete fermentation or putrefaction, and is reduced into a somewhat earthy state, so as to be dug or taken up by the spade or shovel in a sort of spit manner.

SPIT-SHOVEL, that sort of tool of the shovel kind which is employed in digging out or shovelling up such dung, or

other matters, as are in a reduced earthy condition. And the term is also sometimes applied to it when used in taking up grain for the purpose of having it cleaned or removed into another situation.

SPITAL, in *Geography*, a town of Austria; 6 miles S. of Steyr.—Also, a town of Spain, in Catalonia, near the coast of the Mediterranean; 22 miles N.E. of Tortosa.—Also, a town of the duchy of Stiria; 5 miles E. of Muertzenfchlag.—Also, a town of the duchy of Carinthia, on the Lifer, about a mile from the Drave; 8 miles E. of Saxenburg.

SPITHEAD, a spacious reach in the British Channel, about mid-way between the southern coast of Hampshire and the Isle of Wight. It directly faces the mouth of Portsmouth harbour, and is frequently occupied by men-of-war and frigates at anchor. Sometimes a fleet of ships is stationed here. It is said that 1000 sail of vessels may anchor at one time with security. The depth of water, at low tide, is 10, 11, 13, 14, 15, and 16 fathoms. This place is memorable for the shipwreck of the Royal George, of 100 guns, in August 1782. At that time the vessel was occupied by more than 400 men and 200 women, and was hove on one side, for the purpose of repairing her keel. Not anticipating danger, the sailors had neglected to lash down her lower deck ports, and a sudden squall coming on, she was thrown with her broad-side on the water. The hole was filled in a few minutes, and every thing was carried to the bottom. Admiral Kempenfelt, with all the crew and visitors, perished; for there was no time for boats to afford assistance. Many attempts have been made to raise this vessel, but without success; although many articles have been obtained from the cabins, &c. Some of the malts continued to be seen above water for many years after the accident.

SPITHEAD Creek, a river of the western territory of America, which runs into the Ohio, N. lat. 39° 56'. W. long. 80° 46'.

SPITTER, among *Sportsmen*, a red male deer near two years old, whose horns begin to grow up sharp and spittlewise.

It is otherwise called a *brocket* and *pricket*.

SPITTLE. See SALIVA and SPUTUM.

SPITTLE, a corruption of the word *hospital*.

SPITTLE, in *Agriculture*, the name of a spaddle or small sort of spade. See SPADE.

SPITTLING, a term applied to an operation performed in the cultivation of teale crops, in which the workman, with a tool of the spittle, shoe, or small spade kind, turns over the surface-mould between every plant in a careful manner, in the first summer season after planting, when the plants have acquired some degree of growth. By this means they are kept perfectly clean from weeds, and their growth promoted as much as possible.

The work commonly costs about a guinea and a half the acre and drink, in most districts where this sort of cultivation is carried on. See TEASLE.

SPITZ, in *Geography*, a town of Austria, on the Danube; 10 miles above Krens.—Also, a town of Bohemia, in the circle of Leitmeritz; 9 miles N.E. of Kamnitz.

SPITZBERG, a considerable mountain of Silesia, in the principality of Liegnitz.

SPITZBERGEN, or SPITSBERGEN. See East GREENLAND.

SPITZEBACH, a river of Germany, which runs into the Eltzach, near Ober Winden.

SPIZA, in *Ornithology*, a name by which the ancient naturalists called the chaffinch.

SPLA-BOARDS, in *Ship-Building*, boards or planks fixed

to an obtuse angle in the light-room, to throw the light into the magazine.

SPLACHNUM, in *Botany*, a name adopted by Montin and Linnæus from Dioecorides, whose *σπλαχχιον* is synonymous with his *βρυον*, and belongs to the Mosses in general, or rather perhaps Lichens, which grow upon trees. This name becomes peculiarly appropriate, when we advert to its identity with *σπλαγγχιον*, the Greek appellation of the principal *viscera*, the heart, lungs, &c.; because the essential character of the genus before us consists in a peculiar fleshy glandular organ, supporting the capsule; whence its English name, Gland-moss.—Montin Diff. 7. Linn. Am. Acad. v. 2. 270. t. 3. Gen. 563. Schreb. 759. Hedw. Fund. v. 2. 88. t. 7. f. 33. Sp. Musc. 51. Sm. Fl. Brit. 1169. Turn. Musc. Hib. 15. Swartz Musc. Suec. 22. Juss. 11. Lamarck Illustr. t. 874.—Class and order, *Cryptogamia Musci*. Nat. Ord. *Musci*.

Ess. Ch. Capsule cylindrical, placed on a fleshy receptacle. Fringe simple, of sixteen teeth, standing in pairs.

This genus is one of the most remarkable of its tribe for size and beauty, as well as for singularity. Twelve species are defined in Hedwig's *Sp. Musc.*; thirteen in the *Fl. Brit.* six of the latter not being known to Hedwig. Linnæus, in the original account of the genus, describes but two, which are far the most extraordinary, natives of the most northern part of Europe, and not found in Britain. We shall describe these, with a few of the others best worth notice.

S. muscioides. Green Tapering Gland-moss. Linn. Fil. Meth. Musc. 26. Hedw. Sp. Musc. 51. Crypt. v. 2. 35. t. 11. Fl. Brit. n. 1. Engl. Bot. t. 1589.—Receptacle inversely conical, green. Leaves elliptic-lanceolate, bearded, entire.—Native of moist alpine situations in Scotland, Wales, and other parts of Europe, generally, in Wales, growing on the dung of foxes and badgers, according to Mr. Griffith's remarks. This is one of the smaller species, resembling some common *Bryum*; its leafy stems about an inch high; its fruit-stalks rather more. The capsule is cylindrical, brown, with a blunt lid. Its short green receptacle at the base might almost be overlooked, as a swelling of the stalk.

S. sphaericum. Green Globular Gland-moss. Linn. Fil. Meth. Musc. 33. t. 1. f. 1. Hedw. Sp. Musc. 55. Crypt. v. 2. 46. t. 16. Fl. Brit. n. 8. Engl. Bot. t. 785.—Receptacle globular, green. Leaves ovato-lanceolate, pointed, entire. Fruit-stalk capillary.—Native of alpine situations in Lapland, Germany, Carniola, Scotland, &c. usually on cow-dung. Dr. F. Buchanan first met with it at Leney near Stirling, in 1782. This forms green tufts, each plant being simple, apparently annual, about half an inch high in the leafy stem, which terminates in a stary blossom. Some of these blossoms are most perfectly male, others female. The latter produce each an elegant slender wavy tawny fruit-stalk, from one and a half to three or four inches high, bearing a green, nearly globose, smooth receptacle, much larger and thicker than the little brown cylindrical capsule, bordered with eight pair of spreading brown teeth.

S. gracile, Dickf. Crypt. fasc. 4. 3. t. 10. f. 5. Fl. Brit. n. 9. Engl. Bot. t. 1921, is supposed by Mr. Turner to be a variety of the last, rather smaller, with ferrated points to the leaves, and a brown receptacle.

S. ampullaceum. Purple Gland-moss. Linn. Sp. Pl. 1572. Hedw. Sp. Musc. 55. Crypt. v. 2. 41. t. 14. Fl. Brit. n. 10. Engl. Bot. t. 144. Fl. Dan. t. 822. (S. n. 3; Linn. Am. Acad. v. 2. 280. Bryum ampullaceum, foliis thymi pellucidis, collo striatioribus; Dill. Musc. 343. t. 44. f. 3.)—Receptacle inversely conical, ob.ule, greenish-purple, thrice as thick as the capsule. Leaves lanceolate, acute, ferrated.

ferrated.—One of the most common species, at least in England, growing chiefly on rotten cow-dung on moist turfy heaths in the spring, ripening fruit in summer. It seems no less frequent in other parts of Europe. This is larger than *S. sphaericum*, annual like that, but distinguished by the narrower ferrated leaves, stouter stalks, and especially the large purple pear-shaped receptacles, each crowned with a little slender tawny capsule.

S. Turnerianum, Dickf. Crypt. fasc. 4. 3. t. 10. f. 11. Fl. Brit. n. 11. Engl. Bot. t. 1116, is, we fear, but a small, or starved, variety of the last.

S. vasculosum. Crimson Globular Gland-moss. Linn. Sp. Pl. 1572. Hedw. Sp. Musc. 53. Crypt. v. 2. 44. t. 15.—Receptacle blood-red, nearly globular. Leaves spatulate, bluntnish, entire.—Native of turfy bogs near Upsal, and in other parts of Sweden. About the height of the last, but distinguished by its blunt entire leaves, and the globular form, greater size, and deep rich hue of its receptacle. This fine species has also been found in Germany, but not in Britain.

S. rubrum. Red Umbrella Gland-moss. Linn. Sp. Pl. 1572. Hedw. Sp. Musc. 56. Crypt. v. 2. 51. t. 18. (S. n. 1; Montin Diff. 8. t. 1. f. 2. Muscus norwegicus, umbraculo ruberrimo insignitus; Petiv. Musc. 11. t. 1. f. 70. Dill. Musc. 547. t. 83. f. 9.)—Receptacle orbicular, convex, red. Leaves ovate, partly toothed.—Native of Norway, Finland, Russia, and most parts of Siberia. The stem, like most of the rest, is simple, leafy, about an inch high. Upper and floral leaves ferrated. Fruit-stalk about six inches long, erect, red, bearing a small cylindrical capsule, which is subtended by a most beautiful, large, and conspicuous receptacle, like an inverted cup, half an inch wide, of a rich crimson, finely reticulated, and certainly one of the most curious productions in this whole natural order.

S. luteum. Yellow Umbrella Gland-moss. Linn. Sp. Pl. 1572. Hedw. Sp. Musc. 56. Crypt. v. 2. 48. t. 17. (S. n. 2; Montin Diff. 9. t. 1. f. 1.)—Receptacle orbicular, flattish, deflexed, yellow. Leaves obovate, entire.—Native of boggy woods in Lapland and Westbothland. This vies with the last in magnitude and singularity, but the receptacle is pale yellow, and though deflexed, scarcely convex. By Hedwig's figures, as well as the Linnæan specimens, this part seems to be small and green till the capsule is fully formed, after which it expands and assumes its proper colour.

SPLAIT-SHOULDER. See SHOULDER.

SPLANCHNICA, a name given to medicines appropriated to diseases of the bowels.

SPLANCHNOLOGY, formed from *σπλαγχνον*, intestine, and *λογος*, discourse, in Anatomy, a discourse on, or explication of, the viscera.

Sarcology is divided into three parts, viz. splanchnology, myology, and angiology; of these, splanchnology is that which treats of the internal parts, and particularly of the viscera.

SPLEEN, in Anatomy and Physiology, (*σπλιν*, lien, *la rate*;) a body about the size of a small fist, of a texture rather resembling that of glands, situated in the left hypochondriac region of the abdomen, between the great end of the stomach, and that portion of the diaphragm which lines the concavity of the tenth and eleventh ribs.

The organ is usually single; but occasionally one, two, or more small secondary spleens (*lienes succenturiati*), of a round or oval figure, about the size of hazel-nuts, of a texture exactly similar to the principal one, are found near its anterior end, in the great omentum, connected by the latter and by their blood-vessels to the principal spleen.

It has been asserted that the spleen has been in some cases entirely deficient. It may have been greatly diminished by disease, or consumed by suppuration; but we have no sufficient testimony of its entire absence as a defect of original formation.

Every thing belonging to the spleen is irregular, and its figure is remarkably so. Usually the outline described by its circumference is elliptical: it represents, indeed, on the whole, the section of an ellipsoid carried through the axis. Its largest surface is convex, like the superficies of an egg; the margin oval, with two ends, and a longer and shorter axis. The convex surface of the organ, then, is the most extensive, rising in the middle, and sloping towards a comparatively thin edge: this is rather broader towards the back part, and grows narrower, terminating in an obtuse point in front. The opposite aspect is concave, and divided into two surfaces by a slight notch running along its long axis, at which the blood-vessels enter, and to which the omentum is affixed. Both ends of the spleen are obtuse: the posterior or superior is thicker, the inferior or anterior thinner. Sometimes the spleen is more rounded, or more triangular. Often the edge is notched in one or more places, and more or less deeply.

The situation of the spleen varies, as well as its figure. We may, however, state generally, that in a healthy subject of the ordinary formation, it will be found in the upper and back part of the left side of the abdomen, covered by the false ribs, lying between the back of the great end of the stomach and the diaphragm in such a way, that it is not visible on opening the abdominal cavity until the stomach is drawn aside. Its convexity corresponds to the concavity of the diaphragm, and of the tenth and eleventh ribs; its concavity to the great end of the stomach: one end is turned backwards; the other forwards.

In this situation it is closely tied to the stomach by its blood-vessels, which send branches to that organ; and by the great omentum, which is attached to its notch, and to the neighbouring portion of the stomach. There are, besides, certain folds of peritoneum, connecting it to the surrounding parts. One of these, *ligamentum verticale*, or *suspensorium lienis*, or *phrenico-splenicum*, passes from the lower part of the diaphragm to the upper end of the spleen. Another, *ligamentum mesocolicum*, or *gastro-splenicum*, passes from the mesocolon, stomach, and œsophagus, to the posterior part of the notch. A fold of peritoneum may also be seen going from the spleen to the left renal capsule and kidney.

The changes of place in the stomach are attended with corresponding alterations of the spleen. When the former is full, the spleen is situated nearly transversely, with one end turned backwards, and the other forwards, with its concavity touching the colon in front, and the renal capsule behind. As the stomach becomes empty, the position of the spleen is more perpendicular; with its ends upwards and downwards. The motions of the diaphragm are necessarily accompanied with change of position in the spleen. When that muscle descends, it pushes the stomach and spleen downwards and forwards, thrusting them from under the ribs; they are brought back again to their former place by the re-action of the abdominal muscles.

When it is enlarged, it passes out of the hypochondrium, and can be felt in the umbilical region, or even the hypogastric: it has descended as low as the groin or bladder. In cases of transposed viscera, it has partaken the inversion with the other thoracic and abdominal organs.

The size of the spleen, like other circumstances belonging to this organ, is subject to much variety. Soemmerring states

states its weight at from six to fifteen ounces; and its specific gravity to that of water, as 1060 to 1000. It has been asserted, that the kind and the circumstances of death influence the size of the spleen; and we may readily believe that a part of spongy texture, containing so much blood, will be smaller in an individual who has perished from hæmorrhage than in one who has died of apoplexy. All physiologists have represented that the size of the spleen is influenced by the state of the stomach, which they conceive to act on it in two ways. They suppose that the full stomach presses the spleen against the ribs, and thus mechanically forces out the contents of its cells, which are expanded again as soon as this pressure is removed. It has been also imagined, that when the stomach is full of aliment, blood passes in larger quantity into its vessels, which admit it more easily; while, in the empty stomach, the vessels fall into folds, and do not receive so much blood. In the former case, the blood which goes to the stomachic arteries is partly drawn away from the splenic vessels, which also admit it less readily, because the spleen is at the same time compressed: in the latter, these circumstances are just reversed. These observations seem purely hypothetical; and they present a mechanical solution of vital processes, which are certainly governed by other principles. Not a single fact is adduced as a foundation of this fanciful superstructure. It seems, on the contrary, that there are facts sufficient to overturn it. "Numerous comparative experiments," says Bichat, "made at different points of time in the digestive process, during the plenitude and emptiness of the stomach, on animals of similar size, and under similar circumstances, have shewn, indeed, sensible variations in the volume of the spleen, but not that invariable coincidence, which has been asserted, between the contraction of the stomach and the increase of the spleen, and *vice versa*. The opposite relation was often noticed; so that we could only conclude, that the differences of volume were independent of the succession of the digestive phenomena, and constituted permanent peculiarities of individual organization. The kidney, the liver, &c. do not exhibit an uniform size in all subjects; but we do not trouble ourselves by endeavouring to find causes for such variations.

"Lastly, admitting that the volume of the spleen varies during life, whether these variations coincide or not with determined states of the digestive organs, it is repugnant to the spirit in which modern physiology contemplates the phenomena of life, to assign the laxity of the spleen, when the stomach is empty, as a cause for the derivation of blood from the vessels of the latter organ, or its mechanical compression by the distended stomach, as a means of explaining the more rapid passage of the blood into the system of the vena portarum." *Anatomie Descriptive*, t. v. p. 58.

We cannot doubt, that, independently of disease, or of such natural causes as may produce changes in the state of the spleen, the volume of this organ is different in different individuals. Animals of the same species and age, and under circumstances in all respects similar, exhibit such differences. We frequently, too, find the spleen after death, in the human subject, considerably larger or smaller than what may be regarded as the standard size, though alike in all other points; so that the kind of death, or other accidental circumstance, will not explain the difference.

The colour of the spleen is red or livid, or of some tint between these. The convex surface is often red, while the edge and concavity are livid. The former colour is more prevalent in young, the latter in old subjects. When the organ is cut, its internal colour seems to depend on the large quantity of blood it contains; and nearly resembles

that of a coagulum, with divided blood-vessels interspersed through it.

It is spongy, soft, and delicate in its texture, so that it can be broken down by moderate pressure with the fingers.

The spleen is surrounded externally by a smooth, thin, and closely-adhering serous membrane, derived from the peritoneum. This coat is so intimately united to the next, that they cannot be separated. The proper membrane immediately incloses the spleen. Although this and the former are inseparably united, we cannot doubt that such a proper membrane exists, because the covering is much thicker than the peritoneum in any situation. Just at the notch, the peritoneum may be separated for a short distance from the proper membrane. From the internal surface of this covering, numerous fine filaments are continued into the substance of the spleen, where they form part of the peculiar tissue of the organ. The proper membrane is so thin, that its nature is not easily ascertained: it seems, however, to belong to the fibrous class, as it is corrugated by boiling, and easily receives depositions of gelatine, or phosphate of lime. Thickenings of the splenic coats from this cause are very common. This membrane is softer than those of the fibrous kind usually are; and it is elastic, so as to accommodate itself to the varying bulk of the organ.

The spleen is remarkable from the size of its artery, which is larger in proportion to the organ than in any other instance, although no secretion takes place. There are great varieties in the number of secondary branches, by which it penetrates the notch of the spleen. The hepatic artery is rather larger than the splenic in young subjects; but smaller in the adult; yet the liver in the latter is at least five times larger than the spleen. The branches of the splenic artery are said to be very large in comparison with the trunk; and the coats of the artery are remarkably strong. Its resistance, compared to that of the aorta, near the emulgents, was as 1312 to 1000. The spleen has a large single vein, which constitutes one of the principal trunks of the vena portarum. In a child of three months, according to Haller, the artery measured $\frac{1}{3}$ of an inch, the vein $\frac{1}{2}$: in a child of eighteen months, the numbers were 13 and 19; at three years, 14 and 26. According to sir Everard Home, "the trunk of the splenic vein, compared with that of the artery, when both are filled with wax, is found to be in the proportion of five to one in its size. This was ascertained both by an accurate measurement of their diameters, and by weighing half an inch in length of each in a very nice balance: the disproportion between them is greater than between corresponding veins and arteries in other parts of the body." (*Phil. Trans.* 1807. pt. ii. p. 49.) It has no valves. Injected fluids of all kinds pass with the greatest facility from the artery into the vein. There are numerous superficial absorbents, belonging principally to the peritoneum: of deep-seated absorbents, there is little known. The absorbents are easily demonstrated in the calf. If air is impelled under the membrane of the spleen, numerous knotted lymphatic trunks appear, arising from the whole surface of the viscus, and passing with the great blood-vessels towards the receptaculum chyli. Many observers have noticed and described them in animals; but they are not so conspicuous in man. The nerves are small; they come from the celiac plexus, and form a slender splenic plexus, surrounding the artery, and entering the spleen with its branches. If the organ, in its natural state, possesses any sensibility at all, it is very inconsiderable. For further particulars on these points, see ARTERY, VEIN, NERVE, and ABSORBENT.

The substance of the healthy spleen readily yields to any force,

SPLEEN.

force, and is easily broken down. It appears, when divided, soft and spongy. Its colour is deeper than that of the surface. It seems thoroughly penetrated with blood, which is not coagulated, which may be squeezed out, but does not flow very readily. In some subjects, more particularly young ones, there is a granular appearance, arising from numerous small bodies, called acini: these are rendered more visible by breaking the spleen, and observing the broken surface. If the divided surface be scraped with a knife, blood is expressed, and some of the parenchymatous substance is usually detached. If we subject it to frequent washings, the blood is discharged from it, and the organ is reduced to a loose spongy tissue of whitish fibres and laminae; many of which adhere to the internal surface of the fibrous membrane. If the blood is carefully pressed out from the vessels, and they are then washed out by repeated injections of water, the spleen, carefully inflated and dried, exhibits a mere cellular and spongy mass.

This parenchyma of the spleen consists of the blood-vessels, ramified in the usual way, and terminating in a capillary system, and of certain cells, which are easily injected from the splenic vein with coarse injection. The ramifications of the veins, and these cells, are of very delicate structure, so that they easily give way under injection.

The cells of the spleen were noticed by Malpighi, who describes in the organ a number of small glands, hollow, and surrounded by arterial zones, into which he had never been able to trace any venous branches. Cuvier describes small corpuscles, whose use is unknown. Sir Everard Home says, in his observations on the structure and uses of the spleen, "I have examined it after death, under the ordinary circumstances, and have found the appearances described by Cuvier. I have also examined it frequently immediately after the stomach had received unusual quantities of liquids, and in that state have found invariably that the corpuscles of Cuvier, which were the glands of Malpighi, are distinct cells, containing a fluid, which escapes when the cells are punctured, and renders their membranous coat visible; so that it would appear that the distention of these cells is connected with the state of the stomach, and therefore only takes place occasionally; and that the elastic capsule, by which the spleen is surrounded, adapts the organ to these changes in its volume." Sir Everard states farther, that "in the spleen of the bullock, horse, and hog, the cells, when the arteries and veins are injected with coloured size, are seen to have numerous arterial branches ramifying in their coats, but no venal ones, which confirms the statement of Malpighi: and when the cells are empty and contracted, and the blood-vessels filled to a great degree of minuteness, the appearance of cells is entirely lost, as stated by Cuvier. When the cells were in a distended state, their cavities, in a great many instances, were very distinct, having been laid open in making a section of the spleen. The intermediate parts of the spleen are but sparingly supplied with arterial branches; and the smaller ones (arteries?) do not appear to have any particular distribution. When the veins only are injected, their branches appear more numerous, and larger than those of the arteries, making the whole substance of the spleen of a red colour. They appear to arise from the outside of the cells, going off at right angles to their circumference, like radii. Where the injection has not been very minute, they are seen to arise at not many points of the capsule; but where the injection has got into smaller branches, their number is so much increased, that they appear to form plexuses round the cells." *Phil. Transf.* 1808, p. 47—49.

In a second paper on the same subject, sir Everard informs us, "that the spleen is met with in two very different states,

one of which may be termed the distended, the other the contracted, and that in the one its size is double what it is in the other. In the distended state there is a distinct appearance of cells containing a limpid fluid, distinguishable by the naked eye: in the contracted, these only become distinct when seen through a magnifying-glass. The distended state takes place when the stomach has received unusual quantities of liquids before the animal's death; and the contracted state, when the animal has been kept several days without any drink, before the spleen is examined." *Ibid.* p. 140.

It is observed by Haller, that in the calf, and most other herbivorous quadrupeds, the structure of the spleen is more obvious, and easily exhibited, than in the human subject. "In these animals, very strong and evident fibres and laminae arise from the external covering of the spleen, penetrate into the interior of the organ, are attached to the coats of the blood vessels, and lastly, having decreased in size, end in all directions in the pulpy structure of the spleen. In this way they compose a cellular tissue much more loose than in man. If water be thrown into the vein, the organ then pressed, and these proceedings repeated, until the fluid comes out clear, the whole may be distended, by inflation of the vein, into an appearance very much like that of the lungs. From this texture, there is a very free passage into the vein, which seems to open by very short branches, as it were foramina, into the cellular tissues. The fibres are neither muscular nor vascular, but cellular; on account of their strength in the larger animals, some have called them ligamentous." *Elem. Physiolog. lib. xxi. sect. 1. § 15.*

Heretofore great disputes existed about the small bodies called acini, which are observed in the substance of the spleen. Malpighi, who first noticed them, deemed them small hollow glands. Ruysch insisted that they were merely the minute vessels assuming a peculiar arrangement; and that this structure could be demonstrated by successful injections. The latter opinion has been gradually adopted by the best anatomists; among whom we may enumerate Albinus, Haller, and Soemmerring. "Qui nonnunquam occurrunt, acini vel glomeruli, microscopii ope accuratissime explorati, nihil aliud sunt nisi vasorum fasciculi, vel teretes penicilli, aut cirri vasculosi." *De Corp. Hum. Fabric. t. vi. p. 157.*

The resemblance of the spleen to glands in its structure, has led to a very careful search after an excretory duct; but nothing of this kind has ever been detected; although such discoveries have heretofore been published. We know of no connection between the spleen and any other organ, except by means of blood-vessels or nerves.

In a paper, containing experiments on the passage of fluids from the stomach into the general circulation, &c. published in the *Phil. Transf.* 1812, p. 51, sir Everard Home advances the opinion, that a secretion takes place into the cells of the spleen, that the fluids thus secreted are conveyed by the absorbents into the thoracic duct; and, consequently, that those vessels are excretory ducts of the spleen. With deference to this ingenious and indefatigable inquirer, we may suggest, that the fact of the spleen performing any secretion is not yet proved; consequently, that we need not employ ourselves in discovering the means of conveying away such secretion.

The blood of the spleen seems to be distinguished by some peculiarities. It is never seen coagulated: Haller says that he never saw it in that state; but according to Soemmerring, a true clot (polypus) has been observed in the splenic vein. (*Elem. Physiolog. t. vi. p. 404. De Corp. Hum. Fab. t. vi. p. 156.*) It is said to be darker coloured than other venous blood; but exposure to oxygen gives it the scarlet tint.

Haller says also that it contains more water, the proportion of this element in it, compared to that in other blood, being as $\frac{3\frac{1}{2}}{4}$ to $\frac{3}{5}$. The thick part subsiding to the bottom of the vessel was less; as 3 to 6. Sir Everard Home confirms the fact of the greater quantity of serum in splenic blood. (Phil. Transf. 1808, p. 138.) Neither, according to the representation of Haller, are these the only distinguishing characters of splenic blood. It has been found, he says, to contain more volatile salt, and less empyreumatic oil. The experiments on which the above observations are grounded afforded similar results on repeated trials, and in various animals.

The spleen is very small in the fœtus, and appears remarkably so, if compared to the kidneys or liver. It rather increases towards the end of pregnancy. No remarkable changes occur in it after birth: in old persons it is often diminished; and its external coat is thicker.

A spleen, or at least a body so considered, and called by that name, exists in all the orders of the vertebral division of animals; but, if we may judge from the size, its importance seems to diminish successively from mammalia to birds, thence to reptiles, and from them to fishes. Mammalia resemble man in having the spleen placed close to the left end of the stomach; but they exhibit considerable varieties in the size, figure, colour, and texture of the organ. It is proportionally large in man, being twice as large as in the ox for example. In birds, reptiles, and fishes, the spleen is not only smaller, but firmer and more rounded; not so constantly placed near the stomach, but in the midst of the mesentery for example. The relations and sources of its blood-vessels are also different. Instead of a large peculiar branch, it has small branches from a stomachic artery, or from the mesenteric.

The use of the spleen still remains a problem, towards the elucidation of which the investigations of so many anatomists and physiologists have hitherto afforded very imperfect data. In beginning his observations on this subject, Haller very sensibly admonishes his reader that "he is plunging into the region of mere conjecture, darker than in the case of any other viscus." We might have hoped to derive some light from the diseases under which it frequently suffers, and from the experiments, in which it has been removed in animals. The inferences, however, to which we arrive in this way, are only of the negative kind; they enable us to destroy or refute, but not to build up or establish. The spleen may be found considerably altered in texture, where the individual has enjoyed good health before death, or has died of other complaints. It is often enormously enlarged, without materially affecting the health; and, on the other hand, where ill effects are produced, they have no peculiar character, affording illustration of the use of the organ.

The experiment of removing the spleen seems to have been performed in very ancient times. Pliny says, that animals will live after this part has been torn out (lib. xi. c. 30.); and the same fact is noticed in the Talmud (Ginzburger, Medic. Talmud. p. 11.) Haller cites various instances, in which the spleen has been lost in the human subject; particularly Leon Fioravanti, tesoro della vita umana, l. ii. c. 8. Phil. Transf. N° 451. The removal of it from the dog is an experiment repeated over and over again. (See Haller, t. vi. p. 421.) We find that animals, and even human subjects, have lived without a spleen, and enjoyed tolerable health. Sometimes the experiment has been fatal, but not from the loss or interruption of any function, that could be ascribed to the spleen. We find that dogs have been lively, fat, and even plethoric; that they have had good appetites; that bitches have produced

young. Some thought they were more falacious; others, that they made water more frequently. In some cases appearances were noticed, that might be referred to imperfection in the digestive process, as borborygmi. The liver is said to have suffered, in a few instances: in most, however, there seems to have been good bile made; and generally no particular ill effect was experienced.

The inference, then, to be collected from these sources is, that the function of the spleen is of so little importance, that the alteration of its texture by disease is not marked by any unequivocal symptom, and even that its entire removal is hardly followed by any sensible effect.

It has been a generally received, and long prevalent notion, that the office of the spleen is related to that of the liver; that the blood, either by its retarded motion through the serpentine splenic vessels, its stagnation in the splenic cells, or other changes wrought in it by the actions of the spleen, acquires peculiar properties, rendering it fit for the secretion of bile in the liver. It is supposed that the splenic blood is loaded with carbon, which the action of the liver separates from it. We do not usually meet with such arrangements as these in the animal economy: indeed no instance could be adduced of the like nature;—one organ to carbonize the blood, that it may be decarbonized by another; or a part to produce changes in the blood, fitting it for the secretion which is to be performed by another. The tissue of each gland has the power of extracting its peculiar secretion from the common mass. That the spleen produces changes in the properties of the blood is not yet clearly proved: still less is it proved that such changes, if produced, are in any way concerned with the biliary secretion. Further, bile is secreted where the spleen has been removed; and it was secreted, in the case recorded by Mr. Abernethy, where the vena portarum emptied its blood into the inferior vena cava. We observe no constant relation between the spleen and liver: the former is extremely small in many birds, reptiles, and fishes, where the liver is large.

The close neighbourhood of this organ to the stomach, and the connection of their blood-vessels, have led to the conjecture that they are connected in function. It has been imagined, that when the stomach is empty, the spleen, like a sponge, swells with blood, and affords a reservoir for the quantity of that fluid, which the blood-vessels of the stomach do not require in the inactive state of the organ; while, on the contrary, when this bag is distended with food, and the process of digestion demands a more copious afflux of fluids into the stomachic vessels, the pressure of its great extremity empties the splenic sponge, and thus causes a greater flow in the other parts of the cœliac system. This, again, is all imaginary: not a single point of it founded in observation. It is quite inapplicable to the three lower classes of vertebral animals, where the position of the spleen in many instances, and its firmness in several, are quite incompatible with the explanation.

In two papers, published in the Philosophical Transactions for 1808, on the structure and use of the spleen, Sir Everard Home attempted to prove, that fluids are conveyed from the cardiac end of the stomach into the spleen, and thus arrive in the general circulation, without the intervention of the general absorbing system and thoracic duct. Having tied the pylorus, he injected coloured fluids into the stomach: they were partly absorbed, and manifested their presence in the circulating system by changes produced in the urine. When rhubarb was used, the cut surface of the spleen produced a decided yellow tint on paper, and the serum of the splenic blood manifested the presence of rhubarb, on the addition of potash; when no such phenomena were

were exhibited by the cut surface of the liver, or in the serum of blood from the vena cava. There was a corresponding difference between the effects of potash on fluids, in which the substance of the liver and that of the spleen were broken up. The author abandons this notion in a subsequent communication to the same society, on the passage of fluids from the stomach into the general circulation; having found that corresponding phenomena were exhibited, after the spleen had been removed. Phil. Trans. 1812.

Of numerous other dreams about this mysterious organ, such as that it forms the red globules of the blood, that it is the seat of laughter, or of the sentient soul, that it is designed to balance the liver, &c. &c. we can say no more than that those who are interested in such speculations will find ample amusement in Haller's Elem. Physiol. lib. xxi. sect. 2; or in Soemmerring de Corp. Hum. Fabrica, t. vi. p. 158, et seq. One fact, mentioned by the latter author, may be stated, viz. that steel given for some time to animals has the effect of diminishing the size of the spleen.

SPLEEN, Diseases of the, in Medicine. Much more has been written by the older writers respecting the diseases of this organ, than by those of the last half century. This may have arisen partly from the greater accuracy of modern pathologists, but chiefly perhaps from the actual diminution of these maladies, in consequence of the diminution of the prevalence of intermittent fevers, of which many of the chronic derangements of the spleen were the *sequela*, or direct result. The *infarction* of the spleen, of which the older authors so often treat, was of this nature. The two principal modifications of disease, to which this viscus is subject, are inflammation, and their indolent enlargement of its substance, formerly called infarction. We shall treat of these diseases separately; and then enumerate some of the other morbid conditions, with which the spleen has been occasionally observed to be affected.

SPLEEN, Inflammation of, splenitis of the nosologists. This may occur, as in the other viscera, in two forms; either attacking the investing membranes, or the substance of the gland. Under both forms, however, it is a rare disease, but especially under the latter, the symptoms of which are apparently obscure, and not satisfactorily understood.

The peritonæal coat of the spleen is, in fact, seldom inflamed, according to the testimony of that excellent anatomist, Dr. Baillie, unless when the peritonæum in the neighbourhood is also affected. The proper capsule of the spleen, he remarks, is so intimately connected with the peritonæum, which is reflected over it, that it must necessarily partake of any inflammation affecting that membrane. Accordingly the symptoms, attending this inflammation of the coats of the spleen, are not to be distinguished from those which characterize inflammation of that portion of the peritonæum which lies in the left hypochondrium (see PERITONITIS); that is to say, there is pain in that region, more or less violent according to the degree of the inflammation, which is increased by pressure, and is accompanied by a sense of heat and tension in the part. There is also more or less of symptomatic fever, heat of skin, quickness and hardness of pulse, thirst, &c.; and, if the inflammation be considerable, some difficulty of breathing. The last symptom arises from the pressure of the diaphragm, when descending, in the act of inspiration, upon the inflamed parts. As the use of the spleen in health is unknown, we cannot, of course, look for any symptom characteristic of its disordered function, as in the case of other large viscera; but must infer that it is the seat of inflammation, from the situation of the pain, and from the absence of disturbance, in any considerable degree, in the functions of the neighbouring viscera;

as in that of the kidneys, exhibited in the urine; in that of the stomach, great intestine, &c.

It is probable, however, that the investing membrane of the spleen is liable to some degree of inflammation, which is not always noticed; for it has been remarked by the able pathologist just quoted, that it is not uncommon to find adhesions between the spleen and the neighbouring parts. Those adhesions consist of a white transparent membrane of more or less firmness, and generally connect the broad surface of the spleen more or less closely to the diaphragm. They often also connect the spleen to the great end of the stomach, and a part of the transverse arch of the colon. See Baillie's Morbid Anatomy of some of the most important Parts of the Human Body, chap. xi.; and Morgagni de Sedibus et Caus. Morborum.

The inflammation or suppuration of the substance of the spleen is a very rare occurrence; but such cases have been occasionally observed, and related by authors. (See Lieutaud, Histor. Anatom.-Medica, tom. i.) This writer has even related instances of mortification of the substance of the spleen; but neither Morgagni nor Baillie have observed such cases. The symptoms which have been described, as belonging to inflammation of the substance of the spleen, are, a dull pain, with a sense of fulness, in the left hypochondrium, the pain being increased on pressure, and accompanied by the general disturbance of the system, called fever. The disease, however, is so rare, that sufficient observations have scarcely been made to determine satisfactorily the diagnosis of this malady. In two cases, in which the inflammation of the spleen had advanced to suppuration, which were examined by Dr. Hunter, the patients were unable to define accurately the seat of their pain, which seemed to travel a good deal over the general cavity of the abdomen.

Although the diagnosis be imperfectly established, however, the same practice will be efficacious, which experience has found to be remedial in the inflammation of the peritonæal coat, or of the substance of other viscera, and of the peritonæum lining the abdomen; that is, the early use of blood-letting, and purgatives, with blisters and local bleeding, as circumstances may require; and the steady adoption of the antiphlogistic regimen, as directed in the treatment of other visceral inflammations. (See PERITONITIS, HEPATITIS, &c.) We shall, therefore, proceed to describe the second form of disease peculiar to the spleen.

SPLEEN, Tumid. This disease of the spleen consists of an indolent enlargement of the substance of the viscus, which, at the same time, becomes much harder than natural. It will occasionally be enlarged to five or six times its natural size, and it then forms a tumour very capable of being distinguished in the living body. When examined after death, the natural structure seems to be preserved, except that it is much more compact, the parts being much more closely applied together. When this tumour and induration are the consequence of intermitting fever, the mass is called an *ague-cake*. In general, this state of the spleen is considered as scirrhus; but its structure, as Dr. Baillie remarks, is not similar to scirrhus in other parts of the body. It may, therefore, be doubted whether this is a proper scirrhus affection of the spleen, or whether it is not, in fact, something essentially different.

The symptoms accompanying an enlarged and indurated state of the spleen, in its early stages, are not very manifest or urgent; in fact, the existence of the disease is commonly not suspected, till it has made a considerable progress. It is usually not accompanied by any pain or uneasiness; and will even bear a pretty strong pressure, with-

out any painful sensation. But when the tumid spleen has attained a considerable size, it may be distinctly felt by the hand, and distinguished by its situation and general shape. Its anterior edge may be traced under the margin of the ribs upon the left side, and it is sometimes ascertained by this examination to be notched. Under this state of the disease the patient can only lie upon the left side; but he usually complains of a sense of fulness and weight, rather than of pain, dragging downwards towards the left side, and of some oppression of the stomach after eating. The complexion is always of a dirty, fallow, or leaden hue. The patient is also said to be liable to hæmorrhages of the nose. If the enlargement goes on, it reduces the body to great emaciation, and at length terminates in an incurable dropsy. Dr. Pemberton mentions a tumid spleen, which he saw, which weighed three pounds two ounces. See Baillie, loc. cit. Pemberton on Various Diseases of the Abdom. Viscera, chap. v.

The last-mentioned author conjectures, that the spleen may be thus affected with a *swelling* of its substance, merely from a larger quantity of blood being conveyed to it by the arteries, without these arteries taking on that action which is essential to inflammation. It is evident, indeed, that this enlarged and compact state of the viscus is something entirely different from the ordinary results of inflammation, and is perhaps peculiar to the structure of the spleen alone. It will not unfrequently subside spontaneously, or with the assistance of medicines, to its natural size, and seems to be accelerated in that progress by the use of mercurial friction upon the abdomen, and by the administration of purgatives. The patient should persevere in the mercurial course, till the mouth is slightly affected, and then it should be gradually laid aside. Small doses of calomel, in union with the extract of conium, answer the double intention of allaying the irritation of the stomach, and of promoting absorption; and if there is a considerable degree of tenderness, which is sometimes produced by an enlarged spleen about the articulations of the false ribs with the spine, it may be removed either by leeches or cupping. The diet of the patient should consist of milk, gruel, and a small quantity of animal broth.

With respect to the prognosis, Dr. Pemberton observes, the most favourable symptoms are, a diminution of the uneasy sensations in the left side, and an improvement in the colour of the skin: the most unfavourable are, an increase of the swelling of the left side, and the lower part of the abdomen becoming enlarged: and if this part gives a sensation of fluctuation, the case is almost hopeless. Loc. cit.

SPLEEN, Morbid Changes of the. Among the other morbid conditions of the spleen, to which we have already alluded, may be mentioned, first, an extreme *softness* of the organ, which is not uncommon in middle and more advanced life. In these cases, the substance of the spleen seems to consist of little else than a very soft brownish-red mucus, intermixed with a spongy fibrous texture. This state of the spleen is not marked by any peculiar feelings, so as to make the persons conscious of any disease, and is probably of very little consequence in the general economy of the animal. The spleen, indeed, is said to be occasionally wanting, as a defect in the natural formation, and it has even been cut out, both from men and quadrupeds, without occasioning them to suffer any inconvenience afterwards. Another disease of the spleen is the occurrence of *tubercles* in its substance, very similar to the scrofulous tubercles of the lungs, which are placed at regular distances from each other, and do not run into masses, and seldom or never sup-

purate. *Hydatids*, of the same kind with those found in the liver, are occasionally formed in the spleen; but they are much more common in the former viscus. *Calcareous concretions* have also been seen occasionally in the spleen, but they are very rare. Sometimes the spleen has been ruptured, in consequence of external pressure upon that side of the body where it is situated. This accident can seldom take place, when the spleen is of the common size, because it is well defended by the ribs; but it may readily happen, when the spleen is very large, so that a part of it passes below the margin of the ribs into the cavity of the flank. The only other morbid condition of any importance, which affects the spleen, is an occasional conversion of its coats into a *cartilaginous* substance, which is almost exclusively observed in this viscus. The cartilage is generally found in its convex surface, and rather resembles the cartilages of the ears and nose, than that which is found at the extremities of bones. These varieties of disease are not to be distinguished during life by any peculiar symptoms.

SPLEEN, in Ichthyology. The spleen in fishes is usually situated near the stomach in the left side of the abdomen. Its figure is generally triangular, sometimes oblong. Its colour is always more dusky and obscure than that of the liver. See FISH.

SPLEEN of Birds, in Ornithology. See *Anatomy of BIRDS*.
SPLEEN-Wort, in Botany, &c. See *ASPLENIUM* and *MILT-waste*.

SPLEEN-Wort, Rough. See *LONCHITIS*.

SPLENECTOMIA, the name given to the surgical operation of cutting out the spleen.

SPLENETIC, *σπληνικός*, a person affected with oppilations and obstructions of the spleen.

In splenic people, the spleen is swelled beyond the natural bulk; or it is hardened so, as to shew a scirrous tumour in it.

Splenic people are distinguished by a livid, lead-coloured complexion; and their character is, to be very prone to laughter; which is an expedient nature is supposed to make use of, to evacuate the too redundant humour the spleen is charged withal; whence it is, that the ancients made the spleen the organ of laughter; and hence that popular saying, of a person laughing heartily, that he *vents his spleen*.

SPLENETIC Waters. See *WATER*.

SPLENIA, compresses resembling the spleen in shape.

SPLENIC VESSEL, a large artery and vein of the *spleen*; which see.

SPLENITIS. See *SPLEEN, Inflammation of*.

SPLENIUS, called also *massoides posterior*, in *Anatomy*, a flat, broad, oblong muscle, situated obliquely between the back part of the ear, and the posterior and lower part of the neck.

It is partly single, and partly made up of two portions, one superior, the other inferior. These two portions are closely united backward, making only one plane, but they are divided above.

The two splenii represent a great Roman V, and the splenius, and sterno-mastoideus of the same side, form a figure like a Roman A, or the legs of a pair of compasses, the points of which are in an horizontal plane.

The two splenii serve to support the head in an erect posture, whether in standing or sitting; to moderate the flexion of the head forward, and to bring it back again to its natural posture. They serve alternately to co-operate with either of the sterno-mastoidei for the rotation of the head. The complexi are assistants to the splenii, to keep the head straight in sitting or standing, to hinder it from

inclining forward, and to raise it when inclined. When they act together, they, as well as the splenii, may move the head backward, while the trunk is bent forward, or when we lie upon the belly; this latter motion is commonly called *extenſion*, the other *flexion*. See STERNO-CLEIDOMASTOIDEUS.

SPLENIUS Capitis, a name given by Albinus to a muſcle, called by Winſlow, and others, the *maſtoideus ſuperior*, or upper portion of the ſplenius. Riolanus, and others, call it the *triangularis ſplenii*.

SPLENIUS Colli, a name given by Albinus to the muſcle, called by Winſlow, and others, *maſtoideus poſterior*, or the lower portion of the ſplenius; and by Cowper, the *muſculus inferior ſplenii*.

SPLENOCELE, a ſwelling of the hernial kind, produced by the ſpleen. Although ſuch is the meaning of this word, we believe the diſeaſe expreſſed by it is more imaginary than real. Its poſſibility may well be doubted.

SPLENT, or **SPLINT**, among *Farriers*, a callous, inſenſible excreſcence or griftle, that ſometimes ſticks to a horſe's ſhank-bone, generally on the inſide below the knee. If there be one oppoſite to it on the outſide, it is called a *pegged* or *pinned* ſplint; becauſe it does as it were pierce the bone, and is extremely dangerous. Some call this a *double ſplint*, and others a *thorough ſplint*.

Some horſes are more ſubject to ſplints than others; but young horſes are moſt liable to theſe infirmities, which often wear off, and diſappear of themſelves. Team-horſes are very apt to have them. Few horſes put out ſplints after they are ſeven or eight years old, unleſs they meet with blows or accidents. A ſplint that ariſes in the middle of the ſhank-bone is no ways dangerous; but thoſe that ariſe on the back part of this bone, when they grow large and prefs againſt the back ſinew, always cauſe lameneſs or ſtiſſneſs by rubbing againſt it; the others, except they are ſituated near the joints, ſeldom occaſion lameneſs.

It may be noticed, in reſpect to the cure of ſplints, that the beſt way is not to meddle with them, unleſs they are ſo large as to diſfigure a horſe, or ſo ſituated as to endanger his going lame. Splints in their infancy, and on their firſt appearance, ſhould be well bathed with vinegar or old verjuice; which, by ſtrengthening the fibres, often puts a ſtop to their growth; for moſtly the membrane covering the bone, and not the bone itſelf, is here thickened; and in ſome conſtitutions, purging, and afterwards diuretic drinks, will be a great means to remove the humidity and moiſture about the limbs, which is what often gives riſe to ſuch excreſcences. Various are the remedies preſcribed for this diſorder: the uſual way is to rub the ſplint with a round ſtick, or the handle of a hammer, and then touch it with oil of origanum. Others lay on a pitch plaſter, with a little ſublimatè, or aſenic, to deſtroy the ſubſtance: ſome uſe oil of vitriol, ſome tincture of cantharides; all which methods have at times, it is ſaid, ſucceeded; only they are apt to leave a ſcar, with the loſs of hair. Thoſe applications that are of a more cauſtic nature, often do more hurt than good, eſpecially when the ſplint is grown very hard, as they produce a running for ſeveral months, which often leaves an ugly ſcar. Mild bliſters, often repeated, ſhould be firſt tried as the moſt eligible method, and will generally ſucceed, even beyond expectation; but if they fail, and the ſplint be near the knee or joints, fire and bliſter, in the ſame manner as for the bone ſpavin.

Splints on the back part of the ſhank-bone are difficult to cure, by reaſon of the back ſinews covering them; the beſt way is to bore the ſplint in ſeveral places with an

iron not very hot; and then to fire in the common way, not making the lines too deep, but very cloſe together.

SPLENTS, in *Surgery*, pieces of wood uſed in binding up broken limbs. See FRACTURE and SPLINTS.

The word is alſo ſometimes uſed for the pieces of a fractured bone.

SPLICE, *To*, in *Sea Language*, is to join the two ends of a rope together, or to unite the ends of a rope to any other part of it. There are ſeveral different methods of performing this operation, according to the ſervices on which it is to be employed. The *ſhort ſplice* is made by untwilling the ends of two ropes, or the two ends of one rope, and having placed each of the ſtrands of one oppoſite to, and in the interval between two ſtrands of the other, to draw them cloſe together; and then interweave the ſtrands of the one into the alternate ſtrands of the other, by penetrating the latter with a fid or marline ſpike, parallel to the axis or length of the rope. This ſplice is uſed on the cables, ſlings, block-frops, and in general all ropes which are not deſigned to run through blocks, or where the ſplice is not in danger of being looſened or ſeparated.

The *long ſplice*, being fixed in three places, occupies a greater extent of the rope; but by the diviſion of the joinings, the bulk is alſo divided into different parts of its length. Hence, it is much neater and ſmoother than the ſhort ſplice, and better adapted to run through the channel of a block, &c. for which uſe it is generally calculated.

The *eye-ſplice* being intended to make a fort of eye or circle at the end of a rope, the ſtrands are untwilled, and their extremities thruſt through the three ſtrands in that part of the ſaid rope on which the ſplice is to be formed, and thence paſſing over the ſurface of the ſecond ſtrand, they are again thruſt through the third, which completes the operation.

The *cut-ſplice* is conſtructed in the ſame manner as the eye-ſplice; being no other than the ends of two lines faſtened together, at a ſhort diſtance from each other, the extremities of either being interwoven into the bight of the other, ſo that the line becomes double in the extent of the ſplice. This is chiefly uſed in lead-lines, log-lines, and fiſhing-lines, where the ſhort ſplice would be liable to ſeparation, as being frequently looſened by the water. Falconer.

The *tapered ſplice*, moſtly uſed on cables, is made by unlaying a certain length of each cable, then placing them together, and interplacing the ſtrands, as in the ſhort ſplice, twice each way, and hauled tight each time; then inlay the ſtrands, or ends, ſucceſſively, and reduce them to a ſingle ſtrand, which is again thruſt through, and cut off. The ſplice is then ſerved over with ſpun-yarn, ſomething more than the whole length. *Drawing-ſplice*, uſed on cables, is made by unlaying about three fathoms of the ends; then place them together, and make a ſhort ſplice; then leave about one fathom, and from thence reduce each ſtrand to a long taper, by gradually cutting away as many yarns as neceſſary, and neatly point over the taper; then lay the ends up the cut-lines, and clap in a quarter-ſeizing at each end of the ſplice, an end-ſeizing at the beginning of the pointing, and a ſtop at the ends of the tails. This is the beſt ſplice for cables, as it may be readily taken aſunder. Another good method of making a *cable-ſplice* is to put the ends in twice each way; then to pick out the ſtrands, worm part of them round the cable, and taper away the reſt, which ſhould be marled cloſe down; then clap on a good throat and two end-ſeizings of ratline.

SPLICE, *To*, among *Gardeners*, is to graſt the top of one

tree into the stock of another, by cutting them sloping, and fastening them together.

SPLINTS, in *Ancient Armour*, a defence for the arms, which constituted part of the suit denominated an *Almaine ryvatt*.

SPLINTS, are long pieces of thin wood, or pasteboard, used in *Surgery*, for affording support and steadiness to fractured bones.

SPLINTERS of the *Bone*, in *Fractures*. In cases of fractures, the surgeon is frequently troubled with splinters of the bone in the way, which vellicate and prick the neighbouring parts, and render the proper execution of his office very difficult. If these splinters are loose, and have no connection with the bone, they must be carefully lifted out of the wound; if they hang to the bone in some part by the periosteum, that must be cut off with the scissors; but if they adhere pretty firmly to the neighbouring parts, and do not hinder the reduction of the bone, it is best to replace the bone, and leave them either to loosen, and come out of themselves by the suppuration of the parts, or to grow again, as they sometimes will safely and firmly do, to the rest of the bone. When they adhere pretty firmly to the principal parts of the bone, they should never be extracted by force, but replaced with the greatest exactness; for when this is properly performed, they will frequently unite to the rest of the bone.

When the points of splinters of bones stick so far out, that they are a great hindrance to the reduction of the bone, you are diligently to consider whether you can, by any means, contrive their reunion to the bone, which may be determined, by observing at what distance they are from the large bone, and what quantity of flesh there is intervening: when they cannot be reduced, or reunited to the bone, they must be removed with a pair of strong forceps, or, if they stick very firmly, with a fine saw. If the splinters are buried under the skin, and cannot be got at with hands, it is proper first to try if they can be reduced to their natural situation; and if they cannot, an incision must be made through the skin, that they may be taken out. See **FRACTURE**.

SPLIT, in *Botany*, a name given by some authors to the great *fumaria bulbosa*, or hollow root.

SPLIT, at *Sea*. When a sail is blown to pieces, the seamen say it is split.

SPLIT, when applied to a ship, denotes the state of being stranded and bilged on a rock or shore.

SPLIT *Rock*, in *Geography*, a rocky headland on the W. side of lake Champlain; 56 miles N. of Skenesborough.

SPLITTING, in *Agriculture*, a term employed in the practice of paring land with the plough in some districts. In it the plough always turns upon the left of the first furrow, and the coulter is held close all the way to the lifted slice previously turned over, and which now covers a balk or rib of whole unmoved ground. The same sort of work, in some of the eastern districts of this country, is denominated wrest-balking; but the practice has there a very different intention to that which induces it in the county of Devon and some others.

It is a term which is likewise used in common ploughing to signify the division of the ridges, by making the furrow parts of the old ones the middle parts of the new ones. Thus, by beginning at the furrows, and laying the furrow slices of the different ridges towards each other, by continually turning in that direction, the furrows become the middles and the middles the furrows. It is used in opposition to *gathering*, which has the contrary effect.

It is used too in setting and taking up some sorts of crops

which are set in particular manners, as those of the potatoe kind, when set in the ridge method, as by splitting the ridges with the plough or other tool, the sets are uncovered, and persons are enabled to pick and secure the potatoes, &c.

SPLITTING. To split a thin piece of metal, as an old silver groat, place the metal on the heads of three pins stuck up triangularly, and let a heap of flour of brimstone burn out upon it; then throwing it hard against the floor, the upper part will separate from the lower. Boyle's Works, abr. vol. i. p. 134.

SPLUGEN, in *Geography*, a mountain in the county of Chiavenna; 8 miles N.W. of Chiavenna. Towards the summit of the mountain is an oval plain, about two miles long and one broad, encircled with craggy points: it produces no trees, but yields rich pasture: near the summit are rude blocks of a whitish kind of marble. Above this oval plain is the source of the Lira, which falls into the lake of Chiavenna. On the other side of the highest ridge the torrents flow towards the Rhine. The passage over mount Splugen is principally used for the transport of merchandize to and from Coire; it is kept open even in winter, though not without great difficulty: in that season the merchandize is chiefly transported on sledges, of which forty or fifty pass in a day.—Also, a town of the Grisons, situated upon the rise of a hill, at the bottom of a rugged chain of Alps, and principal place of a jurisdiction, in the Rheinwald; 16 miles N.W. of Chiavenna. Two high roads meet at Splugen; one from Chiavenna, and the other leading over the Bernard into Bellinzone. From Splugen to Arder the road continues by the side of the Hynder Rhine, through a mountainous region, which presents at every step the most awful magnificence of scenery.

SPODDEN, a river of England, which runs into the Roch, at Rochdale, in Lancashire.

SPODIUM, in *Pharmacy*, a kind of absorbent calx, or ashes, esteemed drying, and by some held to have the same virtues with coral.

The spodium of the ancient Greeks was a greyish kind of recrement, found in form of ashes, on the hearths of furnaces in which brass was made; and called by them *σποδιον*, which literally signifies *ashes*.

Spodium is a metalline powder, nearly akin, both in origin and use, to tutia and pompholyx; only it is heavier than either.

The spodium of the Arabian physicians, as Avicenna and others, was made of the burnt roots of rushes and reeds. Some moderns also make a spodium of ivory burnt and calcined to a blackness. This is sometimes counterfeited by burning bullocks' or dogs' bones; but these are of no value.

The anti-spodium, which the ancients substituted for their spodium, was made of myrtle-leaves, galls, and some other ingredients calcined.

SPODUMENE, in *Mineralogy*, *Triphane*, *Haiü*, a mineral which bears some resemblance to adularia, but differs from it in the structure, which is foliated, with a threefold cleavage. It divides into prisms with rhomboidal bases, having alternate angles of eighty and one hundred degrees. It is translucent and frangible, but somewhat harder than glass. The colour of spodumene is a greenish-white or grey, and sometimes oil-green. The specific gravity is from 3.192 to 3.218. It occurs, both massive and disseminated, at Uton, in Sudermanland, Sweden, at which place it has only been found at present. Before the blowpipe it separates into small gold-coloured laminæ, which melt by a continuation of the heat into a greenish-white glass.

The constituent parts of this mineral are given by Vauquelin as under.

Silex	-	56	to	64
Alumine	-	24	to	24.4
Lime	-	5	to	3
Potash	-	-		5
Oxyd of iron	-	5	to	2

SPOHREN, in *Geography*, a town of Saxony, in the circle of Leipzig; 2 miles S. of Zorbig.

SPOIL-BANK, a term expressing any heap of spare earth or stuff which remains, or is laid by in the cutting of a canal.

SPOILS, SPOLIA, whatever is taken from an enemy in war. See BOOTY.

Towns and lands taken from the enemy are usually called "conquests;" and allmoveable things constitute the "booty." This booty naturally belongs to the sovereign making war, no less than the conquests; for he alone has such claims against the enemy as warrant him to seize on his goods, and appropriate them to himself. His soldiers, and even the auxiliaries, are only instruments in his hand for asserting his right. He maintains and forms them. Whatever they do is in his name, and for him. Thus there is no difficulty even with regard to the auxiliaries; if they are not associates in the war, it is not made for them, they have no more right to the booty than the conquests. But the sovereign may grant the troops what share of the booty he pleases. At present, most nations allow them whatever they can make on certain occasions, when the general allows of plundering what they find on enemies fallen in the field of battle, the pillage of a camp which has been forced, and sometimes that of a town taken by assault. The soldier in several services has also the property of what he can take from the enemy's troops when he is on a party, or in a detachment, excepting artillery, military stores, magazines, and convoys of provision or forage, which are applied to the wants and use of the army. This custom being once admitted in an army, it would be injustice to exclude auxiliaries from the right allowed to the national troops. The Roman soldier was obliged to bring in all the booty he had taken to the public stock. This the general caused to be sold, and after distributing a part among the soldiers, according to rank, the rest was assigned to the public treasury.

Instead of the pillage of the country and defenceless places, a custom has been substituted more humane, and more advantageous to the sovereign making war; *viz.* that of contributions. Whoever carries on a just war, has a right of making the enemy's country contribute to the support of the army, and towards defraying all the charges of the war. Thus he obtains a part of what is due to him, and the subjects of the enemy, on submitting to this imposition, are secured from pillage, and the country is preserved. But a general who would not sully his reputation, is to moderate his contributions, and proportion them to those on whom they are imposed. An excess in this point is not without the reproach of cruelty and inhumanity: if it shews less ferocity than ravage and destruction, it glares with avarice. If for weakening an unjust enemy, or for punishing him, it be lawful to carry off his goods, which is allowed to be the case, the reasons that justify the former act, may also be pleaded in vindication of destroying what cannot conveniently be carried off. Thus a country is ravaged, the provisions or forage destroyed, that the enemy may not find a subsistence there. When his ships cannot be taken or brought off, endeavours are used to sink them; all this tends to put

an end to the war. But these means are to be used only with moderation, and according to the exigency. To tear up vines, or cut down fruit-trees, is accounted illegal and savage, except inflicted to punish some crime committed by the enemy against the laws of war. This is to desolate a country for many years, and what no safety can require. Such a conduct is not dictated by prudence, but by hatred and fury.

However, on certain occasions, matters are carried still farther; a country is totally ravaged, towns and villages are sacked, set on fire, and the inhabitants put to the sword. Dreadful extremity, even when forced to it! Savage and monstrous excesses, when committed without necessity! However, they are authorized by two reasons. 1. The necessity of chastising an unjust and barbarous nation, for checking its brutality, and preserving one's self from its depredations. 2. A country is ravaged, and rendered uninhabitable, for making a barrier, in order to cover a frontier against an enemy, who cannot be stopped in any other way. A hard resource indeed! says Vattel; but may it not be used against an enemy, when with the same views and purposes a sovereign lays waste his own provinces? But for whatever cause a country be ravaged, we ought to spare those edifices which do honour to human society, and do not contribute to the enemy's power; such as temples, tombs, public buildings, and all works of a remarkable beauty. What advantage is obtained by destroying them? He who acts thus declares himself an enemy to mankind, wantonly depriving them of these monuments of art and models of taste. This is the light in which Belisarius represented it to Tottila, king of the Goths. We still detest those barbarians for destroying so many wonders of art, when they over-ran the Roman empire. Though the resentment of the great Gustavus against Maximilian, duke of Bavaria, was entirely just, he rejected with indignation the advice of those who were for demolishing the stately palace of Munich; and took particular care to preserve that admirable structure.

However, if for carrying on the operations of a war, or the works of a siege, there be a necessity for destroying buildings of this nature; there is doubtless a right of so doing. The sovereign of the country, or his general, makes no scruple when reduced to it by necessity and maxims of war. The governor of a town evidently threatened with a siege, sets fire to the suburbs, that they may not be of use to the besiegers for lodging themselves in them. Nobody offers to blame him who lays waste gardens, vineyards, or orchards, for pitching a camp or throwing up an intrenchment; if some fine edifice be destroyed thereby, it is an accident, an unhappy consequence of the war, and the general is not at all blameable; unless, without the least inconvenience, he might have made his dispositions elsewhere.

In bombarding towns, it is difficult to spare the fine edifices; at present it is only the ramparts and defences of a place which are usually battered. To destroy a place with bombs and red-hot balls, is an extremity never practised without great reasons. But it is warranted by the laws of war, when an army has no other resource for reducing a place on which may depend the success of the war, or when it greatly annoys us. It is also sometimes practised when there is no other expedient of facing an enemy to make war with humanity, or for punishing him for some other illegal outrage. But it is with reluctance that good princes make use of their rigorous rights, and never but in extremities.

Fortresses, ramparts, and every kind of fortification, relate solely to war, and as in a just war nothing is more natu-

ral than to raze those which we do not intend to keep, so nothing is more lawful. The enemy is thereby weakened, and no innocent person is involved in the damages.

Although to ravage or burn a country is not in general against the laws of war, yet if an enemy of a much superior strength treats a town or province in this manner, which he might easily keep for procuring to himself an equitable and advantageous peace, he is generally accused of making war like a barbarian. Thus the voluntary destruction of public monuments, of temples, tombs, statues, paintings, &c. is absolutely condemned, even by the voluntary law of nations, as always useless to the lawful end of war. The pillage and destruction of towns, the desolation of the country, ravages, burnings, are not less odious and detested on all occasions, when evidently practised without necessity, or without urgent reasons. But as all these enormities may be excused under pretence of punishment, which the enemy deserves, Vattel adds, that by the neutral and voluntary law of nations, only enormous offences against it are to be punished in this manner: and when rigour is not of an absolute necessity, it is always beautiful to listen to the voice of humanity and clemency. Cicero condemns the destruction of Coriath for its insults towards the Roman ambassadors; because Rome was able to assert the dignity of its ministers, without carrying its revenge to such extreme rigour. Vattel's Law of Nations, b. iii. ch. 9.

SPOKEN-CHAIN, in *Rural Economy*, signifies provincially a chain of great strength, and sufficiently long for fixing upon the spoke of the wheel of a waggon, when the team is set fast in a slough, to draw it out by, &c.

SPOKES, the bars of a wheel that pass from the nave to the felly.

SPOKE-SHAVE, in *Block-making*, a kind of plane to smooth and finish the shells, which is a piece of steel, four or more inches long, and one and a half broad; sharp at one edge as a knife, and a quarter of an inch thick at the back: at each end are left about two inches of narrow steel, bent up as pegs, by which it is regulated and secured in a piece of wood ten inches long, and narrowed at each end, for handles.

SPOLETO, in *Geography*, capital of Umbria, or the duchy of Spoleto, the see of a bishop, immediately under the pope. It became a Roman colony A. U. C. 512; and 22 years afterwards, withstood the forces of Hannibal, after the battle near the Thrasymene lake. It was the residence of some of the Gothic kings, and under the government of Longinus, exarch of Ravenna, was made the capital of Umbria, with the title of duchy. It was very ill-treated by Frederic Barbarossa, for siding with pope Alexander III.; but the inhabitants of Perugia ruined it entirely. It contains 22 churches, 21 convents, and 17 hermitages. Here are several ruins of Roman antiquities, the chief of which are a triumphal arch, an aqueduct, and an amphitheatre. The cathedral is built almost entirely of marble, and contains some good pictures; 90 miles S. of Florence. N. lat. 42° 45'. E. long. 12° 48'.

SPOLETO, *Duchy of*, a province of the Popedom, bounded on the north by the Perugian and the duchy of Urbino, on the east by the marquisate of Ancona, on the south by Abruzzo Ultra and the Sabina, and on the west by the Orvietan and Patrimonio, about 40 miles in length, and nearly as much in breadth. It was anciently called *Umbria*, and received the name of Spoleto in the time of the Lombards, being erected into a duchy under duke Faroald. On the extinction of the Longobardian monarchy, it fell to the dominion of the Franks, still retaining its former

constitution, and afterwards was annexed to the papal territories. In 1798 this duchy was over-run by the French.

SPOLIARIUM, among the ancient *Romans*, the third part of the bath, used for undressing and dressing in.

Spoliarium was likewise a part of the gladiatorial schools, where their clothes and ornaments were laid, and where the wounded and killed were carried.

SPOLIATION, in *Law*, is an injury done by one clerk or incumbent to another, in taking the fruits of his benefice without any right to them, but under a pretended title. It is remedied by a decree to account for the profits so taken. This injury, when the *jus patronatus*, or right of advowson, does not come in debate, is cognizable in the spiritual court; as if a patron first presents A. to a benefice, who is instituted and inducted to it; and then, upon pretence of a vacancy, the same patron presents B. to the same living; and he also obtains institution and induction. Now, if A. disputes the fact of the vacancy, then that clerk who is kept out of the profits of the living, whoever he be, may sue the other in the spiritual court for spoliation, in taking the profits of his benefice. And it shall there be tried, whether the living were, or were not vacant; upon which the validity of the second clerk's pretensions must depend. But if the right of patronage comes at all into dispute, as if one patron presented A., and another patron presented B., there the ecclesiastical court hath no cognizance, provided the tithes sued for amount to a fourth part of the value of the living, but may be prohibited at the instance of the patron, by the king's writ of *indicavit*. So also if a clerk, without any colour of title, ejects another from his parsonage, this injury must be redressed in the temporal courts: for it depends upon no question determinable by the spiritual law (as plurality of benefices or no plurality, vacancy or no vacancy), but is merely a civil injury. Blackst. Comm. b. iii.

SPOLTORA, in *Geography*, a town of Naples, in Abruzzo Ultra; 12 miles S.E. of Teramo.

SPONDAULA, *σπονδαυλη*, formed from *σπονδη*, *libation*, and *αυλος*, *flute*, in *Antiquity*, a player on the flute, or other wind-instrument of that kind; who, during the offering of sacrifice, performed some suitable air in the priest's ear, to prevent his hearing any thing that might distract him, or lessen his attention.

SPONDE, HENRY DE, in *Biography*, a French prelate and ecclesiastical historian, was born in 1568. His father was secretary to Joan, queen of Navarre, and, being a Calvinist, educated his son in the same persuasion. He displayed, at a very early age, a great facility in learning languages, one of which was the native tongue of Scotland, which he acquired in a journey to that kingdom in the suite of the French ambassador. Upon his return, he studied the civil and canon law, and was made master of requests to the king of Navarre. In 1595 he abjured Protestantism, and in the following year declared his new opinions in a work, "De Cœmeteriis Sacris." In the year 1600, he accompanied cardinal de Sourdis to Rome, and some years after he was ordained priest. He then began to labour on his great work, *viz.* the "Abridgment of the Annals of Cardinal Baronius," to which has been added a "Continuation," brought down to 1640. In 1626 he was nominated by Louis XIII. to the bishopric of Pamiers, which he accepted only through the command of pope Urban VIII. He published "Ordinances Synodales," which were intended to assist in the conversion of his former associates. He also founded an ecclesiastical congregation, some seminaries and religious houses, and distinguished himself by all the

the episcopal virtues. He died at Touloufe in 1643, at the age of 78. Besides the works mentioned above, he published "Sacred Annals of the Old Testament to the Time of Jesus Christ," which are, properly speaking, an abridgment of Tormiel's Annals. His elder brother was author of "Commentaries on Homer;" "An Account of the Motives which induced him to unite himself with the Catholic Church;" and "An Answer to Beza's Treatise on the Marks of the Church." He died in the year 1595.

SPONDEE, **SPONDÆUS**, in the *Greek and Latin Prosody*, a foot of verse, consisting of two long syllables; as *vertunt, divos, campos*.

The spondee is a grave measure: all Greek and Latin hexameters regularly end with a spondee.

There are also *spondaic verses*; that is, verses composed wholly of spondees, or, at least, that end with two spondees; as,

"Constitit, atque oculis Phrygia agmina circumspexit."

SPONDIAS, in *Botany*, a name borrowed from the ancient Greeks, whose *σπονδιας*, or *σποδιας*, was a kind of wild plum, very distinct, most assuredly, from the present Indian genus, though there may be some similarity in their fruits.—Linn. Gen. 229. Schreb. 308. Willd. Sp. Pl. v. 2. 750. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 3. 108. Juss. 372. Lamarck Illustr. t. 384. Gært. t. 103. (Moubin; Plum. Gen. 44. t. 22.)—Class and order, *Decandria Pentagynia*. Nat. Ord. uncertain, Linn. *Terebintaceæ*? Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, somewhat bell-shaped, small, five-cleft, coloured, deciduous. *Cor.* Petals five, oblong, flat, spreading. *Stam.* Filaments ten, awl-shaped, erect, shorter than the corolla, the alternate ones longer; anthers oblong. *Pist.* Germen ovate; styles five, short, distant, erect; stigmas obtuse. *Peric.* Drupa large, oblong, marked with five scars from the fall of the styles. *Seed.* Nut ovate, woody, fibrous, with five imperfect angles, and five cells.

Obf. Jussieu remarks, that the stamens are inserted into a glandular disk; or, in Linnæan language, receptacle of the flower; probably a nectary.

Eff. Ch. Calyx five-toothed. Petals five. Drupa superior, with a nut of five cells.

1. *S. Mombin*. Spanish Plum. Linn. Syst. Nat. ed. 10. v. 2. 1036. Syst. Veg. ed. 14. 428. Willd. n. 1. (*S. purpurea*; Linn. Sp. Pl. 613. *S. Myrobalanus*; Jacq. Amer. 139. t. 88. S. n. 1; Browne Jam. 228. *Myrobalanus minor*, folio fraxini alato, fructu purpureo, officulo magno fibroso; Sloane Jam. v. 2. 126. t. 219. f. 3—5.) Common footstalk compressed. Clusters much shorter than the leaves.—Observed by Jacquin to be wild in the territory of Carthage, South America, from whence it has been brought into the West Indian islands, in some of which, particularly Hispaniola and Jamaica, it abounds, being known by the name of the Spanish Plum-tree. The tree is various in height, of no regularity of growth, sometimes as tall as thirty feet, with a thick bark, and white brittle wood. Leaves about the ends of the branches, alternate, stalked, deciduous, pinnate, four or five inches long, of about ten pair of elliptical thinning, partly serrated, leaflets, an inch long, with an odd one of the same size. Flowers small, red, in short clusters, appearing before the leaves. Fruit ovate, purple, above an inch long, acid, with a singular but agreeable aromatic flavour, for which it is much esteemed.

2. *S. Myrobalanus*. Yellow Hog Plum. Linn. Syst. Nat. ed. 10. v. 2. 1036. Willd. n. 2. Ait. n. 1. (*S.*

lutea; Linn. Sp. Pl. 613. *S. Mombin*; Jacq. Amer. 138. S. n. 2 and 3; Browne Jam. 229. *Myrobalanus folio fraxini alato, fructu luteo, officulo magno fibroso*; Sloane Jam. v. 2. 125. t. 219. f. 1, 2. *Prunus americana*; Merian Surin. t. 13.)—Common footstalk round. Leaflets pointed, four or five pair. Clusters compound, about as long as the leaves.—Native of South America; cultivated in the West Indies. Miller had it alive at Chelsea in 1739. This is described as a tree resembling a common Walnut-tree in size and appearance, while the ample clusters of pale yellowish flowers are much like Elder, except in having no smell. The leaves are twice the size of the foregoing, with pointed, less serrated, leaflets. Fruit yellow, two inches long, in large clusters, its pulp fragrant, sweet, and agreeable, but the great size and fibrous nature of the stones render it not commodiously eatable. Hogs are fattened with these plums in Jamaica. We cannot but observe that Linnæus has changed his own original names of these two species, much for the worse; and those he has given are the more unfortunate, as they are directly contrary to what Jacquin had previously adopted.

3. *S. Mangifera*. East Indian Spondias. Willd. n. 3. (*S. amara*; Lamarck Dict. v. 4. 261. *Mangifera pinnata*; Linn. Suppl. 156. Retz. Obs. fasc. 5. 4. *Ambalâm*; Rheede Hort. Malab. v. 1. 91. t. 50, not 51.)—Common footstalk round. Leaflets entire, pointed, about three pair. Clusters repeatedly compound.—Native of the East Indies, flowering in January and July, and bearing two crops of fruit. This is difficult to distinguish by a specific character from the last, though widely different in many respects. That they are one genus, there can be no doubt. The trunk is a foot in diameter. Leaves of three pair, besides an odd one, of elliptical, pointed, entire, smooth, pliant leaflets, each four or five inches long, with one rib, and many parallel transverse veins. Rheede says they are agreeably acid. Clusters hardly so long as the leaves, thrice compound; their principal branches alternate, widely divaricated, smooth, purplish; flower-stalks crowded, bracteated, very short, but much elongated and spreading when in fruit. Flowers small and pale, sometimes six-cleft. Fruit oval, of a yellowish-green, an inch and a half long, eatable and agreeably fragrant. The *Cat-Ambalâm*, Rheede p. 93, seems to be the wild state of the same tree.

4. *S. dulcis*. Otaheitè Apple. Forst. Prod. 34. Pl. Esc. 33. Willd. n. 4. Ait. n. 2. (*S. cytherea*; Sonnerat Ind. Or. v. 2. 222. t. 123. Lamarck Dict. v. 4. 260. Jacq. Hort. Schoenbr. v. 3. 12. t. 272.)—Common footstalk round. Leaflets serrated, about six pair. Clusters repeatedly compound, spreading.—Native of Otaheitè, from whence it has been transported to the Mauritius, where also the last-described species is cultivated, as appears by specimens from Commerçon marked *Evia Amra*; for he distinguished the two. The present is a large erect tree, with brittle wood. Its leaflets are serrated, twice as numerous, and not half the size of the last. Flowers small, whitish. Fruit oval, orange-coloured, twice as big as the last, aromatic and eatable, resembling an apple in flavour, and by some voyagers much commended. Forster compares its taste to a pine-apple, and praises its salubrity. Sonnerat says it is like a rennet apple, but not so good; at least in the Mauritius.—This fruit has ripened in the stoves at Schoenbrun.

SPONDIAS, in *Gardening*, contains plants of the exotic tree kind, of which the species cultivated is the purple hog-plum, or Spanish plum (*S. mombin*).

This plant is cultivated in its native state by many for the sake of the fruit, which is pretty pleasant. And there

is a variety of this sort of fruit called the leather-coat, from the appearance of its skin.

Method of Culture.—It is increased by sowing the stones of the fruit in pots filled with light mould, plunging them in the bark-bed of the stove ; and by planting, cuttings, or putting down layers, and managing them in the same way : the plants may be taken off and removed into separate pots when they have stricken good roots, being re-plunged in the bark-bed.

They require afterwards to be kept constantly in the stove, and to have the same management as other woody exotics of the same nature.

They afford variety in stove collections among other similar plants.

SPONDYLI, Σπονδυλοι, in *Antiquity*, pellets of brass used in giving sentence, before the *κυμαροι*, or *beans*, came into use.

SPONDYLOLITHOS, a name given by authors to a stone found in the country of Tyrol, and elsewhere, resembling the vertebræ of an animal. It is in reality no other than the vertebræ of some sea-fish petrified, as is common with us.

SPONDYLUS, σπονδυλος, a term anciently used for a vertebra of the spina dorsii.

SPONDYLUS, in *Natural History*, a genus of the class and order Vermes Testacea, of which the generic character is : Animal a tethys ; shell hard, solid, with unequal valves ; one of the valves is convex, the other rather flat ; hinge with two recurved teeth, separated by a small hollow. There are four

Species.

CÆDAROPUS. The shell of this species is slightly eared and spinous. It inhabits the Mediterranean, the Indian, and other seas, and is found in almost infinite varieties, as to size, thickness, and colours ; sometimes entirely purple, orange, white, or bloom-colour ; sometimes marked with various streaks, spots, dots, or bands.

REGIUS. Shell without ears, and spinous. There are four varieties. One inhabits India, and one is found near Malta, which is very rare. The shell is sub-globular ; within it is white ; without purplish, scarlet, flame-coloured, orange or white ; the spines are usually two inches long ; it is sometimes cylindrical, with a crenate margin.

PLICATUS. Shell without ears or spines, plaited. It is found in India, some parts of America, and in the Mediterranean. The shell is white, with yellowish, reddish, brownish, or violet lines and veins.

CITREUS. Shell oblong, plaited, spinous. The shell is imbricate, about two inches long, and nearly as broad ; it is of a citron-colour, or red, with an orange inner margin.

SPONGE. See SPONGIA and SPUNGE.

SPONGE-Tree, in *Botany*. See MIMOSA.

SPONGIA, the *Spunge*, in *Natural History*, a genus of the class and order Vermes Zoophytes. The generic character is as follows : Animal fixed, flexile, torpid, of various forms, composed either of reticulated fibres, or masses of small spines, interwoven together, and clothed with a gelatinous flesh, full of small mouths on its surface, by which it absorbs and rejects water. There are about fifty species, of which nine or ten belong to this country.

The sponges consist of a ramified mass of capillary tubes, that were formerly supposed to be the production of a species of worms, which are often found within these cavities ; an idea, however, which is now generally exploded. Others have imagined them to be only vegetable productions : that they are, however, possessed of animality, appears evi-

dent, from the circumstance of their pores alternately contracting and dilating, and from their even shrinking, in some degree, from the touch, when examined in their native situations. Their structure enables them, it is thought, to absorb nourishment from the surrounding fluid. Sponges are the most torpid of all the zoophytes. The individuals differ very much from each other in form and structure. Some of them, as the *S. officinalis*, or common sponge, are of no determinate figure, but others are cup-shaped, tubular, &c. ; irregularly formed, porous, rough, lobed, and woolly.

Species.

VENTILABRUM. Fan-shaped, regular, soft, with reticulate woody veins, covered with pores like those of a honey-comb. It is found in the Norwegian and American seas ; about six inches high, and five broad : it exactly resembles a small gorgonia flabellum in its shape and ramifications, except that the pores are angular, and the substance is spongy.

FLABELLIFORMIS. Fan-shaped, orbicular, cartilaginous, with square articulate fibres. This species inhabits the Indian and Red seas. It is from six to eight inches in height, and four or five broad, and resembles the ventilabrum.

INFUNDIBULIFORMIS. This is funnel-formed, flexile, with the surface more or less roughened. It inhabits the Mediterranean and Indian seas, adhering to rocks, and is from six to eighteen inches in diameter ; in colour it is a pale brown, and less tenacious than common sponge.

FISTULARIS. Tubular, simple, brittle, and growing gradually larger. It inhabits the Indian ocean, is from three to four feet long : when dry it is blackish fulvous.

ACULEATA. Tubular, branched, tough, the tubes erect, proceeding from one side of the stem, and tapering. It inhabits the Indian ocean ; is from four to six inches high, of a deep orange-yellow colour, and hollow through the whole inside.

* **CORONATA**. Minute, consisting of a single tube, and crowned at the tip with a ray of spines. This is found in our own country, on the Sussex coast : its colour is of a pale yellow ; the rays that compose the crown are of a bright pearl yellow, hollow, and open at the top ; and when seen through a magnifier, it appears covered with little rising points.

CILIATA. Simple, tubular, conic, flexuous, tapering upwards, and fringed at the tip. It inhabits the Greenland seas, adhering to the larger ulvæ ; is about eight inches long ; white, silky, downy on the outside, and rarely found double.

CANCELLATA. Tubular, porous, with cancellate fibres. It inhabits the ocean ; is ferruginous, elastic, with a prickly surface ; the tube as thick as the finger, with a few elastic perforations.

RUBRA. Tough, simple, carious, dull red, roundish, depressed with elevated tubercles and equal pores. Inhabits the Red sea, fixed to stones.

NIGRA. Tough, globular, equal, inflated, black without, cinereous within. It is found on rocks in the Red sea.

OFFICINALIS. This species is irregularly formed, porous, tough, lobed, woolly. It is elastic, and very full of holes ; it grows into irregular lobes of a woolly consistence, and generally adheres, by a very broad base, to the rocks. It is chiefly found about the islands in the Mediterranean, where it forms a considerable article of commerce. A variety of small marine animals pierce and gnaw into its irregular winding cavities. These appear on the outside, by large holes raised higher than the rest. When it is cut perpendicularly,

SPONGIA.

ularly, the interior parts are seen to consist of small tubes, which are divided into branches as they appear on the surface. These tubes, which are composed of reticulated fibres, extend themselves every way, by this means increasing the surface of the sponge, and ending at the outside in an infinite number of small circular holes, which are the proper mouths of the animal. Each of these holes is surrounded by a few erect pointed fibres, that appear as if woven in the form of little spines. The tubes, with their ramifications, in the living state of the sponge, are clothed with a gelatinous substance, properly called the flesh of the animal. When the sponge is first taken, it has a strong fishy smell, and the fishermen take great care in making it perfectly clean, in order to prevent its growing putrid. See SPUNGE.

* **OCULATA.** Porous, soft, and very much branched, the branches a little compressed, erect, and often uniting together. This, as the asterisk indicates, inhabits the British seas. It is from five to ten inches high, of a pale yellow colour; the branches end obtusely.

MURICATA. Porous, much branched, angular, tough, the pores are cylindrical, fubulate, prominent, equal, many-cleft, and hispid. It inhabits Guinea, on rocks; it is grey, corky; the branches are surrounded on all sides with small, obtuse, shaggy tufts; the stem is as thick as a man's finger; the branches are about the thickness of a quill.

NODOSA. Porous, slightly branched, irregularly formed, rough and very tough, with knotty perforations on the branches. It is found on rocks in the American ocean; it is of a reddish-grey, or whitish, and about the size of the finger.

* **TOMENTOSA.** Porous, irregularly formed, brittle, soft, downy, interwoven with the minutest spines. This species inhabits the British, African, and Indian coasts, adhering to marine substances; when fresh it is of a bright orange colour, and full of gelatinous flesh; when dry, it is whitish, and very light; and if broken, it resembles the crumb, or soft part of bread. It appears to be composed of a number of minute spines, and upon handling, it stings and raises blisters like cow-itch.

BACILLARIS. Irregularly formed, caulescent, erect, with porous branches. It is found in the Norwegian seas; is about eighteen inches high, and of the thickness of the finger. It is round, of the consistence of common sponge, but somewhat more compact, with very numerous pores, appearing as if perforated with a fine needle.

* **DICHOTOMA.** This species is dichotomous, with erect, cylindrical, elastic, woolly branches, proceeding from one side of the stem. It inhabits European and Indian seas: it is from five to six inches high; in colour it is of a pale yellow, and full of minute pores.

* **STUPOSA.** This species has round, soft, downy branches. It is found on the Sussex coast; is three inches high, and of a pale yellow.

* **CRISTATA.** Flat, erect, soft, with rows of small pores, a little projecting along the top. This is found on the British shores, adhering to rocks; generally about two inches high and three long; it is of a yellowish colour, and growing in the shape of a cock's-comb.

* **PALMATA.** This species is, as its name imports, palmate, with finger-like divisions round the surface; the pores are a little prominent, and irregularly disposed. It inhabits the Sussex coast; it is of a reddish colour, inclining to yellow, with a soft woolly substance, like *S. oculata*.

PROLIFERA. Flat, with numerous palmate branches, ending in finger-like divisions. It is found in the North American seas; grows in large bunches, is about six inches

high, very porous, reticulate within, and full of minute spines on the outside.

* **BOTRYCIDES.** This is a very tender species, is branched, and covered with bunches of ovate tubercles, open at the top. It inhabits the British coasts; is of a bright shining white colour; the bunches are made up of oblong, oval tubercles, like grapes, open at the end. The surface, when seen through magnifiers of considerable power, seems covered with masses of three-rayed spinous stars.

* **PANICEA.** Irregularly formed, whitish, soft, very tender, and full of minute pores. It inhabits the seas between this country and Holland, intermixed with fuci, and other marine productions; and is thought, from the similarity which it bears to the *S. tomentosa*, to be a variety of that species.

FULVA. This species is irregularly formed, but slightly branched, fulvous, and it is very rigid. It inhabits the American ocean; is gelatinous, and brown between the fibres.

TABULARIA. Compressed, sessile, a little rigid and yellowish, with small longitudinal tubes. This also is an American species, generally seated on rocks, frequently blackish within.

FIBRILLOSA. This species is irregularly shaped, a little flattened and tender, with divergent, crowded, interwoven fibres, and scattered toothed pores. It inhabits the Indian ocean, is grey, soft, fan-shaped, or divided, or caulescent.

FASCICULATA. This is rigid, sub-globular, composed of fibrous, prismatic, branched, fastigate bunches. This is found in the Mediterranean sea; is pale, fulvous, or yellowish-grey.

BASTA. A little rigid, blackish, in undulate divisions, with a round stem. It is an inhabitant of the Indian ocean, and found adhering to stones. It is as thick as the finger.

LICHENOIDES. This is irregularly shaped, with soft, branching, scattered, and somewhat connected fibres. It inhabits the Indian ocean, and resembles a shrubby lichen.

PAPILLARIS. Cruetaceous, tender, soft, with perforated papillæ. It inhabits the American ocean, as does the next; it is of a pale grey, and gelatinous.

CAVERNOSA. Irregularly formed, sessile, very tough, cavernous, hence its name, with numerous, prominent papillæ on the surface. It is about the size of a man's hand: yellowish-white, sometimes fulvous within.

SINUOSA. Cruetaceous, tender, tough, with a thickly porous surface. This is found in the Indian ocean, incrusting other bodies; it is of a yellowish-grey colour.

FRONDOSA. Grey, leafy, jagged, tough, sub-reticulate, and separated into divisions on one side. This is an Indian species.

AGARICINA. Compressed, lobed, sessile, downy, reticulate and muricate with stiff hairs on the outside. It is found in the Indian ocean, and is of a yellowish-brown.

TUPNA. Branched, soft, with ascending branches, every where muricate with stiff hairs. It inhabits the Mediterranean, and is of a woolly kind of substance.

MEMBRANOSA. Irregularly formed, slightly branched, cellular, muricate outwardly, purplish-black. This is found in the Indian ocean.

COMPRESSA. Simple, compressed, conic, with a longitudinal cleft or aperture internally. It inhabits the Greenland seas, is an inch long; erect and tawny.

PORCILLUM. Cylindrical, pedicellate, with a perforated top. It inhabits the North seas; is not more than a quarter of an inch long; whitish, and said to resemble a glass tumbler.

COALITA. This is very much branched, soft, tender, yellow; the branches are a little compressed. It inhabits the North seas; as do the three following.

PLANA. Expanded, crustaceous, fan-shaped.

CRUCIATA. White, compressed, with pinnatifid, obtuse, muriate, woolly branches.

OSSFIFORMIS. White, slightly branched, with a thickened pitted top.

MACIDA. White, crustaceous, projecting into spines.

FIGIFORMIS. This is porous, rigid, turbinate, with a perforated tip. It inhabits the Barbary coast.

* **LACUSTRIS.** Creeping, brittle, with erect, round, obtuse branches. It is found at the bottom of lakes in England and Sweden, covered with scattered pores, in which are sometimes found, during autumn, small blueish shining globules.

* **PULVIATILIS.** Green, erect, fragile, of many irregular branches. It inhabits the fresh waters of this country, Prussia, and other parts of Europe. It is of a dull green, with hardly the appearance of animal life, of a fishy smell, and with the pores full of green, gelatinous granulations; it very much resembles the last.

FRIABILIS. Cinereous, friable, sessile, irregularly shaped, and slightly branched. Found in the lakes of Germany, and is the food of fish.

CANADIUM. This is known by its dichotomous, round, incurved branches. It is found in old aqueducts, and has been thought not to belong to this genus.

SPONGIOLI, a word used by some authors to express the small button mushrooms, which are gathered before they expand or open their heads.

SPONGIOSUM, in *Anatomy*, spongy; a name given to a small separate bone of the nose, and to a process of the ethmoid bone. In the older writers, the ethmoid bone altogether has been called os spongiosum, from its complicated apparatus of bony plates, and numerous perforations. See **CRANIUM.**

SPONGY CHEESE, in *Rural Economy*, such as is soft and full of eyes, from neglect and want of attention in making. The remedies are, careful breaking, powerful squeezing, good skewing, and heavy pressing. See **CHEESE** and **DAIRYING.**

SPONHEIM, in *Geography*, a town of France, in the department of the Rhine and Moselle, late capital of a county, to which it gives name; 27 miles W. of Mentz. N. lat. 49° 54'. E. long. 7° 40'.

SPONHEIM, or *Spanheim*, late a county of Germany, in the circle of the Upper Rhine, situated between the Rhine and the Moselle, formerly governed by particular counts, at present divided between the elector palatine, the duke of Deux Ponts, and the margrave of Baden. The matricular assessment of the whole for a Roman month was 290 florins, and the tax to the imperial chamber 108 rix-dollars 20 kruetzers. The soil is in general mountainous, but fertile. Game and fish are plentiful, and the mutton esteemed excellent. The hills towards the Moselle and Nahe are covered with vineyards. Here are mines of copper, lead, iron, &c. and some medicinal springs. The principal towns were Cruetznach, Sponheim, and Traarbach; all now annexed to France.

SPONSIO, in *Political Economy*, denotes an agreement relating to affairs of state, made by a public person, who goes beyond the terms of his commission, and acts without the orders or commands of the sovereign. He who treats in this manner for the state, without having a commission, promises by this means to take such measures, that the state, or the sovereign, shall approve and ratify the agree-

ment; otherwise his agreement would be vain and illusive. The foundation of this agreement can be no other, on either side, than the hope of the ratification. The Roman history furnishes examples of this kind of agreements.

SPONSIO Judicialis, in *Law.* See *Feigned Issue.*

SPONSORS. See **GOD-FATHERS.**

SPONSUS, one of the many names given by the chemists to mercury.

SPONTANEOUS, SPONTANEUS, formed from the Latin adverb *sponte, of one's own accord*, in the *Schools*, a term applied to such motions of the body and mind as we perform ourselves without any constraint.

Thus, in morality, those actions performed upon an inward and natural principle, conformable to our own inclinations, excluding all constraint, are called spontaneous actions.

In medicine, an evacuation, effected without any application for that purpose, is called a spontaneous evacuation. And a lassitude or weariness, not occasioned by any preceding fatigue, is called a spontaneous weariness.

SPONTANEOUS Generation. See **EQUIVOCAL Generation.**

SPONTANEOUS Precipitation. See **PRECIPITATION.**

SPONTOON, in *Military Language*, is a weapon resembling a halberd, now used instead of a half-pike by the officers of foot. When the spontoon is planted, the regiment halts; when pointed forwards, the regiment marches; and when pointed backwards, it retreats.

SPOON-BILL, PLATEA, in *Ornithology*, the name of a bird of the long-necked kind, approaching to the nature of the stork and heron, and called the spoon-bill from the remarkable figure of its beak, which is different from that of all other birds, being broadest at the extremity, and terminating in a large, rounded, flat process, resembling a shovel; or, if it were hollow, a spoon. The whole bill of this bird is of a fine shining black, except a bright orange-coloured spot just above the point of the upper mandible, which is a little bent downward at its extremity; at the angles of the bill, on each cheek, there is also a spot of the same colour; the upper surface of the bill is elegantly waved with dotted protuberances; a depressed line, extending from the nostrils, is continued round it near its edge; its substance appears like whale-bone, being thin, light, and elastic; the tongue is short, and heart-shaped, and when drawn back, serves as a valve to close the entrance of the throat; when pulled forward, it has the appearance of a triangular button; the ears are large, and placed an inch behind the angles of the mouth; the plumage of the whole body, wings, and tail, is white; on the back part of the head is a beautiful crest of white feathers, hanging behind the neck; the legs are black, and also the thighs, which are naked about half their length; and the toes are connected by a small web, extending to the first joint on each.

This bird breeds on high trees, feeds on fish and water-plants, and can swim; it inhabits the continent of Europe, South America, and the Philippine islands.

A flock of these birds migrated into the marshes near Yarmouth in Norfolk, in April 1774. Pennant. See **PLATALEA.**

SPOON-DRIFT, in *Sea Language*, a sort of showery sprinkling of the sea-water, swept from the surface of the waves in a tempest, and flying according to the wind, like a vapour.

SPOONING, or **SPOOMING,** was formerly used to denote that movement in sailing, which is now called *scudding*.

SPOON-WORT, in *Botany.* See **COCHLEARIA.**

SPORADES, in *Astronomy*, a name which the ancients gave to such stars as were not included in any constellation.

These

These the moderns more usually call *informes*, or *extra-constellary stars*.

Many of the sporades of the ancients have been since formed into new constellations; *e. gr.* of those between Leo and Urfa major, Hevelius has formed a constellation, called *Leo minor*; of those between Urfa minor and Auriga, the same person has formed another constellation, called *Lynx*; and of those under the tail of Urfa minor another, called *Canis venaticus*, &c.

SPORADIC, *σποραδικος*, formed from *σπορας*, *dispersed*, of *σπειρω*, *I strew*, &c. in *Medicine*, an epithet given to such diseases as have some special or particular cause, and are dispersed here and there, affecting only particular constitutions, ages, &c.

Sporadic stands in opposition to epidemic diseases, which are those arising from a general cause, and that are common to all kinds of persons, of what complexion and quality soever.

SPORÆ, in *Botany*, from the Greek *σπορα*, *seed*, a name given by some botanists to the seeds of certain cryptogamic plants; by which they seem to imply a doubt of their being truly *semina*, or exactly analogous to the seeds of plants in general. We know not on what such doubts are founded. If the parts in question be produced or perfected by sexual impregnation, they are to all intents and purposes real seeds, nor does any peculiarity, or apparent simplicity in their structure, invalidate the propriety of their being so called. Seeds of different orders of phænogamous plants differ, as is well known, in their conformation, and even in the number of internal parts, as well as external coats, of which they are composed. Those of the more obscure cryptogamous tribes may therefore be expected to differ from them more widely. If such apparent seeds be not the offspring of sexual impregnation, they are GEMMÆ, see that article; where, as well as in our biographical account of the great HEDWIG, we have lamented that this distinguished philosopher and botanist should have been seduced, by less accurate observers, to adopt a term entirely subversive of his own doctrines and discoveries.

SPORANGIUM, from *σπορα*, *seed*, and *αγγος*, *a vessel*, a name used by Hedwig for the capsule of mosses, to which we have the same objection as to the term SPORÆ for their seeds. See that article, and HEDWIG.

SPORLING'S ISLAND, in *Geography*, a small island near the coast of New Zealand, a little to the N.E. of Gable End Foreland.

SPORLIVOI, Nos, a cape of Russia, on the S. coast of Nova Zembla. N. lat. 70° 30'. E. long. 60° 34'.

SPOROBOLUS, in *Botany*, from *σπορα*, *seed*, and *βωλλω*, *to throw*, because, as we presume, of the round deciduous seed.—Brown Prodr. Nov. Holl. v. 1. 169.—Class and order, *Triandria Digynia*. Nat. Ord. *Gramina*.

This genus of grasses is separated by Mr. Brown from *Agrostis*, by the following characters.

Calyx of two unequal unarmed valves, containing a single flower; the outer valve smallest. Corolla of two rather acute valves, without awns, sessile, longer than the calyx. Nectary of two scales. Stigmas villous. Seed obovate, tumid, naked, deciduous.

The species are found between the tropics, scarcely beyond the latitude of 35°. Some have only two *stamens*. The *flowers* are panicled. Sheaths of the *leaves* bearded, with hardly any membranous *glipula*. They are akin to *Agrostis*, especially to *A. virginica*. *A. diandra* of Linnæus is a *Sporobolus*, as well as *A. indica*. Besides the latter, two new species have been observed by Mr. Brown in New Holland, *S. elongatus* and *pulebellus*.

SPOROW, in *Geography*, a town of Lithuania, in the palatinate of Brzesc, seated on a lake to which it gives name; 28 miles W. of Pinsk.

SPORTS, in the *Customs* of Flanders, were in great vogue through Flanders and the Low Countries some centuries ago. Every city had a solemnity of this kind peculiar to itself: thus Bruges had that called the *Forester*; Valenciennes, the *Prince of Pleasantry*, and the *Prince of the Horse-Comb*; Cambray, the *King of Ribaldry*; and Bouchain, the *Provost of Sots*. Lille, one of the richest towns in Flanders, was not behind hand with its neighbours in celebrating sports, by the magnificence and diversions of which to draw together a vast concourse of people from all parts. One of the chief of these diversions was called the *King of the Spinet*, *Roy d'Épinette*, which was celebrated with great pomp and show. See Hist. Acad. Inscript. tom. iv. p. 452, seq.

SPORTULA, or SPORTELLA, in *Antiquity*, a dole, or largess, either of meat or money, given by princes, or great men, to the people or poor.

The sportula was properly the panner or basket in which the meat was brought, or with which the poor went to beg it; thence the word was transferred to the meat itself, and thence to money sometimes given in lieu of it. The basket was supposed to contain a quantity of hot provisions, of the value of 100 quadrantes, or 12½ pence; and these baskets were ranged in order in the hall, and distributed ostentatiously to the hungry or fervile crowd, which waited at the door. This indelicate custom is very frequently mentioned in the epigrams of Martial, and the satires of Juvenal. (See likewise Suetonius, in Claud. c. 21, in Neron. c. 16, in Domitian. c. 4. 7.) These baskets of provisions were afterwards converted into large pieces of gold and silver coin, or plate, which were mutually given and accepted, even by persons of the highest rank (see Symmach. epist. iv. 55. ix. 124. and Miscell. p. 256.) on solemn occasions, of consulships, marriages, &c.

Sportula was also frequently used in opposition to *recta cana*, a formal or plentiful meal; as in Martial.—“*Promissa est nobis sportula, recta data.*”

St. Cyprian gives the denomination *sportulantes fratres*, to such clergymen as then received gifts, or gratuities, for their maintenance.

SPOT, in *Ornithology*, the name of a particular species of pigeon, called by Moore the *columba maculata*. It is of the size of a small common pigeon, and was brought over to England from Holland. This species has always a spot upon its head, just above its beak, from whence it has its name. The feathers of the tail are always of the same colour with this spot, and the rest of the body is all white. The spot and tail are black in some, red in others, and yellow in others. They look very beautiful when they spread their tails and fly, and are a distinct species, as they always produce young ones of their own marks.

SPOTICO, in *Geography*, an island in the Grecian Archipelago, of an irregular form, about four miles long, and from one to two broad; 6 miles W.S.W. of Paros. N. lat. 36° 59'. E. long. 25° 12'.

SPOTS, in *Astronomy*, dark places observed on the disks, or faces, of the sun, moon, and planets.

The spots in the sun are only visible through a telescope: some distinguish them into maculæ, or dark spots; and faculæ, or bright spots; but there seems but little foundation for any such division.

The solar spots have not been long observed. They were first discovered by Galileo, in the year 1610, soon after he had finished his telescope.

In opposition to the received opinion of the unalterable

state of the heavens, he maintained, that these spots consisted of a kind of matter that admitted of very great and sudden alterations; that they adhered to the sun, which carried them round an axis of his globe in about a month; which axis he first supposed to be perpendicular to the plane of the earth's annual orbit, because the course of the spots appeared on the sun's disk as straight lines parallel to that plane; which then happened through a particular direction of the floating motions of the spots upon the sun's surface, as he soon inferred from the visible alterations in their shapes and situations to one another, when several of them appeared together: and thence he concluded, that the general course of the spots was frequently varied a little, in like manner as, to a person viewing the earth from a great distance, the clouds would appear to move parallel to one another, and to the equator, with the uniform velocity of the earth's diurnal revolution, unless disturbed a little from that regular course by their floating in the atmosphere. At first he took the apparent motion of the sun's to be, as we have stated, rectilinear and parallel to the ecliptic; but in consequence of a subsequent observation of the entire transit of a large spot, and of marking its place at noon, day after day, upon a circular paper answering to the sun's disk, he found its course was a little incurvated; and thence he concluded, that the sun's axis was a little inclined to the plane of the ecliptic.

Since Galileo's time, the subject of the sun's spots has engaged the attention of several astronomical observers. The position of the sun's axis, and the periodical time of his motion round it, have been more exactly determined, the knowledge of which depended upon the observation of these spots. In the year 1639, Scheiner published his "*Rosa Urфина*," containing near 2000 observations of solar spots for 20 years; in which time he frequently saw above 50 at once: but for 20 years after, betwixt 1650 and 1670, scarcely any appeared. He found that many of his spots scarcely exceeded 25 days in making an apparent revolution from a given place on the disk to the same again, that others took up 27 days, and some others near 28. Scheiner and Cassini the son have also observed, that the periodical times of the nearer spots to the equator are shorter than those of the remoter; and Cassini the father observed the like property in Jupiter's spots. These irregularities create great difficulties in determining the time of the sun's exact revolution about his axis. Cassini the father, however, by comparing many distant observations together, found a common measure of many such intervals of time to be $27^d 12^h 20^m$ very nearly. Hence it has been concluded, that the periodical time of the sun's revolution to a fixed star is $25^d 15^h 16^m$.

All spots consist of a black part in the middle, of some irregular figure, encompassed with a nebulous border of a colour less dark; and it often happens, after a gradual decay and disappearing of the black part, that its place seems brighter than the rest of the sun, and continues so for two or three days. These brighter spots are called *facule*; which see.

The sun's spots are very changeable as to number, form, &c. and are sometimes in a multitude, and sometimes none at all.

Some imagine they may become so numerous, as to hide the whole face of the sun, at least the greatest part of it; and to this ascribe what Plutarch tells us, *viz.* that in the first year of the reign of Augustus, the sun's light was so faint and obscure, that one might look steadily at it with the naked eye.

To which Kepler adds, that in 1547 the sun appeared

reddish, as when viewed through a thick mist; and hence conjectures, that the spots in the sun are a kind of dark smoke, or clouds, floating on the surface of it.

Others will have them stars, or planets, transiting the body of the sun; but it is much more probable they are opaque bodies, in manner of crusts, formed like the scums on the surface of liquors.

Dr. Derham, from a variety of particulars which he has recited, relating to the solar spots, (see *Phil. Trans.* abr. vol. iv. p. 235, &c.) and their congruity to what we observe in our own globe, infers, that they are caused by the eruption of some new volcano therein, which, at first, pouring out a prodigious quantity of smoke, and other opaque matter, causeth the spots: and as that fuliginous matter decays and spends itself, and the volcano at last becomes more torrid and flaming, so the spots decay and become umbræ, and at last faculæ; which faculæ he supposes to be no other than more flaming lighter parts than any other parts of the sun.

Dr. Franklin (in his *Exper. and Observ.* p. 266.) suggests a conjecture, that the parts of the sun's sulphur, separated by fire, rise into the atmosphere, and there being freed from the immediate action of the fire, they collect into cloudy masses, and growing, by degrees, too heavy to be longer supported, they descend to the sun, and are burnt over again. Hence, he says, the spots appearing on his face, which are observed to diminish daily in size, their consuming edges being of particular brightness. For other solutions of these phenomena, by Wilson, Lalande, Herschel, &c., see *MACULE* and *SUN*.

The lunar spots are fixed; and astronomers reckon about forty-eight of them on the moon's face, to each of which they have given names. The twenty-first is one of the most considerable, and is called *Tycho*. See *Nature, &c. of the MOON*.

SPOTS, Circular, in Electricity. See *CIRCULAR Spots and COLOURS*.

SPOTS, Planetary. Astronomers find that the planets are not without their spots. Jupiter, Mars, and Venus, when viewed through a telescope, shew several very remarkable ones: and it is by the motion of these spots, that we conclude the rotation of the planets round their axes, in the same manner as that of the sun is deduced from the motion of his maculæ. See each planet in its proper place.

SPOTS, Lucid, in the Heavens, are little whitish spots, of which there are several, that appear magnified, and more luminous when seen through telescopes; and yet without any stars in them. One of these is in Andromeda's girdle, and was first observed, A. D. 1712, by Simon Marius: it has some whitish rays near its middle, is liable to several changes, and is sometimes invisible. Another is near the ecliptic, between the head and bow of Sagittarius; it is small, but very luminous. A third is in the back of the Centaur, which is too far south to be seen in Britain. A fourth, of a smaller size, is before Antinous's right foot, having a star in it, which makes it appear more bright. A fifth is in the constellation of Hercules, between the stars ζ and ν , which spot, though small, is visible by the bare eye, if the sky be clear and the moon absent.

SPOTSWOOD, in *Geography*, a small town of Middlesex county, New Jersey, near the west side of South river, which discharges itself into the Rariton, in a south-east direction. It is well situated for extensive manufactories; 9 miles S.E. of Brunswick.

SPOTSYLVANIA, a county of the American state of Virginia, bounded north by Stafford, and east by Caroline county. It is hilly, and well watered by branches of the

the Mattapony and Rappahannock rivers. It contains 13,296 inhabitants, of whom 7135 are slaves. At the court-house is a post-office; 78 miles from Washington.

SPOTTED ISLAND, an island in the North Atlantic ocean, on the east coast of Labrador. N. lat. $53^{\circ} 30'$. W. long. $55^{\circ} 20'$.

SPOTTING, FINGER, known also by the name of *Brocading*, in the *Manufacture of fanciful ornamented Cloths*, is a very beautiful, though rather expensive, mode of interweaving flowers, either of the same or different colours, with various kinds of grounds. Of its primary origin we are totally unacquainted, as we find it practised alike, and with little variation of apparent effect, in the silks of Europe and the muslins of India. It is probable that the whole range of fanciful cloths, with which we are acquainted, are originally Asiatic; and that the knowledge of them has gradually reached Europe, at various times, and through various channels. In spots wrought with the shuttle, the flowers being at intervals, and the woof passed across the whole fabric, what passes between the flowers, and is not interwoven with the fabric, must be cut away, when the cloth is taken from the loom, and before it undergoes the succeeding processes of bleaching and dressing. Some specimens of brocaded muslins have been occasionally brought from India, which are entirely effected by a continued and patient exercise of manual labour truly astonishing. The low price of labour paid to the natives of that country may produce these figured muslins, at prices accessible to the opulent natives, and to the more wealthy classes of the European settlers. In this country, even at the most reduced prices, capable of affording to the operative the most penurious and scanty subsistence, they could not be afforded under four or five guineas *per* yard; a sum immensely beyond what could be expected for a commodity so flimsy and perishable as a muslin dress.

In finger-flowers, or brocaded muslins, the draught through the heddles is generally successive from the back to the front, as in most kinds of fanciful weaving. The treddles are moved by the feet, as in the common processes, for forming the plain ground or fabric of the work. For the flowers or raised part, those leaves which require to be raised are most commonly pulled by cords above the weaver's head, as in the diaper and patent draw-loom; and, like them, secured by a knot upon the cord, being fixed in a notch in the board. The weaver then proceeds to pass the substitute, which is to form the flowers, through the warp; each end being separated from, and independent of, all the others. In this he is generally assisted by a boy, who sits at the loom along with him, and who manages one side of the web, while the weaver is employed on the other. From this tedious and laborious operation being done entirely by the fore-finger, the appellation *finger-flower* is derived. Our limits will not allow of a very lengthened detail, nor would it be of any essential service; for, from the causes already assigned, there is no probability of its ever becoming an article of extensive manufacture in this country.

SPOTTISWOODE, JOHN, in *Biography*, a prelate and ecclesiastical historian of Scotland, descended from an ancient family in that country, was born in 1565. His father, who was a minister of Calder, sent him to the university of Glasgow to be educated for the church; and his proficiency in his studies was such, that at the age of eighteen he was thought to be qualified to be his father's successor. When Lodowick, duke of Lenox, was sent, in 1601, on an embassy to France, for the purpose of confirming the ancient amity between the two countries, Spottiswoode, with the hope of conciliating the two na-

tions, accompanied him as chaplain, and returned with him to England. His reputation was at that time so high, that, on the accession of king James to the crown of England in 1603, he was one of the persons appointed to attend his majesty to his newly acquired kingdom; and in the same year he was promoted to the archbishopric of Glasgow, and nominated a privy-counsellor for Scotland. It was the favourite object of James to assimilate as much as possible the church of Scotland to the model of that of England; and archbishop Spottiswoode was very eager in promoting this intention, and is said to have made fifty journeys to London on that account. Having held the see of Glasgow eleven years, he was translated, in 1615, to that of St. Andrews, the metropolitan of Scotland; and he presided at various assemblies for the restoration of the episcopal form of government. He continued in high favour with king James during his whole reign; and Charles I., after his accession, was crowned by him in the abbey church of Holyrood House. In 1635 he was appointed chancellor of Scotland. When the civil commotions broke out in that country in 1639, the archbishop withdrew to England, where he died, and was interred in Westminster Abbey. He was author of "A History of the Church of Scotland," beginning with the year 203, and continued to the end of the reign of James VI., which was published in London in 1655. This work was undertaken at the command of king James, who, when Spottiswoode told him some passages might bear hard on the memory of his mother, said, "Write the truth, and spare not." Spottiswoode was author of "Refutatio Libelli de Regimine Ecclesie Scoticanæ," written in defence of the ecclesiastical establishment of Scotland.

SPOULT, in *Rural Economy*, a word signifying brittle, as applied to wood, &c.

SPOUT, the name of a trunk for conveying water from off the roofs of buildings, which should always be attached to those of the farm-kind. Spouts on such buildings are not only useful for freeing them of water, but in collecting it for the purpose of the live-stock, &c.

SPOUT, or *Water-spout*, in *Natural History*, an extraordinary meteor, or appearance, at sea, and sometimes on land, very dangerous to ships, &c. oftenest observed in hot, dry weather; and called by the Latins *typho*, and *sipho*; by the French, *troupe*, &c.

Its first appearance is in form of a deep cloud, the upper part of which is white, and the lower black. From the lower part of this cloud there hangs, or rather falls down, what we properly call the spout, in manner of a conical tube, biggest at top. Under this tube is always a great boiling and flying up of the water of the sea, as in a jet d'eau. For some yards above the surface of the sea, the water stands as a column, or pillar; from the extremity of which it spreads, and goes off, as in a kind of smoke. Frequently the cone descends so low, as to touch the middle of this column, and continue for some time contiguous to it; though sometimes it only points to it, at some distance, either in a perpendicular, or in an oblique line.

Frequently it is scarcely distinguishable, whether the cone or the column appear the first, both appearing all of a sudden against each other. But sometimes the water boils up from the sea to a great height, without any appearance of a spout pointing to it, either perpendicularly or obliquely. Indeed, generally, the boiling or flying up of the water has the priority, this always preceding its being formed into a column. Generally the cone does not appear hollow till towards the end, when the sea-water is violently thrown up along its middle, as smoke up a chimney: soon after this the spout,

spout, or canal, breaks and disappears; the boiling up of the water, and even the pillar, continuing to the last, and for some time afterwards; sometimes till the spout form itself again, and appear anew; which it sometimes does several times in a quarter of an hour. See a description of several water-spouts by Mr. Gordon, and by Dr. Stuart, in *Phil. Transf. Abr.* vol. iv. p. 103, &c.

M. de la Pryme, from a near observation of two or three spouts in Yorkshire, described in the *Philosophical Transactions*, N^o 281, or *Abr.* vol. iv. p. 106, concludes, that the water-spout is nothing but a gyration of clouds, by contrary winds meeting in a point, or centre; and there, where the greatest condensation and gravitation are, falling down into a pipe, or great tube, somewhat like Archimedes's spiral screw; and, in its working and whirling motion, absorbing and raising the water, in the same manner as the spiral screw does; and thus destroying ships, &c.

Thus, June the 21st, he observed the clouds mightily agitated above, and driven together; upon which they became very black, and were hurried round; whence proceeded a most audible whirling noise, like that ordinarily heard in a mill. Soon after there issued a long tube or spout from the centre of the congregated clouds, in which he observed a spiral motion, like that of a screw, by which the water was raised up.

Again, August 15, 1687, the wind blowing at the same time out of the several quarters, created a great vortex and whirling among the clouds; the centre of which every now and then dropped down, in shape of a long, thin, black pipe, in which he could distinctly behold a motion like that of a screw, continually drawing upwards, and screwing up, as it were, wherever it touched. In its progress it moved slowly over a grove of trees, which bent under it like wands, in a circular motion. Proceeding, it tore off the thatch from a barn, bent an huge oak-tree, broke one of its greatest branches, and threw it to a great distance. He adds, that whereas it is commonly said, the water works and rises in a column, before the tube comes to touch it; this is, doubtless, a mistake, owing to the fineness and transparency of the tubes, which do most certainly touch the surface of the sea, before any considerable motion can be raised in it; but which do not become opaque and visible, till after they have imbibed a considerable quantity of water.

The dissolution of water-spouts he ascribes to the great quantity of water they have glutted; which, by its weight, impeding their motion, on which their force, and even existence, depends, they break, and let go their contents; which generally prove fatal to whatever is found underneath.

A notable instance of this kind we have in the *Philosophical Transactions*, N^o 363, or *Abr.* vol. iv. p. 108, related by Dr. Richardson. A spout, in 1718, breaking on Emmotmoor, near Coln, in Lancashire, the country was immediately overflowed; a brook, in a few minutes, rose six feet perpendicularly high; and the ground on which the spout fell, which was sixty-six feet over, was torn up to the very rock, which was no less than seven feet deep; and a deep gulf was made for above half a mile; the earth being raised on either side in vast heaps. See a description and figure of a water-spout, with an attempt to account for it, in *Franklin's Exp. and Obs.* p. 226, &c.

Signior Beccaria has taken pains to shew that water-spouts have an electrical origin. To make this more evident, he first describes the circumstances attending their appearance, which are the following.

They generally appear in calm weather. The sea seems to boil, and send up a smoke under them, rising in a hill to-

wards the spout. At the same time, persons who have been near them have heard a rumbling noise. The form of a water-spout is that of a speaking-trumpet, the wider end being in the clouds, and the narrower end towards the sea. The size is various, even in the same spout. The colour is sometimes inclining to white, and sometimes to black. The position is sometimes perpendicular to the sea, sometimes oblique; and sometimes the spout itself is in the form of a curve. Their continuance is very various, some disappearing as soon as formed, and some continuing a considerable time. One that he had heard of continued a whole hour. But they often vanish, and presently appear again in the same place.

The very same things that water-spouts are at sea, are some kinds of whirlwinds and hurricanes by land. They have been known to tear up trees, to throw down buildings, make caverns in the earth; and, in all these cases, to scatter earth, bricks, stones, timber, &c. to a great distance, in every direction. Great quantities of water have been left, or raised by them, so as to make a kind of deluge; and they have always been attended with a prodigious rumbling noise.

That these phenomena depend upon electricity, cannot but appear very probable from the nature of several of them; but the conjecture is made more probable from the following additional circumstances. They generally appear in months peculiarly subject to thunder-storms, and are commonly preceded, accompanied, or followed, by lightning, rain, or hail; the previous state of the air being similar. Whitish or yellowish flashes of light have sometimes been seen moving with prodigious swiftness about them. And, lastly, the manner in which they terminate, exactly resembles what might be expected from the prolongation of one of the uniform protuberances of electrified clouds, mentioned before, towards the sea; the water and the cloud mutually attracting one another; for they suddenly contract themselves, and disappear almost at once; the cloud rising, and the water of the sea under it falling to its level. But the most remarkable circumstance, and the most favourable to the supposition of their depending upon electricity, is, that they have been dispersed by presenting to them sharp-pointed knives or swords. This, at least, is the constant practice of mariners, in many parts of the world where these water-spouts abound; and he was assured by several of them, that the method has often been undoubtedly effectual.

The analogy between the phenomena of water-spouts and electricity, he says, may be made visible, by hanging a drop of water to a wire communicating with the prime conductor, and placing a vessel of water under it. In these circumstances, the drop assumes all the various appearances of a water-spout, both in its rise, form, and manner of disappearing. Nothing is wanting but the smoke, which may require a great force of electricity to become visible.

Mr. Wilcke also considers the water-spout as a kind of great electrical cone, raised between the cloud strongly electrified, and the sea or the earth; and he relates a very remarkable appearance, which occurred to himself, and which strongly confirms his supposition. On the 20th of July, 1758, at three o'clock in the afternoon, he observed a great quantity of dust rising from the ground, and covering a field and part of the town in which he then was. There was no wind, and the dust moved gently towards the east, where appeared a great black cloud, which, when it was near its zenith, electrified his apparatus positively, and to as great a degree as ever he had observed it to be done by natural electricity. This cloud passed its zenith, and went gradually towards the west, the dust then following it, and continuing to rise higher and higher, till it composed a thick pillar, in the form

of a fugar-loaf, and at length seemed to be in contact with the cloud. At some distance from this there came, in the same path, another great cloud, together with a long stream of smaller clouds, moving faster than the preceding. These clouds electrified his apparatus negatively, and when they came near the positive cloud, a flash of lightning was seen to dart through the cloud of dust, the positive cloud, the large negative cloud, and, as far as the eye could distinguish, the whole train of smaller negative clouds which followed it. Upon this the negative clouds spread very much, and dissolved into rain, and the air was presently clear of all the dust. The whole appearance lasted not above half an hour. See Priestley's *Electr.* vol. i. p. 438, &c.

This theory of water-spouts has been farther confirmed by the account which Mr. Forster gives of one of them in his *Voyage round the World*, vol. i. p. 191, &c. On the coast of New Zealand he had an opportunity of observing several, one of which he has particularly described. The water, he says, in a space of fifty or sixty fathoms, moved towards the centre, and there rising into vapour, by the force of the whirling motion, ascended in a spiral form towards the clouds. Directly over the whirlpool, or agitated spot in the sea, a cloud gradually tapered into a long slender tube, which seemed to descend to meet the rising spiral, and soon united with it into a straight column of a cylindrical form. The water was hurled upwards with the greatest violence in a spiral, and appeared to leave a hollow space in the centre, so that the water seemed to form a hollow tube, instead of a solid column; and that this was the case, was rendered still more probable by the colour, which was exactly like that of any hollow glass tube. After some time, this last column was incurved, and broke like the others; and the appearance of a flash of lightning which attended its disjunction, as well as the hail-stones which fell at the time, seemed plainly to indicate that water-spouts either owe their formation to the electric matter, or at least that they have some connection with it.

Mr. Cavallo (*Elem. of Phil.* vol. ii.) has detailed the following facts, as the most remarkable, relative to water-spouts.

Two or three, or more, water-spouts are frequently seen within the space of a few miles, and they are mostly seen at sea.

Their size is various, not exceeding, however, a few feet in diameter; and the same water-spout sometimes increases and decreases alternately; it also appears, disappears, and re-appears, in the same place.

The water-spout sometimes proceeds a little way from a cloud, or a little way from the sea; and often those two short and opposite spouts are not only directed towards each other, but they are extended, and meet each other.

When it proceeds from the sea, the water about the place appears to be much agitated, and rises a short way in the form of a jet, or spray, or steam, in the middle of which a thick, well defined, and generally opaque body of water rises, and proceeds to a considerable height into the atmosphere, where it is dissipated into a vapour, or it seems to form a cloud.

When it proceeds from a cloud, the clouds about the spot frequently appear much agitated, and an agitation of the water immediately under the spot is generally seen at the same time.

The water-spout is frequently seen to have a spiral or screw-like motion, and sometimes is attended with considerable noise.

Some of them stand in a perpendicular direction, others

are inclined, and some water-spouts form a curve, or even an angle.

The water-spouts generally break about their middle, and the falling waters occasion great damage, either to ships that have the misfortune of being under them, or to the adjoining land; for such spouts are sometimes formed on a lake or river, or on the sea close to the land.

Sometimes the water-spouts are seen where there is no appearance of whirlwind, or where the wind, at least to a spectator at some distance, appears to blow regularly one way.

The oblique spouts almost always point from the wind; for instance, when the wind is N.E. the spout will point to the S.W.

The water-spout has been attributed principally, if not entirely, to the meeting of different winds. In that case, the air in its rotation acquires a centrifugal motion; whence it endeavours to recede from the axis of the whirl, in consequence of which a vacuum, or, at least, a considerable rarefaction of air, takes place about the axis; and, when the whirl takes place at sea, or upon water, the water rises into that rarefied place, for the same reason which causes it to ascend into an exhausted tube, and forms the water-spout or pillar of water in the air: nevertheless it is observed by Mr. Cavallo, that the various appearances of water-spouts do not seem to be quite reconcilable to the above-mentioned theory. Several ingenious persons have considered the water-spout as an electrical phenomenon; having observed, that thunder-clouds and lightning have been frequently seen about the places where water-spouts appear, and likewise that by means of artificial electricity, a water-spout may in some measure be imitated. (See the preceding part of this article.) Mr. Cavallo, however, suggests, that the lightning and other electrical phenomena appear to be rather the necessary consequence than the cause of the water-spout; it being well known that electricity is produced whenever water is reduced into vapour, or vapour is condensed into water. A water-spout of the most complete form is represented in *Plate XXIV. Miscellany, fig. 8.*

In Pliny's time, the seamen used to pour vinegar into the sea, to alluage and lay the spout, when it approached them: our modern seamen think to keep it off, by making a noise with filing and scratching violently on the deck, or by discharging great guns to disperse it.

SPOUTING FOUNTAIN. See FOUNTAIN.

SPOUTY Ground or Land, in *Agriculture*. See SOIL, and SPRING-Draining.

SPRAGGE, Sir EDWARD, in *Biography*, a celebrated naval hero and commander, of whose early history nothing has been collected, but who deserves a place in the annals of England, and whose services will be ever remembered with gratitude by his country. He is compared by Campbell to Alcibiades, who was equally able and esteemed in the camp, in the court, and in the closet. "In every character which he assumed, he so far excelled as to seem born and designed for that alone. The same thing his contemporaries, his companions, those who knew him, and the world too, perfectly well, affirm of Sir Edward Spragge, who with a fine person, and gentle temper, had as solid an understanding, and as bold a spirit, as any counsellor or captain of that age. With all these advantages, with the favour of the duke of York, with the merit of great services which he rendered his country, and with the still greater merit of dying gloriously in his country's service, which, indeed, procured him remains an interment in Westminster Abbey, he was not honoured with a tomb; or any memorial, as far as

I can

I can discover, where he was born, of what family, or how he attained his first preferment."

We find him a captain in the first engagement with the Dutch, after the restoration of Charles II., viz. on the 3d of June, 1665, in which he behaved with great reputation, and on account of which he was knighted. He was likewise in the four-days' battle in June 1666, at which time he was particularly noticed by the duke of Albemarle; and in the succeeding battle, which was fought on the 24th of July, he carried a flag under sir Jeremiah Smith, admiral of the blue squadron, who engaged Van Tromp, shattered his vice admiral, so that she was absolutely disabled, and having ruined the rigging of the rear admiral, and killed the commander, contributed very much to the glory of that day. He greatly distinguished himself when the Dutch daringly ventured up the Thames in 1667: he was employed on this occasion to maintain the fort of Sheerness, which he defended with gallantry, till it would have amounted to an act of rashness to expose his garrison any longer: and when he could act no more by land, he began to collect as great a force as possible by sea. This amounted to no more than five frigates, seventeen fire-ships, and some tenders; and yet when the Dutch admiral Van Nes came up the river, sir Edward engaged him, and burnt eleven or twelve of his ships, with only six of his own. The wind, after this, obliged him to shelter himself from the enemy's superior force, under the cannon of Tilbury fort. The next day, the weather being more favourable, he again attacked the Dutch, and drove them disgracefully out of the river.

In 1671 he was employed against the Algerines, and destroyed seven of their men of war, and did them other damage which was esteemed irreparable. They had picked out their chief and most renowned commanders, on purpose to meet sir Edward Spragge; had furnished them with their best brass ordnance from on board all the rest of their vessels, with nearly 2000 chosen men double officered, of whom about 400 were killed, the castles and towns miserably torn, and a vast number of people in them slain and wounded; and, which increased the misfortune, all their surgeons' chests were burnt on board their ships, so that numbers died for want of having their wounds dressed. In this engagement sir Edward Spragge had but 17 men killed, and 41 wounded. Dr. Campbell mentions it as honourable to the English name and heroism, that in all our wars with the pirates of Algiers at that period, the Spaniards allowed us the free use of the harbour of port Mahon, as to the champions of the Christian cause, and protectors of the commerce of the Mediterranean, and thither sir Edward repaired to refit before he returned home.

Sir Edward Spragge was raised to the rank of admiral of the blue in the year 1673, having in the preceding year been employed by the duke of York to assemble the fleet in order to attack the Dutch, and in that year he was present in the Solebay fight, May 28th, and in it distinguished himself by sinking a Dutch ship of sixty guns.

Before the fleet put to sea in 1673, sir Edward was sent, with the character of envoy extraordinary, to France, where he was received with all possible respect, and at his taking leave, had a present made him of great value.

On the 28th of May, 1673, he took a most gallant part in the engagement with the Dutch: he fought Van Tromp seven hours, forced him from the Golden Lion into the Prince on Horseback, and thence into the Amsterdam, and from that into the Comet, where he would have been killed or taken if he had not been relieved by De Ruyter. Sir Edward also twice changed his ship. These circumstances

were not mentioned in the account published by order of government, but the matter is fairly stated by prince Rupert, notwithstanding there had been a private quarrel between the prince and admiral. "Sir Edward," says his highness, "did on his side maintain the fight with so much courage and resolution, that their whole body gave way to such a degree, that, had it not been for fear of the shoals, we should have driven them into their harbours, and the king would have had a better account of them."

On the 4th of June he behaved with great resolution, forced Van Tromp to change his ship twice, and finally obliged him to retreat. In the third battle, which took place on the 11th of August, sir Edward Spragge, with the blue squadron, was in the rear, but being provoked by Van Tromp, he laid his fore-top sail to the mast to wait for him, and having engaged his squadron, continued fighting many hours, at a distance from the body of the fleet. Sir Edward was at first on board the Royal Prince, and Van Tromp in the Golden Lion; but after a dispute of about three hours, sir Edward's ship was so disabled, that he was forced to go on board the St. George, as Van Tromp for the same reason went on board the Comet. Then the fight between them began again with greater fury than before: at last the St. George was so battered, that sir Edward thought it right to leave her, in order that he might go on board the Royal Charles; but before his boat had rowed many yards it was pierced by a cannon shot, and the admiral was drowned.

Bishop Parker describes this last scene in the following words: "There was a remarkable fight between Spragge and Van Tromp; for these having mutually agreed to attack each other, not out of hatred, but through a thirst of glory, they engaged with all the rage, or, as it were, with all the sport of war. They came so close to one another, that, like an army of foot, they fought at once with their guns and swords. Almost at every turn, both their ships, though not sunk, were yet bored through and through, their cannon being discharged with common gun-shot: neither did our ball fall in vain into the sea, but each ship pierced the other, as if they had fought with spears. But at length, three or four ships being shattered, as Spragge was passing in a long boat from one ship to another, the boat was overturned by a chance-shot, and that great man, not being skilled in swimming, was drowned, to the great grief of his generous enemy, who, after the death of Spragge, could hardly hope to find an enemy equal to himself. But thus it happened, that when that brave man had overcome so many dangers, his country being now victorious and safe, no honour remained for him to receive, but the reward of a glorious death." The bishop adds, in another part of his history, that sir Edward Spragge was a person the love and delight of all men, as well for his noble courage, as the gentle sweetness of his temper. See Stockdale's edition of Campbell, vol. ii.

SPRAIN, in *Surgery*, signifies an injury done to a joint, which has had its ligaments violently stretched, without there being any sensible luxation.

The motion of the articulations cannot be carried beyond their natural limits, without the ligaments, intended for uniting the bones and bounding their movements, being either forcibly stretched or lacerated. A sprain, therefore, is always accompanied with the first of these circumstances, and sometimes with the second.

Custom has limited the term *diastasis* to the lateral separation of two long bones, articulated together by corresponding surfaces at their extremities, and, especially, to such injuries,

SPRAIN.

juries, when they affect the immoveable joints, like those betwixt the tibia and fibula, those betwixt the bones of the pelvis, &c. But, as Boyer has observed, it is plain that these accidents do not at all differ from common sprains, since they cannot happen without a violent stretching and even a rupture of the ligaments.

The orbicular joints, those which allow to the bones the most varied and extensive motions, are so disposed, that their ligaments, which are protected by a great number of powerful muscles, can only suffer a considerable extension by an extraordinary effort; and when it is adequate to produce this extension and rupture of the ligaments, the displacement which follows is necessarily permanent, in consequence of the spherical form of one of the articular surfaces; which form will not permit a spontaneous reduction.

On the contrary, in the ginglymoid joints, and those which resemble them in the trivial degree of their motions, which are usually limited to two alternate directions, and sometimes very obscure, the natural relations of the bones are assured by the disposition of the articular surfaces themselves, and by the strength of the ligaments, but hardly at all by the muscles. The action of these last organs, consequently, not increasing the resistance made by the ligaments in cases of necessity, in proportion to the violence which operates, the latter parts are the more apt to be stretched and ruptured. On the other hand, as the surfaces of these joints are generally extensive, and cannot be forced away from each other without great difficulty, the effort which tends to separate them, for the most part only occasions a stretching and rupture of the ligaments. Hence, dislocations are very common in the orbicular joints, and sprains are most frequent in those of the ginglymoid kind. The ankle joint, which affords a striking instance of the conditions just now explained, and which is besides exposed to considerable and frequent shocks, is also that in which sprains are most observed. Then follow the articulations of the bones of the tarsus, of the wrist, knee, and elbow, in which last a sprain is not so often met with, notwithstanding the suitable dispositions in appearance; for the ligaments which strengthen this joint being extremely strong, an excessive violence is requisite to stretch or break them, and then it is always capable of also occasioning a dislocation.

The differences of sprains depend upon the importance of the joint, the degree of violence which has been applied, and the extent of the disorder attending these cases. Consequently, some sprains are slight, the ligaments having been merely stretched, while others are severe, the ligaments and surrounding cellular substance having been lacerated, and the tendinous nerves and vessels of every kind, and even the skin itself, more or less violently stretched.

When a sprain occurs, the external violence which produces it, must either act so as to carry the motions of a ginglymoid joint beyond their natural limits; or so as to cause movements in a direction in which they are not natural; or, lastly, so as to make a joint move, which in the natural state performs no motion whatsoever. Thus, in a fall upon the hands, where the extension or flexion of the wrist is forced, a sprain is very liable to happen. In a fall upon the feet, where one of the two, being in the state of adduction, or abduction, supports nearly the whole weight of the body; also in falls backward, where the point of the foot is so locked as not to allow any motion of the leg backward; and when the sole of the foot is twisted inward while a patient is running quickly; the ankle, or joints of the tarsus, or all together, are liable to be sprained. With regard to the ankle, it may be remarked, that there are cases, in which a predisposition to serofula acts also as a predis-

position to sprain. We allude to instances, in which the articular extremities of the long bones having been enlarged at an early period of life, the ligaments of the neighbouring joint have suffered a considerable elongation, or relaxation. This occurrence, which is particularly observable at the lower end of the tibia, makes the foot flat, and its articulation much freer and weaker than it ought to be; and patients who are thus formed, are also more subject to sprains. Under these circumstances, it is not uncommon to see the same accident happen several times to the same joint. With respect to the sort of injury which has received the name of *diastasis*, it is difficult to comprehend the possibility of it, unless combined with a fracture of one of the two bones. In taking for example the bones of the leg, it is difficult to conceive how the lower articulation of the tibia with the fibula can be affected by external violence; how the surfaces of this joint can be separated, its ligaments elongated or ruptured, without there being at the same time a fracture of the fibula. It is an accident which to Boyer seems very difficult to prove. A mere separation of the articular surfaces, without fracture, would hardly admit of detection, because the swelling, which takes place almost immediately, must hinder the examination of the parts. Boyer thinks it extremely probable, that, in many cases, the consequences of an undiscovered fracture of the fibula have been mistaken for the consecutive proofs of a *diastasis*.

Sprains are accompanied with a variety of symptoms, amongst which pain and swelling come on immediately. It is easily comprehensible, that the ligaments, and other soft parts which surround a joint, cannot be stretched and more or less torn, without an instantaneous pain being excited proportionate to the sensibility of these parts, and the degree of violence which they have sustained. The pain and irritation are soon followed by swelling, which, from being at first inconsiderable, afterwards increases, and at the end of four and twenty hours it is usually at the highest degree, and exhibits signs of the presence of inflammation. The blood, which escapes from the small ruptured vessels, passes into the cellular substance, and occasions an ecchymosis, which sometimes extends a great way. Immediately after the accident, the joint is capable of performing all its motions; but, as soon as the swelling has taken place, these motions are impeded, and, on force being used to make the joint move, acute pain is produced, and the case is rendered worse.

When a sprain is slight, it is a disease of little consequence, and easily cured. The pain gradually diminishes, the swelling and tension disappear, the ecchymosis is dispersed, the motion of the limb is restored, becoming daily more and more extensive, and the joint in due time returns to its natural state. But when a sprain happens to a joint, the motion of which is naturally very confined, and which is strengthened by exceedingly strong ligaments, whose resistance can be overcome only by great violence, the symptoms are generally very severe, and disappear much more slowly. Then, according as the ligaments have suffered more or less, and as the swelling of the soft parts has been more or less considerable, sometimes the joint remains affected with a weakness, which renders it particularly susceptible of the same accident; sometimes it contracts a stiffness, which renders all motion extremely difficult, and which does not go off till after a very long while; and, indeed, occasionally, such rigidity lasts during life.

In subjects who are well formed, and free from all constitutional disease, it seldom happens that a sprain, even the most considerable, has any other consequences but those which have just now been described. Serious errors in the

treatment, however, and particularly the unmanageableness and imprudence of patients, who fatigue the joint in using it too soon and before the pain is over, may render a sprain very bad even in subjects who are in other respects perfectly sound. In this case, sometimes the pain and swelling, after having undergone a greater or lesser abatement, still continue in a degree, so that a disease, which might have been cured in five or six weeks, lasts five or six months, and frequently a whole year. Sometimes the symptoms get worse instead of becoming better. The pain and swelling occur in the highest degree, and suppuration itself, followed by caries of the bones, may follow, and even create a necessity for amputation in order to save the patient's life.

But symptoms of this violent nature are seldom remarked after sprains, except in subjects who labour under some constitutional disorder, which may extend its effects to the joints. The most common, and at the same time the most afflicting, is scrofula. In patients disposed to this disease, sprains often become the occasional or exciting cause of white-swellings, which too frequently baffle all the efforts of the most skilful surgeons, and make amputation indispensable.

The symptoms which characterize sprains are easy of comprehension. An application of external violence, the nature and direction of which are always known; a more or less acute pain in the affected joint, without deformity, without any manifest alteration in the natural relations of the articular surfaces; a free power of motion immediately after the accident; and a sudden swelling proportioned to the violence of the shock. Such are the circumstances denoting a sprain. A sprain may readily be distinguished from every other affection of the joints. Uninformed practitioners have been known, however, to mistake its nature, and thence do considerable mischief, by ill-judged attempts to remedy a separation of bones, or to reduce a dislocation which never existed. So gross a mistake may easily be avoided by the least attention.

The prognosis of sprains differs according to the degree of the injury, the nature of the joint, and the particular constitution of the patient. A slight sprain is a case of little importance, being generally cured in a few weeks, when properly treated, and when the patient, obedient to the advice of the surgeon, keeps the joint perfectly motionless, and avoids using the limb until the pain and swelling are entirely removed. A violent sprain, occurring to a joint that is strengthened by very strong ligaments, like that of the ankle for example, is a severe case, which often lasts several months, and which, as we have already explained, may have afflicting consequences, when it is badly treated, or the patient does not conform to the advice of his surgeon. Even a slight sprain is always a severe accident in scrofulous subjects, because it may become an exciting cause of a white-swelling, and produce a necessity for amputation.

The treatment of sprains consists in preventing the inflammatory swelling, dispersing it when it has taken place, promoting the union of the torn ligaments, and re-establishing the tone, force, and freedom of motion in the affected joint.

Experience has taught, that cold water is the best application which can be used for fulfilling the first indication. This discutient appeases the pain, and tends to prevent swelling and inflammation. Cold water is rendered more sedative and efficacious, when a little of the liquor plumbi acetatis is added to it. Thus, when a surgeon is consulted immediately after the accident, the part should be immersed in a pail of spring water, into which the liquid acetate of lead has been put in the proportion of a drachm to a pint.

Some practitioners make the quantity greater; but, we believe, what is here mentioned is quite sufficient. In order to derive all the advantage possible from the employment of cold water, the part should remain immersed several hours without interruption, and the water should be changed as soon as it becomes warmed. Boyer does not approve, however, of using this application for women who have their menses on them; or for patients whose lungs are weak, or who are subject to hæmoptysis; or for any persons who are in a great perspiration. Perhaps, in such instances, it may be as well to use a warm linseed poultice.

After the part has been taken out of the water, it is to be covered with linen wet with the same application, and care must be taken frequently to wet the cloths anew, so that they may be as cold as possible, and the evaporation effectual.

When the sprain is slight, discutients are commonly adequate to the prevention of the inflammatory swelling, and they may be continued till the case is quite well. But if the injury be too severe to yield to these means, or should they not have been tried in the first instance, so that tension and swelling have already come on, recourse must be had to the means proper for fulfilling the second indication, that is to say, for dispersing the pain and inflammatory swelling. The patient may be bled more or less copiously according to his age, strength, constitution, and severity of the accident. Low diet and absolute rest are to be directed, and topical emollient anodyne applications are to be made to the part affected; such as linseed poultices, and fomentations of white poppy-heads. When the pain is excessively severe, a small quantity of laudanum, or of a watery solution of opium, may be mixed with the poultice.

The use of these local applications is to be continued as long as the pain and swelling exist; but as soon as they are removed, discutients must be employed; such as camphorated spirit of wine, soap liniment, ammoniated oil, and many kinds of mineral waters.

During the whole treatment, and even a long while afterwards in severe cases, the part affected must be kept strictly at rest. On one hand, moving the joint might keep up the irritation and inflammation; on the other, when the sprain has been considerable and the ligaments lacerated, a firm union of them, and the return of the strength which is essential to the perfect functions of the articulation, can only be obtained by long rest.

When a sprain happens to the ankle, as is most common, the patient should not be suffered to walk before the pain and swelling are entirely removed. As there remains in the joint almost always a weakness, which subjects the patient to the same accident again, when he walks too quickly, or carelessly, it is proper, with a view of obviating this inconvenience, to apply a moderately tight roller to the part, or to direct him to wear for some time a laced soft leather buskin.

It frequently happens, after the cure of a sprain, when the joint has recovered all its strength and freedom of motion, that the surrounding cellular substance is puffy and œdematous, especially in the evening, after the patient has been long in the erect position. The most efficacious means which can be used against this local infirmity, which may continue a long while, is the compression of a bandage, or laced dog-skin stocking.

In other cases, the ligaments, which have been violently distended and lacerated, become rigid, and the motion of the joint remains imperfect. Here fomentations, emollient baths, vapour baths, and oily liniments, are indicated.

Lastly,

Lastly, when the stiffness of the joint resists these means, the efficacy of hydro-sulphurated waters may be tried.

In scrofulous subjects, sprains may be followed by the most severe consequences, as already related, and may become the existing cause of an inveterate disease of the joint. The consideration of the treatment of the disorder here alluded to, will be found in a future article of this publication. (See WHITE-SWELLING.) Boyer *Traité des Maladies Chirurgicales*, tom. iv. ch. 1.

SPRAIN, among horses, and other sorts of live-stock, a violent extension of some tendinous part, by which sudden lameness is not unfrequently produced. It is mostly capable of being removed by saturnine, spirituous, or acid washes, with proper elastic bandages, and a little rest. It often happens in the legs of horses, and some other animals.

SPRAIN, in *Agriculture*, a term applied to the sowing of seeds by hand, signifying to throw them into their places with a single motion of the hand, at a certain distance from one another. It is particularly applied to beans, and some other kinds of seed. Spraying in crops is not unfrequently practised in particular places where labour is cheap.

SPRAINTS, among *Sportsmen*, a term used for the dung of the otter.

SPRANGENBERG, in *Geography*, a town of the principality of Hesse Cassel; 6 miles S. of Lichtenau.

SPRANGER, BARTHOLOMEW, in *Biography*, was the son of Joachim Spranger, a merchant of eminence at Antwerp, and was born there in 1546. As he exhibited an inclination for painting, he was placed as a disciple with John Madyn, a painter of some reputation at Haerlem, and afterwards with Francis Molaert. He then went to Italy through France, and resided some years at Parma as a student, under Bernardino Gatti, who had been a disciple of Correggio. He thence went to Rome, where the cardinal Farnese favoured him with his patronage, and engaged him to paint, in the Villa Caprarola, several landscapes in fresco. By the cardinal he was introduced to the pope, Pius V., who appointed him his painter, and gave him apartments in the Palazzo Belvidere. His first work for his holiness was a picture of the Last Judgment, a composition of five hundred figures, painted upon a copper-plate six feet high. This picture is said to have taken him three years to complete, and to have been, of course, finished with great care; and in consequence of its being highly esteemed by the pope, it was placed upon his tomb, after his decease. The same kind patron commissioned him to paint twelve pictures of the passion of our Saviour, but did not live to witness their completion.

The renown of Spranger now reached the court of Vienna, to which he was invited by the emperor Maximilian II. in 1575, and appointed his principal painter. On that emperor's death in the following year, his successor, Rodolphus II., continued to shew the same favour to Spranger, and engaged him in several works of importance both at Vienna and at Prague; respecting him highly, not only for his abilities as a painter, but also for his literary acquirements, and other accomplishments. In 1588 he was ennobled by his imperial majesty, who honoured him by placing round his neck, with his own hands, a chain of gold, with a medal attached to it. Spranger died at Prague, in 1623, aged 77.

The style of this painter is that which was built upon the defects of Michael Angelo, or rather in the perversion of his style, by a crude and indigested adoption of its most prominent character, without the judicious taste and feeling in which it originated. It was consequently extravagant

and bombastic, presenting inflated muscles, and knobby excrescences for bones, redeemed only in some eyes by a lively fancy, an agreeable facility of execution, and a pleasing colour.

SPRAT, THOMAS, bishop of Rochester, a writer of considerable eminence in the 17th century, was born in 1636 at Tallaton, in Devonshire, where his father was a clergyman. He received his academical education at Wadham college, Oxford, of which Dr. Wilkins was then warden, under whom he acquired a proficiency in mathematical knowledge. In 1657 he was elected a fellow of his college; and on the death of Oliver Cromwell, he gave a specimen of his poetical talents in an "Ode to the happy Memory of the late Lord Protector," addressed to Dr. Wilkins. This ode was followed by one on the "Plague of Athens," which, as well as the former, afforded proof of a warmth and readiness of conception. At the Restoration, like many others, he made a short turn, and atoned for his former delinquency by zealous loyalty, and was made chaplain to the duke of Buckingham, who was his zealous friend and patron. He was chosen a member of the Royal Society, which was then in its infancy, and which had originated from the meetings of the scientific men held at the lodgings of Dr. Wilkins, in Wadham college. In 1667 Sprat published the history of this society, and its foundation; and obtained a high reputation for the elegance of the style and sentiment exhibited in the work. He had published, two years previously to this, "Observations on Sorbiere's Voyage to England," which were well received, and considered as a seasonable castigation of a superficial foreigner who had vilified the country. In 1668 he was editor of Cowley's Latin poems, to which he prefixed a life of the author, in the same language. This he afterwards enlarged in English, and annexed to the English works of that poet. He had now attained a degree of reputation, which, joined to his talents for conversation and society, caused him to be rapidly advanced in the career of preferment. He was successively made a prebendary of Westminster, rector of St. Margaret's, canon of Windsor, dean of Westminster, and finally, in 1684, was raised to the episcopal bench as bishop of Rochester. This last preferment was considered as a reward for the service of drawing up, at the command of the king, an account of the Rye-house plot. This was first printed in 1685, and was reprinted in the following year, after James II. had succeeded to the throne. The manner in which he had executed this task rendered it expedient for him to publish an apology, after the Revolution. He had reflected on the characters of those, whose names have been long ranked among the martyrs to liberty. Of lord Russell, Sprat observes, "that he was carried away into this traitorous conspiracy from a vain air of popularity, and a wild suspicion of losing a large estate by an imaginary return of popery." His favour under the new reign was manifested by his appointment to the place of clerk of the closet to the king, and his nomination as one of the commissioners for ecclesiastical affairs. At the revolution he submitted to the new government, and was allowed to remain unmolested in his see. His principles, however, being well known, he was involved, in 1692, with others, in an information laid before the privy council, of a pretended conspiracy for restoring king James. He detected the infamy of the informers, and effectually cleared himself from the charge; but he was so much affected by the danger he had undergone, that he ever after commemorated his deliverance by annual thanksgiving. He passed the rest of his life in the practice of professional duties and virtues, by which he engaged the esteem and af-

fection of those with whom he was connected, and died in 1713, in the 79th year of his age. Besides the works already mentioned, he published a relation of his examination before the privy council, two letters to lord Dorset, and a volume of sermons. Biog. Brit.

SPRAT, in *Ichthyology*, a species of the clupea, with the lower jaw the longest, and the belly very acute, and the dorsal fin consisting of thirteen rays. See CLUPEA.

The sprat, or *clupea sprattus* of Linnæus, has generally, but erroneously, been supposed a herring not grown to its full size. Its usual length is about four or five inches, and the body much deeper than that of a young herring of equal length; the back fin is placed more remote from the nose than that of the herring: but one great distinction between this fish, the herring, and the pilchard, is the belly; that of the two first being quite smooth, that of the last very strongly serrated; and another is, that the herring has fifty-six vertebrae, this only forty-eight. Besides, sprats visit our coasts, and continue with us in large shoals, when the others, in general, have retired to the great northern deeps. They come into the river Thames, below bridge, in the beginning of November, and leave it in March, and are, during their season, a great relief to the poor of the capital. At Gravesend and at Yarmouth they are cured like red herrings: they are sometimes pickled, and are little inferior in flavour to the anchovy, but the bones will not dissolve like those of the latter. Pennant.

SPRATT, in *Agriculture*, a name applied in some places to a plant, which is found to rise in great abundance, in a spontaneous manner, in most watery situations of the more found boggy kind. It is stated in a paper in the third volume of the "Transactions of the Highland Society of Scotland," that though it abounds much in that part of the kingdom, the proper culture of it is by no means well understood. It should, it is said, be suitably manured for with compost manure, once in three years; or watering sometimes answers the same intention very well, in cases where it is grown for hay; the land being preserved from cattle, or other sorts of stock, from the month of March; and the plants cut for hay in July at the latest. The feeding stalks are also stated to have been mown, after the cattle in pasturage, to benefit.

The spring frosts occasionally, however, destroy some inches of the tops of the plants.

Sheep may safely eat it, without danger of rotting them; and it raises young cattle, it is said, to a great size of bone. But that when suffered to run up to seed, it is not palatable; though cattle not unfrequently get it for hay in that state. Where manure is used, and it is cut in the sap, it constitutes, it is observed, a most excellent and abundant kind of hay for black cattle. In this management, it has been seen ready for the scythe as soon as rye-grass; and one of the best samples of meadow hay seen in the above part of the country was cut in the year 1804, and consisted of spratt and common poa.

Others, however, do not think so highly of it, as it has been noticed in situations in the Highlands, where cattle were often stinted or straightened for food, and generally remained untouched by them. The same has likewise been the case in other places of the above districts.

Its strong root is also thought an objection to its being cultivated as a grass-crop, even if it were capable of it, as being difficult of extirpation.

It has been farther used for making cushions, to be put under the yokes used by oxen in ploughing; for which purpose it seems, it is said, well suited, on account of its toughness. See JUNCUS.

SPRAWL, *To*, in *Military Language*, is to widen out in an irregular and unfoldier-like manner: a term chiefly applicable to the cavalry.

SPRAWLING CHARGE, a loose and irregular movement of cavalry, instead of a close, compact, forward attack.

SPRAY, in *Sea Language*, denotes the sprinkling of the sea, which is driven from the top of a wave in stormy weather. It differs from spoon-drift, as being only blown occasionally from the broken surface of a high wave, whereas the latter continues to fly horizontally along the sea, without intermission, during the excess of a tempest or hurricane. Falconer.

SPRAY, in *Agriculture*, the twiggy branches of any sort of underwood, which are useful for many different purposes. The spray of many extensive woods, in different places, are cut over occasionally for burning lime, &c.

SPRAY-Faggots, such as are made from the spray or small branches, and other offal, of different kinds of wood of the undergrowth kind, and bound up in proper quantities. This sort of faggot, as well as those which are made of furze, and some other inflammable matters, are much employed in burning chalk into lime, in what are called flame-kilns, in some districts, as in Sussex, &c.

SPREADING and setting out Manure, the practice of dispersing and distributing it in or upon land, and putting it on in a proper manner for the purpose. This sort of work is performed somewhat differently on arable or grass-land, and according to the nature of the cultivation. This can never be done in the most proper and complete manner, unless the necessary attention has been bestowed in setting the manure out, to see that it is not deposited in too large heaps, but put out in equal proportions, of a moderate size, at pretty exact distances between the different heaps. In the business of setting out manure to the greatest advantage, the carts employed should be rather small, and conveniently formed for the purpose. With large carts the work is liable to be done not only with much inequality, but in far too large heaps, so that it is done with great trouble and loss of time. Single-horse carts are perhaps, in general, the most useful in this way or intention.

The writer of the corrected account of the Agriculture of the County of Perth, has noticed an ingenious contrivance for facilitating the unloading of carts filled with substances of the manure kind, which is in use in that district. It consists in suspending the box or body-part of the cart at different heights, while it is emptying; but it can only be used with advantage in carts which are constructed on a sort of moveable frame, or those which are denominated coup-carts, and where the load is to be discharged in several different portions. For this purpose a thin piece of iron, of about two inches in breadth, is fixed on the fore-part of the box or body of the cart, exactly in the middle, extending in length to the top or height of the body or box-part, in which are formed and inserted three or four oblong holes, corresponding in size to a rod or pin, which is fixed with a staple in the middle of the first bar that keeps the shafts of the cart together. The length of this rod or pin is mostly about eighteen inches, but longer when necessary, as the height or length of that part of the body or box of the cart which rests on the frame may require. The top part of it is formed into somewhat the shape of a crescent, an inch in width, with the point upwards, which corresponds with the holes in the iron plate. When the rod or pin is not in use, in order to prevent its dangling, it is made to rest on a hook in the front of the box, or body of the cart. When the driver wishes or is desirous to unload a part of

the contents of the cart, he raises the box or body-part of it, putting the rod or pin into the first nick or hole, and makes the first heap; and then moves on to the place or distance where he intends to put down the second, when he again raises the same part of the cart to the second nick; continuing the same method until the whole of the contents be discharged or set out.

In spreading out manure on the surface of arable land, where it is to be turned into the soil by the plough, so much exactness is not necessary; though it should always be done in as even and regular a manner, and to as equal a thickness, as possible. And on ridges, especially where they are rather narrow, care should be taken that it does not fall into the ridge-furrows, by carefully spreading it out at first all along the borders of them in a regular manner. In cases where it is to be placed and spread out in drills or furrows made for the purpose, it should constantly be executed in as even a manner, in regard to thickness, as it will readily permit, and in a way which will allow of its being covered in as completely as possible, as it is equally wasteful and disgraceful to have it presenting itself externally.

In spreading different sorts of materials of the manure kind over grass-land, it is always necessary to see that the work be performed in an exact and even manner, as well as that all the lumps and clods be well broken down, and as much reduced as possible, by beating them with the fork or shovel, or in some other way. On arable as well as grass-land, as favourably dry a season as can be obtained should mostly be chosen for this sort of work. In wet seasons, the materials clog and hang about the feet and tools of the workman, and are never capable of being so divided as to be spread out with the necessary degree of evenness and regularity, especially on grass-land. On this sort of land, when the heaps have been set out, they should never be suffered to remain so long as is too frequently the case, before they are spread out, as the grass-plants underneath them become blanched and tender, and are liable to be destroyed; great injury being often done to the surface or sward, in such cases. In spreading manure from the carts, injuries of this nature are likewise prevented, as is found in the midland and some other districts, where the practice prevails; but in this mode, it is probable, the work can neither be performed in so perfect a manner, nor with so much economy of time and labour. In this manner, the inconvenience of hill or heap-steads will, however, be avoided; and, of course, the disadvantage of their getting too large a proportion of manure guarded against and prevented.

The tools mostly employed in this sort of work are those of the dung-fork and the shovel, but others are occasionally used for particular sorts of manure.

After the substances of this kind have been spread out in this manner on grass-land, they may often be farther usefully reduced and distributed, by passing a bush-harrow over them a few times in a dry season, some weeks after the spreading has been performed.

Where manure, in its more recent or fresh state, is employed either on arable or grass-land, more attention will be necessary in spreading it out over or into the land, so that it may be done in an even and perfect manner. See *YARD-DUNG*.

SPREE, or **SPREME**, in *Geography*, a river which rises on the frontiers of Bohemia, crosses Lusatia, enters the marquisate of Brandenburg, and, after passing by Berlin, joins the Havel at Spandau.

SPREMBERG, or **SPREHENBERG**, or *Grodtk*, a town of Lusatia, on the river Spree, which gives name to a circle, or district; 29 miles S.S.W of Guben. N. lat. 51° 32'.

E. long. 14° 25'.—Also, a town of Saxony, at the source of the Spree; 28 miles E. of Dresden.

SPREMONT, a town of France, in the department of the Ourte, seated on a brook which runs into the Ourte, and together with a small country, called the "Ban of Spremont," insuladed within the bishopric of Liege; 13 miles S.W. of Liege.

SPRENDLINGEN, a town of France, in the department of the Rhine and Moselle; 8 miles E. of Creutznach.

SPRENGELIA, in *Botany*, received that name from the writer of this article, in honour of Mr. Christian Conrad Sprengel, master of a grammar-school at Spandow, in Brandenburg, who published at Berlin, in 1793, a most ingenious work, on the manner in which insects promote the impregnation of plants. This fact is illustrated by several hundred particular examples, accompanied with figures of each. Dr. Curtius Sprengel, now Professor of Botany at Halle, may also claim his share of botanical commemoration in the above name. His *Prodromus* of a work on the arrangement of Umbelliferous Plants, published in 1813, to say nothing of his letters on Cryptogamic Vegetables, and his edition of the *Philosophia Botanica* of Linnæus, may well entitle him to such distinction.—Sm. in the Stockholm Transactions for 1794, 260. t. 8. Tracts relating to Nat. Hist. 269. Willd. Sp. Pl. v. 1. 833. Ait. Hort. Kew. v. 1. 320. Brown Prodr. Nov. Holl. v. 1. 554. (Poiretia; Cavan. Ic. v. 4. 24.)—Class and order, *Pentandria Monogynia*. Nat. Ord. *Ericæ*, Juss. *Epacridæ*, Brown.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, chaffy, coloured, in five deep, equal, lanceolate segments, erect after flowering, permanent. *Cor.* of one petal, wheel-shaped, beardless, in five very deep equal segments, the length of the calyx. Nectary none. *Stam.* Filaments five, inserted into the receptacle, linear, flat, smooth, shorter than the corolla; anthers vertical, oblong, parallel, more or less combined, of one cell. *Pistl.* Germen superior, roundish, depressed, with five furrows; style simple, cylindrical, about as long as the stamens; stigma obtuse. *Peric.* Capsule somewhat cylindrical, obtuse, with five furrows, of five valves and five cells, the partitions longitudinal, from the centre of each valve. *Seeds* numerous, roundish, minute, inserted into the angles of the central column, which is shorter than the valves.

Ess. Ch. Calyx in five deep segments, permanent, coloured. Corolla wheel-shaped, in five deep segments, beardless. Stamens inserted into the receptacle. Anthers converging or combined. Nectary none. Capsule of five valves and five cells, the partitions from the middle of each valve.

1. *S. incarnata*. Flesh-coloured Sprengelia. Sm. Tracts, 272. t. 2. Willd. n. 1. Ait. n. 1. Br. n. 1. Andr. Repos. t. 2. (Poiretia cucullata; Cavan. Ic. t. 343. Lamarek Dict. v. 5. 449.)—Anthers combined, hairy. Calyx entirely coloured. Points of the leaves elongated.—Native of Port Jackson, New South Wales; found also by Mr. Brown in Van Diemen's island, and on the south coast of New Holland. Messrs. Lee and Kennedy raised the plant in 1793, and in their greenhouses it still flourishes, flowering from April to June. This is a pretty and singular shrub, about two feet high, rigid and much branched, leafy, ever-green, very smooth; the branches round. Leaves alternate, sheathing, sometimes imbricated in three ranks, recurved, lanceolate, acute, concave, entire, very smooth, rather glaucous, without rib or veins, tawny when faded, and finally loosened at their base, so as to turn round on the branch. *Stipulas* none. *Flowers* terminating the numerous, short, crowded, lateral branches, clothed with smaller leaves,

leaves, and making a very pretty appearance. We do not find that they have any scent. *Calyx* rose-coloured, half an inch in diameter. *Corolla* and *filaments* flesh-coloured. The name of *Poiretia*, given by Cavanilles, was not published till three years after our *Sprengelia*.

2. *S. montana*. Mountain *Sprengelia*. Br. n. 2.—“Anthers unconnected, beardless. *Calyx* partly coloured. Points of the leaves short.”—Gathered by Mr. Brown in Van Diemen’s island. We have seen no specimens of this species.

Mr. Brown’s *PONCELETIA* (see that article), as well as his *Anderfonia*, Prodr. Nov. Holl. v. 1. 553. Ait. Hort. Kew. v. 1. 321, seems very nearly related to the present genus, both in aspect and character.

SPRETZA, in *Geography*, a river of Bosnia, which runs into the Bosna.

SPREWIL, a town of North Carolina, on the south coast of Albemarle sound. N. lat. 35° 56'. W. long. 76° 39'.

SPRIG, a small eye-bolt, ragged at the point.

SPRIG is also a small branch or spray. It likewise signifies a brad.

SPRIGE, in *Geography*, a township of Ohio, in the county of Adams, containing 1664 inhabitants.

SPRIGNO. See *SPIGNO*.

SPRING, *FONS*, in *Natural History*, a fountain or source of water, rising out of the ground.

The origin of springs or fountains has been much controverted among our late naturalists. Messrs. Mariotte and Perrault ascribe them to rain, to which others have added dew; their doctrine is, that the rain-water penetrates the earth till such time as it meets a clayey soil, or stratum; which proving a sufficient solid bottom to sustain and stop its descent, it glides along it that way to which the earth declines, till meeting with a place, or aperture, on the surface, through which it may escape, it forms the head of a river.

Now, that the rain is sufficient for this effect, appears hence; that, upon calculating the quantity of rain and snow which falls yearly on the tract of ground, that is to furnish, for instance, the water of the Seine, it is found that river does not take up above one-sixth part of it.

Springs ordinarily arise at the bottom of mountains: the reason, they say, is, that mountains collect the most waters, and give them the greatest descent the same way: and that if we sometimes see springs on high grounds, and even on the tops of mountains, they must be brought from other remoter places considerably higher, along beds of clay, or clayey ground, as in their natural channels. If, then, there happen to be a valley between a mountain on whose top is a spring, and the mountain that is to furnish it with water, the spring must be looked on as water conducted from a reservoir of a certain height through a subterraneous channel, to make a jet of an equal or somewhat less height.

This theory M. de la Hire (Parisian Mem. for 1703) has taken under examination, in its most essential article, and that where the authors seem to have been the least distrustful. He has endeavoured to find by experiment, whether rain or snow-water could penetrate the earth as low as the clayey stratum: with this view he procured a leaden vessel eight feet deep, having a pipe at the bottom: this he buried in the earth, and filled with soil of sand and loam, exposing the surface to receive all the rain that fell. After fifteen years’ trial, he found that no water had run through the pipe at the bottom. Again, he took another vessel, eight inches deep, which he filled with earth, and exposed in like

manner. No rain penetrated so as to run out at the bottom from June to February; but after that time it yielded a quantity after most rains. Another vessel of twice the depth, or sixteen inches, gave a result much like that of eight inches. When herbs were planted in this last-mentioned vessel, he found that as soon as ever any of these came up, and were grown to any bulk, so far was the rain that fell from being able to gather itself at the depth of sixteen inches, that it was not sufficient even to feed the plants, but there was a necessity for watering them.

With respect to the first-mentioned fact, says Mr. Dalton, (Manchester Memoirs, vol. v.) we need not wonder that no water penetrated through eight feet of earth at Paris, where the annual rain is but 20 inches, when only eight or nine inches penetrated through three feet of earth here, where the rain is 33 or 34 inches annually. But it does not follow, that rain may not descend down declivities of the ground into vallies or lower parts, at Paris as well as here, and being accumulated, may penetrate into the earth to a considerable depth, especially if it meet with channels or chafms of any kind, or declining strata of earth, that are impenetrable by water. Paris, Mr. Dalton believes, however, is not very liberally supplied with springs, as might be expected. As to the experiment upon vegetation, it only proves that the rain in spring and summer is sometimes not sufficient to support vegetable life, a fact which may readily be granted; but then in his experiment the plants were precluded from a supply of moisture from the earth beneath the vessel, which is a reserve of the utmost consequence in dry seasons.

This circumstance of water ascending again in the earth, on whatever principle it is effected, cannot be denied. There were four inches and three-quarters of rain here in July last, none of which passed through the earth in the evaporating vessel; this earth, however, at the end of the month, was far from that degree of dryness which is unfit for the support of vegetation. During the first four days of August there fell about three inches of rain, and only half an inch penetrated through the earth in the evaporating vessel. Consequently three feet in depth of earth that was moderately moist imbibed nearly three inches of rain, before it was saturated; whence we may conclude, that three inches nearly had ascended and been evaporated. This evidently shews, that earth is capable of holding a very great proportion of water, that in summer the water ascends to supply the exigencies at the surface, and that earth far under the point of saturation with moisture is still fit to support vegetation.

This observation suggested the following question—How much water is there in a given depth of earth, when the soil is at the point of saturation, or in that state, when it begins to yield water from the lower pipe of the evaporating gauge?

To determine this, Mr. Dalton took a quantity of garden soil, that had been soaked with rain a day before, and pressed it into a crucible; in this state he found its specific gravity to that of water, as five to three. It was then exposed to a moderate heat, till it appeared, as near as he could judge, of the same moisture as garden soil two inches deep in dry summer weather; afterwards it was exposed almost to a red heat, till it became a perfectly dry powder; in the former case it lost one-twelfth of its weight, and in the latter one-third. When it had lost one-sixth, it did not appear too dry to support vegetation. When it had lost two-ninths, it appeared like the top soil in summer. Hence it follows, that every foot of earth in depth, so saturated, contains seven inches of water, and that it may part with a quarter

SPRING.

a quarter of its water, or even a half, and not be too dry for supporting vegetation.

Clay, just dug out for the purpose of making bricks, was tried in the same manner. It gave the same specific gravity as the earth, and yielded not much less water.

These experiments and observations prove, that M. de la Hire's conclusions, drawn from the vegetation of plants in a given quantity of soil, precluded from any communication with the earth at large, are erroneous, or at least unwarranted; as it does not thence appear, that the evaporation for the whole year exceeds the rain in the year, whatever it may do for a month or two in summer.

The origin of springs may still, therefore, be attributed to rain, till some more decisive experiments appear to the contrary.

Upon the whole it should seem, that at the commencement of spring, the ground is nearly saturated with water for five or six feet in depth, as the rains and dews in autumn and winter far exceed the evaporation. There are then five or six inches of water at least to be raised up again to the surface in case of exigence in the spring and summer. If this happen to be so, then it is at the expence of springs; for we find the generality of springs become languid, or entirely cease to flow at the end of a long drought. As to the few springs that seem to be little affected by dry or wet seasons, they form exceptions, which it would not be difficult to account for. See EVAPORATION.

Dr. Halley refers the origin of springs merely to vapours raised by the heat of the sun, or of subterraneous fires, from the sea, lakes, rivers, &c.

Now, to shew that vapour is a sufficient fund to supply all our springs, rivers, &c. the same excellent author makes an estimate of the quantity of vapour raised from the Mediterranean sea, by the action of the sun: for the result of which, see VAPOUR.

Yet the quantity of water thus raised, great as it is, is only the remains of what is raised another way; *viz.* by the winds, which sometimes sweep the water off much faster than the sun takes it up.

To find, now, the quantity of water the Mediterranean receives, allow the most considerable rivers it receives, *viz.* the Iberus, Rhone, Tiber, Po, Danube, Neister, Borysthenes, Tanais, and the Nile, each to furnish ten times as much water as the Thames; not that any of them are in reality so great, but so to allow for the lesser rivulets; but the Thames is found, by calculation, to evacuate 20,300,000 tons of water daily. All the nine rivers above-mentioned, therefore, will only evacuate 1827 millions of tons in a day; which is little more than a third of what is raised in that time in vapour. The whole Mediterranean, according to calculation, is computed to contain 160 square degrees, yielding at least 5280 millions of tons. (Phil. Trans. N^o 189. or Abr. vol. ii. p. 110.) For a more correct estimate by Mr. Dalton, see RIVER.

The prodigious quantity of water remaining, Dr. Halley allows to rains, which fall again into the seas, and for the purposes of vegetation, &c. As to the manner in which this water is collected, so as to form reservoirs for the different kinds of springs, it seems to be this: the tops of mountains, in general, abound with cavities and subterraneous caverns, formed by nature to serve as reservoirs; and their pointed summits, which seem to pierce the clouds, stop those vapours which fluctuate in the atmosphere, and being condensed by them, they precipitate in water, and by their gravity easily penetrate through beds of sand and lighter earth, till they are stopped in their descent by more dense strata, as beds of clay, stone, &c., where they form

a basin or cavern, and work a passage horizontally, and issue out at the sides of the mountains. Many of these springs discharge water, which running down between the ridges of the hills, unite their streams, and form rivulets or brooks; and many of these uniting again on the plain, become a river.

After all that can be said in favour both of rain and vapour, it must be owned, they are both still encumbered with great difficulties; though by no means insuperable.

The perpetuity of divers springs, always yielding the same quantity of water, when the least rain or vapour is afforded as well as the greatest, is a strong objection to both. Dr. Derham mentions one in his own parish of Upminster, which he could never perceive by his eye to be diminished in the greatest droughts, even when all the ponds in the country, as well as an adjoining brook, had been dry for several months together; nor ever to be increased in the most rainy seasons, excepting perhaps for a few hours, or at most for a day, from sudden and violent rains. Had this spring its origin from rain or vapour, there would be found an increase and decrease of its water corresponding to those of its causes; as we actually find in such temporary springs as have undoubtedly their rise from rain and vapour: add to this, another considerable thing in this Upminster spring, and thousands of others; *viz.* that it breaks out of so inconsiderable an hillock, or eminence, as can have no more influence in the condensation of the vapours, or stopping the clouds, than the lower lands about it have. The very highest ground in the country he finds is not above a hundred and thirty-three yards above the level of the sea; and what is such an inconsiderable rise of land, to perennial condensation of vapours, fit to afford so considerable a spring? or the high lands of the whole country, to the maintaining all its fountains and rivulets?

Other naturalists, therefore, have had recourse to the sea, and derive the origin of springs immediately thence; but how the sea-water should be raised up to the surface of our earth, and even to the tops of the mountains, is a difficulty, in the solution of which they cannot agree. Some fancy a kind of hollow subterranean rocks to receive the watery vapours raised from channels communicating with the sea, by means of an internal fire, and to act the part of alembics, in freeing them from their saline particles, as well as condensing and converting them into water. This kind of subterranean laboratory, serving for the distillation of sea-water, was the invention of Descartes. (Princip. part iv. § 64.) Others, as M. de la Hire (Mém. de l'Acad. an. 1703), &c. set aside the necessity of alembics, and think it enough that there be large subterranean reservoirs of water at the height of the sea, whence the warmth of the bottom of the earth, or even the central fire (if there be such a thing), may raise vapours; which, pervading not only the intervals and fissures of the strata, but the bodies of the strata themselves, at length arrive near the surface; where, being condensed by the cold, they glide along on the first bed of clay they meet with, until an aperture in the ground lets them out. M. de la Hire adds, that the salts of stones and minerals may contribute to the detaining and fixing the vapours, and converting them into water. But we have a still more natural and easy way of exhibiting the rise of the sea-water up into mountains, &c. by putting a little heap of sand, ashes, a loaf of bread, or the like, into a basin of water; in which case the sand, &c. will represent the dry land, or an island; and the basin of water the sea about it. Here the water in the basin will rise to or near the top of the heap, in the same manner, and from the same principle, as the waters of the sea, lakes, &c. rise in the hills. The principle

principle of ascent in both is accordingly supposed to be the same with that of the ascent of liquids in capillary tubes, or between contiguous planes, or in a tube filled with ashes; all which are now generally accounted for from the doctrine of attraction. See RIVER.

Against this last theory, M. Perrault and others have urged several unanswerable objections. It supposes a variety of subterranean passages and caverns, communicating with the sea, and a complicated apparatus of alembics, heat and cold, &c. of the existence of which we have no sufficient proof. Besides, the water that is supposed to ascend from the depths of the sea, or from subterranean canals proceeding from it, through the porous parts of the earth, as it rises in capillary tubes, ascends to no great height, and in much too small a quantity, to furnish springs with water, as M. Perrault has sufficiently shewn. And though the sand and earth through which the water ascends may acquire some saline particles from it, they are nevertheless incapable of rendering it so fresh as the water of our fountains is generally found to be. Not to add, that in process of time, the saline particles of which the water is deprived, either by subterranean distillation or filtration, must clog and obstruct those canals and alembics by which it is supposed to be conveyed to our springs, and the sea must likewise gradually lose a considerable quantity of its salt.

In speaking of the situation of the earth, as connected with the formation of springs, Dr. Darwin has observed, that it consists of strata, many of which were formed originally beneath the sea. The mountains were afterwards forced up by subterraneous fires, as appears from the fissures in the rocks of which they consist, the quantity of volcanic productions all over the world, and the numerous remains of craters of volcanoes in mountainous countries. Hence it is contended, that the strata which compose the sides of mountains lie slanting downwards, and that one or two, or more, of the external strata not reaching to the summit when the mountain was raised up, the second or third stratum, or a still more inferior one, is there exposed to day; this may be well represented, it is said, by forcibly thrusting a blunt instrument through several sheets of paper, a bur will stand up with the lowermost sheet standing higher in the centre of it. On this uppermost stratum, which is colder as it is more elevated, the dews are condensed in large quantities, and sliding down, pass under the first or second or third stratum, which compose the sides of the hill; and either form a morass below, or a weeping rock, by oozing out in numerous places, or many of these less currents meeting together, burst out in a more copious rill.

But that, as the springs consist of the water which slides down between those inclined strata; it is evident that, in some eminences of ground they are only to be met with on one side of the mountain; and in other eminences of ground, on all sides of it. In searching for springs, therefore, attention should be given to the inclination of the strata of that part of the country, which may be often seen in marle-pits, gravel-pits, or in hollow lanes. But they may in general be found above any moist or morassy place, or valley; the moisture of which shews that springs exist in the strata on that side of the hill or mountain. And another observation for the purpose of detecting springs, may, it is said, be made on misty evenings; as those parts of the ground where the mist commences, are moister than those in their vicinity on the same level, and in consequence may generally, if they are not hollow basons, possess springs nearer the surface; for these moister parts of the ground, having evaporated more during the day, are become colder on their surfaces than the drier ground in their vicinity; and in misty evenings,

which are at the same time calm, the stationary air over these moist parts of the ground is also more loaded with the evaporated moisture; and on both these accounts, these moister situations are liable to shew a condensation of aerial vapour sooner than other places on the same level. And there may be other causes of springs in the nature of hilly situations, for as mountains are colder in proportion to their height, 1st, their being in a manner insulated or cut off from the common heat of the earth, which is always of 48° , and perpetually counteracts the effects of external cold beneath that degree, may be one cause. 2. From their surfaces being larger in proportion to their solid contents, and hence their heat more expeditiously carried away by the ever moving atmosphere. 3. The increasing rarity of the air as the mountain rises. All those bodies which conduct electricity well or ill, conduct the matter of heat likewise well or ill. Atmospheric air is a bad conductor of electricity, and thence confines it on the body where it is accumulated; but when it is made very rare, as in the exhausted receiver, the electric aura passes away immediately to any distance. The same circumstance probably happens in respect to heat, which is thus kept by the denser air on the plains from escaping, but is dissipated on the hills, where the air is thinner. 4. As the currents of air rise up the sides of mountains, they become mechanically rarefied, the pressure of the incumbent column lessening as they ascend. Hence the expanding air absorbs heat from the mountains as it ascends. 5. There is another, and perhaps more powerful cause, it is suspected, which may occasion the greater cold on mountains, and in the higher parts of the atmosphere, and which has not yet been attended to; it is meant that the fluid matter of heat may probably gravitate round the earth, and form an atmosphere, which may diminish or become rarer, as it recedes from the earth's surface, in a greater proportion than the air diminishes. And the greater condensation of moisture on the summits of hills has another cause, which is the dashing of moving clouds against them; in misty days this is often seen to have great effects on plains, where an eminent tree, by obstructing the mist as it moves along, shall have a much greater quantity of moisture drop from its leaves, than falls at the same time on the ground in its vicinity. Hence it is concluded, as suggested above, that the evening mist commences sooner on them than in the valleys, but is seen earlier in the situations over the moister places, if they are on the same level with the drier ones, exactly as on the plains or valleys; and may therefore indicate the existence of springs, unless these moister places consist of hollow basons, containing water, which, if not attended to, may in all situations deceive the observer. And further observations for detecting springs may be made in rimy mornings; for as moist earth is a better conductor of heat than dry earth, the rime will sooner melt on those parts of the soil which are kept moist by springs under it than in other parts; as the common heat of the earth, which is 48° in this country, will sooner be conducted upwards in moist places to dissolve the rime on the surface. On this account the rime is frequently seen on frosty mornings, when the heat of the air is not much above 32° , to lie an hour longer on dry cakes of cow-dung, or on bridges, or planks of wood, than on the common moist ground, as the latter much better conducts the common heat of the earth to the incumbent rime which is in contact with it. But as the heat of the common springs in this country is 48° , where they exist, the rime is sooner dissolved than on the stagnant moisture of bogs or morasses. It is therefore concluded, that the common cold springs are thus formed on elevated grounds by the condensed vapours, and hence are stronger when the nights are cold, after hot days

days in spring, than even in the wet days of winter. For the warm atmosphere during the day has dissolved much more water than it can support in solution during the cold of the night, which is thus deposited in large quantities on the hills, and yet so gradually, as to soak in between the strata of them, rather than to slide off over the surfaces, like showers of rain. The common heat of the internal parts of the earth is ascertained by springs which arise from the strata of earth too deep to be affected by the heat of the summer, or the frosts of winter. Those in this country, as has been seen, are of 48° of heat, those about Philadelphia were said by Dr. Franklin to be 52°. Whether this variation is to be accounted for by the difference of the sun's heat in that country, according to the ingenious theory of Mr. Kirwan, or to the vicinity of subterranean fires, is not yet, it is thought, decided. And in the winter months, the rise of springs may be detected in moist ditches by the presence of aquatic plants, as of the water-cress, water-parsnip, brook-lime, &c.; as in those ditches which become dry in summer these plants do not exist; and when those ditches with springs in them are nearly dry, it may be discovered which way the current has formerly descended, by the direction of the points of the leaves of aquatic plants, as certainly as by a level; an observation which was learnt from Mr. Brindley, the great canal conductor of Staffordshire.

The proper application of these principles may lead to many useful conclusions, both in respect to agriculture and rural economy, and is a sort of knowledge which those engaged in the providing of water for wells or pits should be well acquainted with. See DRAINING, WATER, and WELL.

For the method of preventing or remedying the injury done to land by springs, &c. see SPRING-Draining.

SPRINGS, *Different Sorts of.* Springs are either such as run continually, called *perennial*; or such as run only for a time, and at certain seasons of the year, and therefore called *temporary* springs. Others, again, are called *intermitting* springs, because they flow and then stop, and flow and stop again; and *reciprocating* springs, whose waters rise and fall, or flow and ebb, by regular intervals, which are also called "ebbing and flowing wells." In order to account for these differences in springs, let A B C D E (Plate XV. *Hydraulics*, fig. 7.) represent the declivity of a hill, along which the rain descends; passing through the fissures or channels B F, C G, D H, and L K, into the cavity or reservoir F G H K M I; in this cavity let there be a narrow drain or duct K E, which discharges the water at E. As the capacity of the reservoir is supposed to be large in proportion to that of the drain, it will furnish a constant supply of water to the spring at E. But if the reservoir F G H K M I be small, and the drain large, the water contained in the former, unless it is supplied by rain, will be wholly discharged by the latter, and the spring will become dry; and so it will continue, even though it rains, till the water has had time to penetrate through the earth, or to pass through the channels into the reservoir; and the time necessary for furnishing a new supply to the drain K E, will depend on the size of the fissure, the nature of the soil, and the depth of the cavity with which it communicates. Hence it may happen, that the spring at E may remain dry for a considerable time, and even whilst it rains; but when the water has found its way into the cavity of the hill, the spring will begin to run. Springs of this kind, it is evident, may be dry in wet weather, especially if the duct K E is not exactly level with the bottom of the cavity in the hill, and discharge water in dry weather; and the intermission of the spring may continue for several days. But if we suppose

X O P to represent another cavity, supplied with water by the channel N O, as well as by fissures and clefts in the rock, and by the draining of the adjacent earth; and another channel S T V, communicating with the bottom of it at S, ascending to T, and terminating on the surface at V, in the form of a *siphon* (which see); this disposition of the internal cavities of the earth, which we may reasonably suppose that nature has formed in a variety of places, will serve to explain the principle of reciprocating springs. For it is plain that the cavity X O P must be supplied with water to the height Q P T, before it can pass over the bend of the channel at T, and then it will flow through the longer leg of the siphon T V, and be discharged at the end V, which is lower than S. Now if the channel S T V be considerably larger than N O, by which the water is principally conveyed into the reservoir X O P, the reservoir will be emptied of its water by the siphon; and when the water descends below its orifice S, the air will drive the remaining water out of the crooked channel S T V, and the spring will cease to flow. But in time the water in the reservoir will again rise to the height Q P T, and be discharged at V, as before. It is easy to conceive, that the diameters of the channels N O and S T V may be so proportioned to one another, as to afford an intermission and renewal of the spring V at regular intervals. Thus, if N O communicates with a well supplied by the tide, during the time of flow, the quantity of water conveyed by it into the cavity X O P, may be sufficient to fill it up to Q P T; and S T V may be of such a size as to empty it, during the time of ebb. It is easy to apply this reasoning to more complicated cases, where several reservoirs and siphons, communicating with each other, may supply springs, with circumstances of greater variety. See Muschenbroeck's *Introductio ad Phil. Nat.* tom. ii. p. 1010. *Desag. Ex. Phil.* vol. ii. p. 173, &c.

We shall here observe, that Desaguliers calls those *reciprocating* springs which flow constantly, but with a stream subject to increase and decrease; and thus he distinguishes them from *intermitting* springs, which flow or stop alternately.

It is said, that in the diocese of Paderborn, in Westphalia, there is a spring which disappears twice in twenty-four hours, and always returns at the end of six hours with a great noise, and with so much force, as to turn three mills not far from its source. It is called the *bolder-born*, or *boiliterous* spring. *Phil. Transf.* N° 7. p. 127.

There are many springs of an extraordinary nature in our own country, which it is needless to recite, as they are explicable by the general principles already illustrated.

Springs are farther divided into *oozing* or *weeping* springs, where the water gently trickles through the pores of the land; *pipe* springs, where they appear in a single rill; and *wall* springs, where the water issues, as it were, through the joints of a wall. But besides these, springs have many other local names, which serve to distinguish them in their particular situations, where they break out in grounds. See SPRING-Draining.

SPRINGS, *Burning, or Boiling.* The burning spring near Grenoble, in Dauphiné, is famous. St. Augustine speaks of it as extinguishing lamps which are lighted, and lighting those which are extinct. But it is now cold, like others; only near it is a spot of ground, which still emits a light flame; over which some imagine it might anciently have passed. *August. de Civ. Dei*, lib. xxi. cap. 7, and 11. *Mem. Acad. Inscript.* tom. ix. p. 565. *Mem. Acad. Scien.* an. 1699, p. 26.

At Boseley, near Wenlock, in Shropshire, there is a famous

mous boiling well, which was discovered in June 1711, by an uncommon noise in the night, so great, that it awakened several people, who being desirous to find what it was owing to, at length found a boggy place under a little hill, not far from the Severn; and perceiving a great shaking of the earth, and a little boiling up of water through the grafs, they took a spade, and digging up some part of the earth, the water flew to a great height, and was set on fire by a candle. This water was for some time afterwards constantly found to take fire, and burn like spirit of wine; and after it was set on fire, it would boil the water in a vessel sooner than any artificial fire, and yet the spring itself was as cold as any whatever. Phil. Transf. No. 334.

This well was at length lost for many years, and not recovered till May, 1746, when by a rumbling noise under ground, like to what the former well made, it was hit upon again, though in a lower situation, and thirty yards nearer the river.

The well is four or five feet deep, and six or seven wide; within that is another less hole of like depth, dug in the clay, in the bottom of which is placed a cylindric earthen vessel, of about four or five inches diameter at the mouth, having the bottom taken off, and the sides well fixed in the clay, rammed close about it. Within the pot is a brown water, thick as puddle, continually forced up by a violent motion, beyond that of boiling water, and a rumbling hollow noise, rising and falling by fits five or six inches. It may be fired by a candle at a quarter of a yard distance; and it darts and flashes in a violent manner, about half a yard high. It has been left burning forty-eight hours, without any sensible diminution. It may be extinguished by putting a wet mop upon it, which must be kept there a small time. On the removal of the mop there succeeds a sulphureous smoke, lasting about a minute, and yet the water is very cold to the touch. Phil. Transf. No. 482, sect. 6.

SPRING, *Lancarim*. See LANCARIM.

SPRINGS, *Medicinal*. See WATER.

SPRINGS, *Artificial*, those kinds of springs, or collections of water, which are made by art in different views and intentions, by the farmer and land proprietor.

The methods of proceeding in these sorts of undertakings may be those of making a sufficient number of under-drain springs for the purpose of the above kind, in different directions, so as that they may unite in one, at or near their terminations in the wells or cisterns, as, in these ways, the water may be drawn from a much larger space of ground than would otherwise be the case, and, of course, better supplies of water be afforded.

Country-houses and residences may sometimes be supplied with good water in somewhat this way, where there is either a deficiency in the quantity or quality of that which is provided. A very distinguished proprietor in the county of Berks, E. L. Loveden, esq. of Buscot Park, had recourse, it is said, to the following very ingenious and successful contrivance, in order to accomplish this purpose, which deserves to be particularly noticed, as it may be applicable to many other situations, where the scarcity of water, or of such as is good, is felt. It is stated in the Agricultural Report of the above district, that, the seat of this proprietor standing near the very brow of the eminence on which it is built, there was only a superficies of about an acre and a half of grass-land in front, from which there was not the least descent. A semicircular drain with a mole-plough, scarcely perceptible on walking over the ground, in the line of the greatest elevation, was made to communicate with two small iron grates on the side of the gravel-drive up to the principal front. All the water which falls on this drive passes to one

or other of those grates, between which there is an underground drain, with a very moderate fall to that which is the most westerly, where a channel commences which is capable of receiving all the water within the compass of the semicircular drain, and which passing through proper strainers, is conveyed to a large sunk reservoir, in a court to the westward of the mansion; and a pump being placed there, the family is supplied, it is said, with a pure soft water, no less salutary than useful for every domestic purpose.

Springs of the above artificial kind may likewise be applicable in many other cases, where there is a want of water for particular uses.

SPRINGS, *Land*, such of the more superficial kind as rise and exist in situations where the collecting surface of the water, together with the containing stratum, are of a rather small and confined extent. They are often met with about the bases of hilly lands, on slopes, at the feet of the little risings in valley tracts, in their variously mixed banks, as well as in many other situations and circumstances of land. The term is also sometimes applied to the drains which are made by art for the procuring of water for different purposes.

They are always such as are of the more superficial kind. The writer of the work on "Landed Property" considers these springs as partial effects, partaking of the nature of cold, or of weak lands, according to the quality of the soil that covers them. They may, it is said, be considered as the most common disease of land where water is concerned.

It is supposed that the causes of these sorts of springs are mostly of a topical nature, the disease being commonly produced by rain-water falling on an absorbent soil which has a broken sub-stratum. A broad, flat-topped swell of sandy or gravelly loam, beset with plots or masses of clay, is, it is thought, singularly productive of this sort of watery lands. The means of remedying the injurious wetness arising from these kinds of springs, are shewn in speaking of spring-draining. See SPRING-Draining.

SPRING-Drain, that sort of drain or channel which is prepared and constructed in land for the purpose of taking away such kinds of over-wetness in it, as is caused by internal or other springs. These drains are made in many different methods, according to the nature and circumstances of the grounds, and the degrees of the wetness which are present in them; but, for the most part, in a deeper and more substantial manner than in the other modes of forming drains.

Drains of this sort are constructed of many different kinds of materials, but mostly of those which are of the more solid and durable descriptions, such as the common brick, bricks made in different forms and shapes for the purpose, pipes made in different ways, flat stones of the free-stone and other kinds, common stones laid in different modes, and some other similar substances. Where common bricks are employed, they are often built in a firm manner on the sides and arched over the tops, but in other cases laid lengthwise over each other to the necessary height, and then covered over with flat stones, and the earth filled in upon them. They have also other modes of construction, which are sometimes much less expensive, according to the nature of the drainage, as will be more fully seen and explained in speaking of surface-drains. But where bricks made for the purpose are used in these cases, other methods are followed. There are many different forms of bricks contrived in this intention; one of which is so constructed, as to form, when laid, a small neat arched drain four inches in diameter, and is principally made use of where only small drains are necessary, as in the conveying of the water of
springs

SPRING.

springs to houses and other buildings, &c. A second sort is made of three pieces, so as to constitute a square drain six inches in width and height; and a third kind is formed with a circular opening six inches in diameter, having long square openings in the top part, and light parts two inches in breadth, to rest upon, on the sides. It was invented by Mr. Couchman, of Bosworth Temple, in the county of Warwick. The two last sorts are well suited for forming large drains, but more especially the latter. In stiff soils, they are for the most part best when laid singly, without any common bricks or tiles being placed underneath them; but in light sandy lands, it is mostly better to lay common bricks, or strong tiles, under their sides, in order to prevent their sinking down into the soil too much. See *SPRING-Draining*.

Another sort of bricks that may be employed in this way, it is supposed, with still greater advantage than the above, has been invented by John Ashworth of Turton, near Bolton, in the county of Lancashire. These are contrived in different forms and shapes, so as to be laid in different manners, and form different sorts of openings. When they are placed in such a manner as to constitute a sort of inclosed triangular opening for the discharge of the water from the land, eighty-four bricks are required to every eight yards; while with common bricks, one hundred and ninety are necessary. There is consequently a saving, by this means, of one hundred and six bricks in every eight yards of draining that is performed. By another form of these bricks, laid so as to slant against each other, without any thing under them, fifty-five bricks are only necessary for draining eight yards in length; and, of course, one hundred and thirty-seven bricks are saved in that extent. In another form in which these bricks are laid, which represents a sort of inclosed diamond-formed opening, one hundred and ten bricks of this kind are taken to complete the same length of drain, by which eighty-two bricks are saved. This form is, however, only necessary where the quantities of water to be carried off, or taken away, are very large. In a further different form and manner of laying these bricks, the same number are made use of as in the first case, and the saving of common bricks is in the same proportion. A farther still different form and manner of laying these bricks, employs them in the same proportion as in the third case, and saves common bricks in the same extent. This is particularly useful in the drainage of boggy, swampy, soft lands, and where quicksands are present. There is yet another form and manner of laying these bricks, which saves common bricks in the same manner as in the second of the above cases. And there is, lastly, a still different form and manner of laying these bricks, which takes them in the same quantities as in the third and fifth cases above, and consequently saves common bricks in the same proportion as they do. See *SPRING-Draining Bricks*.

It is not improbable but that bricks for this purpose may have been invented by other persons, in different other districts, which may answer well for forming spring-drains in different cases. See *SURFACE-Drain*, and *SUBSOIL Brick-Drain*.

Drains formed of these materials, though they are commonly very effectual for the purpose, are in general attended with considerable expence.

Large pipes formed of burnt clay, and some other sorts of materials, are not unfrequently employed in the making of drains of this nature, as well as in some cases for those of the surface kind.

Where stones are made use of in constructing drains, for the purpose of carrying off the water of springs, there are

several different modes of laying them. They are sometimes built up on the sides, to the necessary heights and widths, by the smaller stones, and then covered over the tops, and connected by the large flat ones of the freestone, limestone, or other similar kinds: at other times, the flat stones, whether of the freestone, limestone, or other sorts, are set up edgeways in the bottoms of the drains, in a kind of triangular manner, or, which is better, in somewhat the form of the reverted letter A, the latter being laid over on the tops with broad flat stones. These constitute excellent cheap drains.

There are also several other matters of this nature, as those of the flaggy and slaty kinds, which may be used for this purpose, with equal advantage in different situations. See *SURFACE-Drain*.

It has been suggested, that in constructing main drains of this sort for carrying off and discharging the water of springs, besides the particular consideration of the nature of the soils through which they are to be cut and formed, which is constantly to regulate the whole of the future operations, processes, and works about them, where they are of a loose gravelly quality, or of the nature of a quick or running sand, the round or barrel form of drain, when turned with either common bricks or stones, the *lower* half being laid in mortar, and the *upper* half dry, may probably be the most effectual as well as the most durable of any that can be had recourse to, in such cases. In most instances, also, of drains for carrying away wetnesses of this kind, the outlets of them, where the water is discharged, should be well secured in some way or other, in order to prevent any injury that might be sustained by the force of the passing current of the water out of them.

As the common openings of the foughs or passages in these drains are mostly about six inches square, a piece of wood of that size, and about one yard in length, is often found very useful for laying in the bottoms of the drains, while forming, for building the stones or other materials on each of the sides of it, and which is capable of being drawn or shifted forward, as the workman proceeds in completing the foughs or drains.

The different tools used in forming and cutting drains are described under their proper heads.

The making of drains of this nature, in some districts and places is termed *foughing*, especially when they are formed with some sort of hard materials, such as bricks, stones, or other similar substances, and is a method of spring-draining which is very commonly had recourse to by the drainer. See *SOUGH* and *SPRING-Draining*.

SPRING-Draining, the removing of that sort of wetness in land, which is caused by, or which arises from, springs, in its internal or other parts, in the manner already explained under the article *DRAINING of Land*.

Its practice principally depends upon the discovery of the main springs in the different cases, upon the proper taking of their levels, and upon making use of such means as are capable of drawing off the water in particular instances, without the expence of too much cutting; as, without finding out the *main* spring, or cause of the mischief, nothing effectual can, it is said, be done; or without taking the exact level of it, and ascertaining the *subterraneous* bearings which it may have; as where the drains, in such cases, are cut even a very small distance beyond the lines of the springs, the water which issues from them can never be reached; whereas by exactly ascertaining those lines, by the practice of levelling, the springs can be cut off in an effectual manner, and the land be rendered dry in the least expensive and most eligible method. The superabundant

wetness of the land, where necessary, may be taken away, where the depth of the drains do not reach it, by making use of implements of the auger kind, so as to bore down, and tap or let off the water of the springs which lie still lower.

It is constantly necessary in this, as well as other kinds of draining, to pay great attention to the direction or mode of conducting the drains, and likewise to the application of the tools which are employed for tapping or drawing off the springs. It is perhaps principally in the superiority of management in these respects, that the excellence of Mr. Elkington as a drainer of land consists. But though the mode of tapping springs by means of the auger, and letting off the water from the bottom parts of the drains, without the trouble and expence of more cutting and digging, was unquestionably brought to practical perfection by this able drainer, its use for other similar purposes had long been known and experienced; as it has been asserted, that in attempting to discover mines by means of this tool, springs have been tapped, and the adjoining wet grounds, in consequence, drained or laid dry, either by letting the water down into a porous substratum below, or giving it a vent and exit at the surface. The same tool has also been employed in bringing water into wells, by boring with it in the bottoms of them, to save the expence of more digging. This is supposed to be the case more especially in Italy, where it is probable that the practice is of great antiquity, as Buffon has stated in his Natural History, that in and about the city of Modena, whatever part is dug, when the depth of sixty-three feet is reached, and five feet deeper bored with this tool, the water springs up with such force, that the well is filled in a very short space of time. It is likewise noticed, that, in these cases, the tool often bores through large trunks of trees, &c. which give great trouble to the workmen. This is consequently a tool which is not only well calculated for the purposes of spring-draining, in many instances, but for a great variety of different other rural uses and applications.

The porous rocky chalks are excellent conductors of water, it has been observed, where they have only a thin covering of an absorbent loamy material, as they imbibe, after the surface-soil has been saturated, every particle of water that may come upon them in the form of rain or otherwise. This is seen to be the case in many hilly situations formed chiefly of such matters, in the south-west parts of the kingdom, as in the counties of Wilts and Dorset. The water which is absorbed and taken up by so porous a substance as chalk, it is said, soon escapes the power of evaporation, and continues to descend, in the manner of that which passes through a filtering-stone, until it meet with an impervious or non-conducting stratum or layer, upon which it collects; and if this surface, on which it is collected, should lie above the level of the sea, or other collection of water, it forces its way out, in the manner of a spring, or more copious fountain; not always in one constant stream, but often periodically: the springs of chalk-hills differing, in this respect, from those of the more open conducting kinds; which is a fact, it is thought, that is entitled to be more fully and philosophically investigated. The action or operation of the waters of chalk-hills, it is suggested, is most clearly seen on the sea-coasts, where the bases of the chalk-cliffs rest upon an impervious or non-conducting stratum or bed, which being softened and worn away by the impression of the waters collected upon it, the cliffs are undermined, and the faces of them thrown down. Where the base of the chalk dips beneath the surface of the sea in low tides, the whole collection of water regains its "native home," it is said, unseen. And it is not doubted but that

much rain-water, passing through other strata, finds its way to the sea in a somewhat similar manner.

Rocks of the open kind, it is supposed, when they are examined as conductors of subterraneous water, will be found to have various effects in producing the necessity of this sort of draining, according as there may be a difference in their natural properties. Sand-rock, where it is present, always acts, in the manner of chalk and loose sand, as a filter, letting the water freely through it. There are many different parts of the kingdom in which it is found in considerable quantity and extent, the surface-soil being mostly dry in quality. Where the rock is of the nature of slate, from being of an argillaceous or clayey quality, it is often in a high degree impermeable to water; but as it in general abounds with cracks, fissures, and still finer crevices, especially near the surface, water readily finds its way into it, and either filtrates or percolates slowly through it, or finds a vent and exit in the clefts or separations of the masses; and, collecting in such parts, forces its way to the surface, as a spring; or continues to descend, until it meet with a more compact stratum, which dips towards the face of some hill or shelving ground, where, reaching the surface or outer limits of the rock, it either forces its way through the soil, and feeds a fountain, or, if the quantity of water is too small, or the thickness and texture of the soil are too powerful to permit it to escape in a body, spreads itself beneath the surface materials or thicker covering, and produces watery land. A shelf of slate-rock, under these circumstances, operates, it is believed, as a stratum of sand or gravel. Rocks of this nature are common to many different parts of the country, as to the counties of Devon, Cumberland, and Westmoreland, to Wales, and the western Highlands of Scotland; being, it is imagined, peculiar to the more western parts of the island.

Limestone rocks, which are most various in texture and arrangement of parts, are met with in many places as a substratum of soils. The soft and granulous kind, of which the Cotswold hills may be said to be composed, as well as those which arise in the environs of the city of Bath, and which are found in some places in Yorkshire, Northamptonshire, and probably in some other parts of the kingdom, is of a porous absorbent texture; water acting upon it as upon chalk. But the more ordinary sort of limestone, which may be said to be met with in almost every department of the kingdom, is of a more close texture. It is, however, commonly either divided and parted out into large blocks, or broken into fragments, though sometimes found distributed in continuous masses. Still more frequently, the blocks seem as if they had been thrown together in a fortuitous manner into their present situations, being separated by irregular interspaces, either filled with earth, or other fossil substances, or forming open fissures, cracks, and chasms of different widths; and, in a few known instances, form caves or openings of extraordinary dimensions. This class of limestone rocks may, it is supposed, without risk, be considered as the most free and extensive conductor of internal waters of any in this country. There are other kinds of this sort of rocky substrata, which have directly the contrary quality and effect in respect to the distribution of water in soils.

The next sort of material, which displays the most simple explanation of the effects which are produced by water falling or coming upon land, is that of sand, and especially where the lands are of the deep sandy kind, such as the county of Norfolk is chiefly composed of; sand, it is remarked, being of a more open and porous nature than chalk, and the hills formed by it, or the more depressed masses of it,

it, being in general of much less depth than those of that substance, the effect is more quickly produced. Presently after a glut of rain, the springs, in these cases, are said to fly out. Besides, there is another difference, which is more interesting, it is thought, to the present inquiry, between the effects produced by chalk and by sand, as conductors of rain or other water. Chalk, for the most part, throws it out from the sides or at the bases of the hills formed by it, in clear streams, producing no other effect on the surfaces of the lands than that of forming channels of conveyance for it to the rivulets or brooks, to which the particular cast of surface may incline them. The waters absorbed or drank up by chalk-hills seldom occasion, it is said, any thing of the nature of upland bog, unless when they rise in the area of a flat-based valley, or are impeded and obstructed therein, and by spreading and stagnating over its surface, encourage the growth and decay of aquatic plants. On the contrary, sand-hillocks are, it is said, singularly productive of this baneful disease of land; owing, in part, it is supposed, to a want of uniformity in their internal structures, as well as of an evenness of base, when compared with chalk hills, which generally rest on impervious strata of clay; and likewise owing to the openness of the texture of the sandy material, which suffers the contained waters to spread out and distend themselves freely in every direction.

Gravel is more porous, or conducts water still more freely, than sand; and is mostly found in thin strata or veins, but sometimes in detached masses, though very rarely in extended hills. In some situations it is free from the admixture of any sort of earthy matter. In this condition it conducts water as a pipe; or when embanked with impervious matters on every side, contains it as a cistern. When a stratum or layer of subterranean gravel, or any other free conductor, is supplied with, or has descending waters coming upon it, it either conducts them to the surface, leads them to a fountain, or, when the surface is too strongly guarded to allow of their escape, stores them up, and confines them in quantity beneath the soil. Where the gravel is partially deposited in veins, and the covering is thin, and of an absorbent or porous quality, the water, wherever it approaches the surface, fills every pore of the soil, and though unable to break its way out in a stream, as a strong spring, occasionally trickles and percolates through it; thus encouraging the growth of supraquatic plants; which, being too gross and unpalatable for pasturing stock, fall where they have grown, and, during a succession of ages, raise detached mounds of vegetable earth; partaking, like the moory basins of sand-hill vallies, of the nature of morafs.

If the containing stratum or bed be more generally and evenly spread beneath the soil, and where this is of an absorbent porous quality, and moreover so thin as to be easily permeable, as well as lying nearly level, a large extent of ground may, it is said, be rendered worthless,—may become a mere morafs, or extended bog. But if, under these circumstances, the land lies with much descent, the lower side only will be much affected. Further, if the soil or covering, though of an absorbent porous nature, be conjointly of a sufficient thickness and texture to prevent the contained waters from rising to the surface, an uniform breadth of cold weak land will be produced. Where the covering is not only thick, but impervious or non-absorbent, so as to prevent the depressed waters from rising to the roots or feeding fibres of field-plants, lands of a valuable quality are met with: even when in the state of perennial herbage, the finer grasses are, it is said, produced; but that, owing to the coolness which subjacent waters communicate to the soil, in the early spring, vegetation is more backward, and the

produce less than it would be, if the cause of the coolness were removed by this mode of draining. Land of this description is met with extensively, and in great abundance, on the slopes, and at the bases of the rising grounds, in almost every vale-district of the kingdom.

Pebbly matters, which are a common substratum of land, it is said, in the more mountainous parts of the country, act in a similar, but more complete manner; being a still more free conductor of subterranean waters than gravel.

The manner in which chalk conducts subterranean water to the sea, without injury to the surface of the land, is seen above; and open rock, sand, gravel, or any other porous or conducting material, either singly or in conjunction, have the same effect, when they form a free and continued connection between it and the surface of the open absorbent lands. But the same substructure, when situated at a distance from the shore, and cut off from all subterranean communication with the sea or other waters, by the intervention of impervious or repellent matters, produces widely different effects; and is capable of doing much mischief to the lower lands which more immediately invest it, as well as to those close around it. In these circumstances, the subsiding waters, unable to find a passage downwards, fill every fissure, crevice, and pore; continuing to collect, until the surface of the embodied waters reaches some friendly porous stratum, to conduct the overflow horizontally towards some open outlet; or until the collection has gained a sufficient ascendancy and weight to break its bounds, and force its way to the surface, or blend with the superficial waters. The bottom of a lake, or the channel of a deep-sunk river, first offers the means of relief, in many cases; and it is not unusual to see spring-waters curling at the surface of a deep river-pool. In many situations, it is supposed probable that rivers receive larger supplies from their own beds than is evident to the eye of common observation. Where the river-bed is shut against them, the impounded waters naturally continue to rise, until they reach an open stratum of the lands on its banks, and thus effect their escape. Where no such conducting stratum offers itself, deep cleft dingles and narrow dells, branching out of the rivered valley, or wider vale, may, it is said, be considered as the next places calculated for giving vent to rising waters: and here they are not uncommonly found boiling up through beds of sand or gravel, or the shattered fragments of rock; and by spreading, in a state of nature, over the base of the dell, give rise to moory grounds; or issuing from its banks, give birth to a more active stream. No deep sunk dell occurring, or any absorbent stratum of the vale lands being ready to receive the internal waters, or, having received them, being unable to give them vent, by reason of their being closed on their lower margin or border, the surface of the embodied waters necessarily continue to rise above the base of the hill, until, having reached a proper conductor, a spring or fountain is formed; or meeting with a descending substratum of absorbent or porous matter, it enters it with the effect of descending waters, and produces different sorts of wetness according to circumstances. On extensive continents, and even in the interior parts of this island, instances of a similar nature must necessarily, it is said, frequently occur.

It may be also noticed, that it must likewise not unfrequently happen, that waters which have been absorbed by the porous materials of high lands are checked in their descent, before they reach the base of the hill or mountain which has imbibed them; in the interior of which, it is more than probable, minor reservoirs are formed by rising waters, and there act in a similar manner to those which are
formed

formed at a greater depth. The perpetual springs which may be said to be every where issuing from the sides of hills, are strong evidences, it is thought, in favour of such a position. For what, it is asked, but an extended surface of embodied waters, could send forth these *constant*, and, in some instances, almost *uniform* streams? A lake, it is well known, thus regulates the stream which flows from it. But to produce this effect, it is not requisite, it is supposed, that the lake should be formed in the interior of a mountain. It matters not what the receptacle is, provided it be of sufficient extent, and its several parts, if anomalous, have a free communication with each other; whether it be a cave, an extended series of fissured rocks, or an extensive stratum of gravel, or any other freely conducting material, the surface of the water will be equally level, and equally capable of regulating the supplies received, so as to discharge an uniform or a moderated stream; as the wide naked waters do, which are seen to spread on the surface in mountain situations. A sudden shower does not sensibly affect, it is said, the overflow of a lake, nor does a heavy fall of rain cause a sudden flood; as it does where there is no such extent of surface to regulate the supply: nevertheless, after much rain, and still more after a long continued wet season, the overflow is increased, and the stream enlarged. And precisely so, it is said, are these sorts of springs or fountains affected.

The marles which abound in calcareous matter are mostly of an open, porous, and absorbent nature, and not unfrequently form the substrata of lands in different places, which may receive and hold water, in some cases so as to let it break out and produce springs on the surface, which are highly injurious to the soils. Some marles are, however, of an impervious and retentive quality.

There are also some sorts of materials which are highly impervious under some circumstances, but which become porous or open in others, as clay in certain states; this, however, has little to do with the nature of spring-draining. See *DRAINING of Land*.

In laying down the general principles and theory of draining land under its proper head, the manner in which the principal agents and causes which operate in the production of springs are capable of producing such effects in different circumstances, has been particularly explained, though the great internal springs which supply the intersecting rivers of countries have not been touched upon, as they have not yet been by any means sufficiently investigated or explored; and besides, they mostly lie at such great depths, as not to affect the surface, consequently have nothing, or very little, to do with the present inquiry.

Draining, on the principle of removing springs, not only produces extraordinary effects in the laying of the lands dry which are near to them; but in causing springs, in wells, wet grounds, and other places, at very considerable distances, to become dry, though they had no evident communication or connection.

Drainage of Boggy, Morassy, Swampy, and other wet Land, produced by Springs.—See *BOG* and *DRAINING of Land*, under which articles this subject is discussed as far as our limits will allow.

A pump has been lately contrived by Mr. Wakefield, the ingenious drainer of Trafford and other moorles in Lancashire, for ascertaining the lines of springs in this sort of draining, which is said to answer well. See *SPRING-Draining Pump*.

In many cases of this sort, it may be known, it is said, whether the channel of the water lie deep or not, by the appearance of the surface. Where the land is dry imme-

diately above the place where the water springs up, it is an evidence that the channel or reservoir lies deep, and that the water is forced up so as to issue in a perpendicular manner; but, on the contrary, where the land is wet for some distance above the principal outlet of the spring, it is a sure sign that the water is flowing in a channel near the surface, and that the *overflowings* of it cause this wetness. It will be a certain evidence of this, if there be only one spring in the wet ground; but if the internal strata do not lie horizontally, or regularly, and several springs appear, arising from water running in different channels, the land above the largest or principal spring may be wet, not from the *backing-up* of that spring, or its channel being near the surface, but by the breaking out of the lesser springs in their *descent*, the channel of the waters of which has thus found a vent and exit to and out of the surface, higher than that of the larger spring. It is in cases of this kind that draining is attended with most difficulty; and where all the cutting and other matters necessary cannot be so easily ascertained at first, until such time as what is absolutely requisite be executed, which will lead to the discovery of what further is wanted, and in what manner it should be accomplished, by exposing to view the subsoil, or under strata, in which the water flows. The making of *exploratory bores* with the auger, is, it is said, useful in this and all other difficult cases.

Where, in such cases as the above, there are different lines of drains cut one below another, from the highermost springs between the wet and dry land, not of such depth as to catch and intercept the water all the way down the slope, as formerly practised, however they may be filled with loose stones, though they may render the surface drier while they continue to run, they soon choke up, and bursting out in different parts, the land soon becomes equally, if not more wet, than it was before they were made, and so formed out. It is more difficult to drain this ground a second time, even in the proper manner; as the surface, by means of the former drains, being so much altered from its natural appearance, the true situation of the springs cannot so easily be hit upon, and the frequent bursts of the old drains increase the perplexity in no small degree. It frequently happens that the uppermost, where they are the *strongest* outlets, are the *main* springs, and those below only *leakages*; which implies, that some of the water from the main spring finds a passage through some opening in the *upper soil*, near the surface, and breaks out lower than the main spring, when it meets with resistance from any bed of clay: by cutting off the main spring, this of course becomes dry; therefore the same caution is necessary to ascertain this before proceeding to mark out the drain or drains in such cases, as from the *main spring only* the level must be taken. In irregular banks, where the ground, owing to the perpendicular situation or pressure of water behind, has *slipt*, or fallen down, the drain must be carried higher up the declivity than where the water has its apparent outlet, to the found ground that has undergone no change, and where the *real* spring will be intercepted; the water in the *slipt* sand below being only leakages from that above, but which is apt to deceive in cutting the upright trench, or that which is made from the outlet up to the cross one, along the line of the springs. When the main spring rises in a steep bank a considerable height above the level of the brook or place where the drain is to discharge itself, it is unnecessary to cut a deep trench, or to lay a covered drain, all the way from the brook up to it; for the descent being too rapid, and if deep cut by crossing veins of sand, that are always met with in such situations, the bricks or stones with which the *fough* or conduit of the drain is laid, would be undermined by

by the rapidity of the current, which would also carry down a great quantity of the loose sand; but it should be begun only so far down the bank, as, by *cutting in level*, the drain may be six or seven feet lower than the outlet of the spring, or whatever depth is necessary for drawing down the water to such a level as it may discharge itself without rising to the surface, or injuring the ground adjoining it. The remaining part of the cut, down to the brook, either in a straight or sloping direction, may be left open, and need not be deep, but guarded from the cattle, and from the plough when the field is in tillage. If covered, it need not be deeper than two feet; and there is no occasion for boring in any part of it.

When there may be any difficulty in ascertaining the exact line of the spring and that of the cross-drain, where it does not *appear* on the *surface*, or when there is no apparent outlet from whence to take the level, in bringing up the leading drain for carrying off the water, it can be then discovered when it crosses the proper line, and without cutting any farther up, the cross-drain must be carried on that level, so far to each side, along the *tail* or termination of the rock or sand containing the water, as the situation of the ground and other circumstances may require. And if, in cutting the cross-drain, the line marked out by the spirit-level should be found in some places to be below that of the springs; and if in boring along that line no water be found, then small cuts must be made, of the same depth, from the drain up to where the spring lies; for if the drain be cut *below* the line of the spring, all possibility of reaching it, even by the auger, is lost, as boring can have no effect where the substratum is clay, and where there is no *under* water; and if it be cut *above* the line of the spring, it will require deeper cutting and boring to reach it, as there, for the most part, the ground rises higher, and that part of the porous strata below the drain may contain as much water as may injure the ground, and which may easily pass under the bottom of the trench, between the auger-holes, and find vent below it. If the expanse of the valley or bog betwixt two banks be so narrow, that the stratum of rock or sand containing the springs, unites within reach of the auger below the clay, one trench up the middle, with auger-holes, will do the business, without any cross or branch-drains. Although the springs that injure ground in this situation break out of the banks all round nearly on the same level, yet the reservoir from whence they proceed may, it is said, be hit on in the middle of the valley, by boring through the superincumbent body of clay that forces the water to rise and ooze out along the upper edge of it, at its junction with the higher porous ground. The drain being cut in the hollow part of the ground, and the spring below bored into, it is evident that the depth of the drain being so much lower than the natural outlet of the springs, the pressure of water above that level, which is the bottom of the drain, will force that under the trench through the auger-holes; or even for some time, until the water subside, it might be made to rise higher than the level of its natural outlet. The consequence of this will be, it is further said, that the water of the spring having found, by means of the drain and boring, a new and easier channel, will soon abandon its former outlets, and cease to overflow the ground that formerly lay below it. Many remarkable instances of this sort of drainages are stated to have been performed by Mr. Elkington in different places, and particularly at Scarisbrick-Hall, near Ormskirk, in Lancashire.

However, bogs, or wet grounds of the same nature in similar situations, may, it is supposed, proceed from different causes, and, of course, require different sorts of treatment

in the removal of their wetnesses. In such cases, the first thing to be considered, in examining the ground, is, whether the springs proceed from one side only, from both sides, or lie in the middle of such bogs; as, according to the nature of these circumstances, the line or lines of the drain or drains must be directed. In order to properly ascertain this, it will be necessary to have recourse to the use of the spirit-level. If the bog should have a descent from one side to the other, although the wetness may appear all round, it will be evident that the water proceeds only from the higher side, but passing over and under the surface, part of it is absorbed by the dry ground along the lower side; from whence, if the level were not previously ascertained, it might be supposed also to proceed. In this case, one drain cut along the upper side will be sufficient to keep it dry. If the bog should have a descent from both sides to the middle, or be perfectly level, the springs may proceed from both sides; and will, consequently, require a drain on each, if they do not unite in the same stratum below the middle of the bog, and can be hit on by boring in one drain cut in the centre, as already shewn.

In case a bog of this nature between two hills is of great extent, it may be requisite to have three different drains; one on each side, and one in the middle; which last must be an open one, to receive the whole of the surface-water, as well as to cut off any springs that may arise in that part of the bog. In all cases of this nature, where there is any difficulty of discovering from whence the principal springs proceed, or what is the nature and inclination or disposition of the substrata, the application of the auger may be had recourse to for the purpose.

But in very wet swamps, or bogs of great extent, it is necessary to have other cuts than those that carry off the springs: for although the upper springs, which are the principal cause, be cut off, there may be veins of sand or gravel lower than those, out of which it is also necessary to extract the water. If the ground is to be divided into inclosures, the open ditches may be so directed as to hit on these lower collections of subjacent water, as well as to carry off any that might stagnate in the hollow parts of the surface. The next thing to be considered in this sort of draining is the conducting of the drain, after the levels have been taken, and the true line of it fixed; and whether it should be covered or open. If the land is to be inclosed, and as the line of the trench may serve as a proper division of the ground, it may be made an open cut, or sunk fence; if not, a covered drain: but it is first necessary to ascertain which, as the depth, width, and other circumstances, may be regulated accordingly. After finding the nearest outlet, where the water collected in the drain can be discharged, from that a trench must be brought up to the cross one that is to be carried along the line of the spring, allowing a small declivity of a few inches in every ten yards, for the water to run. In cutting the drain that is to carry off the spring, if, after passing the clay, there be a stratum of hard gravel betwixt that and the sand containing the water, it is preferable to lay the *fough* there, being a more solid foundation for it, and either to perforate the gravel with the *punch*, or open small pits through it with the spade; by means of which the water will flow up, and run as speedily off, and with more safety, than if the fough had been laid in the sand itself; which would not only increase the depth and difficulty of working it, but in many cases the level of the orifice will not admit of the drains being cut to such depth. Also, if, in cutting the trench along the tail of the rock, the level of the orifice will not admit of its being cut so deep as to touch the rock, the clay or impervious stratum that lies immediately

above it must be bored through, when the water will flow up through the fissures of the stone, and through the auger-holes, into the fough; but it is preferable, in cases where the level will admit, to dig the drain through the clay, and so far into the rock as will furnish stones for laying the fough; and then the water will meet with less resistance, and have a freer issue, than if the stone had not been opened or broken. This will increase the expence of cutting the drain, but lessen that of quarrying the stones elsewhere, and of carrying them to the place where the drain is made. Although in the ground to be drained there may be a ditch, or other old water-course, in which it may be practicable, by means of boring, to *tap* the spring, yet it is better to make a new trench, in which the water of the spring only can have admittance; and where this must cross any ditch or old water-course, it must be secured by *puddling* with clay, or be conveyed in a *wooden trough*, so as not to receive any surface-water: which, by being augmented in time of floods, might soon blow up and destroy the fough. As the water thus obtained by means of boring may be converted to several useful purposes, as those of irrigation, serving small mills, canals, houses, fish-ponds, pastures, fields, &c. caution is necessary in using the auger, lest the water procured in one part of the drain may be lost at another, in the same manner in which it was found; and, in the endeavouring to procure a greater supply, it may by that means be let *down* from a *wet*, into a *dry, porous substratum*, as will be seen in its proper place.

Such are the chief objects that require consideration before beginning to cut the drains: the following directions will be useful in guiding the execution of them. If the drain is to be cut through a soft boggy soil, it is better to be open than covered, especially where it may receive other water than that collected from below, and can at the same time serve as the side of an inclosure or division betwixt the upland and low grounds. Stones laid in such drains are soon apt to sink, owing to the softness of the bottom, and the fough may also be soon choked up. The width of a covered drain may be from three to four feet at top, and one and a half or two feet wide at bottom, thus allowing six or nine inches for each side-stone, and six inches between, for the passage of the water, forming a square conduit, or what is termed the fough, being also six or nine inches in height. Or, when the quantity of water collected, or to be conveyed in the drain, is small, it may only be coupled at the bottom. This is a considerable saving, both in materials and labour, requiring much fewer stones, and a great deal less time in laying them. It is equally secure when the bottom is solid, the stones good and properly laid, being well packed at the sides, to prevent them from shifting. It is also a saving in cutting the drain, as it requires less width at the bottom for this manner of laying the stones, than it does for a square conduit. In most cases, however, where circumstances are favourable, the other method should be preferred. The depth is regulated by the level of the place where the drain is to empty itself, and the nature of the ground through which it is cut, which is commonly four or five feet, and never less than three. Where the drain is only to act as a conductor for the water which is brought up by the borer where the soil is *all* clay, its depth may only be three feet, which will be sufficient to allow a proper depth of earth above the stones laid for the conduit at bottom, which need not exceed, nor should ever be less than one and a half or two feet. Drains are sometimes seen, in ground apparently very wet on the surface, cut to the depth of three and even four feet, and several hundred feet in length, without any water being collected by them; but when the borer

has been applied, and holes put down at the distance of six yards apart, and eight or ten feet deep, a considerable stream of water has been procured, and which has continued to flow. In a particular instance, a drain has been directed to be cut in a very retentive clayey soil, which, at the depth of four feet, met with no water; which gave occasion to the workmen to say, and the proprietor to think, that he was laying out his money to very bad account; but they were soon convinced to the contrary. As the drain had a smooth and uniform slope in the bottom, in order to expedite the work, several men were employed to lay the stones, beginning at the *lower* end, and proceeding upwards, while others were engaged in boring at the *upper* end, to proceed downwards. When those below began their work, the drain was quite dry, and had no appearance of water, either from the sides or bottom; but by the time they had proceeded a few yards, and two or three holes were made above, an unexpected stream of water made its appearance, to their no small astonishment; and which has since had the effect of laying dry a piece of very wet land. This fully shews, that without the use of the auger in similar cases, many drains may be cut to an extensive depth, without effecting the desired end, or without making any material change in the appearance of the land.

In soft boggy soils it is often necessary, where the drain is to be covered, to cut to a much greater depth than in other cases, or to the bottom of the moss, in order to have a secure foundation for the stones, as a great part of the water is constantly lodged between the moss and the next stratum. In digging the drain, it is best to cut the whole length to the depth of two or three feet, at which there is no danger of its falling in; and when the ground near it by that means has become more firm, and the stones have been laid down by the side of it, then cut to the depth required. In this way the stones are at hand, and ready to lay so soon as the proper depth is dug, and the laying should be begun at the upper side, proceeding downwards, smoothing and clearing the bottom of the drain. By this means, the fall of the water will be seen and kept, as there is a danger, when the work is begun at the lower end, and laying upwards, in level ground, of digging too deep in clearing the bottom, and thereby causing a stagnation of water and sludge in the fough, which ought to be carefully avoided. The turf, in opening the drain, should be first pared off thin, and laid to one side for after use, and all the mould thrown out to the other. The most difficult part of the work is laying the fough in running sands, where it is necessary to have the sides of the trench supported with flat boards and props, which are removed forwards as they proceed in working, and which keep the sides from falling in, and the loose sand from falling amongst the stones with which the conduit is laid. If the fough or conduit be laid with brick, a small aperture must be left betwixt each, to admit the water from the sides of the drain, and the thin turves must be laid above, grass-side downwards, to prevent the mould from getting through the openings. The turves are laid grass-side downwards, *immediately* above the *stones*, without any loose stones above the laid ones, as the water is all collected from the bottom of the drain, very little from the sides of it, and none admitted from the top; unless in such cases as where the stratum containing the water, or that may receive it in time of rains, is cut through to a greater depth than the height of the conduit, then small stones must be laid above the conduit or cover stone, to the height of such stratum, or as far up as the water appears to ooze out. These small stones admit the water to subside through their interstices to the conduit or fough below, and
thus

thus prevent the bad effects that would otherwise proceed from its confinement to near the surface. In quick or running sands, turves must also be laid at the bottom of the drain, under the fough, to prevent the loose sand from flowing up, and to render the foundation of brick or stone more secure in case of their sinking. Before boring, it is proper to lay the side-stones of the conduit; after which the holes may be put down, at the distance of every four or six yards. But if the water, on withdrawing the auger, rush up with violence, and continue to have a boiling appearance, it indicates a strong body of water confined below, and, consequently, requires a great number of openings to give it a speedy and sufficient vent. When the force of the water is great, the width of the holes enlarges, and consequently the discharge is increased. By a careful examination of the adjoining ground, it is sometimes possible to say at what depth the stratum containing the spring lies, and consequently how deep the *bores* must be made; but the general rule is to go down until the water rise immediately on withdrawing the auger. Thirty feet have been bored down before the water flowed in a full and free manner; but about from ten to fifteen feet may be said to be the average depths of boring. One case is stated, in which, after boring thirty feet, the water issued in a quantity equal to *three* hogsheds in a minute, by which a great extent of wet ground in the vicinity was drained. In these sands, it is also better to dig a little into the sides of the trench, off the line of the fough, where the auger is to be used, and, after boring, to cover the places in the same manner as the rest of the fough, leaving out a side-stone opposite the hole, as the sand thrown up by the spring can thus be more easily taken out with the hand till it subside and give over running, and is likewise off the main current, coming down the middle of the drain. That part of the fough above the auger-holes should be left uncovered till the sand is all thrown up, and the openings clear; but, till then, the sand must be taken out, and the fough may afterwards be covered up with safety. Above some of the auger-holes, or at any other convenient part of the drain, a kind of funnel may be built to the top of the trench with a flat stone laid over it, whereby it can at any time be looked at to see if the issue is clear, and if the quantity of water diminishes or increases. When the circumference of the auger-holes is not sufficient to let up the quantity of water which the springs would otherwise issue, where it is not far from the bottom of the trench to the stratum containing the water, and where there is a bed of hard gravel intervening, impenetrable by the auger, holes must be dug with the spade, down to the spring, and these holes filled up with loose stones; first putting down a round stake in the middle, which, after the stones are filled in, must be drawn out, which leaves an opening for the water to flow up. No apprehension need be entertained of the holes made by the auger being filled up, whether the drain be open or covered, provided no other water is admitted; for such is often the force of the spring, that it will throw up any earth or other sludge that may accidentally get into it; and it can be injured only by the admission of great quantities of surface or flood-water coming up on it at once. When flat stones can be got, they are preferable to brick for this use; but there are several kinds of brick besides the common sort invented and used only for the purpose of draining, in several parts of the kingdom, where the expence of stone would become greater. When small drains are wanted, and when the water is to be conveyed to a house, &c. that which is of the arched form is commonly made use of. For larger drains, those of the square, hollow, pantile form are well adapted, especially the latter. They are laid single,

without one reversed under; for when that is done, the water running on the under one occasions a kind of sludge, which in time becomes so encrusted on it, as totally to obstruct the passage of the water, and render the work useless in a few years. In clay bottoms they may be laid single, or without any thing under; but in soft sandy bottoms, a common building brick should be laid under each side to prevent them from sinking down, and be so laid as to form a regular arch, by the side-bricks being laid with an equal height, the better to support the pressure above from breaking them. They may be constructed in the above shape to any dimensions, suitable to the quantity of water the drain is to convey.

Although the earth that is thrown out of the drain should, when filled in again, be considerably higher than the surface of the ground on each side, it must remain so; for in a year or two it will subside to the level of the surface on each side. What remains may be spread or laid in some adjoining hollow; for, if levelled at first, the earth immediately above the drain sinks down, and the rain by that means lodging in the hollow and subsiding downwards, may injure the fough, by carrying part of the surface of the earth along with it.

While the drain is cutting, in very wet peaty soils, the surface-water, or what may ooze from the sides before coming to the spring, must be stopped here and there; and when let out to run through the fough, a turf or bunch of grafs must be laid so as to prevent any sludge which it may bring down from running through along with it, as this might choak the laid part of the drain and stop the passage of the water. When trees, especially ash, happen to be in the course of the drain, they must be entirely grubbed up, otherwise the roots will get into the fough, and expanding through the joints of the stones, will soon put a stop to the passage of the water. When the water issued by the drain becomes of a red ochrey colour, it indicates a stagnation either from the above cause, if amongst planting, or from some part of the fough having fallen in; which should be speedily repaired, otherwise the grounds will soon become equally wet as before. In the last place, the mouth of the drain should be carefully railed in, or otherwise guarded, to prevent the cattle from trampling it or choaking it up, being fond of drinking there for the sake of the cool water, even although there be watering-places in the field; and where there is any defect of this kind, it should immediately be remedied. Likewise the outlets of the drains where they empty themselves into an open ditch, or run of water, should be often examined and kept clear, as they are very apt to be choaked up with grafs and sand when neglected in such places. The first symptoms of the drain's having effect, and which soon appear when the spring is properly tapped, are, that all the *surface-drains* that may have formerly been made, and also any adjacent pits, ditches, or places to which it may have backed up, immediately become dry, and remain so afterwards. On the whole, it appears from the foregoing observations, that this mode of draining bogs, or land injured by subterraneous water, is by far the most effectual of any that has yet been suggested; and that such ground may be made completely dry, by cutting off one spring alone, with which the particular place to be drained may have no apparent communication, but which may be so connected under ground, that from it all the others derive their source, and being therefore the *principal* cause of the whole, to hit on it seems the chief desideratum of the business. Many instances of this have occurred in the practice of draining boggy land, under the direction of the above expert drainer, where by a few auger-holes, hitting upon the particular spot where the *lowest* part of the main spring lay, a considerable extent of

ground, with which the drain had seemingly little connection, has been laid dry, and caused much surprize to those who witnessed the effect. At Odstone Hall, in Leicestershire, a considerable tract of wet marshy ground, of very little value, divided in the middle by a small river, was so completely drained, it is said, by the same experienced drainer, by making a small trench at one side, and by boring in it, that the part of the marsh on the opposite side of the rivulet, which was at a very considerable distance from the drain, became, in a short time, equally dry with that where the cut was made; has continued so ever since; and, from being formerly of little or no value, is now converted into excellent water meadow, producing, *without manure*, abundant crops of grass and herbage.

At Madeley also, near the town of Newcastle, in Staffordshire, there was likewise a very considerable bog of some hundred acres, the drainage of which was deemed impracticable, being of so wet and soft a nature that no cattle could pass over any part of it, until this able drainer lately obtained a lease of it for a certain number of years, and, by means of a very little cutting and expence, has in consequence so effectually drained it, that it may now be considered as not only a singular instance of the success of this sort of draining, but as being likely soon to become highly productive as a farm, in consequence of other improvements, which this has produced, on it.

Extensive bogs too, which were formerly considered as incapable of being reclaimed, have within these few years been effectually laid dry, by this sort of drainage, at or near Woburn, belonging to the noble duke who resides near that town, at but very little expence, considering the manner and nature of the undertaking in such bogs. The drainage, in these cases, was accomplished by the same skilful drainer.

Successful drainages of this kind have also been performed in different parts of the northern district of the island: and particularly in the extensive park of the duke of Buccleuch, where the work has been carried on in exactly the same manner, and in perfect conformity to the principles, and the rules and directions which have been laid down for the drainage of the first class of these spring-bogs. In this case, the ground has not only been rendered dry and much more valuable than formerly, but the drains have likewise served the useful purpose of affording a constant supply of spring-water to different parts of the park.

It has been suggested by the writer of the Middlesex corrected Agricultural Report, that, wherever there may be any bogs, draining is unquestionably the first step to be taken towards their improvement; for the accomplishment of which, the principles and practices which have been laid down above should be resorted to, though the drainer should not be too sanguine, or imagine that it is, in every case, an easy operation. It is much feared, that there are *some* bogs which could not, without great difficulty, be drained at all; and *others*, that would cost the value of the land, in drains and machinery, to fully effect it. Yet, notwithstanding some *unsuccessful* trials may have been made, they should, it is said, not discourage or prevent the making of such attempts, in all cases, where there is tolerable prospect of succeeding in them. The instances are, no doubt, very numerous, it is thought, in which this sort of land may be effectually drained at an easy expence; and thereby be brought from a state of *annoyance* to yield considerable *profit* to the owners, as well as the community. See BOG, MORASS, &c.

Drainage of Ground on the Sides of Rivers, and flat swampy Land, below the Level of artificial Leads or Runs of Water.— It is also stated, that many extensive tracts of land are wet

and rushy, from a cause that cannot be removed by any number of open or covered drains. This is called *haugh* or holm-land, and lies along the sides of brooks and rivers, which having altered their course so often between the opposite banks, and depositing sand and gravel as they recede from their last channel, the water of the river constantly percolates through the ground thus formed to the level of its present course, keeping it so moist and wet as to produce rushes and other coarse aquatics; and wherever a drain or pit is dug in such ground, it immediately fills with water to the level of that in the river. Where the river has a quick descent, it is less apt to produce this effect; but where the current of it is slow, and the level of its surface little below that of the ground on either side, the soil will be very much saturated with water. Any number of drains cut in any direction, can have no good effect while the river continues in its present course at such a height. Consequently the only remedy, where it can be had recourse to at a moderate expence, is, it is supposed, deepening and widening the bed of the river, the earth taken out of which will, at the same time, serve to form an embankment on either side; for while it can rise higher than the outlets of the drains, and flow back into them, it renders the ground equally wet as before they were made, and the expence of making them is laid out to no advantage. Besides being injured in this way by the *river-water*, springs, in many situations, issue from the bottom of the higher banks or ground, and ooze through the soil higher than its level. The water of these can easily be cut off or lowered to the level of the river by a proper drain, as will be afterwards seen. As this sort of land is mostly formed by the rivers changing their courses, and thereby leaving considerable extents of flat level ground on one or both sides of them, which is of an alluvial nature, and commonly of a very rich quality, being for the most part constituted of very fine earthy particles, which are either deposited by the water in the time of or after floods, or washed down from the higher grounds in time of heavy rains, and sometimes by both; its drainage and embankment must consequently, when necessary and practicable, or capable of being performed without any extraordinary expence, be highly desirable and important. See HAUGH-Land.

But in some cases the wetness proceeds entirely from springs, where the soil of the flat ground betwixt them and the river does not consist of loose gravel or sand, but of a loam or clayey mixture. In order to drain this ground, a trench must be begun at the lower end of it, and brought from the river along the bottom of the bank from whence the springs issue. This trench should be cut *below* the line of the springs, where it can more easily be done, and kept open to receive the river-water in floods, and also any runs of water from the high grounds in time of rains, which would *blow it up* if covered; and must discharge itself into the river at the lowest possible level. Where the ground by the side of the river is of such extent as to render a regular embankment along the side of it a matter of consideration, a flood-gate might, it is supposed, be placed at the mouth of the outlet-drain, which would shut with the pressure of the river-water in a flood, and thereby exclude it entirely from the inner ground, and would open by that of the water accumulated in the drain during the inundation, and so be emptied into the river when it subsides. The construction of such a gate is simple, and the only remedy in cases where it is desirable to have the flood-water excluded in such instances.

From this trench, short covered drains must be cut up a little way into the bank, to lead in the springs that are
above

above it, where boring opposite to them has not that effect. The bottom of these must be higher than the level of that of the open cut, to prevent any of the water in it from flowing back into them. In these the auger must also be used to tap the springs, if the depth of this level does not reach the stratum containing the water. There will be no occasion for any cross-drains betwixt the open cut and the river, as all the water that is intercepted will be carried along the bottom of the bank, and emptied into the river at a lower level, unless the ground be of such extent that it may be divided by cross-ditches into separate inclosures. The open drain along the upper side will serve as a division betwixt the meadow and higher ground.

This sort of land, from its peculiar situation, and the nature of the soil, is mostly well adapted to the purpose of being watered after it has undergone proper drainage.

In cases where a mill-lead, or other similar artificial runs of water pass through land, there are many valuable tracts which are not unfrequently considered as impracticable in their drainage. Also where they glide along the sides of them to which the falls incline. From the low situation of the ground in such circumstances, and the height of the water in the leads or runs, there is no fall for discharging into them the water of any such drains as may be cut to the necessary depth. The only expedient for the remedying of this difficulty is supposed to be the following, which has been had recourse to in different instances, where no other mode was practicable, with the most complete success. In all such cases, the first thing is to begin, it is said, at the river or natural stream, and bring up a cut to the lead or run at the point where the outlet of the upper drain is to cross it. This cut must be as deep as the river will permit, or the drains above require. A cut must then be made across the lead or run to the same depth, and a strong wooden trough, or square box, for which larch wood is the best, made of a sufficient size to admit the water collected above to pass through it, be placed across it. The length of this trough must be several feet on each side more than the width of the lead or run, and must be secured by stakes firmly driven down into the ground on each side, with cross-bars or pieces above, to hold it securely down. The space between the top of it and the bottom of the lead or run, must be well filled with clay closely beat or rammed down. After this, the cut to the higher side of the ground may be made as deep as the level of the trough will allow, and continued along the upper side of the wet land, so as to cut off the springs that rise in that quarter. This may either be a covered or open drain, as circumstances may require. From the trough, also, an open cut should be made parallel to, and along the back of, the lead or run, to receive the surface-water from the ground above, and from the division ditches that may be necessary, if the ground be of great extent. The earth from this cut should be laid between it and the lead or run, to strengthen and secure the bank. In like manner, an open cut may be necessary along the other side of the lead or run, to receive the water that may ooze from it, and injure the ground between that and the river; and this ground, if extensive, may likewise be divided by cross-ditches, or such as serve the double purpose of fences, on the sides of inclosures, and drains. The cross or division ditches, in the upper part of the ground, should not join the upper drain, but a small space be left uncut, to prevent any connection between the spring-water in the upper drain, especially when it is covered, and that which is collected in the cross open ditches; and which may likewise serve as a passage from one division of the field to another. The parts of the land between the division

ditches are mostly well calculated for watering, where there is a full command and supply of water from the leads or runs.

Something of this manner of drainage has succeeded, it is said, in a case of land lying along the side of a river, below gently rising ground, where the wetness was commonly believed to be owing to a mill-lead penning up the water above the level of the low meadow-land; after attempts to drain it, on the supposition of the wetness originating from springs rising in the higher grounds, by cutting them off by means of a trench, had completely failed. This was lately done at Petworth by lord Egremont, according to the writer of the "Corrected Account of the State of Agriculture in the County of Sussex." In this case, the water in the river was higher than the meadow-land to be drained; but there was an old ditch for carrying the water from the low meadow-land into the river, at such times as when it was low. This ditch was intended to be stopped up in case of the success of the above mode of drainage, as the trench-drain would, it was thought, serve the purpose. But on the drain or trench being cut, the effect was, that when the ditch was stopped up, the low meadow-land was flooded by the springs, as the drain did not answer the purpose of taking away the water; and when the ditch was open, the same meadow-land was flooded by the river. The banking of the river out at the ditch, and the building of a wind-pump to render the ditch dry, were afterwards advised as the only means to be taken for accomplishing the drainage.

A different method, of somewhat the above kind, was, however, had recourse to with complete success. Upon the levels of the meadow-land, on each side of the river, having been taken, it was found that the meadow-ground on the opposite side was beneath the level of the meadow-land which required to be drained, and consequently that the drainage of it could be effected by a trunk-drain laid across the bed of the river; a wooden pipe was, of course, laid at the bottom, to receive and convey the water of the ditch, and which was carried on forward by an open drain being cut so as to pass through the other meadow-land, on the opposite side of the river, which was also drained by the cut thus made, quite up to the bridge under which it passes, close to the turnpike gate, fixed there by means of a pipe, and which empties itself into the river at the mill-head. This mode of drainage has answered, it is said, most effectually, so that the water in the old ditch now stands always a foot below the surface of the meadow-land which was wet; and more than one hundred acres of contiguous meadow-ground have been highly improved by the new drains which have been thus made: much of it, which was a mere bog or swamp before this drainage of it was completed, is now, it is said, converted into a fine water-meadow, and worth full three pounds the acre. These grounds are, it is remarked, at any time capable of being flowed by means of sluices made through the towing-path, which acts as an embankment; and in the summer season, if the river be too low, by fresh streams which flow into it from the upper grounds; and besides, the water can at pleasure be drawn off by drains into the lower level, below the locks, sometimes, when particular circumstances render it necessary, by the means of culverts carried across the bottom of the river. This interesting manner of freeing such low dammed up meadow-lands from the effects of the water so kept up in them, may be applicable in many other cases and situations of a similar nature.

Drainage in boggy and other wet Ground, by perforating through a retentive to a porous Substratum.—There is a sort of

boggy and other wet land, which is mostly caused in a different way than by that of springs, but which, as partaking in some degree of the nature of that kind of bogs, and being capable of having the wetness removed by such means as are had recourse to in spring-draining, may be considered in this place without impropriety. In many parts of the kingdom there are considerable tracts of land which lie waste and uncultivated, owing to wetness in a particular situation, that might, by means of letting down the waters into a porous under-stratum, be easily drained, and rendered much more productive. The cause of their wetness proceeds not from springs lying under the surface, nor from the overflowings of any of the adjoining higher grounds, but from the accumulation of rain-water stagnating on a retentive body of clay, or other impervious substance, through which the water can have no descent; and being also surrounded with higher ground of the same impervious nature, the water of itself can have no natural outlet. Such ground, when it becomes boggy, is commonly called *land-locked* bogs. The situation of these bogs being often so much lower than the grounds that surround them, the cutting of a main drain, or conductor, through the bank, for carrying off the water collected by the smaller drains, would, in many cases, be attended with an expence greater than the value of such land when drained. The thickness of the impervious stratum that retains and upholds the water is often so great, that although the strata under it be of a porous and open nature, as rock-sand or gravel, the water can find no passage whereby of itself to descend through the one into the other; and, therefore, by its long stagnation above, all the coarse vegetables that have, for a series of years, been produced on its surface, and even the upper part of the soil itself, are formed into a body of peat-earth, equally soft and less productive than that of any spring-bog, and which is only passable by cattle in very dry seasons, when the wind and sun exhale part of its moisture; and is even then inaccessible to the plough. The drainage of these bogs must be effected in a manner different from that of those above, or spring-bogs, the cause of both not being the same in their nature, as already seen. It may probably be done in the following manner at the least expence. The first drain must be made in the middle or lowest part of the ground, and into this all the others must lead. The number and direction of these must depend on its extent. They must be cut through the peat, or wet, spongy, upper soil, to the top of the clay or retentive sub-stratum, which must be perforated by the auger, in order to give an *outlet* downwards for the water, which will be absorbed by the porous strata below. The making one large pit or well in the middle or lower part of the bog, dug through into the porous substrata, with the drains leading into it, would answer equally well, and would save boring along each of the drains: this is a method which has frequently been practised with success in different districts. In Hertfordshire, according to the corrected account of the agriculture of that district, if a pit be sunk twenty or thirty feet in depth, in the middle of a field, through the red, flinty, and impervious clay of the county, into the chalk below, when the usual quantity of chalk is taken out, the pit-shaft is filled up with the flints which are collected out of the chalk and clay, and the top, or surface-drainage, of this part of the field, much shortened for ever afterwards, by making principal drains from the part of the field above the level of the top of the pit terminate therein, and the superabundant moisture will escape through the flints in the pit-shaft to the chalk below. And if a drain be carried into a limestone quarry, it is seldom necessary to carry it farther.

In dells or hollows of considerable extent, which are covered with an impervious stratum, and from which there is no natural drainage; such, for instance, as the valley between Mold, the shire-town of Flintshire, and the adjoining high land; a pit about four feet in diameter, and fifteen feet in depth, more or less, as the case may require, is sunk through the impervious super-stratum into a pervious stratum of gravel, and the rain-water, and that of some adjoining springs, are carried from the surface thereby: the pit is railed round to prevent cattle from falling into it. It is here remarked, that though in this, as well as in many other instances that might be given, the top-water escaped through the pervious sub-stratum, the effect might have been directly the contrary. It is, consequently, advised, that the impervious super-stratum, in all such cases, should first be perforated by bore-rods, as the holes made by them are easily stopped up.

Where the first method is had recourse to, the drains should be cut as narrow as possible, and, after the auger-holes have been made, should be filled with loose stones to within a foot and a half of the surface; and this vacancy may be filled up with part of the earth taken out, having a turf, grass-side downwards, next the stones. The water and noxious moisture, contained in the peat or upper soil, will be extracted by the drains, and will subside through the auger-holes into the porous strata below. If the ground is afterwards ploughed, care must be taken in forming the ridges, and giving them a proper descent towards the main drain, which will greatly assist the others in discharging any heavy falls of rain-water.

Before proceeding to drain this kind of land in the manner described, the following observation must be attended to. It should be discovered, in the first place, whether the porous strata immediately under the clay be dry, and will receive the water, when let down into it from above; or, being saturated with water itself, may, in place of receiving more, throw up a greater quantity to the surface; and thus, instead of remedying the evil, render it worse. This may sometimes be the case; and the substrata may contain water that makes no appearance on the surface, at *this* place, owing to the superincumbent body of clay, but which, being connected with some higher spring, may flow up, when a vent is given to it by the auger. Thus would a greater quantity of water be brought to the surface, which, having no outlet through the circumjacent bank, would render the ground much more wet, and might even, in some situations, almost form a lake. If the surrounding high ground declines deeper or lower than the bog, although at some distance, by means of a spirit-level, and the appearance of the surface, the nature of the under-strata may in a certain measure be discovered; and although it should already contain water, a drain may be there cut to draw off that water, and also what is let down into it from above.

It not unfrequently happens, that springs, or *spouts*, as they are commonly termed, rise in the middle of a field, or portion of ground at a distance from any ditch or open drain, into which the water may be discharged; so that a covered drain, brought from the nearest outlet, would pass so far through dry ground, as to render the expence of conducting the water from the spouty part greater than the injury done by it. In order to remedy this evil, it is necessary to begin by cutting a drain a few yards in length, or by sinking a pit into the porous soil immediately between the *lower* side of the wet and next dry ground; and from that to bring up an upright drain to the *upper* side of the wet ground, from which a branch must be taken to both sides, along the upper side of the wet, so far as it goes.

SPRING.

This upper drain will cut off the water, when it rises to the surface; while the upright drain will convey it to that cut along the lower side of the wet ground, where the water will subside into the porous subsoil. An easier method may be practised, where the retentive or impervious substratum is not deep, which is first to cut the drain along the upper side of the wet ground, and after coming to the stratum in which the water flows, either to bore through the retentive substratum, or cut the drain to that depth; by which means the water cut off above will be let down into the absorbent or porous stratum below, and thus be got rid of more easily than by any other method. But if the ground be steep, and the stratum, into which the water is let down, tails out any where below, or lower down on the slope or declivity, the water will again flow out, and cause a similar *spout* or wet place in the field. This, however, will seldom be the case, it is said, and may easily be remedied, by being made perhaps near the extremity or lower side of the field.

It has been stated, that Dr. Nugent, in his Travels through Germany in 1766, has shewn the mode of draining marshes in that country to be nearly on the same principles as those explained above. The draining of marshes is said to be conducted in much the same manner as that of lakes; but the operation has there been seen performed only on what we call moor or turf-grounds. These are most easily drained, by carrying trenches through those grounds, when the disposition of the country is such that the water can be conveyed to some neighbouring stream.

In these cases, the first thing they do is, it is said, to carry a ditch to the middle of the moor in a direct line, its depth and breadth adapted to the extent and wetness of the ground, and thus to the supposed quantity which is to be carried off. At every six, eight, or ten perches, as the ground is more or less swampy, cross-trenches on both sides are drawn in a direct line, and communicating on both sides with the main trench. But, in case of water coming from any neighbouring eminences, they dig a trench round the whole ground as a reservoir; and this likewise communicates with the main trench, &c. In case the draining of the water into some natural receptacle be not practicable, at least not under a very great expence, then they have recourse to sinking ponds or reservoirs in some neighbouring bottom, and to these they carry all the trenches. These ponds are likewise said to be of use as a fishery; but even if the sinking of such pond be too chargeable, there still remains an expedient which is of good effect, and chiefly if the moors are not too wet and marshy. It is the nature of moors, in general, that, beneath the turf or moss, there is a loam which hinders the moisture from penetrating; and this, indeed, is what makes the marsh, and causes the luxuriant growth of the turf or moss: but this loam or clay is only a stratum, and far from being of an immense depth; under it is generally a sand, or some other stony or loose soil. Here reason readily informs us, it is said, that a middling morass may be drained by *perforating* the clay, and thus making way for the moisture to penetrate. In order to this, a pit is dug in the deepest part of the moor, till they come below the obstructing clay, and meet with such a spongy stratum as, in all appearance, will be sufficient to imbibe the moisture of the marsh above it. Into this pit the ebbing of the morass is conveyed through a trench, and both the trench and pit are filled up, after the first drain, with large broad stones, setting them edgewise, so as to leave interstices for carrying off the water: then such stones are laid over breadthwise, and these covered with loose earth, like that on the surface. When no such stones are

to be had, strong piles are rammed down the sides of the trench, and broad boards laid across; and these are covered with earth to a height fit for culture. This is a matter of no great expence, the pit being as near the morass as the water will admit, and the trenches but short; then they have a drain unperceived, which leaves the surface of the trenches for the plough. And in middling marshes, or especially in such moors as are only wet and damp, this method, though sometimes slow, never fails taking effect; and many tracts are thereby made serviceable to the farmer or grazier. Much land, in some parts of this country, has been drained in the manner here described.

It has been done with great success, to a considerable extent, near Aberdeen, in Scotland, as well as in the county of Roxburgh, according to the writer of the Agricultural Report of that district, on such waste lands as might be made arable, in which, at the depth of from one to six feet below the surface, is found, it is said, a large seam of black slaty or metallic substance, generally from twenty to twenty-five feet in thickness; and below this is discovered a mass of whinstone rock, both lying in a tolerable regular straight line. The thickness of the whinstone rock, it is supposed, is unknown, as it is not believed to have ever been bored into. The black slaty or metallic substance is commonly found so closely cemented, as it were, without chinks or fissures, as that it is impenetrable even to water, or any other liquid; while, on the contrary, the whinstone rock, when come at, abounds with chinks and fissures, and will receive and swallow up any quantity of water that may be poured into its bosom. The surface of the earth, above the slaty or metallic substance, is found every where of a light, kernelly, and mossy nature; apparently having, in the course of a series of ages, been produced and formed from the vegetable substances which had attached themselves to it; falling in the autumnal seasons, and having no receptacle to receive the rain-water, as it falls below its stratum, it preserves it on its surface; and in the winter months becomes swelled and enlarged in a considerable degree. In the spring months, when the sun and wind absorb it, and cause it to exhale, the moss becomes of tolerable firmness, and produces a coarse kind of unprofitable grass, mixed in many places with a sort of short heather, which is of no use either for the rearing or feeding of sheep or cattle.

Two portions of this sort of waste land, amounting to twenty acres, the one lying nearly on a level, and the other on the slope of a hill, were broke up in the autumn of the year 1784. The level part was gathered up in small ridges, ploughing rather deeply, and making the furrows narrow; labourers being employed, after the ploughs, to remove any obstructions that might arise from stones or roots, as well as to turn the upper rind or surface underneath, when not effected by the ploughs. It was then allowed to remain in that state until the middle of the summer of 1785, being only eaten and trodden in the spring season by sheep and cattle, which were occasionally driven about the ground for the purpose, the benefit of which was very great. At the above period the land was again gathered up; but finding, although the ridges were getting high, being only set out eight feet at first, the plough did not reach or get to the slaty substance in the hollow of the ridge, it was necessary to lay out the ridges to sixteen feet. This cost much trouble, but the plough was at last got down to the slaty substance. When the work was so far advanced, the next business was directed to the getting the water drawn out of the hollows of the ridges, which were at least four feet below any level that could be obtained. In order to accomplish this, a pair of bore-rods was procured, and put down

the slaty substance, to the whinstone rock, at sundry places, and which effectually answered the purpose; the tops of the holes or canals being kept covered with a basket of loose stones, which was allowed to remain or to be removed at pleasure, as the weather proved more or less wet.

By this means of draining, the land was found to be, in the spring of 1786, brought into a condition for sowing, nearly as early as any other part of the farm; the winter rains falling through the soil upon the ridges into the bosom of the slaty substance, which was laid bare in many places, in the hollows of the ridges; the water was gently drawn off, and glided regularly into the bore-holes or canals: and the production of crops in the following years was very good.

On the contrary, the other part of this wet waste ground, lying on the slope of the hill, was ploughed in thin broad furrows; using the same measures and precautions as in the above case, and being allowed to remain to the same period, after breaking up, was then endeavoured to be brake-harrowed, and afterwards prepared for burning. But both these methods failing, it was left in a more backward state than the former part; and was at last, in the spring of 1786, after two ploughings, braking, &c. being left in a large lumpy condition on the surface, sown with pease, in drills, in a close manner, for the sake of shade and the improvement of the land; which had these effects, besides producing a good crop. The after-crops on it were likewise good.

As the soil above the slaty substance, in this part, was not above two feet and a half deep, the plan of setting off the ridges eight feet in breadth is said to have answered well.

Drainage in hilly Lands and Sheep-Pastures, with the means of procuring and raising Water for certain Purposes, &c.—In hilly districts, and other steep places, where sheep are the staple or chief produce and stock of the land, less attention seems to have been paid to the drainage of such parts of their walks and pastures as are wet and unproductive, in the opinion of the writer of the work on draining, according to Mr. Elkington's principle, than to that of arable ground, although the effects in the one case are equally beneficial with those in the other. This neglect is often attended with considerable loss. From the nature of the herbage which a superabundance of moisture produces, whether stagnant on the surface, or long confined under it, proceeds that almost incurable malady the rot, to which so many thousands of valuable animals fall a sacrifice. For this, draining is a most infallible preventive; and in such situations it is attended with little expence, as the drains may, for the most part, be left open, with here and there covered passages, over which the sheep may cross with safety. It is stated to be the practice, in many of the southern sheep-farms of Scotland, to cut small open drains in the wet pastures, only one foot in width, and the same depth; but this, it is believed, has very little effect either in carrying off the superfluous water, or preventing the rot in the animals. One rood of such a drain, as has been advised above, would answer these purposes, it is thought, more effectually than fifty of the other, and, on that account, would not be more expensive.

And although in places where the depth of the cut does not reach the spring, the auger must be applied, no apprehension need, it is thought, be entertained of the holes filling up, where the drain is left open; for the force of the spring will, of itself, throw up any sand or sludge that may get into them, provided no great quantity of flood or surface-water is admitted. But the better to secure them

against any obstruction, small openings may be made along the upper side of the trench: and in these the perforations may be made, leaving the mouth of the auger-holes about six inches or a foot higher than the bottom of the drain, which will be without the reach of the water that may accumulate in time of rains. From the irregular disposition of the component strata, the sides of many hills are covered with alternate patches of wet and dry soil. By the appearance of the surface, and by the vegetables it produces along the declivity, the internal strata, and manner in which they lie, may often be ascertained with such a degree of precision, as to guide the direction of a drain without investigating *below* the surface; for the difficulty or facility with which such ground may be drained, depends entirely upon the *lie* of the different strata of which the hill is composed, and upon the perpendicular or horizontal inclination of the rock or body in which the water is contained. If the rock lies in a horizontal direction, all the different outlets or springs that appear on the surface may proceed from, or be connected with, the same body of water, and may all be *dried up*, by cutting off or letting out the main body of water that supplies them, at the lower part of the reservoir, or place where the water would of itself run off more easily, if it was not confined under an impervious covering of clay. But, where the rock lies in a perpendicular manner, and contains only partial collections of water amongst the more open fissures of the stone, which empty themselves at numberless outlets unconnected with one another, it would be preposterous to attempt cutting them off by *one* drain, or by *tapping* any particular one of them, without a drain being cut into each. In this manner it is better to cut the main drain *all* in the clay, with small cuts up to each outlet, than along the line or place where the springs break out, as it would in that direction be *too* much in the *rock*, and difficult to cut, from the nature and inclination of the stone. Where the water issuing out in certain parts, can, by means of the auger, be hit on in the main drain, at particular points it will be more effectually cut off; but if that is not practicable, the depth of the small cuts will reduce it to such a level as to prevent its overflowing or injuring the surface *below*. In many hills composed of alternate strata of rock, sand, and clay, the surface of the latter is commonly wet and swampy, while that of the former is dry and productive, and therefore requires as many cuts to drain it completely as there are divisions of wet and dry soil. The highest part of the hill, being for the most part composed of porous soil, receives the rain-water which descends through it, till it meet some impervious stratum, as clay, which obstructing its percolation any further downwards, it then rises to the surface, and forces itself a passage over that impassable stratum. After it has thus overflowed the *upper* clay surface, it is immediately absorbed by the next porous stratum, and, descending into it in like manner as above, it again issues at the lower side of it, and injures the surface of the next clay-bed, as it did that of the first. In this manner the same spring will affect the other similar strata of which the hill is composed, down the whole declivity, and form at last, in the hollow, a lake or bog, if there be not a proper outlet or descent to carry off the water. In order to drain a hill-side of this description, it is necessary, it is said, to begin by making a trench along the upper side of the *uppermost* rushy soil, which will have the effect of cutting off the highest spring; but as the rain falling on the next porous soil subsides to the lowest part of it, and forms another spring, and as it may likewise be partly supplied from some other internal source, a second cut is necessary there, to prevent that water from injuring the surface of the next clay-bed.

bed. Thus, similar cuts will be requisite lower down the descent, so far as the same springs and appearances continue to injure the ground, which may produce a quantity of water sufficient to irrigate the lower ground, or which may be useful in some other respects and manners.

In some hills, the strata of which they are formed lie so regular, that it is practicable to extract the water from either side on the same level, which would be a very considerable advantage in draining the one side, and in irrigating and procuring water for the other; for there is often found on the one side a wet swamp, and on the other the soil is too dry. This is owing to the bed of clay that upholds the water not lying horizontally, but *dipping* more to the one side than to the other, and by the one (the dry) side being *overlapt* by a covering of clay, whereby the water is forced to issue at the open side; but if an outlet is given to it on the *dry* side, by means of a drain lower than that from which it flows on the wet side, the course of the spring may be easily diverted. The opposite side being porous, and covered with sand, will act as a reservoir, to receive the rain-waters, which will afterwards flow through the opening made in the clay. This may be of great use in supplying a house with water that is situated on the dry side of the hill, and save the additional expence of conveying it in another manner. Care must, however, be taken in conducting the drain for conveying water to supply a house, &c. not to cut it or bore in it so deep as to reach a porous stratum, otherwise the water that may have been found at one place, may, by the same means, be lost at another. Puddling may, it is supposed, in some degree, secure it, but not in every case.

A spring in a low situation, adjacent to higher ground, may be raised to supply a house, or for any other useful purpose, although much below that level, by confining it in a pipe, or brick chimney. The reservoir from whence the spring or outlet of water is supplied being confined, and pent up between two impervious strata, and the upper part of it extending perhaps to a considerable height and distance in the high ground, it is evident, that if a perforation be made through the superincumbent stratum into the *tail* or lowest part of the porous stratum containing the spring, the water may be raised by confining it nearly as high as the level of the head of the reservoir. Of this kind there have been, it is said, several instances in actual practice, where the water procured from draining low grounds has been raised to a considerable height above the level of the drains. The drains in such cases should be closely built with brick, and puddled above with clay, to prevent the water from oozing through the joints. It is thus made to rise, through some sort of confined passage, to the height which is required, by the pressure which it receives in the high ground. The advantages of such operations, it is remarked, must be very great in many situations, and may often be accomplished with success, where many would think them impracticable. Of the practicability of this, however, and that water may often be raised to a very considerable height, by means of its pressure in distant ground, the following remarkable occurrence, which happened lately in digging a well in the vicinity of London, is a proof: earl Spencer, for the preservation of his noble mansion-house at Wimbledon against fire, and to be well supplied with water, ordered a well to be dug at a little distance from the house, which was sunk to the amazing depth of nearly 600 feet, before any spring was found. It was begun on the 31st of May, 1795; and on the 12th of August, 1796, the man who was employed in the undertaking, gave a signal to the person above to draw him up, as he had found the spring, and was immersed in water so

deep, that his life became endangered. In the space of four hours the water rose to the height of 350 feet, and during two days following its increase was more than a foot an hour. The water, proceeding from a rock, is remarkably fine, and, from the strata it passes through, is strongly impregnated with mineral qualities. As there is no extent of higher ground near that where the well is sunk, and as the depth of it is some hundred feet below the bottom of the Thames, the source of the reservoir from whence the spring is supplied, must be situated at a very great distance, and must contain a very large body of water to raise it so suddenly to such a height.

There are many other cases of wetness in the deep moory or heathy grounds, which often take place and occupy the bases of the narrow vallies at the bottoms of such hilly lands, hang on the sloping surfaces of their sides, or spread over the more flat lands which lie at their feet.

The most simple case of this kind is probably that in which the more superficial parts of the soil are of an impervious or porous nature, the subsoil of the absorbent porous kind resting upon a repellent impervious base or bottom; the porous subsoil part being uniformly charged with the descending waters, which are conveyed or brought down from some internal higher source, by a substratum of the gravel or other preconducting kind. In these circumstances, where the under soil is sufficiently free and open, a single drain, properly made or cut across the lower margin or edge of the rising ground, may be fully equal to the prevention, even of the flatter lands below it, from being surcharged with water. But though this may be the case, such an easy mode of removing the wetness may not always be the most suitable or proper, but must be decided upon by the full and mature consideration of the particular case; as it is in cases of this nature that waters for different useful purposes are to be procured, and the higher they may be drawn off, the more capable they will, for the most part, be of becoming beneficial in such ways: besides, where the absorbent porous stratum of the lower lands is not sufficiently open to permit the waters of a wet season to pass so freely through them as to prevent a temporary surcharge, a threefold benefit, it is thought by some, may possibly arise, by cutting and taking off the internal descending waters at the foot of the sloping ground. As, in addition to the advantages already suggested, another good effect may be produced; which is that of taking off the *weight* of the waters which are pent up in the higher grounds from the lands below; and thereby relieving them from a common disease or complaint to which lands so situated are very liable; and which is occasioned by the water, thus compressed, being forced up, through some fissure or defect in the soil, to the surface of the ground in some particular part or parts. But by a suitable fully efficient drain, made all along the upper margin of the flatter declining grounds, they may be entirely relieved from such internal descending waters, and become in a healthy productive state. It may, however, be added, that a drain so made, is in general more difficult and expensive in cutting, than one which is formed at the lower part of the more flat declining land; the soil at the foot of a slope being commonly of a greater depth than it is either above or below that part; besides the additional labour and trouble in cutting and sinking the trench when to be fouled or filled, and still more in keeping an open drain free, by reason of the greater press of water in that part. The upper side of the trench too, in such cases, is liable to shoot in; especially if it be sunk in a wet season, the water acting the most forcibly there. Besides, unless the trench

be sunk or cut down to a firm basis or stratum, it is ineffectual; the lands below are still liable to be affected with a portion, at least, of the descending waters; besides that which may fall on the particular surface of them. They consequently demand nearly the same labour to render them dry, as they would without an ineffectual drain being made along their upper margin or border; notwithstanding, however, in many instances, water, descending internally from a higher or more elevated source, and insinuating itself beneath the superficial soil of the lower grounds, so as to injure them, may be cut off by a drain running along at the foot of the lilly land, when cut or formed to a proper depth, as to the solid or impervious body; which may, at the same time, sufficiently relieve the lands which are below, as well as afford a valuable supply of water for different economical purposes about the farm or ground.

Another case of this kind of draining is where the superficial parts of the soil are of a porous or repellent quality, and the under or subsoil open or various, and partially charged with descending waters, passing through beds or veins of the sandy, gravelly, or fissured rocky kinds. This is a situation of land which occurs more frequently than the above, but from which it principally differs, in the manner in which the internal waters act upon the lower lands. Instead of being diffused, in an uniform manner, beneath the soil, they enter or come into the substrata in collected streams; and unless the subsoil be singularly open, and spreads out in an even manner, operate very irregularly on the land. Thus, if the soil be deep, and of an impervious or repellent quality, plots of cold wet land are formed and produced;—if thin, and of a porous freely absorbent nature, moory excreescences are raised on the surface; and if the stream be powerful and narrowly confined, a spring or fountain is the consequence.

The nature of the means which are to be pursued in the removal of the wetness in this case is of a more complicated kind than in the preceding instance. In cases where the supply of water cannot be cut off, the circumference of the flat ground is to be relieved by covered drains formed in a greatly declining manner from the diseased parts, to a common drain or outlet in some proper place. In this case, the supply of water is cut off with less certainty, than when it is conducted by an evenly charged stratum, resting on an impervious or repellent base or stratum. It may have only one, or many conduits situated at different depths. This too is a case in which the supply of water, with a sufficient fall, may take place; and under circumstances which particularly demand it, every expedient should be had recourse to in order to intercept the descending waters at the foot of the slope on the higher side of the lands which are to be drained.

A third case of draining in these situations is, where the surface-soil is impervious, or open and absorbent; the under soil porous and absorbent, with a closed bottom, and charged with descending waters, resting on an impervious or repellent base, which has an under base that is open and freely absorbent. This is a situation of land that may not often occur in such a state as to have the stratum or base on which the water rests, only of a few feet in depth or thickness; but in which, it is probable, an open or porous stratum may not unfrequently be found, by careful examination, at a greater depth; particularly when the land is situated below rising ground, at the base of which such a stratum is indicated to be present, by the flowing of a natural spring or fountain.

The means of removing the wetness in such a case as this,

is obviously that of opening a communication between the impervious or closed and the open porous strata; in order that the injurious waters, which are pent up in the former, may be permitted to pass down into the latter. It is in this way, it is said, that marle-pits are drained in some districts, as in Norfolk; the beds of marle which hold up the water being cut through so as to let it down into the great body of sand on which they rest. In order to effect which, a large earth borer naturally presents itself; and where the subsoil is free and open, and the surface-soil in a state of *perennial herbage*, the operation of it, when duly directed, and performed in a suitably dry season, may be found very effective for the time, if not durable: in the practical management of which a thick turf is to be raised on the surface, and at the bottom of the little pit which is made thereby, the borer is to be inserted, the turf being returned into its place, as soon as the work has been completed, in order to prevent extraneous matters from getting into and obstructing the opening made by the borer.

In land under the *arable* state, the operation may not, it is supposed, be so efficient; but, however, if pits were sunk down beneath the soil, it is suggested, so as to secure the tops of the bores from the operations of tillage, as to the depth of twelve or fourteen inches below the surface, sods being then laid over the tops of the bores, and the excavated soil or mould returned to their places, such drains might continue efficient for a short length of time. In cases, however, where the subsoil is so *tenacious* as to stand in need of many drains to draw the water effectually out of it, this mode of draining, or the use of the borer, it is thought, would appear a less eligible practice. In the bottom of a drain, whether open or covered, more or less current takes place, by which earthy matters are liable to be washed down into the bores; and these, in consequence, to be choaked up. The operation and effects of water falling down a pipe or tube, and that of its rising in them, are, it is thought, perfectly different; as rising waters loosen, and force upwards the obstructing matters they may meet with in their passage; whereas falling water, on the contrary, adds the pressure of its own weight to that of the obstructions; and by dissolving earthy matter, and thereby filling every chink and cranny, tends to close up the passage in the most effectual manner. Rising waters too enter the pipe or tube in a pure state, leaving their impurities below, while falling water carries down with it all the foulness that its current is capable of bearing to the mouths of the orifices of such pipes or tubes. Hence, even under the first mentioned circumstances, it is probable, it is said, that the salutary effects of the bores would only be of a temporary nature. Besides, where drains are necessary to extract the water from the subsoil, why, it is asked, may it not be collected into a body, and be carried away upon the surface, where it may in many cases be applied to different useful purposes?

Where, however, a superficial descent cannot be had for the water thus collected, and an open stratum lies beneath the subsoil, which is ready and fit to receive it, the making of a communication between them becomes a point of great advantage and importance; as the trouble and expence of raising and removing the water by other means may be avoided.

In all such circumstances of land in these situations, the lowest point of the space of ground to be drained is to be ascertained, in which it is advised to sink a shaft down into the receiving open stratum, which is then to be filled up, to within a few feet of the surface, with rough clean stones, the roots of trees, or other open materials; on the top of which

which a filter is to be formed with heath and gravel, or any other substances which will prevent earthy matter, or water in a foul state, from entering the shaft or opening. The collected waters are to be led to this filtering drain or opening in all cases.

Where, however, the water is collected by means of covered drains, and where the filtering parts have likewise coverings placed over them, the whole process will, it is said, be free from external injury; and drains or works of this kind might, it is supposed, remain unimpaired for ages, or a very great length of time. Even if the waters were collected by open drains, and the filters, or filtering parts of them, were suffered to continue in a state of neglect, until the shaft, in the course of time, should become defective, the remedy, it is thought, would be easy; as by embracing a dry season to re-open it in, and to clean it, as well as the materials with which it may have been filled, from their impurities, it may be restored to its original condition at but little expence or trouble. It may be noticed further, that where the land to be drained and improved is liable to have any other surface-water coming upon it than what falls upon its own space, such waters ought to be drawn and conducted away from it superficially, by cutting it off at such a height as will gain a sufficient fall. And further, when the quantity of water which descends into it subterraneously, or which would descend into it if a free passage were opened for it, is found to be too copious to be readily discharged by such a drain or shaft in the manner here proposed, proper means should be taken to cut off the supply, or as much of it as may be, by making a perforated trench, or otherwise, at a sufficient height to be able to convey it away in a superficial manner; and with a suitable fall, so as to prevent its entering the space of land to be improved; which by this means will only have its own superfluous waters to discharge by the shaft-drain. See *SHARP-Drain*.

There are many instances of low, flat-lying, moory valleys in different districts of the kingdom, and especially in Norfolk, from the bases of which it would be difficult to make superficial drains, which have for their substrata or substructures, most probably, infatiable beds or depths of sand, or sandy matters, in which this mode of draining might, it is said, be practised with vast benefit. The practice in these cases also affords additional explanation of what has been said above, in speaking of the removal of the wetness of land by perforating through a retentive stratum to the porous one below, as well as the nature of the drainage in bogs arising from springs.

In cases where the superficial soil is impervious and repellent, or porous and absorbent, the subsoil being uniformly absorbent, but closed in the bottom part, and charged with rising waters, the effect produced varies in some measure with the nature of the furcharged lands. Where the absorbent substrata are imperfectly closed, or where the furcharging waters find some other partial vent at the same level, the effect is merely that of an under soil, which is liable to be saturated in a wet season, and which is left dry after a long continued drought. But where the subsoil of the land to be improved, together with the substrata in its vicinity, on the same level, are equally impermeable, and the embanked waters are, in consequence, under the necessity of rising, to a higher level, the lower lands become subjected to perpetual furcharge: even the surface-soil, when in any degree absorbent, becomes liable to a similar degree of saturation, by reason of the weight of water which lies above it; as the compressed waters, acting in conformity to the general law of fluids to gain a common level, press upwards against the soil: and where this is freely

and uniformly absorbent, it becomes fully saturated; the inevitable effect of which is a bed of super-aquatic plants; and, in the course of time, an extent of deep moory bog: if partially absorbent only, plots of moor are the consequence.

The means of relief in cases of this nature are much the same as those in the first of the above cases. Where the subsoil is uniformly free, and a supply of water is not wanted above what is called the running level of the lower margin of the land to be improved, a trench, with a sufficient outfall there, will lay the whole effectually dry; and will, in addition, become the common outlet of the internal waters; instead of the natural spring, which will consequently cease to flow.

But if, on the contrary, the subsoil be not sufficiently open to permit a free passage for water through it, or where economical intentions demand a fall from the upper margin, it will be right and proper to attempt to take off the head and weight of the water, by a trench made at the foot of the hill; and then to free the space of land diseased by one or more drains, as the particular circumstances of the case may direct. Where a supply of water is particularly desirable, or the improvement of cold lands, hanging on the slopes of rising grounds, is wanted, it may be the most proper, when it is found that a deep trench alone, made at the foot of such slopes, by reason of the too great depth of the impervious or repellent materials, is insufficient for the purpose, to try the effect of the borer, and by this means endeavour not only to accomplish the supply of water that may be desired, but by bringing down the surface of the subterraneous collection to a level with the bottom of the trench, to relieve the plain below from the upward pressure; and thereby probably remove the evil in a sufficient manner, especially on the higher side, without additional trouble and expence.

In cases similar to the above also, where a freely conducting stratum, which is charged with water, lies too deep to be easily reached by a trench, and too level to be relieved by the borer, and in all cases where the water lies too low, and in too flat a situation to admit of a superficial channel being sunk deep enough to draw it from its natural bed, yet without an open stratum beneath to render a shaft-drain effective, a well-drain sunk in the lowest part of the ground to be improved, may, it is supposed, be had recourse to with good effect. See *WELL-Drain*.

In cases where the quantity of water to be raised is considerable, and the depth at which it lies not more than six or eight feet, it may be forced up into an open drain, sunk to about half the depth, by the use of the common draining-mill of marsh-land districts: or, where the depth is too great, or the substrata too loose and unstable to admit of a deep open drain, and that of an arched one too expensive, a pump wrought by wind, or by water, where a sufficient stream can be commanded, may be sufficient to raise it to the surface; care being taken in this, as well as the above case, that no extraneous waters interfere. See *SURFACE-Draining*.

There are other cases of draining besides these, in which the wetness is removed by drawing off the springs that cause them. See *TAPPING Springs*.

Cases of the same nature as those given above are illustrated by means of sections, in all the different instances, by the writer of the work on "Landed Property."

In many cases too, a great deal is capable of being effected in these and other sorts of hilly grounds, and very astonishing effects produced, in some instances, by means of cuts or drains alone, properly directed, without the necessity

of either boring, or having recourse to the making or sinking of pits in the land, for removing and taking away the wetness. It has been found that fields or grounds of considerable extent, which lie upon irregular banks, hills, or knolls, have been readily drained in this manner; though the water which rose and issued out from the springs in particular parts of them, rendered them before of but very little value: and though many drains, in improper directions, and not properly cut, had been before formed in them, at great expence, for draining off the wetness without effect. This has been accomplished by cutting drains to suitable depths through the porous strata, and in such directions as to cut off the springs coming from the higher grounds; or to take the water of them away, which lodged in the hollow parts of the land. Such drains have often speedily removed the wetness, without costing a tenth part of what was paid for the others, or taking into the account the difference of keeping them in order, which must be a mere trifle, when compared with that of the others, as they were mostly on a loose bottom, and made so small, as to be readily choaked up and destroyed. The nature of the situation, and the lie of the strata of which such lands are formed and composed, readily explain the reason why the moisture in such cases is so quickly removed by properly cut and directed drains, as it arises, in most instances, from the inclination of the strata, which is commonly towards the hollow parts of the grounds, and from their frequently terminating on the sides of such banks, hills, or knolls, under the impervious, clayey, marly, or stiff loamy strata, though for the most part upon them.

Mistakes in the modes of cutting the drains, and in the directions they should have for properly intercepting and taking away the water of the springs, are almost every where in such cases committed, and vast expence thereby not unfrequently incurred; it is consequently of much importance, in all such instances, to have a proper plan laid down before any part of such works be undertaken.

There are sometimes springs and wetnesses found on the tops of banks and hills, where the ground which is contiguous is much lower on all sides; but in such cases they are, in many instances, supplied with the water from higher ground at a distance, by means of metallic, mineral, or other substrata, lying in a particular curving direction, between impervious strata, from the higher parts of the land to the lower. The springs, in these cases, issue forth at the points where the metals *crop* out.

The drainage, in such cases, is to be accomplished by forming suitable outlets for the water, and by boring or sinking pits through the porous or metallic strata, so that the water flowing through them may be intercepted, and reduced to such a level, that the source of the springs may be cut off, and the ground on the top and on both sides of the declivity become dry. By this means the metals, to that depth, may be rendered capable of being wrought, without any inconvenience from the water.

In the above method, the continuation of the strata is supposed to keep on the same rise, in the high ground on the north side of the rivulet, to a much higher level than the line of springs, by which means, the springs issuing from the *crop* of the metals are supplied.

By bringing up a cut from the rivulet into the bank an outlet will be obtained for the water, free from that of the rivulet; and by boring or sinking a pit, the water flowing through the porous strata will be reduced to a level, and of course the source of the springs will be intercepted, and the ground on the top, and on both sides of the declivity, become dry; and the metals, to that depth, may be wrought free of water.

This could not be effected by boring from the bottom of the rivulet, or any run of water, for the pressure of the running water above would prevent that below from rising freely, and small stones or sand would be lodged in the hole. If the strata crop out to the surface, and cause wetness, the pit or bore may be continued till it reach it; but lying at such a depth, and covered with so much clay on the surface, the water contained in it may do no injury to the ground above it.

Drainage in Lands composed of alternate Beds of Clay and Sand; and other mixed Soils.—In districts where the soil is composed of an intermixed variety, and where clay forms the most predominant part, draining is, according to the first writer above noticed, a work attended with much greater difficulty and expence, than in those where both the surface and internal strata are more regularly disposed. In these kinds of soils, where every reservoir of water is unconnected with another, being separated by intervening beds of clay, the partial collections of water that these reservoirs contain are so much augmented in time of great rains, that, being full to the level of the surface of the surrounding clay, the water having then a free issue, as over the edges of a dish, so overflows and surcharges the surface of that clay, and renders it so wet and sour, that its produce becomes every year more scanty, and the nature of the soil itself more barren. As these sand-beds have no communication with each other, it requires as many drains as they are in number to extract the water from each of them. From the nearest and lowest part of the field to be drained, a trench must be cut up to the highest or most distant sand-bank, in such a direction, as, if possible, to hit on some of the intermediate sand-beds, and save the making a longer side-cut, otherwise necessary; but where this would give many awkward turnings to the main trench, it would necessarily lengthen it; and where, by crossing the beds in places higher than the surface of the surrounding clay, it would considerably increase the depth of it, and be difficult to work, especially if rock or running-sand; drains in form of the letter Y must branch off to such beds, to draw off the water they contain, and convey it into the leading one. Although the sand-beds throw out the water they contain on all sides, so as to injure the clay-surface immediately round them, a drain on the one side will completely extract the water from the whole, and prevent it from breaking out at either side, provided that where it is cut be the lowest. It may be observed, that unless the drain is so cut, it cannot be supposed to have this effect, while the water can find an outlet on the opposite side of the bank, lower than the bottom of the drain. This ought, therefore, to be previously considered; and by carefully examining the ground, and applying the spirit-level, the proper side for the drain may easily be found: or, if the water bursting out round the bank has been observed in dry seasons to run at one place, and not at others, it is a proof that this is the lowest point; and by cutting the drain in the direction of this level, the water will afterwards be prevented from rising to the height of the upper outlets, or above the level of the bottom of the drain, even in the wettest seasons. In many cases, the whole water that causes the wetness, and supplies the other sand-beds below, may arise from the upper springs, passing over the upper soil, and through the different sand-beds; by being prevented from descending deeper than the retaining bed of clay. In this case, the drainage of the whole field may be accomplished with much less difficulty and expence than in the former. After the main conducting drain from the outlet has been cut, a drain on the upper or higher top part, quite across, must next be made, which will intercept and cut off

the principal springs, and may by this means render the lower drains, on the different sides of the main conducting one, unnecessary, unless merely to extract the partial supply of water which the lower sand-beds may receive in time of rains, and which, where these sand-beds are of small extent, can do little injury to the adjoining surface. From this it appears, that one spring rising in the highest ground may be the sole cause of injuring a considerable tract lying below; from its water overflowing the surface at one place, and subsiding into it at another, according to the tenacity or openness of the soil; and therefore, in such cases, the upper spring, or *feeder*, should be first cut off, and the effect of that known, before any more drains are made in the lower ground.

Besides soils corresponding to this description, there are others nearly of a similar nature; but each bed being of less extent, and lying more regularly together, their drainage can be more easily effected, by means of less cutting, and consequently less expence. Under the beds of sand and clay that thus lie alternately together, and almost parallel to one another, is found a general body of impervious clay, that keeps up the water contained in the sand, which continues always full, moistening the adjacent clay, and, in wet seasons, running over it. As this *main under-stratum* of clay is seldom above four or five feet below the surface, a drain must be cut to that depth through the middle of the field, if it have a descent from both sides; or, if the ground declines all to one side, the drain must be cut there, where the water will more easily discharge itself into it; and, unless the field is of a considerable extent, and have more hollows in it than one, one drain will answer the purpose effectually; for, by crossing all the different beds that hold the water, it will draw it from each.

The great difficulty, however, in draining lands of this description, and which is impracticable by one drain, is, if the direction of the alternate beds of clay and sand lie *across* the declivity of the grounds; so that one drain, in this case, can have no other effect than that of carrying off the water after it has passed over the different strata, and would here naturally stagnate in the lowest part of the field, if there was no other outlet for it: therefore, when the ground lies in this manner, which is often the case, besides the drain in the hollow, others must be cut up from it, in a sloping direction, *across* the declivity, which by crossing all the different veins, or the very thin and narrow strata of sand, will extract the water from each. Where these alternate strata are of great extent, and the wetness produced by greater springs forming swamps at different levels on the side of the hills, the method of draining them has been already described.

The first thing to be observed, in the drainage of such alternate soils, is to discover minutely the inclination of the alternate strata, or how they lie with regard to the situation of the field to be drained, as upon this the direction of the drain entirely depends; and as the external signs that distinguish the different beds are easily perceptible, from the appearance of the surface, and difference of the herbage that each produces, there is little difficulty in attaining this part of the object. In drains of this kind there is seldom any need for applying the auger, as the necessary depth of the trench reaches far enough down; and as there is no spring for want of connection with the higher ground to force itself up through the auger-holes, or, if there is, it cannot, at so great a depth, and below such a body of clay, do any injury to the ground above.

The drain, after being formed like a fough at the bottom, or set like a triangle, must be filled a considerable way up with small stones, before the mould is thrown in, taking care

to have *tough* fods laid immediately above the former. Where stones are scarce, and plenty of brush-wood at hand, faggots may be substituted in their place with propriety. The under part of the drain, however, should be laid or *coupled* with stones, as a canal to carry off the water subsiding through the faggots; and which has also the good effect of prolonging their duration; for when the water cannot get off, which must be the case where there is no open conduit of stones, its stagnation amongst the branches must soon cause their decay, and choke up the passage of the drain. In no case whatever should the drain be filled with stones thrown in in a promiscuous manner, without a course for the water at the bottom being first formed. There is one thing more to be attended to in completely accomplishing the drainage of these soils: if the field lies very much on the descent, care must be taken in laying out the *branch*-drains in a direction sufficiently horizontal, so as not to make the fall too precipitant, by which the bottom of the trenches would be worn uneven, and this would obstruct the passage of the water, which might soon blow them up; but the fall should be such as to enable the water to clear its course. The reason why fewer drains are required in fields that lie nearly horizontal, as those of the second kind here mentioned, is, that the water is drawn equally from both sides, whereas those on a sloping declivity, drawing only from the higher sides of the drains, require them to be more in number, or closer to one another. This is the case in every situation where surface-draining is necessary, and particularly so in some sorts of soils, as will be seen described in that kind of draining. See *SURFACE-Draining*.

In Lancashire, where these soils, composed of alternate beds of clay and sand, very much predominate, and which have there acquired the names of *sand-pots*, or *guts*, a term properly enough applied to them from their holding water like a pot, it is observed, that several drainages have been executed by Mr. Elkington in the manner here described, and also a very difficult one of the same kind at Sutton-Hall, Derbyshire, where the water was contained in small beds of rock, crossed and intercepted by beds of clay.

There are still other cases of these intermixed soils, such as those which have a porous, or partly impervious superficial soil, while the under-strata are constituted of different distinct masses of impervious repellent materials, disposed in a regular manner. The lands which lie near the bottoms of hills and slopes are often composed of such impervious masses of the clayey, strong marly, or stiff loamy kinds. Such an intermixed, irregular construction of land, has naturally the effect of forcing the internal waters, which descend from springs in the higher grounds, as well as that which is taken up by the surface-soil, where it is porous, upwards towards the surface of the lands, or other directions, so as to cause or induce wetnesses which have different appearances, according to the nature or quality of the superficial parts of such grounds, as wet, rusty, feggy, or other cold moist lands, oozing, springy, wet lands, land-springs, quagmires, quicksands, and actual springs of water, either of the temporary or more permanent kinds, as the circumstances of the several cases may be.

The means of draining such intermixed portions of wet ground of this springy nature, although attended with some difficulty, is mostly capable of being accomplished without any very great trouble or expence: this is to be effected by cutting up from the main conducting drain, which should always be carried through the most depending masses, small drains into the separate upholding masses or strata, at suitable depths, so as to find the waters which rest upon them

and draw them off. Such drains, where properly made and directed, must not only be effectual, but durable in their nature. The bottoms of the drains or channels in all these cases should constantly be cut a few inches into the firm impervious beds or strata, and their higher sides be made to communicate well with the openings in which the waters are lodged. In these ways this sort of land may, in most instances, be rendered perfectly dry, and in a state fit for cultivation.

A full and perfect knowledge of the business of spring-draining is of the utmost utility and importance; as more labour and money have, probably, been uselessly thrown away upon this sort of rural improvement than that of any other, merely for want of such information. In many cases, from three to five times as much money may have been expended, and trouble caused, as the nature and circumstances of the different cases demanded. It is indeed not improbable, but that for one-fifth part of each, the business might, in different instances, have been more effectually and completely performed, if the person employed had been sufficiently informed on the subject. It has been the too common practice of the ordinary class of drainers, in removing the wetness caused by springs, whether from interest and design, or the want of adequate knowledge, to fill the ground with a number of drains, cut so as to spread and extend themselves in all directions, wherever the slightest appearances of moisture or wetness presented themselves; while in all probability, by the cutting of a single drain in a suitable and proper direction, so as to intercept the springs, or draw off the internally collected waters, which caused such wetness by their spreading branches, the whole of the land might at once have been effectually laid dry. The prevention of this useless waste of labour and money is only, perhaps, to be found in the endeavour to bring the nature of the theory and practice of this sort of draining into a more clear and comprehensive point of view, somewhat in the manner which has been attempted above, so as to enable those who undertake this kind of business, to superintend and direct all the various operations and processes of it in the most suitable, proper, and efficient manner, without incurring unnecessary expence. There can be no doubt that improvements of this principal kind in land would be much more generally attended to and extended than they are at present, if this were the case, and the ineffectual modes in which they are executed, in too many different instances, less frequent. As the chief and best skill of the artist, in this sort of business, probably lies in the readiness and certainty with which he is capable of discovering the main springs, collections, and passages or channels of the water which produce the different kinds of wetness which are to be removed; and as neither long custom, nor the most extensive practice, has hitherto been sufficient to lead to the means of attaining these, in all cases, even when guided and assisted by the outward superficial appearances which the surface of the ground may afford; it is somewhat extraordinary that other aids and methods have not been had recourse to for the purpose. This has, however, so far as we know, not been at all attempted until lately, and yet in one or two instances only. The ingenious drainer of Trafford-moors, in Lancashire, as already noticed, has contrived a pump for this use, which is to be put down into the soil in different places, in order to ascertain the presence of springs, or collections of water in it, before the work of draining is begun. It is an implement of very simple construction, and ready application, and which may be of very great utility in this intention. See *SPRING-Draining Pump*.

The writer of the work on "Landed Property" has also

suggested, that the borer is a tool which particularly presents itself as useful in this way. On the supposed similarity of the modes of searching for springs or internal waters, and for mineral or fossile substances, it is thought extraordinary that the same method of proceeding should not have long since been adopted. In the latter cases, in fresh districts, the work of searching for coal is not, it is said, begun by sinking a shaft, though appearances may be ever so favourable; the ground is first tried by the borer, at a comparatively trifling expence, to ascertain the proper place of sinking the pit. In trying for other matters, as ochres and other similar kinds, the same tool too may be said to be that which is in common use. And there can, it is thought, be no risk in saying, that it may be equally well and more profitably employed, as a common tool of the drainer, for the purpose of *finding* the springs, reservoirs, and channels of subterraneous waters, in the practice of that art, and by which it may be rescued from the difficulty and mystery in which it has hitherto been so greatly involved. See *BORER*.

It is stated, that an instance in the practice of a first-rate drainer has been seen, in which the use of the borer, for the purpose of *finding* the water before the spade was set to work, would have saved a large sum of money, which had been laid out under an error in the mode of practice which had been pursued.

There will be some difference in the depth and manner of using the tool, according to the circumstances and disposition of the land, and the intentions and methods of the draining which are to be undertaken, as has been shewn already in considering the nature of the drainage in different cases. And it may be necessary and convenient to have the bores and boring rods properly marked and regulated, especially in particular cases.

Thus, though there may be some instances of wetness in lands, in which it may be easy at once to judge and determine, with a great degree of certainty, of the nature and situation of the causes by which they are produced, and consequently to operate and perform the means of their removal without any difficulty or trouble of this sort; there are still numerous others, in which the use of such tools and implements may be of the highest and most material importance and advantage, not only in pointing out, with accuracy, the peculiarity of their situations and directions, but in preventing uncertainty and unnecessary cutting, and thereby procuring considerable savings in different ways. They must, of course, contribute much to render the practice of spring-draining more complete and perfect.

SPRING-Draining Auger, that sort of tool which is employed in this kind of draining for boring down into the substrata of the earth, after the drains have been dug, and tapping or letting off the springs, or for perforating the stiff soil or other parts, and letting the water down into a porous stratum below. It is a tool of very great utility in this sort of draining, and which has much similarity to that which is employed in searching for coal and other subterraneous minerals. The auger, or shell part that forms the hole or bore in the earth or strata through which it passes, is mostly from about two and a half to three inches in diameter; the hollow portion of it being about one foot four inches in length, and constructed nearly in the form of the common auger of the carpenter, only the sides of the shell part are made to come closer to each other. The rod parts are formed in separate pieces, of four feet long each, which screw into one another, to any suitable length, one after another, as the depth of the hole or bore may require. The size of the stem above the auger part is about an inch square, except

SPRING.

except at the joints, where, for the sake of strength, they are a quarter of an inch more. There are also a chissel and punch for serewing on, in going through hard gravel, or metallic substances, in order to expedite the passage of the auger, which could not otherwise perforate such hard bodies. The punch is often used, when the auger is not applied, to prick or open the sand or gravel, and give a more easy issue or discharge to the water. The chissel is an inch and a half or two inches broad at the point, and made very sharp for cutting stone, and the punch an inch square, like the other part of the rods, with the point sharpened also. There is a shifting handle of wood, which is fattened with two iron wedges affixed to it, for the purpose of turning round the rods in boring, and also two iron keys for serewing and un-serewing the rods, and for assisting the handle when the soil is very stiff, more than two men being required to turn the tool.

It is remarked by Mr. Elkington, that it has been considered a difficult part of the business of draining, to judge properly when to make use of this boring tool. Some, it is said, who have not seen it employed in this sort of work, have been led into a mistaken notion, both as to the manner of using it, and the purposes for which it is applied. They think, that if, by boring indiscriminately through the ground to be drained, water be found near enough the surface to be reached by the depth of the drain, the proper direction for it is along those holes where water has been found; and thus make it the first implement that is used. The contrary is the case, the auger being never made use of until after the drain is cut, and then for the purpose of perforating any retentive or impervious stratum lying between the bottom of the drain and the reservoir or strata containing the spring. Thus it is capable of greatly lessening the trouble and expence that would otherwise be requisite in cutting the trench to that depth, to which, in many instances, the level of the outlet will not admit. See *SPRING-Draining*.

The manner of using the tool in working of it is simply thus: two or rather three men are necessary. Two stand above on each side of the drain, who turn it round by means of the wooden handle; and when the auger part is full they draw it up out of the hole, and the man in the bottom of the trench clears out the earth with the instrument for the purpose, assists in pulling the auger up out of the hole, and in directing it into it again, and can also assist in turning with the iron handle or key, when the depth and length of the rods require additional force to perform the operation. The workman should be careful in boring, not to go deeper at a time, without drawing, than the exact length of the shell, otherwise the earth, clay, or sand, through which it is boring, after the shell is full, may make it very difficult to pull out. For this purpose the exact length of the shell should be regularly marked out on the rods, from the bottom upwards. Two or four flat boards, with a hole cut into the side of one of them, and laid alongside of one another over the drain, in the time of boring, are of very great use for directing the rods in going down perpendicularly, for keeping them steady in boring, and for the men standing upon, when performing the operations.

The *horizontal* draining auger is another tool of this kind, which was invented in Leicestershire, and is probably not yet become well known, or in general use. It is capable, however, of having considerable utility and application in the practice of spring-draining, as well as in other ways. It has the advantages, in many cases, of greatly lessening the expence of cutting, that would otherwise be necessary, and of performing the work in a much shorter space of time. It may be of great benefit when employed for forming a

suitable passage for the water without opening a trench-drain, where the water of a drain, brook, or rivulet has to pass under a bank, hedge, road, wall, or any other similar place, and where pits are to be laid dry; as well as in many other cases, as for tapping springs, or detecting water at the bottom parts of hilly lands, in order to the draining of the ground or the supplying of the water for different useful purposes, as the water of the springs, in these cases, when it may be hit upon, will flow with more facility and readiness, as well as in greater abundance, through such horizontal or level openings, than through perpendicular outlets. It may likewise be useful for laying or putting down leaden pipes for the passage or conveyance of water, in making the holes into which the pipes may be introduced, and laid without the necessity of forming open cuts for the purpose, which are often very laborious and troublesome in performing.

The manner of using the tool in working is this: where, for instance, water is to be discharged from any situation in which it is contained, that has high banks surrounding it, if the land declines lower on one side, after finding the level of the bottom of the water on that side, it is to be traced to the face of the bank, where the perforation is to be made through it by the auger. In doing which, the surface of the ground is there first to be made smooth, so as to place the frame of the tool nearly level, with the auger part of it pointing a little upwards. It is then to be wrought, which is done by two men turning the handles at the top part. When the auger or shell part is full, the rods are drawn back by reversing the lower handle, and other rods may be added at the joints when the distance requires it. In boring or working through a bank composed of the hardest clay, or other such materials, two men will, for the most part, get through from thirty to forty feet in the course of a day, if they be not obstructed by hard stones, or other such matters, which will require a chissel to be fixed on in the tool in the place of the shell, and longer time in working through. Where the length or distance to be bored or wrought through is considerable, and longer than the whole length of the different rods when serewed together, a pit or opening is necessary to be dug or sunk down, at a suitable distance, upon the line to the proper depth of the hole, for placing the frame and tool in when removed from its former place, and the work be then carried on in the same manner as before in the former part of the operation.

SPRING-Draining Level, that sort of level which is employed in forming and cutting drains where springs are concerned. It is the spirit-level which is, for the most part, made use of in cases of this sort, and which serves to ascertain, after a principal spring has been discovered, a line on the same level, to only one, or the different sides of it, in order that the direction of the drain may be better and more certain. The use of it is mostly the first and most important work in setting out drains in this sort of drainage. It is employed in determining the level from one particular sight, or from different stations, for a considerable length or distance. It is also necessary to decide the quantity of fall that can be gained from a drain to the nearest outfall or outlet for the discharge of the water, as the more short that is the better, when sufficient fall can be had. It has likewise several other applications in the practice of spring-draining, as may be seen in speaking of implements or contrivances of this nature. See *LEVEL*.

Scarcely any thing can be done, in this or any other mode of draining, nor even in irrigating or watering land, without the use of a proper level of some kind or other.

SPRING-Draining Pump, that sort of contrivance of the pump kind, which is made use of for the purpose of detect-
ing

ing and ascertaining the nature, situation, and direction of under-ground springs and collections of water, as well as, in some measure, the nature and position of the different strata in land, before the work of cutting and forming the drains for taking off the injurious wetness is begun. It is constructed of copper, in the pipe form, in a very neat, simple, and cheap manner, so as to admit of being put down into the ground in holes formed by the boring-auger; and by being made to be wrought as a pump, is capable of shewing the presence of water, where the pressure of it in the higher grounds above is not sufficient to force it up through the auger-holes, which is the case in many instances. The nature and direction of the under-strata are, in some degree, found in boring and putting the pump down through them. It is the invention and discovery of Mr. Wakefield, who has been long much engaged in the practice of draining in several different places and parts of the kingdom. See *SPRING-Draining*.

This is a contrivance which, with the boring-rod, would seem to be capable of being of very great importance in the business of spring-draining, as tending, by the facility and certainty which it affords of discovering and pointing out the nature, existence, and lines of springs, before any thing is done, to prevent a great deal of unnecessary labour in cutting at random, as has hitherto mostly been the case, and thereby save much useless expence to those who are under the necessity of having such works performed. The utility of these contrivances is more fully shewn under the head alluded to above.

SPRING-Draining Bricks, the several different kinds, forms, and shapes of bricks which are contrived for this use, and which differ from those of the common sort employed in building purposes. They are of many different descriptions. These kinds of bricks are mostly well calculated for forming drains which are to carry off the water coming from springs, as a large extent of land may often be rendered dry by no very great quantity of such materials; but they are not so well suited for drains which are to remove water which stagnates on the surface of land, though they are occasionally made use of for that purpose. They sometimes form hollow passages for the water to run along, as in stiff soils; but in such as are soft they are made to form a sort of pipe or cylindrical passage for the same, by being laid one upon the other. See *SPRING-Drain*.

SPRING-Bog, a term applied to that sort of bog or boggy wetness which is caused by springs, in contradistinction to that, or the swampy wetness, which proceeds from the stagnation of rain or other water upon the surface of land where these prevail in land-locked situations.

Spring-bogs are, for the most part, more confined than those of the contrary kind, but they are sometimes equally extensive with them.

SPRING-Brine. See *SALT-Brine Spring*.

SPRING, Elater, in *Physics*, denotes a natural faculty, or endeavour, of certain bodies to return to their first state, after having been violently put out of the same by compressing, bending them, or the like.

This faculty philosophers usually call *elastic force*, or *elasticity*.

Fleas only jump to excessive heights by means of a springy membrane, easily visible by a microscope; and of which we have a curious figure in Dr. Hooke's *Micrographia*. By the elastic force of this spring they are enabled to leap two hundred times the height of their own body. See *FLEA*.

Nature has provided for the regular sowing of the seeds of several kinds of plants, by furnishing them with a spring,

which is wound sometimes round the outside, and sometimes round the inside of the case in which the seeds are contained. See *SEMINATION*.

SPRING, in *Mechanics*, is any elastic body, commonly of steel properly tempered, and formed in various ways, according to the purpose it is intended to answer, whether it be for giving motion to a machine, or for equalizing and modifying motion derived from some other agent. Springs are also introduced into instruments, called spring steel-yards, for ascertaining the weights of bodies, as well as having various other applications, which it would be useless to enumerate in this place.

Considering, therefore, the numerous uses to which this kind of force may be directed, it must appear very remarkable that so little is known of the true principle of the action of springs, and of the laws by which their powers are regulated; we know, indeed, of no regular set of experiments, that have yet been made, which are at all adequate to reducing their operation to correct mathematical principles.

Dr. Hooke seems to have been the first writer who undertook experiments on the action of springs, with a view of drawing from them general conclusions, and by this means to introduce them into the theory of rational mechanics: and the result which he thus obtained, was his celebrated law "ut tensio sic vis," the tension is as the force: a law which some subsequent experimenters have stated to be correct, while others of considerable eminence have denied its accuracy and agreement with experiment in numerous cases. The fact, therefore, seems to be, that in springs of a certain form, and *within certain limits*, the principle is just; but that others of different form, and in *all*, when the force is very considerable in regard to the strength of the spring, it does not apply: and, consequently, that much still remains to be done before the actions of different springs can be admitted to form a part of theoretical mechanics.

Dr. Jurin, by adopting the principle above referred to, *viz.* "the tension is as the force," succeeded in rendering the action of springs susceptible of mathematical computation. See *Phil. Trans.* N^o 472. p. 46; or vol. ix. p. 19. of *Hutton's Abridgment*.

This paper certainly displays great ingenuity, and would be of considerable utility, provided the hypothesis there assumed were perfectly correct; and even as it is, although a different law may have place between the space through which the spring is drawn or compressed, and its resistance, the same principle of investigation must still be preferred; and it may, therefore, be considered as the foundation on which the true theory must be raised, after a sufficient number of experiments has been made to assure us of the correct law of their action, not merely within the narrow limits contemplated by the founder of the hypothesis, but through all degrees of compression and extension, short of that which destroys their original elasticity. We shall therefore offer no apology for exhibiting a concise view of the principal theorems and deductions of this ingenious author.

Dr. Jurin commences his memoir with a few necessary definitions; as the

Length of a spring, which is used to signify the greatest length to which a spring can be forced inwards, or drawn outwards, without prejudice to its elasticity. He observes, this would be the whole length, were the spring considered as a mathematical line; but in a material spring, it is the difference between the whole length, when the spring is in its natural situation, or the situation it will rest in when not disturbed by any external force, and the length or space it takes

SPRING.

takes up when wholly compressed and closed, or when drawn out.

Strength or force of a spring is used for the least force or weight which, when the spring is wholly compressed or closed, will restrain it from unbending itself. Hence also the force of a spring bent, or partly closed, is used for the least force or weight which, when the spring is bent through any space less than its whole length, will confine it to the state it is then in, without suffering it to unbend any farther.

We have before stated, that the principle which this author assumes is, that if a spring be either compressed or stretched by any external force, its resistance is proportional to the space by which it is removed from its original and natural situation. Thus, suppose, for instance, a spring (*Plate XXXVIII. Mechanics, fig. 6.*) CL , resting with the end, L , against any moveable support, but otherwise lying in its natural situation, and at full liberty; then, if this spring be pressed inwards by any force, p , or from C towards L , through the space of one inch, and can be there detained by that force, p , the resistance of the spring and the force, p , exactly counterbalancing one another; then will the force $2p$ bend the spring through the space of two inches, $3p$ through three inches, $4p$ through four inches, &c. The space, Cl , (*fig. 7.*) through which the spring is bent, or by which its end, C , is removed from its natural situation, being always proportional to the force which will bend it so far, and will detain it so bent.

And if one end, L , be fastened to an immoveable support (*fig. 8.*), and the other end, C , be drawn outwards to l , and be there detained from returning back by any force, p , the space, Cl , through which it is so drawn outwards, will be always proportional to the force, p , which is able to detain it in that situation.

And the same principle holds in all cases, where the spring is of any form whatsoever, and is in any manner whatsoever forcibly removed from its natural situation.

It may be here observed, that the spring, or elastic force of the air, is a power of a different nature, and governed by different laws from that of a material spring. For supposing the line LC (*fig. 6.*) to represent a cylindrical volume of air, which by compression is reduced to Ll (*fig. 7.*), or by dilatation is extended to Ll (*fig. 8.*), its elastic force will be reciprocally as Ll ; whereas the force or resistance of a spring will be directly as Cl .

This principle being premised, Dr. Jurin gives us a general theorem concerning the action of a body striking on one end of a spring, while the other end is supposed to rest against an immoveable support. And lest any objection should be formed against the possibility of an immoveable support, since any body, how great soever, may be removed out of its place by the least force, he observes, that the objection may be easily removed. Thus, if the spring LM (*fig. 9.*) be supposed continued to N , so that $LN = LM$, if a body M , with any velocity in the direction ML , strikes one end of the spring, and a body N , at the same time, with an equal velocity, and a contrary direction NL , strikes the other end, N , of the continued spring, the point L , the end of the first supposed spring, will be immoveable.

Theorem.—If a spring of the strength P , and the length CL (*fig. 10.*), lying at full liberty on an horizontal plane, rest with one end, L , against an immoveable support; and a body of the weight M , moving with the velocity V , in the direction of the axis of the spring, strike directly on the other end, C , and thereby force the spring inwards,

or bend it through any space CB ; and a mean propor-

tional, CG , be taken between the line $CL \times \frac{M}{P}$, and

$2a$, a being the height to which a heavy body would ascend in vacuo, with the velocity V ; and upon the radius $R = CG$, be erected the quadrant of a circle GFA : then,

1. When the spring is bent through any right sine of that quadrant, as CB , the velocity, v , of the body, M , is to the original velocity, V , as the cosine to the radius;

$$\text{that is, } v = V \times \frac{BF}{R}.$$

2. The time, t , of bending the spring through the same sine CB , is to T , the time of a heavy body's ascending in vacuo with the velocity V , as the corresponding arc to

$$2a; \text{ that is, } t = T \times \frac{GF}{2a}.$$

After demonstrating this proposition, the author proceeds to draw from it several curious corollaries, which, for greater simplicity, he divides into three distinct classes, according as they appertain to the following cases: *viz.*

Case 1.—When the spring is bent through its whole length, or is entirely compressed or closed, before the moving force of the body is destroyed and its motion ceases.

Case 2.—When the moving force of the body is consumed, and its motion ceases before the spring is bent through its whole length, or wholly closed. And

Case 3.—When the moving force of the body is expanded, and its motion ceases at the instant that the spring is bent through its whole length, and is entirely closed.

We shall enumerate a few of the most interesting corollaries in each of these classes, premising first, that P = strength of the spring, L = its length, V = the initial velocity of the body closing the spring, M = its mass, t = time spent by the body in closing the spring, A = height from which a heavy body will fall in vacuo in a second of time, a = the height to which a body would ascend in vacuo with the velocity V , C = the velocity gained by the fall, m = the circumference of a circle, whose diameter is 1.

CASE 1. Cor.—When the spring is bent through any right sine, CB , (*fig. 10.*) the loss of velocity is to the original velocity, as the versed sine to the radius; or $V -$

$v = V \times \frac{Gg}{R}$, where v is the present, and V the original velocity.

2. When the spring is bent through any sine, CB , the diminution of the square of the velocity is to the square of the original velocity, as the square of the sine to the square

$$\text{of the radius; that is, } V^2 - v^2 = V^2 \times \frac{CB^2}{R^2}.$$

3. When the spring is bent through any space, l , the velocity, v , of the body is equal to $V \times \sqrt{\frac{2MLa - Pl^2}{2MLa}}$;

$$\text{or to } V \times \sqrt{\frac{2Ma - pl}{2Ma}}.$$

4. The time, t , of bending the spring through any space, l , is proportional to the arc, GF , divided by \sqrt{a} ; l being

l being the right sine of the arc, and $R = \frac{2MLa}{P}$ being the radius.

CASE 2. Cor. 1.—If the motion of the body cease when the spring is bent through any space, l , the initial velocity is

$$V = Cl \sqrt{\frac{P}{2MLA}}, \text{ or } V = C \sqrt{\frac{pl}{2MA}}.$$

2. If the motion of the body cease when the spring is bent through any space l , the time, t , of bending it is

$$t = 1'' \times \frac{m}{2} \sqrt{\frac{ML}{2PA}}, \text{ or } t = 1'' \times \frac{m}{2} \sqrt{\frac{Ml}{2pA}},$$

where $m = 3.1416$, viz. the circumference of a circle to diameter 1.

3. In the same case, the time of bending the spring is proportional to $\sqrt{\frac{ML}{P}}$, or to $\sqrt{\frac{Ml}{p}}$; and if $\frac{L}{P}$ be given, t will be as \sqrt{M} ; and if both $\frac{L}{P}$ and M be given,

t will always be the same, whatever be the original velocity, or through whatever space the spring is bent.

4. If the motion of the body cease when the spring is bent through any space, l , the product of the initial velocity, and the time of bending the spring, or Vt , = $1'' \times \frac{mCl}{4A}$, and is proportional to l , the space through which the spring is bent.

Hence, any two of the three quantities, V , t , and l , being given, the other is readily determined.

5. In the same case the initial quantity of motion MV = $C \sqrt{\frac{PM}{2LA}}$, or $MV = C \sqrt{\frac{plM}{2A}}$.

CASE 3. Cor. 1.—If the motion of the body striking the spring cease, when it is wholly closed, the initial velocity

$$V = C \sqrt{\frac{PL}{2MA}}.$$

2. The initial velocity V is proportional to $\sqrt{\frac{PL}{M}}$.

3. If PL be given, either in the same or in different springs, the initial velocity V is reciprocally as \sqrt{M} .

4. The product of the initial velocity, and the time spent in closing the spring, or Vt , = $1'' \times \frac{mCL}{4A}$; and is proportional to L , the length of the spring.

5. The initial quantity of motion, or MV , = $C \sqrt{\frac{PLM}{2A}}$.

6. MV is proportional to \sqrt{PLM} , or to Pt . And if PL be given, either in the same or different springs, MV is as \sqrt{M} .

7. If $\frac{P}{L}$ be given, either in the same or in different springs, the initial quantity of motion is as the length of the spring into the time of bending it.

8. If a quantity of motion, MV , bend a spring through its whole length, and be consumed by it, no

other quantity of motion equal to the former, as $\pi M \times \frac{V}{n}$, will close the same spring, and be wholly consumed by it.

9. But a quantity of motion, less or greater than MV , in any given ratio, may close the same spring, and be wholly consumed in closing it; and the time spent in closing the spring will be respectively less or greater, in the same given ratio.

10. The initial *vis viva*, or MV^2 , = $\frac{C^2 PL}{2A}$; and $2aM = PL$.

11. The initial *vis viva* is as the rectangle under the strength and length of the spring: that is, MV^2 is as PL .

12. If $\frac{P}{L}$ be given, the initial *vis viva* is as P^2 , or as L^2 .

13. If the *vis viva* MV^2 bend a spring through its whole length, and be consumed in closing it; any other *vis viva*, equal to the former, as $n^2 M \times \frac{V^2}{n^2}$, will close the same

spring and be consumed by it.

14. But the time of closing the spring by this *vis viva* $n^2 M \times \frac{V^2}{n^2}$, will be to the time of closing it by the *vis viva* MV^2 , as n to 1.

15. If the *vis viva* MV^2 be wholly consumed in closing a spring of the strength P , and length L ; then the *vis viva* $n^2 MV^2$ will be sufficient to close, 1, either a spring of the strength $n^2 P$, and length L ; 2, or a spring of the strength $n P$, and length $n L$; 3, or of the strength P , and length $n^2 L$; 4, or if n be a whole number, the number n^2 of springs, each of the strength P , and length L , one after another. We may add, that it appears from hence, that the number of similar and equal springs a given body in motion can wholly close, is always proportional to the squares of the velocity of that body. And it is from this principle that the chief argument, to prove the force of a body in motion to be as the square of its velocity, is deduced. See FORCE.

The theorem above-mentioned, and its corollaries, will hold equally, if the spring be supposed to have been at first bent through a certain space, and by unbending itself to press upon a body at rest, and thereby to drive that body before it, during the time of its expansion: only V , instead of being the initial velocity with which the body struck the spring, will now be the final velocity with which the body parts from the spring, when totally expanded.

It is also to be observed, that the theorem, &c. will hold equally good, if the spring, instead of being pressed inwards, be drawn outwards by the action of the body. The like may be said, if the spring be supposed to have been already drawn outwards to a certain length, and in restoring itself draw the body after it. And, lastly, the theorem extends to a spring of any form whatever, provided L be the greatest length it can be extended to from its natural situation, and P the force which will confine it to that length. See Phil. Trans. N^o 472. sect. 10. or vol. xliii. art. 10.

SPRING is more particularly used, in the *Mechanic Arts*, for a piece of tempered steel, put into several machines to give

give them motion, by the endeavour it makes to unbend itself.

In watches it is a fine piece of well-beaten steel, coiled up in a cylindrical case, or frame; which, by stretching itself forth, puts the wheels, and the whole movement, in motion. See FUSEE, and WATCH.

The spring of a watch is prepared by forming a very thin plate of steel into a double ring, bending it round with wire, and putting it into a proper furnace, in order to give it a suitable degree of heat. When that is acquired, it is taken out, and dropped into a kettle of oil, or warm mutton suet, in consequence of which process it possesses a degree of hardness, very little inferior to that of glass. After this it is reduced or let down, if the steel be of a proper kind for the purpose, to a fine violet or blue colour; in which state it becomes exceedingly elastic, inasmuch, that to make it stand bent, it must be brought into a very acute curve; nor can it easily be brought, by twisting horizontally, to alter its form, without endangering its being broken to pieces. But as it afterwards requires to be planished by the hammer, filed, and polished, it is again deprived in a considerable degree of its elasticity: and, therefore, when it has received its last polish, it must again be blued upon a brass plate over a lamp, by which means its former elasticity is perfectly restored. Dr. Hooke, in his *Micrographia*, says, that this blue covering is owing to the fine sulphur, pressed through the pores by heat, and fixed by the ambient air in a fine vitrified lamina upon the surface. See STEEL.

The spring of a lock, pistol, or the like, is a piece of steel violently bent, which beats back the bolt, or strikes down the cock, when set at liberty.

SPRING-*Arbor*, in a *Watch*, that part in the middle of the spring-box, about which the spring is wound or turned, and to which it is hooked at one end.

SPRING-*Box*, the cylindrical case, or frame, that contains within it the spring of the watch.

SPRING-*Compasses*. See COMPASSES.

SPRING-*Rings*, in *Rural Economy*, the large ring contrivances of the strong spring kind, through which the reins pass in stables, in order to prevent horses from being injured by being entangled in them. They have a different form from the rings which are commonly employed, and are fixed in an immoveable manner to the items, shanks, or parts, which screw into the wood and hold them fast. The springs in them are so contrived, as that the reins of the head-stalls can be slipped into and out of them with great ease and facility. They are a very useful and safe sort of ring contrivance, for this purpose, in many cases, especially where horses are restless, and much liable to the above kind of accidents. The expence of them is not great, while the security which they may afford is considerable. They are equally necessary and beneficial in farm stables as those of the saddle-horse kind. See STABLE *Rings for Stalls*.

SPRING of the *Air*, or its elastic force. See AIR and ELASTICITY.

SPRING, in a *Ship*, is a rope passed out of one extremity of a ship, and attached to a cable proceeding from the other, when she lies at anchor. It is usually performed to bring the ship's broadside, or battery of cannon, to bear upon some distant object: as another ship, or a fortress on the coast, &c.

SPRING is likewise a rope reaching diagonally from the stern of a ship to the head of another, which lies alongside or abreast of her, at a short distance. This is generally performed to make one of the ships sheer off to a greater distance from the other; or to make merchant-ships lie uni-

formly in the same tier. Springs of this sort are, therefore, occasionally applied from a ship to a wharf or key, for the same purpose. Falconer.

SPRING a *Leak, To*. See LEAK.

SPRING the *Luff, To*. See LOOF.

SPRING a *Mast*. See MAST.

SPRING, *To*, in *Military Language*, is to give vent to any combustible matter upon which gunpowder principally acts by the power of explosion. Hence the phrase to spring globes of compression, &c. which are frequently used for the same purposes with sky-rockets, &c. to serve as signals when any sudden attack is to be made.

SPRING, *To*, is also to step forward with a certain degree of elasticity.

SPRING the *Firelock, To*, is to bring it briskly up to any ordered position, *c. g.* in the recover.

SPRING *Up*, a word of command occasionally used, and signifying the same as double up; sometimes used singly, as *spring!* particularly to light infantry men.

SPRING, *Cear*. The cear is a piece of hardened iron or steel in a gun-lock, which moves on a pivot, and the point of which is received in a notch cut in the tumbler, and the other end is acted upon by the trigger. The cear spring is a small spring, which throws the cear into the said notch, when the piece is at half cock or full cock.

SPRING, *Feather*, the spring of a gun-lock beneath the foot of the hammer, called likewise hammer-spring.

SPRING, *Main*, the spring of a gun-lock, which operates on the tumbler, and gives force to the cock.

SPRING, *Ver*, in *Cosmography*, denotes one of the seasons of the year; commencing, in the northern parts of the world, on the day the sun enters the first degree of Aries, which is about the twenty-first day of March, and ending when the sun leaves Gemini.

Or, more strictly and generally, the spring begins on the day when the distance of the sun's meridian altitude from the zenith, being on the increasing hand, is at a medium between the greatest and least. The end of the spring coincides with the beginning of summer.

Spring is the season in which plants vegetate and grow with the most force and luxuriance. Late springs are, however, in general, the most beneficial to the farmer, and occasionally to the gardener.

In such springs as are late in their appearance, there is, for the most part, less danger in the climate of this country of the crops of different kinds suffering from the checks and injuries which they may receive in them, than in those which are early, as the changes in them are mostly much less frequent, and at the same time much less severe.

Fruit-trees of various kinds are often greatly injured in the formation and production of their fruit by early springs. This is particularly the case with the almond, the apple, the plum, and the cherry-tree, as well as with the gooseberry-bush, and some others. The peach, the nectarine, and some other fine fruited trees, are also sometimes much injured in their fruiting by early springs, as where they are planted against walls or palings, in the open ground in exposed situations.

Garden-crops of many different kinds not unfrequently suffer greatly from early springs; whole crops of particular sorts being, in some instances, nearly destroyed, as is not seldom the case, in such seasons, in the first sown onion, pea, and several other kinds of culinary crops.

SPRING *Crops*, in *Agriculture*, such as are put into the ground in the spring season of the year, as oats, barley, some sorts of wheat, and different other crops. See these heads.

SPRING *Food*, that sort of food, whether of the turnip,

rye, tare, rape, cabbage, preserved grafs, artificial grafs, natural grafs, or any other kind, which is made use of for live-stock, especially sheep, in the spring season.

SPRING Garden, that sort of ornamental garden which is chiefly designed for the introduction of all sorts of curious early budding and flowering trees, shrubs, and flower-plants, in the intention of affording beauty, variety, and effect.

Gardens of this nature should be suitably situated somewhat contiguous to those of the winter kind, being connected with them and the residences by suitable walks of the gravel kind, so as that they may be gone into at any season or period without inconvenience. The ground or soil for them should be of the more light, friable, and dry kind, and be so situated as to be well exposed to the influence of the sun, being completely sheltered on the northern sides, so as to prevent the blasts from that quarter having any injurious effects on them. They should also have some sort of neat ornamental erection in them for containing the heaths, the auriculas, and different other tender early flowering plants.

Gardens of this sort have a fine effect in many situations, when well laid out and managed. See **PARTERRE**.

SPRING Grafs, a term sometimes applied to the sweet-scented vernal or meadow-grafs, from its being so forward or early in its growth. See **ANTHOXANTHUM odoratum**.

It also signifies the grafs of any kind that springs early in the spring season, and which affords the first bite for live-stock of any sort.

SPRING Sowing, such sowings as are performed in the spring season, as that for spring wheat, oats, barley, and many other crops. See **SOWING of Seeds**.

SPRING Sowing, in **Gardening**, comprehends all those sowings which are made at that season of the year, especially for any sort of general feed crops, as those of the pea, bean, and small seed kinds. Small flower and other seeds are put into the ground at an early period with advantage, as they are much less liable to be injured by insects in their after-growth, and rise more favourably than where the contrary is the case. The same is sometimes the case with small grafs seeds sown in the field. See **SOWING of Seeds**.

SPRING Tare, a term used to signify that sort of tender tare, which is sown and cultivated in the spring season for summer use, in contradistinction to the winter tare, which is usually sown in the autumn, and stands the severity of the winter season. See **TARE**.

SPRING Tide is the increasing of a tide after a dead neap; or the periodical excess of the elevation and depression of the tide; which see.

SPRING Wheat, that sort of this kind of grain, which is capable of being sown or put into the ground in the early spring season, and cultivated or grown with the same or greater success and advantage, than the common kind. It has been stated by sir Joseph Banks, that real spring wheat, the *tritium aestivum*, or summer wheat of the botanists, is a grain too tender to stand and bear the frosts of the winter in this climate, but as quick in its progress from its first shoot to ripeness, as barley, oats, or any other spring corn. See **TRITICUM**.

The writer of the tract on the result of an Inquiry into the nature and causes of the blight, the rust, and the mildew, which have affected the wheat-crops on the borders of England and Scotland, has suggested, that common or winter wheat requires the most expensive culture, being generally put into the ground in the autumn, and usually requiring eleven months before it arrives at maturity; that consequently the returns from such a species or sort of grain, should be more lucrative than when spring corn of this kind is raised, which, after remaining only about four

months in and on the ground, is then in a proper state to be cut down. Nor is the difference in point of produce supposed to be so very material, as to render it indispensably necessary to exclusively cultivate winter wheat, with a view to profit; and, indeed, it would appear, it is said, that in several other respects, it would be desirable to grow a considerable quantity of spring wheat in this kingdom, as being better calculated for the different soils and situations in different parts and places, as being less liable to disease, and as furnishing a most important resource in case there be reason to apprehend that the autumn or winter-sown wheats may become unproductive, or of a bad quality.

It is well known, that in some parts of the kingdom it is the practice to sow winter wheat in the spring, seldom, however, it is supposed, later than the month of February, or the middle of March, and have occasionally good crops from it; and it is understood, from the most respectable authority, that though the winter wheat sown in the spring is at first later in ripening than the same sort sown in autumn, yet that this disadvantage, in regard to becoming ripe, lessens, when the crop of wheat of that sort which was sown in the spring, is sown again in the succeeding spring. Winter wheat sown in spring thence acquires a tendency, it is said, to earlier maturity, if resown in the spring; but from an experiment which was tried in the county of Middlesex, it does not appear, that when sown in the autumn it becomes ripe earlier than common winter wheat. But still, it is admitted, that it does not ripen quite so soon as wheat sown in autumn, nor as real spring wheat, nor can it be sown so late in the season. An intelligent farmer, it is said, states the difference between real spring wheat and winter spring-sown wheat, at three weeks; which is a most material advantage in favour of the former. But as we have a species or sort of wheat which is peculiarly calculated for spring culture, why, it is asked, should we endeavour to force another sort to alter its nature and properties, and to grow and acquire maturity in a shorter period of time than nature intended? And if considerable quantities of wheat too can be sown in the spring, with perfect safety and success, why, it is also asked, should we confine our Lent or spring crops of grains to oats and barley? It is suggested, as being also understood by the same writer, on respectable authority, that the spring-sown wheats were, at one time, getting out of use or fashion in France; but that they were soon under the necessity of again returning to them as an essential source of supply.

In this place we may then shortly consider the history, nature, qualities, uses, and advantages of it, as well as the sorts of land and exposures most suited to its growth, and the means by which the seed of it may be the best and most readily procured; leaving the methods of its cultivation, growth, application, and other points and circumstances, to the head wheat, to which indeed they as well as it properly belong. See **WHEAT**.

Spring, or this sort of wheat, is supposed, and with great probability, to have been originally produced in Sicily, where it is known, it is said, under the name of *Tumenia*, a corruption of *Trimenia*, or three months' grain. It is also much cultivated in Barbary, in Spain, in Portugal, in France, in Germany, and in almost all the corn countries, with the exception of this country, where, on account of the immense consumption of malt-liquors, barley is more in demand, than where wine is the common beverage of the people. The former of the above writers considers it as well known over all parts of the continent of Europe, and to be much used and employed in cultivation in France, where it is called *Blé de Mars*, from the season in which it is usually sown; and in some provinces

provinces of that tract of country *Bleds-tremois*, from the time it takes between seed-time and harvest; that in Spain, it is called *Trigo de Marzo*; in Portugal, *Trigo Tremes*; and in Germany, *Sommer Weitzen*; according to the languages of the different countries; all of which names are said to mark in a distinct manner the difference between this and the winter corn of the same sort. It has also been asserted on the same authority, that spring wheat may be sown in autumn, and that if it should succeed, it will produce a beautiful sample, but that as it is, like barley, a tender plant, a severe frost will kill it. Some have, however, supposed it to be a native of some part of Tartary, but it is evidently the production of a warm climate, such as that noticed above. It has been classed by Ray, and probably others, as a distinct species or sort of wheat. In regard to its introduction into this country, it is commonly believed to have been introduced or brought into it about the year 1773, or probably a little earlier, under the names of Siberian wheat, Switzerland wheat, or blé de Mars, as above. It is said, however, to have been mentioned by Harrison, an historian in the time of Elizabeth, though he represents it as having been then only known to a few husbandmen or farmers.

It has also been said that spring wheat was known to the Romans as a species or sort distinct from the common autumn or winter kind, and described as such by Columella, who considered and believed it very acceptable to the farmer, when, in consequence of floods, rains, or other similar causes, the autumn or winter wheat was prevented from being sown or put into the ground by him. And that the Rev. Mr. Dickson, in his "Husbandry of the Ancients," has likewise considered it as well adapted to the wet cold climate of Scotland, where, on account of heavy rains, and other causes, the farmers are not unfrequently restricted in regard to the quantity of autumn or winter wheat that can be sown or got into the ground.

The writer first noticed has, however, remarked, that it does not appear from the older books on husbandry, that it was at any former period much grown or cultivated in this country; and that the more modern ones are in general silent on the subject of it: they mention, indeed, under the name of spring wheat, every kind of winter wheat which will ripen when sown after turnips in the month of February; but little or nothing is said on real spring wheat. This, it is conceived, is probably the reason why the real spring wheat has been so little known, the cultivators of land in general conceiving themselves to be actually in the habit of sowing spring wheat, when, in reality, they were only substituting winter wheat in its place, have been little inclined to inquire into the properties or qualities of the real spring wheat, when they had an opportunity and the means of so doing.

The inquirer already noticed states, on the authority of an intelligent correspondent, that above thirty years ago, the empress Catharine sent a bushel of spring wheat to his majesty, which the king gave to Mr. Duckett, the celebrated farmer of Esher, in the county of Surrey, who cultivated it for some time, and sold a number of bushels from it for seed. Notwithstanding which, not a vestige of it now, it is said, remains in all that neighbourhood. On which, it may be observed, that, as coming from Russia, it might not be the best sort of spring wheat, of which there are so many varieties, as will be seen below: that a small quantity, thus accidentally introduced into a district, might get into improper hands, and be given up from thoughtlessness or inattention: that the difference of price between wheat and barley, considering the difference of produce, was then so inconsiderable, as to induce farmers to give

up the culture, not only of spring, but even of winter wheat: and that the introduction of many other useful objects and practices, besides that of spring wheat, has at first many obstacles, difficulties, and impediments to contend with. The late Dr. Walker, in a work noticed below, has likewise observed that this sort of wheat, or the true *summer* wheat, as he calls it, is a grain very little known in this country, though much grown in the northern parts of France, as well as in Jersey, Guernsey, and in other places. It was first brought into Ayrshire, in Scotland, from the island of Jersey, by John, earl of Loudoun, during spring, in the year 1766. And that, on being sown in a heavy clayey soil, and upon one of a more early kind, in the former on the 7th of April, and in the latter on the 4th of the same month, it was reaped or cut down on the 26th of September in the first case, and on the 4th of the same month in the last. In both instances, it afforded ten Linlithgow bolls of wheat, which are above forty Winchester bushels, upon the Scotch acre. When the grain was weighed, a boll of it was found to be only two pounds lighter or less than a boll of winter wheat.

Spring wheat of the true kind, though sown so late as near the middle of May, has been found to become ripe at the same time with the autumnal or winter wheat, and that there is no benefit gained by early sowing with it, as that which has been put into the ground in April, has become ripe as early as that sown in the beginning of the preceding month. In its growth, it is said by some that it does not tiller in the manner of common or winter wheat, but shoots up and advances immediately and directly from the moment of its appearance above the surface of the ground. The grains or corns, which are smaller than those of the common winter wheat, become larger and finer by being grown on better and more fertile land. It is supposed to succeed well on low fenny sorts of land, which are apt to be flooded during the winter season: and that it is highly deserving of being tried in the mountainous parts of Derbyshire, Yorkshire, Lancashire, and some other northern districts, where little or no wheat is sown, the situations and exposures being too cold and open for wheat sown in the autumn to stand the severity of the winter frosts, thaws, and rains, without perishing and being destroyed. It has been noticed, that though, under particular circumstances, spring wheat, when lately tried, has not always answered perfectly well, yet that in many cases it has succeeded to a wish, and that it is now the prevailing husbandry in an extensive district in the county of Lincoln: that the growth of wheat has become more important and essential than ever, since it has become so much more generally used as food: and that the price now so much better and more fully rewards the industry of the grower or husbandman. All these circumstances being taken into full consideration, no substantial reason can, it is thought, be assigned, why spring wheat should not be raised in every district of this country which is calculated for the growth and cultivation of so important a national resource in this sort of grain, and without the possession of which, it is indeed thought that this country cannot be permanently independent of foreign supply.

The writer of the above Inquiry states, that there are, it is said, about fifty varieties of spring, or this sort of wheat; but that the kind or variety best known in this country has awns like barley, and hence that it is sometimes known under the name of *rough* or *bearded* wheat. The pickle or grain in it is red; but it has not so bold or full a sample as winter wheat, yet it weighs better; it is consequently preferred by all honest millers, who know its nature and

value, as the persons engaged in this business are now mostly beginning to do. Some farmers mix it with different proportions of winter red wheat, as the red Lammas, which resembles it so much in colour, that they never fail to profit by the practice, as it increases the weight of the mixture more than it diminishes the quality of the sample; and besides renders it more productive at the mill. The proportions employed are usually about one half, or rather less than that quantity, in such mixtures. The average weight of spring wheat is mostly about sixty pounds the bushel. The bread made from the flour of it is, it is said, sweeter than that from winter corn of the wheat kind. And that it is likewise more nutritious, as containing a larger proportion of gluten, or half animalized matter, in its composition. The bread is also allowed to be more palatable, it is said, to those who are in the habit of constantly eating it. In proof of its greater power of nourishment and support, the analysis of sir Humphrey Davy has shewn, that it has more gluten or real nutrient matter in it, when compared with other grains of the same kind, than in good winter wheat, in the proportion of twenty-four to nineteen in the hundred. And that in regard to the insoluble matter or part, or the bran, there is only a difference of two parts more in the hundred, when compared with good winter wheat of this country. Consequently, that the difference in price between it and such wheat, when of equal weight, should only be in that proportion.

The advantages which attend the more general introduction and growth of this sort of grain or wheat, are partly of a private, and partly of a public nature. In the former point of view it is of great importance, it is said by the writer of the above inquiry, to have it in the power of the farmer to raise so valuable an article as wheat, though sown late in the spring, or even in the beginning of summer. It was formerly generally conceived that after turnips, which was considered as the basis of good husbandry on light sorts of land, that barley, including bear or bigg, was almost the only crop that could be raised and grown with advantage, as the sowing of winter wheat in the spring could only be attempted or practised in a partial manner. But it now appears that spring wheat may be raised and grown with as much ease and facility, and with more profit, than the inferior sorts of barley, too great a quantity of which is grown at present, since the exportation of grain has been checked and restricted, and such enormous duties laid on malt. But here is a resource, it is said, which, if aided by a prohibition of foreign wheat from being imported, unless at augmented rates or prices, would always enable the farmer or grower, where his situation and the nature of his land are suited to the cultivation of it, to proceed in his useful and industrious career with proper inducement, energy, and spirit.

A still further most important circumstance in favour of spring wheat is, that, it is said, of its not only being exempt from the blight or mildew, but also of its not being liable to any risk of damage or injury from the grub or wire-worm: and this is a matter which is not to be attributed to the nature of lands or seasons; for the farmers of the extensive tract or district of country known by the name of South Holland, in the county of Lincoln, in which there are various kinds of land, uniformly declare, that they were compelled, many years ago, by the frequent attacks of the blight and mildew, to abandon almost entirely the sowing of winter wheat, and to substitute spring wheat in its place or stead. That spring wheat is not liable to the disease of blight or mildew, has also been lately shewn by a field of twelve acres, which was totally, it is said, exempt from that disease, in a

district where every other field was in a most miserable state or condition with it. In the corrected account of the "Agriculture of the County of Essex," it is stated, however, that there is an instance of spring wheat being mildewed: and that Mr. Bailey, of Chillingham, states, in a letter to the writer of the "Inquiry," that spring wheat, sown in the month of March, was affected with the mildew, while the same sort, sown on the 2d, the 3d, and the 10th of May, escaped; also, that some spring or bearded wheat of the last crop, suffered from that disorder where it was thick on the ground, probably owing to the want of air; for where it was thin, it escaped. The writer of the "Inquiry," however, conceives, that a few exceptions cannot overturn a general rule, which was recognized above a century ago in the "Systema Agriculturæ," printed in the year 1681, and which repeated experience has since sanctioned. They, however, sufficiently prove that it is not wholly incapable of receiving the disease under particular circumstances and modes of growth. The authority of the work quoted is probably of no great consequence, as real spring wheat was at that early period but little if at all known or cultivated in this country. The fact or matter can perhaps only be satisfactorily ascertained and decided by more full and correct experimental trials than any which have hitherto been made. It is a very material point in its favour, however, that it is a vast deal less liable to the disease than autumnal or winter wheat, which is allowed on all hands.

It should, however, be noticed, that it is liable, as in the other kind of wheat, to be affected with the smut, and consequently that it must be carefully washed, brined, or pickled, in order to avoid any risk of the disease, with a very highly saturated solution of common salt, in such a manner as to prevent the danger of this sort of infection being communicated in any way, and then dusted over with quicklime, as has been occasionally practised, and as will be more fully shewn in speaking of steeps and steeping grain. See STEEP, and STEEPING Grain. See also SMUR.

In the latter of the above points of view, the advantages of raising this sort of wheat are not less important. The writer of the "Inquiry" states, that for several years past we have depended on importation for a part of our food. We have sent abroad, it is said, above thirty millions sterling, to enrich and improve foreign countries, the most part of them lately in a state of hostility against us; and that so regular were our demands, that they were led to imagine that we could not exist without their assistance in this way. What, therefore, can, it is asked, be more desirable than to put an end to such a disgraceful dependence upon such nations, which, by the growth and cultivation of spring wheat to a considerable and sufficient extent, may at once be completely and effectually accomplished? It seems to the writer, indeed, of such essential importance, that until the system or practice is thoroughly established, some legislative encouragement, to increase the growth and cultivation of this sort of wheat, would be in the highest degree expedient. How much better, it is said, is it to promote domestic cultivation and improvement, than to bestow bounties on the importation of mere trash, the refuse of foreign granaries, of which such quantities are commonly sent to this country in times of scarcity?

It may consequently be fairly asked, whether the cultivation and growth of spring wheat should not be considered as a national resource of very great magnitude and importance; and as such be strongly inculcated on, and recommended to, the attention of the public? The utility and consequence of it in this way, in times of scarcity, have indeed

indeed been enforced by the first of the above writers and others, by observing that the price of wheat seldom advances much, even in very scarce years, until a considerable portion of the crop has been threshed out, and the yield of it by this means ascertained, but that this does not take place until the seed-time of winter wheat is wholly over and past; no speculation, consequently, of sowing an increased quantity of that grain, can be entered into, during the first year of a scarcity; but before the end of April, the question of the average yield of the preceding crop will be generally known, and when it is much below the usual proportion, there can, it is supposed, be no doubt, that a large quantity of spring wheat will be sown, if the seed can be easily procured. And that when there is, in the early spring months, any general appearance of defect or deficiency in the autumnal sown crops, from whatever cause it may arise, spring wheat ought to be sown, in such proportion as may suffice for yielding a produce equivalent to such probable defect or deficiency: and that if the stock of wheat on hand should prove scanty, or of inferior quality, either from mildew or other causes, there is, on these accounts, a necessity to have recourse to the sowing of spring wheat, in order to augment and increase the stock on hand. It is thought more especially necessary by the writer of the "Inquiry," to promote the cultivation and growth of spring wheat in a more general manner, because, unless it be grown to some extent, no quantity of seed will be capable of being procured, however necessary it may become from the circumstances of the times, as for instance, a complete failure of the winter-sown wheat, at once to increase the quantity that is to be sown. And that though spring wheat may not be so saleable, in favourable seasons, as winter wheat, at least in the metropolis, and its immediate neighbourhood; yet as it can be raised in various parts of the country, where winter wheat will not grow; and as it may be applied to different useful purposes besides the article of bread; there is no reason, it is supposed, why the cultivation of it should not be promoted. It is always a resource which can be resorted to in times of scarcity, with much more advantage to the country than importing foreign grain, to the disgrace, and it might almost be added, it is said, to the destruction of the agriculture of this country. There are some, however, who think foreign wheats more valuable and useful than those of this country, as will be seen in speaking of wheat. See **WHEAT**.

It is said, that it has been objected to the grain of this sort of spring wheat, that it is of a hard and stinty quality; but that our millers find no difficulty in grinding it; and it is well known, that the harder and more stinty the pickle, the better and livelier is the flour. The most stinty wheat, it is remarked, may be ground with facility, when properly damped. And that the French, when in Egypt, were taught by the millers there, to suffer their wheat to steep a few hours in water, and the grain, when afterwards dried in the sun, was ground without difficulty. In this country, it is suggested that it might be kiln dried, or otherwise, perhaps, by fire heat.

The same writer observes, it is also said, that barley is a safer crop, and that oats would be more profitable. In regard to safety, no crop, it is said, can be more certain than spring wheat, when it is sown in a proper season, with good, well washed, or pickled seed, in the manner already stated, and on land properly prepared for its reception; and as to profit, were a crop of oats to be equally, or even more valuable, which is far from being the case, yet such a scourger or exhauster of the ground could not be recom-

mended, in preference to a crop that does not exhaust or deteriorate the land more than barley would; and yet, if other crops of wheat should fail, would be much more valuable and useful.

In the metropolis, however, it is said, where they are accustomed to the finest wheats, and where fashion and habit render it necessary to make the bread as white as possible, this kind of wheat is objected to as coarse, thick-skinned, and as producing clammy flour. It consequently finds no favour with the millers in the neighbourhood of that great city, who, it is said, in times of scarcity, would only buy it in small quantities, at a price two-thirds lower than that of the common sorts; and in years of medium produce, would not purchase it, in quantities, at almost any price. This, however, it is said, is altogether owing to the prejudices and habits of a rich and luxurious capital, and will not probably influence the rest of the kingdom. Besides, if it be thought essential for the public interest always to have a considerable quantity of this species or sort of corn grown in this country as a national resource, the policy of which, it is thought, would seem unquestionable, government might in various ways promote the sale of this spring sort of wheat; as, by permitting the exportation of it, when the price is ten shillings the quarter less than that of other wheat; by restricting the manufacture of starch to the use of it, if it can be employed in that way; by permitting the consumption of this sort of wheat in the distilleries, while a prohibition exists as to other wheats; by making all the biscuits for the navy of it alone, as it seems peculiarly well suited for that use; and probably by different other means.

It is stated, it is said, that these advantages cannot be given to spring wheat, because it is impossible to distinguish it from coarse or partially mildewed winter wheat; but some risk must be run, the writer thinks, to insure so great a public object and advantage as a regular supply of food by domestic industry. And if some low-priced or damaged winter wheats were mixed with spring wheat, and exported, distilled, or made into starch, it is not seen that any injury or inconvenience from such a circumstance would be sustained by the public. It is better, it is supposed, except in instances of dearth and scarcity, to get rid of inferior wheats in any way, than in bread.

In regard to the sorts of land, and the situations in which this sort of wheat can be produced, it has been found, that almost all the kinds, from the clayey marly descriptions, to those of the light sandy sorts, are capable of affording it; but that it is obviously the most suited to such light lands as are remarkable for promoting a quick vegetation and growth in the grain. And it is of great importance to be known, that land of the fenny kind, with a bottom of the turf-earthly sort, is particularly calculated for the growth of this sort of wheat, and that it rises in a more quick and speedy manner on such land than on any other kind. Lands of this quality not being well suited to the growth of winter wheat, which is liable to be thrown out of them by frosty seasons, on account of their lightness; by having all such lands, in the different parts of the united kingdom, sown in suitable courses with spring wheat, a vast scarcely calculable advantage, it is thought, would be produced.

It is also a matter of very great moment, it is said, that spring wheat is capable of being grown in different districts where winter wheat cannot be raised at all, nor any other sort of crop of nearly the same value or importance; as, for instance, in the northern parts or Highlands of Scotland, where they grow an inferior sort of barley, commonly called

bear or bigg, which is now become of little value, in consequence of the pressure of taxation; as, from the quickness of its growth, it would be the most likely to answer and succeed in such situations. Were only one half of the ground now employed in the growth of bear or bigg crops, it is said, appropriated to the raising of spring wheat; it would furnish a quantity of this sort of grain, equal to the usual average of imported wheat, and any foreign supply be unnecessary. The propriety of growing spring wheat in these situations, and the islands connected with them, is still more strongly enforced, it is said, by the high opinion which has been formed of it by the late Dr. John Walker, professor of natural history in the university of Edinburgh, in a work lately published, entitled the "Economic History of the Hebrides and Highlands of Scotland," which is equally deserving the attention of the southern, as well as the northern cultivator, though more particularly calculated for the latter. After noticing the time and manner in which it was brought into that country, as already seen, and the nature of its growth and produce in different sorts of land, it is remarked, that it "will be allowed, that our common winter wheat could not have afforded such a crop, or indeed any crop in the same space of time. It appears, therefore, to be a grain better adapted for a northern than a southern climate; that it might be raised in many parts of the south of Scotland, where winter wheat is not sown; and that of all the different sorts of wheat, it is the most promising to be attempted in the Highlands."

In respect to the means of procuring or providing the seed of this sort of wheat, it has been stated by Sir Joseph Banks, in a paper inserted in the fifth volume of Communications to the Board of Agriculture, that as in the neighbourhood of the towns of Bolton and Spalding in Lincolnshire, the growth and cultivation of it are now fully established, and likely to continue; from either of these places, consequently, the seed may at any time be procured without difficulty, in such quantities as are wanted, even when considerable; and that, as there is a water communication between these two places, and as the former is a sea-port, it may always be brought to the metropolis, or any other maritime part of the country, at a small charge. It may constantly be had at the above sea-port at the same or somewhat less prices than winter wheat. And any of the principal merchants at it may be depended on for a proper supply. In small portions, many of the chief seedsmen in the metropolis or any large towns can mostly supply it.

It would appear on the whole, from the account which has been given of the history, nature, properties, uses, and advantages, as well as other circumstances in respect to spring wheat, that a more full and general introduction of it into the systems and practices of arable farming, especially on light and some other lands, where the regular wheat husbandry cannot be carried on, must be of very considerable importance, not only to the interests of individuals, but to the nation at large, in affording better and more certain profits, and at the same time guarding against the danger of scarcity.

SPRING Bay, in *Geography*, a bay on the N.E. coast of the island of Barbadoes.

SPRING Island, a small island near the coast of South Carolina. N. lat. 32° 22'. W. long. 80° 57'.

SPRING Township, a township of Pennsylvania, in Centre county, containing 1550 inhabitants.

SPRINGE, or *HALLERSPRINGE*, a town of Westphalia, in the principality of Calenberg, the chief trade of which consists in beer; 12 miles E. of Hameln.

SPRINGER, in *Ichthyology*, a name given by authors to the grampus.

SPRINGERS, in *Architecture*, the ribs of a groin, or concentrated arch, which spring from their respective impost, and meet together in an orb or knot in the centre of the whole vault. The ribs of the arches were usually made of hard stone, while light top stone or chalk was preferred for filling up the interstices.

SPRINGES, a sort of horse-hair nooses, made so as to run very easy, and planted in the places where birds run in some particular path, to take them as they pass.

Those birds that frequent the waters, or love to paddle and feed in wet and plashy places, are the most easily taken by snares.

The sportsmen who would use them to advantage, must first carefully search out the haunts and places where the fowls come in flocks, or in couples, and feed in the morning and evening hours. The furrows and water-tracks in these places are principally to be regarded; and wherever the several furrows, or water-courses, meet in one, and afterwards divide into several others, these places are to be remarked above the rest: the places which have most marks of the birds' feet, give also the surest of all proofs, that they are well frequented. When these places are found, there should be placed a number of small and short sticks cross-wise athwart all the other passages, one stick being placed about half an inch from another, and making together a kind of fence, guarding every way, except that one through which it is intended the fowls should pass. This being done, a good stiff stick is to be provided, cut flat on each side; both ends of this stick are to be planted under water, so that the upper part of the flat side may only be upon a level with the surface; then a bow is to be made of hazel, or willow, in the form of a pear, broad and round at one end, and narrow at the other, and at least a foot long, and five or six inches wide: at the narrow end of this there is to be a nick, or dent. Then a stiff young grown plant of hazel, elm, or withy, is to be chosen, being bushy and clear, and without knots, three or four inches about at the bottom, and about an inch at the top. Having made the bottom end of this sharp, at the top of it there must be fastened a very strong loop, made of about a hundred horse-hairs, platted very fast together with strong packthread, and made to slip any way with great ease. This noose or loop should be just of the dimensions of the pear-fashioned hoop before-mentioned. Then hard by this loop, and within an inch of the end of the plant, there is to be fastened, with strong horse-hair, a broad and thin trigger, made sharp at both ends. Then the bigger sharp end of the plant being made fast in the ground, just by the edge of the water, the smaller end, with the loop and the trigger, must be brought down just to the first bridge; and the pear-fashioned hoop being set upon the bridge, one end of the trigger must be set upon the nick in the hoop, and the other end on the nick made on the small end of the plate, which by the violence and bend of the plant will make them all stick together till the hoop be removed. This done, the loop is to be laid upon the hoop in such fashion as the hoop is proportioned; then from each side of the hoop little sticks are to be pricked, as before directed, making as it were a kind of impaled path-way, widening it all the way as it goes farther from the hoop, and making it so considerably wide at the end, that any fowl that chances to come that way may be entered a considerable way in before she perceives the fence; by this means the bird will be enticed to go straight on to the springe, and as soon as she touches it, either with head or feet, she will be certainly caught; and thus, if the plant

be strong enough, the largest bird may be caught as easily as the least.

When the smaller fowls, that frequent watery places, are to be taken by this engine, it is to be made only a great deal lighter. When it is intended for snipes, woodcocks, or the like, the main plant may be of willow, hazel, or grown osier, or any other pliant wood that will easily bend, and will recover its straightness again. The use of this engine is limited to the winter season, and to times when there is much wet upon the ground. If there happen any great frosts, so that there is no advantage to be made of the wet places first described, then the sportsman is to look for some place where there is a considerable fall, and where the current is not frozen, and in this place the springes are to be set; and the greater the frosts are in this case, the more birds will be taken.

There is another use of springes for birds, which is the taking, by means of them, certain birds on the boughs of trees and in hedges, which is often attended with very great success. The sportsman, for this purpose, must first mark some tree where the birds very much resort; then fix on some particular branch that is tolerably straight, and cutting off all the twigs to within a foot or two of the top, he is there to bore a hole through the branch with a piercer or wimble, large enough to admit a goose-quill. Then another branch is to be pitched upon, at about a foot distance from the first, and all its boughs are to be pared away up to a certain height. There is to be fixed to this branch a packthread of half a foot long, and at the end of this is to be tied a noose of plaited horse-hair. The branch to which the packthread is fastened is then to be stooped so far, that the noose may be brought through the hole in the other branch, and fastened there by means of a little stick four fingers long, and hooked at the end just fitting the hole, and so brought into it, as just to stop the flying back of the other branch. Then there is to be placed beyond the noose some bait of a fruit, or insect, as a cherry, a pear, or a worm, or any other thing of which the bird, intended to be taken, is known to be fond; this is to be set in such a manner, that the bird can no way get at it but by setting its feet on the small stick which supports the noose and stops the hole. The weight of the bird will throw down the stick, and the bird will then be caught by the legs, and tied fast to the branch where the hole is, by the flying back of the other branch where the packthread is fastened.

There is yet another method in use for the taking many kinds of birds, from the partridge or pheasant to the black-bird. This is made in the following manner, and is to be placed either on the ground, or on a tree, bush, or hedge, according to the nature of the bird intended to be taken by it. A straight and even piece of willow, or fallow, is to be chosen, of about six feet long, and of the thickness of a walking cane; this is to be sharpened at one end, and stuck down into the ground, and at the other end there is to be fastened a small crook; then two holes are to be made in the stick, the one big enough to admit a goose-quill, the other smaller: and a piece of stick is to be chosen, which being bent, will spring back to its straightness again, such as holly, or the like: this should be about three feet long, and the larger end of it is to be fixed in the larger hole of the first stick; the smaller end must have fastened to it a packthread, at the end of which there is a noose of horse-hair: this is to be brought through the smaller hole, and be pegged in so slightly, as just to prevent its flying back of itself. Then the springe or noose is to be spread on the peg, and a bait, proper for the bird to be taken, is to be

placed at a proper distance; so that the bird cannot come at it but by treading on the peg, which will give way under its weight, and the stick, to which the packthread is fastened, will fly back, and the bird will be consequently caught in the noose, and have its legs drawn close to the other stick.

SPRINGFIELD, the *Aaggavan* of the Indians, in *Geography*, a post-town of America, in the state of Massachusetts, and county of Hampshire, on the E. side of Connecticut river; 97 miles W.S.W. of Boston. This township was incorporated in 1645, and contains 2767 inhabitants, a congregational church, a court-house, and a number of dwelling-houses, many of which are spacious and elegant. The town lies chiefly on one spacious street, running parallel with the river. A stream from the hills, at the eastward of this town, falls into this street and forms two branches, which run in opposite directions, one northerly and the other southerly, along the eastern side of the street, supplying the inhabitants with a supply of water for domestic uses. This place has a considerable inland trade, with a paper-mill, arsenal and armoury.—Also, a town of New Hampshire, in the county of Cheshire, containing 814 inhabitants.—Also, a town of Vermont, in the county of Windsor, on the W. side of Connecticut river, opposite to Charlestown in New Hampshire, containing 2556 inhabitants.—Also, a post-township of New York, at the northern extremity of Otsego county; 58 miles W. of Albany; its area being equal to about six miles square. Its surface is undulated with hills and vallies, and well divided into arable, meadow, and grazing lands. The soil in the vallies is principally a deep rich mould. It has several mill-streams; three houses for worship, one for Presbyterians, one for Congregationalists, and one for Baptists; and twelve or thirteen school-houses. In 1810 it contained 1346 inhabitants, principally composed of English, Irish, Dutch, and Scots emigrants. It derives its name from a large, deep spring.—Also, a town of New Jersey, in the county of Essex, on Rahway river, which furnishes fine mill-seats; 8 or 10 miles N.W. of Elizabeth town; containing 2360 inhabitants, of whom 45 are slaves.—Also, a post-town of New Jersey, in Burlington county, having good soil, and famous for its cheese. The inhabitants, who are principally Quakers, having three meeting-houses, amount to 1500. The business is chiefly transacted at a village called Job's Town, 10 miles from Burlington. In this township is a hill, called mount Pisgah, which furnishes stone for building. This township has a grammar-school.—Also, a township of Pennsylvania, in Montgomery county, containing 550 inhabitants.—Also, a township of Pennsylvania, in Bucks county, containing 1287 inhabitants.—Also, a township of Pennsylvania, in Delaware county, containing 541 inhabitants.—Also, a township of Pennsylvania, in Huntingdon county, containing 751 inhabitants.—Also, a township of Pennsylvania, in Mercer county, containing 330 inhabitants.—Also, a township of Ohio, in the county of Champaign, containing 598 inhabitants.—Also, a post-town in Hampshire county, Virginia, 140 miles from Washington.—Also, a post-town in Washington county, Kentucky, 629 miles from Washington.—Also, a township of Ohio, in the county of Columbiana, containing 601 inhabitants.—Also, a township of Ohio, in the county of Hamilton, containing 2063 inhabitants.—Also, a township of Ohio, in Jefferson county, containing 746 inhabitants.—Also, a township of Ohio, in the county of Muskingum, containing 919 inhabitants.—Also, a township of Ohio, in Portage county, containing 510 inhabitants.—Also, a township of Ohio, in Ross county, containing 972 inhabitants.—Also, a town

town of Kentucky, in Washington county, containing 249 inhabitants.—Also, a poll-town in Robertson county, Tennessee, 763 miles from Washington.

SPRINGHILL, a township of Pennsylvania, in Fayette county, containing 1837 inhabitants, of whom nine are slaves.—Also, a township of the Indiana territory, in the county of Clark, containing 1107 free inhabitants and seven slaves.

SPRINGVILLE, a township of the Indiana territory, in the county of Clark, containing 1380 free inhabitants and 13 slaves.

SPRINGY or **ELASTIC Body**. See **ELASTIC Body**.

SPRINGY Land, in *Agriculture*, such as is subject to the breaking forth of small oozing springs. It is a sort of ground very troublesome to the farmer in the cultivation, as requiring much draining, and other management, to render it proper for cropping. See **DRAINING of Land**, and **SOIL**. See also **SPRING-Draining**.

SPRINTZNSTAIN, in *Geography*, a town of Austria; 7 miles S. of Aigen.

SPRIT, in *Agriculture*, a term sometimes made use of to signify a young sprout or shoot, as in the case of new-sown grain of any kind. Thus, new-sown corn is often said to be just sprit, by the farmer. It also denotes, in some cases, sprouted corn; as that which is grown or sprit in the sheaf or straw, in the field, from moist weather.

SPRIT, in *Sea Language*, is a small boom, or pole, which crosses the sail of a boat diagonally, from the mast to the upper hindmost corner of the sail, which it is used to extend and elevate: the lower end of the sprit rests in a sort of wreath or collar, called the *snolter*, which encircles the mast in that place: sails of this kind are accordingly called spritsails. See **SAIL**.

SPRITSAIL, a square sail used under the bowsprit.

SPRITSAIL-Top-sail, a square sail used under the jib-boom, but is no longer to be supplied in the navy.

SPRITTING, in *Agriculture*, a term applied to the act or process of germinating, sprouting, or shooting forth, either in the work of vegetation, or the operation of malting barley, or other kinds of grain. It is of much consequence, in both these cases, that the process takes place in a proper manner; as, without it, neither good and perfect field seed-crops nor malt can be produced. In moist or wet harvest seasons, the spritting of the grain, or other matters, in the sheaf or stouk, in the field, is often of much injury, inconvenience, and loss to the farmer, and should always be guarded against as much as possible, by proper stouking, hutting, mowing, or some other means in such a situation. See **HARVESTING Grain**.

SPROD, among the fishermen of many parts of England, a name given to the salmon while in his second year's growth.

SPROE, in *Geography*, a small island of Denmark, situated in the Great Belt. Vessels which pass the Great Belt in winter are often obliged to shelter here, though there is only one farm on the island. During winter the post regularly stops here; and an ice-boat, conducted by five men, is provided for the convenience of passengers, letters, &c.; 8 miles N.W. of Corfoer. N. lat. 55° 22'. E. long. 10° 50'.

SPROTTAU, a town of Silesia, in the principality of Glogau, on a river of the same name, at its conflux with the Bober; 21 miles W.S.W. of Glogau. N. lat. 51° 32'. E. long. 15° 32'.—Also, a river of Silesia, which runs into the Bober, at the town of Sprottau.

SPROUT, in *Agriculture* and *Gardening*, the common

name of the young shoot, offset, or sucker, which is thrown or sent off from any part of a vegetable of the plant, tree, or shrub kind.

Fruit-trees and shrubs, which are designed for production, must constantly be kept pretty free from these sorts of sprouts, shoots, and suckers, or their capability of affording good fruit will be much lessened and restricted. This is particularly the case in the gooseberry and currant shrubs, which scarcely produce any at all, where they are let remain. See **OFFSET** and **SUCKER**.

In hedge plants, however, the sending off numerous sprouts or shoots from the inferior and bottom parts of their roots and stems, is often of very considerable utility, in rendering the lower portions of the fences more thick and close, where it does not too much injure the growth and strength of the plants which are made use of for the purpose, as is sometimes the case. See **HEDGE** and **QUICKSET Hedge**.

In the practice of gardening, sprouts or shoots are occasionally, though not frequently, employed for raising new crops of vegetables of the same kind as the original plants. This is sometimes the case in the cabbage, and a few other similar kinds, as well as in some sorts of tree and shrubby plants.

But though the slips of the sprouts or shoots, in the cabbage tribe of plants, will readily take root and grow, when planted out while they are in a young state, they are only proper to be made use of in this way in an occasional manner, in particular cases and circumstances; as, for instance, in planting them for seed in any particularly good and valuable sort. In which case, some of the best slips of the sprouts, in the more early crops, may be taken off, on the approach of the autumnal season, and be planted out in rows, at the distance of about two feet from each other, giving them frequent waterings at first, when they will take root and grow so as to establish themselves in a ready manner, shooting up to form seed-stems in the ensuing spring, from which seed of the most perfect kind may be collected and secured.

The sprouts, suckers, and shoots, of plants of the tree or shrub kinds are, in some cases, slipped off and used in raising young trees and shrubs of the same sorts as the originals, with the greatest certainty, and in the most easy and expeditious manner. In such intentions, the slips or shoots are, for the most part, taken off in the early spring, or towards the autumn, and planted out in rows in the nursery grounds, at suitable distances, according to their nature and habits of growth; or placed in pots, to be set out in the open ground, or to be forced forward by the heat of the hot-beds, in the stoves, hot-houses, frames, and other similar compartments of the garden. They are afterwards, as soon as they have stricken or taken full root, in many cases, removed and put out in different ways, according to circumstances, and their particular nature and habits, as is shewn in speaking of the culture of the different sorts, under their proper heads.

SPROUTS, Esculent, the fine, small, young, tender, green shoots, which are sent off and produced from the sides or other parts of different kinds of culinary vegetables or plants, and made use of as human food at different periods and seasons of the year. There is a great number of garden vegetables which afford sprouts of this nature, and some in considerable abundance as crops for this purpose; as those of the *brassica* tribe in particular, as seen below.

In some herbaceous esculent plants the young sprouts are excellent eating, as in the cabbage kinds, and some others, affording

affording a very profitable after-crop. The sprouts produced on the stalks of the early-cut cabbages often also cabbage into tolerable little firm heads towards autumn, in the sugar-loaf cabbage particularly, and other forward kinds; producing abundance of fine sprouts in summer, which, being gathered while young and green, constitute some of the most excellent culinary greens of the season. Likewise forward favoys, being cut early in autumn, the remaining stalks produce fine large sprouts the same year, fit for use in the early part of winter: later crops of the same plants produce also abundance of small sprouts in the spring; and the borecole is remarkable for its great production of sprouts towards spring, emitted all along the small stems from the very bottom to the top: also, purple broccoli never fails to produce a secondary crop of excellent sprouts, furnished with little tender heads.

In the culture of all the varieties of the cabbage kind, it is proper, therefore, after gathering the main heads, to leave a quantity of the stalks of the best and more forward crops, of the respective sorts, to produce sprouts; and if, towards autumn or winter, and other seasons, the ground should be wanted for other crops, the stalks may be removed, and trenched in by the roots in another place, not in a shady bye corner, as often practised, nor placed too close, as the sprouts would, in such cases, prove small and trifling, and be liable to be eaten up by slugs; but in an open situation, in rows a foot asunder: in which method the sprouts will continue their growth in much greater perfection, though probably not in so good condition as if the stalks had remained undisturbed.

As the stalks of cauliflowers and cauliflower-broccoli rarely produce any sprouts, it is needless to leave them standing on the ground, after their heads have been cut from them.

The sprouts of this kind which are produced in the summer and autumnal seasons are by much the finest, and continue the longest in perfection; yet, though the spring sprouts may be of a smaller size, and continue a much shorter time before they run up for producing seed, they are, notwithstanding, often found highly advantageous, useful, and acceptable at such a season, on account of the great deficiency of other sorts of green vegetable products, and for the variety which they afford at the table.

All sprouts of this nature, and for this use, should constantly be plucked or taken off from the stems of the old plants while they are in their young, full, and early growth, in order that they may boil in a green and tender manner; as they are liable to become hard and sticky, when left to an old state of growth, and are not by any means so saleable in the market.

SPROUTS or Shoots of Potatoes, Planting of. These are the sprouts, shoots, or running branches, which are sent off from them in their early growth. Such young sprouts or shoots have lately had different experiments made with them, by which it has been shewn, that they are capable of being used with advantage in raising crops of this very necessary root, in some cases. In Sussex, the earl of Egremont, according to the writer of the corrected account of the agriculture of that district, has taken much interest in trials for raising them in this way.

In regard to the method of breaking off the sprouts or shoots from the potatoes, there is no reason, it is said, to be apprehensive how or in what manner they are taken off; and if the sprouts or shoots, after they have been separated from the potatoe, be put into a basket, and have a little earth thrown over them, they will keep in this state, it is asserted, if not immediately wanted, for months. The

kidney potatoe, after its second cropping, is noticed to decrease in the number of its sprouts or shoots. No sort is supposed to equal the red cluster kind. The early kidney comes up before any other sort; the cluster is the next; and the ox-noble the last. The cluster throws out more sprouts or shoots than any other kind, even so far as up to thirty at a time.

The sprouts or shoots are planted promiscuously from one to six or seven inches in length. Until the third or fourth month after planting, the sprouts or shoots have, it is said, but a small apple, not above the size of the end of a person's finger; but afterwards they wonderfully increase their size. Hence it follows, it is supposed, that the eye, having a greater and more substantial root to support the vegetative power of the plant, comes easier to perfection; but that the sprout or shoot, though stationary at first, will in the end more than equal the other in produce; and if to this be added the saving of seed, the advantage will be still more considerable.

Hence it is said, that it may be inferred, that this method of cultivating the potatoe, which is practised at Petworth, in the above county, with success, merits the attention of farmers, and probably of garden cultivators also. For an early market it is the only method, it is thought, of raising them; and besides, the seed and expences of cutting are saved.

It has been long known that the potatoe is capable of being readily raised by planting the sprouts or shoots, and recourse has, for a considerable length of time, been had to it, in some measure, for the production of early crops, in the county of Lancaster.

The want of substance in the sprouts or shoots would seem to be a great objection to the sprout manner of raising potatoe crops, as there must be a deficiency of support in the early growth of the plants which constitute such crops; as it has been found that even small cuttings, where the eyes are preserved, are not so good for raising full crops, on account of their want of substance, as those of large ones; and scooped eyes, as sets, have now almost been wholly rejected by cultivators, in consequence of their defect of substantial nutrient matter for the support of the young plant in its first or very infant growth. The matter remains, however, to be fully cleared up, and placed in a decided point of view, by more full and more correct trials made directly in this intention, as the sprouts or shoots are unquestionably the natural modes in which the plants are raised. See POTATOE and SOLANUM.

SPROUT-Hill, a name sometimes given to the ant-hill. See *ANT-Hill*.

The most ready way of removing sprout-hills is probably by frequent heavy rolling of the land, immediately on their first appearance. The turning of a stream of water over the ground, where it can be conveniently done, may also sometimes perhaps be effectual in the same intention. There are different implements and machines which perform this sort of work in a very complete, expeditious, and effectual manner, that may be had recourse to for the purpose. See *SWARD-Cutter*, and *STRIKING Ant-bill Machine*.

SPROUTING, the germination or first sending forth of young sprouts from seeds, cuttings, or plants.

The sprouting and early growth of almost all sorts of field and garden seeds and plants are greatly promoted by placing them to proper depths, in properly dry and suitably rich soils and situations, as well as by a nice attention to their culture, while they are in their young rising state or condition. This is particularly the case in the latter sorts of seeds and plants.

SPRUCE, *Essence of*, a fluid extract, prepared by coc-tion of the twigs of the wild pine or Scotch fir. See **PINUS Sylvestris**.

SPRUCE-Beer, a beverage made of the essence of spruce, fermented with sugar or molasses and water.

SPRUCE, in *Geography*, a small American lake of New Hampshire, near Chesterfield.

SPRUCE Creek, an American creek, which winds its course through the marshes from the mouth of Piscataqua river five or six miles to Kittery, in York county, Maine.

SPRUNT, in *Rural Economy*, a term signifying a steep road, or one on which there is much difficulty in passing with teams, and which requires great exertion in them.

SPRY, in *Agriculture*, a name sometimes applied to the flat broom which is used with the casting shovel, in the operation of cleaning grain, for sweeping off the chaffy materials that collect in the work.

SPRY Harbour, in *Geography*, a bay on the south-east coast of Nova Scotia. N. lat. 44° 42'. W. long. 62° 40'.

SPUD, in *Agriculture*, a tool or implement of the fork sort, with three broad prongs of considerable strength, which is useful for several different purposes. See **HOP**.

SPUDING, the practice or operation of digging over the hop-grounds, by means of the spud, in different districts. This sort of work should always be fully, carefully, and expeditiously performed, as a great deal of the success of the crops depends upon these circumstances. See **HOP**.

SPULLERS of Yarn, in our *Old Writers*, persons that work at the *spole*, or *wheel*. It also denotes triers of yarn, to see if it be well spun, and fit for the loom.

SPUN-HAY, in the *Military Art*, hay twisted in ropes, very hard, for an expedition in the winter time; each trooper carrying as much as he can behind him.

SPUNGE, or **SPONGE**, *Spongia*, in *Natural History*, a kind of marine substance, found adhering to rocks, shells, &c. under cover of the sea-water, or on the sides of the rocks about the shore. See **SPONGIA**.

The ancients distinguished two kinds, *male* and *female*: but the moderns make only one kind; which, however, they distinguish, with regard to its texture, into *coarse* and *fine*.

Naturalists have been embarrassed in all ages, whether to range sponge in the animal, mineral, or vegetable family. Some would have it a concretion formed of the sea-mud; others have commonly supposed it to be a vegetable production: but it is now allowed to be, like the corallines, of animal origin; being the fabric and habitation of some species of worm or polype.

Dr. Peyssonel has actually discovered and described the worms that form four different species of sponges, without having it in their power to dilate and contract them, as some naturalists have supposed; the sponges being altogether inanimate bodies, and insensible to the touch, or to any motion of the sea, or any other accident, and formed by the juice or slaver which is deposited by the worms that inhabit them. *Phil. Transf. vol. l. art. 78. p. 590, &c.*

Mr. Ellis, to whose observations on productions of this kind the public are much indebted, informs us, that if we carefully examine a small part of one of those sponges, whose ramifications are large and distinct, in the microscope, we shall find that they rise from many small tubes: these, as they extend themselves upwards, send outside branches in various directions, which inosculate, and, uniting thus with each other, form a compound reticulation quite through the inside of the whole mass. In viewing the extremities of the upper or ast shoots, we may perceive small openings at the

end of their fibres; and as we trace these fibres back from the opening downwards, we see a soft whitish substance, which fills the internal hollow part of all the ramifications through the whole sponge; which ramifications have much the appearance of transparent catgut of an amber colour, and are, without doubt, the lodgments of animals of a particular class. For though we cannot distinguish either vesicles, or cells, or discover any other kind of organization, than that of a hollow tube variously inflected, and wrought together into a multitude of agreeable forms, some branched like corals, some expanded like a fungus, some rising up straight like a column; others broad at top, with a narrow base, and hollow like a funnel, with regular cavities, entrances, or apertures, which are nearly alike in all sponges of the same species; yet, from many obvious resemblances to divers other classes of sea productions, which are found to be of animal construction, and from the chemical analyses of sponges in general, there seems sufficient reason for referring them to the class of animal productions. *Ellis's Nat. Hist. of Corallines, &c. p. 78.*

SPUNGE, or *Sponge*, in *Chemistry* and the *Materia Medica*, is the *spongia officinalis*, for an account of which, see **SPONGIA**. This species of sponge is found chiefly in the Mediterranean and Red seas.

On some of the islands of the Archipelago, the inhabitants are trained from their infancy to dive for sponges, which are generally found attached to the bottom of the rocks. This substance, formerly supposed to be of a vegetable nature, but determined by the observations of Mr. Ellis (see *Phil. Transf. vol. lv.*) to be of animal origin, has been, not long ago, examined by Mr. Hatchett, in the course of his valuable experiments on the component parts of animal membrane. (See *Phil. Transf. vol. xc. p. 352, &c.*) The sponges particularly examined by this ingenious chemist, are the *S. cancellata*, *S. oculata*, *S. infundibuliformis*, *S. palmata*, and *S. officinalis*. When the sponges had been immersed in nitric acid (diluted with three measures of distilled water) during fourteen or sixteen days, the acid became pale yellow, and was changed to an orange colour, by the addition of pure ammonia. After this process the sponges became more or less transparent, and were considerably softened. In this state, if they were touched with ammonia, the part thus touched assumed a deep orange colour, inclining to a brownish-red; and when much softened by the acid, (if afterwards immersed in ammonia,) they were completely dissolved, and formed a deep orange-coloured solution. When digested with boiling distilled water, the sponges afforded a portion of animal jelly or gelatin (see **GELATIN**), which was precipitated by infusion of oak-bark. In consequence of their loss of gelatin, which was imparted to the water, the sponges became less flexible, and more rigid; and the remaining part, when dry, crumbled between the fingers; or, when moist, was torn easily, like wetted paper. From these properties it appears, that sponges only differ from the horny stems of the gorgoniae, and from the antipathes, by being of a finer and more closely woven texture; and this is particularly observable by comparing the coarse sponges (such as *S. cancellata*) with the finely reticulated parts of certain gorgoniae, especially the gorgonia flabellum, when divested of the external membrane. When the sponge, either in its natural state, or especially when its gelatin has been extracted by long boiling with water, is boiled with lixivium of caustic potash, it is completely dissolved in it, and forms an animal soap. Sponge, when heated in a close vessel, gives out an ammoniacal fetid smoke, and is reduced to a black charcoal, which, after incineration, leaves a small quantity of com-

mon salt and some carbonate of lime. The principal constituents of sponge, according to Mr. Hatchett's experiments, are animal gelatin, albumen (which see), a small portion of common salt, and carbonate of lime. Sponge, when cleaned and fit for use, is of a brownish-yellow colour, soft, light, and very porous; absorbing rapidly by capillary attraction as much as it can contain of any fluid in which it is immersed, and again yielding it when compressed.

Sponge is a very useful substance in the arts. In its usual form it is never employed as a remedy; but in surgery, it is a very useful instrument on various occasions.

A sponge applied to bleeding vessels has been found a very successful method of stopping the effusion of blood. *Phil. Transf. N° 478. p. 33.*

For this purpose, a very dry and solid piece, of a cubical or conical form, should be applied in close contact with the vessel, and retained by proper compression; and it will soon adhere with great force. Very large arteries have been prevented from bleeding by this application.

Dry sponge, from its property of imbibing and swelling by moisture, is sometimes used as a tent for dilating wounds and ulcers: for this purpose, after being carefully freed from the small stones generally lodged in it, it is dipt in melted wax, and the wax squeezed out from it in a press. *Lewis.*

Taken inwardly, it chokes; and is, for that reason, cut small, and fried or dipped in honey, and given to quadrupeds to kill them, which it seldom fails to do, by swelling and preventing the passage of the food into the intestines.

The official preparation of sponge for medical purposes is the "spongia usta," or burnt sponge. The London Pharmacopeia directs to cut sponge into small pieces, and to bruise it, that it may be thus freed from any adhering extraneous substance; then to burn it in a covered iron vessel, until it become black and friable; and, lastly, to reduce it to a very fine powder. Burnt sponge consists of carbonate and phosphate of lime, subcarbonate of soda, and charcoal. The principal active ingredient is the subcarbonate of soda; but it is asserted, that a mixture of this principle and charcoal does not produce the effects of burnt sponge. This substance is tonic, deobstruent, and antacid. It has been much recommended in bronchocele, scrophulous affections, and hepatic eruptions. The dose is from ʒj to ʒiij, mixed into the form of an electuary, with powdered cinnamon and honey. In bronchocele the patient is directed to swallow the portion of electuary very slowly, from a supposition that some local effect is produced. See BRONCHOCELE.

Some have pretended to cure the leprosy with it, and others extol it against the bite of a mad dog; but these last are virtues not universally received.

In sponges are found a kind of stones called *cyssolithi*, held good for the worms in young children, and to this purpose given in powder.

SPUNGE, in the *Manege*, is the extremity, or point of a horse's shoe, that answers to the heel of his foot; upon it the calkins are to be made. Thick sponge ruins the horse's heels, and therefore ought never to be used. See SHOENING of Horses.

SPUNGES, *Pyrotechnical*, are made of the large mushrooms or fungous excrescences growing on old oaks, ashes, firs, &c. which, being boiled in common water, then dried and well beaten, are put into a strong ley, prepared with salt-petre, and again dried in an oven.

These make the black match or tinder brought from Germany, used to receive and sustain the fire struck from a flint and steel, &c.

SPUNGE is used, in *Gunnery*, for a cylinder of wood, from ten to twelve inches long, of the same diameter with the rammer, with a piece of sheep or lamb-skin wound about its end, to serve for scouring great guns when discharged, before they be charged with fresh powder; hence called *spunging*. In small guns it is commonly fixed to the other end of the handle of the rammer; but has a separate one in those of a larger calibre.

SPUNGING. See SPUNGE.

SPUNK, a term used indifferently for half-rotten wood, match for guns, and a substance growing on the sides of trees. See AGARIC.

SPUN-YARN, among *Sailors*, a small line or cord, formed of two or three rope-yarns twisted together by a winch; the yarns, of which it is usually made at sea, are drawn out of the strands of old cables, or other ropes, and are knotted together, and tarred. It is employed for several purposes, particularly to fasten one rope to another, to seize block-strops to the shrouds, and to serve ropes which are liable to be chafed, &c.

SPUR was anciently a piece of the armour of a cavalier, fastened to the talar, that is, the hind part of that piece of a complete armour which covers the legs and feet.

The word is derived from the German, *spohr*; or rather the Saxon, *spora*; or Danish, *spor*; which all signify the same.

At present, the spur is a piece of iron, or other metal, consisting of two branches encompassing the horse's heel, and a rouelle or rowel in form of a star, advancing out behind, to prick the horse.

Louis le Debonnair forbade ecclesiastics the profane fashion of wearing spurs. Anciently the difference between the knight and esquire was, that the knight wore gilt spurs, whence the appellation of *equus auratus*; and the squire, silvered ones.

Two sorts of spurs seem to have been in use about the time of the Conquest, one called a pryck, having only a single point, like the gaffe of a fighting-cock; the other consisting of a number of points of considerable length, radiating from and revolving upon a centre, thence named the rouelle, or wheel-spur. Delineations of the first occur in the seals of most of our kings and great barons, prior to the reign of Edward III., and also on the engraved and sculptured figures of cross-legged knights. The rouelle is sometimes found on figures of equal antiquity; instances occurring of the same person being delineated with the pryck-spur on one seal, and the rouelle on another. Some specimens of the pryck-spur are still to be found in the cabinets of the curious.

SPUN, *Order of the Golden*, in Rome, is supposed by several writers to have been instituted by pope Pius IV., in 1559. The badge is a star of eight points argent, and between the two bottom points a spur or.

SPUR, in *Agriculture*, the name of a vegetable disease, which frequently attacks rye, and which sometimes likewise damages wheat. It is found that the grains which have the spur are thicker and longer than the sound ones, and generally project beyond their hulks, appearing sometimes straight, and sometimes more or less crooked; and that their outsides are brown or black; their surface is rough, and three furrows may frequently be perceived in them, which run from end to end. Their outward end is always thicker than that which sticks to the chaff, and the mottled end is sometimes split into two or three parts. It is not unusual to find on their surfaces cavities which seem to have been made by insects. Further, that when a spired grain is

broken, in the middle or centre of it is seen a pretty white flower, covered with another flower, which is reddish or brown. Though this vitiated flower has some consistency, it may nevertheless be crumbled between the fingers. M. Aimen has sometimes found this powder almost as black as that of smutty wheat. These grains, when put into water, swim at first, and afterwards sink to the bottom. If chewed, they leave a bitter taste on the tongue. The chaff appears sound, though what is outmost is somewhat browner than when the ears are found. But all the grains of the same ear are not ever attacked with the spur. The grains which have this distemper stick less to the stalks than sound grains do. And the above writer imputes the distemper to the grains not being impregnated; and asserts, that he has not ever found a germ in grains which had the spur.

It may be noticed, that it has been supposed by some that fogs, dews, rain, and the moisture of the earth, may give the distemper to rye, but without any sufficient reason. M. Tillet is however strongly inclined to think that it is occasioned by an insect, which turns the rye into a kind of gall; and he suspects a small caterpillar as being the cause of this mischief, but cannot speak affirmatively on this point. It has been absurdly supposed to affect those who consume the bread made from grain thus diseased with a sort of dry gangrene in the extreme parts of the body. The nature of this disease in grain, like those of many others, is still far from being fully investigated, so as to form any correct notion of the means of removing or preventing it.

SPURS, in *Old Fortifications*, denote walls that cross a part of the rampart, and join to the town-wall.

SPURS, in *Ship-Building*, large pieces of timber, the lower ends of which are fixed against the side of the bilge-ways, and the upper ends fayed and bolted to the ship's side, to support the ship in launching. They have been much discontinued of late years.

SPUR-Shell, a species of the cochlea.

SPURGE, in *Botany*. See **EUPHORBIA**.

SPURGE-Laurel, or *Mezerion*, *Laureola*, or *Daphne*. See **DAPHNE**, and **DAPHNE Mezerium**.

SPURGE, Olive, the English name of a genus of plants, called by some botanists *chamelæa*; which see.

Others have made the olive spurge a species of euphorbia, or spurge. See **EUPHORBIA**.

SPURGE, Sun, a name by which some call several species of *tithymalus*; which see.

SPURGE-Root, in the *Materia Medica*. See **ESULÆ Radix**.

SPURGEN, in *Geography*, a town of America, in North Carolina; 22 miles N.N.E. of Salisbury.

SPURIOUS DISEASES, in *Medicine*, are such as, in some symptoms, cannot be brought under any distinct head, and, therefore, are called by the name of others with which they most agree. Whence, also, they are often denominated *bastards*, *nothi*.

Such are a spurious or bastard pleurisy, a spurious peripneumony, a bastard quinsy, and the like. See **PLEURISY**, **PERIPNEUMONY**, &c.

SPURIOUS Flesh, is an appellation given by some to the flesh of the lips, gums, and that of the glands, &c.

SPURIOUS Medals. See **MEDALS**.

SPURIOUS Ribs. See **RIBS**.

SPURIOUS Suture. See **SUTURE**.

SPURKETS, in a *Ship*. See **SPURKETING**.

SPURN HEAD, in *Geography*, a cape of England, at the S.E. extremity of the county of York, at the mouth of the Humber, on which is a light-house. N. lat. 53° 38'. E. long. 0° 18'.

SPURNESS, the south cape of Sunda, one of the Orkney islands. N. lat. 59° 7'. W. long. 2° 35'.

SPURNWATER, in *Ship-Building*, a channel left above the ends of a deck, to prevent the water from coming any further.

SPURRE, in *Ornithology*, a name given by many to the bird more commonly called the sea-swallow.

SPURREY, in *Botany*. See **SPERGULA**.

SPURREY, Corn, in *Agriculture*, the common name of a plant of the weed kind, which is common in many parts and situations. It seldom rises above six inches in height, flowers in the beginning of July, ripens its seed in August, and is an annual plant. When it is troublesome as a weed, the best method of exterminating it is by summer fallows, and cutting it down before it can scatter its seeds, which are very small.

Two species of this plant, however, are said to be cultivated in Holland and Flanders, for the winter food for cattle, when there is a scarcity of grass. It is said to enrich the milk of cows, so as to make it afford excellent butter; and the mutton fed on it is preferable to that fed on turnips. Hens eat this plant and its seeds greedily, and they are supposed to make them lay a great number of eggs.

It is a plant which is sown twice a year; the first time in April and May, to be ready in June or July; and the second time after the rye-harvest, to serve the cattle in November and December. The usual allowance of seed is about twelve pounds to the acre.

It is said, that though not cultivated in the county of Berks, it grows there in an abundant manner, and that the seeds of it might be easily collected in any quantity. The cultivation of it has been recommended, by way of trial, on the poor soils about Frilsham and Yattendon, in the above district, by the writer of the account of the agriculture of the county, on the suggestion of an intelligent person. It is stated also, that Roucel, in his "Flora du Nord de la France," has considered it as an excellent late fodder for cows; and that it is made use of in the above countries, as well as in Germany, both in its green state, and when made into hay.

It is likewise suggested, that as the knotted sort of spurrey, though perhaps not equally grateful to animals, naturally over-runs the peat-pits in the Kennets, in the above county, it might therefore be sown with certain effect in such situations.

SPURREY, Purple, an annual weed in dry sandy meadows, and corn-fields of the same dry quality. There are other sorts which are troublesome in wet hedges and woodlands.

SPUR-WAY, in *Rural Economy*, a term applied to a bridle, or horse-way, or road through inclosed lands or fields, and free to any one to ride in by right of custom or usage.

SPUR-WING, in *Geography*, a river of America, in the state of Maine, which runs through Scarborough, W. of Cape Elizabeth, and is navigable a few miles for vessels of 100 tons.

SPUTT, a river of England, in the county of Westmoreland, which runs into the Ken.

SPUTUM, in *Medicine, &c. the spittle or excrement voided at the mouth. See **SALIVA**.*

An examen of the sputum is of great consequence in pthifical cases: and Bennet, in his "Theatrum Tabidorum," applies himself in a particular manner to it. The *sputum sanguinis* is a very dangerous symptom in that disease.

SPY, a person paid to watch the actions, motions, &c. of another, particularly as to what passes in an army.

The use of spies is a kind of clandestine practice or deceit in war. Spies are generally punished capitally, and immediately when they are discovered in a camp; and, says Vattel, not unjustly, there being scarcely any other way to prevent the mischief they may do. For this reason, a man of honour, who would not expose himself to die by the hand of a common executioner, ever declines serving as a spy; he counts it beneath him, as it can scarcely be done without some kind of treachery. The sovereign, therefore, cannot lawfully require such a service from his subjects, unless in some singular case, and that of the last importance. The mercenaries are allured to it by great rewards. If those whom a sovereign employs make a voluntary offer, or if they be not the enemy's subjects, or have no connection with him, he may unquestionably make use of their service, without offence to justice or honour; but it may be asked, is it lawful, is it decent, to solicit the enemy's subjects to act as spies, and betray him? Let the following paragraph serve as a reply.

If it be asked in general whether it be lawful to seduce the enemy's men, to engage them to transgress their duty by an infamous treachery? Here we must distinguish between what is due to the enemy, notwithstanding the state of the war, and what is required by the internal laws of conscience, and the rules of probity. Now the enemy may be weakened by all possible means, provided they do not affect the common safety of human society, as poison and assassination. The seducing a subject to turn spy, that of a governor to deliver up his place, does not strike at the foundation of the common safety and welfare of society. Subjects acting as the enemy's spies, are not a fatal and inevitable evil, they may in some measure be guarded against; and as to the security of fortresses, it is the sovereign's concern to choose proper governors. Thus these means are not contrary to the external law of nations, nor can the enemy complain of them as odious proceedings. Accordingly, they are practised in all wars. But are they just, and compatible with the laws of a pure conscience? Certainly not. And of this the generals themselves are sensible, as they are never heard to boast of having practised them. Seducing a subject to betray his country, suborning a traitor to set fire to a magazine, practising on the fidelity of a governor, enticing him, persuading him to deliver up a place, is prompting such persons to commit detestable crimes. Is it honest to incite our most inveterate enemy to be guilty of a crime? If such practices are at all excusable, it can be only in a very just war, and for saving our country, when threatened with ruin by a lawless conqueror. The guilt of a subject or general who betrays his prince in a cause manifestly unjust, does not appear so very odious. He who himself tramples upon justice and probity, deserves, in his turn, to feel the effects of perfidy and wickedness. And if ever it is excusable to depart from the strict rules of probity, it is against such an enemy, and in such an extremity. Vattel's Law of Nations, b. iii. ch. 10.

Wicquefort says, an ambassador is an honourable spy, under the protection of the law of nations.

SPYCKENS, in *Geography*, a town in the island of Voorn; 9 miles E. from the Brill.

SPYRUS, the *dung of goats*. This is usually found in small round masses, and is recommended by Hippocrates as a fumigation in the diseases of the womb.

SQUACCO, in *Ornithology*, the name of a large bird of the heron kind. Its head and neck are variegated with black, white, and yellow, and it has on the back part of its

head a crest of the same colour. Its back is of a ferruginous yellow, its breast and belly are white, as are also its wings and tail, at least in great part, and its legs are green. It is a bold and fierce bird.

SQUAD, in *Military Language*, a diminutive of Squadron; used to denote any small number of men, horse or foot, that are collected together for the purposes of drill, &c. See ESCOUADE.

Hence, to *squad* is to divide a troop or company into certain parts, in order to drill the men separately, or in small bodies, or to put them under the direction and care of some steady corporal, or lance corporal. Each troop ought to be divided into two squads, when under 40, and into three, or even four, when above this number, with an equal proportion of non-commissioned officers in each: and when the eldest is on duty, the charge of the squad falls on the next in the squad, and so on. Recruits should always be quartered and squadded with old soldiers, who are known to be steady and well behaved; and those men that are at all irregular in their conduct, must be separated and distributed in squads which are composed of good old soldiers.

SQUAD, *Aukward*, consists not only of recruits at drill, but of formed soldiers, that are ordered to exercise with them, in consequence of some irregularity under arms. The term has likewise been used, by way of ridicule or reproach, to mark out those officers who are negligent of their duty.

SQUADRON, a body of horse, whose number of men is not fixed, but is usually from eighty to a hundred and twenty men.

The word is formed from the Italian *squadrone*; of the Latin *squadro*, used by corruption for *quadro*: in regard, at first, the squadrons were always square, and called also by the Latins *agmina quadrata*.

The squadron usually consists of two troops, and each troop of about forty men; a greater number cannot be advantageously posted, nor have room to act in narrow grounds, woods, marshes, desiles, &c.

The eldest troop takes the right of the squadron, and the second the left.

SQUADRON of *Ships*, denotes either a detachment of ships employed on any particular expedition, or the third part of a naval armament.

The number of ships in a squadron is not fixed: a small number of vessels, if they be in a body, and have the same commander, may make a squadron.

If there be a great number, they are usually divided into three squadrons; and if the squadrons be numerous, each squadron is divided into three divisions, distinguished by their flags and colours. See DIVISION and FLEET.

SQUAIOTTA, in *Ornithology*, the name of a bird of the heron kind. Its beak is yellow, but blackish at the extremity; its legs are green; its head is variegated with grey and black; and its back very elegantly with white and red. It seems to have had its name from its note, which it often repeats in flying.

SQUAIL, in *Sea Language*, a sudden and violent blast of wind, usually occasioned by the interruption and reversion of the wind from high mountains. These are frequent in the Mediterranean, particularly in the Levant, as produced by the repulsion and new direction which the wind meets with in its passage between the various islands of the Archipelago. Falconer.

SQUAILLEY, a note of faultiness in the making of cloth. 43 Eliz. cap. 10. Blount. Cowel. See REWEY.

SQUALLY, in *Agriculture*, a term provincially applied to such crops of turnips, corn, rape, &c. as are broken or detached

detached by vacant or unproductive spots or patches. Crops which are thus produced have an extremely disagreeable appearance, and are never promising or productive to the farmer.

SQUALLY Land, a term sometimes applied to that sort of ground which is of the irregularly wet thin kind.

SQUALUS, the *Shark*, in *Ichthyology*, a genus of fishes of the order Chondropterigous, or, according to more modern naturalists, of the Cartilaginous order: the generic character is as follows. The mouth is situated beneath the anterior part of the head, with numerous teeth disposed in rows. On each side the neck, in most of the species, there are five spiracles of a femilar shape. The body is oblong, and somewhat cylindrical.

The animals of this genus are altogether marine; and are said to be rarer in the Baltic than in any other sea: they are viviparous, and are observed to produce more young at a time than the rays; but each is included, as is the case with those fishes, in a quadrangular capsule or involucrum, each extremity of which is extended into a long, contorted, cartilaginous thread of great length. Many of the sharks are said to emit a phosphoric light during the darkness of night: they are chiefly of a solitary nature, and, in general, devour, with the most indiscriminating voracity, almost every animal substance, whether living or dead. A few species are said to feed chiefly on fuci, and other marine vegetables. There are about thirty-four species enumerated by Gmelin, which are separated into different sections.

Species.

A. With temporal Orifice and anal Fin.

ISABELLA. The first dorsal fin is opposite the abdominal. It inhabits the southern Pacific ocean, and has been observed about the coasts of New Zealand. It is thirty inches long; in colour it is yellowish; the teeth are compressed, short, triangular, furnished on each side the base with a smaller lobe, and disposed in six rows; the tongue is very short and thick; the dorsal fin is subquadrangular; the second placed opposite the anal fin; the pectoral fins are very large; the ventral are separate, and pointed behind.

* **CANICULAR**; Spotted Dog-fish. Nostrils surrounded with a lobe and vermiform appendage; the ventral fins are distinct. This inhabits most seas, is about four or five feet long, is very voracious, and feeds chiefly on fish; the body is of a reddish-brown, with large distinct spots, which are black above, but white beneath, a little compressed at each end; the skin when dried is used for various purposes. The head is small; snout short; eyes oblong; pupil sea-green, iris white; the mouth is wide and oblong, with three rows of teeth; the tongue is cartilaginous, and with the palate rough; the vent is before the middle of the body; the first dorsal fin behind the ventral, the second less, and nearly opposite the anal; the tail is narrow, ending below in a sharp angle.

* **CATULUS**; Lesser Spotted Dog-fish. This species is specifically described as having nostrils covered with a lobe and vermiform appendage; the ventral fins are connected. It inhabits the Northern, Mediterranean, and Indian seas. Its habit is rather slender; in length it is from two to three feet; the head is large; snout prominent, and slightly pointed; the skin is rough; the body cylindrical; the colour pale brick-red, marked with very numerous, small, rounded, blackish or dusky spots; the abdomen is whitish; both the dorsal fins are placed much nearer to the tail than the head; the ventral fins are connate, large, and of a slightly pointed form; the anal fin is small; the tail is long, bilobate, with

the lower lobe continued to a considerable distance beneath. It is a most voracious fish. According to Mr. Pennant, it breeds from nine to thirteen young at a time; it is numerous on our own coasts, and very injurious to the fisheries. The liver, when taken or tasted as food, is highly noxious, causing a long-continued stupor, succeeded by a universal itching, with a total peeling off of the cuticle.

STELLARIS. Lobes of the nostrils double. This is found in the European ocean, and is from two to six feet long; it feeds chiefly on cruicaceous animals, molluscs, and lesser fish; the body is reddish, with unequal blackish spots; beneath it is of a dirty ash, and resembles the *S. canicula*, but the spots are larger and fewer; the snout is a little longer, the tail somewhat shorter, and the nostrils nearly closed; it brings forth about twenty at a time. The dorsal fins are equal; the first a little behind the middle of the body, the second a little behind the anal.

* **GALEUS**; Tope. Teeth nearly triangular, serrate on the inner edge. This species is of considerable size, often measuring several feet in length, though the specimens usually seen about the British coasts scarcely exceed the length of about five feet. In its habits it resembles the white SHARK (which see), being a very bold and rapacious fish, attacking such as happen to be accidentally exposed to it with great violence and rapidity; its shape is rather slender; its colour pale cinereous above, and whitish beneath; the nose is long, flat, and pointed; the nostrils are situated near the mouth, and behind each eye is a small orifice; the teeth are numerous, disposed in three rows, small, very sharp, triangular, and serrate on their inner edge. The first dorsal fin is placed about the middle of the back, and is rather large; the second is small, and situated near the tail, which is small, and terminates in two unequal lobes, of which the lower is the broadest. It has been alerted by able and well-informed naturalists, that this fish is so bold as to pursue its prey to the very edge of the shore, and even to attack those who are walking near the water's edge. It is supposed to be the fish mentioned by the name of *canicula*, which is described as highly dangerous to those employed in diving for corals, sponges, &c.

* **MUSTELUS**; Smooth Hound. The teeth of this species are very small and obtuse; it has short pectoral fins. The fish of this species are of a slender habit; their snouts are slightly sharpened, and lengthened; the first dorsal fin is large, and placed nearly in the middle of the back; the second nearly opposite the anal fin; the tail is shaped as in most others of this tribe, or slightly bilobate; the lower lobe is continued to some distance beneath; the teeth are very numerous, small, slightly convex, and set as in RAYS (which see.) The general colour of the animal is of a greyish-brown, paler or whiter beneath; sometimes varies in being marked above by numerous white spots. The stomach in this fish is furnished with several appendices, situated near the pylorus; it is found on our own coasts, and in other European seas, and also in the Indian sea, and when full grown it is about two feet long.

CIRRATUS. The nostrils have a worm-shaped appendage. This species inhabits the American and Pacific seas, and is from one to five feet long; the body is coated with large flat shining scales; when young it is spotted with black. The head is depressed; the snout is short, obtuse; the eyes and temporal orifice small; lips thick at the sides; teeth numerous, sharp, long, dilated at the base; the two hindmost spiracles are approximate; the vent is in the middle; the first dorsal fin is opposite the ventral; the anal is small; the tail is about a quarter as long as the body.

BARBATUS. The gape of the mouth is bearded with vermiform

SQUALUS.

vermiform appendages. It is found about the coasts of New Holland, and is from three to four feet long; the body is covered with small, hard, smooth shining scales, and marked with black spots, round and angular, surrounded with a white circle. The head is large, depressed, and short; the teeth are lanceolate, in many rows; cirri unequal, about an inch and a half long, and branched before. The temporal orifice is large; vent in the middle; first dorsal opposite the vent; the tail subdivided.

TIGRINUS. Tail elongated; the two hindmost spiracles are confluent. It inhabits the Indian ocean, and grows to the length of fifteen feet; the body is thick, oblong, black, with irregular white spots and bands; feeds on telluraceous animals and crabs. The head of this species is broad, flat, and sloping on the fore-part; the mouth transverse, with two cirri; the upper lip is thick and prominent; the teeth are minute, those on the upper jaw are moveable, and rough like a rasp; the tongue is thick, short; the eyes are small, oblong, and the pupil is blue; the iris is black; belly broad; pectoral fins short, broad; first dorsal opposite the ventral; the second is opposite the anal; the tail is compressed on each side, thin like a leaf at the end; the fin is long, and notched at the tip.

AFRICANUS. Body with several parallel, longitudinal, blackish bands above. This, as its specific name imports, is found in the African ocean, and is about two feet and a half long; the body is covered with minute subquadrate scales; above it is glaucous, beneath whitish.

OCELLATUS. On each side of the neck is a large, round, black blotch, surrounded with white. It inhabits the Pacific ocean and New Holland, is two feet and a half long; the body is long, cinereous, dotted; beneath it is of a greenish-ash colour.

ZYGÆNA. Head very broad, hammer-shaped. It inhabits the Mediterranean, American, and Indian seas; grows to six feet long, and to the weight of five hundred pounds; it is the most rapacious of all its tribe. See SHARK.

TIBURIO. The head is very broad, heart-shaped. It inhabits the South American seas. It very much resembles the last, except that the head, instead of being widened on each side into a long process, is rather subtriangular, and rounded off in front; the fins are glaucous.

GRISEUS. Spiracles six on each side. It inhabits the Mediterranean; is two feet and a half long; the body is of a mouse colour, a little rough; in the dried skin there is the appearance of small scales, with an elevated line in the middle.

VULPES; Sea-fox, or Long-tailed Shark. This species inhabits the Mediterranean sea, and often wanders on the British coasts; is seven feet long; the body above is of a blueish-ash colour; beneath it is paler; the scales are very minute. This is a very voracious fish. It is distinguished by its plump, short, subovate body, and very long tapering tail; the head is small and pointed; the first dorsal fin is triangular, and placed on the middle of the back; the second is set above the beginning of the tail, which gradually tapers to the tip, and is furnished with a shallow fin or process beneath, running from the base to the tip, which is sharp and slightly bilobate; the pectoral fins are of considerable size; the eyes are large; the mouth small; the teeth triangular, small, and disposed in three rows. The colour of the fish is dusky ash above, and whitish beneath. It grows to the length of thirteen or fourteen feet; the tail measures more than half the length of the whole animal. It is an inhabitant of the Mediterranean and other seas, and is considered as a voracious and artful fish; but the name of sea-fox is ap-

plied to it rather from the length of its tail than from its supposed sagacity.

LONGICAUDUS. Upper jaw with two cirri; the tail is long, as its specific name denotes; the head is obtuse; the nostrils near the mouth; there are four spiracles.

APPENDICULATUS; Botany Bay Shark. Upper jaw with two jagged, cartilaginous appendages, and four others on each side between the first and the spiracles. This inhabits New South Wales; is nineteen inches long; the body is brown, with three rows of large pale spots, dark within, rounded and nearly equal for half its length, and then growing suddenly very small. It is an extremely fierce animal. The head is broad, but angular; the mouth is placed near the end of the head; it has nine teeth in front, which are sharp, crooked, and in three rows, with a great number of small ones on each side; the eyes are projecting; dorsal fins placed far back; the pectoral near the spiracles; ventral near the middle of the body; the anal more than half way between the last and the tail, with a fin-like projection behind it to the end of the tail.

B. *With the anal Fin, but no temporal Orifice.*

* **GLAUCUS;** Blue Shark. The sides of the tail are smooth; the lower part of the back with a triangular dent. This is found in our own and almost all other seas. See SHARK.

* **CORNUBICUS;** Probeagle Shark. The snout of this species is projecting, sharp; body round, depressed and angulate near the tail. It inhabits the British coasts; is from three to four feet long; the body above is of a deep blue, beneath it is silvery; round, except near the tail, where it is depressed. This species is slightly described by Pennant, from an engraving which he found in Borlase's History of Cornwall, which was copied by Mr. Jago, who was esteemed a very observant and skilful ichthyologist. A specimen observed in 1793, on the coast of Hastings, is described in the third volume of the Linnæan Transactions. Its length from the tip of the snout to the extremity of the tail, was three feet ten inches; the colour of the body was a deep blue on the back, and white or silvery beneath; the shape was round, except for about six inches from the tail, where it was depressed; at about an inch from the tail was a semilunar or lunar impression, the points of which were towards the tail; where the body was depressed, the sides were raised into a sharp angle or elevated line, of about eight inches in length, running to the middle of the tail, or a little beyond; the nose was prominent, and sharp; and on either side, from the nose to the eyes, were numerous perforations or minute pores; the tail was of a lunar form, the upper lobe nearly a third longer than the lower.

* **CAMERICUS;** Beaumaris Shark. Snout short, blunt; body cylindrical, angulate near the tail. This is chiefly found on the British coasts; is seven feet long; very much resembles the last, except that it does not taper so much towards each end; the body is of a lead-colour, and smoothish.

CINEREUS. Seven spiracles on each side. It inhabits the Mediterranean; is three feet long; the body is glaucous, and a little rough.

* **MAXIMUS;** Basking Shark. Teeth conic, not ferrate. See SHARK.

* **CARCHARIAS;** White Shark. In this species the teeth are triangular. This is the most dreadful and voracious of all animals. See SHARK.

C. *With temporal Orifice, but no anal Fin.*

* **SPINOSUS.** Body covered over with large mucronate tubercles.

tubercles. This is about four feet in length; the colour is grey-brown above, whitish beneath; the body is roughened with scattered unequal tubercles, consisting of a broad round base, and curved, sharp-pointed tip; in some they are bifid; eyes large; snout prominent and conic; its gape is moderate; the teeth of a squarish shape, compressed, cornered at the margins, and placed in several rows; dorsal fins placed near the tail, the first opposite the ventral, which are set at an unusual distance from the head, and are almost as large as the pectoral; the tail is angular.

* *ACANTHIAS*; Picked Dog-fish. Dorsal fins spinous; the body is roundish; a variety has an ocellate body. This species inhabits most seas: it is about three feet and a half long; the body above is blackish, dotted sparingly with white; the sides are white, inclining to violet, with a few angulate transverse furrows, beneath white; the flesh is often salted and eaten.

JACKSONII. Eyes with a prominence over them on each side; before each of the dorsal fins is a strong spine. This inhabits Port Jackson, New Holland. It is not more than two feet long; the body is tapering, skin rough, above brown, beneath paler; the head is somewhat convex; teeth numerous, in many rows, larger as they are placed backwards, forming a bony plate.

SPINAX. Body beneath blackish. It is found in the Indian ocean; and, in its spinous back-fins, it very much resembles the last.

SQUAMOSUS. Body coated with small oblong scales. The body of this is three feet long, thick, round, resembling the next, except in having a longitudinal elevated line of scales down the middle.

CENTRINA. Body nearly triangular. It is from three to four feet in length; the body above is brown, carinate, beneath whitish, broad; skin covered with hard, erect tubercles; the flesh is very hard.

INDICUS. Back variegated, unarmed; teeth acute. It inhabits the Indian ocean.

AMERICANUS. Dorsal fins unarmed, the hinder one larger, ventral large near the tail. It is found in the South American seas; is three feet long; body round; scales small, angular.

* *SQUATINA*; Angel Fish. Pectoral fins very large, and notched on the fore-part. This species inhabits the Northern seas, and is from six to eight feet long; it feeds on lesser fish, and brings forth thirteen young at a time. The body above is cinereous, rough, with small recurved prickles; beneath it is smooth, white. In its shape it approaches very nearly to the Ray genus.

D. Without Teeth.

MASSASA. Pectoral fins long. An inhabitant of the Red sea.

KUMAL. Pectoral fins short; the mouth with four cirri. It inhabits the Red sea.

SQUALUS is also a name given by Varro, Columella, Salvia, and others, to a species of cyprinus, distinguished by Artedi by the name of the oblong cyprinus with long scales, and with the pinnae containing eleven rays, and commonly known with us under the name of *chub* or *chevin*.

The generality of authors call it *capito* and *cephalus*, but it is very improper to give distinct general names to fish, which are genuine species of other genera.

The name *squalus* is originally Latin: it is used by Pliny, and many other of the old Roman authors, and is derived from the word *squalor*, because this fish is found to delight in impure and dirty places.

SQUAM, in *Geography*, an American lake, partly situ-

ated in the township of Holderness in Grafton county, New Hampshire, and partly in Strafford county; about five miles long and four broad.—Also, a river of New Hampshire, the outlet of the above lake, which, after running a south-west course, joins the Pemigewasset, at the town of New Chester, 10 miles above the mouth of the Wine-piscogee branch.

SQUAM Beach, lies on the sea-coast of New Jersey, between Barnegat inlet and Cranberry new inlet.

SQUAM Harbour, lies on the north-east side of Cape Amen, in the state of Massachusetts. *Squam* (Pidgeon-hill) lies in N. lat. 42° 40'. W. long. 70° 36'.

SQUAMARIA, in *Botany*, from *squama*, a scale, in allusion to its scaly root, or subterraneous stem, is Rivinus's appellation for the Toothwort (see *LATHRÆA*); and is still used generically by Haller and Scopoli, though only specifically by Linnæus. The scales in question, bearing a great resemblance in every thing but hardness to the human fore-teeth, have given rise to the English name, and to that of *Dentaria*, used by Matthioli. But this plant must not be confounded with the Linnæan *DENTARIA*. See that article.

SQUAMIS, in *Ichthyology*, a name given by Albertus, and others, to the fish called by us the monk, or angel-fish, by the generality of authors *squatina*, and by the old Greek writers *rhine*. See *SQUALUS*.

SQUAMOSÆ Sutura Additamentum, in *Anatomy*, the portion of suture which connects the posterior inferior length of the parietal to the mastoid part of the temporal bone. See *CRANIUM*.

SQUAMOSE CULM, among *Botanists*. See *STALK*.

SQUAMOSE Root, one composed of, or covered with lesser flakes. See *ROOT*.

SQUAMOUS, in *Anatomy*, a suture of the head, made by the thin edge of one bone overlapping a corresponding thin edge of another.—Also, the portion of the temporal bone entering into the formation of the *squamosæ suture additamentum*. See *CRANIUM*.

SQUARCIONE, FRANCESCO, in *Biography*, a painter, born at Padua in 1394, more and better known as the founder of a school of art, than for any particular works of his own production. The school he maintained was furnished with designs and vestiges of antiquity, which he had acquired not only in Italy, but also in Greece, whither he travelled for the purpose; and it was at one time attended by upwards of 130 students, so that he acquired from it the respectable title of the father of the young painters. One picture of his is more particularly noticed by Lanzi, which was formerly in the church of the Carmelites at Padua, and afterwards in the private possession of the Conte de Lazara, representing St. Jerome surrounded by three saints; and he speaks of it in terms of praise for so early a production. It was painted, according to an inscription upon it, for the noble family of Lazara, in 1452, and is signed Francesco Squarcione. He died in 1474, at the age of 80.

SQUARE, QUADRATUM, in *Geometry*, a quadrilateral figure, whose angles are right, and sides equal.

SQUARE, To find the Area of *a*. Seek the length of one side; multiply this by itself; and the product is the area of the square. Thus, if the length of a side be 345, the area will be 119025; and if the side of a square be 10, the area will be 100.

Since, then, a decempeda contains 10 feet, a foot 10 digits, &c. a square decempeda contains 100 square feet, a square foot 100 square digits, &c.

SQUARE, the Properties of *a*, are, that its angles are all right, and, consequently, its sides perpendicular; that it is divided

divided into two equal parts, by a diagonal; that the diagonal of a square is incommensurable to the side.

SQUARES, for the Ratio of. They are to each other in the duplicate ratio of their sides. *E. gr.* a square whose side is double another, is quadruple of that other square.

SQUARE of the Cube.

SQUARE of the Surdefolid. } See POWER.

SQUARE Number, in Arithmetic and Algebra, is the product arising from multiplying any number by itself. Thus, $9 = 3 \cdot 3$, $16 = 4 \cdot 4$, $25 = 5 \cdot 5$, &c. are square numbers: and since, by the rules of algebra, $-3 \times -3 = 9$; $-4 \times -4 = 16$; $-5 \times -5 = 25$, &c.; it follows, that the square root of every positive number has two different roots; the one *plus*, or affirmative; the other *minus*, or negative; while the square root of every negative number is imaginary, or impossible.

Square numbers have several remarkable properties, of which the following are some of the most interesting, *viz.*

1. Every square number is of one of the forms $4n$ or $4n + 1$; that is, every square, when divided by 4, will leave either 0 or 1 for a remainder: and understanding this expression still in the same sense, the following table will express the forms of square numbers to the moduli, or divisors, 3, 4, 5, 6, 7, 8, 9, 10, 11, and 12.

Moduli.	Possible Forms of Squares.				
3	$3n$	$3n + 1$			
4	$4n$	$4n + 1$			
5	$5n$	$5n + 1$			
6	$6n$	$6n + 1$	$6n + 3$	$6n + 4$	
7	$7n$	$7n + 1$	$7n + 2$	$7n + 4$	
8	$8n$	$8n + 1$	$8n + 4$		
9	$9n$	$9n + 1$	$9n + 4$	$9n + 7$	
10	$10n$	$10n + 1$	$10n + 4$	$10n + 5$	
11	$11n$	$11n + 1$	$11n + 3$	$11n + 5$	$11n + 9$
12	$12n$	$12n + 1$	$12n + 4$	$12n + 9$	

2. And hence, by exclusion, we may derive the following table of impossible forms, *viz.*

Moduli.	Impossible Forms for Squares.				
3	$3n + 2$				
4	$4n + 2$	$4n + 3$			
5	$5n + 2$	$5n + 3$			
6	$6n + 2$	$6n + 5$			
7	$7n + 3$	$7n + 5$	$7n + 6$		
8	$8n + 2$	$8n + 3$	$8n + 7$		
9	$9n + 2$	$9n + 3$	$9n + 5$	$9n + 8$	
10	$10n + 2$	$10n + 3$			
11	$11n + 2$	$11n + 6$	$11n + 7$	$11n + 8$	$11n + 10$
12	$12n + 2$	$12n + 3$	$12n + 5$	$12n + 6$	$12n + 8$
	$12n + 10$				

These formulæ, as they involve no higher power of the indeterminate n than the first, are called *linear* forms; but, by means of them, we easily arrive at a variety of *quadratic* formulæ, which it is extremely useful to be acquainted with, in practising the Diophantine or indeterminate analysis.

If a person, unacquainted with these exclusions, were required to find two such numbers, that double the square of the one, added to triple the square of the other, should be

a square, he would see nothing impossible in the proposition, and might, therefore, lose many useless hours in the research; whereas, by a little attention to the impossible and possible forms, he would find the problem absolutely impossible, and hence spare himself much useless labour.

3. The method of deducing impossible quadratic forms from the linear ones above given, will be seen immediately from a single example. Let it be required to ascertain whether the equation, $2x^2 + 3y^2 = w^2$, be possible or impossible. First, we may assume x , y , and w , prime to each other; for if x and y have a common divisor, w must have the same, and the whole equation may be divided by it; whereby it will be reduced to another equation $2x'^2 + 3y'^2 = w'^2$, in which these quantities have no longer a common divisor, or, in other words, they are prime to each other.

Since, then, x and y are prime to each other, they cannot be both of the form $3n$; for, in this case, they would have a common divisor 3. Let then, first, x^2 be of the form $3n$, and y^2 of the form $3n + 1$; then $2x^2$ is of the form $3n'$, and $3y^2$ of the form $3n' + 3$, and consequently their sum will have the form $3n$, which is impossible, because, in this case, w and x would have a common divisor 3; and if we suppose x^2 of the form $3n + 1$, and y^2 of the form $3n$; then $2x^2 + 3y^2$ is of the form $3n + 2$, which is an impossible form: and, lastly, if we assume both of the form $3n + 1$, then $2x^2 + 3y^2$ would have again the same impossible form $3n + 2$; therefore, in no case can $2x^2 + 3y^2 = w^2$ be possible in integral numbers.

In the same manner a variety of other impossible forms may be deduced, of which the following are those which most commonly occur.

(5) *Modulus 3.*

$$2t^2 + 3u^2 = w^2$$

$$5t^2 + 3u^2 = w^2$$

$$8t^2 + 3u^2 = w^2$$

$$(3p + 2)t^2 + 3u^2 = w^2$$

(6) *Modulus 5.*

$$2p^2 \pm 5u^2 = w^2$$

$$3p^2 \pm 5u^2 = w^2$$

$$7t^2 \pm 5u^2 = w^2$$

$$(5p \pm 2)t^2 \pm 5u^2 = w^2$$

Or the two latter general forms may be rendered more comprehensive, by the introduction of another indeterminate q ; observing only that, in this case, the quantity must always be prime to the modulus. With this condition, the two latter may be written thus:

$$(3p + 2)t^2 + 3qu^2 = w^2, \text{ and}$$

$$(5p \pm 2)t^2 \pm 5qu^2 = w^2.$$

(7) *Modulus 7.*

$$(7p + 3)t^2 \pm 7qu^2 = w^2$$

$$(7p + 5)t^2 \pm 7qu^2 = w^2$$

$$(7p + 6)t^2 \pm 7qu^2 = w^2$$

(8) *Modulus 11.*

$$(11p + 2)t^2 \pm 11qu^2 = w^2$$

$$(11p + 6)t^2 \pm 11qu^2 = w^2$$

$$(11p + 7)t^2 \pm 11qu^2 = w^2$$

(9) *Modulus 13.*

$$(13p \pm 2)t^2 \pm 13qu^2 = w^2$$

$$(13p \pm 5)t^2 \pm 13qu^2 = w^2$$

$$(13p \pm 6)t^2 \pm 13qu^2 = w^2$$

$$(13p \pm 7)t^2 \pm 13qu^2 = w^2$$

SQUARE NUMBERS.

(10) *Modulus 17.*

$$\begin{aligned} (17p \pm 3) t^1 \pm 17qu^2 &= w^2 \\ (17p \pm 5) t^2 \pm 17qu^2 &= w^2 \\ (17p \pm 6) t^1 \pm 17qu^2 &= w^2 \\ (17p \pm 7) t^2 \pm 17qu^2 &= w^2 \end{aligned}$$

A great variety of impossible forms might have been given to other moduli; but the above are sufficient for our present purpose.

There are also many formulæ, which, though possible singly, become impossible in pairs: such are the following:

$$\begin{aligned} 11. \begin{cases} x^2 + y^2 = z^2 \\ x^2 - y^2 = w^2 \end{cases} & 12. \begin{cases} x^2 + y^2 = 2w^2 \\ x^2 - y^2 = 2z^2 \end{cases} \\ 13. \begin{cases} 2x^2 + y^2 = z^2 \\ 2x^2 - y^2 = w^2 \end{cases} & 14. \begin{cases} x^2 + 2y^2 = 2z^2 \\ x^2 - 2y^2 = 2w^2 \end{cases} \\ 15. \begin{cases} x^2 + 2y^2 = z^2 \\ x^2 - 2y^2 = w^2 \end{cases} & 16. \begin{cases} 2x^2 + y^2 = 2z^2 \\ 2x^2 - y^2 = 2w^2 \end{cases} \end{aligned}$$

These might also be carried to a much greater extent, and many collateral properties drawn from them relative to the impossibility of some higher powers: we must not, however, carry the subject farther in this place. The reader, who is desirous of more detailed information, may consult Barlow's "Elementary Investigation of the Theory of Numbers," where this part of the doctrine of numbers is carried to a considerable extent. We shall merely select a few other distinct properties of squares, as they are given by the same author, in his "Mathematical Dictionary."

17. The sum of two odd squares cannot be a square.

18. An odd square, taken from an even square, cannot leave a square remainder.

19. If the sum of two squares be itself a square, one of the three squares is divisible by 5.

20. Square numbers must terminate in one of the digits 0, 1, 4, 5, 6, or 9.

21. No number of repetend digits can be a square.

22. The area of a rational right-angled triangle cannot be equal to a square.

23. The two following series are remarkable for being such, as, when reduced to improper fractions, the sum of the squares of each numerator and denominator is a complete square; or, which is the same, they are the sides of rational right-angled triangles. These series are as follows, *viz.*

$$\begin{aligned} 1\frac{1}{2}, 2\frac{3}{5}, 3\frac{3}{7}, 4\frac{4}{9}, 5\frac{5}{11}, \&c. \&c. \\ 1\frac{1}{4}, 2\frac{1}{2}, 3\frac{1}{4}, 4\frac{1}{2}, 5\frac{3}{4}, \&c. \&c. \end{aligned}$$

24. The second differences of consecutive square numbers are equal to each other, thus:

Squares	1, 4, 9, 16, 25, &c.
First difference	3, 5, 7, 9, &c.
Second difference	2, 2, 2, &c.

To these we may also add the following; which are more particularly applicable to the indeterminate and Diophantine analysis.

25. If a number be the sum of two squares, its double is also the sum of two squares; for

$$(x^2 + y^2) \times 2 = (x + y)^2 + (x - y)^2.$$

Hence also, the sum of two squares multiplied by any power of 2, is the sum of two squares.

26. The product of two numbers, each being the sum of two squares, is itself the sum of two squares; for

$$\begin{aligned} (x^2 + y^2) \times (x'^2 + y'^2) &= \\ \{ (xx' + yy')^2 + (xy' - x'y)^2, \text{ or} \\ \{ (xx' - yy')^2 + (xy' + x'y)^2 \end{aligned}$$

$$\text{Thus, } \begin{array}{l} 5 = 2^2 + 1^2 \\ 13 = 3^2 + 2^2 \end{array}$$

$$\text{Product } 65 = 8^2 + 1^2 \text{ or } 7^2 + 4^2$$

27. The product of the sum of four squares, by the sum of four other squares, is itself the sum of four squares; thus

$$\begin{aligned} (w^2 + x^2 + y^2 + z^2) \times (w'^2 + x'^2 + y'^2 + z'^2) &= \\ \{ (ww' + xx' + yy' + zz')^2 + (wx' - xw' & \\ \quad + yz' - y'z)^2 + & \\ \{ (y'w - xz' - yw' + xz')^2 + (wx' + xy' & \\ \quad - yx' - xw')^2 \} & \end{aligned}$$

as will appear by the development of these formulæ.

28. Every integral number is either a square, or the sum of two, three, or four squares.

The latter is one of the celebrated numerical theorems of Fermat, which was first demonstrated by Lagrange.

For a variety of other properties, see the works above referred to.

We shall conclude this article with a table of the squares and cubes of all numbers from 1 to 1200. A table of the square and cube roots, to the same extent, is given under the article Root.

SQUARE NUMBERS.

SQUARE Root, a number considered as the root of a second power or square number: or a number, by whose multiplication into itself a square number is generated. See **ROOT**.

To extract the Square Root out of any given Number, see EXTRACTION of Roots.

SQUARE, Norma, is an instrument made of wood or metal, serving to describe and measure right angles; such is **L E M**, *Plate XIV. Geometry, fig. 10.*

It consists of two rules or branches fastened perpendicularly at one of their extremes. When the two branches are moveable on a joint, it is called a *bevel*.

To examine whether or not a square be exact, describe a semicircle, **A E F**, of any length, at pleasure; and therein, from each extreme of the diameter, **A** and **F**, draw right lines to a point taken at pleasure in the periphery, as **E**: to the sides of the angle, **A E F**, apply the square, so as its vertex may fall on **F**. If this be possible, that square is just.

SQUARE, The, an instrument used in drawing, which consists of a flat ruler *h g* (*fig. 11.*), at one end of which are fastened two transverse pieces; one of them, *a b*, fixed at right angles to it, and the other, *c d*, moveable round the centre *f*, so as to be fixed at any angle required. These transverse pieces are applied close to the side of the drawing-board, which is a smooth board made in the form of a square, or parallelogram, while the ruler lies upon it; and by sliding them along the board, lines may be drawn parallel to one another with much less trouble than by the help of a parallel ruler. By the fixed transverse, lines may be drawn parallel to one side of the board, and perpendicular to the other; and, by the moveable transverse, lines that have any degree of obliquity to the sides of the boards, may be drawn parallel to one another: and if, without moving the transverse, the ruler be removed to the other side of the board, lines may be drawn perpendicular to them. But if the obliquity be very great, it will be impossible to apply the square, so as to intersect the lines at right angles in some parts of the board. In this case recourse must be had to a parallel ruler.

SQUARE, Geometrical, a compartment frequently added on the face of the quadrant, called also line of shadows and quadrant.

SQUARE, Gunner's. See **QUADRANT**.

SQUARES, Magic. See **MAGIC Square**.

SQUARE, in Glass-Making, an instrument with which the conciator, or founder, stirs and mixes together the metal, when in fusion in the melting-pots. When this instrument is grown red-hot, it is always to be quenched in a pail of water, otherwise the metal will stick to it.

SQUARE, in the Manège, is used for working in a square. The pite or tread of a volt, instead of being always circular, and traced upon a circumference round a centre, ought to be imagined as if it formed four straight equal lines laid in a square, and equally removed from the centre or the pillar, which represents it in the middle of the manege-ground; so that, to work in a square, is to ride along each of these four lines, turning the hand at every corner, and so passing from one line to another.

SQUARE, The, in the *Military Art*, a particular form into which troops are thrown on critical occasions; particularly to resist the charge of cavalry.

SQUARE Battalion, Hollow, and Solid. See the several articles.

SQUARE Cap. See **CAP**.

SQUARE Character. See **HEBREW**.

SQUARE Foot, Nails, Niche, Pedestal, Pillar, Roof, and Winding-stairs. See the substantives.

SQUARE, in Sea Language, a term peculiarly appropriated to the yards and their sails, implying that they hang at right angles with the mast or keel, or that they are of greater extent than usual.

Thus, when the yards are so balanced by their lifts, as to hang at right angles with the mast, they are said to be square by *the lifts*; when they hang perpendicular to the ship's length, they are called square by *the braces*; but when they lie in a direction perpendicular to the plane of the keel, they are square by *the lifts and braces*; or, in other words, they hang directly across the ship, and parallel to the horizon.

The yards are said to be very square when they are of extraordinary length; and the same epithet is then applied to their sails, which by consequence acquire an additional breadth.

SQUARE of an Anchor, denotes the upper part of the shank. See **ANCHOR**.

SQUARE-Body, in *Ship-Building*, all the midship part of the ship, or that between the cant-bodies, whose timbers stand at right angles, or square with the keel.

SQUARE-Maker, a shipwright, who cuts the butts of the planks when required to receive the oakum, and prepares the work ready for the caulkers.

SQUARE-Ribbands, the same as horizontal ribbands. See **RIBBANDS**.

SQUARE-Rigged, is an epithet applied to a ship which has long yards at right angles with the length of the deck, and low masts; and hence it is used in contradistinction to all vessels whose sails are extended by stays or lateen-yards, or by booms and gaffs; the usual situation of which is nearly in the plane of the keel.

Hence, square-sail is a sail extended to a yard, which hangs parallel to the horizon, as distinguished from the other sails, which are extended by booms and stays, placed obliquely. This sail is only used in fair winds, or to scud under in a tempest. In the former case it is furnished with a large additional part, called the bonnet, which is then attached to its bottom, and removed when it is necessary to scud. Falconer.

SQUARE-Sterned, a term applied to ships having broad sterns, and the butts of the planks of the bottom ending on the wing-transom. All British ships are now built upon this principle, whilst many of other nations are still constructed by the ancient methods; hence we so frequently hear the phrase of "square-sterned and British-built," as our practice in this respect justly claims the superiority over that of all other nations.

SQUARE-Timbers, the timbers which stand at right angles, or square with the keel. See **SQUARE-Body**.

SQUARE-Tuck, a name given to the after-part of a vessel's bottom, when terminated in the same direction up and down as the wing-transom; and the planks of the bottom end in a rabbet at the fore-side of the fashion-piece.

SQUARE Handkerchief, in *Geography*, a cluster of islets and rocks in the Atlantic, formerly called "Bazos de Babuca;" extending above 100 miles in circumference. N. lat. 21°. W. long. 69°.

SQUARE Island, a small island in the N. part of lake Superior. N. lat. 48° 40'. W. long. 87° 22'.—Also, an island near the E. coast of Labrador. N. lat. 52° 54'. W. long. 55° 34'.

SQUARING, in Mathematics. See **QUADRATURE**.

SQUARING the Circle, is the making a square whose area shall be equal to the area of a given circle:

The best mathematicians have found it impossible to solve this

this problem so as to be precisely exact; but they can easily come so near it, as not to err so much in the area as a grain of sand would cover in a circle, whose diameter is equal to the diameter of Saturn's orbit. The following proportions are near enough to the truth for any real use that can arise from this problem.

As 100000000 is to the diameter of the given circle, so is 88622692 to the side of the square required. Therefore,

If the Diameter of the Circle be	The Side of the Square will be
100000000	88622692.
10000000	8862269.2
1000000	886226.92
100000	88622.692
10000	8862.2692
1000	886.22692
100	88.622692
10	8.8622692
1	0.88622692

And, as 100000000 is to the side of a given square, so is 112837917 to the diameter of a circle very nearly equal to the square. Therefore,

If the Side of the Square be	The Diameter of the Circle will be
100000000	112837917.
10000000	11283791.7
1000000	1128379.17
100000	112837.917
10000	11283.7917
1000	1128.37917
100	112.837917
10	11.2837917
1	1.12837917

See CIRCLE, DIAMETER, and QUADRATURE.

SQUARTIA, in *Ichthyology*, a species of fish found in the East Indies, the skin of which makes the shagreen.

SQUASH GOURD, in *Gardening*, the common name of a particular sort of gourd-plant, with erect stems or stalks. See CUCURBITA.

SQUASH Pear-tree. See PEAR-tree.

SQUATAROLA, in *Ornithology*, a name given by the Venetians to the grey plover, or *pluvialis cinerea*.

SQUATINA, in *Ichthyology*, the monk-fish, a species of the squalus, called, in Italian, the *pesce angelo*, and thence in English the angel-fish and monk-fish. See SQUALUS.

SQUATINATORIA, a name by which some authors have called the *rhinobatos*, a sea-fish of a sort of middle nature between the monk-fish, or angel-fish, and the ray.

SQUATT, in *Mineralogy*, a term given by the English miners to a peculiar sort of bed of ore, less valuable than a load or vein, because of its reaching but a little way.

Though the ore of the squatts is generally very rich and good, not inferior in quality to the best vein-ore, the miners are often disappointed, on finding these squatts instead of the right veins, after a long search. In the tin countries, the way of searching for mines is by looking after the SHOAD-STONES, which see.

These upper parts of the veins have been washed off, and carried down the sides of the hills, in which the mines usually lie, into the flat country; but they always lie in a regular and continued train, from the orifice of the mine to the farthest part of the train; so that when but one stone of this kind is found, the miners are certain of coming to the bed of metal, on tracing it up to its head by the train. This is a laborious and expensive work, because the stones never

lie on the surface, but at the different depths of one to ten feet, or any depth between these. The squatts have their trains of shoad-stones as well as the regular veins, and when these are traced to the orifice, there is the appearance of a rich load, which the proprietor is not thoroughly undeceived in till the diggers come to the end of it.

The squatt is a bed of ore from three to ten fathoms long, and usually is about half as broad as it is long; few are larger than this standard, but many much less. This is always flat, and thence has its name; the round collections of ore of the same kind being called *bonnies*. The squatt communicates with no other load or vein, but is entire of itself, and its extremities terminate at once, without running into several little strings, in the manner of those of the right veins. It does not lie within walls, as the loads or veins always do, though it is always deposited in the shelf, or fast ground; that is, in strata that have not been moved. Phil. Trans. N^o 69.

SQUATUS, in *Ichthyology*, a name used by Pliny, and other of the old Roman authors, to express the fish called by the old Greek writers *rhine*, and by the moderns *squatina*. See SQUALUS.

SQUIB and Mince-meat Manures, in *Agriculture*, are terms which are applied to those sorts which are collected in large towns, as the metropolis, and others. The former chiefly consists of the more small mixed powdery kinds, but the latter principally of the more reduced animal matters. They would both seem to be superior to foot or malt-dust in the trial of a writer in the Agricultural Report of the County of Middlesex. See SOOT and MANURE.

SQUIBS. See FIRE-Works.

SQUILACHI, in *Zoology*, the name by which the modern Greeks call the jackall, or *lupus aureus* of authors.

SQUILL. See SQUILLA.

SQUILL, *Official*, or *Sea-onion*, *Scilla Maritima*, in the *Materia Medica*. The roots, or rather the bulbs, of this species are the parts that are used in medicine. Of these bulbs there are two sorts, the red and white, which are supposed to be accidental varieties; but for medicinal use the red is generally preferred, as it has been supposed to be more efficacious than the other. They grow naturally on sea-shores, or in ditches where the salt-water flows in with the tide, in most of the warm parts of Europe; particularly on sandy shores in Spain and in the Levant, from whence we are annually supplied with them. They should be chosen large, plump, fresh, and full of a clammy juice. They are preserved fresh in sand; but as they are apt to spoil, it is best to keep them in the dried state. However, the fresh bulb loses in drying about four-fifths of its weight, without any considerable loss of its taste or virtue: hence four grains, which are the mean dose of the dry bulb in powder, are equivalent to near a scruple of the fresh squill. Nevertheless, its acrimony, on which its virtue depends, is partially dissipated by drying and long keeping; and completely destroyed by heat. The most convenient way of drying it is, after peeling off the outer skin, to cut the bulbs transversely into thin slices, and expose them to a gentle warmth. The ancients, in order to abate the acrimony of the squill for certain purposes, after separating the skin and fibres, enclosed it in a paste made of flour and water, and then baked it in an oven, till the paste became dry, and the squill thoroughly soft and tender. The squill, so prepared, was beaten with two-thirds its weight of flour, the mixture formed into troches, and dried with a gentle heat. These troches were supposed to be alexipharmic, and on this account were used as an ingredient in theriaca, with which view they are still retained. Water, wine, proof-spirit, and rectified spirit, extract the virtues

both of the fresh and dry bulb. Nothing rises in distillation with any of these menstrua, the entire bitterness and pungency of the squill remaining concentrated in the inspissated extracts: the spirituous extract is smaller in quantity than the watery, and its taste is proportionally stronger, almost fiery. Alkalies considerably abate both the bitterness and acrimony of the squill: vegetable acids make little alteration in either of these respects. These acids extract its virtue equally with watery or spirituous menstrua; and, as an expectorant in disorders of the breast, excellently coincide with it.

The expressed juice, when diluted with water, filtered, and boiled, yields white flakes of albumen. Nitrate of mercury and superacetate of lead separate from it white curdy precipitates. Infusion of galls forms in it pale brownish flakes; sulphate of iron throws down a copious pale green precipitate: lime evolves ammonia. When the insoluble part of dried squill is digested in muriatic acid, filtered, and ammonia added in excess, a copious precipitate is thrown down, which is oxalate of lime. Ether digested on dried squill acquires a pale green hue, and when evaporated on the surface of water, a thin pellicle of very bitter resin is deposited; while the water acquires an intensely bitter taste, and yields copious precipitates with solutions of acetate of lead and nitrate of silver. From these imperfect experiments, squills appear to contain extractive, albumen, a small portion of resin, mucus, carbonate of ammonia, the bitter principle, starch, and oxalate of lime.

The root of the squill has been known in medicine in the early ages of Greece; so that the introduction of its medical use has been referred by some to Epimenides, and by others to Pythagoras. It is noticed by Dioscorides, Hippocrates, Galen, Aëtius, Celsus, Pliny, Cælius Aurelianus, and the Arabian physicians. Its medical character has been retained ever since to such a degree, that it is still deservedly held in high estimation, and frequently used. It seems, however, to manifest a poisonous quality to several animals, as many medical writers have testified. If administered in large and repeated doses, it not only excites nausea, tormina, and violent vomitings, but it has been known to produce strangury, bloody urine, hypercatharsis, cardialgia, hæmorrhoids, convulsions, with fatal inflammation and gangrene of the stomach and bowels. Nevertheless, under proper management, and in certain cases and constitutions, it merits recommendation as a medicine of great practical utility, and real importance in the cure of many obstinate diseases. In small doses it is expectorant and diuretic; but in large doses, emetic and purgative: but when these latter effects take place, the medicine is prevented from reaching the blood-vessels and kidneys, and the patient derives no benefit from its diuretic efficacy. In such cases it should be given in smaller doses, at more distant intervals, or an opiate should be joined to it, which, according to Dr. Cullen, will answer the same purpose. By repeated use the dose may be increased, and the intervals of administering it diminished; and accordingly, when the doses are tolerably large, the opiate may be most conveniently employed to direct the operation of the squill more certainly to the kidneys. In cases of dropsy, he says, when there is an effusion of water into the cavities, and therefore less water passes to the kidneys, neutral salt, accompanying the squill, may be of use in determining it more certainly to the kidneys; and when it is perceived to take this course, he is persuaded that it will be always useful, and generally safe, during the exhibition of the squills, to increase the usual quantity of drink. The diuretic effects of squills have been supposed to be promoted by the addition

of some mercurial; and Dr. Cullen is of opinion, that the less purgative preparations of mercury are best adapted to this purpose; and accordingly he recommends a solution of corrosive sublimate or oxymuriate of mercury, as the most proper, because it is the most diuretic.

Wagner recommends the powder of squills, given with nitre, in hydropical swellings, and in a nephritis, and mentions several examples of cures which he performed, by giving patients from four to ten grains, with a double quantity of nitre.

When squill has been employed as a diuretic, it has been usual to give it in powder, because in this state it is less apt to produce nausea; and it has been customary to add neutral salts, as nitre, or crystals of tartar, especially if the patient complained of much thirst; others recommend calomel: and with a view to render the squills less offensive to the stomach, it has been usual to conjoin an aromatic.

In asthmatic affections, or dyspnoea, occasioned by the lodgment of tenacious phlegm oppressing the lungs, or when the primæ viæ abound with mucous matter, it has been the expectorant usually employed; and held in general estimation. As an expectorant, the squill may be supposed not only to attenuate the mucus, and thus facilitate its ejection, but by stimulating the excretory organ and mucous follicles, to excite a more copious excretion of it from the lungs, and thereby lessen the congestion, upon which the difficulty of respiration very generally depends. Hence, in all pulmonic affections, excepting only those of actual or violent inflammation, ulcer, and spasm, the squill has been found to be a very useful medicine.

The root of squill is to the taste very nauseous, intensely bitter and acrimonious; but without any perceptible smell: much handled, it excoriates the skin. It is rendered more useful as an expectorant, when combined with nitrate of potash, tartarized antimony, or ipecacuanha; and in asthma and dyspnoea without fever, squill combined with ammoniacum is perhaps the best remedy we can employ.

Dr. Hefs says, he has cured the asthma with the powder of squills. The efficacy of this powder, from four to twelve grains, in curing the asthma, is attested by several. Med. Ess. Edinb. Com. Norimb. 1737, and 1739.

As an emetic, squill is very uncertain in its effect, producing in some persons the most cruel vomiting, and in others exciting no nausea in the largest doses: nevertheless, when it readily and moderately induces vomiting, it proves more useful in hooping-cough and croup, than any other emetic.

For producing expectorant and diuretic effects most effectually, squill must be given in substance; but to excite vomiting, its infusion in vinegar, or the oxymel, is more usually employed. Of the dried squill, gr. j, in the form of a pill, may be given at first for a dose, morning and evening, or every six hours; and the quantity gradually increased to grs. v or grs. vj, or till some degree of nausea is induced, and its expectorant or diuretic operation obtained.

The official preparations of squills are the following: viz. *acetum scillæ*, *oxymel scillæ*, *pilule scillæ comp.*, *pulvis scillæ*, *syrupus scillæ maritimæ*, and *tinctura scillæ*. The "*acetum scillæ*," or vinegar of squill, of the Lond. Ph. is prepared by macerating 1lb. of fresh squill root (bulb) dried in six pints of acetic acid, in a covered vessel, for 24 hours; then expressing the liquor, and setting it aside, that the feculencies may subside; and lastly, adding half a pint of proof-spirit to the clear liquor.

The "*acetum scillæ maritimæ*," or vinegar of squill, of the Edinb. Ph. is prepared by macerating 2 oz. of the squill root (bulb) dried, with 2½ lbs. of distilled vinegar, for seven

seven days; then expressing the liquor, and adding to it 3 oz. of alcohol; and when the feculencies have subsided, pouring off the clear fluids.

The "acetum scillæ," or vinegar of squill, of the Dub. Ph. is obtained by digesting half a pound of fresh squill root (bulb) dried, with three pints of wine vinegar, for four days in a glass vessel, with frequent agitation; then expressing the vinegar; and, after the feculencies have subsided, adding to it four fluid-ounces of rectified spirit.

This has been long used as an expectorant and diuretic in chronic catarrh, humoral asthma, and dropsies. The dose is from fʒs to fʒij, given in cinnamon or mint-water. In large doses it produces vomiting, and is occasionally used as an emetic in the above-mentioned diseases, when the stomach is loaded. For the "oxymel of squill," see OXYMEL *Scilla*. For the "pills of squill," see PILLS.

The "pulvis scillæ," or powder of squill, of the Dub. Ph. is prepared by freeing squill roots (bulbs) from their membranous integuments, and cutting them in transverse slices, then drying them upon a sieve with a low degree of heat; and afterwards reducing them to powder, which must be preserved in well-stopped glass phials.

The "syrupus scillæ maritimæ," or syrup of squill, of the Edinb. Ph. is formed of 2 lbs. of vinegar of squill and 3½ lbs. of refined sugar powdered; dissolving the sugar by a gentle heat, so as to make a syrup. This syrup has the same properties, and is used for the same purposes, as the oxymel of squill. The dose is from fʒj to fʒij, given in any aromatic distilled water.

The "tincture of squills" of the Lond. and Dub. Ph. is prepared by macerating 4 oz. of recent squill root (bulb) dried, with two pints of proof-spirit, for 14 days, and filtering. The Dub. Ph. directs digestion for seven days, setting it aside until the dregs are subsided, and pouring off the clear liquor. The dose is from ℥x to ℥xxx, given in almond mixture, ammoniac mixture, or mucilage. Lewis. Woodville. Thomson.

SQUILLS, *Wine of*, is an infusion of the roots of squills in white wine for forty days, after which the squills are taken out, and the liquor preserved for use. It is a gentle emetic, and is good against defluxions of rheum.

SQUILL, *White, Lesser*, in *Botany*, a species of *pancratium*; which see.

SQUILL, *Squilla*, in *Natural History*, a large class of animals, comprehending the shrimp, or *cancer crangon*; the crawfish, or *cancer fluviatilis*, or *cancer asellus* of Linnæus; the crab, or *cancer*; lobster, or *cancer gammarus*; prawn, or *cancer squilla*. The *squilla* is also a genus described under CANCER: all which, according to Dr. Hill, make only one genus of insects of the podaria kind. They properly belong to the genus of CANCER, under which they are described.

SQUILLA, in *Botany and Gardening*. See SCILLA.

SQUILLA *Aque Dulcis*, or *fresh-water shrimp*. Few persons are aware of the damage done by the fresh-water shrimp among the small fry of fish. This insect is commonly very plentiful in standing waters, and particularly in breeding-ponds, where they always have their prey in plenty before them; and often suffer none, or scarcely any of the numerous young fry hatched from the spawn of carp and tench, to live to grow up. They may be observed following the shoals of the young fry, and seizing multitudes one after another; and at other times lurking among the weeds to seize such as straggle by themselves. If one of these insects be put into a basin of water with a dozen or two of these young fish, though as big as itself, it will very

soon destroy them all. They kill numbers that they cannot eat, but leave them to rot.

SQUILLACE, in *Geography*, a sea-port town of Naples, in Calabria Ultra, built on the verge of a rocky mountain, sloping to the east, about three miles from the sea; and giving name to a gulf of the Mediterranean. It is the see of a bishop, suffragan of Reggio, and contains eleven parishes and six convents. Virgil, for reasons unknown, gave this city the epithet of "Navisragum," breaker of ships, as there are no hidden or apparent dangers attending the approach of vessels; and we cannot suppose, that this correct poet should be so negligent, as to confound the capacious bay of "Scyllacæum," as this is called, with the narrow pass of Scylla in the Faro of Messina. In forming the body of Grecian commonwealths on the Italian shores, Athens furnished emigrants for Scyllacæum; but this settlement never made any figure in the confederacy. Rome sent a colony hither. In the year 982 the emperor Otho II. was defeated under its walls by the forces of the Greeks. Montfort obtained this lordship in fee from Charles of Anjou; but in the next reign it was given to the Marsans. When this powerful house was overturned by the Aragonese, the fief was bestowed upon that of Borgia, and was afterwards vested in the marquis Gregori, who, from being a commissioner of the victualling office at Messina, rose to be prime minister of Naples, and afterwards of Spain. Squillace prides itself on having given birth to Cassiodorus, a statesman of great abilities, and, considering the times he lived in, a very respectable author, beloved and honoured by Theodoric, and other Gothic monarchs. To this town, which was the place of his nativity, he retreated in his old age; and he amply describes it; 33 miles S.S.E. of Cosenza. N. lat. 38° 48'. E. long. 16° 44'.

SQUINANCY, or ESQUINANCY. See QUINZY.

SQUINDER, in *Rural Economy*, a word signifying to burn inwardly, or in a smothering manner, as charcoal and some other substances are burnt.

SQUINTING, in *Medicine*, *Strabismus*, an irregular position and motion of the eyes, in which their axes do not converge to the object looked at.

It is certain, that when the axes of the eyes of persons who do not squint are directed in different lines, objects are seen double; squinting persons, however, do not see objects double. Yet it is well known that the principal reason which has been adduced for the singular phenomenon, that the images impressed upon the two eyes excite only one image in the mind, is, that the two images fall upon corresponding points of the eyes. The probability, therefore, is, that, in a squinting person, both eyes do not see the object looked at. In many cases, indeed, "this is pretty evident to a by-stander," as sir E. Home has remarked, "who is able to determine, that the direction of one of the eyes differs so much from that of the other, that it is impossible for the rays of light from any object to fall on the retinas of both; and therefore that one eye does not see the object. The same thing may be proved in another way. For since a small deviation in the direction of either eye from the axis of vision produces double vision, any greater deviation must have the same effect, only increasing the distance between the two images, till it becomes so great, that one eye only is directed to the object. In squinting there is evidently a greater deviation from the axis of vision than in double vision, and the object does not appear double: it is therefore not seen by both eyes." (See Phil. Trans. vol. lxxxvii. for the year 1797, p. 13.) It is manifest, indeed, that the perception is not distinct; but this, as Dr. Porterfield remarked, may be

the result of habit and experience, by which the mind learns to correct the impressions of the senses. (See Edin. Medical Essays, vol. iii. § 12.) In order to ascertain the nature of this affection, it will be necessary to investigate its varieties and causes.

Dr. Cullen was of opinion, that all the varieties of strabismus, described by Sauvages and others, might be included under three species, which he designated by the appellations *habitualis*, *commodus*, and *necessarius*. The *first* of these may arise from the habit of using only one eye in viewing objects, while there is no defect either in the organ itself, or in the muscles which move it. In this way children may learn to squint from having objects, which attract their attention, placed obliquely near the cradle; in which case it will be more easy to view them with the opposite eye alone, than to direct both towards the same point, and they will thus acquire the habit of neglecting the use and motions of the other eye. In a later period of life, the power of squinting voluntarily appears to be acquired by some by this practice of using one eye. Thus persons who look much through telescopes, and of course employ one eye almost exclusively, may acquire the power of moving the one more than the other, or lose a part of their command over the muscles of the neglected eye.

Dr. Darwin mentions a singular case of squinting, in which the patient was equally expert in the use of either eye, but viewed every object presented to him with only one eye at a time, and always with the eye on the side opposite the object. Thus, if the object was presented on his right side, he viewed it with his left eye; and when it was presented on his left side, he viewed it with his right eye. At the same time, Dr. Darwin found that he turned the pupil of that eye which was on the same side with the object in such a direction, that the image of the object might fall on that part of the bottom of the eye where the optic nerve enters it, and where it would of course excite no impression; and this insensible portion of the retina, Dr. Darwin ascertained by some ingenious experiments to be four times greater in this patient than in ordinary persons. When an object was held directly before this patient, he turned his head a little to one side, and observed it with but one eye, *viz.* with that most distant from the object, turning away the other in the manner just mentioned; and when he became tired with examining it with that eye, he turned his head the contrary way, and observed it with the other eye alone, with equal facility; but never turned the axes of both eyes on it at the same time. Phil. Transf. vol. lxxviii. p. 86.

The *second* species of squinting, however, which Dr. Cullen styles *commodus*, and which is the effect of some imperfection in one of the eyes, is the most common form of the disease. It has generally been admitted, or ascertained by experiment, in those who have a confirmed squint of this nature, that one of the eyes is too imperfect to see distinctly. Of this, however, the patient is not always conscious, as was evinced in a young lady, whose case is related by sir Everard Home. Neither herself nor her friends believed that any defect of the eye existed; and upon being asked if she saw objects distinctly with both eyes, she said certainly, but that one was stronger than the other. To ascertain the truth of this, he covered the strong eye, and gave her a book to read, when, to her astonishment, she found she could not distinguish a letter, or any other near object. More distant objects she could see, but not distinctly: when she looked at a bunch of small keys in the door of a book-case, about twelve feet from her, she could see the bunch of keys, but could not tell how many there were.

The obscurity of vision in one eye, then, is the cause of this common species of squinting, and may occasion this irregularity in the following way. The obscure image, being so imperfectly formed in the weak eye, as to excite little attention in the mind, the use of the eye, and its uniform direction to the same object with the other, may have been neglected from the beginning; for as distinct vision was obtained at once by the perfect eye, the end was answered, and therefore there was no necessity for any exertion to employ the other. Or on the other hand, in the effort to get rid of the confused image, the muscles may have acquired an irregular and unnatural action. It is remarked by sir E. Home, that the direction, which the eye takes under either of these circumstances, is inwards, towards the nose; because the *adductor* muscle is stronger, shorter, and its course more in a straight line, than any of the other muscles of the eye. Phil. Transf.

In the *third* species, or *strabismus necessarius* of Cullen, the squinting is the result of some peculiarity or change in the form or situation of the eye or its parts; whence a perfect and distinct image of any object can only be obtained by an oblique direction of the axis of the eye. Dr. Porterfield has pointed out two varieties of this kind, arising, the one from an oblique position of the crystalline lens within the eye, by which the image of an external object is refracted out of the line of the axis of the eye;—and the other, from an oblique position and greater protuberancy of the cornea, which produces a similar effect. (See Edin. Medical Essays, vol. iii. art. 12.) These appear to be synonymous with the *strabismus à crystallino*, and *S. myopum* of Sauvages (Nosol. Meth. class. iv. gen. i. spec. 12 & 9.) Other partial diseases of the eye may contribute to render oblique vision the most convenient; such as *leucoma*, *hypopion*, *pterygium*, &c. enumerated by Sauvages as constituting his eleventh species, *S. caligantium*.

Cure of Squinting.—The two first species of squinting, arising from the habit of using one eye only, or from the weakness or imperfection of the other, may be sometimes cured. The third, which arises from some malformation of the eye or its parts, is scarcely remediable.

The principle of cure in the two first species is nearly the same; namely, the constant exercise of the neglected eye, whether naturally weak or not. This may be effected by covering the strong eye, or that which is always employed, and confining the person to the use of the neglected or weak eye. For in this way, the muscles of the latter, from constant action, will become perfect in the habit of directing the eye upon the object, gain strength in that action, and acquire a power of adjusting the eye. When this is established in a sufficient degree, the other eye may be set at liberty. The time that will be necessary for the cure, will depend upon the inveteracy of the habit, the length of time that the muscles have been left to themselves, and the degree of weakness of the sight: for it is with difficulty that muscles acquire an increased degree of action after having been long habituated to a more limited contraction. Dr. Darwin observes, that if the squinting has not been confirmed by long habit, and one eye be not much worse than the other, a piece of gauze stretched on a circle of whalebone, to cover the best eye in such a manner as to reduce the distinctness of vision of this eye to a similar degree of imperfection with the other, should be worn some hours every day.

For the cure of the curious case related by the same ingenious physician, in which there was no defect in either eye, but merely a depraved habit of using both eyes separately, Dr. Darwin says, “a gnomon of thin brads was made to

SQUINTING.

stand over his nose, with a half circle of the same metal to go round his temples; these were covered with black silk, and by means of a buckle behind his head, and a cross-piece over the crown of his head, this gnomon was managed so as to be worn without any inconvenience, and projected before his nose about two inches and a half. By the use of this gnomon he soon found it less inconvenient to view all objects with the eye next to them, instead of the eye opposite to them.

“After this habit was weakened by a week’s use of the gnomon, two bits of wood, about the size of a goose-quill, were blackened all but a quarter of an inch at their summits: these were presented for him to look at, one being held on one side the extremity of his black gnomon, and the other on the other side of it. As he viewed these, they were gradually brought forwards beyond the gnomon, and then one was concealed behind the other. By these means, in another week, he could bend both his eyes on the same object for half a minute together.

“By the practice of this exercise before a glass, almost every hour in the day, he became in another week able to read for a minute together with his eyes both directed on the same objects; and I have no doubt, if he has patience enough to persevere in these efforts, but he will in the course of some months overcome this unsightly habit.” Phil. Trans. vol. lxxviii. p. 89.

Philosophers, as well as physicians, have adopted various hypotheses, in order to account for this defect in vision. It has been generally supposed to proceed, according to the preceding statement, from the want of a due correspondence in the muscles of the eyes, which not acting in a proper concert with one another, are not able to point both eyes at one object. M. de la Hire apprehended, that this disorder proceeded from a defect in the eye itself having the most sensible part of the retina not placed in the axis of the eye, but at some distance from it on one side or the other; and that, therefore, not the axis, but this more sensible part of the retina is turned towards the object on which the axis of the other eye is fixed, so that both axes are not directed to the same point.

He supposed squinting, also, sometimes to be owing to the oblique situation of the crystalline humour in one of the eyes. These hypotheses are examined and refuted by Dr. Jurin, who, in order to account for this defect, considers the disposition and situation of the eyes in a sound state. When we look directly forwards at a distant object, the pupil of each eye lies in the middle of the aperture formed by the eye-lids; so that the distance between the two pupils consists of the breadth of the nose and half the breadth of the aperture of each eye; and this distance between them is always preserved, however obliquely we turn our eyes. In looking at near objects, the distance between the pupils is somewhat less, but still it is always the same in all oblique directions of the eyes, as well as when we look straight forwards; by which means the axes of both eyes are directed forwards to the same point, in both these cases of looking at distant and near objects. But in those who squint, when the pupil of the undistorted eye is seated in the middle of the aperture, as in looking directly forwards, the pupil of the other eye is drawn close to the nose, and consequently, the distance between the two pupils is considerably less than in other persons; and this less distance continues the same in all oblique directions for the eyes; so that two axes are never pointed at the same object, though the muscles do so far act in concert with each other, as to move both eyes the same way at the same instant of time.

This vicious habit, Dr. Jurin observes, may easily be

contracted by a child, if he is often laid into his cradle in such a position as to be able to see either the light, or any other remarkable object, with one eye only: and when by this means he is brought to squint, and the habit is confirmed, he apprehends it will be in vain to attempt a cure by his wearing tubes, or shells, with small holes to look through; for, notwithstanding every help of this kind, he will continue to see through them distinctly with one eye only, and will still distort the other. The true method of cure he takes to be the following: when the child is arrived at such an age as to be capable of observing directions, place him, says he, directly before you, and let him close the undistorted eye, and look at you with the other. When you find the axis of this eye fixed directly upon you, bid him endeavour to keep it in that situation, and open his other eye. You will now see the distorted eye turn away from you towards his nose, and the axis of the other eye will be pointed towards you. But with patience and repeated trials, he will, by degrees, be able to keep his distorted eye fixed upon you, at least for some little time, after the other is opened; and when you have brought him to keep the axes of both eyes fixed upon you, as you stand directly before him, it will be time to change his posture, and to set him first a little on one side of you, and then to the other, and so to practise the same thing; and when in all these situations he can perfectly and readily turn the axes of both eyes towards you, the cure is effected. An adult person, he says, may practise all this by a glass, without a director, though not so easily as with one; but the older he is, the more patience will be necessary. Smith’s Optics, Rem. p. 30.

M. Buffon infers, from a great number of observations, that the true and original cause of squinting is an inequality in the goodness, or in the limits of distinct vision in the two eyes. When one of the eyes, he says, is much weaker than the other, we do not direct it towards the object, but make use of the stronger eye only: when the eyes are equally good, we see more distinctly with both eyes than with one, by about a thirteenth part; but when they are unequal in goodness, objects appear less distinct with both eyes than with one. It is no wonder, therefore, that persons, subject to this inequality, chuse to make use of one eye, and turn the other aside. This inequality in the goodness of the eyes is the general cause of squinting, according to M. Buffon; and others, with respect to this, are accidental. All the persons whom he examined, if they squinted at all, did so from this cause; and this effect is so necessary, that, he says, it is not possible to cure a person of squinting, whose eyes differ much in point of goodness, except, perhaps, by first bringing them nearer to an equality by means of glasses. To the same purpose Dr. Reid observes, that, having examined above twenty persons who squinted, he found in all of them a defect in the sight of one eye. And this writer is of opinion, that the centres of the two eyes of squinting persons correspond with them as with others, so that if they could be brought to the habit of directing their eyes aright to an object, they would not only remove a deformity, but likewise improve their sight.

In examining the limits of distinct vision in several children who did not squint, M. Buffon found, (contrary to Dr. Jurin’s observation,) that they did not see by any means either so far off, or so near as adult persons; so that, as we advance in age, the limits of distinct vision are extended both ways; and this, he says, is one reason why children squint more than adult persons.

When the eyes of those persons who squint do not differ much in point of goodness, M. Buffon thought that the most

most simple, the most natural, and the most effectual method of curing it, would be to cover the good eye for some time; for the distorted eye would thus be obliged to act and turn itself directly towards objects, and, by degrees, this would become natural to it.

The reason why those persons who squint generally turn the weak eye towards the nose, he says, is, that in that situation, the direction of its axis is as distant as possible from that of the good eye: and besides, in this place, the nose conceals many objects from its view, so that this situation is the least disadvantageous to it of any other.

In some cases, M. Buffon observes, that the eyes have what is commonly called a *cast* only, in consequence of the optic angle being too great or too small, when they are of equal goodness. This, he says, is generally the result of habit, acquired very early, in consequence of the mismanagement of children, and that it is often easily cured. If the eye that squints be turned towards the temples, he says, he has generally found that there is no great inequality in the goodness of the two; and that, in this case, the cause being only a vicious habit, the cure has been completed by covering the good eye for a fortnight only. In order to judge with any certainty of the inequality of goodness in the two eyes, and the possibility of the cure of squinting, it is necessary, he says, to cover the good eye for some time, in order to exercise the bad eye, and give it an opportunity of gaining strength, after which it will be more easy to judge whether the cure be possible or not. Acad. Par. 1743, p. 329. 342. Reid's Inq. into the Human Mind, p. 253—257. See *Physiology of the Eye*.

SQUINZANO, in *Geography*, a town of Naples, in the province of Otranto; 6 miles N.W. of Lecce.

SQUIRE, SAMUEL, in *Biography*, a learned English prelate, was born at Warmiafter in 1714. He was educated at St. John's college, Cambridge, of which he became a fellow. After various instances of preferment, he obtained the vicarage of Greenwich, and was appointed clerk of the closet to the prince of Wales, his present majesty. In 1760 he was promoted to the deanery of Bristol; and in the following year he was advanced to the see of St. David's. He died in 1766, leaving behind him several works of reputation, besides a number of single sermons. His principal pieces are as follow. In his profession as a divine, he wrote "The ancient History of the Hebrews vindicated;" "Indifference for Religion inexcusable;" and "The Principles of Religion made easy to young Persons." In classical literature, he published "Two Essays: (1) A Defence of the ancient Greek Chronology; (2) An Inquiry into the Origin of the Greek Language;" and an edition of "Plutarch de Iside et Osiride," Gr. and Engl., with commentaries and various readings. His works, as a political writer, are, "An Inquiry into the Nature of the English Constitution, or an historical Essay on the Anglo-Saxon Government both in Germany and England;" "An Essay on the Balance of Civil Power in England;" and "Remarks upon Mr. Carte's Specimen of the General History of England." He left in MS. a Saxon grammar, compiled by himself. Dr. Squire was a fellow of the Royal and Antiquarian Societies. Gen. Biog.

SQUIRREL, SCIURUS, formed of *σκια*, *shade*, and *ερα*, *tail*, because the tail serves this animal for an umbrella, is a genus of animals described under **SCIURUS**.

There is great diversion in hunting the common English squirrel, and its flesh is very delicate and well tasted. The only season for hunting it is in autumn, and the beginning of winter, at which time the creature is fat; and the leaves being off the trees, it may be seen as it leaps from bough

to bough, which, when pursued, it does with surprising agility.

In the summer they build their nests, which the sportsmen call *drays*, very artificially in the tops of trees, with sticks, moss, and such other things as the woods afford: to their nest they have two holes, and they stop up that on the side the wind blows, as Pliny has remarked; they fill this lodging, during the season, with nuts and other fruits, which are to serve them in the severe weather, when the trees afford nothing. They sleep in the midst of this provision a great part of the winter, and that so soundly, that they will not be waked by ever so loud a noise made just under their drays; though at other times they fly out immediately on hearing any noise, even at a considerable distance.

In the spring the female is seen pursued from tree to tree by the males, feigning an escape from their embraces.

The tail of the squirrel, which is as large as the body, though composed almost entirely of hair, serves the creature in some sort instead of wings; for by means of it the body is kept suspended in the air, without any visible sinking, while the creature throws itself from the boughs of one tree to those of another of equal height. But the more general leaps the squirrel takes, are from the outermost branches of a high tree to another somewhat lower at a distance: it is wonderful to see how far it will be carried in these leaps; and if it misses the tree it aims at, and by that means falls from the top of ever so high a tree to the ground, the tail supports it so well that it comes softly down, and receives no harm. The hunting of the squirrel is most agreeably performed in woods of a young growth, the trees of which may be shaken by the hands; and it is necessary to take out some means of dislodging them from the clefts of trees, in which they will take refuge, and from which they will never be removed by mere noise.

Many people usually go together on this expedition, and sometimes they carry bows and arrows for the dislodging of the prey from these places; sometimes bludgeons, or short or thick staves, loaded at one end with lead, to prevent their lodging in the tree when they are thrown up. The squirrel, which in its fright has taken refuge in any part of a tree, and is not to be dislodged either by hallooing or shaking the tree, will always quit the place as soon as an arrow or bludgeon has been well aimed at it, and will give a farther chase.

The squirrel is always fond of a large oak in time of danger, and runs to the nearest it can find, as soon as it sees itself pursued: in some part of the upper boughs of this tree it sits secure from the men and dogs, and as it is too troublesome to the sportsmen to climb every tree, the only method is to shoot arrows, and throw bludgeons at it; it is very seldom hurt by these, unless hit just upon the head, for its back-bone is so strong, that it will bear nearly as hard a blow as a dog, without danger of hurt. So long as the strength and spirits of the creature last, it always keeps in the tops of the highest trees; but when it grows weary, it comes down, and takes shelter in the hedges. The squirrel then soon becomes a prey to the dogs, or is very often killed upon the ground, in attempting to gain the hedge in places where there is no continued chain of trees by which it can come at it.

It is observed, that the gullet of this animal is very narrow, to prevent it from disgorging its food in descending of trees, or in its leaps downwards.

SQUIRTING or **SPURTING Cucumber**, in *Gardening*, the common name of a wild sort of cucumber, which is sometimes cultivated in gardens for the sake of curiosity, and for the

the peculiar property which it **possesses of instantly bursting** the capsules of the ripe fruit, on being touched, with much elasticity and violence, so as to throw the juice and seeds which they contain forcibly to a great distance all around, to the great surprize of those who may have touched them. See **MOMORDICA**.

It likewise affords the medicinal substance known by the name of *elaterium*.

SQUIRZINA, in *Geography*, a town of the duchy of Warlaw; 50 miles W.N.W. of Posen.

SRADHA, the name of a ceremony among the Hindoos, of a very interesting and affecting nature; being obsequies in honour of departed ancestors.

The Hindoo Pantheon furnishes some particulars explanatory of this interesting and affecting ceremony, which, the author tells us, is an oblation of daily recurrence with Brahmans and rigid Hindoos who can afford it. It is offered not only in honour of deceased ancestors, but for their comfort; as the manes, as well as the gods connected with them, enjoy, like the gods of the Greeks, the incense of such offerings; which are farther of an expiatory nature, similar, it may be presumed, in their efficacy, as well as in the motives that induce them, to the masses of the Romish church. Over these ceremonies of Sradha, Yama presides, in his character of Sradhadeva, or lord of the obsequies. See **SRADHADEVA** and **YAMA**.

Mr. Colebrooke tells us (*Af. Ref.* vol. vii.), that the priests, in the performance of the Sradha, meditate the gayatri, and thrice repeat "Salutation to the gods, to the manes of ancestors, and to mighty faints; to Swaha (gods of fire) to Swadha (the food of the manes); salutation to them for ever and ever." Of the gayatri, &c. of this quotation, see **O'M**, **SWADHA**, and **SWAHA**.

M. le Gentil found a strong resemblance between the funeral rites of the Chinese and the Sradha of the Hindoos. On which Sir William Jones (*Af. Ref.* vol. ii.) says, "that all the circumstances which have been mentioned, under the two heads of literature and religion, seem collectively to prove, (as far as such question will admit of proof,) that the Chinese and Hindoos were the same people; but having been separated near four thousand years, have retained few strong features of their ancient consanguinity; especially as the Hindoos have preserved their old language and ritual, while the Chinese very soon lost both. And the Hindoos have constantly intermarried among themselves; while the Chinese, by a mixture of Tartarian blood from the time of their first establishment, have at length formed a race distinct in appearance from both Indians and Tartars."

In the third chapter of the *Institutes of Menu*, the rules for the performance of the Sradha are detailed with proximity. Among other particulars of the most important of those ceremonies, we learn that Brahmans only ought to be invited to the feast, which forms one important rite; and such Brahmans should be of holy and learned habits. A Sudra, that is, one of the fourth or servile class, is urgently prohibited as a guest. Let the housekeeper, it is said, who knows his duty, perform each day a Sradha with boiled rice, and the like, or with water, or with milk, roots, and fruit; for thus he obtains favour from departed progenitors, &c. &c. &c.

The following extract is taken from Colebrooke's *Dissertation on the religious Ceremonies of the Hindoos*, in the seventh volume of the *Asiatic Researches*; which article contains much valuable matter, and many curious particulars of the Sradha, or feast attending funeral obsequies.

"A dying man, when no hopes of his surviving remain, should be laid on a bed of Kusa grass (see **KUSA**), in the

open air, his head sprinkled with water drawn from the Ganges, and smeared with clay brought from the same river. A Salagrama stone (see **SALAGRAMA**) should be placed near him, holy strains from the Veda (see **VEDA**) should be chanted aloud, and leaves of holy basil scattered over his head.

"When he expires, the corpse must be washed, perfumed, and decked with wreaths of flowers, and carried by the nearest relations to some spot in the forest, or near water: the funeral pile is lighted from the consecrated fire maintained by the deceased. (See of this under our articles **SAGNIKA** and **SAMI**.) The nearest relation applies the flaming brand to the pile, hung round with flowers; and the attendant priests recite the appropriate invocations: 'Fire! thou wast lighted by him; may he, therefore, be reproduced from thee, that he may attain the regions of celestial bliss. May this offering be auspicious!' All who followed the corpse walk round the pile, but may not view the fire. They then proceed to the river, and, after bathing, present oblations of water to the manes of the deceased, saying, 'May this oblation reach thee!' Elegiac verses, such as the following, are then recited.

"1. Foolish is he who seeks for permanence in the human state; insolid, like the stem of the plantain-tree; transient, like the foam of the ocean.

"2. When a body, formed of five elements, to receive the reward of deeds done in its own former person, reverts to its own five original principles, what room is there for regret?

"3. The earth is perishable; the ocean, the gods themselves pass away: how should not that bubble, mortal man, meet destruction?

"4. All that is low must finally perish; all that is elevated must ultimately fall; all compounded bodies must end in dissolution; and life be concluded by death."

Exclusive of the daily Sradhas, or feasts, given by wealthy individuals, formal obsequies are performed ninety-six hours in every year, on particular days. "It should be observed," Mr. Colebrooke tells us, respecting the practice of giving food at these obsequies, "that Brahmans generally give it to one or more of their own relations. A stranger, unless indigent, would be very unwilling to accept the food, or attend at a Sradha, for the purpose of eating it. The use of flesh meat is positively enjoined to Hindoos at certain obsequies, and recommended at all. (See *Inst. of Menu*, c. iii. v. 124. 268, &c.) But the precepts of their lawgivers are, by some, deemed obsolete in the present age; and are evaded by others, who acknowledge the cogency of these laws. These commonly make a vow of abstaining from flesh meat, and consider that vow as more binding than the precepts here alluded to. Others, again, not only eat meat at obsequies and solemn sacrifices, but make it their common diet, in direct breach of their religion." It hence appears clear, that the idea so common in Europe, of the universal abstinence of Hindoos from flesh meat, is as erroneous as general. Some pages of the Hindoo Pantheon are devoted to prove this fact; and it is fully proved, that not only all Hindoos may, but that a great majority of those who can obtain it, including Brahmans themselves, actually do, eat meat.

The feast attendant on the ceremonies of the Sradha can be given only by the son, or grandson, or male issue of the defunct; and as the greatest importance is attached by Brahmans and others to the due performance of these ceremonies, default of male issue is deprecated as among the heaviest of misfortunes. The Hindoo books, therefore, abound in instances of the efficacy of prayers, sacrifices,

alms to Brahmans, pilgrimages, austerities, &c. in obtaining this grand object of comfort to departed souls. "Appeasing the manes," by the Sradha, is as common in the mind of a Hindoo, as relieving the pains of purgatory by masses is in that of a Papist. Though the ceremonies differ, the principle is strikingly similar. Being childless is felt as an angry visitation of the gods, inflicted partly for sins in a former state of existence: they are, therefore, propitiated by alms, pilgrimages, &c. One mode of removing sterility is by circumambulating an image, or tree, sacred to some deity. (Of this see under PRADAKSINA, the name of this ceremony.) If every thing fail, there is, however, still a remedy by adoption, accompanied by certain ceremonies, expensive, according to the means of the party. Another is by giving daughters in marriage with like ceremonies; all of which are minutely detailed in the ritual. For all these proceedings divine authority can be quoted. Holy men, or even divinities, in the times of their terrestrial sojournments, are related to have done the like. "He," says Menu, "who has no son, may appoint a daughter to raise up a son for him, saying, 'The male child who shall be born from her in wedlock shall be mine, for the purpose of performing my obsequies.'"

"In this manner Daksha himself, lord of created beings, anciently appointed all his fifty daughters to raise up sons to him, for the sake of multiplying his race."

SRADHADEVA, in *Hindoo Mythology*, a name given to the Pluto of their infernal regions. It means lord of the Sradha, a feast often, by many daily, offered in commemoration of deceased ancestors. (See SRADHA.) The more common name for the lord of the obsequies is *Yama*; which see.

SRAMANA, a name of the Eastern deity *Boodb*; which see.

Sakya, Sravaka, and Sugata, (which see,) are others of his names. So is Gotama, or Godama. The union of the first and last of these names, a little altered in the pronunciation, produced that of Somnecodom, by which he is called by some writers. See GODAMA.

SRAVAKA, the name of the laity of the Jainas, a sect of schismatic Hindoos. Their priests are called Yati. (See JAINA and YATI.) A name also of the god Budha, or *Boodb*; which see. For a notice of the religion and customs of the sect of Sravaka, see Moor on Hindoo Infanticide, p. 174. Among the Mahrattas, the Sravakas are called Shevari.

SRBORNICK, in *Geography*, a town of Bosnia; 40 miles N.N.E. of Bosnaferai.

SREDNEI, an island in the Frozen ocean, at the mouth of the Indigirda, about 40 miles in circumference, of a triangular form. N. lat. 72° 52'. E. long. 154° 155'.—Also, a town of Russia, in the government of Tobolsk; 20 miles N.N.W. of Tassievkoi.

SRI, in *Hindoo Mythology*, is a name given to several goddesses; oftenest perhaps to Lakshmi, the goddess of prosperity and abundance. This name is in the first case Sris, which sir William Jones remarked as resembling, both in name and character, the goddess of abundance of the Latins; and he says, that in very ancient temples near Gaya there are images of Lakshmi, with full breasts, and a cord twisted under her arm, like a horn of plenty, which looks very much like the old Grecian and Roman figures of Ceres. (See LAKSHMI.) The word Sri, however, although given as a name or epithet to the Ceres of India, and to the other great goddesses Parvati and Saraswati, is not confined to them: it means fortunate, happy, &c. as well

as blessed or divine; and is sometimes prefixed to the names both of gods and men.

SRI BHAGAVATA, the title of a work in the Sanscrit language, of great celebrity among the Hindoos. It is usual to ascribe this work to Vyasa, the reputed compiler or author of the Vedas, Puranas, Mahabarat, and other works. But the real author of the Sri Bhagavata is Vopadeva, who, in attempting to revive the leading doctrines of Vyasa, opened a door to the reconciliation of the various sects of Hindoos, numerously divided and subdivided as they are, and, as far as historical evidence can be traced, ever have been. We must refer the reader to our article SECTS of Hindoos, for farther information on these points. (See also VYASA.) Under our article PURANA we have given a succinct account of the mythological romances so called, that are so highly venerated in India as inspired poems. Of these the Sri Bhagavata is reckoned the eighteenth and last; and whatever differences of opinion may exist, and very wide differences do exist, as to the antiquity and form of the other Puranas, it seems a point generally agreed on, that the Bhagavata is much more modern than the rest, and cannot, in its present form, claim an age of more than six hundred years.

The main subject of the Bhagavat is the life and actions of Krishna; including the extravagant and mystical details of his incarnation, miracles, debaucheries, and various fooleries; intermixed, however, with sublime effusions of pure theology and morals. (See MYSTICAL Poetry.) Like most of the other respected writings of the Hindoos, it contains much to applaud and admire; but more, whether viewed philosophically or morally, to reprehend. It is comprised in twelve books, and, like the other poems bearing the common denomination of Purana, contains, besides the general thread of sectarial theology interwoven throughout, five subjects, viz. primary creation, or creation of matter in the abstract; secondary creation, or the production of subordinate beings, both spiritual and material; chronological account of their grand periods of time called Manwantara; genealogical rise of families, particularly of those who have reigned in India; and, lastly, a history of the lives of particular families.

This work is in general estimation, and is found in most of the vulgar dialects of India, and in the Persian language. It has also appeared in a very imperfect and abridged form, in French, under the title of Bagavadam, translated from the Tamul version. Its title is derivable from Bhagavan, one of the names of Krishna and Vishnu; and Bhagavan from Bhaga, meaning, it is said, the author of existence, or lord of nature. (See SIVA.) Sri is a prefixure of respect, extensively applied. (See SRI.) The modern sect, who adhere to the liberal doctrine expounded in this work, are called Bhagavatas. But we must again refer to our article SECTS of Hindoos, for an explanation of the nature of the Hindoo sectarial distinctions. See also KRISHNA, for an account of the hero of the Bhagavat.

SRI DEVI, in *Hindoo Mythology*, is a name given by several sects to the goddesses of their adoration; such individual goddesses being called the fakti, or energy of her lord. In explanation of this, we refer to our article SAKTI. Sri-devi means the blessed goddess, and is given to all the three great goddesses, Lakshmi, Parvati, and Saraswati.

Sridevi is likewise the name of the wife of Daksha, who was Brahma in a human shape. In this character she seems to be both the daughter and mother of Parvati. See PIKE-SWARI and SRADHA.

SRIMANA, a name of Kartikya, the Hindoo regent of the firmament. See KARTIKYA.

SRIMANT, an appellation of respect used in the third person to the Peshwa, or chief person of the Mahratta empire. See PESHWA.

SRINAGUR, in *Geography*. See SIRINAGUR.

SRIPADA, a name, or word, used among the Hindoos, meaning a divine footstep, for which supposed impressions they have a very reverential feeling. On the top of the lofty mountain on the island of Ceylon, which European geographers call Adam's peak, the Hindoos fancy there is a fripad; and accordingly pilgrimages are made to it from distant parts of India. Vishnu, it is said, alighted on this spot, and left the holy and indelible impression. In the neighbourhood of temples, or at their threshold, it is not unusual to see a flat stone embossed or engraved with the impression of two feet, joined from heel to toe; such being the attitude of adoration: and it is said that such stones are the last terrene substance pressed by the feet of the unhappy victims of superstition, who burn themselves alive on the pile of their husbands. They step from these flat stones upon the pile, and then appertain more to the next world than to this. The next step is into the presence of the gods; or, in the case of temples, to their holy place.

The Hindoos are not the only people who have a veneration for the mystical impressions of feet. The fripad above mentioned on Ceylon was said by our early zealous missionaries to have been left by Adam; they endeavouring to establish the fact of that chosen island having been the Eden of our first parents. (See LANKA.) In the holy land, miraculous fripada, or footsteps, are still shewn and revered, as left by the last pressure of our Saviour on the earth. On this subject the reader will find some interesting discussion in Dr. Clark's Travels, vol. ii. p. 584.

SRIRANGA, a name of the Hindoo god Siva. The name is Ranga, with the epithet Sri prefixed, meaning holy or blessed. (See RANGA, SIVA, and SRI.) Seringapatam, or Seringapatana, means the city of Sriranga, or of the holy Ranga.

SRIVIRUPAKSHA, a name of Siva, the destructive or transforming power of the Hindoo divine triad. Virupaksha is said to mean with *three eyes*, Siva being so gifted; and hence named *Trilokan*; which see. (See also SIVA.) An eminent Sanscrit scholar translates the name Virupaksha, "with a disagreeable countenance." The epithet Sri prefixed means blessed or divine. See SRI and VIRUPAKSHA.

Madame Dacier, in a note on the ninth book of the Iliad, has a passage applicable to the mythological subject of this article. The ancients, she says, gave the name of Jupiter not only to the god of heaven, but likewise to the god of hell, as is seen here by the epithet of "infernal Jove," and to the god of the sea, as appears from Eschylus. They thereby meant to shew, that one sole deity governed the world; and it was to teach the same truth, that the ancient statuaries made statues of Jupiter, which had three eyes. Priam had one of them in that manner in the court of his palace, which was there in Laomedon's time. After the taking of Troy, when the Greeks shared the booty, it fell to the lot of Stenelus, who carried it into Greece.

Siva, the Indian Jove, is, in like manner, deemed variously the god of the three regions of the universe, as denoted by his three eyes, trident, &c. See PARVATI and TRISULA.

SRODA, or **SVODA**, in *Geography*, a town of the duchy of Warfaw; 14 miles S.E. of Posen.

SRSEM, or **STRIM**, a town of the duchy of Warfaw; 20 miles S. of Posen.

SRSERED. See SERAT.

VOL. XXXIII.

SSE-TCHUEN, a town of Corea; 33 miles S.W. of Tsin-tcheou.

SSIDA, a town of Japan, in the island of Nippon; 18 miles S. of Fitaqua.

SSIERSCH, a town of the duchy of Warfaw; 16 miles N. of Ploczk.

SSOKAL, a town of Austrian Poland, in the palatinate of Belz; 10 miles N.E. of Belz.

SSUUS, a town of Japan, on the N. coast of Nippon; 20 miles S.E. of Noto.

ST, an indeclinable term, chiefly used to command silence. The Romans had these two characters written over the doors of the eating-rooms, as who should say, *sed tace*, or *silentium tene*.

Porphyry observes, the ancients made a point of religion of it, not to speak a single word in passing in or out of the doors.

STAAL, *Madame de*, in *Biography*, an ingenious French writer, first known by the name of Mademoiselle de Launay, was daughter of a painter at Paris. Her father being obliged to quit the kingdom, she was left in a state of poverty. She had enjoyed the advantages of a good education at a priory in Rouen; but her patroness dying, she was under the necessity of engaging herself as bed-chamber woman to the duchess of Maine; who soon discovering the talents of her servant, employed her in all the theatrical entertainments which she gave at her seat of Sceaux. For some of these De Launay wrote verses, and for others she formed the plans, and thus obtained the perfect and unlimited confidence of her mistress, and the friendship of all the men of wit and letters who frequented that court. Following the fortunes of her mistress, she was involved in the disgrace incurred by the duchess during the regency of the duke of Orleans, and was two years a prisoner in the Bastille. After her liberation, the duchess, as a reward for her fidelity, married her to M. de Staal, lieutenant, and afterwards captain, in the Swiss guards. From her own description, she appears to have possessed few personal attractions, yet her gallantries were a great source of the vexations with which her life was disquieted. She sometimes loved without a return, and she sometimes attracted attentions to which she paid no regard. She died in 1750, and after her death were printed, in 3 vols. 12mo. "Memoirs of her Life," written by herself. These are agreeably written, and in a pure and elegant style. There has been added a fourth volume, containing two comedies acted at Sceaux, entitled "L'Engoument," and "La Mode," the chief merit of which is said to consist in the sprightliness of the dialogue. Her memoirs have been translated into the English language.

STAATEN LAND, in *Geography*. See *New ZEALAND*.

STAATSBERG, an opulent farming neighbourhood in Clinton, Duches county, New York, in which is a post-office; 70 miles from Albany, and 10 from Poughkeepsie.

STAATZ, a town of Austria; 5 miles W. of Falkenstein.

STAAVIA, in *Botany*, was so called by Dahl, in compliment to Mr. Martin Staaf, of Gottenburgh, a great patron of botany, and an assiduous disciple of the great Linnæus, to whom he formerly communicated many natural productions from China.—Dahl. Obf. Bot. 14. Thunb. Prodr. 41. Willd. Sp. Pl. v. 1. 1144. Ait. v. 2. 35. Poiret in Lamarek Dict. v. 7. 363. (Levisanus; Schreb. Gen. 149, excluding the reference to Gärtner.)—Class and order, *Pentandria Monogynia*. Nat. Ord. *Rhamni*, Juss.

Gen. Ch. *Common Calyx* hemispherical, many-flowered, 4 P imbricated,

imbricated, of numerous linear leaflets. Perianth superior, erect, of one leaf, in five deep acute segments, permanent. Cor. Petals five, short, oblong, obtuse, nearly upright, with slender claws. Stam. Filaments five, awl-shaped, inserted into the bottom of the calyx; anthers roundish. Pist. Germen inferior, turbinate; styles two, combined, capillary; stigmas simple. Peric. Berry coated, of five cells. Seeds solitary. Common Receptacle convex, villous, or chaffy.

Ess. Ch. Flowers aggregate. Stamens inserted into the calyx. Styles two, united. Berry coated, with five seeds. Common receptacle chaffy.

1. *S. radiata*. Rayed Staavia. Willd. n. 1. Ait. n. 1. (*Brunia radiata*; Linn. Mant. 2. 209. *Phyllica radiata*; Linn. Sp. Pl. 283. *Chrysanthemum ericoides coronatum*; Breyn. Cent. 165. t. 82.)—Leaves lanceolate-triangular. Coloured rays of the calyx shorter than the diameter of the head of flowers.—Native of the Cape of Good Hope. A greenhouse plant in England, flowering in May and June, but of no striking appearance. The straight hairy branches of the bushy stem are clothed with numerous, little, alternate, heath-like, smooth, glaucous leaves, on short stalks. The flowers are corymbose, four or five together at the summit of each branch, looking not unlike some small kind of *Aster*. The disk is a quarter of an inch broad, reddish. Rays nearly the same in length, pale, obtuse, recurved.

2. *S. glutinosa*. Clammy Staavia. Willd. n. 2. Ait. n. 2. (*Brunia glutinosa*; Linn. Mant. 2. 10.)—Leaves linear-triangular. Coloured rays of the calyx rather longer than the diameter of the head of flowers.—From the same country. Introduced into England by Messrs. Lee and Kennedy in 1793. We find no figure that can be trusted, though Plukenet's t. 431. f. 1. bears some resemblance to this species. The leaves are longer and more slender than the foregoing. Flowers solitary, full twice as large, with copious, long, and slender rays. The disk is glutinous, perhaps from abundance of honey, and is covered in the dried specimens with sand, whence the name.

STAB, in *Geography*, a town of Bohemia, in the circle of Pilsen; 11 miles S.S.W. of Pilsen.

STABAT *Mater Dolorosa*. This celebrated elegy in monkish rhymes, written about the 14th century by Jacoponus, a minor Franciscan friar, has been set by all the great masters in Italy, and Roman Catholic composers in Germany; but by none in so happy and captivating a manner as by Pergolesi.

STABBIA, in *Geography*, a town of Etruria; 11 miles S.S.W. of Pistoia.

STABBING, in *Law*. See MANSLAUGHTER.

STABBING of *Hoven Cattle*, in *Rural Economy*. See HOVEN.

STABILI SUONI, in the *Ancient Greek Music*, were the extremes, or lowest and highest sounds of each tetrachord, which, sounded together, constituted the diatessaron, or 4th, that was never changed as the two middle strings were, which were elevated or lowered according to the genera, and on that account were called *mobiles*, *mobili suoni*.

STABLE, in *Rural Economy*, a building or house constructed for horses and other animals, being furnished with stalls and proper contrivances to contain their food and other matter.

Nothing conduces more to the health of a horse than the having a good and wholesome stable. The situation of a stable should always be in a good air, and on a firm, dry, and hard ground, that in winter the horse may come in and go out clean. It should always be built somewhat on an ascent, that the urine and other foulnesses may be

easily conveyed away by means of drains or sinks cut for that purpose.

As there is no animal that delights more in cleanliness than the horse, or that more abominates bad smells, care should be taken that there be no hog-stie, hen-roost, or necessary-house, near the place where the stable is to be built; for the swallowing of feathers, which is very apt to happen when hen-roosts are near, often proves mortal to horses; and the steams of a hog-house, or hog's dung, will breed many distempers; and particularly they will bring on the farcy and blindness in many horses. It is much better to build the walls of a stable of brick than of stone, for the former is always dry, the other often sweats, and is very apt to be damp, and to cause rheums and catarrhs to horses that are fet in the stable in damp weather.

The walls ought to be made of a moderate thickness, both for the sake of safety, and warmth in winter, and to keep off the heat of the sun in the midst of summer, which would spoil the horse's appetite, and sink his spirits. The windows should be made on the east and north sides of the building, that the north air may be let in to cool the stables in summer, and for the benefit of the rising sun all the year round, especially in winter.

The windows should either be lashed, or have large casements, for the sake of letting in air enough; and there should always be close wooden shutters, that the light may be shut out at pleasure; by which means the horse will be brought to sleep in the middle of the day, as well as in the night, when it is judged proper that he should do so.

Many pave the whole stable with stone; but it is much better to have that part which the horse is to lie upon, boarded with oak-planks; for it will be not only easier, but more warm and comfortable to the animal.

The boards must be laid as even as possible, for this is the way to make the creature lie most at his ease, and in the most healthful posture. The dealers in horses generally, indeed, make the boards be laid higher toward the top, and slanting down: this shews a horse to more advantage as he lies, but it is very uncomfortable to the creature, and his hinder parts are always slipping down, and the hind legs are often made subject to swellings by it.

The planks should be laid crosswise, not lengthwise; and there are to be several holes bored through them to receive the urine, and carry it off underneath the floor into some drain or common receptacle. The ground behind should be raised to a level with the planks, that the horse may always stand even, and the floor behind should be paved with small pebbles, and the place where the rack stands should be well wainscotted. There are to be two rings placed on each side of the stall for the horse's halter to run through, and a logger is to be fixed to the end of this, sufficient to poise it perpendicularly, but not so heavy as to tire the horse, or to hinder him from eating. The best place for him to eat his corn in is a drawer, or locker, made in the wainscot partition; this need not be large, and consequently need not take up much room, so that it may be easily fixed, and taken out to clean at pleasure; by this means the common dirtiness of a fixed manger is to be avoided.

Many people are against having a rack in their stables; they give the horse his hay sprinkled upon his litter, and if they think he treads it too much, or too soon, they only nail up three or four boards, by way of a trough, to give it to him in. The reason of this is, that the continual lifting up of the head to feed out of the rack is an unnatural posture for a horse, which was intended to take his food up from the ground, and makes him, as they express it, withy-cragged.

eraged. In the way of sprinkling the hay on the litter, or laying it in a trough even with the ground, he not only takes it up as if from the earth in a natural way, but can eat as he lies, which is a kind of indulgence, that a horse takes great pleasure in.

It is proper, however, in most cases, to have some sort of rack, or other contrivance, for the purpose of containing the hay, or other sort of fodder which the horse may want, and from which he might eat it with ease and convenience to himself. The best and most economical kinds are probably those which are placed in an upright manner in recesses in the walls, or in the corners and angles of the stalls.

When there is stable-room enough, partitions are to be made for several horses to stand in; these should always allow room enough for the horses to turn about, and lie down conveniently in, and they should be boarded up so high toward the head, that the horses placed in separate stalls may not be able to smell at one another, nor molest each other any way. One of these stalls ought to be covered in, and made convenient for the groom to lie in, in case of a great match, or the sickness of a valuable horse. Behind the horses there should be a row of pegs to hang up saddles, bridles, and other necessary utensils; and some shelves for the hanging up brushes, &c. and the standing of pots of ointment and other preparations.

The stables of the nobility are often incommoded by bins for oats placed in them, which take up a great deal of room with very little advantage. Dr. Plott has given us, in his History of Oxfordshire, a very convenient method, used by a gentleman of that county, to prevent this. It is done by making a conveniency to let the oats down from above, out of a vessel like the hopper of a mill, whence they fall into a square pipe of about four inches in diameter, let into the wall, which comes down into a cupboard also let into the wall, but with its mouth so near the bottom, that there shall never be more than about a gallon in the cupboard at a time; which being taken out, and given to the horses, another gallon immediately succeeds it from above, without any trouble to the groom or any body else. By this means there is not an inch of room lost in the lower part of the stable where the horses stand: and there is this great conveniency beside, that the oats are always kept sweet by it, for every gallon that is taken away puts the whole quantity above in motion, by the running down of the gallon that supplies its place, and no mustiness ever comes where there is this continual airing and motion. There may easily be contrived two of these, the one for the oats, the other for split-beans; and both of these may be let into the range of presses, the oats and beans being separated above by partitions. The other requisites for a stable are, a dung-yard, a pump, and a conduit; and if some pond or running river be near, it is much the better.

But with regard to farm-stables, it is not, however, necessary to attend so much to elegance in their construction as in the above cases; it is sufficient to have them neat, handy, and convenient. And in order to this, they should be situated so as to be contiguous to the other offices, with which they may have the greatest connection or relation.

It has been observed by Mr. Bealton, in the first volume of Communications to the Board of Agriculture, that in the contriving and fitting up of the racks and mangers in these buildings, great attention should be had to economy and the convenience of labour. The most common and usual method of making them, so as to extend quite across the upper end of the stall, is a bad and expensive practice, and which has much inconvenience in the foddering of the horses; as,

in order to save trouble, servants are very apt to fluff the racks full of hay, however large they may be, from which many bad consequences arise, and much hay is lost or destroyed by being pulled down and mixed with the litter, or trodden under the feet of the animals. Besides, various bad effects result from the practice of suffering horses to be continually stuffing themselves with hay, as is well known to those who are accustomed to the proper management of such animals; as under their directions they are never permitted to have much hay in their racks at a time. Another disadvantage also attends this mode of fitting up stalls, especially for farm-horses, as it ought to be the object to preserve every thing; the hay-seeds are totally lost, which, if good, and carefully secured, might be of great utility and value. And by the practice of placing the racks with so much inclination outwards, the seeds are also very apt to fall into the horse's ears and eyes, which often cause disagreeable effects. For these reasons, it is supposed that racks should have a perpendicular direction, not having a space of more than fourteen or sixteen inches from the wall; the bottom being sparred, in order to let the seeds fall down through below, whence they may be removed by a sort of sliding shutter. These advantages may also be neatly and conveniently obtained by leaving niches in the walls for the racks, on which plan the spars will be equal with the insides of the walls. Where the niches and racks are made in the middle of the stalls, two feet, or two feet and a half wide, will in most cases be sufficient; they should, however, be carried down low enough to admit of a small box or drawer being placed under them, for the reception of the hay-seeds. Racks of this sort may likewise be placed in the corners of the stalls, and be made in such a way, as that one niche may serve two stalls. And they may be placed in the angles of the stalls without having any niche, and may be made of a semicircular form. But in whatever way they are formed, there should constantly be a division betwixt them, which is probably best made of deal. Where the racks are put in the corners of the stalls, it may, perhaps, be more advantageous to have them straight than circular; but in whichever way they are formed, the farmer should always have a hatch fixed for each stall, as by that means a great deal of time may be saved in feeding his horses.

If the above methods be adopted, it must be unnecessary to make a manger of the same width with the stall; as a box or drawer, sixteen or eighteen inches long, and twelve or fourteen inches wide, will answer every intention perfectly well. But it should be so contrived that it may be readily taken out and cleaned whenever it is fouled, or becomes furred with dirt. With the fixed mangers this can never be done.

Besides this, there is another method of making stalls, which, as being cheaper and more economical, deserves to be regarded by the farmer: on this plan the stable has neither racks nor mangers; the head of the stall is boarded about three feet from the ground, having a space of about two feet from the wall, in which the hay is to be deposited, the horse pulling his hay from below, instead of drawing it from above; which is not only more natural, but prevents the waste of hay, much of which drops down and is lost when the horse eats from a rack. But even in this construction, it will be necessary to have the bottom sparred within eight or ten inches of the ground, and a box, hopper, or hay-manger and drawer, so contrived as to receive the seeds of the hay: where there are double stalls, the boxes may be divided in the middle. Single stalls, where they can be conveniently made, should, however, always be preferred, as

STABLE.

being much more safe and convenient in different points of view, both for the horses and persons employed about them.

Further, it is likewise conceived, that the paving of stables is a matter of great importance, though it has been hitherto but little attended to: whether the stall should have a slight declivity, or be perfectly level, has not, perhaps, yet been so fully determined as it ought. It would appear, however, to be more natural and easy for these animals to stand and rest themselves on a level surface, than on one that is sloping, as it is evident that the tendons or sinews of the pastern joints must be kept more upon the stretch in the latter than in the former case. The main difficulty in regard to a level stall has been the conveying away of the moisture; but this may be well effected by paving the stall perfectly level, and only leaving a small drain in the middle, extending within two or three feet of the upper end of the stall; but which should not be more than seven or eight inches wide at top, forming an angle at the bottom. The depth at the end nearest the head of the stall need not be more than three or four inches deep, having as much slope as can be conveniently given it backwards, in order that it may carry the moisture off quickly to the main drain, into which all the stall-drains should have a fall, and the moisture be discharged. And the small stall-drains must also be covered with a piece of good strong oak-plank, in which a great number of holes are bored, and which must be so fattened, as to admit of its being readily raised up and let down; as by this means the drains may be washed, and kept clean and sweet, as often as they are found to be furred up and obstructed. And besides these, main drains must be made at the end of the stalls, or in some other convenient situation, for carrying off the moisture into the general receptacle. Where they are placed at the bottoms of the stalls, they should not be closer to the stalls than two feet, in order that the stale of mares may get readily into them, which would not be the case if they were nearer, unless the pavement behind the stalls was made to decline a little towards them. These main drains need not be more than seven or eight inches wide at the top, but they should be covered with plank, in which holes are perforated for conveying away the moisture and wetness. But with the view of saving the expence of making main drains within the stable, a shallow open drain may be made in the common way, with which the stall-drains may communicate by means of very small grates at the ends. And it should be observed, that the pavements or floors of the stalls should have a very slight declination from their sides towards the drains, to prevent moisture standing on them; an inch, or an inch and a half in the whole, will, however, be quite sufficient for these purposes.

It may be noticed, in regard to the sizes of stalls, that they differ much according to circumstances; but four feet and a half in width are the least they should ever be made, and five feet are much better. The divisions between them should be high, so that strange horses may not see each other. But where stallions are kept, or young horses required to be left loose in a stall, they should be so inclosed as to be incapable of doing mischief. And for these purposes, one or more stalls may be sparred to the top, or doors provided, which may be hung to the back posts of the stable. Where this last method is followed, the stalls serve extremely well for keeping different mares and their foals separate from others, as well as many other useful purposes in the business of horse-management with the farmer.

But the writer of the East Lothian Agricultural Survey

has remarked, that sometimes stalls are made double; and as farm-horses generally work in pairs, each pair that work together have one of these double stalls; for horses are social animals, and it is said they feed better, and are more cheerful, when they live in society. But even in this case it is proper they should be fastened to the opposite sides of the stall, and that each horse should have his own rack and his own manger; for although they may seem to have a very great attachment to each other, yet if the dividing of their food is left to themselves, it is more than probable they will quarrel about it, and that the strongest horse will have the best share. But such farm-stables as contain only one row of stalls, with one horse in each stall, are, on the whole, the most useful and convenient; and if the stalls are sufficiently large, and the divisions between them raised sufficiently high, not with spars, as often is the case, but with boards closely joined, each horse will be allowed to eat his proportion of corn and hay equally, and allowed to take the necessary rest, without danger of being disturbed; by a troublesome neighbour. The stable ought to be well paved, and of a sufficient breadth, to leave a space of at least six or seven feet behind each horse, for a safe passage to the servants in hanging the harness upon the wall, &c. The pavement should decline very gradually from the horse's head backwards, towards the channel at his heels, which should also decline, in the same gradual manner, towards one end of the stable, where the urine may be received into a reservoir. Proper openings should also be left in the walls, for the purpose of ventilation; these should be fitted with sliding or flap-boards, opened in the morning, when the horses go out to work, and shut in the evening: in this way the stables will be properly ventilated; and every risk of cold, from having these openings uncovered during the night, be avoided.

The smell of a stable, where the dung has been allowed to remain for a week or ten days, is intolerable; and the volatile alkali generated is so strong as to penetrate and affect both the eyes and noses of persons entering into it, in a very disagreeable manner. The consequence is, the horses are sickened and enervated by the heat and offensive smell during the night; a part of their food, being impregnated with the effluvia, is loathed and rejected; and, in the morning, when they are taken out to work, instead of the sprightly appearance exhibited by animals that have been well fed and had a comfortable bed, their hanging ears and heavy sluggish appearance distinctly mark the state of the stables they have quitted.

However, in order to render the forming and constructing of the different internal parts of stables more clear and easy, it may be necessary to have recourse to some account and explanation of them. In the old common and usual modes of placing the racks and mangers in stables, as in some measure suggested above, the former are mostly put in a slanting outward upward direction, so as that the top parts of them may have a projection or space of two feet or more from the walls, while the lower parts rest against them. The latter are constantly placed a little below and underneath them, mostly extending quite across the stalls. In these modes of fixing these internal parts of stables, there is seldom or ever any sort of contrivances for either preserving the feeds, or preventing their falling upon the heads of the horses, while they are eating. Nor is the hay, or other fodder, guarded against being pulled out, trodden under foot, and wasted by the animals. They are consequently very uneconomical in their nature and consequences.

But in the improved methods of placing these internal parts,

STABLE.

parts, the positions of the racks, as well as the nature, dimensions, and other circumstances of the mangers, are quite different. In some cases, the racks are fixed about fourteen inches from the walls, with but very little, if any, slant; having their bottom parts laid with small spars, or thin narrow pieces of wood, in an open manner, so that the hay-seeds can fall down through between them, and be received in a drawer, or box, made for the purpose below, where they are capable of being drawn or taken out at pleasure. A small box, or trough, is placed in some convenient part, answering the purpose of a manger, and which is sometimes made as a drawer, to put in and draw out as there may be occasion. The divisions of the stalls sometimes rise pretty high at the head parts, in the ordinary way; and, at other times, in a curving manner at the upper ends, from the tail-posts to nearly the ceilings of the stables; and flap-doors, the height of the lower parts of the divisions, are sometimes fastened with hinges to posts, or the walls behind the horses.

In other instances, the racks are placed in half-circular niches or recesses in the walls of the stables, opposite the divisions of the stalls; each niche being made to serve two stalls, by having a division in the middle betwixt them; and the racks themselves are sometimes made in half-circular forms. The same kind of half-circular racks are occasionally, also put in the angles or corners of the stalls, without any niches; there being divisions between them, so as that they may serve two stalls: but the racks, in these cases, have not always the half-circular form, but are made and fixed up in a straight manner.

In all these cases, small drawers or boxes serve as mangers, for the horses to eat their provender out of, as may be necessary. There are some few other modes of fixing up racks and mangers in stables, as will be seen below; but these are probably the most eligible and convenient, as well as the most economical and least expensive in their nature and means of putting up.

The manner of fixing the window and the shutters in the windows of stables is important in several respects, as they contribute much to the proper regulation of the atmosphere and state of heat in them, as well as to other matters. They are both probably the best and most convenient, when suspended and balanced upon two iron pins, fixed in the middle parts of them, so as to render them capable of turning and standing in either or any direction, and to be readily wholly removed, in case of necessity. When the windows are made to slide up and down, the shutters may also be fixed in this way with advantage and good effect. By these means the air may be easily let out or in, and be regulated in an exact manner, which will be of much advantage in different cases and circumstances of stable management. There is sometimes a hopper sort of contrivance in stables, where neither racks nor mangers are employed, which is broad at the top, and has about fourteen inches width in the bottom part; being sparred, in order that the seeds may drop through into a drawer made for the purpose below. In each corner there is a small box for corn, which serves as a manger; the hopper part being divided in the middle, so as to serve two stalls as hay-mangers. This is a neat and convenient mode in some cases, though rather expensive in making and putting up.

There are still other contrivances in fitting up racks and stalls for preventing the unnecessary waste of labour and food, as well as to guard against the inconveniences of hay-seeds falling into the eyes and ears of horses, which have been suggested by experienced farmers in other countries. In one set of contrivances in this intention, the racks are placed in an upright manner, and the perpendiculars of

them are made to fall on the inner edges of the troughs below, which have shelving leaves. In these cases, when the animals pull out the hay from the racks, the waste parts fall on the leaves, and thus slide down into the troughs, where they are secured from being spoiled by the breath of the horses; while the distance between the bottoms of the racks and the troughs is quite sufficient for the admission of the heads of the horses, so as that they may get at the hay which is dropped. The racks, in these cases, are two feet four inches in depth, and two feet at top from the edge parts of them; being planed within, in order that the hay may fall to the bottoms of the racks gradually, in proportion as it diminishes in quantity, and the animals be saved the trouble of a long reach, which they are often obliged to make in the stables which are fitted up in the old usual manner. The animals are fed and supplied with the fodder from the entry, which is six feet in width; the hay being dropped through a trap-door from the store-room above the stable. This plan is the suggestion of Mr. West, an intelligent North American farmer. Another plan in the same intention has been proposed by Mr. Cooper, of another part of the same country, in which the racks of the stalls of the stables have a somewhat different construction and position, being formed with what are called *flats*, or thin strips or pieces of wood. In these the advantages are supposed to be very great, as the upright flats prevent the horses from walling the hay, as well as from blowing upon it: and besides, the animals are prevented from looking round, a habit to which horses are much accustomed when any person enters the stable; neither can they thrust their heads over the troughs, as the flats compel them to feed directly over them, without turning to either side. This mode of fitting up the stalls of stables may be found of much utility, in different situations and circumstances, in the management of both saddle, farm, and team-horses.

Very great utility and saving in point of duration may not unfrequently be produced, by having the internal and some other parts of the mangers and boxes, or other contrivances from which the horses eat their feeds of corn and other provender, lined and plated, or cased with different metallic substances. At Holkham-Hall, in the county of Norfolk, Mr. Coke has his mangers themselves, it is said by the writer of the corrected agricultural account of that district, plated with sheet-iron; and the front edges, which are rollers, covered with tin-plates. The bottoms of the stall divisions are likewise made of slate. It has also been found that for stables, as well as all other offices, those locks which have copper wards are the best, as being much more durable than any other kinds.

Stables, or the lofts over them, for saddle as well as for farm, team, and carriage-horses, are also not unfrequently fitted up and provided with different sorts of machinery and contrivances for preparing and reducing the different articles of food, which such horses are to have, into the most proper, convenient, and economical forms, for their being given to and consumed by them. These are, for the most part, straw or chaff-cutters, bean, barley, or malt-crackers, and oat-crushing and bruising machines. Such contrivances are often of very great utility and convenience, when properly managed, and put up in such stable buildings, or the rooms connected with them; and particularly where other more valuable uses are to be made of straw, pea and bean-haulm, and other similar materials, than that of merely littering animals. They are likewise useful in saving much labour, by their being always ready and at hand for performing these different necessary operations, as well as in several other ways.

This

STABLE.

This sort of machinery is arranged and placed in a variety of different ways, according to the circumstances of the different cases. In a two-stalled stable, paved in the manner which is directed above, or in that which has been recommended by a writer in the first volume of Communications to the Board of Agriculture, a very simple and convenient apparatus has been contrived for working a chaff-cutter and a bean and barley-cracker, situated in the upper part of it, by the Rev. Mr. Froud, of Dartington Parsonage, in the county of Devon, merely by the power of one horse. It consists, according to the writer of the corrected agricultural account of the husbandry of the above district, of a block of oak sunk in the ground below the stable, with a perpendicular shaft or stem passing through the hay-loft floor, upon the top of which is fixed a crown-wheel of two-inch elm-plank, with six cast-iron segments, so as to compose a wheel of this sort of one hundred and eight cogs. There is also a pinion-wheel with fourteen cogs, the shaft of which passes through a drum, which is eighteen inches in diameter. From this drum the motion is communicated by a belt to the barley-cracker, and by the same belt to the chaff-cutter, where it is drawn tight over a sheave of eighteen inches in diameter. The barley-cracker has likewise a fly-wheel, and a wooden hopper for receiving the grain. The lever by which this machinery is worked, and which passes through a mortise made in the lower part of the shaft, makes, it is said, the division of the stalls of the stable, when tied or fastened to the mangers and other parts.

Stables may, however, be accommodated with these sorts of necessary machinery in other ways and manners, perhaps, with equal, if not greater, convenience and benefit than as above; as by having them put up in particular parts of such buildings exclusively appropriated for them, and the materials which they are to work upon; or by placing them in distinct separate erections constructed purposely for them, and such matters in immediate connection with the stables. By either of these means every possible advantage may be gained, without the horses being so much disturbed as in the preceding method. Besides, the materials which are to be operated upon may be a great deal more amply provided, and much better stored up and secured; and there will be far more extent for the fixing up and working of such sorts of machinery, as well as more room and convenience provided for putting by the different cut and prepared substances as food for the animals: and above all, a confidential servant can have the command and control of such situations, without interfering with the general management of the stables in such instances, especially where there is a proper corn and provender bin arranged somewhat in the manner that is suggested below; by which method a vast waste and loss of expensive food may, in different cases, be guarded against, and the machinery be wrought with a great deal more effect and security.

Stables for all sorts of saddle-horses, as well as for those of the light carriage kinds, should constantly be raised, constructed, and fitted up in a neat, warm, and sometimes, in particular situations and circumstances, in a rather elegant manner; as such sorts of horses can never be made to look so sleek and well in their coats as they ought to do, without the stables in which they are kept are in some degree warm and comfortable. And near the seats and residences of persons of distinction, handsome stables have an ornamental effect, in conjunction with the other sorts of offices and buildings, which is mostly desirable, and which should seldom or ever be overlooked or neglected in the plans and distributions of the office-buildings, in such cases. The

particular manner in which such stables are to be built must be left to, and regulated by, the tastes of the proprietors, and the peculiar nature and circumstances of the situations; but in the external walls, effect should almost always be well considered and attended to, while the necessary warmth and security are provided in an effectual and proper manner.

In the stalls, and the modes of fitting them up in these kinds of stables, the same sort of neatness, elegance, and ornamental effect, should, for the most part, be carefully preserved and kept in view; though, in some cases, this need not be so very much regarded. In the former, or stalls, there should constantly be a sufficiency of capacity or size, as already suggested, in order that the animals may not be too greatly confined, and that full room may be given for performing the various daily operations that are necessary about them. The latter, or the fitting up of the stalls, may be variously regulated and executed, according to the different methods and rules which have been laid down above, and the particular taste of the owners; having a constant regard to neatness, ornament, convenience, and economy, in the distribution of the different kinds of food and labour which are necessary, and to be performed about them.

In the construction of stables for farm and most sorts of heavy team-horses, a much less attention and regard to neatness will always be requisite and proper; and any sort of elegance or fineness in such cases must invariably be useless, absurd, and improper. In the building and contriving of these sorts of stables, convenience and the health of the animals are the principal circumstances which deserve to be materially considered and regarded. In the external inclosing materials for such stables, any sort which can afford the necessary warmth, shelter, and security, and which are at the same time cheap, will be proper for the purpose. The stables for these uses need seldom, if ever, be raised to such heights as those for other sorts of horses; nor need they always have lofts over them, or, at least, over the whole of them; though some extent of loft is mostly desirable, and often of considerable utility, for containing provender for the horses in a convenient and readily applicable manner. A small extent or proportion will, however, mostly answer the purpose very effectually, when properly arranged and fitted up in such intention; by which a very considerable saving of expence may not unfrequently be made.

The arrangement of all such stables must be according to the nature and circumstances of the farms, and purposes for which they are intended. The single range or row mode, which has been already noticed, is very good, in many instances; but they may be quite differently arranged, placed, and situated, in other cases, with equal or more advantage; and sometimes, under particular circumstances, stables with double rows of stalls may be found beneficial on farms, and for other uses. In fitting up the internal parts of such stables, the main objects are those of convenience, the safety of the animals, the prevention of the waste of food, and economy in the labour of those who have the providing, preparing, and giving of it, as well as the management of the animals, in such cases.

Some have advised the having short distinct stalls in stables, so that each horse may consume his feeds in a separate manner, and be harnessed and prepared for work with more facility and readiness; and that the partitions, in such cases, should not be carried quite up to the ceilings of the stables, in order that a more free and open circulation of air may be produced and preserved. Others, again, contend for quite open shed-stables, where the racks and mangers are fixed low down near the ground; the horses having small yards

STABLE.

for them to go into at pleasure, furnished with pumps and cisterns, as in these. With this sort of management they are supposed to do better, even without dressing, than in regular stables, by the ordinary management which is bestowed on them by farm-servants in such cases. These sorts of stables are said to have answered well in practice, in some instances. They are found beneficial, when with yards, in the winter feeding of the horses on dry fodder and carrots, or other similar roots; also in summer, feeding them with different sorts of green food and dry meat. It has been suggested, however, that as such cold shed-stables seldom do well for horses, those of the regular stable kind may be the most proper in general, and especially in all the more northern districts of the kingdom; though the open shed sort may sometimes be useful and advantageous in the more southern parts of the country, where the winter seasons are more mild and favourable, as well as more short in their duration. Low shed-stables, with large sliding shutter openings behind the horses, may often be cheap, proper, convenient, and useful, where soiling farm and team-horses, during the summer season, is practised to any great extent; as the animals, it is said, not only do better in them, but are much more easily managed in supplying them with the different sorts of green fodder in the most suitable and proper manner; and, at the same time, there are advantages produced in the way of raising manure. These stables should always be provided with suitable racks for the purpose; and there should be proper drains for conveying away all the liquid matters that may be produced, in such modes of feeding, into the littered yards, or other places destined for forming and containing the manure. They should likewise have proper places provided in or near them, for the reception of the new-cut green food, from which it can be readily and with facility distributed to the different animals in small suitable proportions, as it is wanted; there being large suitable openings into them, left for the purpose of receiving the carts, or other conveyances by which it may be brought to the stables. The horses are probably the best and most advantageously managed, in all such cases, when kept constantly tied up in the stalls.

In all sorts of stables, or very contiguous to them, as has been already suggested, there should always be proper places provided for the reception and securing of different sorts of harness and other articles and things of that kind in; as well as suitable well-secured and convenient places for fixing up properly contrived corn-bins in. When these stables are small, it is in general most convenient to have the corn-bins placed and put up in the rooms above them, and so contrived and constructed, as that the feeds may be regulated and drawn from a spout carried down into the stable part below, as by such contrivances, much time, labour, trouble, and occasionally food, may not unfrequently be saved, which would otherwise have been spent in going to the bins, measuring the grain or other sorts of provender from them, and securing them again. By having such sorts of contrivances duly provided in stables, many other sorts of substances and materials, as food, can be kept safely and ready prepared, beside those of corn, either in a mixed or separate state, as may be most suitable and convenient; such, for instance, as split-beans, cut-straw, bean and pea-haulm, and a great variety of other similar matters, which are of much consequence in the feeding and foddering of all sorts of horses.

On large farms, and in other situations where there is much room and convenience, it is always the best way to have such chests, bins, or other contrivances, constructed and fitted up on the most improved principles, as those of

the aerated granary or some others, which have the means of preserving the grain or other matters in a perfectly sweet and sound state. Where the former of these plans is adopted and had recourse to, the best form is probably that of somewhat the cubical, the bottom part being made, in some degree, in the manner of the common hopper, having the slider in the lower part of it so fixed and contrived, as that it may stand about eighteen or twenty inches from the floor of the place in which the bin or chest is put up; as by such means, sufficient room and convenience will be afforded for receiving and taking out the corn or other provender as it may be wanted. In all these kinds of bins or chests, the spouts for aerating the grain or other matters may with perfect ease, facility, and convenience, be formed and fixed from one side to the other of them; the external openings or air-holes being constantly well secured by gratings of iron-wire. In the spout parts of these bins, which molly project considerably below them, there are plate-iron sliders at their bottoms, which are secured by a small lock and key, where necessary. They have often also other small sliders put just above these, for the purpose of ascertaining and regulating the feeds of the horses, by which they can readily and without inconvenience be taken out as wanted for them.

The most useful and convenient machine for the use of stables, in crushing and bruising the grain and other substances which are necessary in them, is probably that constructed by Rawntree, as it takes up but little room, while it is very effective in reducing all such materials. It is found to operate well on oats, beans, peas, barley, and other kinds of grain employed as horse-food; and at the same time is capable of bruising malt for brewing.

Machines of the mill-kind are likewise sometimes beneficial in stables for the purpose of preparing particular sorts of horse-food. The turning horizontal hand-mill, invented by Mr. Wright, may probably be found a good and useful contrivance for performing the necessary business in these situations, as it occupies but a very small space, is readily managed, and sufficiently effective for the purpose.

It may also be of importance, that stables should be better lighted than what is commonly the case, as the blindness which is so frequently met with among horses, has lately been attributed, and not without considerable probability, to an excess of the stimulus of light on their coming out of dark or dusky stables, where the irritability of the organs of sight has been for some length of time accumulating, into the full and broad glare of day-light.

As farm-stables are mostly, during the summer months, very generally much exposed to the full open air, the doors, wickets, or windows of them being very seldom shut, except at night, and then but very rarely; the consequence of such full exposure is, that flies, which are attracted by the horse-dung and other similar matters, have very free access into them; but as it may commonly be observed, that in such exposed stables, too, the spider is very prevalent, as is seen by the number of cobwebs which are present; it may, of course, be unwise and improper to disturb or destroy them, as the insect should probably be cherished in such stables, as it may save the horse from the irritation of a variety of little troublesome enemies and disturbers. The provision of such an insect is natural, and the useful consequences of it should not be disregarded by the farmer in such stables.

In concluding the account of stables, it may be just noticed, that the manner of treating and managing saddle and light carriage-horses in them is often very negligent, uneconomical, and improper, as the different kinds of food
which

which are made use of are not unfrequently given to them in very ineligible states and modes, equally as to time, manner, preparation, and quantity; the natural habits or methods of feeding in the animals being scarcely at any time, or in any cases or circumstances, if they be ever at all attended to or regarded, so as to lead to better practices. The stuffing the racks of horses in stables at all times and seasons with large quantities of hay and other similar sorts of fodder, as is too commonly the case, is, in all circumstances and cases, a wasteful and highly improper manner of proceeding in stable-foddering. And the letting them have their feeds of corn or other sorts of provender in irregular manners and quantities, is not less detrimental and inconvenient to the animals, than stuffing them so much with hay. They never succeed well when there is much irregularity in the practices of feeding them. All the other operations about them should also be performed, as much as possible, in exact manners, and at proper periods.

But with the farm and heavy team-horses, both in the stables and on the roads, as well as in other places, the manner of treatment is still more exceptionable and improper in a variety of different districts and situations of this country. It has been observed by Mr. Vancouver, that, except in Ireland, where the method of treating farm-horses is extremely bad indeed, those in the county of Devon have perhaps as hard a measure of neglect and ill-usage dealt out to them, as is any where to be met with in the whole united kingdom. From the injudicious manner in which they receive the corn that is occasionally given them, it is supposed, in some measure, a questionable point, whether it affords them a benefit, or, by diverting their appetites from the hay, pea-haulm, or other sorts of straw, absolutely produces an injury and disadvantage, in consequence of the avidity with which they swallow the corn in an un-masticated or unchewed state. In order to rectify and remedy such improper modes of management in the stable and other treatment of farm and heavy team-horses, a better and more desirable example, it is thought, can no where be found, than that which may be drawn from the management of farm and waggon-horses in Pennsylvania and Maryland, in North America. These horses, it is said, perform journeys of two and three hundred miles over the stupendous mountains of that country, with prodigious loads of wheat and flour from the interior, and wet and dry goods from the sea-ports to the different points of embarkation, at Fort Pitt, Red-stone, Charlestown, Wheeling, and other places on the Ohio river. Notwithstanding which, these waggon-horses, through the whole extent of that country, are, it is asserted, seldom seen in a less high condition than the brewers' and other large cart-horses in the metropolis of this country. The manner in which these American horses are sustained and supported, so as to perform these labours, is, it is said, generally by feeding them, in the stables and on the roads, with hay and straw chopped in short pieces about half an inch in length, with which is mixed about half a peck of rye, oat, and Indian corn-meal, to about two and a half or three pecks of hay chopped in the same manner. A feeding-trough, sufficiently large for four or five horses to eat out of at the same time, is attached to each waggon, it is said, while on the road. The chaff is put into this trough, and after being well mixed with the given quantity of meal, is moistened, and again well stirred together, until every shred or part of the hay or chopped straw is found to be covered, or, as it were, frosted over by the meal. The avidity with which the horses eat their meat or provender, when thus prepared, may, it is supposed, be readily conceived. Their feed or meal being finished, they either

pursue their journey or lie down to rest; but in either case, it is observed, not without being well dressed, and perfectly freed and cleansed from the muddy and other effects of their last labour. It is the pride and pleasure, it is said, of the carters, as well as of the waggon masters in that country, to see their horses in a condition rather above than under the labour which they have to perform; and in a hundred miles travelling, from Baltimore to Philadelphia, it is confidently asserted, that as many prime waggon-horses, and in as high condition, may be seen, as is the case in any direction for the same distance from the chief city of this country. The adoption of a similar manner of treatment in the management of farm and waggon-horses in the stables and on the roads in this country, needs, it is thought, no further recommendation than the certainty of these facts and statements, which are unquestionable.

The practice of baiting post, stage, and travelling horses with rye, oat, or bean-bread, in the manner performed on the continent, is likewise, it is supposed, an infinitely more economical and facile mode of administering refreshment to jaded, exhausted, and labour worn-out animals, than that of giving them the crude corn in its unbroken state, which is so commonly and indeed almost universally practised in this country.

That there are great waste, want of economy, and loss of nourishment, in the too general practice of giving unbroken corn to animals, especially horses, is extremely evident, from the state it is in after it has passed through their bodies, as it is found, in many cases of horses thus fed, to have lost but a little of its nutrient property, being still capable of supporting other sorts of animals, particularly those of the granivorous kinds, in a perfect manner. In its unbroken condition, when not completely masticated or broken by the teeth of the animals, as is frequently the case, the digestive process of the stomach would seem to have but little effect upon it, as it passes in nearly its natural state, while, when broken or crushed by art, it readily acts upon it, and the whole of its nourishing property is taken up there, and in its long course through the bowels, in consequence of its being so much more fully and extensively applied to their surfaces. All horses are, therefore, far better fed and supported, where the grain is reduced in its preparation before it is given, than in the common usual modes of giving it whole. The supposed defect from want of chewing and mixing the saliva of the mouth with it, where broken grain is given as the feeds of the animals, is probably complete supposition, being founded on an imperfect consideration of the matter, and not upon the result of actual trials, as it has been a great deal talked about without any sort of proof, which can be depended on, being given in its support.

STABLE Bin or Hopper, that sort of box, or contrivance of that kind, which is fixed up in stables for the purpose and convenience of containing the corn or other sort of provender, which is to be given to horses in such places.

STABLE Logger, Lump, or Ball, the oval, oblong, or round piece of solid wood, which has a hole through its middle, for the purpose of receiving and passing the rein of the horse's head-stall or halter through, and fastening it by a knot or otherwise, after it has been put through a ring fixed to the manger or other part of the stall, in order to poise and keep it tight, but not to be so heavy as to inconvenience the horse in feeding or otherwise. There are often in good stables, two reins to each head-stall balanced in this manner. The forms and weights of these pieces of wood should always be well suited and proportioned to the nature and powers of the horses.

STABLE Rings for Stalls, the strong iron rings which are fixed to the mangers or sides of the stalls of stables for the purpose of the halter or head-stall reins of the horses running in. There are not unfrequently two to each stall in well fitted up stables, but common stables have seldom more than one. These rings are mostly of the common kind, made so as to work in a shank, which screws into the part of the stall to which the rings are to be fixed; but a great improvement has lately been made in them, by having them formed in somewhat the manner of and as a strong spring, by which, in case of the horse becoming entangled in the reins, accidents may be prevented by their giving way. At all other times they are as perfectly safe as the common ring. In these cases, they have also a screw-shank, in order to be fixed in their proper places, but are not moveable in it, as in the common ring.

STABLES'S STRAIT, in *Geography*, a channel between Sugar-loaf island and Banker's island, in the Mergui Archipelago.

STABLESTAND, in the *Forest-law*, is when a person is found at his stand in the forest, with a cross-bow or long-bow, ready to shoot at a deer, or else standing close by a tree with greyhounds ready to slip.

This is one of the four evidences, or presumptions, by which a man is convicted of intending to steal the king's deer; the other three being back-berond, bloody-hand, and dog-draw. See **FOREST**.

STABLO, or **STAVELO**, in *Geography*, a town of France, in the department of the Ourte, and chief place of a canton, in the district of Malmedy, situated on the river Rechte, and deriving its name from that of an ancient abbey, founded in the year 657 by Sigebert, king of Austrasia, for the accommodation of St. Remacle, bishop of Maestricht, who preferring solitude to the episcopal dignity, retired hither, and became the first abbot. The place contains 2604, and the canton 7903 inhabitants, on a territory of 292½ kilometres, in 10 communes. The manufacture and trade, which are considerable, consist of cloth and stuffs, and the tanning of leather; 20 miles S. of Aix-la-Chapelle.

STACCATO, Ital. is a term in *Musick*, which implies a distinct separation of one note from another, in a plain and articulate manner. The term is confined to instrumental music, and chiefly to that of the violin kind, where the stroke of the bow is to be given to every note, and none of the passages are to be slurred; that is, no two or more notes are to be played with the same bow.

STACHYS, in *Botany, from *σταχυς*, a spike, because the flowers, though whorled, are more crowded into a spiked form than most others of the same natural order; which may, in some measure, answer Ray's objection to this ancient name, as not peculiarly apposite.—Linn. Gen. 293. Schreb. 390. Willd. Sp. Pl. v. 3. 97. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 632. Prodr. Fl. Græc. Sibth. v. 1. 407. Ait. Hort. Kew. v. 3. 397. Pursh v. 2. 407. Juss. 114. Tourn. t. 86. Lamarck Dict. v. 7. 364. Illustr. t. 509.—Class and order, *Didynamia Gymnospermia*. Nat. Ord. *Verticillata*, Linn. *Labiata*, Juss.*

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, angular, permanent, cut about half way down into five awl-shaped, pointed, awned, rather unequal, teeth. *Cor.* of one petal, ringent; tube very short; throat oblong, gibbous downwards at the base; upper lip erect, nearly ovate, vaulted, often emarginate: lower larger, reflexed at the sides, three-cleft; its middle segment very large, emarginate, folded backward. *Stam.* Filaments four, two of them shorter than the rest, all awl-shaped, curved towards

each margin of the throat after flowering; anthers simple. *Pist.* Germen superior, four-lobed; style thread-shaped parallel to the filaments, and as long; stigma in two acute divisions. *Peric.* none, except the scarcely altered calyx. *Seeds* four, ovate, angular.

Eff. Ch. Calyx five-cleft, awned. Upper lip of the corolla vaulted: lower reflexed at the sides; its middle segment largest, emarginate. Fading filaments reflexed towards the sides.

Stachys is chiefly an European genus, of herbaceous, or somewhat shrubby, mostly perennial, plants. Loureiro indeed has a *S. Artemisia*, found in China and CochinChina; but we cannot, from his account, be certain as to its genus. Mr. Pursh enumerates four American species, three of which are new. The fourteenth edition of Linn. Syst. Veg. contains seventeen, Willdenow has twenty-six. We shall particularize some of the most remarkable, especially the five British species, and a new one from Crete.

S. sylvatica. Hedge Woundwort! Linn. Sp. Pl. 811. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 416. Curt. Lond. fasc. 3. Riv. Monop. Irr. t. 26. f. 2. t. 34. (*Galeopsis vera*; Ger. Em. 704.)—Whorls of six flowers. Stem solid. Leaves heart-shaped, stalked.—Native of hedges and shady situations, throughout Europe, frequent with us, flowering in July and August. The root is somewhat creeping, perennial, not annual. Herb erect, two or three feet high, of a dark green, covered with fine, rather glittering hairs, and exhaling a pungent, disagreeable, very peculiar scent. Stem solid. Leaves broad. Spike interrupted, leafy at the bottom, bracted above. Calyx hispid. Corolla of a deep dull blood-red, elegantly variegated in front with purple and white.

S. ambigua. Ambiguous Woundwort. Engl. Bot. t. 2089. Ait. n. 5.—Whorls of six flowers. Stem hollow. Leaves oblong, heart-shaped at the base, stalked.—Found in the Orkneys, very abundantly, in potatoe-fields and other cultivated ground, as well as in the north of Scotland, and near the Pentland hills, flowering in August and September. It seems intermediate between *S. sylvatica* and *palustris*, some specimens more resembling the former, others the latter. The root is white and creeping. Stem hollow, its hairs more or less deflexed. Lip of the corolla less strikingly variegated. The stalked leaves distinguish this species from *S. palustris*; while their narrower oblong form, more silky surface, and the want of any very strong setor, render it unlike the *sylvatica*.

S. palustris. Marsh Woundwort. Linn. Sp. Pl. 811. Willd. n. 4. Fl. Brit. n. 2. Engl. Bot. t. 1675. Curt. Lond. fasc. 3. t. 35. Riv. Monop. Irr. t. 26. f. 1. (*Panax Coloni*; Ger. Em. 1005.)—Whorls of six flowers. Leaves linear-lanceolate, half embracing the stem.—Found in marshy watery places, about the banks of rivers, throughout Europe; common in England, flowering in August, and very troublesome in low, wet cultivated fields. The root is fleshy and tuberous, creeping extensively, and very difficult of extirpation. Stems erect, two or three feet high, strongly quadrangular, rough, with deflexed bristles. Leaves sessile, ferrated; silky above; rather woolly beneath. Spike of many leafy whorls. Corolla light purple; its lower lip streaked with white and violet. The herb is fetid. Gerard calls it Clown's Woundwort, because he was instructed by a clown to use it as a vulnerary, with so much success, that, according to his account, it might supersede all other surgical applications!

S. germanica. Downy Woundwort. Linn. Sp. Pl. 812. Willd. n. 6. Fl. Brit. n. 3. Engl. Bot. t. 829. Fl. Dan. t. 684. Jacq. Austr. t. 319. (S. Fuchii; Ger. Em. 695.

S. montana; Riv. Monop. Irr. t. 27. f. 1.)—Whorls of many flowers. Leaves crenate. Stem woolly, erect.—Native of Germany, Siberia, France, England, and Greece. With us it is rare, occurring only on some chalky or limestone soils, flowering in July. The stems are densely clothed with soft white wool. Leaves stalked, ovate, acute, covered with soft white pubescence, most woolly beneath. Flowers numerous, silky and silvery at the outside; purple and white in front.

S. lanata Woolly Woundwort. Murray in Linn. Syst. Veg. ed. 14. 536. Jacq. Misc. v. 2. 342. Ic. Rar. t. 107. Willd. n. 8. Ait. n. 9.—Whorls of many flowers. Leaves woolly. Stems procumbent and rooting at the base.—Native of Siberia. Frequent in gardens, where it proves a hardy perennial, flowering throughout the summer, and forming large tufts, conspicuous for their very white woolly appearance. The leaves are more obtuse, and far more densely woolly, than in the last. Dr. Sibthorp's manuscripts inform us that the present species is called *σαχυσ*; by the modern Greeks in Laconia.

S. coccinea. Scarlet Chili Woundwort. Willd. n. 3. Ait. n. 3. Jacq. Hort. Schoenbr. v. 3. 18. t. 284. Curt. Mag. t. 666.—Whorls of six flowers. Leaves ovate, crenate, hairy; heart-shaped at the base, with dilated footstalks.—Native of South America. Said to have been brought from Spain in 1798, by the late marchioness of Bute. This is a hardy greenhouse plant, readily increased by cuttings, or by parting its roots, and producing abundance of large flowers, of that rich scarlet hue so prevalent in the vegetable productions of Chili and Peru.

S. hyssopifolia. Hyssop-leaved Woundwort. Michaux Boreal-Amer. v. 2. 4. Pursh n. 1. (*S. palustris*? Walt. Carol. 162.)—"Whorls of about four flowers. Stem erect. Leaves sessile, linear-lanceolate, slightly toothed, nearly smooth."—Native of Carolina. A slender, upright, nearly smooth plant, with about four flowers in each whorl. Michaux.

S. aspera. Harsh Woundwort. Michaux Boreal-Amer. v. 2. 5. Pursh n. 2. (*S. tenuifolia*; Willd. n. 11. *S. arvensis*? Walt. Carol. 162.)—"Whorls of about six flowers. Stem erect, very rough, with deflexed bristles. Leaves lanceolate, acute, serrated, very smooth. Teeth of the calyx spinous, divaricated.—In low fields and on the banks of rivers, from New York to Virginia, flowering from June to August. It resembles *S. palustris*. Root perennial. Flowers purple. Pursh.

S. hispida. Britly Woundwort. Pursh n. 3. (*S. foliis lanceolatis*, &c.; Gron. Virg. ed. 2. 89, but not the plant of Linnæus, nor of any other author cited, except Clayton, n. 271.)—"Whorls of about six flowers. Stem bristly. Leaves stalked, ovate-oblong, bluntly serrated, bristly. Calyx smoothish."—In old fields and low pastures, from Virginia to Carolina, flowering in July. Flowers purple. Gronovius's synonym has been erroneously referred to *S. annua*, from which his original specimen proves widely different. Pursh.

S. Faniculum. Fennel-scented Woundwort. Pursh n. 4.—"Whorls of about six flowers. Stem erect, downy. Leaves ovate, somewhat heart-shaped, toothed; smooth above; whitish and downy beneath."—On the banks of the Missouri; annual, flowering in July. Flowers blue. The whole plant smells extremely like Fennel. Pursh.

S. spinosa. Thorny Woundwort, Asses' Thyme. Linn. Sp. Pl. 813. Willd. n. 13. Ait. n. 12. Sm. Fl. Græc. Sibth. t. 559, unpublished. (Gaidarothimo di Candia; Pon. Bald. 106.)—Hoary. Branches crossing each other, tipped with spines. Flowers axillary, ternate.—Native of Crete,

where most botanical travellers have gathered this species, and from whence it came into the gardens of Parkinson and other curious cultivators of that time, though now scarcely to be met with. The plant is bushy, of humble growth, spinous, pale green, with small leaves. Flowers white, their lip prettily spotted with red.

S. palestina. Greek Woundwort. Linn. Sp. Pl. 1674. Willd. n. 15. Prodr. Fl. Græc. n. 1363. (*S. alba*, angusto salvia folio; Barrel. Ic. t. 279.)—Whorls of about six flowers, crowded, leafy. Leaves sessile, lanceolate, entire, veiny, finely downy; as well as the nearly round stem.—Native of the Levant. Dr. Sibthorp found it plentiful throughout Greece, in rough and stony mountainous places, as Dioscorides mentions of his *σαχυσ*, and therefore concludes it to be that identical species. It answers, indeed, well enough to the description. The stems are erect, bushy, somewhat shrubby, leafy, nearly round, clothed with peculiarly fine, close, dense, woolly hoariness. Leaves an inch and half or two inches long, scarcely one-third of an inch broad, very soft and downy on both sides; the floral ones short and ovate. Calyx unarmed, downy, like the outside of the corolla, whose lips are purple, the throat variegated with white.

S. rugosa. Rugged Yellow Woundwort. Ait. ed. 1. v. 2. 303. ed. 2. n. 17. Willd. n. 20. Jacq. Ic. Rar. t. 493.—Whorls of six flowers. Leaves lanceolate, serrated, rugose, downy; tapering at the base, and somewhat stalked. Stem round, finely downy.—Native of the Cape of Good Hope, from whence Mr. Maffon is said to have introduced it in 1774, yet Thunberg has it not in his Prodrömus. The stem is shrubby, bushy, quite round, very white, as in the last, to which the leaves also bear a great resemblance, but are more stalked. Jacquin's plate shews no serratures. The flowers are axillary, with a white tube and yellow lips.

S. annua. Pale Annual Woundwort. Linn. Sp. Pl. 813. Willd. n. 23. Ait. n. 19. Jacq. Austr. t. 360. (*Sideritis flore albo*, barbâ luteolâ; Riv. Monop. Irr. t. 70. *S. latifolia glabra*; Ger. Em. 699.)—Whorls of six flowers. Leaves ovate-lanceolate, serrated, stalked, smooth, three-ribbed. Stem branched, erect.—Native of Germany and the south of Europe. Kept sometimes in curious gardens, rather for curiosity than any valuable property. The root is annual. Stem erect, square, with opposite spreading branches. Leaves green; the larger ones stalked; uppermost narrower, and sessile. Calyx-teeth spinous. Corolla white, with a yellowish lip.

S. arvensis. Corn Woundwort. Linn. Sp. Pl. 814. Willd. n. 24. Fl. Brit. n. 4. Engl. Bot. t. 1154. Curt. Lond. fasc. 4. t. 41. Fl. Dan. t. 587. (*S. arvensis minima*; Riv. Monop. Irr. t. 27. f. 2.)—Whorls of six flowers. Stem weak, spreading. Leaves heart-shaped, obtuse, crenate, rather hairy.—Common in the fields of Britain, and other parts of Europe, especially where the soil is light and sandy, flowering in July and August. Root annual, small. Stems spreading, often prostrate, a span long, square, hairy or smooth. Leaves stalked, ovate, fetid, an inch long. Flowers small, light purple, with a white and dotted palate; their calyx hairy, with violet teeth.

S. spinulosa. Prickly-branched Woundwort. Prodr. Fl. Græc. n. 1368. (*S. foliis hormini*; Riv. Suppl. t. 15. *Sideritis cretica maxima*, ocymastri valentini facie; Tourn. Cor. 12.)—Whorls of six flowers. Leaves heart-shaped, crenate, hairy. Stem erect, branched, minutely prickly.—Native of Crete, where Dr. Sibthorp found it. Arduino sent a specimen to Linnæus, marked with Tournefort's synonym; and we have lately noticed a figure of this plant, in the rare unpublished supplement to Rivinus, of which the only copy known to exist, apparently once belonging to the

the author, is in sir Joseph Banks's library. The *root* is fibrous, probably annual. *Stem* a foot or foot and half high, erect, branched, square, with prickly angles. *Leaves* stalked, an inch and half long, bluish, ribbed and veiny, green, more or less hairy. *Whorls* leafy, rather crowded. *Calyx* bell-shaped, hairy, with short spinous teeth. *Corolla* yellowish, twice as long as the calyx; its upper lip entire.

STACHYTARPHETA, from *σάχυν*, a *spike*, and *ταρῆν*, *dense*, a name of Vahl's, intended to express the close uninterrupted disposition of the flowers.—Vahl Enum. v. 1. 205. Juss. Annal du Mus. v. 7. 75 Ait. Hort. Kew. v. 1. 46.—Class and order, *Diandria Monogynia*. Nat. Ord. *Verbenaceae*, Juss. Brown.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, angular, with four acute teeth, permanent. *Cor.* of one petal, salver-shaped; tube cylindrical, longer than the calyx, somewhat recurved at the upper part; limb spreading, divided half way down into five roundish unequal segments, the lowest being the smallest. *Stam.* Filaments four, inserted into the upper part of the tube, not reaching to its top, two of them imperfect; anthers of two cells, one over the other. *Pist.* Germen superior, two-lobed; style the length of the tube, capillary; stigma peltate. *Seeds* two, linear, the length of the calyx.

Ess. Ch. Calyx tubular, with four teeth. Corolla salver-shaped, unequal, five-cleft, curved. Two abortive stamens. Seeds two.

A handsome and distinct genus, of tropical, chiefly West Indian, annual or shrubby plants, previously confounded with *Verbena*. Their *branches* are obscurely quadrangular, divided in a forked manner in the upper part. *Leaves* opposite, stalked, tapering down into the footstalks. *Spikes* from the forks and summits of the branches, solitary, elongated, cylindrical, tapering, acute. *Flowers* alternate. *Bractees* tapering into a bristly point. *Calyx* as long as its corresponding channel in the common stalk.

Twelve species are defined by Vahl.

1. *S. angustifolia*. Narrow-leaved Bastard Vervain. Vahl n. 1, excluding Jacquin's synonym. (*Verbena angustifolia*; Mill. Dict. ed. 8. n. 15.)—"Leaves lanceolate, tapering at each end, distantly serrated, smooth."—"Gathered at Vera Cruz, by Houlbourn, who sent seeds to Miller. The latter describes it as an annual branching plant, a foot and half high. *Leaves* pale green, acute, three inches and a half long, half an inch broad. *Spikes* fleshy. *Flowers* blue, appearing in August, and in warm seasons ripening seed in our gardens.—We agree with Vahl that Miller's plant, though we have not seen it, is probably distinct; but Jacquin's *indica* surely is the following.

2. *S. indica*. Indian Bastard Vervain. Vahl n. 2. Ait. n. 1. (*Verbena indica*; Linn. Sp. Pl. 27. Jacq. Obs. fasc. 4. 7. t. 86.)—"Leaves lanceolate-oblong, tapering at the base, coarsely toothed, smooth as well as the stem. *Bractees* linear-lanceolate.—Native of Ceylon. Van Royen sent seeds to Linnæus, who raised the plant in his stove. It is annual, flowering in August and September. The *leaves* are an inch or more in breadth; the lower ones obtuse. *Spikes* long and slender. *Bractees* finely striated, membranous at the edges. *Corolla* blue. Jacquin represents the *leaves* more narrow and acute, with more regular serratures, than in the Linnæan specimen, which came from the Upsal garden, and is accompanied by a branch with narrower leaves. This latter, evidently a mere variety, may be similar to what Vahl had from the same garden, and took for Miller's *Verbena angustifolia*.

3. *S. aristata*. Awned Bastard Vervain. Vahl n. 3. (*Verbena aristata*; Vahl Ecl. Amer. v. 2. 2. t. 11.)—

"Leaves oblong, serrated, acute; villous and slightly hoary beneath. *Bractees* ovate, pointed. Stem shrubby."—Gathered by Von Rohr in South America. *Branches* purplish-grey. *Leaves* an inch and a half long, tapering at each end, equally and deeply serrated, entire at the base, ribbed; the ribs most hoary underneath. *Spike* sometimes near a foot long. Lower *bractees* spreading; upper imbricated, somewhat fringed, longer than the *calyx*. Vahl.

4. *S. jamaicensis*. Jamaica Bastard Vervain. Vahl n. 4. Ait. n. 2. (*Verbena jamaicensis*; Linn. Sp. Pl. 27. Jacq. Obs. fasc. 4. 6. t. 85. V. folio subrotundo ferrato, flore cæruleo; Sloane Jam. 171. t. 107. f. 1. *Cymburus urticifolius*; Salis. Parad. t. 53.)—"Leaves ovate, obtuse, serrated, nearly smooth. *Branches* hairy. *Bractees* ovate, shorter than the calyx.—Native of the West Indies. Introduced very early into our stoves. The *stem* is naturally shrubby and perennial, though it seldom survives after flowering in a hot-house. *Leaves* two inches long, tapering down into a winged *footstalk* half that length; their veins and margins roughish with short hairs. *Spikes* a span long, hardly thicker than a crow's quill. *Bractees* close-pressed. *Corolla* blue, somewhat resembling the elegant *Duranta Ellisia*.

5. *S. dichotoma*. Forked Bastard Vervain. Vahl n. 5. ("Verbena dichotoma; Fl. Peruv. v. 1. 23. t. 34.")—"Leaves oblong-ovate, serrated. *Branches* hispid. *Bractees* lanceolate, the length of the calyx."—Native of woods in Peru. *Stem* shrubby, erect, a yard high, slightly branched; the branches compressed in each joint at the upper part. *Leaves* acute, veiny, minutely hispid beneath; their serratures pointed. *Spikes* a foot long, curved. *Seeds* striated externally. *Fl. Peruv.*

6. *S. marginata*. Bordered Bastard Vervain. Vahl n. 6.—"Leaves roundish-ovate, smooth, with tooth-like serratures; the edges of the teeth cartilaginous. Stem shrubby."—Found by Von Rohr in the West Indies. *Branches* round, smooth, like the rest of the plant. *Leaves* an inch long, firm, very obtuse, ribbed, without veins, with pointed coarse teeth. *Spikes* six inches long, as thick as a pigeon's quill. *Bractees* linear-lanceolate, tapering, the length of the calyx, finely striated. Vahl.

7. *S. strigosa*. Strigose Bastard Vervain. Vahl n. 7.—"Leaves ovate-oblong, crenato-serrated, hairy like the branches."—Native of the West Indies. *Ventenan*. Shrubby, with round *branches*, which are besprinkled, like the *leaves* and *footstalks*, with white hairs. *Leaves* very blunt, an inch long, ribbed, veinless. *Spikes* no thicker than packthread, about four inches long. Vahl.

8. *S. cajanensis*. Cayenne Bastard Vervain. Vahl n. 8. (*Verbena cayennensis*; Richard Act. Soc. Hist. Nat. Paris. v. 1. 105.)—"Leaves ovate, crenato-serrated, smooth, very obtuse. Stem shrubby."—Native of Cayenne. *Branches* round, their young extremities hairy, as well as the *flower-stalks* and the *leaf-stalks*. *Leaves* two inches long, coarsely crenate, ribbed. *Spikes* slender, four inches in length. *Bractees* slender, hairy like the *calyx*. Vahl.

9. *S. orubica*. Orubian Bastard Vervain. Vahl n. 9. Ait. n. 3. (*Verbena orubica*; Linn. Sp. Pl. 27. Pluk. Almag. 382. t. 228. f. 4, and t. 327. f. 7. *Sherardia urticæ folio subtus incano, floribus violaceis*; Ehret. Piët. t. 5. f. 1.)—"Leaves ovate, serrated, rough and rugose. Stem shrubby. *Bractees* ovate, larger than the calyx.—Native of Panama. A greenhouse or stove shrub, early introduced, but not often met with in our collections. The *stem* is a yard high, branched. *Leaves* deeply serrated, rounded. *Spike* twelve or eighteen inches long, with squarrose *bractees*. *Corolla* violet, with a dark divided spot.

10. *S. mutabilis*. Changeable-flowered Bastard Vervain. Vahl n. 10. Ait. n. 4. Curt. Mag. t. 976. (*Verbena mutabilis*; Jacq. Coll. v. 2. 334. Ic. Rar. t. 207. Andr. Repof. t. 435. Venten. Malmaif. t. 36. *Cymburus mutabilis*; Salif. Parad. t. 49.)—Leaves ovate, ferrated, rugose, fomewhat hoary as well as the stem. Braçteas lanceolate, shorter than the calyx.—Native of South America. A ftove-plant, flowering throughout the fummer, and propagated by cuttings. This is larger and more fplendid than any of the foregoing. *Leaves* often four inches, or more, in length. *Spikes* a foot long. *Flowers* large, crimfon, with a central ring of a blood-red, round the white throat. The *corolla* fades before it goes off, occafioning a perpetual variety of hues in each fpike.

11. *S. prismatica*. Germander-leaved Bastard Vervain. Vahl n. 11. Ait. n. 5. (*Verbena prismatica*; Jacq. Coll. v. 2. 301. Ic. Rar. t. 208. *V. fpicata jamaicana*, *Teucii pratensis folio*, difpermos; Pluk. Alm. 382. t. 321. f. 1.)—Leaves ovate, obtufe, ferrated. *Spikes* lax. Braçteas awl-shaped, fhorter than the calyx.—Native of the Welt Indies. Biennial in our hot-houfes, flowering in May and June. The *ftem* has many fmoth, fender, forked branches. *Leaves* one or two inches long, green, roughifh, ribbed. *Flowers* fewer and more difperfed than in the reft, of a violet blue, fmall and rather inconfpicuous.

12. *S. Squamoſa*. Scaly Bastard Vervain. Vahl n. 12. (*Verbena Squamoſa*; Jacq. Hort. Schoenbr. v. 1. 3. t. 5.)—Leaves elliptic-lanceolate, alternate, with fhallow wavy ferratures. Flower-ftalks axillary, fcaly, much longer than the leaves. Stem fhubby. Corolla ringent.—This flowered in the imperial ftoves at Schoenbrun, but its native country is unknown. We fhould preſume the plant to be of South America origin. The *branches* are villous. *Leaves* dark green, fpreading, three inches long. *Flower-ftalks* very peculiar, numerous, from five to ten inches long, hairy, thread-shaped, fometimes branched, covered entirely with innumerable clofe braçteas. *Flowers* very fmall, pale blue; their upper lip erect, fhort, cloven; lower larger, fpreading, in three cloven fegments. Vahl has doubts reſpecting the genus of this plant, its leaves being alternate. We fufpect it to be more allied to *Juſſicia*; at leaft to the Linnæan *J. acaulis*, which is Vahl's *Elytraria erenata*.

STACK, NORTH, in *Geography*, a cape on the W. coaft of the ifland of Angleſea; 2 miles N. of Holyhead.

STACK, in *Agriculture*, a quantity of corn, pulſe, hay, ſtraw, stubble, or other fimilar material, regularly built or piled up, and generally thatched, as a defence from the weather. Stacks are of various forms and dimenſions, according to circumſtances; but for grain, thoſe of the long, narrow, ſquare ſhape are probably the moſt advantageous, where the quantity of corn is conſiderable; as they are found to ſtand more firmly, have a better appearance, are more conveniently and readily built, and preſerve the grain better than thoſe of other forms. And they have the great advantage of requiring leſs thatch, as well as labour in putting it upon them. But where the corn is only in a ſmall proportion, the round or oblong ſhape may be more proper and fuitable, as being more readily drawn up in the roof; and the circular, with a conical top and cylindrical body diverging a little at the eaves, is eſteemed the beſt form of any in ſuch caſes by the author of the *Agricultural Report* of Perthſhire. For hay, the form of the ſtack is a matter of ſtill leſs conſequence: the long ſquare or oblong ſhapes are perhaps the moſt ſafe and convenient, eſpecially when not too broad, as they admit the air the moſt fully. Befides, they are the moſt convenient to cut from in truſſing hay for ſale at the market. But the circular form for farm

ufe, where ſtraw is ſcarce, may be more advantageous in ſaving ſtraw in thatching or covering them.

The octagonal form of corn-ftack has ſometimes a pleafing and very ornamental effect in particular circumſtances and ſituations, eſpecially in the ſtack-yards of the farms about country ſeats and refidences, but it requires more time and trouble in building and finiſhing than thoſe of moſt other ſhapes, conſequently is improper, in general, except in ſuch places, circumſtances, and ſituations.

The oblong and long ſquare forms of corn-ftacks, with circular ends in the latter caſe, are ſometimes very convenient, uſeful and advantageous, as they are built and finiſhed in a ready and eaſy manner, take up but little room in comparison with ſome other forms, and keep the grain remarkably well and ſafe. In building them, the different courſes of the ſheaves, which are not many in the width, are laid ſo as to bind on each other and ſecure the whole, as will be ſeen in ſpeaking of ſtacking grain in a more full and clear manner.

In the ordinary circular form of corn-ftack, the thatch, which ſhould always come down to the termination of the moſt bellying-out or ſpreading-out part of the ſtem, is uſually ſecured and kept on in the common way, without the uſe of any ſort of rope or other contrivance of that kind. Ropes are, however, ſometimes employed.

But there is another form of corn-ftack, which is common in the northern parts of this country and that of Scotland, which is of the round kind, and which moſtly reſts on a wooden frame upon high ſtone ſupports with flat caps. The ſtem is made perfectly upright to the eaves, where the ſheaves of the upper part are made to project ſome way at fiſt, and then gradually taken into a point at the top. The thatch or covering in this caſe, in conſequence of the windy and ſtormy ſituations in which the ſtacks are moſtly expoſed, are, for the moſt part, ſecured by means of ſtraw-ropes, or thoſe of other kinds, put on in a ſort of checquered manner, one rope being made to croſs or paſs over the other, ſo as to afford ſomething of this appearance. There are two ſtraight ropes, to which all the others, which are oblique, are faſtened, the ends being well ſecured by being paſſed round a ſtrong belt-rope which ſurrounds the top of the upright ſtem of the ſtack. The different oblique ropes are put on alternately from the different ſides of the ſtack. In ſome caſes, the ends of the oblique ropes are fixed to the butt-parts of the ſheaves, without any ſort of belt-rope being employed. See *THATCHING of Grain-Stacks*.

There are a few other forms of corn-ftacks, which are occasionally made uſe of in particular circumſtances and caſes of farms; but more for the ſake of curioſity, than any utility they may have in practice.

In ſtacks with any ſort of pulſe crops, as peas, beans, feeding tares, and other ſimilar matters, the ſame forms may be moſtly had recourſe to, but their ſtem-parts need ſeldom be ſo much bellied out at the eaves as in corn-ftacks, as there is moſtly leſs danger from wet; they ſhould always, however, have ſo much outward diverging at the tops of the ſtems, as fully to carry off the water from them. The ſtalk or butt-ends of all ſuch ſorts of produce, when put into ſtacks, ſhould conſtantly be carefully laid in an outward direction, ſo that as few of the pods as poſſible may be expoſed to the moiſture of the air. The top-parts in ſtacks of this kind have rarely any occaſion to be carried up to ſo much height, as is the caſe ſometimes in corn-ftacks. Theſe ſorts of ſtacks, as well as thoſe of corn, ſhould always be put on ſtands or ſtaddles which are conſiderably raiſed from the ground.

In the forms of hay-ftacks there is leſs variety than in thoſe

those of corn, but they have some degree of variety according to circumstances, and the nature of the situations in which they are placed, as well as some other causes. The most useful forms are probably those of the square, long square, oblong, and perfectly round kinds. There is a curious sort of low very bellying form, which rests on a very small basis or saddle at bottom, and which has an equally low top, which is sometimes in use. This is somewhat the form or shape of a sort of hay-stack, which in Scotland, and some of the more northern English districts, is often denominated a hay-sow.

In stacks with hay of the artificial grass kinds, as that of clover, saintfoin, tares, and other similar sorts, the stacks should never be made so large as in the case of natural grass-hay, as such sorts of hay, in order to secure them in the best manner, should never be so much or so well made as that of the natural grass kind, consequently never be put together in stacks in such large quantities, as there may often be danger, inconvenience, and loss in such practices.

In stacks of the straw and stubble kinds, very little more is seldom necessary than merely the securing of the materials; they need but rarely have so much labour and time bestowed upon forming the top-parts of them, as is often the case in corn and hay-stacks, as the matters scarcely ever remain in them for any great length of time, being mostly in a state of gradual removal for different uses.

It may be farther observed, in respect to the sizes of stacks of the first sort, that they of course vary greatly according to circumstances; but they should never be made too large, as there is a great deal more labour and risk in securing and getting in the grain for them, than in those of a smaller size; and from their being built at different times, they do not settle altogether in so equal and perfect a manner, or resist the effects of the weather, and keep the grain so well, as those of less dimensions, that can be completed at once: and, in addition, they are more convenient in the threshing out, especially where the flail manner is employed. The chief advantages they possess are those of taking something less in thatch and labour in covering them, as has been just noticed. But, in common, from about twenty to thirty-two horse cart-loads may be sufficient for one stack, on all the middling-sized farms in most of the grain districts of this kingdom.

And in regard to the proper size of the hay-stack, it should probably be different in some degree, according to the state and nature of the hay; but a middling size is perhaps the best, as from twenty to thirty loads of about one ton each; as there are inconveniencies in both small and large stacks, the former having too much outside, while the latter are liable to take on too much heat, and at the same time permit less moisture to be preserved in the hay. In small stacks, the bellying forms, with very narrow bottoms, have often much advantage, and are in some districts termed sheep-stacks, probably from the slovenly practice of sheep having been permitted to feed at them. It is observed by Mr. Middleton, in his Agricultural Survey of Middlesex, that there are no hay-stacks more neatly formed nor better secured than those of that county. At every vacant time, while the stack is carrying up, the men are employed in pulling it with their hands into a proper shape; and about a week after it is finished, the whole roof is properly thatched, and then secured from receiving any damage from the wind, by means of a straw-rope extending along the eaves, up the ends, and near the ridge. The ends of the thatch are afterwards cut evenly below the eaves of the stack, just of sufficient length for the rain-water to drip quite clear of the hay. When the stack happens to be

placed in a situation which may be suspected of being too damp in the winter, a trench of about six or eight inches deep is dug round, and nearly close to it, which serves to convey all the water from the spot, and renders it perfectly dry and secure.

It may be noticed, that in stacks of all kinds, proper stands or saddles should constantly be provided, being well proportioned to the intended size of the stacks. Those for grain should have copings placed so as to prevent the entrance of vermin: but for hay there is no necessity for this, nor need they be raised so high, but be quite plumb and upright. It is evident, that by the common method of placing them upon the ground, on a little drift, or a few pieces of wood laid across each other, there must constantly be great loss in the bottom parts of the stacks, from the moisture being absorbed by the hay, and it becoming in a rusty condition; while by the use of stands, this may be almost wholly avoided, and the expence be but trifling, as any old rough pieces of wood, or other materials, will answer the purpose in a pretty perfect manner, when other better sorts of saddles are not at hand, or to be procured. See STADDLE and STAND.

All sorts of stacks should be carefully attended to, while they are forming and getting up, and never be left for any length of time, as is too frequently the case, without being properly topped up; as injury and loss are always to be apprehended wherever that is the case. Every kind of stack should likewise constantly be suffered to have completely settled in all its different parts, before it be attempted to be covered in; as otherwise the covering may be deranged and rendered unsightly, by the shrinking that may afterwards take place, and the matters be not rendered so secure or so well preserved.

Stacks of the corn kind are sometimes conveniently placed upon low frames of wood, and on low cast-iron wheels, moving in circular iron railways, contrived in such a manner as that three or four horses may, in most cases, in moderate sized stacks, draw them to the barn or threshing machine. Placing them on these sorts of contrivances is often of great utility and advantage, in saving the expence of labour and time in carting, or otherwise conveying them to such places; and is, besides, capable of being performed at any time, without waiting for the coming of fine and favourable weather for the purpose. The expence in this way of placing stacks is very trifling, and will in a great measure prevent the necessity of having capped stone standings for them. It is likewise a necessary and useful plan, in many instances, as being that alone which allows of a choice of any particular stack for threshing, without waiting for the whole or a great number of others being previously removed or taken out of the way. In some other cases the placing the stacks in straight lines, leading by and past these places, may answer the same intention, though in a much less perfect manner in different points.

STACK, *Hay-Sow*, a name given in some places to that low bowl-like bellying form of stack, which has an equally low top, secured by hay, or other similar kinds of ropes, put on in somewhat the checkered form. It is chiefly in use in such situations as are much exposed to winds and storms.

STACK, *Mow Arish* or *Errish*, that particular sort of stack or mow which is made with grain in the field, in some districts, as Cornwall, in wet and catching harvest seasons. The corn usually remains in these stacks for a fortnight or three weeks. And it is said by the writer of the corrected account of the agriculture of the above county, that these arish stacks or mows, of which he has given a representation,

ation, are admirable contrivances in such like seasons; and that if proper care be taken in forming and making of them, to keep the middle parts well up, so as that the butt-ends of the sheaves may have a considerable slope outwards, the corn will receive no damage, though it were to remain in the field a month or six weeks, or perhaps longer. See *STACKING Grain*.

STACK, Sheep Hay, a name sometimes applied to that sort of low, circular, diverging form of hay-stack, in some districts, which was formerly had recourse to about farms, for sheep to feed at during the severity of the winter season. This littering, wasteful, and slovenly mode of foddering sheep has now mostly been done away by the great value of hay, and the introduction of proper sheep-yards, with suitable contrivances for the purpose. See *SHEEP-Yard*.

STACKS, Supporting of, the practice of propping and storing them up, where they may happen to lean or incline too much to either side, so as to be in danger of falling without such aid and assistance. In those of the grain kind, it is always a good practice to arm and ease the props, or posts, which are made use of for the purpose, with a sheet of tin, nailed round them, at more than half way up, in somewhat the form of an inverted funnel, as this serves to stop vermin in their progress and attempts to get up and into the stacks; and tin, on account of its cheapness and polished surface, is found particularly well suited to the purpose.

The props or posts for this use should, in all cases, have sufficient strength, and be firmly set up to or against the stacks; having a portion of strong thick board laid to the stacks, where their upper ends come against them, to prevent their entrance into them.

This method is found to succeed well in the practice of some farmers in Gloucestershire, according to the corrected account of the agriculture of that district.

STACK-Bars, a term applied to the large bars or hurdles by which hay-stacks in fields are inclosed and secured.

The bars and hurdles for inclosing stacks should always be of a proper thickness and strength, so as not to readily give way, but resist any stress that may be brought against them by animals, in getting at the hay, or in any other way. They should also be put so near together in the fence, as to prevent any hurtful sort of animal from getting at them.

STACK-Guard, a cloth or other covering suspended over stacks, during the time of their being built, to protect them from rain, &c. It is applicable both to the securing of corn and hay-stacks, as well as those of other kinds. It is usual for this purpose to employ a large sheet of sail or other cloth, which answers perfectly, and prevents much injury and loss in wet bad seasons. In the districts of Kent and Surrey, the old or half-worn sails of ships are, according to Mr. Marshall, made use of as guards for stacks. But he thinks, that a sail-cloth, thrown over and immediately upon the hay of a stack in full heat, is liable to do more injury, by increasing the heat, and at the same time checking the ascent of the vapour or steam, than service in shooting off rain-water.

The improved method of spreading the cloth, which he observed in the district of Maidstone, in the former of the above counties, is, he says, this: Two tall poles, or fir-balks, are stepped firmly into two cart-wheels, which are laid flat upon the ground at each end of the stack, and loaded with stones to increase their firmness. Another pole of the same kind, and somewhat longer than the stack, is furnished at each end with an iron ring or hoop, large enough to admit the upright poles, and to pass freely upon them. Near the head of each of the standards is a pulley, over which a rope is passed from the ring, or end of the hori-

zontal pole, by which it is easily raised or lowered, to suit the given height of the stack. In the instance observed, the rick was begun with two loads of hay; yet even these two loads were as securely guarded from rain, until more could be got ready, as if they had been housed: for a cloth being thrown over the horizontal pole, and its lower margins loaded with weights, a complete roof is formed, and exactly fitted to the stack, whether it be high or low, wide or narrow; the eaves being always adjusted to the wall-plate, or upper part of the stem of the stack, thus effectually shooting off rain-water, while the internal moisture, or steam arising from the fermentation of the hay, escapes freely at either end, as the wind may happen to blow. And what renders this ingenious contrivance the more valuable is, its being readily put up or taken away. The poles, being light, are easily moved from stack to stack, or laid up for another season; and the wheels are as readily removed, or returned to their axles. On these hints Sir Joseph Banks seems to have made a considerable improvement, which is equally simple, cheap, and easy in the execution; and, at the same time, perfectly calculated for the purpose.

This improved apparatus, as given by a writer in the tenth volume of the *Annals of Agriculture*, is thus described. There are two long upright posts, poles, or barks of wood, which are firmly fixed and set into two wheels, somewhat in the same manner as the above; one of which is placed at each end of the stack, to which ropes and a block-tackle are so attached as to be capable of suspending the cloth or sheet over the stack in such a way as to render it readily raised or depressed at pleasure, without difficulty or much trouble; the middle part of the cloth being well prepared and secured, in order that the hooks of the tackle for regulating it may be attached to it in a suitable manner. There are three ropes on each side of each post or pole, which are fastened to rings in the upper and top parts of them, and fixed by strong large pegs down to the ground, by which means the upright posts or poles are held steady and firmly in their places. The block-tackle, by which the cloth is rendered capable of being raised or let down, as there may be occasion, consists of an upper and larger, and of a lower and smaller block, which answer the purpose very effectually. There are also four pieces, or more, of ropes, which are attached by rings to the bottom parts or edges of the cloth, on each side, by which they fix it to the ground or stack, by means of pegs driven firmly into them. The whole of the apparatus is so contrived, as to be easily and readily taken down and removed, as there may be occasion; and when not wanted, it takes up but little room in a dry secure place.

STACK Hay-Rod, the strong or stout iron rod of the bolt kind, which is forced into hay-stacks, in order to make way and form a passage for an iron gun ram-rod, which has a strong worm or screw at the lower end of it. In this way a sample of the hay is screwed and forced or taken out, and the state or condition of the stack discovered and determined. This neat and useful discovery and contrivance was made by the late Mr. Duckett, the ingenious farmer at Esler, in the county of Surrey; and the method practised by him, not only for ascertaining the state of the heat in hay-stacks, and preventing its proceeding to too great a degree, but for shewing the colour of the hay in them. When the heat is too great, it serves also for making holes in different parts and places of the stacks, in order to let it pass off, and to admit air more freely, so that the hay may be prevented from being injured in any way by it. This is an invention which, of course, may be beneficial to the hay-farmer in many different ways.

STACK-Tackle, any sort of tackle or contrivance employed about a stack of any kind, either for the purpose of assisting and expediting the work of forming, preparing, and building it, or for protecting and securing the materials of which it is composed, while the stack is forming and finishing. These different kinds of tackles and contrivances are often very necessary about stacks, while the work of forming and finishing them is in hand and going on with; as they may save much time, labour, and trouble, as well as be of great utility in preserving the different sorts of articles in a safe state from the effects of the weather, or other causes. Every kind of tackle, or contrivance of this nature, should always be made as readily applicable and convenient as possible, and so that it may perform its intended use in the easiest and most ready and complete manner there is a capability of, without having any sort of complexity or difficulty in making use of it.

STACK-Hay-Barn, that sort of open barn which is contrived for the purpose of receiving and having hay stacked up in it, in contradistinction to those of the close common kind in which it is sometimes put. These barns are constructed in several different manners, as the nature of the materials may allow, but mostly on posts of oak, or some other durable kinds, with open frames, so as to admit air in a very free manner. They have not unfrequently a capacity of holding from thirty to fifty loads of hay, and, in some instances, even so many as a hundred loads. See **HAY-BARN**.

The question has not yet been fully decided, whether hay keeps better when stacked up in the open air, or in common barns, and those formed expressly for the purpose. The opinion of most of the best hay-farmers in the southern parts of the kingdom is directly in favour of the open stack manner, so far as the quality of the hay is in any way concerned; and there can be no doubt but that the stack-barn method, described above, may be equally or more beneficial in that way, and still more advantageous in other respects. But how far the close common barn is suited to the purpose of containing hay, has probably not yet been fully shewn. However, in many of the more northern parts of the country, hay is not unfrequently secured in barns of this kind, and, on examination, has been found to be equally sweet and good as when preserved in stacks in the open air. The experimental trials of others, in the more southern districts, have likewise shewn the same thing, so far as they have gone; it being found, on cutting and binding up, that it was not less good than that from the stack-yard, being equally free from dust. It cannot, however, be disputed, that hay put up in close barns is, in general, more liable to become dusty, and of a mouldy fusty quality about the sides next the walls, and other such parts, than such as is contained in stacks in the open air, or in such barns as the above.

Many other sorts of buildings and roofed contrivances, besides those of the large stack hay-barn kind, may be had recourse to for containing hay, in different situations and circumstances, and be formed and raised in a much more ready and cheap manner.

STACK-Roofed Corn-Barn, that sort of barn which has the roof formed for the fully securing of the stacks of grain, or other such matters as may be put into it, and the sides and other parts so raised and made open, as to produce perfect security from vermin, and full ventilation of the contained materials. In the construction of it, upon the low timber platform, which is put on posts or pillars, as in stables for grain, the frame or skeleton of a perfect barn is raised, with ends, sides, and roof. The sides and ends are

left open for the full admission of air; but upon the roof is put a complete and substantial coat of thatch, or some other suitable, light, safe material, which being exposed to no injuries or mischief from mice, rats, or any thing else, excepting fire and the inclemency of the weather, will last, it is said, for upwards of thirty years.

This is considered by Mr. Howlett, in the corrected account of the state of agriculture in the county of Essex, as a very great improvement on the staddle erections for corn-stacks or ricks; for though it is remarked, that the pillars and frame in that mode, together with the care and time employed in raising and providing them, and in thatching the stacks, must obviously be attended with considerable charge beyond what would have been necessary for the mere laying up the corn in the common barn; and, after all, it must be again taken down and removed, before it can be threshed;—the height from the ground secures it from vermin; the thatch preserves it from the weather; and the exposure of its ends and sides to the air, which are merely the butt-ends of the sheaves, keeps it entirely sweet and pure, far beyond the best common barn or granary in the world. And, indeed, the farmers' ricks and barns are, it is supposed, the only kind of granaries which a wise and patriotic government in this country will ever encourage: their contents will generally be brought forth at the properest time, not stinking and spoiled by conveyance in ships from abroad, or by lying and rotting in the warehouse of the merchant, but pure, sound, and good, as when carted from the field.

The superior advantages of this stack-roofed mode over that of the common barn, and the common rick or stack manner, are, however, it is thought, great and numerous.

These sorts of barns are often made from fifty to sixty feet in length, having a breadth or width of sixteen or eighteen feet; but they may have smaller dimensions, as may be necessary. They are sometimes raised on large scales, and so contrived as to serve as cart-lodges for loaded corn, and other ways, upon the moveable rafters on the sides being taken away. See **STADDLE**, **GRAIN STAND**, and **WHEAT Rick Stand**.

STACK-Yard, the inclosure or yard in which the stacks of hay and grain, as well as those of other field produce, are placed. These yards should always be conveniently situated for the barns or threshing-mills. They should also always be sufficiently spacious and airy, having a firm dry bottom, and some advise them to be ridged up, to prevent the accumulation of surface-water; as by these being pretty well raised in the middle, and covering the places where the stacks are to be built, either with rough stones, with a mixture of gravel, or paving them in the same manner as streets, much advantage would be gained at little expence. But a much better method is to have the bottom parts for the stacks raised considerably above the surface, and placed upon pillars of wood or stone, with a covering of wood or stone round the circumference, and beams laid across. The inclosing of stack-yards is also a matter that should be attended to more particularly, and be well performed in some manner or other, either by means of low walls or palings.

On large arable farms the stack-yards are not unfrequently divided for different sorts of produce; but this is seldom or ever necessary for those of the middling or smaller sizes, as it creates an additional expence and trouble, without any adequate advantage being derived from it, especially where the yards, in these cases, are sufficiently extensive for the quantity of corn-stacks which are to be put into them.

In these yards the stacks should be arranged somewhat according to the nature of the matters or produce which are put

put into them: those which require to be kept the most dry and sweet, as the grain, pulse, and hay kinds, in the higher and more open airy parts; and those of the contrary kind in the lower and more confined parts.

Stack of Wood, among *Husbandmen*, is a pile of wood three feet long, as many broad, and twelve feet high.

STACKHOUSIA, in *Botany*, received that appellation from the writer of the present article, in honour of John Stackhouse, esq. F.L.S. of Pendarvis, in Cornwall, author of a splendid work on submarine plants, entitled *Nereis Britannica*, and of some botanical illustrations of Theophrastus.—Sm. Tr. of Linn. Soc. v. 4. 218. Brown Bot. of Terra Australis, 23.—Class and order, *Pentandria Trigynia*. Nat. Ord. *Terebinaceæ*, Juss.? Sm. *Stackhouseæ*, Brown.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, bell-shaped, divided half way down into five equal, acute segments, permanent. *Cor.* Petals five, equal, inserted into the calyx, linear-lanceolate, cohering by their claws in the form of a tube much longer than the calyx, their borders narrow, spreading horizontally, shorter than the tube. *Stam.* Filaments five, thread-shaped, unequal, inserted into the calyx; anthers roundish, concealed within the corolla. *Pist.* Germen superior, three-lobed; styles three, short; stigmas obtuse, simple. *Peric.* Capsule of three roundish, coriaceous, corrugated cells, each of one valve, not bursting. *Seeds* solitary, nearly globular, attached to the permanent central column.

Eff. Ch. Calyx in five segments. Petals five, connected by their claws. Capsule of three lobes and three cells, not bursting. Seeds solitary.

Obf. The styles, as well as the cells of the capsule, are sometimes two only.

1. *S. viminea*. Slender Stackhouseia.—Gathered near Port Jackson, New South Wales, by John White, M.D. to whom we are obliged for specimens. The root is tapering, whether annual or perennial we know not. *Stems* several, erect, twelve or eighteen inches high, simple or branched, round, leafy, striated, smooth. *Leaves* scattered, sessile, slightly spreading, elliptic-lanceolate, or oblong, obtuse, entire, smooth, rather fleshy, and somewhat glaucous, single-ribbed, an inch or more in length, tapering at the base. *Clusters* terminal, elongated, erect, many-flowered. *Flowers* small, yellowish, in little distant tufts, two or three together, on short partial stalks, with minute bractæas at their base. *Capsule* of three rugged lobes, each the size of a mustard-seed, subtended by the permanent expanded calyx. The flowers bear a resemblance to some species of *Struthiola* or *Daphne*, but are very different when examined.

This is the only species that has fallen in our way. Mr. Brown probably may have seen more. This learned botanist considers *Stackhouseia*, "and an unpublished genus, exactly agreeing with it in flower, but remarkably different in fruit," as forming a small natural order, sufficiently distinct from all hitherto established. He places it between his *Celastrineæ* and *Euphorbiaceæ*, "to both of which, but especially to the former, it seems to be related in a certain degree." Mr. Brown thus defines the order in question.

STACKHOUSEÆ. *Calyx* of one leaf, in five equal segments, with a swelling tube. *Petals* five, equal, inserted into the top of the tube; their claws cohering in a tubular form, longer than the calyx. Their borders narrow, spreading like a star. *Stamens* five, distinct, unequal (two alternate ones being the shortest) inserted into the throat of the calyx. *Germen* distinct, of from three to five separate single-seeded lobes, the seeds erect. *Styles* three to five, sometimes cohering at their base. *Stigmas* undivided. *Seed-vessel* of

three to five lobes, each without valves, sometimes winged; the central column permanent. *Embryo* erect, central, almost as long as the fleshy albumen.

The plants of this order are herbaceous, with simple, entire, scattered, sometimes minute, *leaves*, and lateral, extremely minute, *stipulas*. *Spikes* terminal, with three *bractæas* to each *flower*. "The *Stackhouseæ* are peculiar to Terra Australis, and though found chiefly in its principal parallel, extend more sparingly both to the southern extremity of Van Diemen's island, and to the north coast of New Holland."

STACKING, in *Agriculture*, the art and manner of forming, building, and making all sorts of stacks with any kind of farm produce.

In forming, building, or stacking any sort of material of the farm kind, it is mostly proper to begin in the middle of the staddles or stands on which they are to be raised, so as to form and lay it out to the sides, ends, or other parts, in a very slightly inclining manner, the ear-parts the highest in corn or other similar matters, keeping such middle part always well up, and the outside parts on the sides, or in other ways, in a constantly very gradual, but scarcely perceptible, outwardly swelling or overhanging manner, proceeding course after course, in the same way, until the top of the stem or shaft part of the stack be reached, from which, in forming the top part, it is to be taken or drawn in, in placing the different courses of the substances in nearly the same easy, gradual, though in rather a quicker manner, until the ridge or top be arrived at; always carefully keeping up the middle, as in the stem or shaft part. The top or ridge part must constantly be well and safely secured; it is sometimes ornamentally formed. In somewhat this way every sort of stack about a farm may be raised without any very great difficulty or trouble, if the labourer or person who is to form and construct them be but a little conversant with the nature and practice of stacking, though he may not be greatly experienced in this sort of business. He cannot, however, raise or form stacks in the very neat, exact, and perfect manner, that complete and professed stack-building labourers are capable of performing the work. Nor will he be capable of finishing them with the same exactness, or the same degree of neatness or elegance. See the next article.

STACKING of Grain, the art and practice of building or forming stacks of corn, and other similar matters; which is performed in different methods, according to the particular nature and circumstances of the different cases. In the execution of this business, the stems of the stacks should, however, in general, be so formed as to swell gradually outwards, quite up to the part termed the eaves, as by this method they are more perfectly secured against the entrance of moisture, and at the same time require a less space to stand or rest upon. And when the building of them is well performed, they have equal solidity, and stand in as firm and safe a manner. But Mr. Marshall, who has probably not fully considered the advantages of this practice, advises that the stem or body of the stack should be carried up as plumb as possible, except the last course of sheaves, which should project five or six inches, to form the eaves: for the weight of the roof will, he thinks, press out the upper part of the stem sufficiently. If it overhang in making, its own weight and the weight of the roof will, it is supposed, squeeze it too flat, will spoil the appearance of it, and waste both thatch and time in thatching. The stem or body of a stack should commonly contain about two-thirds, and the roof one-third of the whole stack. If it be built on a frame, the stem should, however, contain less, and the roof more;

STACKING.

more; if on a bottom, the reverse. The corners of the item should not be built too sharp; should be carried up snug; by which the sides will look fuller, and the swell given by the pressure will be more perceptible. The ends of the roof should have a gentle projection, answerable to the stem; and the sides should be carried up rather convex, than flat or concave. Perhaps a roof greatly convex shoots off the rains preferably to any other. A corn-stack should not, it is said, contain above twenty-one loads, as the risk of making and getting in is much less on a small than on a large stack; besides, a large stack does not settle so true as a small one, and of course will not stand the weather so well. It is true, a large stack does not, in proportion, take so much thatch and thatching, which are its only advantages.

But in cases where corn is stacked in a loose manner, it is the usual practice to have a number of persons upon the stack, the corn being forked up and deposited on the different sides all round in a similar method; after this, other parcels are laid all round on the inside of these, so as to bind them in a secure manner from slipping outward; the operator proceeding in the same manner till the whole of the middle space is perfectly filled up; when he begins another course in the same method, and goes on in this mode, with course after course, till he has raised the whole of the stem or body part; then he begins to take in for the roof in a very gradual manner, in every succeeding course, until the whole is brought to a ridge or point, according to the manner the stack is formed in. But in order that the roofs may throw off the water in a more perfect and effectual manner, they should be made so as to have a slight degree of fulness or swell about the middle of them, and not be made flat, as is too frequently the practice with indifferent builders of stacks of this sort.

The method of proceeding where the corn is bound into sheaves, is, however, quite different, as there is seldom more than one person employed in managing the work of building the stack, except in cases where the dimensions are very considerable; in which cases it is found necessary to have a boy to receive the sheaves from the pitcher, and hand them to the man that builds the stack. And in executing the work, it is of the utmost importance that the centre of the stack be constantly kept in a somewhat raised state above that of the sides, as by this means the sheaves have a sloping direction outwards, by which the entrance of moisture is more effectually guarded against and prevented. And in order to accomplish this in the most perfect method, it is said to be the best practice for the workman to begin in the middle of the stand or saddle, setting the sheaves together, so as that they may incline a little against each other, placing the rest in successive rows against them, till he comes to the outside, when he carries a course of sheaves quite round, and in a more sloping manner than in the preceding courses. The bottom of the stack being formed in this way, it is afterwards usual to begin at the outside, and advance with different courses round the whole, placing each course a little within the other, so as to bind them in an exact and careful manner, till the stacker comes to the middle. And all the different courses are to be laid on in a similar manner, until the whole of the stem is raised and completed; when the last outside row of sheaves is, in most cases, placed a very little more out than the others, in order to form a sort of projection for the eaves, that the water may be thrown off more effectually. But in cases where the stems of the stacks are formed so as to project outwards, in the manner already noticed, this may be omitted without any bad consequences, as the water will be thrown off easily without touching the walls of the stack. And the roof is to be formed by placing

the sheaves gradually a little more in and in, in every course, until it comes to a ridge or point, according to the form of the stack, as has been already observed. But in forming and constructing this part of the stack, great care should constantly be taken to give the ear-ends of the sheaves a sufficiently sloping direction upwards, in order that they may be the better secured from wetness. And to the outside should be given a rounded form, in the manner that has been already noticed.

In respect to the stacking of grain, it is observed in the Farmer's Magazine, that the corn and its straw must necessarily be a great deal more dried in the field, to render it proper for being secured in barns, than when it is built in ricks, as these latter, being exposed to the free air all round, are by no means so apt to heat or mould the grain and straw, as if it were stored in common barns. And that, in consequence of that superior degree of dryness necessary for barn-harvesting, the grain is certainly a great deal more apt to shake out from the ear, in handling and forking into the carts or waggons for being led home. And further, that when built in ricks properly contrived, the grain is likewise placed altogether out of the reach of rats and mice, which commit very great waste in common barns, however well constructed; that it is of course better that all grain should be built in round ricks in the yard, upon wooden frames open below, raised on stone supports, similar to those on which granaries are fixed. By this plan, it would, it is supposed, be more effectually secured against the depredations of vermin; and besides, the air having free access all round, and even underneath, through the interstices of the frame, it will be completely prevented from all danger of spoiling any way in the rick. And further, that in this way of securing grain, the ricks do not by any means require to be thatched so very substantially, and, of consequence, expensively, as is practised in general.

Further, it is also advised, that in building a corn-rick, effectual care be taken to keep the centre or heart of the rick always considerably higher than the outer range of sheaves, as noticed above; so that every sheaf in the rick has a considerable slope outwards and downwards. When this is properly attended to, and all the sheaves carefully locked together, and the crown properly put on, the rick will, it is observed, turn a very heavy shower of rain, even before the thatch is applied. The whole rick, after the thatch is laid on, is finally covered with a net-work of straw-ropes, leaving the meshes about nine or twelve inches wide, all the ends of the ropes being secured to a belt-rope, which goes round the rick below the eaves, just within reach of a man, and the middle parts of all the ropes are tied to one that goes straight over the top of the rick by small handfuls of straw. See STACK.

And it has been stated by the author of "Practical Agriculture," that it is the practice in some districts, especially where the stacks are made of a circular form, and the weather is wet and unfavourable, to have a funnel or chimney left in them, in order to prevent their taking on too much heat. This is effected by tying a sheaf up in a very tight manner, and placing it in the middle, on the foundation of the stack, pulling it up occasionally as the building of the stack proceeds all round it. And in setting up ricks in bad harvests, it is a practice in some places, particularly with barley-crops, to have three or four pretty large poles tied together, by winding straw-ropes round them, set up in the middle, round which the stacks are then built. But that except the stacks are large, or the grain when put into them in an imperfect condition, such openings are quite unnecessary. These openings in the northern parts of the

STACKING.

kingdom are denominated *favuses*, or *faufes*. And it is probable that in some instances they may be prejudicial to the stacks, by the admission of too much moist air. See *HARVESTING of Grain*.

A curious practice in this mode of stacking grain prevails in some parts of the northern districts of the kingdom, where the operation is performed round about a high conical frame of wood, which has, in some cases, a small door, provincially termed a *logie*, formed in it on the side or quarter from which the wind commonly blows, in order that a more free admission of air may be secured, a lateral vent, or small opening, being sometimes, perhaps, made in the body, a little below the point of the wooden frame, which has in different parts of these districts of country the names of *faufe* house and *windy* house. The writer of the Corrected Account of the Agriculture of the County of Inverness suggests, that where wood is scarce, the same effect and advantage may nearly be produced, without an upright timber-frame, by filling a sack with straw or hay, and fixing a rope to the mouth of it. This sack is set down adjoining to the logie, and in the centre of the space on which the stack is to be built; and as the stacking advances, the sack is gradually pulled up, so far as is thought necessary and useful, by which means a future draught of air is freely admitted. These precautions are, however, it is said, mostly used when the material is damp, and the stack to be formed on the ground. See *STADDLE*.

In some damp situations and moist wet seasons, grain is occasionally stacked up in the field in different forms and methods. The writer of the Account of the Husbandry of Middlesex has remarked, that to the westward of the city of Bath, the excessive moisture of the climate has necessarily induced and obliged the occupiers of arable land to secure their corn or grain crops in the field, immediately after they are bound into sheaves, by stacking them in round ricks or stacks, which contain about a cart-load each; the sheaves being placed in such a manner as to secure the ears equally against the rain and damp arising from the ground. They are set on their butt-ends in the bottom parts, but every sheaf, from the eaves upwards, is placed sloping in a thatch-like manner, and in the form of a cone. One sheaf is inverted at the top, and spread over this cone-like point; which method secures the whole, until it may suit the convenience of the farmer to carry the matters to be re-stacked, or built up in the barns or stack-yards. When these ricks or stacks are well made or put up, they are secure, it is said, against every possible quantity of rain, and for any reasonable length of time; even for a whole winter, if it were necessary to keep them out so long. This is a practice of stacking in the field, which, it is thought, deserves imitation in all wet climates, and indeed in all others, in cases of wet harvest seasons.

The method of stacking or making the arish mow or stack, which is another mode of stacking grain in the field in some of the south-western districts of the kingdom, is thus described by the writer of the "Western Tour." A sort of cone or pyramid is first formed with sheaves set upon their butt-ends, and in a leaning manner towards their centre; the workman then gets upon them with his knees, an assistant putting the sheaves in their proper places before him, while he creeps or crawls round the mow or stack, forcing and beating them down in a perfect manner with his knees applied about the binding-place; and continuing in this manner to lay course after course, until the mow or stack be deemed high enough; observing to contract the dimensions of it as it rises in height, and to set the sheaves more and more upright, until they form at the top a sharp point, which is

capped with an inverted sheaf, either of corn or reed. In cases where corn or grain is put up or built in these stacks, it is mostly thought to be quite safe.

The stacking of corn, when carried to the yards, is frequently performed on oblong and other forms of raised wood, on frames covered with loose poles or other matters, so as to admit air freely to all parts of the bottoms of the mows or stacks, and at the same time to prevent rats and other such animals getting into them.

The stacking of grain is mostly performed in a neat and exact manner in many districts towards the middle and more northern parts of the kingdom; but in many of the more southern and eastern counties, it is often done in an extremely bad and slovenly manner. In Oxfordshire and Berkshire stacks are formed with peculiar neatness, and have much merit in their different forms and shapes, being not unfrequently duly arranged, and placed in neat clean stack-yards. In the latter of the above counties, it has been remarked, that a farmer who was negligent in these respects, would be the object of observation and derision in his neighbourhood. And that the labourer who can make a handsome rick or stack, prides himself on his skill; and as good as well as bad examples are catching, others, in imitation, endeavour to gain credit by the same means.

In finishing the stacking of grain in many places, the stem or body parts of the stacks or mows are neatly pared round, in order to prevent the vermin, which might leap against them, from finding any thing to hold by; and the whole is completed in a neat and exact manner.

STACKING of Hay, the work or business of putting hay up into ricks or stacks. This is an art which requires much care and attention in the person employed for the purpose, though much less than that of building corn-stacks. There should constantly, though it is often too much neglected, be a proper stand or foundation, somewhat raised by wood or other materials, prepared for placing the stacks upon; but nothing of the shelving outward direction or of the coping kind is here necessary. See *STACK*, *STADDLE*, and *STAND*.

It may be noticed, that in performing the business of stacking hay, the work should constantly be performed as much as possible while the sun is upon the hay, as much advantage is thus gained in the quality of the hay: and it is necessary to have a stacker that has been accustomed to the business, and a proper number of persons to help upon the stack, in order that it may be well spread out and trodden down. The building of these sorts of stacks should be conducted much in the same way as those of the grain kind; the middle of the stack being always well kept up, a little higher than the sides, and the sides and ends be well bound in by the proper application of the successive portions of hay as the work advances; and during which it is a good way, where there are plenty of hands, to have the sides and ends properly pulled into form, as by this means much after-labour is prevented. It is likewise of advantage, that the hay should be well shaken and broken from the lumps during the operation of stacking. The form in which the stacks are built is not, as has been already seen in speaking of stacks, of much consequence. See *STACK*.

With the intention of preventing too much heat, sometimes in building these stacks, as well as those of the grain kind, holes, pipes, and chimnies are left in the middle, that the excessive heat may be discharged. But there is often injury sustained by them, from their attracting too much moisture. See *HAY*, and *HAY-making*.

For this purpose, square spouts or troughs, bored full of large holes, and two opposite boards, secured about nine inches apart, by nailing short laths on them, are sometimes employed;

STACKING.

employed; as well as the drawing up the middle of the stacks, while they are building, a basket or a sack full of hay, straw, or other similar materials. And in some cases, on the stacks heating too much, square openings are cut from the tops to the bottoms of them.

In stacking of hay, the use of salt has likewise been found to have the valuable property of keeping it from heating too much in such situations, and, by that means, preserving it of a finer green colour than would otherwise be the case. Its disposition to counteract or prevent heat is so great, it is said, in such cases, as to render it particularly suitable, proper, and valuable in every instance where it may be suspected that the hay has been put together without being sufficiently made.

The hard benty hay of poor uplands may mostly be stacked up without any risk or danger of heating too much; but that which is of a more open succulent nature and quality, on rich or highly manured lands, is for the most part very liable to take on too great a degree of heat, and should consequently be longer delayed in stacking, as well as put up in smaller quantities together, in order to avoid being injured by being burnt in the mow or stack.

The hay of clover, tare, faintfoin, and some other similar kinds of grasses, are commonly more disposed to heat in too great a degree than almost any other sorts when put up in stacks, not only on account of their being more succulent and fatty, but in consequence of their nature requiring that they should be a good deal less made, in order to preserve their foliage as perfectly as possible. In stacking them, therefore, these circumstances should be carefully attended to and kept in mind, and smaller, as well as more loosely formed stacks of them raised. In the county of Middlesex also, many farmers are said to make use of salt, in such cases, with very good effect, in keeping down the heat.

Where there are great quantities of hay ready on hand at the same time, it is of much consequence that it should all be stacked up as soon as ever it is fully made, which, though difficult to be accomplished in many cases, should seldom be neglected, as its weight and good quality greatly depend upon it, there being every moment from that time a loss in the weight, as well as the nutritious properties of it, by what is forced off by heat into the atmosphere. The difference of even a few hours in very hot seasons, may, it is supposed, be the cause of a loss of fifteen or twenty *per centum* on the hay, by its having been carried beyond the point of perfection in making; and not infrequently a much greater loss is sustained. The stacking, therefore, in such circumstances, should always be done as expeditiously as possible.

In regard to the loss of the materials before and after they have been stacked up, it has been supposed by the writer of the Middlesex Agricultural Report, that four hundred weight of grass wastes in forming into hay, three hundred before it is ready for stacking; it is then further reduced by heat and evaporation, in about the space of a month, to perhaps ninety-five pounds; that at between that and ninety, it is apprehended it continues throughout the winter. That from about the beginning of spring until the commencement of the following autumn, the different operations of trussing and conveying it away, render it considerably lighter, probably to eighty, by exposing it so much to the sun and wind: that is, such hay as would weigh ninety pounds on being taken from the stack, would be reduced to eighty by the time it is disposed of, as in the course of twenty-four hours. On such stacked hay being kept longer, little or nothing is lost in the succeeding winter: it is nearly obvious, it is thought, that the same stacked hay will weigh on being disposed of eighty pounds in the summer, and ninety in the

winter. From this circumstance, and some others which relate to price, the farmer may, it is conceived, determine what season of the year is the most advantageous and proper for him to dispose of his stacked hay: on large hay-farms stacked hay is sometimes kept for four or five years, and there are not unfrequently very large quantities of hay on them in this state.

The stacking or mowing of hay is sometimes performed in large hay-barns constructed for the purpose, which are found to be extremely useful and convenient on many occasions, as well as to produce considerable savings in different ways, besides the safety which they afford. See *STACK Hay-Barn*.

After the work of stacking the hay has been finished, and the stack been properly pulled and topped up, it may be left until it has sweated, and is become perfectly settled, which mostly takes place in the course of a week or two. It is then ready for thatching. See *THATCHING of Stacks*.

It may likewise be noticed, that in building the upper parts of these, as well as grain and other stacks, the use of a stage often becomes necessary, in order that the materials may be pitched more conveniently to the stacker, as has been seen under the head *STACK*. See *STACKING-Stage*.

STACKING of Pulse Crops, the art and practice of putting all the sorts of farm produce, which have pods in the place of ears, up into stacks. It is always necessary, in building them, to keep the pod parts, as much as possible, from being exposed to the action and effects of the atmosphere, as they are very liable to be much injured or quite spoiled by the influence of much moisture or wetness, whether communicated by the air or in any other manner. It is consequently proper in stacking up these different materials, to always let the stem or root-ends of the crops have an outward direction and appearance, they being bound inwardly by such wads, sheaves, or bundles as have but little stem or root parts in them, which is mostly sufficiently the case in all such sorts of produce. The middle parts of such stacks should always be kept well filled up with such materials while building. The stem or shaft parts may mostly be carried up in a pretty plumb or upright manner, but if the outward side parts are made and carried up so as gradually to diverge or project a very little at the top or eave parts, it will be so much the better, and the stack will be so much the safer from the danger of the droppings of the rain-water or any other wetness that may fall upon it.

It is hardly ever necessary to carry up the top parts in constructing such stacks to any great height, the lower they are indeed the better, provided they are formed in a regular manner, and so as to effectually carry off the water that may fall upon them.

The topping-up of such sorts of stacks should never, however, be much delayed, as the seed of such kinds of produce readily swell, and are apt to become injured by a very little moisture in such situations.

These sorts of stacks, as well as those of other kinds, should always be built upon proper saddles in safe yards or other situations.

STACKING and preserving of Hop-Poles, the practice and method of piling them up in stacks, for the purpose of rendering them safe and secure against wind and bad weather; and the means of preparing their bottom parts against the injuries they may receive from the earth or soil in which they may be placed. See *Hop-Pole*.

In the square manner of stacking up hop-poles, the number of from thirty to forty or more are usually set up to each corner so as to form it, which should mostly stand eight, ten, or twelve feet apart in each or every direction at the

STACKING.

bale or bottom parts of them, the top parts uniting, or coming as closely as possible into contact with each other. By this mode of proceeding, a fort of square inclining pile is formed, while sufficient openings or spaces are produced below and between them, for contributing to render the poles dry, as well as afterwards for preserving them, as much as possible, in that condition, and at the same time for letting the wind pass among them more freely, by which the danger of their being thrown down or overturned is considerably lessened, as in the case of stacks of the conical or circular form. In constructing this, as well as the other form of these stacks, a few poles are first well fixed up, fastened and secured at the top parts, and then set out in a firm spreading-out manner at the bottoms, so as that the proper quantity of poles may afterwards be regularly and gradually laid to them and constitute the stack.

The means of rendering the parts of hop-poles which are set into and come in immediate contact with the mould or soil less liable to decay and destruction than they are in the ordinary mode, is a matter of much consequence to those engaged in the cultivation of hops. The following process has been recommended by Mr. Vancouver, in the Corrected Account of the Agriculture of the County of Essex. Taking into full and due consideration, it is said, the very important benefits which are derived from coal-tar, in preventing the depredations of marine insects on plank and timber, it very naturally occurs, that a preparation of the same substance, judiciously applied, might not only produce a similar effect on and against insects in the ground. but, by its gradual and regular solution there, become matter of food for the nourishment of plants; and that this leads to a very important consideration, as that of how far the application of the same material may become serviceable, by prolonging the durability of posts set into the ground, and in the like manner for the preservation of the parts of hop-poles which are put into the earth, to which particular point, it is stated as the substance of a conversation on the subject with the earl of Dundonald, who has taken a great lead and interest in the invention, manufacture, and introduction of coal-tar into more general use, that he recommends the method of preparing the hop-poles with it, which is given below, to all hop planters.

The parts of the ends of the hop-poles which are intended to be set or inserted into the ground or soil, should first be stripped of their bark for the length of about thirty inches. The poles should then be pointed, and scorched or burnt, until the surface of them, from which the bark has been removed, becomes black, and in some sort charred. The usual or customary depth to which poles are set and fixed in the ground, will mostly regulate with exactness how much of the pointed ends of the poles should be treated in the above manner. The burnt end of the pole, while hot, should be dipped into thin coal-tar, which should previously be made a little warm, in order that the wood may absorb and take up as much of it as possible. There may perhaps, it is supposed, be an advantage in dipping or putting the pole the whole space of the thirty inches which is stripped of the bark, as by that means twelve inches of what is covered and laid over with coal-tar may be above the surface of the ground.

After the paying or coating of the poles with the tar has been completed, they are to be put up or stacked with their pointed and tarred ends upwards, until they become perfectly and quite sufficiently dry; after which they are to be dipped in coal-pitch made boiling hot, and then set up again in the same manner, to remain in that state until the time when they are wanted for use. In cases where the poles are liable to

injury at the upper or smaller ends, dipping them in the coal-tar might also, it is supposed, probably be of use in preventing the separation of the bark, or the harbouring of insects.

It is of very material consequence that the coating or tarring of the poles be performed at such a distance of time before they are wanted for use, as to allow of the whole covering becoming perfectly firm, hard, and dry. And likewise that the poles, before they are begun to be coated over with the tar, be in a quite dry condition, as they take up a much greater quantity of tar when in this situation, than when much loaded with moisture, as is too often the case.

The practice of burning or charring the bottom ends of hop-poles has also been found highly beneficial in preserving them from decay without the application of either the coal-tar or pitch, in many cases and situations, as well as some other methods. See Hop.

It is always proper to have the poles piled up in proper parcels together, or set upright against some sort of support in the hop-grounds, while they have the binds about them, until they can be disengaged from them, as well as afterwards, until they can be staked or pointed, prepared in the above manner, and set up into stacks, instead of having them dispersed all over the ground in a flat manner, as is the too usual custom, as by such means they will become readily more dry, be a great deal more free from injury, and at the same time be rendered more fit for receiving the preparation.

And in extensive plantations, it might probably be the safest, cheapest, and most convenient way, to have open coarse sheds with secure cheap roofs built for receiving and preserving them in, they being piled up in them upon low frames or flools with long arms or branches for keeping them up. In this manner they would in all probability be more readily, more perfectly, more conveniently, and more advantageously secured than in any other way; and thereby a great saving of poles most likely be produced.

STACKING of Straw and Stubble. Straw is often stacked up when bound in trusses, as well as when in the loose state. In the former mode, the different bundles should be stacked in as straight a manner as possible, in order to be kept for sale or other particular uses. In the latter state the stacks should be well pulled while they are forming, in order that they may be close and compact. In building the top parts of stacks of this nature, they need not be carried to any great height, but be so formed as to shoot off the water in a perfect manner.

STACKING-Bands, or Belts, the ropes or bands used in thatching stacks of different kinds, whether of the straw, hay, or other sorts.

STACKING-Stage, the scaffold or platform employed in building stacks of corn, hay, and many other sorts of farm produce.

Stages of these kinds are constructed in different ways, some being fixed together in a sort of frame, so as to be set up against the stack, and suited to the height of pitching by a moveable stage. Lately this sort of stage has been considerably improved, by being so contrived as to be capable of being readily taken in pieces and laid by. It is the contrivance of a gentleman in the county of Suffolk, and described in the Agricultural Survey of that district. It consists of two parts, one of which is a frame eight feet wide, made of two fir-balks twenty-two feet long, braced together in a parallel position, and having several holes bored in them, about fourteen feet from the ground, for the reception of the hinges of the stage; and a hook in each

of them, to hang the chains on which are to support the outward edge of the stage, and serve to raise or lower it at pleasure. The other part is a moveable stage eight feet long, and three feet eight inches broad, having a hinge under each end, at the hinder, or edge nearest the stack; one end of the hinges is made like a bolt, to enter the holes in the balks; the stage likewise has an iron-plate under each end, with a hole in it to receive a hook on the chain. It is added, that in using the stage it is set against the stack, when it grows so high that it is inconvenient to pitch on to it from the buck of an empty waggon. The holes in the balks most commonly used are fourteen feet from the ground, about the height of a waggon-load of hay. Should the stage be fixed lower, it would be of no use, not being wanted whilst a man can conveniently pitch from the buck of a waggon on to a stack; and should it be fixed much higher, it would be found too high for a man to pitch on to, when the waggon is nearly empty.

It has been suggested, that a stage like this is not expensive in the construction, and might be used for nailing up weather-boarding, painting, plastering of walls, and several other purposes.

STACKPOLE HEAD, in *Geography*, a cape on the S. coast of Wales. N. lat. $51^{\circ} 42'$. W. long. $4^{\circ} 57'$.

STACKS of Burgh, rocks near the E. part of Scotland, one mile W. of Duncansby Head. N. lat. $58^{\circ} 23'$. W. long. $2^{\circ} 57'$.

STACKS of Duncansby, rocks in the North sea, near the E. coast of Scotland; $1\frac{1}{2}$ mile S. from the mouth of Wick river. N. lat. $58^{\circ} 36'$. W. long. $2^{\circ} 57'$.

STACKS of Hempriggs, rocks in the North sea, two miles S. from the mouth of Wick river. N. lat. $58^{\circ} 21'$. W. long. $2^{\circ} 57'$.

STACTE, *στακτε*, in *Pharmacy*, a fatty resinous liquid matter, of the nature of a liquid myrrh.

This liquor is very odoriferous, and is held very precious; making alone the perfume called by Dioscorides *στακτε*, which, he says, smells finely, though very bitter to the taste. We have none of it now but what is sophisticated; and what the apothecaries call *στακτε*, is usually no more than liquid storax.

STADARSTAD, in *Geography*, a group of buildings, comprising a church, the habitation of the minister, and a few cottages, in Iceland, situated in the peninsula terminated by SNÆFELL's *Syffel* (which see.) This church was the best which the travellers to whose account we refer had seen, except that of Bessildad. It is constructed entirely of wood, and has a pretty large gallery. The mountains that rise behind Stadarstad are very lofty, and present a bold and precipitous front towards the sea. About six miles from Stadarstad, in the mountains that approach towards the sea, is a hot spring, in a place called Lyfiehous. The water issues from the top of a mount about ten feet high, and fifty yards in diameter, entirely calcareous. The temperature of the spring was 96° , and the water had an acidulous taste. Not far from the mount were great quantities of incrustations not calcareous, which had evidently been formed by some ancient springs. About half a mile from the spring is a stream of lava, that had flown down from the precipices above, and spread over the flat plain intervening between the mountains and the sea. Near Buderstad, which is one of the trading stations of Iceland, and consists of a merchant's house, a large wooden storehouse, a church, and a considerable number of cottages, is an other mineral water, the taste of which was similar to that of Lyfiehous; the temperature was 46° . Mackenzie's Travels in Iceland.

STADDLE, in *Agriculture*, a term applied to the bot-

tom part, or that on which the stack or mow of corn, pulse, straw, hay, or any other sort of field produce, rests, and is formed or built. These sorts of staddles are contrived in many different ways, according to different occasions and circumstances; as, in a walled manner, in the wooden frame method, in the simple log mode, and some others. The two first are, however, by far the most proper, where grain or pulse is to be stacked upon them; but the last may do for straw and hay occasionally, where better and more perfect methods cannot be adopted or put in practice. The first method is expensive, and therefore not common. See *Corn-STAND*.

A method more commonly adopted by farmers, is that of the wooden frame, resting upon low supporters of the stone or other kinds. In many different districts, the staddles, especially for corn, are constructed by means of upright stones with caps, placed about seven feet distance from each other, in a circular, square, or some other suitable form. The upright stone, in some cases, is a truncated pyramid, about four feet in length, a foot being allowed to be let into the ground. On the top, which is about four inches in the square, is placed the cap, which is a round stone, flat and smooth on the under side, and a little convex on the upper, two feet in diameter, and projecting ten inches from every side of the upright stone. Upon these stones strong timbers are framed, first extending in a cross-wise direction, and then all around the sides; a stone and cap being, for the most part, put in the centre, to take off the bearing of the cross-timbers. This is a plan of staddle, which, it is thought by many, effectually secures the grain against rats and other similar sorts of vermin.

In other situations, stone or wooden pillars are put down, at proper distances from each other, into the ground, upon which is laid a firm and strong substantial timber-frame, well compacted and put together, of joists, beams, and other parts, as may be found necessary and expedient. If the supporting pillars be of stone, they are usually of a conical form, with stone caps faced upon their tops, as above; but if of wood, they are cased with tin, ten, twelve, or more inches near their upper ends. In the former case, the stone caps, and, in the latter, the tin coverings, effectually prevent, it is supposed, the rats and mice from climbing up into the stacks.

In some of the more northern districts of the country, the corn-stacks are occasionally set somewhat in the form and manner of little houses, upon pillars, or arches turned in masonry, round or on one or more of the most exposed sides of the straw-yards, where the outlying or other cattle are to be foddered and kept. Where the pillar mode is adopted, a strong solid wall, built in mason work, mostly forms the outside, and the pillars are set round or on the insides of the straw-yards. Beams of a proper size and length are first laid from one pillar to another, and then rafters are laid across from the outside wall to the pillars and beams, so as to form a sort of flooring; upon which the stacks are built of any length and height that may be necessary; their roofs being always well secured. In the turned arch manner, no pillars or frames of wood are at all necessary, the top parts of the arches forming the bases or staddles for raising the stacks upon, while the openings of them, or arches below, form the stalls for the cattle. In both these ways the cattle are well protected below or underneath the stacks; the grain is perfectly preserved from the effects of dampness and vermin, by being so much elevated; and to the former there is a considerable saving of manure in different ways.

In other cases, corn-stacks are built round and against a frame of wood, set up firmly in somewhat a conical shape
or

or manner; the tops of the rafters or boards, of which this sort of staddle is composed, resting or inclining against each other, and reaching somewhat above the eaves of the stack. This is a kind of staddle which is supposed to afford much air and ventilation in moist damp situations, for drying the grain in the stacks. See *STACKING of Grain*.

Where the simple log manner of forming staddles is in use, any sort of rough large pieces of wood, of the tree or other kind, are laid round the outsides, in the form in which the stacks are to be made; in the inside and middle of which, bottoms or foundations are formed with common wood faggots, bushes, or any other similar matters; the whole being then well covered with rough straw or haulm of any sort. See *STACKING of Hay*, and *STAND, Grain*.

The term *staddle*, likewise, sometimes signifies a tree, which is suffered to grow for coarse or common purposes; as the forming and making of posts, rails, and other similar uses.

STADDLE of Hay, a term applied to a plot or portion of hay thrown abroad in making. See *HAY-Making*.

STADDLE-ROOF, any sort of roof or covering which is placed over staddles, and employed for the purpose of protecting or securing the stacks of either corn or hay, or of any other sorts of materials which are built upon them. Staddle-roofs are of many different kinds, and their heights and sizes are various, according to those of the staddles over which they are laid.

In the county of Devon, a mode of this kind of roof prevails for the securing of corn, in some parts of the South-hams in that district, which appears to be entitled to the consideration of the farmer.

It is said to have been borrowed from the Dutch, as it is much used in Holland, and all the low countries upon the borders of the Rhine and Scheldt rivers. It is likewise stated to be almost universally had recourse to throughout the eastern and middle states of North America. And it probably exists in different other countries and districts.

It consists of a light moveable roof, formed of some sort of suitable and convenient materials for the purpose, which is capable of being raised or let down at pleasure over the staddle upon which the stack is built. The methods of forming and managing the arrangement of it are these. At the distance of about four feet from the corners of the staddle or stack-frame, are sunk four strong boxes, well rammed and secured in the ground, and of sufficient capacity to receive about three feet in length of a large pole or spar, rounded from a square of six inches, being made a little tapering towards the top, and thirty feet in length: on the upper end of this spar or pole is fixed a stout ring or ferrule, from which is projected a strong iron hook: the four posts or poles thus formed and fitted up are placed in the boxes at the different corners of the staddle. A two-sheave tackle is then hitched to the hooks at the tops of the poles or posts, and a one-sheave tackle to each corner of the roof, resting upon the staddle, and presenting at each corner a portable hoop, or collar, to enclose the different poles or posts on which it traverses up and down, keeping all firm, steady, tight, and compact together. These four tackles are manned with as many persons as may be found necessary to raise or lower the roof, and thus every sheaf of grain, or any other substance, which is brought home to be stacked under these staddle-roofs, is said to be more immediately and better secured from future damage, than if they were any otherwise placed under cover, or even stowed away in a barn or other similar building. This staddle-roof contrivance is said to be denominated a hay-barrack in the

state of Pennsylvania, in North America, in which district they are equally used for the purpose of protecting hay as well as corn.

It is noticed, that in climates or tracts of country which are frequently liable to sudden and violent storms, or thunder-showers, during the periods of hay-time and harvest, these staddle-roofs are mostly found particularly useful, proper, and necessary for the farmer, in preserving his crops of these kinds in the best and readiest manner.

The loose staddle-roofs, used in some situations, are mostly formed of some sort of very light thin boards of different extents, as ten, twelve, or more feet in length, and which are sometimes bent or curved on one side, and hollowed in the middle, in somewhat the manner of the pan-tiles which are used in covering buildings, so as to hook on to each other and carry off the wet. Roof-boards of this sort are in use on the farms at Winwick, one of the seats of the earl of Derby, in Lancashire, and found to answer the purpose very well, and to be particularly serviceable in showery or rainy seasons.

Staddle-roofs of the cloth kind are sometimes employed; the old sails of ships and other similar sorts of cloth being provided for the purpose.

STADDLE-Stones, those which are made use of in the construction of staddles, especially when they are intended for the purpose of corn, in order to keep rats and other sorts of vermin out of the stacks; and also for granaries, to keep them from climbing up into them. Various kinds of stones are employed in this way, as those of the free-stone, the slate-stone, the lime-stone, and different other kinds. See *STADDLE*.

Staddle-stones are mostly employed also for granaries, wherever the primary consideration of the farmer is the security of his corn. In these cases, the old method was to have them only put at the corners, while the buildings stood upon a frame of wood, but the improved mode is to have them coped all round, in somewhat the same manner as corn-stands, in order that they may be perfectly secure against the inroads of destructive vermin.

For granaries placed on staddle-stones, it has been lately suggested, in order to prevent vermin from getting up the outward steps, that such steps should be fixed on the inside of the lower parts of the door, which are to be balanced with weights, so that a slight effort may be capable of bringing them down on blocks of stone, which are to form the first steps for the purpose, such blocks of stone being twenty-four feet by fourteen in the clear. The doors, in such cases, must, of course, project in some degree in being brought forward, so as to reach the ground, or come near to it, for the purpose of affording a ready and easy entrance into the repositories.

STADE, in *Geography*, a town of the duchy of Bremen, with a strong fort, on a small river, about a mile from the Elbe; formerly the capital of a county and residence of the counts. It is now the seat of the regency of the duchies of Bremen and Verden, and also of the chancery, chief court of justice, and consistory, and contains three churches. Its two burgo-masters are counsellors of state. It was formerly a place of considerable trade, and from the year 1586 to 1612, an English staple, which was removed to Hamburg. After having undergone several revolutions and changes of masters, it was occupied in 1715 by the troops of Brunswick. In 1757 the fortifications of it were completed; 24 miles W. of Hamburg. N. lat. 53° 42'. E. long. 9° 21'.

STADECKEN, a town of Germany, in the palatinate of the Rhine; 11 miles W. of Oppenheim.

STADELHOFEN, a town of Bavaria, in the bishopric of

of Bamberg; 6 miles S.S.W. of Weifmain.—Also, a town of the duchy of Wurzburg; 7 miles S.S.E. of Gemunden.

STADEN, a town of France, in the department of the Lys; 7 miles S.E. of Dixmude.—Also, a river of Germany, which runs into the Nidda, 10 miles N. of Francfort on the Maine.—Also, a town of Germany; 20 miles N.E. of Francfort on the Maine.

STADIUM, σταδιον, an ancient Greek long measure, containing one hundred and twenty-five geometrical paces, or six hundred and twenty-five Roman feet; corresponding to our furlong.

The word is formed from the Greek στασις, station; and it is said, on this occasion, that Hercules, after running so far at one breath, stood still. The Greeks measured all their distances by stadia, which they call σταδίζεω.

Eight stadia make a geometrical or Roman mile; and twenty, according to M. Dacier, a French league; but according to others, eight hundred stadia make forty-one and two-thirds of a league.

Guillette observes, that the stadium was only six hundred Athenian feet, which amount to six hundred and twenty-five Roman, five hundred and sixty-six French royal feet, or six hundred and four English feet; so that the stadium should only have been one hundred and thirteen geometrical paces. It must be observed, however, that the stadium was different in different times and places. See MEASURES.

STADIUM was also the course, or career, in which the Greeks ran their races.

It is said to have derived its name from the measure of length mentioned in the preceding article; which being equal to the space of ground allotted for the foot-race, the course was from thence called the stadium, and the racers were named stadicis, or stadiodromi. The Eleans, indeed, pretended, that the stadium at Olympia was measured by the foot of Hercules, which being longer than that of an ordinary man, made their stadium longer than any other in the same proportion.

Vitruvius describes it as an open space one hundred and twenty-five paces long, terminated at the two extremes with two posts, called *carcer* and *meta*.

Along it was built a kind of amphitheatre, where the spectators were placed to see the athletæ exercise running, wrestling, &c.

Pausanias (lib. vi.) informs us, that the Olympic stadium was a terrace composed of earth; on one side of which was the seat of the Hellenodicks, or Hellenodics (see HELLENODICÆ), and over-against them on the other, was an altar of white marble, upon which the priests of Ceres Chamyne, and some virgins, had the privilege to sit and view the games. At the farther end of the stadium was the barrier, whence those who ran the simple foot-race began their course; and there, according to the tradition of the Eleans, was the tomb of Endymion.

According to the description given by Wheeler, in his travels, of the remains of the stadium at Athens, which was built by Herodes Atticus, it appears to have been a long place, with two parallel sides, closed up circularly at the east end, and open towards the other end, and about one hundred and twenty-five geometrical paces long, and twenty-six or twenty-seven broad, which gave it the name of a stadium.

Though the Olympic stadium does not seem to have been so splendid as this at Athens, or another at Delphi, built likewise of marble by the same magnificent citizen of Athens, yet we may suppose they were all formed upon the same mo-

del, as they were destined to the same use. In the stadium were exhibited those games which are properly called gymnastic. At either end of the course stood a pillar, the one constituting the barrier where the race began, and the other the goal, where the simple foot-race, instituted or revived by Iphitus, ended.

In the fourteenth Olympiad was added the *dioulos*, or double stadium; and the *diulodromoi*, who ran this race, turned round the pillar erected for that purpose at the end of the stadium, and returned to the barrier, where their race terminated. But the *dolichodromoi*, or runners in the race called *dolichos*, or the long course, which was introduced in the fifteenth Olympiad, and which consisted of seven, or twelve, or even of twenty-four stadia, when they came to the barrier, turned again round the pillar erected at that end, in order to continue their course, which required many doublings of the stadium.

The stadium, or race-ground, called the Olympic *hippodrome*, consisted of two parts; the first resembled in shape the prow of a ship, and was called the *barrier*. In this place were the stands for the horses and chariots, and here they were matched and prepared for the course. The next partition was the *lists*, or the spot on which the races were to be run. At the end of the course stood a pillar, which was the goal, round which the candidates were to turn; and that rider or driver who could make the narrowest turn and approach nearest to it, had the fairest chance, *ceteris paribus*, of surpassing his rivals. To this Horace alludes in the expression, *Meta fervidis evitata rotis*. Beyond this goal, there was a figure placed on purpose to frighten the horses, called *Taraxippus*, or the *terrifier of horses*. It is probable, that some tricks were practised under the disguise of this figure, to render the victory more difficult, and of course more honourable, or to try and prove the resolution and temper of the horses. On each side of the course, from one end to the other, the spectators were placed; the most advantageous stations being assigned to the judges of the games, and other distinguished persons. In that place where the horses stood which were to run, a long cable was drawn from one side to the other, which served the purpose of a barrier; about the middle of the prow already mentioned, an altar was erected, upon which stood a brazen eagle with outstretched wings, and the figure of a brazen dolphin was likewise placed at the entrance of it. This last was so contrived, that when the president of the races thought proper to put it in motion, it would ascend at once to such a height, as to be visible to all the spectators. This eagle was dedicated to Jupiter, the patron god of the Olympic games, as the dolphin was sacred to Neptune, the supposed creator of the horse. In the moment when the eagle sprang into the air, the dolphin sunk under ground; and upon this signal, the cable was removed, and the horses advanced from the stands into the course, where they stood ready to start. The signal for starting was probably the same as in the chariot races, and was given by the sounding of a trumpet. The space of ground round which the horses were to run, and the number of times which they were required to run round it, will make their course or heat to amount to about four miles, or somewhat more. See on this subject West's Odes of Pindar, and Preliminary Dissertation on the Olympic Games, p. 43, &c. p. 84, &c. For other particulars, see HIPPODROME.

There were stadia likewise covered over, and encompassed with colonnades and porticoes, serving for the same exercises in bad weather. Captive children used to run the stadium.

A more natural derivation of the word stadium, from στασις,

statis, station, than that popular one mentioned in the last article, may be drawn from the *athletæ* stopping and resting when at the end of this course: whence the name might be applied to the same distance measured in any other place.

STADIUS, JOHN, in *Biography*, a German astronomer, was born in 1527. and studied at the university of Louvain, where he applied himself with so much diligence to mathematical pursuits, that he was very soon qualified to become a professor; he resided some time at Liege, and was allowed a salary by the bishop, for whom he annually calculated an ephemeris, adapted to the meridian of Antwerp, beginning from the year 1554. The ephemerides of Stadius were much used by the celebrated Dutch mathematician Stevin, though they were afterwards proved to be in many respects inaccurate. From Louvain, Stadius went to Savoy, with a commission as mathematician to the king of Spain, and he removed thence to Bruges, in Flanders, where he composed his "*Falti Romanorum*," which were published by Hubert Goltzius, whose daughter was married to his son; after this he was invited to France as professor royal of mathematics, and lived there in high respect and honour till he became enthusiastically attached to judicial astrology, and on the faith of that pretended art he began to predict future events. He died in the year 1579, in the fifty-second year of his age. He is author of some astrological treatises, and translated a work of Hermes Trismegistus, entitled "*Jatro-mathematicæ, ad Amonem Ægyptium conscripta*."

STADL, in *Geography*, a town of the duchy of Stiria; 8 miles N.E. of Gratz.

STADLİN, or STADLAU, a town of Silesia, in the principality of Breslau, on the Stober; 27 miles E. of Breslau.

STADLKIRK, a town of Austria; 4 miles N. of Steyr.

STADMANIA, in *Botany*, so named by Lamarck, in commemoration of a botanical traveller, M. Stadman, to whom he was obliged for the knowledge of the plant.—Lamarck *Illustr. t. 312*. Poiret in *Lam. Dict. v. 7. 376*.—Class and order, *Ötandria Monogynia*. Nat. Ord. *Sapindi*, Juss.

Gen. Ch. *Cal.* Perianth inferior, minute, of one leaf, with five short, oval, rather pointed, teeth. *Cor.* none. *Stam.* Filaments eight, thread-shaped, erect, rather longer than the calyx; anthers terminal, roundish. *Pist.* Germen superior, oblong; style very short; stigma triangular. *Peric.* Berry dry, globose, generally attended by the rudiments of another abortive one. *Seed* solitary, globose, large.

Ess. Ch. Calyx with five teeth. Corolla none. Stigma nearly sessile. Berry dry, with one seed.

1. *S. oppositifolia*.—Native of the island of Mauritius, where the French call it *Bois de fer*, or Iron-wood, from the hardness of the wood, which is employed for many useful purposes. The half-ripe berries, preserved in a moist form with sugar, are said to be tolerably good.—The tree is large and handsome, with a tall erect trunk, and spreading, opposite, round branches, of a greyish hue, downy when young. Poiret describes the leaves as simple, opposite, stalked, elliptic-lanceolate, coriaceous, perfectly entire, obtuse, slightly contracted at their base, smooth; shining above; paler and brownish beneath; their length three or four inches, breadth an inch, or inch and half. Footstalks three lines long. Flowers about the ends of the branches, in long, stalked clusters, with short, thick, often aggregate, partial stalks, having a small tuberculated permanent bractea at the base of each.—Such is Poiret's account; but Lamarck's plate evidently represents the leaves as alternate, pinnate, of from three to six pair of opposite leaflets; the

clusters of flowers being axillary. Such we believe to be the true nature of the plant. We have specimens brought by Commerçon from the isles of Mauritius and Bourbon, and marked *Bois des Gaulettes*, a name which does not occur in Jussieu, which, if not the same species, have every appearance of belonging to this genus. In these the leaves are alternate, abruptly pinnate, their common footstalks slightly winged. The flowers are in short, dense, compound, axillary, silky clusters. *Calyx* and *germen* very silky. *Fruit* nearly smooth, crowned with the permanent style and stigma. We dare hardly suspect so much inaccuracy of description in the authors cited as to take this for their very identical *Stadmania*, but that it belongs to the same genus there can scarcely be any doubt. We find here and there even the appearance of a bud, or abortive leaflet, at the end of the common footstalk, as represented more strongly by Lamarck, which perhaps led Poiret to take the compound leaf for a branch.

STADT-AM-HOF, in *Geography*, a town of Lower Bavaria, on the Danube, opposite to Ratibon, and connected with it by a bridge. It has two convents and an alms-house, to the latter of which Lutherans and Roman Catholics are equally admissible; the objects of relief, as well as the governors, being half Lutherans and half Catholics; its yearly revenue is said to amount to 80,000 florins.

STADTBERG, or MARSBERG, a town of the duchy of Westphalia, on the Dimel; 20 miles S. of Paderborn.

STADTHAGEN, a town of Westphalia, in the county of Schauenburg, endowed in the 13th century with considerable privileges, and surrounded with ditches, ramparts, walls, and towers. From its sufferings during the 30 years' war, it has not yet recovered. The palace of the prince of Schauenburg-Lippe is in this town, and the gardens have a mineral spring; 8 miles E. of Minden. N. lat. 52° 18'. E. long. 9° 20'.

STADTHOLDER, STADTHOULDER, or *Stadholder*, a governor or lieutenant of a province, in the United Netherlands, particularly that of Holland, where the word (now indeed almost obsolete) has been most used, by reason of the superior importance of the government of that province.

Menage derives the word from *stad*, *state*; and *boulder*, *holding*, *q. d.* lieutenant of the states. Others will have it compounded of *stad*, or *stede*, *stead*, or *place*; and *boulder*, *holding*; in regard this officer held the place of the counts, and represented them in their absence.

The stadtholder, *i. e.* the stadtholder of Holland, was the first member of the republic: he was chief of all the courts of justice, and might preside therein when he pleased. All sentences, judgments, &c. were dispatched in his name. When an office became vacant in any of the courts, the states proposed three persons to the stadtholder, who chose one of them. He even pardoned criminals, which is a sovereign prerogative: and he had the choice of scabines, or chief magistrates, in each city; to which end the council of the city always presented him two persons, one of whom he appointed.

In several cities he had the same right of nominating the burgo-masters and counsellors; as at Rotterdam, Dort, &c. He had also a power to cashier the magistrates, and put others in their room, when he found it necessary for the public good, upon giving a reason for the same.

By article VI. of the union of Utrecht, the States constituted him arbiter of all the differences that might arise between the states of the several provinces, or between the cities and the members of the states of the province.

To the dignity of stadtholder was inseparably annexed that

that of captain and admiral-general of the province; in which quality he named all the officers, and disposed of all military posts. He took care of the execution of the ordinances of the states; and his authority gave him a right to receive, and give audience to ambassadors from foreign princes, and even to send ambassadors on his own private affairs.

The office of stadtholder was very ancient: the counts, not being able to reside in Holland, appointed stadtholders to command in their absence in the several provinces; besides a governor-general of all the seventeen provinces of the Netherlands.

William I., prince of Orange, was made stadtholder of Holland and Zealand in 1576, and soon after of the provinces of Guelders, Utrecht, and Overysel, at the time when the Dutch shook off the Spanish yoke; which enabled him to contribute greatly to that happy event.

In 1584, when William I. was assassinated, the same dignity was conferred, by the same provinces, on his son prince Maurice, who was succeeded by his brother Frederic-Henry in 1625. Upon his death, in 1647, his son, William II., became stadtholder, and he possessed this dignity till his death in 1650. The ambitious views of this prince having given offence to the provinces of the republic, they took measures to reduce the authority of the stadtholder; and the province of Holland formed a design of excluding his son, William III. prince of Orange, afterwards king of England, from the dignity possessed by his ancestors. However, in 1672, Holland, alarmed at the progress of Lewis XIV., declared William stadtholder, and captain-general of the forces of the republic, with the same power which his predecessors had enjoyed. Their example was followed by four other provinces; and, in 1674, on account of his signal services to the states of Holland, they declared him hereditary stadtholder, and determined that his dignity should descend to his male heirs. He was succeeded by his appointed heir, the prince of Nassau-Dietz, hereditary stadtholder of the provinces of Friesland and Groningen, from whom the dignity descended to his son, William-Charles-Henry-Frison. In 1722 he was named stadtholder by the province of Guelderland.

In 1747, the stadtholdership was extended to all the seven united provinces, and made hereditary in the male and female representatives of the family of Orange. For other particulars respecting the change of government, &c. see HOLLAND and UNITED PROVINCES.

STADTKYLL, or STATKYL, in *Geography*, a town of France, in the department of the Roer, on the Kyll; 8 miles N.N.W. of Gerolstein.

STADTLAND, a small island in the North Atlantic sea, near the coast of Norway. N. lat. 62° 10'. E. long. 5° 50'.

STADT-LOEN, a town of Germany, in the bishopric of Munster; 23 miles W. of Munster. N. lat. 52° 6'. E. long. 6° 54'.

STADT-OLDENDORF, a town of the principality of Wolfenbittel, containing about 200 houses; 15 miles W.N.W. of Einbeck.

STADTSBUGDEN, a town of Norway, in the province of Drontheim; 10 miles N.N.W. of Drontheim.

STADT-STEINACH, a town of Bavaria, in the bishopric of Bamberg; 7 miles N.E. of Culmbach.

STÆBIS, in *Botany*, a name given by the modern Greeks to a plant growing very plentifully in the island of Crete, and seeming to be the same with the *stabe* of the ancient Greeks, when used as the name of the pheos or hippopheos; for the ancients used it also as the name of a

low plant of the gnaphalium kind, growing in marshy places, with which they used to stuff beds, &c.

STÆBIUM, a name given by the modern Greeks to the plant called *hippopheos* by Dioscorides: that author also sometimes called it *stabe*.

STÆBROECK, in *Geography*, a town of Guiana, on the east coast of the river Demarari.

STÆCHAS, in *Botany*. See CASSIDONY.

STÆHELINA, appears to have been a name of Haller's, which Linnaeus removed to the present genus. There have been several Swiss botanists, authors of inaugural dissertations, or other small treatises not generally current, of the name of Stæhelin, or Stehelin. Haller seems to have intended principally to commemorate his beloved and regretted friend and companion, Benedict Stæhelin, to whom he addresses two epistles among his poems. (See his *Biblioth. Botanica*, v. 2. 175, and *Hist. Stirp. Helvet.* v. 1. 136.) In the latter place he contends that he had given this name to the *Barbisa alpina*, before Linnaeus dedicated that genus to his own, no less tenderly lamented, friend Bartsch. (See *Fl. Succ.* ed. 2. 211.) However the right of priority may be circumstanced, the *Barbisa* of Linnaeus, like his *Stabelina*, has prevailed; nor can the warmest admirer of Haller or of Stæhelin now regret, that the latter has obtained a most elegant and remarkable genus, of the compound tribe; he having particularly written upon that order, in a dissertation published at Basil in 1721, after the distinguished example of Vaillant, of whom he had been a favourite disciple.—Linn. Gen. 415. Schreb. 546. Willd. Sp. Pl. v. 3. 1783. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 4. 512. Sm. Pl. Ic. 71. Prodr. Fl. Græc. Sibth. v. 2. 162. Juss. 175. Gærtn. v. 2. 412. (Serratula; Lamarck Illustr. t. 666. f. 3, 4.)—Class and order, *Syngnesia Polygamia-aqualis*. Nat. Ord. *Compositæ discoidea*, Linn. *Cinarocephala*, Juss.

Gen. Ch. *Common Calyx* oblong, cylindrical, slightly swelling, imbricated with lanceolate erect scales, each terminated by a small, short, coloured scale. *Cor.* compound, uniform, tubular: all the florets equal, perfect, of one funnel-shaped petal, whose limb is bell-shaped, in five equal, acute segments. *Stam.* Filaments in each floret five, capillary; anthers united into a cylindrical tube, each of them having two elongated teeth at the base. *Pist.* Germen very short; style thread-shaped; stigmas two, oblong, obtuse, erect. *Peric.* none but the unchanged calyx. *Seeds* solitary, oblong, very short, quadrangular: down branched or cloven, longer than the calyx. *Recept.* flat, covered with very short, permanent, chaffy, branched scales.

Ess. Ch. Receptacle with branched scales. Seed-down branched. Anthers with a pair of threads at the base. Calyx imbricated, rather swelling.

1. *S. dubia*. Rosemary-leaved Stæhelin. Linn. Sp. Pl. 1176. Willd. n. 1. Ait. n. 1. Dickf. Dr. Pl. n. 13. Gerard Gallop. 190. t. 6. (Serratula; Lamarck f. 4. Chamæchrysocome prælongis purpurascensibusque Jaceæ capitulis; Barrel. Ic. t. 406. Stæchas citrina altera inodora; Lob. Ic. 486.)—Leaves sessile, linear, somewhat toothed; downy and white beneath. Seed-down smooth, about twice as long as the nearly cylindrical calyx.—Native of dry open hills and fields, in Spain, Italy, and the south of France. Parkinson appears to have cultivated it, but we have never met with the plant in any garden, nor does it make a figure even in catalogues. The *stem* is shrubby, of humble growth, bushy, with round leafy branches, clothed with close white cottony down; as are also the backs of the very narrow, toothed, slightly revolute leaves, each above an inch long. *Flowers* terminal, erect, either solitary or

somewhat corymbose, making a singularly elegant appearance, even in dried specimens, on account of their partly downy *calyx*, variegated with rose-colour and brown, furnished by the tuft of silvery *seed-down*, intermixed with the long, tubular, crimson *florets*, which are eight or ten in each calyx. The genus of this species was considered doubtful by Linnæus, because the *seed-down* is described by Gerard as simple. It is, however, curiously branched from the base, which, added to the bearded *anthers*, sufficiently establishes the character, though we have not examined the scales of the *receptacle*. The habit, moreover, is well marked, and proves this genus, which some French botanists have scrupled to admit, to be one of the most natural, as it unquestionably is the most elegant, of the syngeneis family in Europe. Willdenow has fully altered the specific character for the worse.

2. *S. arborefcens*. Storax-leaved Stæhelina. Linn. Mant. 111. Willd. n. 2. Ait. n. 2. Schreb. Dec. t. 1. Sm. Fl. Græc. Sibth. t. 845, unpublished. (Cyanus arborefcens altera, styracis folio; Alpin. Exot. 33. t. 32. Ciano fruticoso di Candia; Pon. Bald. 165.)—Leaves stalked, elliptical, entire; silky beneath.—Native of rocks on the white mountains of Crete, and in the isles of Hyeres. Miller is said to have cultivated this fine plant, before the hard winter of 1740, which was fatal to so many oriental varieties in the English gardens. The *stem* is woody, two feet high, sometimes an inch in diameter, with round, leafy, silky, ascending branches. *Leaves* remarkably handsome, elliptical or somewhat heart-shaped, obtuse, two or three inches long and half as broad; smooth and dark-green above; white and beautifully silky beneath; with one rib, and many branching veins. *Footstalks* silky, about an inch long. *Flowers* terminal, corymbose, light purple. *Calyx* slightly swelling, its scales roundish-ovate, partly silky. *Anthers* with a double feathery beard. *Seed-down* roughish, cloven in a finger-like manner, like the scales of the *receptacle*.

3. *S. fruticosa*. Smooth Plantain-leaved Stæhelina. Linn. Syst. Nat. ed. 12. v. 2. 538. Willd. n. 3. (Centauræa fruticosa; Linn. Sp. Pl. 1286. Serratula; Lamarck f. 3. Cyanus repens; Lob. Ic. 548.)—Leaves obovato-lanceolate, entire, tapering at the base, smooth on both sides.—Native of Crete and the Levant. Dr. Sibthorp mentions having gathered it on rocks in the island of Chéro, but no specimens are found in his herbarium. The *stem* is shrubby, with round, minutely roughish, branches. *Leaves* near two inches long, dotted, tapering down into a winged footstalk. *Flowers* said to be white. *Calyx* nearly cylindrical, with oblong, acute, partly downy scales. *Seed-down* rough. Its peculiar structure, or that of the scales of the *receptacle*, our specimens will not allow us to ascertain.

4. *S. hastata*. Halberd-leaved Stæhelina. Vahl. Symb. v. 1. 70. Willd. n. 4. (Chrysocoma spatulata; Forsk. Ægypt.-Arab. 147.)—"Stem shrubby. Leaves hastate, hoary, sessile."—Gathered by Forskall near Tæss, in Arabia Felix. A low rigid *shrub*, with numerous, round, hoary *branches*. *Leaves* not half an inch long, very obtuse, dilated into an horizontal lobe at each side; most hoary beneath; tapering at the base. *Flowers* solitary, sessile, towards the extremities of the branches. *Calyx* at first cylindrical, then turbinate, with linear keeled scales. *Seeds* villous; *down* rusty, rather rigid, very finely toothed where it projects beyond the calyx. *Receptacle* scarcely chaffy.—Vahl, from whom we borrow this description, as we have seen no specimen, might possibly not be aware of the true characters of a *Stæhelina*, and therefore might, like Linnæus, Gerard, and others, not observe whether the *seed-down* were branched in this species. Its genus therefore remains doubtful.

5. *S. uniflosculosa*. Simple-flowered Stæhelina. Sm. Prodr. Fl. Græc. Sibth. n. 2016. Fl. Græc. t. 846, unpublished.—Leaves ovate, acute, toothed; downy and snow-white beneath. Stem somewhat shrubby. *Calyx* single-flowered.—Found on mount Parnassus, by Dr. Sibthorp. The *root* of this very pretty species is strong and woody, bearing numerous, partly decumbent, branched, leafy, hoary, shrubby *stems*, about a span high. *Leaves* stalked, an inch or an inch and half long; smooth and dark-green above; very white beneath; their points somewhat reflexed. *Flowers* five or six at the top of each stem, corymbose, erect, small. *Calyx* cylindrical, brown, shining, nearly smooth, half an inch long, containing a solitary, purple, flarry *floret*, with tawny *anthers*, whose base is furnished with a double feathery beard. *Seed-down* cloven in a digitate manner. Nothing can be more certain than the genus of this plant, though its single *floret* forms one of those exceptions in its natural order, which render absolute definitions, in botany, scarcely ever possible.

6. *S. ilicifolia*. Holly-leaved Stæhelina. Linn. Suppi. 358. Willd. n. 5. Sm. Plant. Ic. t. 71.—Leaves opposite, on short stalks, heart-shaped, bluntly toothed; smooth and shining above; woolly beneath. Points of the calyx-scales naked.—Native of New Granada, from whence Mutis sent specimens to Linnæus. The *stem* is shrubby, or arborescent, with round leafy *branches*, downy when young. *Leaves* rather above an inch long, rigid, obtuse, revolute, coarsely toothed, reticulated with veins; of a shining green, as if varnished, on the upper side; densely woolly and white beneath; on short, thick, hoary *stalks*, remarkable for being opposite, those of all the foregoing being alternate. *Stipulas* none. *Panicles* terminal, corymbose, densely woolly, with lanceolate woolly *bracteas*. *Calyx* almost hemispherical, very woolly; its inner scales with smooth, membranous, fringed, finally inflexed, points. *Florets* numerous, yellow; their limb erect. *Anthers* with two points at the base. *Seed-down* rough, or feathery, scarcely branched or digitate. Scales of the *receptacle* short, rigid, with two or three teeth.

7. *S. aquifolia*. Kermes-leaved Stæhelina. (Elichrysum arborefcens, ilicis cocciglandiferæ folio; Plum. Cat. Amer. 9. Ic. 114. t. 123. f. 2.)—Leaves scattered, on short stalks, roundish, abrupt, with spinous teeth; smooth and shining above; woolly beneath. *Calyx*-scales downy throughout.—Gathered in South America by Plumier. This is in many respects nearly akin to the last, though essentially distinct. The *leaves* are but half the size, with finer veins, and sharp spinous teeth. *Flowers* yellow, sessile, either solitary, or several together, at the leafy summit of each branch. *Calyx* longer, and more regularly imbricated, its scales lanceolate, finely and uniformly woolly, without any membranous inflexed points. The *anthers* have two bristly naked points at their base, like the preceding, and the *seed-down* is rough; we cannot perceive it to be branched. We have not been able to examine the *receptacle*. There cannot be the least doubt of this plant belonging to the same genus as the last, and the points in which it differs specifically, serve to bring it nearer to other *Stæhelina*.

8. *S. gnaphalodes*. Soft-linear-leaved Stæhelina. Linn. Sp. Pl. 1176. (Leyfera squarrosa; Thunb. Prodr. 160. Willd. Sp. Pl. v. 3. 2133. Jacea æthiopica, flæchadis citrinæ majoribus tomentosis foliis, capitulorum spinis et squamulis ex aureo colore nitentibus; Pluk. Almagest. 193. t. 302. f. 3.)—Leaves thread-shaped, woolly. *Flowers* solitary, on long stalks. Points of the calyx-scales reflexed, membranous, naked, acute.—Native of the Cape of Good Hope,

Hope, but rare, and as yet a stranger in our greenhouses. The *plant* is shrubby, branched, clothed throughout with white cottony down. *Leaves* an inch and a half to three inches long, very narrow, obtuse, alternate. *Flower-stalks* terminal, solitary, erect, simple, single-flowered, twice as long as the leaves, woolly like them. *Calyx* ovate, of numerous imbricated scales, the inner ones gradually longest, as in the last, all woolly, with shining, tawny or brown, membranous edges, and a strongly reflexed, tapering, almost pungent, smooth point, of the colour and texture of the edges. *Florets* apparently yellow. *Anthers* with two slightly feathery points at the base. *Seed-down* feathery, divided at the base into several palmate portions, like the stamens of a polyadelphous flower. *Scales* of the receptacle crenate, or many-cleft, at the summit.—We know not on what grounds this has been referred to *Leysera*, there being in our specimens no appearance of a radius, nor any thing of the peculiar habit or characters of that genus. But if it were so, this, being the original *Stæbelina*, ought not to be changed. The more particular explanation, than heretofore, which we have given of the rest of the species, answering also to this in so many peculiar and essential characters, will we trust establish the genus before us beyond any possibility of doubt. Plukenet's figure of *S. gnaphalodes*, the only one we can find, though rude, is characteristic, especially in the points of the calyx.

9. *S. spinosa*. Thorny-leaved *Stæbelina*. Vahl Symb. v. 1. 69. Willd. n. 6. (*Chryfocoma mucronata*; Fork. Ægypt-Arab. 147.)—Leaves nearly cylindrical, simple or pinnatifid, with awl-shaped spinous points. Calyx-scales elliptic-lanceolate, erect.—Found by Forskall in Egypt. The *stem* is shrubby, bushy, rigid, with angular branches. *Leaves* also rigid, slender, like branched thorns, an inch or inch and half long, roughish, alternate. *Flowers* terminal, few, somewhat corymbose, yellow, according to Vaillant, who is cited by Vahl. *Calyx* at first cylindrical, then spreading and turbinate, of many, nearly smooth, imbricated, straight scales, each tipped with a scarcely discernible, erect, prickle. *Seeds* hairy, their down very minutely toothed according to Vahl, and the *receptacle* clothed with short bristly scales. We have not seen these parts, nor the *anthers*, so that we cannot be certain of the genus. One of Forskall's specimens, now before us, has decidedly pinnatifid *leaves*.

10. *S. Chamæpeuce*. Pine-leaved *Stæbelina*. Linn. Syst. Nat. ed. 12. v. 2. 538. Willd. n. 7. Ait. n. 3. Sm. Fl. Græc. Sibth. t. 847, unpublished. (*Serratula Chamæpeuce*; Linn. Sp. Pl. 1147. *Chamæpeuce*; Alpin. Exot. 77. t. 76. *Stebe capitata*, overo *Chamepino fruticoso* di Candia; Pon. Bald. 75. *Jacea fruticans*, pini folio; Pluk. Phyt. t. 94. f. 3.)—Leaves linear, crowded, elongated, revolute; downy beneath. *Calyx* ovate. Scales lanceolate, erect.—Native of rocks in Crete and Cyprus, where, as well as in Greece, and on mount Athos, it was gathered by Dr. Sibthorp. Parkinson mentions this species as cultivated here in 1640. It is still preserved in curious greenhouses, and may be seen at Chelsea, flowering all summer long. The *stem* is shrubby, bushy, stout, two or three feet high, its round cottony branches clothed with abundance of long, narrow, drooping, revolute, acute *leaves*; smooth and green above; covered with white cottony down beneath; their base somewhat dilated. *Flowers* forming a sort of spare leafy panicle at the top of each branch, erect. *Calyx* ovate, or nearly globose, bigger than a hazel-nut, of numerous, closely imbricated, lanceolate, acute, downy, crimson-pointed scales. *Flowers* crimson. *Anthers* with a pair of simple, not feathery, bristles. *Seeds* polished, ob-

ovate, variegated with brown; their *down* the length of the calyx, feathery, but not branched or palmate. Scales of the *receptacle* in many bristly segments.

11. *S. ? imbricata*. Imbricated *Stæbelina*. Berg. Cap. 233. Linn. Mant. 2. 281. Willd. n. 8. Thunb. Prodr. 143.—“Leaves ovate, pointed, imbricated; downy beneath. *Calyx* turbinate; its inner scales with reflexed coloured points.—Native of the Cape of Good Hope. The *stem* is shrubby, a span high, with clustered downy branches. *Leaves* sessile, above a line in length; of a glaucous green, nearly smooth, and slightly rugose, above; white and downy underneath; closely imbricated. *Flowers* usually two at the end of each branch, one sessile, the other stalked. *Calyx* downy, of numerous, linear-lanceolate, acute, fringed scales; the inner ones rather the longest, and each tipped with a blueish, chaffy, spreading point, resembling a radiant floret. *Seed-down* simple, minutely feathery, violet-coloured. *Receptacle* naked, rough, with elevated points. Such is the description of Bergius, who mentions no appendages to the *anthers*, nor does the *receptacle*, or the *seed-down*, indicate a *Stæbelina*. Having seen neither specimen nor figure, we must leave the matter undecided.

12. *S. corymbosa*. Corymbose Cape *Stæbelina*. Linn. Suppl. 359. Willd. n. 9. Thunb. Prodr. 143.—Leaves wedge-shaped, toothed; downy beneath. Panicles corymbose. *Calyx*-scales rounded, obtuse.—Native of the Cape of Good Hope. The *stem* is shrubby, with hoary, furrowed, leafy branches. *Leaves* scattered, an inch long, on short stalks, abrupt, toothed at the extremity; green and smooth above; white, finely downy, somewhat silky, beneath. *Flowers* numerous, on angular, downy, corymbose, terminal stalks. *Calyx* not half an inch long, of many broad, brown, downy, erect, closely imbricated scales. *Florets* white or yellowish. *Anthers* with a double spur at the base. *Seed-down* rough, simple, scarcely fasciculated. *Receptacle* small, cellular, not perceptibly scaly. The habit, and the spurred *anthers*, seem to justify us in keeping this species among the *Stæbelinae*, notwithstanding the *receptacle*.

STAFARDA, in *Geography*, a town and abbey of France, in the department of the Stura; 3 miles N. of Saluzzo.

STAFF, BACULUS, an instrument ordinarily used to rest on, in walking. Card. Bona observes, in his treatise of liturgies, that, anciently, those who used a staff in the church to lean on, were obliged to lay it by, and to stand alone, firm and upright, while the Gospel was reading, to testify their respect by their posture; and to shew they were ready to obey Jesus Christ, and to go wheresoever he should command them.

The staff is also frequently used as a kind of natural weapon, both of offence and defence. The Lacedæmonians never wore any swords in the time of peace; but contented themselves with a thick, crooked staff, which was peculiar to them.

Among the Romans, M. St. Evremont observes, blows with a staff were the gentlest correction they gave their slaves; inasmuch as they received them over their clothes. Among the masters of honour and arms, it is held a greater affront to be beaten with a staff than with a sword; because the sword is the instrument of war, the staff the instrument of outrage.

Blows with a staff were very severely punished by the French laws: by a regulation of the marshals of France, in 1653, for reparations and satisfactions of honour, it is adjudged, that a person, who shall strike another with a staff, shall be imprisoned a whole year; unless six months be moderated, upon paying three thousand livres, applicable

to the nearest hospital; beside which, the offender is to ask pardon of the offended on his knees, &c. ready to receive from him a like number of blows with a staff; which, on some occasions, the latter may be obliged to give, if he have too much generosity to do it of himself.

By another regulation of the marshals in 1679, he who strikes with a staff after receiving blows with the fist in the heat of a fray, is condemned to two years' imprisonment; and to four, if he struck first with the fist.

STAFF, A, is used as an instrument for taking accessible or inaccessible heights. For the manner of operation, in taking the height of an accessible object, see **ALTITUDE**.

Inaccessible heights may likewise be taken by means of two staves. This must be done at two stations in a right line from the object, at each of which the staves are to be placed in such a manner, that the summit, or top of the height, may be seen along their tops in the same right line. Thus, suppose *A* (*Plate XIII. Geometry, fig. 17.*) the summit of the object whose height is to be measured, *D E*, *F G*, the two staves at the first station; and *R N*, *K O*, the same staves at the second, so placed, that the points *F D A*, *K N A*, are in the same right line. Through the point *N* let there be drawn the right line *N P*, parallel to *F A*: wherefore in the triangles *K N P*, *K A F*, the angles *K N P*, *K A F*, are equal; also the angle *A K F* is common to both; consequently the remaining angles *K P N*, *K F A*, are equal. And $P N : F A :: K P : K F$. But the triangles *P N L*, *F A S*, are similar; therefore $P N : F A :: N L : S A$. Thence alternately $K P : N L :: K F : S A$; *i. e.* as the excess of the distance of the staves at the second station above their distance at the first, is to the difference of their lengths; so is the distance of the two stations of the shorter staves, to the excess of the height sought above the height of the shorter staff. Wherefore *S A* may be found by the rule of three; to which add the height of the shorter staff, and the sum will give the whole inaccessible height, *A B*.

Staves may be used for measuring any distance: suppose *A B* (*fig. 18.*), to one of whose extremities we have access. Let there be a staff fixed at the point *A*; then going back to some sensible distance, in the same right line, let another be fixed in *C*, so that both the points *A* and *B* may be covered or hid by the staff *C*. Likewise going off in a perpendicular, from the right line *C B*, at the point *A*, let there be placed another staff at *H*: and in the right line *C G K*, perpendicular to the same *C B* at the point *C*, and at such a point of it *K*, that the points *K*, *H*, and *B*, may be in the same right line, let there be fixed a fourth staff. Let these be drawn, or supposed to be drawn, a right line, *H G*, parallel to *C A*. The triangles *K H G*, *H A B*, will be equiangular: wherefore $K G : G H (= C A) :: A H : A B$; *i. e.* as the excess of *C K* above *A H* is to the distance betwixt the first and second staff, so is the distance betwixt the first and third staff to the distance sought. *Tr. Pract. Geom. p. 22—25.*

STAFF, in Heraldry. See **BASTON.**

STAFF, in Music, Riga, Ital., Portée, Fr., the five pa-

rallel lines upon which, and between which, musical characters or notes are written.

Guido Aretin, the great improver of the modern music, is said to be the first who introduced the staff, marking his notes by setting points (.) up and down them, to denote the rise and fall of the voice; and each line and space he marked at the beginning of the staff, with Gregory's seven letters, *a, b, c, d, e, f, g.*

But others will have the artifice of an older date; and Kircher particularly affirms, that in the Jesuits' library at Messina, he found an old Greek MS. book of hymns, above seven hundred years old; in which some hymns were written on a staff of eight lines, marked at the beginning with eight Greek letters. The notes or points were on the lines, but no use was made of the spaces.

The ingenious and learned Dr. Burney has proved that parallel lines were of higher antiquity than the time of Guido. It appears from an ancient MS. treatise on music by Odo the monk, written about the year 920, that lines began to be used in the tenth century. They were eight or nine in number; and at first, the syllables of the psalm or hymn that was to be sung, were placed in the spaces between these lines: after this an alphabetic character was placed at the beginning of each line, capitals for the grave sounds, and minuscules for the acute: to this kind of notation succeeded points, a scale formed of which Dr. Burney has given from a tract written by the great musical monk Hubaldus, who flourished about the year 880. He has also produced three examples from ancient missals, one of which was written about the year 900, cited by P. Martini, in which only one line is used to ascertain the predominant sound of the chant; a red line for the clef of *F*, and a yellow one for that of *C*: and this, he says, seems to have been the first time that a line was drawn through notes of the same elevation, and the origin of clefs, which are only Gothic letters corrupted or disfigured.

Vincenzo Gallilei says, that a little before the time of Guido, the points were placed on seven lines only, without using the spaces; perhaps in imitation of the seven strings of the lyre. The regular staff of four lines was not generally used till the thirteenth century. Kircher, indeed, speaks of Guido's using five lines and five spaces, but, as Dr. Burney says, without authority. However, though lines without spaces, and spaces without lines, had been used before the time of Guido, he seems to have first suggested the use of lines and spaces together; and thus the lines, which by some had been made as numerous as the notes, were reduced to four: a number which, in missals and rituals, of the Romish church, has never since been exceeded. Indeed the use of a line for each note above mentioned, may never have arrived at the knowledge of Guido, who speaks the language of an inventor, with respect to lines and spaces, more than on any other occasion; and, if he be allowed the invention of lines and spaces, clefs will of course accompany them. Burney's *Hist. of Music*, vol. ii. p. 34, &c. p. 87, &c.

STAFF, in a Ship, a light pole erected in different parts of a ship, on which to hoist and display the colours. The principal of these is reared immediately over the stern, to display the ensign; another is fixed on the bowsprit, to extend the jack; three more are erected at the three mast-heads, or formed by their upper ends, to shew the flag or pendant of the respective squadron or division to which the ship belongs.

STAFF, Futtock, or Puttock-staff Rigging, are short pieces of rope, served over with spun-yarn, to which the shrouds are confined at the cat-harpins. Those for the lower and top-mast

top-mast rigging are to be made of iron in future in the navy.

STAFF, in *Rope-Making*, is an implement belonging to the nipper, being an oak bar seven feet long, and four inches square, one end of which is fixed in an iron trap on the upper plate of the nipper, whilst on the other end a weight is suspended, sufficient to press the tar out of the yarn. The "nipper" is formed of two steel plates, eight inches square, and half an inch thick, with a semi-oval hole in each, four inches wide, which, by the upper plate moving, enlarges or contracts, as the tarring of the yarn requires. It is thus fixed: a post, twelve inches square, is placed between the kettle and capstern, with a mortise cut eighteen inches long from the kettle's surface, and five inches wide. The under plate is turned up on each side, to form two grooves, and is let into the front side of the post from the lower part of the mortise: the upper plate has a dove-tail on the back, that slides up and down in a groove into the grooves of the lower plate, and by the staff, made fast to its front, it is elevated or depressed, and regulated by a weight suspended at the other end, so that the yarn receives no more tar than is required, and what is squeezed out drops in a trough, and returns into the kettle.

STAFFS for tops are round, from six to eight feet long, and from two and a half to five inches in diameter, which go through a hole in the top, or are confined under it by a bolt and tails: they run on a truck-wheel, as the rope closes. See *SPINNING-Wheel*.

STAFF, in *Surgery*. See *CATHETER* and *LITHOTOMY*.

STAFF, in *Surveying*, a kind of stand, on which to mount a theodolite, circumferentor, plain table, or the like, for use. It consists of three legs of wood joined together at one end, whereon the instrument is placed; and made peaked at the other, to enter the ground. Its upper end is usually fitted with a ball and socket.

STAFF, *Station*, an instrument consisting of two rulers that slide to ten feet, divided into feet and inches, with a moveable vane or sight, two of which are used with a level; and on the edges there are the links of Gunter's chain divided. Its chief use is for the easy taking off-sets. See *OFFSET Staff*.

STAFF, *Shepherd's*, in *Botany*. See *TEAZEL*.

STAFF-Tree. See *CELASTRUS*.

STAFF, in *Rural Economy*, a measure of nine feet, or half a customary rod. It also signifies the rod set up as a mark in levelling, surveying, &c. See *LEVELLING*.

STAFF and Band Hedge, a term applied to that kind of dead fence of this sort, which is formed and constructed by means of stakes and bands, or edders and eathers.

STAFF, *Churn*, a term applied to the round upright stem, or piece of wood of the staff kind, which, in churning in the old common upright churn, forms the butter from the cream or milk.

A very great and useful improvement has lately been made on the staffs of churms of this kind, by Mr. T. Fisher, an ingenious gunsmith at Ormskirk, in the county of Lancaster; which consists in the head or working part of the staff being formed with a sort of bevil, and its turning upon a swivel made of iron.

The two pieces of wood which form the head of the staff have commonly the following dimensions. Thickness one inch and a half, breadth two inches and a half, length thirteen inches, and from that to any other length, according to the size of the churn. They are joined together in a cross-like manner, by halving one into the other in the middle parts. All the edges on the under side are rounded, or bevilled off to some distance, so as to elevate or raise the

middle part a little above the rest of the head. This cross-formed head is connected with the staff by means of a swivel, which is one inch and three quarters in diameter, being turned perfectly smooth and round. There is a sort of tongue, which is four inches in length from the shoulder, and of an oblong form, which is passed up the staff, and held in its place by an iron peg; the lower round end of which, to the length of about half an inch, serves to steady the head of the staff. And there is a button fixed upon the upper side of the head, which notches into the staff, and keeps it steady in the time of collecting the butter, but when churning, the whole is left perfectly loose. The lower end of the staff, in this case, should be left rather thicker than in the common staff, in order that it may receive the button more perfectly.

STAFF, *Hand*, in *Agriculture*, the name of that part of the common flail which is held in the workman's hand while he is working with it, and to which the couple or other part of the flail is attached. The hand-staffs of flails were formerly mostly connected to the other parts of the tools by means of leather caps and thongs; but the improved method is now by iron caps, made in the manner of round half-circular staples in the middle parts, which connect with and work in the same sort of caps on the couples.

STAFF, *Plough Paddle*, a term sometimes applied to the small staff carried in the body of the plough, which is shod with iron, and employed for clearing away the adhesive earthy matter that hangs about the mould-board, and other parts of common ploughs.

STAFF, *Rack*, that sort of staff which is employed in forming racks for horses or neat cattle.

STAFF, *Tuck*, the name of that sort of staff which is made use of in emptying dung and some other kinds of carts.

STAFFA, in *Geography*, one of the islands of the Hebrides, Scotland, is noted in natural history for its vast basaltic columns and caves. (See *BASALT*.) This small island emerges from the Atlantic ocean, in the midst of a spacious bay, formed by several islands, of which those of Mull, Icolm-Kill, Col, and Tiree, are the chief. In civil government and jurisdiction it is included in the district of Mull, and shire of Argyle, and constitutes part of the parish of Kill-Ninian. It is about five leagues W. from the isle of Mull, and three leagues N.N.E. from Icolm-Kill. The form is oblong and irregular, and the whole extends about one mile in length, and half a mile in breadth, with steep and craggy coasts; its sides are entirely bare, and in many places it exhibits superb basaltic columns, with various caverns. It is accessible only by a small entrance on the west side, where the surface slopes towards the sea; but which will only admit a small boat, and that in calm weather. The most elevated part of the island is over the cave of Fingall, where it is 214 feet above the sea, at ordinary tides. The greatest length of Staffa is about one English mile, and its breadth half a mile. During the summer a few cattle are fed on this island, and are attended by a herdsman and his family, who have a small hut. More than half the circumference of the island is occupied by grand and regular colonnades of basaltes, which are completely exposed to the operations of the sea: the rest of the island exhibits the same basaltic appearances; but the pillars are bent and twisted in various directions; some lying nearly horizontal, and others forming segments of circles. The pillars are chiefly of five or six sides; but some of three, four, or seven. The diameters vary from one foot to four feet and a half: the surface of the large pillars is, in general, uneven; some are jointed, having the upper surface concave, with a correspondent convexity in the inferior; but in many

the surface is plain. The spaces between the perpendicular prisms are filled with a yellow sparry matter, of which the oxyd of iron, separated from the basalt, with some argillaceous earth, and specimens of zeolitic crystals, are the component parts. Near the landing-place the pillars are small, but their magnitude increases in the vicinity of the cave of Fingall. This natural curiosity of the island is 53 feet wide at the entrance, 117 feet in height, and 250 feet in length. The arch is composed of two unequal segments of a circle, which form a natural pediment. The mass by which the roof is crowned, or rather formed, is 20 feet in thickness at its lowest part. It consists of small prisms, inclining in all directions, closely cemented with a calcareous matter, and zeolitic crystallizations, which afford a striking contrast with the dark purple hexagons formed by the ends of the pillars, and exhibit the appearance of mosaic work. The bottom of the cave is filled with the sea. In very calm weather, a boat may sail into it; but if such an attempt should be made when the waves are in the slightest degree agitated, the vessel would be dashed to pieces. The only way of entering at such times is by a causeway on the eastern side, not more than two feet broad, formed by the bases of broken pillars, which being constantly washed by the spray, is very slippery and unsafe. At the further extremity is another small cave, which, from certain passages, emits an agreeable noise every time the water rushes into it, whence it has acquired the name of the "melodious cave." Besides the cave of Fingall, there is another, exhibiting the same appearance, though on a smaller scale. It is situated on the north side of the island, and is called the "Corvorant's cave."

Staffa, though one of the greatest natural curiosities in Europe, or perhaps in the world, has been till lately little noticed, and indeed scarcely known. The first person who particularly called the attention of the learned to this singular isle was Mr. Leach, a native of Ireland; who, in the year 1772, having been on a visit to Morven, in Argyleshire, in a fishing excursion, was charmed with the peculiar appearance of its rocks, and landed upon it. Soon afterwards, sir Joseph Banks, Dr. Von Troil, the learned bishop of Lincœeping, and others, in their voyage from Iceland, anchored in the Sound of Mull; and having been informed by Mr. Leach of the wonders which Staffa afforded, they visited the island, and an account of it was communicated by sir Joseph to Mr. Pennant, who published it in his "Tour to the Hebrides." Since that time it has excited the attention of various naturalists, who have given accounts of it in their respective works: among whom, M. de St. Fond and Dr. Garnett may be principally mentioned. The former, who visited the British dominions on a voyage of research, thus expresses himself respecting Fingall's cave. "This superb monument of a grand subterraneous combustion, the date of which has been lost in the lapse of ages, presents an appearance of order and regularity so wonderful, that it is difficult for the coldest observer not to be singularly astonished by this prodigy, which may be considered as a sort of natural palace. I have seen many ancient volcanoes, and I have given descriptions of several basaltic causeways and delightful caverns in the midst of lavas, but I have never found any thing which comes near to this, or can bear any comparison with it, for the admirable regularity of its columns, the height of the arch, the situation, the form, the elegance of this production of nature, or its resemblance to the master-pieces of art, though art has had no share in its construction." Similar to this are the animated observations of the learned prelate before-mentioned. "How splendid," says he, "do the porticoes of the ancients appear in our eyes, from the often-

tious magnificence of the descriptions we have received of them: and with what admiration are we seized on seeing the colonnades of our modern edifices! But when we behold the cave of Fingall, formed by nature in the isle of Staffa, it is no longer possible to make a comparison, and we are forced to acknowledge that this piece of nature's architecture far surpasses that of the Louvre, that of St. Peter at Rome, all that remains of Palmyra and Pœstum, and all that the genius, taste, and luxury of the Greeks, were ever capable of inventing." In Pennant's *Tour in Scotland*, 4to. 1790, and St. Fond's *Travels*, are accounts of this island, with plates.

STAFFELSTEIN, a town of Bavaria, in the bishopric of Bamberg, on the Lauter; 16 miles N.N.E. of Bamberg. N. lat. 50° 8'. E. long. 11° 3'.

STAFFORA, a river of Italy, which passes by Voghera, and runs into the Po, 8 miles W.S.W. of Pavia.

STAFFORD, a borough, market, and county-town, in the south division of the hundred of Pirehill, Staffordshire, England, is situated on the north bank of the river Sow, at the distance of three miles from its junction with the Trent: and is 16 miles N.W. from Lichfield, and 140 miles in the same direction from London. The earliest authentic mention of the town is in the Saxon chronicle, A.D. 913, when Ethelfleda, countess of Mercia, sister of king Edward the Elder, built a castle here, of which no vestige now remains: and Camden states, that in the following year king Edward built a tower on the north bank of the river. This tower Mr. Pennant supposes to have stood on the mount called Castle-hill, and now distinguished by the appellation of Bully-hill. Near it is an ancient structure, called Castle-church, built in various styles of architecture. Nothing worthy notice is mentioned respecting this town, from the erection of these castles till the Norman conquest, when it appears from the Domesday survey, that the king had here "eighteen burgesses in demesne, and twenty mansions of the honour of the earls." The same record states that the king built a castle here, the custody of which was given to Robert de Toncei, who in consequence took the name of Stafford. This castle does not appear to have stood long; but by whom, or on what account destroyed, is unknown. It was, however, restored in the reign of Edward III., and continued till the seventeenth century; when being garrisoned in support of the royal cause, it was taken by the parliament's forces, and demolished. Stafford appears to have been a town of considerable importance prior to the Norman conquest: early in the tenth century it was considered the chief town of the district: in the Domesday-book it is termed a city, and was at that time governed by two bailiffs: but the earliest charter of incorporation now extant was granted by king John, in the seventh year of his reign. This deed, however, evinces that it was incorporated at a much earlier period; as it merely confirms privileges enjoyed from "remote antiquity," and does not confer any new. The word used in this charter to point out the previous existence of these privileges is *antiquitus*, which certainly would not have been used to denote a period then so recent as that of the Conquest. King John's charter was confirmed by Edward VI., and many new privileges added to the town. Queen Elizabeth established the assizes and sessions here by act of parliament, in the first year of her reign. Mr. Gough states, that in her progress in 1575, she perceived the town to be on the decline; and being informed that it was partly owing to the removal of the assizes, she said she would restore that privilege for ever.

The form of Stafford is that of an irregular ellipsis, the greatest diameter whereof extends from south-east to north-west. The situation, though low, is very pleasant: the streets

Streets are well paved, and the houses in general built of stone, in a compact and regular manner. It anciently had four gates, and was defended, except on the side next the Sow, by a wall, and a ditch supplied with water from the river. When taken by the republican army in 1643, the wall was razed, and the ditch filled up, so that no remains of either can now be discovered. Under the charter of Edward VI. the civil government of Stafford was vested in a mayor, a recorder, ten aldermen, twenty common-councilmen, a town-clerk, and two sergeants at mace. Two representatives are sent to parliament, and have been so ever since the 23d year of Edward I. The right of election is in the mayor and burgesses; the number of voters being about four hundred. The chief manufactures in the town are those of boots, shoes, and cutlery. Tanning is likewise carried on to a considerable extent, as well for the exportation as home consumption of leather. A weekly market is held on Saturdays, and seven fairs, annually. In the year 1811, the population of Stafford was returned to parliament at 4868; the number of houses 885. The immemorial custom of *Borough English* is still retained in this town, whereby the youngest son succeeds to property, as heir at law, in preference to the elder children. Though Stafford may with propriety be considered as only one parish, there are two churches, St. Mary's and St. Chad's. The former is a spacious cruciform structure, consisting of a nave, two side aisles, a transept, and a chancel of three aisles, with an octagonal tower in the centre. This church appears to be of very remote origin: it has, however, been almost entirely rebuilt, but some remains of the ancient structure are still visible. The general style of architecture is the early pointed. The font is a singular remnant of antiquity, very large, and awkwardly constructed. Its height is three feet three inches: the lower part is two feet square; and is ornamented on three sides with human figures lying flat on their faces: on the fourth side is the figure of a ram. Among a variety of monuments, ancient and modern, in this church, those most worthy of notice are, an altar-tomb, in honour of lord Edward Aston, of Tixal, and his wife lady Ann; a monument to the memory of sir Edward Aston, who erected the ancient mansion of Tixal, tem. Hen. VIII. and his lady Joan; and one to lady Barbara Crompton, who, as the inscription informs us, "lyeth interred in the parish-church of St. Gregory, by St. Pauls, London." Near the church, to the westward, formerly stood an ancient building, which Mr. Pennant conjectures to have been the dean's house. The church of St. Mary, anterior to the reformation, was collegiate: king Stephen, at the commencement of his reign, bestowed it on the bishop and chapter of Lichfield and Coventry. At the dissolution, a dean and thirteen prebendaries were attached to it. The other church of Stafford, St. Chad, is a very ancient edifice. Early in the last century it was cased with brick; but some portions of the buttresses of the original building are still visible. St. Chad's parish is of very small extent, not containing more than 20 houses, the rents of which are chiefly paid to the dean and chapter of Lichfield cathedral. Besides the churches, there are places of worship for the Quakers, Independents, Presbyterians, and Methodists, of which sects the two latter are numerous. Of the other public buildings, the most conspicuous are; the county hall, a spacious modern edifice, situated near the centre of the town: it extends a hundred feet in front, and contains many handsome apartments. Behind the hall is a convenient market-place. The county infirmary, a plain building, in the Foregate; erected about the year 1772, according to Mr. Pennant; and supported by voluntary contributions, to

the annual amount of nearly 900*l*. The county gaol, situated opposite to the infirmary; an extensive modern structure, containing about 150 cells or apartments. The free-school, an ancient building, founded and endowed (as appears by an inscription in St. Mary's church) by king Edward VI., in the year 1550. Leland says, "there is a free school for grammar in Stafford, made by sir Thomas Countre, parson of Ingestre, by Heywodde and Syr Randol, a chantry priest of Stafford." Various alms-houses, at different periods, have been built and appropriated for the comfortable accommodation of the aged poor: each tenement has a garden annexed to it. Previous to the dissolution of religious houses, Stafford contained several monastic establishments. At the north end of the walls stood a house of Franciscans, or grey friars, founded, Erdeswick says, by sir James Stafford, of Sandon. King Henry VIII. granted it to James Leveson. A priory of black canons was founded here about the year 1180, and dedicated to St. Thomas á Becket, ten years after his death. Richard Peche, bishop of Lichfield and Coventry, had such a partiality for this house (of which he is by some authors considered the founder), that, resigning his see, he entered himself as one of the members, and so continued the remainder of his life. At the dissolution it was granted to Rowland, bishop of Lichfield. This house, which was situated on the banks of the river Sow, about two miles to the E. of Stafford, was inclosed by a strong stone wall; some remains of the building are still extant. About the middle of the fourteenth century, the Auln friars founded a religious establishment at the southern extremity of the town; a portion of ground having been granted to them by Ralph, lord Stafford, for that purpose. This house was given by queen Mary to Thomas Neve and Giles Isam.

About a mile and a half south-west from the town, on the summit of a hill, are the remains of the castle of the barons of Stafford: the chief portion now standing is the keep, of which each angle is surmounted by a small octangular tower. At a small distance to the south of the castle stood the manor-house, the usual residence of the ancient and powerful family to which this town has given the title of baron, viscount, and earl, from the time of William the Conqueror till the beginning of the last century, when it became extinct; but was again revived in the year 1786, by the elevation of earl Gower to the dignity of marquis of Stafford, which title is now enjoyed by his son, the second marquis. Among the more distinguished natives of this town we find John Stafford, a Franciscan friar, a philosopher and divine of considerable celebrity, born towards the close of the fourteenth century; Thomas Atheburn, an eminent divine of the same century, who distinguished himself as a strenuous opponent of Wickliffe and his new doctrines; Edmund Stafford, bishop of Exeter, and chancellor in the reigns of Richard II. and Henry IV.; Thomas Fitzherbert, a learned and able writer of the sixteenth and seventeenth centuries, who was born in 1552, and died in 1640, in the 88th year of his age.

About three miles west from Stafford, on a lofty mount, is an intrenchment, called Billington Bury. Its area is circular, including several acres, and is surrounded in some parts by one, and in others by two deep ditches. Mr. Pennant considers this fortification as having been originally a British post, subsequently occupied by the Saxons, whose stations have generally the addition of borough or bury.

At the distance of four miles south from Stafford, in the angle formed by the junction of the rivers Sow and Trent, is Tixal Hall, the seat of Thomas Clifford, esq. The present edifice is a plain modern brick building; but in front

of it is an old gateway, ornamented with three series of columns, built by sir Walter Alton. Behind this gateway stood the ancient mansion, of which some remains are still visible, erected by sir Edward Aston, in the beginning of Henry VIII.'s reign. Adjoining to the park which surrounds the mansion is Tixal Heath, distinguished by two remarkable tumuli, one called the King's, the other the Queen's Low. But why so named, or on what occasion constructed, no account is extant. Two urns, supposed to be of Roman workmanship, were found near them early in the last century.

Adjoining Tixal is Ingestre Hall, an old mansion, built in the reign of queen Elizabeth, the seat of earl Talbot. Near the house is the village-church, which was built in 1673, by Walter Chetwynd, esq. the then possessor of this estate.

On Hopton Heath, adjoining Ingestre, a severe action was fought between the parliamentary and king's forces, in the time of the civil wars of Charles I.—History and Antiquities of Staffordshire, &c. by the Rev. Stebbing Shaw, folio, 1798. Beauties of England and Wales, Staffordshire, by J. Nightingale, 8vo.

STAFFORD, a county of Virginia, bounded N. by Prince William county and E. by the Patowmac; containing 9830 inhabitants, of whom 4195 are slaves.—Also, a township of Connecticut, in Tolland county, on the S. line of Mailschuffetts, 12 or 15 miles N.E. of Tolland. In this township is a furnace for casting hollow ware, and a medicinal spring, which is the resort of valetudinarians. It contains 2235 inhabitants.

STAFFORD, *New*, a township of New Jersey, in Monmouth county, adjoining Dover on the S.W. and containing 1239 inhabitants.

STAFFORDSHIRE is an inland county, situated nearly in the centre of England, between 52 and 54 degrees N. latitude, and between one and three degrees W. longitude from London. It is in shape an irregular parallelogram; and is bounded on the N. by Cheshire and Derbyshire, on the E. by Leicestershire, on the S. by the counties of Warwick and Worcester, and on the W. by Shropshire. Its greatest length from N.N.E. to S.S.W. is about 60 miles, and its greatest breadth from E. to W. 38 miles. The superficial contents are about 780,800 acres, of which 100,000 are pasture, 500,000 arable, and the remaining 180,800, woods, waters, wastes, &c.

Ancient State: Historical Events.—This county appertained to the Cornavii of the Britons, to the division of Flavia Cæsariensis of the Romans, and was a part of the kingdom of Mercia during the Saxon heptarchy. Bede calls the inhabitants Angli-Mediterranei, the midland English. The two Roman military ways, Watling-street and Icknield-street, pass through this county. The former enters it out of Warwickshire, near Tamworth, and running westward passes into Shropshire. Icknield-street also enters from Warwickshire at the village of Hansworth, near Birmingham, crosses Watling-street, and enters Derbyshire at Monk's bridge. The Roman stations in this county that are known, are Pennocrucium, near Stretton; and Etocetum, at Wall near Lichfield. But Salmon gives to Staffordshire four Roman stations, which, he says, are Mediolanum, at Knightley; Uriconium, at Wrottesley; Uxacona, at Wall-Lichfield; and Etocetum, at Barbeacon. The first of these stations Camden positively fixes in Montgomeryshire; and bishop Horsley places it on a slip of land inclosed by the Tern and another river. Salmon assigns Pennocrucium to Oldbury, in Warwickshire, and refers to Antoninus's second iter for his authority; but Plot, Gale, Horsley, and Stukeley, coincide in opinion that Penkrige is the site of that

station. The ancient inhabitants of Staffordshire, in the opinion of Dr. Plot, were the Iceni; but in this he stands unsupported: Shaw says that tribe was undoubtedly of Derbyshire. Camden and Gough will not allow that they extended beyond Huntingdonshire, westward; while Salmon confines them to Norfolk and Suffolk. Shaw supposes that the Ordovices were the original inhabitants of this district, and it is generally agreed that they possessed it many centuries before the Christian era. They were an intrepid warlike people, whose territories comprised a great portion of Wales and several counties of England. But they were disturbed in their possessions by the Cornabii, who, breaking through the limits of their original settlements on the banks of the Dee, conquered a large tract of country to the west and north-west, and established a monarchy, of which Condate was the capital. The Brigantes, in their turn subdued a portion of the territories of this tribe a short time previous to the arrival of the Romans. On this event the metropolis was transferred from Condate to Uriconium, now Wroxeter, where it continued a considerable time, till the Romans extended their conquest into the interior of the country. During the sanguinary contests which ensued, little is recorded respecting this district and its inhabitants, but that they heroically resisted the invaders, and though at length compelled to submit, their courage and ardour for freedom excited the admiration of their conquerors. The Cornabii, after the subjection of their country, appear to have been the friends and allies of the Romans. It is remarkable that after the decline of the Roman power, the appellation Cornabii never occurs in the annals of English history. When the Britons experienced a second subjugation by the Saxons, and the heptarchy was established, Staffordshire formed a part of the kingdom of Mercia, which extended over all the midland counties, and was founded by Crida in the year 585. During the repeated invasions of the Danes, this county sustained a considerable part of the calamities consequent on their cruelty and rapacity. Several sanguinary battles took place within the kingdom of Mercia; in Staffordshire particularly, two victories were obtained over the Danes in the reign of Edward the Elder. On the partition of England between Edinund Ironside and Canute, this county, as part of Mercia, was awarded to the latter. After the Norman conquest, William divided the estates of the Mercian earls among four of his principal followers, Hugh de Montgomery, earl of Arundel; Robert de Stafford, Henry de Ferrars, and William Fitz-Ansculph; the last of whom held twenty-five manors in this county. The other principal landholders besides the king, were the bishop of Chester, the abbots of Westminster and Burton, the church of Rheims, and the canons of Stafford and Wolverhampton. During the contention between the royal houses of York and Lancaster, a decisive battle was fought at Bloreheath, in this county, between the Yorkists under the earl of Salisbury, and the Lancastrians under lord Audley, when the latter, with double the force and superior position, was completely defeated, himself slain, and 2400 Cheshire gentlemen, whose attachment to king Henry led them into the van, also fell in the action.

In the civil war of the seventeenth century, Staffordshire was considerably engaged: Stafford surrendered to the parliament's forces, and Lichfield was several times taken and retaken by the contending parties. In this county Charles II. lay concealed after the fatal battle of Worcester, till he had an opportunity of escaping. The circumstances attending his concealment, the difficulties he sustained, and the unshaken loyalty of his friends, are amply detailed by Mr. Shaw in his General History of Staffordshire.

STAFFORDSHIRE.

Ecclesiastical History.—Staffordshire did not receive the light of the gospel till the reign of Penda, king of Mercia, whose son, Peadda, was converted to Christianity by the venerable Bede. This was soon declared the established religion of Mercia, and the cathedral of Lichfield was founded, where the episcopal see of Mercia was fixed in 669; but it was soon afterwards divided into five several dioceses, and Lichfield, Worcester, Hereford, Leicester, and Sidnacester, chosen for the respective sees. In the year 786, at the request of king Offa, pope Adrian advanced Lichfield to the dignity of an archbishopric; but this distinction was continued only till the death of Offa, when pope Leo reduced it to its former rank. About the year 1067 the episcopal seat was removed to Chester, and thence soon afterwards to Coventry, where it continued till the end of the thirteenth century, when Walter de Langton was appointed bishop of Lichfield and Coventry. From this period nothing remarkable occurred in Staffordshire, connected with church history, previous to the reformation, when Lichfield cathedral was despoiled of the rich shrine of St. Chad, and the see of Coventry separated from it. The two bishoprics remained distinct till the restoration, when they were again united in the person of Dr. John Hacket. Since that time the diocese has undergone no particular alteration. Staffordshire, which is comprised in this see, contains 181 parishes.

Civil Division.—Staffordshire is divided into five hundreds; Totmanslow, Pyrehill, Cuddleston, Offlow, and Seisdon: and contains one city, Lichfield, and twenty-three other market-towns, *viz.* Stafford, Wolverhampton, Walsall, Burton-on-Trent, Uttoxeter, Newcastle, Leek, Stone, Cheadle, Eccleshall, Rudgeley, Tamworth, Tutbury, Abbot's-Bromley, Breewood, Penkridge, Cannock, Wednesbury, Burslem, Handley-Green, Lane-End, and Longnor. Ten members are returned to the imperial parliament from this county, *viz.* two for the shire, and two each for Lichfield, Stafford, Newcastle, and Tamworth. According to the population survey of the year 1811, this county contained 57,040 houses, occupied by 295,153 persons; of whom 34,011 families were chiefly employed in trade and manufactures, and 18,361 in agriculture.

General Aspect, Soil, and Climate.—The appearance of the county varies in different districts. The middle and south portions are generally level: among the few exceptions are the hills of Dudley and Sedgely, the quartzose and ragstone hills of Rowley, and those of Clent and Barbeacon. The grounds of Byshbury and Effington, and some situations near Tettenhall and Enville, as well as on Cannock-heath, are also considerably elevated. The latter portion of the county was in ancient times covered with oak, but most of these have been destroyed: indeed scarcely a tree now remains to enliven the prospect, through an extent of 2500 acres. The northern portion of the county is of an opposite character to that on the south. Here the surface is mostly bleak and hilly: only a few of the eminences, however, rise to any remarkable elevation. The summit of Bunter, near Ilam, was found by Mr. Pitt, in the course of his "Agricultural Survey," to be 1200 feet above the level of the Thames. The Weaver hills, and some other points, he reports as ascending even 1500 feet. The general elevation of this district above the southern is estimated at from one to two hundred yards. That portion of it called the moorlands, is the commencement of that range of mountains which extend through the centre of England, till they enter Scotland, acquiring different appellations in their progress, and increasing in altitude as they approach the north. The soil is extremely varied. The arable soils may be divided generally into the argillaceous, or stiff and strong clayey;

the arenaceous, or loose, light, and sandy; the calcareous, or lime earth; and a mixed or compound soil, or loam composed of the foregoing, with the addition of stones and other matters. The climate of this county inclines to wet: the annual rains are calculated at upwards of 36 inches, and thus exceed by nearly 16 inches the average computation of rain in London. A great quantity of snow falls in the moorlands, which doubtless is a principal cause of the piercing cold which prevails in that district.

Rivers.—Staffordshire abounds with rivers, but none of them are navigable, at least within the county. The principal are the Trent, the Dove, the Tame, and the Blythe. The Trent, which may be considered as the third river of England, waters, in its course to the sea, some of the most fertile and best cultivated districts of the kingdom. During its passage through Staffordshire, its banks are covered with luxuriant meadows. In the vicinity of Trent-ham, the seat of the noble family of Gower, the efforts of art have greatly added to the natural beauty of the river, by swelling it into an expansive lake. Passing the town of Stone, it flows through a valley diversified with a variety of elegant parks; of which that of Wolfey, bordering on the chase of Cannock, is one of the most remarkable for the romantic beauty of its scenery. Pursuing its course, the Trent becomes the boundary between the counties of Stafford and Derby, till its junction with the river Dove; then, crossing Derbyshire, it runs through the counties of Nottingham and Lincoln, and at length pours its waters into the Humber. The Dove takes its rise among the hills in the moorlands, near the points where the counties of Stafford, Derby, and Chester meet. From the declivity of its channel, its waters flow with uncommon rapidity: in some places it dashes precipitately over rugged rocks; in others it is distinguished by gentle cascades. It falls into the Trent near Burton, on the confines of Derbyshire. The Tame, another river of considerable size, springs from several sources in the vicinity of Walsall and Colehill, enters Warwickshire near Birmingham, returns into Staffordshire at Tamworth, and finally joins the Trent. The Blythe rises in the neighbourhood of Watley moor, in the northern district. Its course is nearly parallel to the Trent, into which it falls near King's-Bromley.

Canals.—Although an inland situation, without navigable rivers, appears to labour under peculiar disadvantage for the purposes of trade; yet in Staffordshire the deficiency is amply compensated by the number and extent of the canals, with which this county is so largely supplied. The principal are the Grand Trunk Canal, the Coventry and Oxford, and the Birmingham Canal. These, with their numerous branches and ramifications, have already been particularly described. See CANAL.

Lakes and Springs.—This county affords but few lakes, and those of no great consequence. Those most worthy notice are that of Aquilate, which extends 1848 yards in length, and 672 in breadth; and Ladford Pool, which occupies the space of about 60 acres. Salt springs are found in various places. The most considerable are those in the parish of Welton, whence salt is produced, equal in quality and colour to that of any part of the kingdom.

Minerals.—The number and value of the mineral productions of Staffordshire claim particular notice. Coal is abundant: upwards of 50,000 acres have been ascertained to contain an inexhaustible supply, near enough to the surface to be easily raised. From the earliest times to the present, the consumption does not appear to have exceeded a tenth part of the whole. In the southern division of the county, the coal district extends in length from the interior

of Cannock-heath to the vicinity of Stourbridge, and in breadth from Wolverhampton to Walsall. To the north, likewise, it abounds in the neighbourhood of Newcastle and the Potteries, Lane-End, Hollybush, Cheadle, and Dill-horne. At Handley-Green a very peculiar species is dug, called the Peacock coal, from the prismatic colours it displays. Limestone is still more abundant than coal. At Sedgley and Dudley-cattle hills, Rushall and Haywood, and on the north-east moorlands, the quantity is immense. The lime-works upon Caldon Low, and near the Weever hills, are particularly extensive. This stone is, in some places, of a marble quality, and capable of taking a fine polish. In other parts it is chiefly composed of tremitholopi, or petrified marine substances of the animal kind. Iron ore is plentiful throughout the coal district. Near Wednesbury, Tipton, Bilston, and Sedgley, and to the west of Newcastle, it is peculiarly excellent and abundant. The strata are generally ranged beneath a stratum of coal. Iron-works of great extent have been recently established on the banks of the Birmingham Canal; and the trade is so rapidly increasing, as to afford a prospect of its precluding the necessity of any considerable importation. Copper and lead ore also abound in this county. A copper-mine is worked at Mixon, near Leek; but a more important one at Ecton-hill, near Warflow, on the estate of the duke of Devonshire. This hill has likewise a considerable vein of lead; and another of the same mineral has been found near Stanton-moor. In this part of the county, but particularly at Whiston, Oakmoor, and Cheadle, smelting and brass-works are carried on to a considerable extent. Quarries of good free-stone for various purposes are found in the different districts. A durable kind for building, easily raised in blocks of any dimension, is found at Tixal. Alabaſter was formerly dug in great quantities, particularly on the banks of the Dove; but though it still exists in plenty, very few of the quarries are now wrought. This county also yields various kinds of marble: that species, to which the name of rance-marble is given, abounds on Yelpersley Tor, and the adjacent hills. Clays of every denomination are abundant. Amblecot produces a clay of a dark-blue colour, of which are made the best glass-house pots of any in England. Glass-houses have, in consequence, been erected in the neighbourhood; and great quantities of the clay are sent to different parts of the kingdom. Potters' clay of various sorts is found here, particularly in the vicinity of Newcastle, where the potteries are chiefly carried on. Yellow and red ochre, and other earths used for colouring and painting, are among the productions of this county. At Darlaston, near Wednesbury, is a blue clay, which is sold to glovers to dye ash-colour. A black chalk is found in the beds of grey marble in Langley Cloſe; and under a rock near Hemley Hall is a reddish earth, nearly equal to the red chalk of France.

The farms of Staffordshire are of all extents, from fifty acres to five hundred; but the number of the smaller has been lately much diminished. The rent of land varies from 15s. to 40s. per acre, making the average about 25s. The cultivated lands of this county are nearly all inclosed, not more than 1000 acres still remaining open. The fences in the southern part are chiefly raised from quickſets, among which the white thorn is most approved.

Timber, Plantations, and Woodlands.—This county, notwithstanding the great recent consumption, is abundantly stocked with wood of every description. Lord Bagot's estate, near Abbot's-Bromley, contains several acres of oaks, not to be surpassed in quality by any in the kingdom: the timber in many of them is to the height of sixty or

seventy feet. Chillingworth estate ranks next to this for the value of its woods. Those at Beaufort, the seat of the earl of Uxbridge, and those at Llamley, the property of lord Dudley, are also very extensive. Teddesley has very considerable plantations. Mansley wood is a coppice of fine oak. Wrottesley, Fisherwick, Trentham park, Sandwell park, Envile, and Hilton, display abundance of well-grown trees of every description.

Waste Lands.—The extent of uncultivated lands in this county is very great; being computed by Mr. Pitt to amount to an hundred thousand acres. The chief waste districts in the southern parts are Cannock-heath and Sutton-Coldfield, with Swindon, Wombourn, and Fradley commons. In the north are Morredge, Wetley-moor, Stanton-moor, Hollington-heath, Careſwell-common, and Needwood forest; which last, however, has been in part recently inclosed and cultivated.

Manufactures and Commerce.—Various branches of manufacture are carried on to a great extent, particularly in the southern parts of the county: the chief are hardware articles, nails, glass, toys, japanned goods, and potters' ware; with productions in cotton, silk, leather, woollen, and linen. The manufacture of glass is most considerable in the vicinity of Stourbridge, where many spacious glass-houses have been built. The potteries occupy an extent of ten miles, toward the north part of the county: these have acquired great reputation from the ingenious Mr. Wedgewood. (See POTTERIES.) Wolverhampton and the neighbouring villages are distinguished for the manufacture of locks: buckles, steel-toys, and watch-chains, are among the esteemed productions of that town. The staple manufacture of Walsall and its vicinity is chiefly shoe-buckles, clasps, and sadlers' ironmongery. Nail-making, in many country parishes, is a source of employment to great numbers of men, women, and children. Bilston furnishes a variety of plated, lackered, japanned, and enamelled goods. At Wednesbury the gun-trade is extensive. At Darlaston, Willenhall, and the adjacent villages, tobacco and snuff-boxes are wrought in various modes. Stafford and its neighbourhood exhibit numerous articles in the cutlery and leather-trade: the hat manufacture is also carried on there, and in some other towns, on an extensive scale. Tin and brass are among the common productions of the county. The cotton manufactures at Roceſter, Fazeley, Tamworth, Burton, and Tutbury, are very considerable; as is likewise the silk-trade of Leek, and that of tape at Cheadle and Teyn. The woollen manufacture is but comparatively trifling; most of the raw wool being sold into the clothing and stocking districts. The making of linen is mostly confined to private families, for their own use.

It is worthy of observation, that the original wooden almanac of the Norwegians and Danes is still in use in this county, under the appellation of the Staffordshire clogg. Engravings of this calendar, something different from each other, may be seen in Dr. Plot's Natural History of the County, and in Camden's Britannia, by Gough. The principal antiquities in this county are the cathedral at Lichfield; Tutbury castle and church; Dudley castle and priory; Eccleshall castle; Croxton abbey; Alton castle; Wolverhampton church; bridge and abbey, at Burton-upon-Trent; Darlaston castle; Tixal manor-house; Hilton abbey; Rowton priory; Uttoxeter church; Careſwell castle; Chartley castle; Heyley castle.

Authorities.—History, &c. of Staffordshire, by the Rev. S. Shaw, 2 vols. folio, 1798, &c. an unfinished work. General View of the Agriculture of the County of Stafford, by William Pitt, 8vo. 1808. The Natural History

of Staffordshire, by Dr. Plot, fol. 1686. A Map of the County, begun in 1769, and finished in 1775, by William Gates, six sheets. Account of Staffordshire, in the Beauties of England, vol. xiii.

STAFFURTH, a town of Germany, in the principality of Anhalt-Bernburg; 9 miles N.W. of Bernburg.

STAFLEFIT, a town of Prussia; 7 miles S. of Culm.

STAG, or *Red Deer*, or *Hart*, in *Zoology*. See *CERVUS Elaphas*. See also DEER, HART, HUNTING, and SHOT.

STAG, in *Rural Economy*, a term applied provincially to a young horse.

STAG-Beetle, in *Natural History*, is the *LUCANUS Cervus* of Linnæus; which see.

STAG-Evil, or *Hart*, in horses and neat cattle, a kind of universal cramp or convulsion. See HART.

This is a disease with which young horses are not unfrequently affected. It mostly comes on after much exposure to severe cold, or a high degree of cold moisture, where heat takes place suddenly afterwards, and sometimes in cooling too quickly after great heat. It attacks the whole body, but more particularly the joints, with a sort of foreness, rigidity, and stiffness, which cause the animals to move about in a slow, awkward, almost lifeless manner. They gradually fall off in their appetites, and become incapable of performing any kind of labour, and often even the mildest exercise distresses and inconveniences them in a high degree.

In its removal, calomel, with opium and the powder of gum guaiacum, may be first had recourse to in the form of a ball, made up with balsam copaiva, for some days; when the use of warm cordial strengthening drinks or drenches, with oak or Peruvian bark in fine powder, may be found necessary to complete the cure; the horse during the time being made to take as much gentle exercise as possible. And the use of a good dry grass pasture is not unfrequently of great benefit in completing the removal of the disorder.

Neat cattle are likewise frequently subject to a disease of the same nature, which, after much exposure to intense cold, comes on with a stiffness in the joints, which is attended with a lumpy swelling on them and the legs, after a little time, without any inflammatory appearances. This stiffness and foreness sometimes extend over the whole body, so that the beasts become incapable of rising, when down, without assistance. Where the chine or back is particularly affected, the disease is mostly denominated the *chine fellon*; but where the joints have more of the disorder than any other part, it is commonly termed the *joint fellon*, or *joint evil*; and where the whole body is deranged and disordered, it has often the name of *cold fellon* given it.

The disease is particularly liable to attack milch-cows and young cattle in the spring season, being occasioned probably by their being kept through the winter in a low weak state, and suddenly exposed in the spring to the extreme coldness of the north and north-easterly winds, in low damp situations, or other similar places.

In order to remove the disorder, a ball of the same kind as that for horses may be given for some days, until the foreness and stiffness begin to go off, when recourse should be had to such powders or balls as those recommended below, given in a hornful or two of warm ale.

The powder of gum guaiacum, in the quantity of about an ounce, with an ounce and a half of Æthiops mineral, or sulphuretted quicksilver, and two ounces of the grains of paradise, in fine powder: or, camphor in the proportion of about a drachm and a half, rubbed with a few drops of the spirit of wine, to which may be added guaiacum and Peruvian bark in fine powder, of each about an ounce and a

half, warm feeds in powder three ounces, and treacle or honey two or three ounces, to form a sort of ball.

The drinks of this sort may be continued occasionally for some time. And much utility may at first be derived from the use of a comfortable house of some kind or other for containing the animals, and afterwards by their being turned into dry warm pastures, when the season admits.

The rubbing of the swellings in the joints with strong camphorated turpentine embrocations, as frequently practised, is mostly improper, sometimes injurious, and always hazardous.

Where the disease changes to, or puts on the appearance of a more inflammatory nature, as that of the acute rheumatic kind, with fever, pain, and tumefaction of or about the joints, it may be on some occasions necessary to resort to remedies of the camphor kind, with calomel, and a small proportion of opium, giving at the same time some sort of active opening or purging medicines. The above cordial strengthening bark-powdery remedy will afterwards, for the most part, be of great utility.

STAG-Horn Tree, in *Gardening*. See RHUS.

STAG-Worms, in *Natural History*, a name given to a species of worms produced from the eggs of a fly, and lodged in a very strange place behind, and under the palate of the stag, or deer's mouth.

They are always found in great numbers together, and are contained in fleshy bags, which are placed as the almonds of the ears in the human species. The huntsmen are well acquainted with these worms, and are of opinion that they are the cause of the falling off of the creature's horns; they eat their way to these, according to their opinion, through the proper parts of the head, and then gnawing them round at the roots, they are forced to fall, like a tree that is sawed off at the bottom. This, however, is a vulgar error.

M. Reaumur has abundantly proved, that these worms never attempt so strange a passage; they always remain where they are first found till they are in a state to change into the flies to whose eggs they owe their origin, and whose forms they are at length to assume. Reaumur's Hist. Inf. vol. ix. p. 8.

STAGE, in the *Modern Drama*, the place of action and representation; included between the pit and the scenes.

The stage answers to the proscenium or pulpitum of the ancient theatre.

For an account of the English stage, see MYSTERY, PLAYHOUSE, and SCENE. See also *DRAMATIC Machinery*, and SCENOGRAPHY.

Unlicensed stage-plays are deemed public nuisances, and may, upon indictment, be suppressed and fined.

STAGE, *Laws of the*, are the rules and decorums to be observed, with regard to the economy and conduct of a dramatic performance to be exhibited on the stage. These relate, principally, to the unities, the disposition of the acts and scenes, the unravelling, &c.

STAGE also denotes a certain distance to which stuff is to be wheeled, at stated prices *per cubic yard*: the usual stage is an interval of 20 yards; but on very steep or quite level wheeling, they are sometimes reckoned 15 yards, and in other cases 25 yards.

STAGE Island, in *Geography*, a small American island, near the coast of Maine, not far from Casco bay, remarkable for being the first land inhabited by Europeans in New England. It is not now uninhabited.

STAGEBORG, a town of Sweden, in East Gothland; 15 miles S.E. of Nordkiöping.

STAGGARD, among *Sportsmen*, a male deer only four years old.

STAGGERS.

STAGGERS, among *Farrriers*, a disease of horses, which has sometimes been denominated *apoplexy* (which see), and which consists of a giddiness in the head, and which, in some cases, is indicated by madness. Of this disease authors have described two species; *viz.* the *sleepy*, and the *mad* staggers. In the first species, the animal becomes inactive, and manifests a heaviness of the eyes, and an inclination to sleep, the head resting in the manger; accompanied with costiveness, and other symptoms of fever. In the second sort of staggers, the horse, without indicating any previous signs of disease, falls down apparently deprived of all voluntary motion, with the eyes insensible to light, the breathing difficult, a great motion of the flanks, and a quick, full pulse. In the mad staggers the horse often rises, plunges violently in the stable, and again falls down in an insensible state.

This disease is frequently occasioned by turning out a horse to graze too soon, before he is well cold: where, by hanging down his head to feed, humours are generated, which oppressing the brain, are the proximate cause of this disease. Sometimes it comes by over-exercise in hot weather, which inflames the blood, &c. sometimes by noisome smells in the stable, excessive eating, &c. the rupture of a blood-vessel, or external injuries on the head.

The signs of it are, dimness of sight, reeling, and staggering, watery eyes, &c. At length, through extreme pain, he beats his head against the wall, thrusts it into the litter, rises and lies down with fury, &c.

The most approved remedy for this distemper is derived from the following treatment. Begin with copious bleeding from a large orifice in the neck-vein, and repeat the operation, if the strength of the horse admit of it, and the symptoms of the disease require it. After bleeding administer a ball, prepared of two drachms of calomel, an ounce of Barbadoes aloes in powder, two drachms of ginger, and a sufficient quantity of honey. Apply also a glyster, prepared by mixing three quarts of oatmeal gruel, three ounces of common salt, and half a pint of olive oil. If the disease continue after this treatment, put a rowel under the jaw, and another in the chest; applying also, behind the ear, some blistering liniment: let the horse be supported at the same time by mashes, or if he refuse these, by gruel in the quantity of two or three quarts, frequently given. After opening the bowels sufficiently, let the following fever-powder be given: *viz.* one drachm of pulverized camphor, a scruple of antimonial powder, and six drachms of powdered nitre, all well mixed. When the symptoms are relieved, mashes of bran or oatmeal may be occasionally given, with a small quantity of corn: hay should be sparingly allowed. Omit the powders, and give the following restorative ball every morning, till the horse recovers strength, taking care to keep his bowels open by mashes: the ball is prepared of Peruvian bark and gentian, in powder, of each $\frac{1}{2}$ th of an ounce; two drachms of ginger, one drachm of vitriolated iron, and a sufficient quantity of honey. The rowel under the jaw should be continued at least a fortnight after the disease has been removed. Attention should afterwards be observed with regard to the kind or quantity of food, the exercise and stable treatment.

Horses are subject to convulsions and staggers, arising from a retention of the dung and aliment; which are indicated by swollen eyes, reeling and tottering motion, short breath and cough, and irregular motion of the flanks; aversion from lying down, costiveness, indisposition to stand, and dark-coloured urine; and sometimes jaundice. Gibbon directs the dung to be raked up by the hand from the rectum, which dung is generally hard, in small balls of

a blackish colour, without moisture. After this operation, administer plenty of emollient oily glysters of marshmallows, or pot liquor, water gruel or water; adding to three pints or two quarts of the liquor a pint of linseed-oil, and half a pound of treacle; which should be given milk-warm, and repeated every day, till the dung comes away with ease, and in a soft state: accompanying this medical treatment with diet of the best hay, scalded bran or chaff, or boiled barley. When the dung comes away with facility, and in great abundance, the following gentle lenitive purge may be given; *viz.* lenitive electuary and cream of tartar, of each four ounces, and two ounces of common sugar, mixed in a pint and half of hot ale; to which, when the tartar is dissolved, add the sugar, and last of all the lenitive electuary. Let this be given in the morning, upon an empty stomach, blood-warm; and repeated three or four times, with a respite of two or three days between the draughts, keeping the horse to an opening diet, with proper exercise, till he recovers his usual vigour.

Mr. Boyle mentions a cure of this disease in horses, by rubbing their gums with the coach-whip till they bleed. Works, Abr. vol. i. p. 88.

STAGGERS, a disease in sheep, in which they are mostly considered as extremely liable to move or turn themselves about in a quick manner.

The remedy for this disorder was formerly to drive them to a change of grounds often, to keep the grounds from tainting. And it has been noticed by Lisle, that those lambs which die of the staggers do not die till they begin to eat grass, and of those the finest and lustiest; whence he concludes, that it is not the cold weather alone that brings staggers, but their feeding on cold watery grass in the months of March and April. The disease was much prevented by the early folding of the lambs. See *GID*.

The disease mostly appears in the autumn, and is said to be produced by a variety of causes; such as improper food, the leaves of the oak-tree, on account of their astringent quality, cobwebs besprinkled with dew, and different others. And it probably often proceeds from local affections, and water in the brain. Some have likewise supposed that it arises from the operation of a poisonous grass, the *lolium temulentum*, which is alone met with in those situations of Scotland where the staggers in sheep prevail. But what effect such cases have on the brain, to produce or cause such a disease, is not pretended to be explained.

Where this disease continues for any length of time in the same sheep, it is liable to become fatal.

The change of pasture is supposed to be the only effectual remedy in such cases, but the use of calomel and bark may often be found of material advantage, as well as other means which have a tendency to remove water from the brain.

STAGGERS is also a disease in neat cattle, which is often very troublesome and unpleasant in its consequences and management. The principal seats of the disorder would seem to be the head and the stomach, which naturally sympathize with each other. It may proceed from a variety of different causes, as improper and insufficient feeding, too much exposure to cold, drinking too largely of very cold water, under particular circumstances, water and local affections of different kinds in the brain and parts about it, and many others of the same nature.

It is most liable to attack such cattle as have been poorly fed, or starved in the winter season, on their being first turned out upon good pastures in the early spring; but it not unfrequently happens to other cattle which have been regularly fed. It likewise occurs in very different states and

degrees of violence, according to the circumstances and habits of body of the animals. And it occasionally takes place in calves, and other young flock of this sort.

The disease shews itself by the reeling, wavering, staggering, and imperfect gait of the animal; by the heavy, dull, and sluggish motion and appearance of it; and an inclination to become drowsy, and the resting or reclining of the head upon any convenient place near it.

It sometimes, however, puts on a more local inflammatory appearance, in which cases the beasts have commonly a less heavy drowsy disposition, with more of the wild raving or raging tendency and quality in their aspects and dispositions.

In the former of these states, the disease may be attempted to be removed by the giving of calomel in pretty large doses, as a drachm or more to a large beast, two or three times in the course of the week, and powders composed of camphor rubbed with a few drops of spirit of wine, in the quantity of about two drachms. Common nitre, or saltpetre in powder, two ounces and a half; and the roots of rhubarb in powder, or some other similar matter, from one to two ounces and upwards, in the intervals between the doses of calomel. The beast, during the time, should be kept moderately warm, and have good hay and warm mashes occasionally given to it, preserving it as much as possible in a temperate state in every respect.

In the latter state it may sometimes be necessary to take away blood in proportion to the size and strength of the beasts, as from one to two or three quarts; after which, the bowels may be well opened by the use of pretty strong purgatives of the saline kind; then, where there is much fever of the inflammatory kind attending the disease, a ball composed of tartarized antimony, in the quantity of from half to a whole drachm, with about two drachms of camphor rubbed as above, and from a drachm and a half to two drachms of prepared ammonia in powder, made up with a little treacle, may be given in a hornful or two of warm oatmeal gruel, once or oftener in the day to the beasts, until it disappears. In tedious cases of this sort, with much affection of the head, great relief may sometimes be gained by the application of strong blisters about the head, or the rubbing of the parts near and upon it, and on the sides of the neck, with strong ointment of the blistering kind, after the hair has been well clipped off and removed from them.

Afterwards it will only be necessary to let the beasts have a strengthening cordial drink or two, and the use of a good dry pasture, when the season will admit of it.

STAGGERWORT, in *Agriculture*. See RAGWORT.

STAGIRA, or STAGIRUS, in *Ancient Geography*, a town of Macedonia, in the vicinity of mount Athos, upon the Strymonic gulf, between Amphipolis on the north, and Acanthus on the south. This town was the native place of Aristotle, hence called the Stagirite.

STAGNANT *Watery Land*. See WATERY *Land*.

STAGNO, in *Geography*, a sea-port town of the republic of Ragusa, on the Adriatic, the see of a bishop, suffragan of Ragusa: about a mile from the town is a fortress, called "Stagno Piccolo," or Little Stagno; 30 miles N.W. of Ragusa. N. lat. 43° 30'. E. long. 17° 59'.

STAGONIAS, a word used by the old authors to express that sort of male frankincense which is in round drops, and very clear and fine.

STAGONIUS, a name sometimes given to storax.

STAGS, in *Geography*. Several rocks on the coast of Ireland are so called; as, the Stags on the south-east entrance of Cork harbour, near Roches tower, where a light-

house is erecting; the Stags of Castlehaven, south of Toehed, county of Cork; and the Stags of Broadhaven, north of Binwy-head, on the Mayo coast.

STAHL, GEORGE ERNEST, in *Biography*, a celebrated physician and chemist, was born at Anspach, in Franconia, in October 1660. He studied medicine at the university of Jena, and laid the foundation of his fame, immediately after his graduation in 1684, by commencing a course of private lectures among the students of that place. His advancing reputation procured for him the appointment of physician in ordinary to the duke of Saxe-Weimar in 1687. On the establishment of the university at Halle, in 1694, Frederic Hoffmann, with his accustomed liberality, solicited the appointment of a medical professorship for Stahl, who accepted the office, and became the rival of that distinguished physician as a teacher of medical systems, but not in the exercise of candour and liberality towards his colleagues. Stahl was conscious of possessing considerable mental powers, and paid little respect to the opinions of others; and he became the leader of a sect or school of physicians, in opposition to the mechanical theorists, in which he was followed by many eminent persons, not only in Germany, but in other countries, as by Perrault in France, Gaubius in Holland, Porterfield and Simpson in Scotland, and by Nichols and Mead in England, notwithstanding the very fanciful nature of the hypothesis on which his system was founded. The "Conspectus Medicinæ" of Juncker was published to illustrate his doctrines in Germany; and a succinct account of the system was given by Dr. Nichols, in his work "De Animâ Medicâ," in this country.

Physicians had always remarked a certain power in the animal body of resisting injuries and correcting some of its disorders, which they had called *nature*, and *vis medicatrix nature*, and Van Helmont had already ascribed some degree of intelligence to this power. But it remained for Stahl to refer this power entirely to the *rational soul*, which, he affirmed, not only originally formed the body, but is the sole cause of its motions, in the constant excitement of which life consists. For he maintained that the soul abhors the dissolution of its body, and therefore excites and directs all its motions, the vital and involuntary as well as the voluntary motions, to prevent that dissolution, by obviating putrefaction, and expelling the corrupted humours by various appropriate organs or excretories; in a word, that all the functions of the body are entirely directed by the mind, which intelligently perceives the tendency of all impressions, external and internal, made upon the body, and excites such motions as may favour the beneficial, and obviate the injurious influence of all causes acting upon it. Whence he farther contended, that diseases, such as fevers and spasmodic affections, were in fact the motions voluntarily excited by the rational soul, for the purpose of opening emunctories, and expelling some offending cause. Generally speaking, therefore, it was maintained, that diseases were salutary efforts of the presiding soul, and were to be assailed, and not interrupted, by the interference of art: yet it was somehow admitted, that the mind, from surprise, fear, or despair, occasioned by too sudden or vehement impressions made upon it, occasionally excited adverse motions, which it was right to moderate. Independently of the visionary character of this hypothesis, it was justly deprecated as leading physicians to neglect the use of remedies, or to use only the most inert and frivolous ones; and also to set little value upon the collateral studies of medical science, even upon anatomical researches, which Stahl maintained had little or no reference to the art of healing. And, in fact, both he and his followers, trusting principally to the attention and wisdom of nature,

nature, adopted that inactive mode of *curing by expectation*, la médecine expectante, as the French have called it; they zealously opposed the use of some of the most efficacious remedies, such as opium, cinchona, and mercury; and were extremely reserved, even in the use of general evacuations, such as bleeding, vomiting, &c. although their system led them to refer almost all the disturbances of the motions of the system to a plethora, or too great abundance of the blood. This hypothesis was maintained by Stahl in several publications, with much ability and ingenuity; and it continued to influence a great number of intelligent physicians for a long time. His principal medical work, in which his system is displayed in its most matured form, is entitled "Theoria Medica vera, Physiologiam et Pathologiam sistens," printed at Halle in 1708.

The merits of Stahl as a chemical philosopher are of a much higher character; and the school which he founded in this science, after extending its influence long and universally among those who pursued the same inquiries, has only been superseded of late by farther discoveries. He was the inventor of the celebrated theory of *phlogiston*, which appeared to explain the phenomena of combustion and inflammability, and was received every where with high applause, and which, in fact, occasioned Germany to become the great school of chemistry. It cannot be denied, indeed, although later experiments have subverted the groundwork, that this hypothesis tended greatly to simplify the ideas, and perfect the operations of chemists, and entitled its author to a high rank amongst the improvers of science. His principal chemical work was entitled, "Fundamenta Chymicæ dogmaticæ et experimentalis," first printed in 1729, and several times reprinted: but before that period he had published several other works on this subject, such as "Disertationes de Metallurgiæ et Docimastiæ Fundamentis," 1697; and, in the same year, "Experimenta et Observationes 300 Chymicæ et Physicæ," in which work he principally advanced his doctrine of phlogiston. He also published in the German language some essays "On Sulphur," and "On Salts."

Stahl was elected a member of the Academy Naturæ Curiosorum in 1700. He was called to visit Frederic William, king of Prussia, at Berlin, in 1716; and afterwards returned several times to that capital, where his reputation was very high, and where at length he was attacked with a fatal disease, in 1734, in the seventy-fourth year of his age. See ELOY Dict. Hist. de la Médecine. Gen. Biog. Cullen's First Lines. Pref. And Hoffmann's essay, "De Differentiâ Doctrinæ Stahlianæ et Hoffmannianæ."

STAIIDENFELD, in *Geography*, a town of the duchy of Wurzburg; 4 miles S. of Schweinfurt.

STAIN, a town of the county of Tyrol; 2 miles S.W. of Meran.—Also, a town of Austria, on the Danube, consisting almost wholly of one street, and containing two churches. It is near Crems, and governed by the same magistrates. It is joined by a long bridge with Mautern, on the other side of the Danube; 32 miles W.N.W. of Vienna.—Also, a town of Austria; 2 miles N. of Steyr.

STAIN. See **STEIN**.

STAINABRUNN, a town of Austria; 6 miles W.S.W. of Ehrnsprunn.

STAINBACH, a town of Austria, on the Teichel; 6 miles S. of Steyr.

STAINER, JACOB, in *Biography*, a German maker of violins of the most sprightly and brilliant tone. His signature, pasted on the inside of the back, is the following; "Jacobus Stainer, in Abiam prope Cenopontum, 1647." Cenopons is the Latin name of Inspruck in Germany, the chief city of Tyrol. These violins, since solos have been

laid aside, have lost somewhat of their former favour, and the Amati and Straduarii violins of Cremona, which are of a more full and rich tone, are preferred for leading a band, playing modern symphonies, and solo concertos à grande orchestra.

STAINES, or **STANES**, in *Geography*, a market-town in the hundred of Spelthorne, and county of Middlesex, England, is seated on the northern banks of the river Thames, over which there is a strong timber bridge at this place, connecting the counties of Surrey and Middlesex. It is sixteen miles from Hyde-Park corner, and most of its houses extend along the sides of the great western road; but the parish church, with a few buildings, are situated nearly half a mile N.W. of the chief mass of building. The parish consists of 748 acres 16 perches of cultivated land, with 666 acres 1 rood and 20 perches of arable land. On a stratum of loam is a soil of fine black mould, and gravel is found in some places. According to the population report of 1811, this parish contained 355 houses, and 2042 inhabitants.

In old records Staines was written *Stana*, a Saxon word for a stone; and Camden supposes that the name was derived from a stone, which was fixed in, or on the bank of the river here, to denote the extent of the jurisdiction of the city of London over the Thames, westward. A stone, bearing the date of 1280, on the margin of the water near the church, is still preserved here. An annual fair of four days was granted in the year 1228 to the abbot and convent of Westminster, and is still continued: a weekly market is held on Fridays. The civil government of the town is vested in two constables and four headboroughs. Staines bridge appears to have been one of the most ancient in the country; so far back as the year 1262, three oaks out of Windsor forest were granted for its repairs by Henry III.; and numerous grants of pontage, or temporary tolls for the same purpose, were made from time to time, in many of the subsequent reigns, as appears by the records in the Tower. These tolls were confirmed and enforced by acts of parliament in 1509 and 1597. In 1791 an act was passed for building a new bridge, and allowing certain tolls to defray the expence of the building. Under this act a stone bridge, of three arches, was begun in August 1792, and opened in March 1797: but in consequence of one of the piers giving way, the bridge was necessarily taken down. One of cast-iron was next substituted, but this also failed, and the builders were obliged to support it by wooden piles and frame-work. The bridge in its present state was completed in 1807. The parish church consists of a chancel, nave, and north aisle, separated by circular columns and pointed arches. The door of the chancel is of early Norman architecture. A square embattled tower at the west end was built by Inigo Jones in 1631, as appears by an inscription on the south side. In an apartment under the gallery staircase are two unburied coffins, covered with crimson velvet, and richly embellished, containing the bodies of Jessie Aspasia, wife of F. W. Campbell, esq. and of her brother, H. Caulfield, esq.; the former died in 1812, the latter 1808. The Quakers, Anabaptists, and Methodists, have each a meeting-house in this town. A school on the Lancastrian principle of education has been recently established, and is supported by voluntary contribution; a convenient building has been erected for this purpose Lyfons's Middlesex Parishes, 4to. 1800. Beauties of England and Wales, vol. x. Middlesex. By J. N. Brewer.

STAINHOF, a town of Austria; 3 miles S.W. of Vienna.

STAINING of Bone, Horn, Hair, and Ivory. See each article, and also **DYEING of Bone, &c.**

STAINING of Marble. See MARBLE, and *Solutions, &c.* of STONES.

STAINING of Paper and Parchment. See PAPER and PARCHMENT.

STAINING of Porcelain. See PORCELAIN.

STAINING of Stones. See *Solution, and Colours* of STONES.

STAINING of Wood. See WOOD and DYEING

STAINKIRCHEN, in *Geography*, a town of Austria; 4 miles N. of Schwanaftadt.

STAINS, a town of France, in the department of Paris; 6 miles N. of Paris.—Also, a lake of Prussia, in Nantangen; 48 miles S.E. of Konigsberg.

STAINTZ, a town of the duchy of Stiria; 10 miles S.E. of Voitsberg.

STAINVILLE, a town of France, in the department of the Meuse; 7 miles S.E. of Bar-le-Duc.

STAJO, or **STAJA**, in *Commerce*, a corn measure of Italy, equal at Florence to 4 quarti, 16 metadeli, or 32 mezzate. The moggio, which contains 8 facchi, or 24 itaja, is equal to about 16 English bushels. Salt is measured by the stajo, which weighs 72 lbs. Florence weight, or 54 lbs. avoirdupois. The stajo of Corfica is equal to 6104 cubic inches, and 28.60 stajo = 10 English quarters. The staji of Leghorn = 1501 cubic inches, and 114.60 staji = 10 English quarters. The staji of Lucca = 1472 cubic inches, and 116.85 staji = 10 English quarters. The staji of Milan = 1055 cubic inches, and 162.96 staji = 10 English quarters. That of Modena = 4297, and 40 staji = 10 English quarters. The staji of Turin = 2388 cubic inches, and 73.56 staji = 10 English quarters. The staji of Venice = 4943 cubic inches, and 34.78 staji = English quarters.

STAJOLUS, among the *Romans*, a measure of length, used in surveying land; it was equal to five palms and three-fourths of a palm.

STAIRCASE, an ascent inclosed between walls, or a balustrade, consisting of itairs or steps, with landing-places and rails; serving to make a communication between the several stories of a house.

The dimensions of stairs are differently assigned by different authors; in this however they agree, that they must not be more than six, nor less than four inches high; nor more than eighteen, nor less than twelve inches broad; nor more than sixteen, nor less than six feet long each stair. But these measures have only regard to fine buildings, ordinary houses are excepted; yet even in these, the stairs are not to exceed eight inches in height, nor be less than nine inches in breadth, nor three feet in length.

To reduce the dimensions of stairs to some natural, or at least geometrical standard, Vitruvius borrows the proportions of the sides of a right-angled triangle, which the ancient school expressed by the numbers 3, 4, and 5. The first for the perpendicular height; the second for the horizontal breadth; and the third for the whole slope or inclination, from the edge of one stair to that of another.

But this rule is set aside, and with good reason, by the modern builders. For, on this principle, the lower the stairs, the narrower they must be; and stairs, for instance, four inches high (such as we find mentioned by ancient architects), must be but five and one-third inches broad.

One rule to be regarded in the making of stairs is, that they be laid according to the Italian phrase, *con un tantino da scarpa*, i. e. somewhat sloping, or a little highest behind, that the foot may, as it were, both ascend and descend at once; which, though observed by few, is found a secret and delicate deception of the pains in mounting.

The construction of a complete staircase is one of the most

curious works in architecture. The common rules to be observed in it are as follow.

1. That it have a full free light to prevent accidents of slipping, falling, &c.

2. That the space over head be large and airy, which the Italians call *un bel sfacato*, good ventilation, because a man spends much breath in mounting.

3. That the half paces, or landing-places, be conveniently distributed for reposing in the way.

4. That to prevent rencounters, &c. the staircase be not too narrow; but this last is to be regulated by the quality of the building.

5. That care be taken in placing the staircase, so that the stairs may be distributed, without prejudice to the rest of the building.

The kinds of staircases are various: in some, the stairs are *straight*, in others *winding*, in others both ways, or *mixed*.

Again, of *straight* stairs, called also *fliers*, some fly directly forwards; others are square; others triangular; and others are called *French fliers*.

Of *winding* stairs, called also *spiral*, or *cockle-stairs*, some are square, some circular, and some elliptical. And these, again, are various; some winding round a solid, and others round an open newel.

Lastly, of *mixed* stairs, some are called *dog-legged*; others both wind about a solid newel, and fly about a square open newel.

STAIRS, *Straight*, are such as always fly, that is, proceed in a right line, and never wind; whence their denomination.

Of these there are several kinds; as,

Direct fliers, or *plain fliers*, which proceed directly from one floor to another, without turning either to the right or left; these are seldom used, except for garret or cellar stairs.

Square fliers, which fly round the sides of a square newel, either solid or open, having at every corner of the newel a square half step, taking up one-fourth of a circle; so that they fly from one half step to another, and the length of the stairs is perpendicular to the side of the newel.

Triangular fliers, which fly round by the sides of a triangular newel, either solid or open, having at each corner of the newel a trapezial half step, taking up two-thirds of a circle; so that they fly from one half step to another; and their length is perpendicular to the side of the newel.

French fliers, which fly first directly forwards, till they come within the length of a stair of the wall; and then have a square half pace, from which you immediately ascend to another half pace, from which the stairs fly directly back again, parallel to their first flight.

STAIRS, *Winding*, are such as always wind, and never fly; of these there is great variety; as,

Circular winding stairs, of which there are four kinds, viz. such as wind about a solid newel, the fore-edge of each being in a right line, pointing to the centre of the newel; commonly used in church-steeple, and great old houses: such as wind round an open newel, the fore-side of each being in a right line, pointing to the centre of the newel; as those in the Monument, London: such as wind round a solid newel, only the fore-side of each an arc of a circle, either concave or convex, pointing near to the circumference of the newel: and such as resemble the last in all other respects, save that they have an open newel. Any of these winding stairs take up less room than other kinds.

In stairs that wind round a solid newel, architects make the diameter of the newel either $\frac{2}{3}$, or $\frac{1}{2}$, or $\frac{1}{3}$, or $\frac{1}{4}$ of that of the

the staircase, according as that is in bigness. If very small, the newel is but $\frac{2}{3}$, and if large $\frac{7}{8}$, &c.

In stairs that wind round an open newel, Palladio orders the newel to be one half of the diameter of the staircase; though there does not appear any reason why the newel here should not be proportioned to the staircase, as in the former.

As to the number of stairs in each revolution; Palladio orders, that, in a staircase six or seven feet diameter, the stairs in each revolution be twelve; if the diameter be eight, the stairs to be sixteen; if nine or ten, the stairs to be twenty; and if eighteen, to be twenty-four.

Elliptical winding stairs, of which there are two kinds; the one winding round a solid, the other round an open newel: they are much of the same nature as circular stairs, excepting that, in the one, the newel is a circle, and, in the other, an ellipsis.

Square winding stairs are such as wind round a square newel, either solid or open; the fore-side of each square being in a right line, pointing to the centre of the newel.

Triangular winding stairs are such as wind round a triangular newel; the fore-side of each being a right line, pointing to the centre of the newel.

Columniated winding stairs.—Palladio mentions a staircase, in Pompey's portico at Rome, set on columns, so as that the light they receive from above, may distribute itself to all parts alike.

Double winding stairs.—Scamozzi mentions a staircase in this form, made by Pedro del Bergo, and Jean Coffin, at Sciamborg, in France, in the king's palace. It is so contrived, as that two persons, the one ascending, and the other descending, shall never meet.

Dr. Grew describes a model of this kind of staircase, kept in the Museum of the Royal Society. The foot of one of the staircases, he says, is opposite to that of the other; and both make a parallel ascent, and within the same cylinder. The newel in the middle is hollow, and built with long apertures, to convey light from candles placed at the bottom, and on the sides of the newel into both cases.

Quadruple winding stairs.—Palladio mentions a staircase of this form, in the castle of Chambor, near Bloys. It consists of four staircases, carried up together, having each its several entrance, and going up one over another, in such manner, as that, being in the middle of the building, the four serve to lead to four apartments; so that the people of the one need not go up and down the stairs of the other; yet being open in the middle, they all see each other pass.

Mixed stairs are such as partly fly, and partly wind; whence some call them *fliers* and *winders*. Of these there are several kinds; as,

Dog-legged stairs, which first fly directly forwards, then wind a semicircle, and then fly directly backwards, parallel to that.

Square fliers and winders have a square newel, either solid or open; and fly by the sides of the newel, winding a quadrant of a circle at each corner.

Solid and open newelled fliers and winders are of two kinds; the one winds a quadrant of a circle about a solid newel; then flies by the side of a square open newel; then winds again by the side of a solid newel; then flies again, and so alternately. The other flies first, then winds, and then flies again alternately.

STAIRING, in *Geography*, a town of Austria; four miles W. of Voglabruck.

STAIRS, in *Building*, the steps by which we ascend

and descend from one story of a house to another. See **STAIRCASE**.

STAITH is a stage or strong wooden scaffold, to which coal-waggons are conducted by a rail-way, in order to shoot their contents into hips, boats, or carts.

STAKE, in *Agriculture*, a long piece of branch-wood, or strong staff or stick fixed upright in the ground, in making hedges, between which the brush-wood is laid and interwoven in the making of them.

STAKE, the name of a small anvil used by smiths; sometimes it stands on a broad iron foot, on the work-bench, to be moved up and down occasionally; and sometimes it hath a strong iron spike at the bottom, by which it is fixed to some place on the work-bench. Its use is to set small and cold work straight, by hammering it on the stake, or to cut and punch upon it with the cold chissel, or cold punch.

STAKE of a Plough. The stake is an upright piece of wood, passing at its bottom through that link of the tow-chain which passes through the box of the plough, and at its upper end receiving the end of what is called the *bridle-chain*, which ties it to the crow-staff, or if it be not long enough, a wyth, or cord, is used to tie it: it is also tied to it again, a little below the pillow of the plough, by another wyth or cord. See **PLOUGH**, **PILLOW**, **CROW-STAVES**, &c.

STAKES, in *Ancient Armoury*, were long and pointed at both ends, and used to protect the archers from the attacks of the enemy's horse: these were planted in the earth, sloping before them. In the first of Edward VI. three hundred and fifty of these were in the stores of the town of Berwick, under the article of archers' stakes: there were also at the same time eight bundles of archers' stakes in Pontefract castle.

STAKE-Heads, in *Rope-making*, are posts, about four feet long and four by three inches square, with four wooden pins fixed in the upper side to keep the strands asunder. For lines they are about two feet long and three by two inches square, and have six pins.

STAKE-Posts, are posts of oak, about four feet high and twelve inches diameter, with a mortise-hole in each, for the stake-heads to go in and out, to keep the rope from the ground. They are placed about ten yards distant from each other, along the whole length of the rope-walk.

STAKING, *Pointing*, or *Sharpening Hop-poles*, the art and practice of rendering their bottom parts pointed and sharp, in somewhat the manner of the common hedge-stake, in order that they may be set into the ground or soil in a firm and ready manner. See **HOP**, and **STACKING and Pre-serving Hop-poles**.

STAL-Boat, a kind of fishing-boat mentioned 27 Eliz. c. 21.

STALACTAGNIA, in *Natural History*, the name of a genus of spars. The word is derived from the Greek *σταλακτιος*, *stillatitious*, or formed by dropping, and *αγνος*, *pure*.

The bodies of this genus are formed by the dropping of water from the roofs of subterranean caverns, and are the purer sort of what are called by authors *stalactites*. They are crystalline sparry bodies, formed into oblong conical figures, composed of various crusts, and usually found in form of icicles. Of this genus there are three known species. Hill.

STALACTITE, plural *Stalactites*, in *Minerology*, are the pendent protuberances from the roofs or sides of caverns, formed by the deposition of calcareous or other earths, from the water which percolates through rocks.

Some

Some waters, that rise from beds of limestone, are so overcharged with calcareous earth, as to form an incrustation of stone round any substance that is immersed in them for a short time; of which we have well-known instances in the waters of Matlock, in Derbyshire, and Knaresborough, in Yorkshire: such are called petrifying springs. It is by a similar process that stalactites are formed, by the water dropping from some projecting point and depositing a part of its contents; succeeding drops continue to enlarge the deposition, which frequently assumes the form of an icicle, and is sometimes of considerable size.

Stalactites form so rapidly in some caverns and mines as to close up the entrance, and even fill up the excavation entirely. The depositions of calcareous earth formed on the floors of caverns, by the water which drops from the roof, are called *stalagmites*.

Though the formation of stalactites apparently depends on the mechanical deposition of earthy matter, and may seem to admit of an easy explanation, there are some peculiarities of structure in stalactitical masses which it is more difficult to account for.

In some stalactites we may observe a radiated diverging crystalline structure; in others, the lamellar structure of calcareous spar is observable when broken, and they divide into rhombs, or the regular primitive crystals of carbonate of lime. The progress from the radiated to the regular crystalline structure may be seen in the same specimen: thus it should appear, that the particles of the stalactite, after they had been mechanically deposited, and formed a solid, were capable of a certain degree of motion, which permitted their crystalline arrangement to proceed to its ultimate form, or the primitive rhomb. Some stalactites have occasionally been found which were tubular; other stalactites, that are solid, are covered with minute crystals, and sometimes are terminated by a knob, resembling a mushroom. Stalactites are not unfrequently formed under the arches of bridges, by the percolation of water through the mortar.

In the Geysers, or boiling springs of Iceland and other parts of the world, siliceous stalactites and stalagmites are formed on the sides of the rocks on which the water falls, or in the basins which surround the springs. These natural basins are indeed entirely formed of siliceous depositions, and it has been ascertained, that the waters contain a considerable portion of silica in solution.

The larger and more compact masses of stalactites are employed in statuary. This substance was much used by the ancients, and called *alabastron* and *alabastrites*. The alabaster of the moderns is more frequently gypsum, or sulphate of lime.

The alabaster from stalactite is sometimes of a pure white, but this kind is not so durable as that which is of a light yellow colour, or veined. The iron, which is the colouring matter, communicates to the stone a great degree of hardness, and on this account the coloured alabaster was more prized by the ancient sculptors than the pure white. See *STONE for Statuary*.

STALACTITIC, formed like stalactite.

STALACTOCIBDELA, in *Natural History*, the name of a genus of spars. The word is derived from the Greek *σταλακτιος*, *stillatitious*, or formed by the dropping of water, and *κιβδηλος*, *impure*.

The bodies of this genus are formed by the dropping of water from the roofs of subterranean caverns, and are the coarser kinds of what authors have called stalactite. They are crystalline-terrene spars, formed into oblong bodies, and

found hanging from the roofs of caverns and grottoes. Of this genus there are only two known species. Hill.

STALAGMITÆ. See *STALACTITE* and *STALAGMOSCIERIA*.

STALAGMITE, in *Mineralogy*, the deposition of earthy matter, formed by drops of water on the floors of caverns. The word is derived from the Greek *σταλαγμα*, a drop. See *STALACTITE*.

STALAGMITIS, in *Botany*, so called by Murray, in the Göttingen Transactions, v. 9, from *σταλαγμα*, a dropping, or *distillation*, because of the gum yielded by this tree.—Schreb. Gen. 729. Willd. Sp. Pl. v. 4. 980.—Class and order, *Polygamia Monoecia*, or rather *Polyadelphia Polyandria*. Nat. Ord. *Guttifera*, Jull.

Gen. Ch. *Cal.* Perianth inferior, deciduous, of four roundish, concave, coloured leaves, fleshy in the middle, bordered; the two outermost coriaceous, smallest; the two innermost thinner and veiny. *Cor.* Petals four, obovate, rather coriaceous, fringed, spreading, larger than the calyx; the two opposite ones largest. *Stam.* Filaments about thirty, inserted into a fleshy quadrangular receptacle, club-shaped, abrupt, somewhat quadrangular, erect, the length of the corolla, united into five sets; anthers erect, of two round lobes. *Pist.* Germen superior, globose; style erect, thick, short; stigma of four inversely heart-shaped, spreading, permanent lobes. *Peric.* Berry globose, of one cell, crowned with the style and stigma. *Seeds* three, oblong, obscurely triangular, "terminated by a joint."

Some male flowers are interspersed, in which there is no germen, only the thread-shaped rudiment of a style in some of them, with a prickly unequal imperfect stigma. Koenig observed the calyx to consist occasionally of six leaves, while the stigma was only three-cleft. Schreber doubted whether the stamens were always polyadelphous.

1. *S. cambogioides*. "Murray Comm. Goett. v. 9. 173." Willd. n. 1.—Native of Camboja and Ceylon. A middle-sized tree, with opposite spreading branches. *Leaves* opposite, ovate, acute, entire, flat, coriaceous, rigid, dark-green, smooth on both sides; occasionally obovate. *Footstalks* very short. *Flowers* axillary or lateral, whorled; the male ones either intermixed with the others, or in a cluster by themselves. *Murray*. This tree appears nearly akin to the *ΧΑΝΘΙΟΧΥΜΟΣ* of Roxburgh, see that article hereafter; Ait. Hort. Kew. v. 4. 420; yet we must presume them to be different on account of the great authorities on which the latter depends.

STALAGMODIAUGIA, in *Natural History*, the name of a genus of spars. The word is derived from the Greek *σταλαγμα*, a drop, and *διαυγης*, *pellucid*. The bodies of this genus are the purer kinds of what authors call stalagmitæ, or drop-stones.

They are spars found in form of small balls, each composed of numerous crusts, and considerably pellucid and crystalline. Of this genus there are three known species. Hill.

STALAGMOS, a term used by authors to express a distillation of rheum from the head.

STALAGMOSCIERIA, the name of a genus of spars. The word is derived from the Greek *σταλαγμα*, a drop, and *σκιερης*, *opaque*, and expresses an opaque spar, which has received its form from the dropping of water.

The bodies of this genus are the coarser kinds of what are called by authors stalagmitæ, and are small round masses, composed of numerous thin crusts, and of an opaque and coarse structure.

Of this genus we have only two known species. Hill. Scotland affords a vast variety of the stalagmitæ. One

cave, about eight miles distant from Aberdeen, on the sea-side, has its whole roof crusted over with stalactites, of a foot in length, hanging down like the fringe of a bed; the floor also is as deeply covered with congeries of stalagmites; the upper coat, both of these and the stalactites, is of a sea-colour, but the inner parts are as white as sal prunellæ; the water which drops from these is of a very peculiar nature, for it is to acrimonious, that if it touch the skin but ever so slightly, it makes it smart. Near this cave there is another hollow rock, in which the stalactites make a very beautiful figure: they are all formed into long and thick columns, and stand perpendicularly, so that they represent the pipes of an organ; when broken, they are all found to be hollow within. The rock, and all the stone thereabouts, is of the limestone kind.

STALBRIDGE, in *Geography*, a small market-town in the hundred of Brownshall, in the Sherbourne division of Dorsetshire, England, is situated near the banks of the river Stour, on the N. side of the county; 9 miles E. from Sherbourne, and 113 miles W.S.W. from London. The manor was anciently the property of the abbey of Sherbourne: after the dissolution of monasteries, Edward VI. granted it to the duke of Somerset; on his death it passed to the Audley family, and afterwards to Richard, earl of Corke; he bequeathed it to his son Robert Boyle, who resided here many years; and his first chemical experiments were made in the manor-house in 1647. Peter Walter, esq. clerk of the peace for Middlesex, afterwards purchased the manor, and in his family it has since continued. The town of Stalbridge, and the greater part of the parish, are seated on a rocky stratum, whence the vicinity is supplied with stone for building and other uses: the principal manufactory here is that of stockings, which is carried on to a very considerable extent. Two fairs are held annually, and a market weekly, on Thursdays. In the population report of 1811, the number of houses in this parish is stated to be 141, of inhabitants 890.

In the centre of the town is a stone cross, which, including the base, is thirty feet high. At the top is a square block, with four niches; those on the east and west fronts have the Crucifixion, with the Virgin, and St. John. On this block stood a cross; and from the top of the free-stone of the pyramid to the hole in which this cross was fixed, the height is ten feet. At the bottom of this block are several coats of arms; one of them seems a chevron or fess between three roses or escallops. The pyramid itself is twelve feet high, and all the angles are fluted. On one side of it is a defaced figure of our Saviour, with the lamb at his feet. The four sides of the base are adorned with reliefs, one of which seems to represent the resurrection of Christ, who holds a cross in his hand. The whole stands on three octagonal flights of steps, each diminishing in the ascent. Hutchins's History of Dorsetshire, 3 vols. fol. 1796, &c.

STALE, in *Agriculture*, a term used provincially to signify the handle of any thing or kind of tool, as a fork-stale, &c.

STALE, in *Rural Economy*, a term applied to the urine of animals: the stale of horses and some other animals should be carefully preserved for use in the way of manure. See URINE.

STALE also denotes a living fowl, put in a place to allure and bring others where they may be taken. See DECOY.

For want of these, a bird, shot, his entrails taken out, and dried in an oven, in his feathers, with a stick thrust through to keep it in a convenient posture, may serve as well as a live one.

STALE Furrow, in *Agriculture*, a term applied to a furrow

which has been long turned up, or in which the slice has been for some time exposed to the weather, in contradistinction to that which is newly formed, or in a fresh state. See SOWING.

STALE Seeding, the custom or practice of seeding or sowing land which has been long turned up, or in the ploughed state. The practice, though common, and held in much esteem with some in different places, should probably never be had recourse to, except in some cases with wheat, as where a firm and solid bottom is required in consequence of the too great friability or loose powdery quality of the soil, as in putting that crop in after potatoes, in some instances, and other similar products, which are apt to cause a very light state of the mould or soil. On account of the convenience of breaking up the lay grounds during a part of the winter season in some situations, stale seeding of the land has been practised, especially with oats and some other sorts of seed; but how far it has been found either beneficial or detrimental, has not yet perhaps been fairly put to the test of experiment. See SOWING.

STALE Sowing, in *Gardening*, the practice of sowing or putting in some sorts of seed into ground which has been dug up some time, and is in a stale condition. This is in some instances the case with peas, beans, and some other leguminous seeds, as well as those of some other kinds; but it ought always to be as much as possible avoided. See SOWING of Seeds.

STALECKE, in *Geography*, a town of France, in the department of Mont Tonnerre; 1 mile N.N.W. of Baccach.

STALIKON, a town of Switzerland, in the canton of Zurich; 6 miles S.W. of Zurich.

STALIMENE. See LEMNOS.

STALING, a term used to signify the act of evacuating the urinary bladder in the horse or mare, or other animal of the same kind. In team as well as other horses, it is a humane and necessary practice to suffer them to void their urine at full leisure, and to encourage them to it by *whistling*, or any other of the soothing methods which they may understand. The evacuation of urine is liable to interruption, profusion, and to be diseased from various causes, and thereby to produce much injury to the animals.

But neither team nor other horses are much subject to stale blood, unless in cases where they have sustained some hurt, or been strained in the loins or kidneys, and when some of the blood-vessels about the neck of the bladder have been ruptured or burst open, or in cases of erosion taking place there, or in the passage of the urine, by means of which some of the smaller and more minute vessels of these parts may have been laid open, and send forth a bloody sort of discharge; but when this last happens, it is mostly very small in quantity, and but of short duration, commonly going off without any assistance in the way of medicine.

In cases where the urine passes off in an intermixed bloody state, or blood comes away in an almost pure or clear condition immediately after the staling of the animal, the complaint may be removed, if the horse is strong, well fed, and in a full condition, by bleeding in a pretty plentiful manner, according to the size and state of the animal; but if he be of the team hard wrought kind, and low in condition, it must be used in a much more sparing way, and, in many instances, be wholly omitted. After bleeding, and in those states of the disease in which it is unnecessary, the use of mild astringent opiate remedies may often be employed internally with great advantage; such as the red restringent gum, in the quantity of two, three, or more drachms, according

ording to circumstances, in *fine powder*; oak-bark, or that of the Peruvian kind, in powder, two or three ounces; and powdered crude opium, from a scruple to about half a drachm; mixed and made up into a ball with a little honey or treacle, and given to the horse once or oftener in the day, until the bloody staling discharge goes off and wholly disappears, which is ascertained by the animal staling in a free and perfect manner. Other similar sorts of astringent substances and barks may likewise be made use of with perhaps equal benefit, where these cannot be had, as well as some restringent tinctures, such as those of the above gummy matter and several others. All these remedies should constantly be given in large quantities of some kinds of mucilaginous liquids, as the free use of such substances is found to be highly beneficial in all cases of this nature.

After such complaints are wholly removed, the strength of the animals may be restored by the giving of such powdery substances as are directed below, in full quantities of oatmeal or other sorts of gruel, as there may be occasion. The powder of the root of gentian, and that of Peruvian bark, in the proportion of from one to two or more ounces; ginger in powder, one ounce or more; and sometimes the rust, or the salt of steel powdered, in the quantity of about half an ounce of the former, and from one and a half to two drachms of the latter. The horses should likewise have a pretty free use of mashes of different nourishing sorts.

There is a profuse sort of staling in horses of the farm, team, and other kinds, which sometimes constitutes and becomes a disease. See DIABETES.

STALK, among *Botanists*, that part of a plant which rises immediately from the root, and which usually supports the leaves, the flowers, and the fruit.

The term *stalk* is used on all occasions; but in speaking of the grasses, and gramineous plants, the word *culm* is used in its place, to distinguish that peculiar kind of stalk which is general to all these plants, and is not found in any others.

The terms used in describing the stalks of plants are, a *simple stalk*, one which runs up undivided from the root to the top.

Naked stalk, one that has no leaves.

Foliose stalk, one with leaves on it.

Ramose stalk, that which sends out branches.

Erect stalk, that which rises straight up.

Oblique stalk, that which is slanting.

Voluble stalk, that which twills round other things.

Flexuous stalk, that which bends.

Reclinate stalk, that which swoops towards the ground.

Procumbent stalk, that which lies on the ground.

Creeping, or sarmentous stalk, that which emits roots as it runs along.

If the stalk be rounded in shape, it is called *round*; if it make two angles, *ancipital*; if three, *trigonal*; if four, *square*; if more, *polygonal*.

If the stalk be lightly ridged and furrowed on the surface, it is said to be *friated*; if more deeply, *canaliculate*; if full of protuberances, *scabrous*; if lightly hairy, *villose*; if more roughly, *hispid*.

In the *branched stalk*, if the branches rise erect, it is expressed by *ascendant*; if they spread, by *diffuse*; if they are very large, it is called *branchiated*.

If the stalk divaricate, or, instead of sending out branches, it divide into them, it is called a *composite stalk*. If these divarications proceed by pairs, or if every branch be divided only into two others, it is called *dichotomous*; if it part into two series of branches, it is expressed by the term *dislichous*;

if it part into a multitude of ramifications, it is called *subdivided*.

All these terms are used also in expressing the different states of the *culm*, which, having no articulations, is called *equal*; when scaly, *squamose*.

STALK, in *Agriculture*, the stem or stock part of any sort of grain, grass, or other kind of plant that is grown as a field crop.

The stalks of many sorts of field plants are much disposed to be affected with different kinds of vegetable diseases, as those of the mildew, the rust, and several other sorts, which produce speckled, spotted, freckled, or other appearances on them.

The stalks or stems of many different field plants of the cabbage, borecole, rape, and other kinds, are not unfrequently left standing as very useful and necessary spring feed for ewes and lambs, as well as other sorts of sheep-stock, by the sprouts or small leaves which they throw out at that season in such an abundant manner.

The cutting over the stems or stalks of some sorts of plants is occasionally practised in the view of increasing the size or quantity of their produce, as in the case of the potatoe, and some other similarly rooted kinds; but from the trials which have lately been made on the subject, it would seem that harm rather than good is mostly the consequence of the practice.

The stalks of grasses and some other plants of that sort may, in some instances, and in particular cases, be cut over, cropped, or fed down by animals, especially of the sheep kind, with great benefit in rendering them more fine and more spreading, by which the herbage as well as the sward of the land is much improved.

There may likewise be other ways in which the management of the stalks in different sorts of plants may probably be beneficial in their cultivation, as by thinning, topping, and stripping off their leaves, &c.

STALK, in *Gardening*, the stem, upright, or rising part of any sort of culinary vegetable or other plant which is raised or cultivated in gardens or pleasure-grounds. The stalks of garden vegetables are, for the most part, of either the crisp, tender, fleshy eatable kinds, or of the more hard and ligneous sorts. The former are, in most cases, rendered more suitable and proper as food by being blanched, or having their colouring matters discharged from them in some way or other, as in celery, endive, sea-kale, and some others. The latter, being commonly only for temporary or future use and produce, rarely require any thing to be done to them, except the cutting and clearing away of the irregular or decayed parts towards the close of the summer, or other season; as they are of the annual, biennial, or perennial kind.

The stalks of some sorts of garden plants occasionally require to be stopped in their growth, in order to render them more productive in fruit, seed, or other matters, by having their extreme parts twilted or cut off, as is sometimes practised with the cucumber and other similar plants, as well as in the bean and other crops of that description. And the hard solid stalks of some kinds of garden plants, after they have been cut over, and their heads removed for use, are still suffered to stand in their places, or to be taken up and replanted in other situations, in the view of throwing out or sending forth fresh crops of edible shoots of the green kind. See SPROUTS, *Esculent*.

The stalks of all garden vegetables should, in general, be kept in as free and open a state of growth as possible, as when too close or too much crowded they never succeed so well, in whatever intention the plants from which they proceed

ceed may be raised or cultivated. They likewise, in some cases, require to rise quickly, in order to be good or of a proper quality.

The stalks of several different sorts, too, stand in need of support, as all those of the twining and some other kinds.

STALKER, in *Brick-making*. See **BRICK**.

STALKERS, in our *Old Writers*, a kind of fishing-nets. Stat. 13 Rich. II. cap. 20.

STALKING, a term of considerable import in fowling; applied to a kind of screen, or device to hide the fowler, and amuse the game, while he gets within shot.

Of such devices there are several kinds.

STALKING-HORSE, is a horse trained up for the purpose. This horse should be chosen of the tallest and largest kind; no matter how old he is, but he must be well trained, and ready at command. The horse, being properly trained, will walk slowly along in any sort of ground, as stubble-fields, moorish places, or the banks of rivers, and will always feed, or pretend to feed, as he is directed. The sportsman is to conceal himself and his gun behind the horse's fore-shoulder, bending his body low by his side, and keeping the whole body of the horse always full between the fowl and himself: when by this means the sportsman is come so near to the birds, that the gun will reach them with strength to kill, he is not to attempt advancing any nearer, that they may not be disturbed. Some recommend the shooting over the horse's buttocks, and some over his neck, but the best way is under the neck, and before the breast, for by this means the body of the sportsman is covered by the shoulder, and his legs by the legs of the horse. When the birds are shot, the dog will bring them to his master, and as they often fall in places where a man cannot come at them, this creature is of very necessary service.

This is the best of all methods of stalking; but as such a horse is difficult to train, chargeable to keep, and is not always to be had, there are many contrivances introduced to supply the place of it: among these, the principal are the stalking-wheelbarrow, the stalking-bush, and the stalking-hedge. The first of these is to be thus contrived; take a wheelbarrow, made on purpose of light fir, and set round about it boughs and bushes in such a manner, that you may fit in it, and not be discovered by the fowl, and drive it along without giving them disturbance.

The stalking-bush is to be contrived of several bushes well platted together, with all their leaves on; it is to be fastened to a stake, which is to have an iron point at the end; the whole is to be the height of a man, and thickly set with boughs all the way, from top to bottom. When the sportsman sees his game before him, he is to advance slowly with this artificial bush between him and them; when he is come within a proper distance, he is to fix the bush into the ground, by running in the iron spike, and then to shoot through the boughs.

The stalking-hedge is generally made about nine feet long, and a yard and a half high: it is to be made of small wands, so woven together, as to give room for the placing of green boughs among them, that it may resemble a great growing hedge: this is to be carried before the sportsman, and, in the manner of the bush, it is to be fastened down when near enough for the gun to kill from it.

As birds, however, are apt to have some apprehension of terror from seeing a tree or hedge move, these machines are to be carried on very slowly; and the resemblance of a real animal, as a horse, or cow, are better for the purpose: these may be made of canvas, supported on a slight frame, and with tails of hair. For pheasants, woodcocks, and the

like foolish birds, the common flat figure of a horse will do; but the water-fowl are generally much more shy, and it is necessary, for the getting near them, to have the body made hollow, and stuffed with hay, or some other matter, to keep it out. The proper time to use these engines is either early in the morning, or late in the evening; for the sun-shine in the middle of the day very soon discovers to the fowl the imperfection of the engine.

STALL, in *Rural Economy*, a sort of inclosed place, in which a horse, cow, or any other kind of animal of the same or other description, is fed, foddered, or kept; as a division or separate portion in a stable, cattle-shed, cow-house, or any other building of the same nature. See **CATTLE-Shed**, **COW-HOUSE**, and **STABLE**.

In the stalls, the cattle, in the most improved modes, are commonly tied up, and fastened to upright round posts of about four inches in diameter, made perfectly smooth on their surfaces, by means of loose iron rings and small wooden bows or bands, which are put round the necks of the cattle, and slide readily up and down in the rings on the posts, as the cattle may want them. The upper parts of the bows, yokes, or bands, are molly flat, and have two holes in them; and the bow or band parts, which are in general formed of tough split ash, have a sort of button or knob at each end of them, which is put into the circular holes of the flat head-pieces, when, by the spring of the bows or bands, the knobs or buttons are prevented from returning, by their slipping over into nicks or notches made in one end of the head-pieces, where they become fixed until the animal be wanted to be let out, which is readily done by a little pressure being made on the bow parts. These stalls have, in many cases, cribs also contrived for the cattle to eat their fodder out of or in. And passages are not unfrequently formed in front, or before the heads of the cattle, for the convenience and facility of giving them their fodder from, as much saving in time and labour is thereby produced.

The stalls in the cow-sheds, houses, or *linneys*, as they are called in some of the south-western districts of the kingdom, have their boxes or cribs so formed, as to contain the hay, straw, and other similar matters for the cows in winter, and the lucern, tares, vetches, and other such materials, in the summer season. They have also troughs for turnips, potatoes, cabbages, and other food of the same kind. And likewise vealing places for the calves, which are rendered a little dark, in order to promote the process of fattening them. There are sometimes, too, large separate stalls or divisions for such cows as are near calving, or have just calved. For young cattle-stock they are occasionally divided, also for three-years old, two-years old, and one-year old ones, in order that the young beasts may not get injured or inconvenienced by running among the others. And the head-ways, by being made shorter in proportion to the size of the different year's growth of the animals, render them capable of all dunging into the same grip or gutter, and consequently of being more readily cleaned and kept in order.

The divisions or stalls for the fattening of bullocks or oxen should always have sufficient space, without allowing any unnecessary waste of it, as where two oxen are fattened in one stall from eight to ten feet, that is, four or five feet to each beast, according to the size of the beast usually fattened. These divisions, in the beds or foundations of them, should constantly decline in a gentle manner backwards, so as to draw off the urine, and have a small rising at the heels of the animals, as in the cow-sheds or houses, and for the same purposes.

There should be a crib or manger in each stall, which should have the conveniency of a separate partition for different

ferent articles of food, as meal, oil-cake, bran, chaff, and others of the same kind, without their mixing or being blended with turnips, cabbages, potatoes, hay, or other such matters of fodder; and besides, a pump for supplying water to the animals, conducting or leading it to the different troughs which are formed for receiving it in each of the stalls.

In some cases, keelers are put in every stall for affording water to the cattle, which have troughs of communication, in order to convey it from pumps in the farm-yards to large general troughs on the outside of the ox-houses, which is afterwards separately conducted to each keeler, so that all the time and trouble in untying, tying, and driving to the water, are ingeniously and usefully avoided. The keelers or troughs, in these circumstances, are placed even with the cribs or mangers, and are mostly of the same sizes and dimensions.

In connection with all large ranges of ox-stalls, there should always be a weighing machine, in order that the owners may at any time instantly ascertain what are the state and progress of the beasts, as well as that the improvement they make, and the expence of food, or the flesh, and the food necessary to produce it, may be fairly compared. By this means, the sorts of cattle which give the greatest quantity of flesh meat with the smallest quantity of food, in these feeding stalls, may likewise be usefully and readily decided, which is a point of the utmost importance to the stock-feeding farmer.

STALL-Fed, a term applied to animals fed in the stall with dry food, and not with grass or other similar matters.

This sort of feeding is highly beneficial to the farmer, in raising and producing large quantities of the best kind of dung manure; but is rather expensive in the materials, and the different conveniencies which are necessary for the practice of it. See the following article.

STALL-Feeding, the art or process of fattening neat cattle in the stall. The best practice in this sort of fattening is, probably, that of wholly confining them to the stalls, which is usually termed stall-feeding; as by this means they are kept quiet, and free from interruption, and of course feed more quickly, and with greater regularity, which seem to be points of great importance in this system of management with these animals; though there are some who are still in favour of the yard management.

In regard to the sorts of food that may be employed in the way of winter fattening the animals in this practice, the principal of the more succulent kinds are carrots, parsnips, potatoes, Swedish turnips, cabbages, common turnips, grains, and some others; and of the more dry sorts, oil-cake, and other matters of that kind, oats, barley-meal, rye-flour, bean and pea-meal, and others of the same nature, with different sorts of straw and haulm cut into chaff by means of machinery, or hay cut in the same manner. It is usual with some to employ the different meals in a state of mixture in nearly equal proportions, except the bean-meal, which, from its heating quality, is mostly made use of in smaller quantities. But on the principle of fresh sorts of food having a more powerful effect on the systems of animals, when first applied, it may be more beneficial to have them given in alternation, or at distant intervals, as their effects may in this way be more fully experienced. And in respect to the cut straw and hay that are made use of in this way, the first should, contrary to the practice usually adopted, be prepared from that which is fresh threshed out, and not such as has been long packed together, and is become stinky. The hay, instead of being of the inferior kind, should be the best the farm affords, and such as is not in the

least injured in the smell or taste by keeping. It has, however, been stated by Mr. Dark of Herefordshire, an experienced grazing farmer, that the more inferior sort of hay has, by the addition of a very small proportion of common salt, been made to be preferred to the best, when prepared in that way. The quantity of it used with flooded meadow hay was only about eight pounds to the ton; and his oxen of the breed of that district did better with it than others which had the best hay. The whole of the advantage is ascribed to the portion of saline matter mixed with it, acting as a stimulus or condiment on the stomachs of the animals.

Upon the principles of this sort of feeding, the author of the System of Practical Agriculture has offered several physiological observations, that deserve attention, but which our limits will not allow us to insert.

In this management, it is a matter of the utmost importance for the animals to be kept constantly free from standing in any dirt or nastiness, by having the dung daily removed and cleaned out, and their standings swept out as clean as possible; being then littered down with dry clean litter, so as to prevent any sort of nastiness from adhering to their skins, or affording them uneasiness during their fattening. And in order to effect the littering in the most perfect manner, as much straw, or other similar matters, should be made use of as can be converted into manure, as from one to two or three tons each beast; as the dung will fully repay the expence of it, in the improvement which it must afford to the land on which it is applied. In this process it is also of much advantage to have the cattle sheltered, and kept in a due degree of warmth, without being too hot; as when the heat is too great, there may be disadvantage by too much perspiration being produced. In regard to the giving of the food in this process, the state of the appetites of the cattle, or other animals, should be nicely watched, and the quantities adapted, so as that it may be eaten up perfectly clean. With the more sweet succulent sorts, too much should not, however, be given at a time; but be duly combined with some of the dry kind. And where cut dry meat is chiefly employed, it is the best practice, probably, to keep some of it always in the cribs or boxes, so that the cattle may take it at pleasure, or as they find themselves disposed.

It has been stated, that where succulent food is made use of with cut dry meat, which is in general a more profitable method to the farmer than that of having recourse to corn and oil-cake, or the different sorts of meals stated above, carrots, parsnips, potatoes, and the Swedish turnip, would seem to stand the highest as articles for this use; the common turnip and cabbages having been found much inferior in their fattening properties. The two first are equal to almost any other sort of food in this view, being capable of fattening the largest cattle. And the most general practice is to employ these roots and plants without any other preparation, except that of being sometimes cut, sliced, or chopped, in a box for the purpose; giving only a small proportion at a time, at three or four different periods in the course of the day, in cribs properly contrived for the purpose; due supplies of such cut straw, in mixture with hay, being, where necessary, provided and given in the intervals of such feeds. It is found that in this method much less water will be necessary, than when dry meat is wholly made use of in the process, as the animals are much less thirsty from the succulence of the food.

Farther, the nutritious properties of the carrot have been found very considerable, when employed in this way; and this root has some great advantages, as the animals readily take

take to it, and a great proportion of food is capable of being raised on the acre. It was found by Mr. Young, in his trials with this root, that the consumption with an ox of about sixty stone weight was *per day* about ten stone, giving in addition cut hay and chaff, or some other similar dry material. The parsnip is also a root of equal, if not superior, merit in this management. An acre of either of these roots would complete the fattening of two such beasts as the above, if taken from the pastures in a half-fattened condition. It has indeed been suggested, that these two roots and the potatoe approach the nearest of any to that of the oil-cake in their fattening properties, but are certainly inferior to that substance in this intention.

The white and red beets, and the scarcity root, or mangel wurzel, have also been found highly beneficial in this application.

And there have been many trials made with potatoes in the stall-fattening of animals, in which it has been fully shewn that, both in the raw and boiled or steamed states, they are a root that occasionally answer very well. It has been found, that small cattle of the Welsh and Scotch runt kind have been ascertained to consume about a bushel each in the course of the day, with from fourteen to sixteen pounds of hay, or some other cut dry food. In the raw state, some dry food of these sorts is indispensibly necessary, in order to correct the purgative quality of the root; and when boiled or steamed, it has likewise a good effect in affording due distention to the stomach. When given to milch-cows in a raw state, the milk is found to be greatly increased, but to be of a poor thin quality. There can be no doubt, but that where the steaming or baking of the root can be accomplished at a cheap rate, and in a convenient manner, the food will be much better suited to the purposes of stall-feeding, as being much more nutrient and agreeable to the animals.

On this subject it is stated by an excellent grazier, J. H. Campell, esq. of Charlton, in Kent, in answer to queries proposed to him by Mr. Young, that 100 bushels of potatoes and 700 weight of hay are generally sufficient to fatten an ox that thrives tolerably well. And in giving the roots, they should at first be used in small quantities, which should then be gradually increased to one or two bushels *per day*, dry food being always intermixed, and the proportion of hay being uniformly regulated by the effect which the potatoes produce on the bowels. There ought to be at least four or five servings in the course of a day, as according to the quantity of roots which a beast can be induced to eat with appetite, he will fatten the sooner, and of course with less expence to the farmer, and consequently more profit be obtained. The hay should be cut once, or, if it be not very weighty, twice along and three times across the truss, so as to be in square pieces of eight or ten inches in proportion; in which state the cattle will eat it and digest it more readily, while their fattening is considerably expedited. But the potatoes need not, he thinks, be cut, except at first, in order to entice the beast to eat them; but they ought always to be fresh and clean. Corn or meal is not absolutely necessary; but when at a moderate price, it may be employed with advantage. But in case a scowering should be brought on by the use of raw potatoes, which often happens, the quantity of hay, meal, or other dry food given with them, should be increased considerably, till the beasts become accustomed to the roots, when this inconvenience will be removed.

Stall-feeding of bullocks with potatoes, given in different states of preparation, has been for some time extensively practised in Sussex, and is much approved of by many. They

there find that a beast of from one hundred and forty to one hundred and sixty stone weight eats from one to two bushels of the roots in the course of the day, but consumes little hay, as not much more than ten or twelve pounds, in that space of time. This root has probably not yet been tried, by giving it when artificially sprouted; but it would perhaps answer well in this way. Some have, however, lately begun to question the merit of potatoes in this mode of cattle-feeding, as not being so valuable, when compared with some other sorts of food. And a careful experimenter, who was largely in the practice of fattening oxen with them, it is said, gave them up, from the conviction that, with every advantage of breed, attention, warmth, and cleanliness, in regard to the animals, they would not pay more than four-pence the bushel.

Further, the Swedish turnip, when it is cultivated in a proper manner, is a most valuable root, when used in this intention, being very sweet and palatable to the animals, and at the same time possessing more nourishing power than the common turnip; of course, going much farther. In some trials which we have lately attended to, it was found to have the advantage nearly in the proportion of one-fourth; and in other experiments, it is said to have gone still farther in this use.

Also cabbages, in combination with dry chaffy materials of different kinds, have been long known to answer well in keeping store animals in the winter; and, when made use of with good hay, to be capable of fattening large cattle in an expeditious manner. It has been found by correct trials, that the daily consumption of this vegetable is mostly in the proportion nearly of one-fifth the weight of the animal: of course, an ox weighing about sixty stone consumes about twelve stone *per day*. In some experiments made long ago by Mr. Turner, detailed in the second volume of Mr. Young's *Six Months' Tour*, an ox of eighty stone was found to consume fifteen stone of this plant, with the addition of half a stone of hay. And that with regard to its properties of feeding oxen put to it, when in low condition, in November, they became in a state of fatness, and ready for the market, in the March following, having the weight of eighty stone; mostly increasing in value in the course of four months, about five pounds ten shillings. It is evident that, in this proportion, an acre of this crop of thirty tons would be sufficient for stall-fattening three beasts of the same size and weight.

And common turnips, according to Mr. Marshall, are, in Norfolk, given in different ways to cattle in fattening them; as by being drawn and thrown thinly and evenly upon the grass, stubble, and other lands, in order that the cattle may consume them in such situations; in which cases, they have not any allowance of hay during the whole process of fattening.

But another mode of giving this root to fattening cattle is, it is said, by means of close bins, or small cribs, with boards or bars nearly close at the bottom, while the beasts are kept in a loose straw-yard. These bins are dispersed over the yard, and the turnips are put into them whole; the tap-root, and also the tops, unless they are fresh and palatable, being previously cut off, so that the fattening animals receive only the bulbs; the tops, if eatable, being consumed by store cattle. And that while the bullocks are in the yard, they have the straw sometimes given them in cribs, and at others it is scattered in small heaps about the yard, twice or thrice a day: the quantity thus eaten is very trifling; and with the last mentioned management, the yard becomes evenly littered without farther trouble. But this mode of fattening is attended with somewhat more

STALL-FEEDING.

labour than that of throwing turnips abroad, which, it is thought, is the preferable management, if the soil be sufficiently dry to support the stock, and light enough to stand in need of being rendered firm by treading: on the contrary, where the land is deep, and the season is wet or severe, the straw-yard is the more comfortable place, provided it be kept dry and well littered, and be furnished with open sheds, in which the flock can shelter themselves. For though the *teat* of fattening cattle abroad is greatly beneficial to light soils; yet, if bullocks, while fed in the yard with turnips, are well littered, they will make a large quantity of excellent manure, that will amply compensate for the additional labour occasioned in that way.

A still farther method consists in keeping the cattle tied up in stalls, hovels, or beneath open sheds, with mangers or troughs for receiving the turnips, which, in this case, are frequently sliced, or more generally, though perhaps less eligibly, cut into quarters, by means of a small chopper, upon a narrow board or stool, beneath which is a basket for catching the pieces.

It has, however, been supposed that turnips, though very frequently employed in the process of stall-feeding, are greatly inferior to cabbages, as, besides their being more liable to injury, they probably possess the fattening property in a less degree than any of the substances that have been noticed above. And the proportion in which they are consumed by the fattening stock has been found to be something more than a third of the weight of the cattle, by some; but by others, about a third in the day, as stated in the Gentleman Farmer. However, in other experiments, carefully made, an ox of from seventy to eighty stone has been ascertained to eat something less than three hundred weight in the course of the day, besides chaff and hay; and small cows of about thirty stone, one hundred weight and three quarters in the same space of time. And in the Rev. Mr. Close's trials, it was found, that when consumed in stalls or sheds, an acre of good turnips will completely winter-fat an ox of fifty score, besides affording manure for an acre and a half of land; but if fed upon the land, two acres will not fatten one so well, and the dressing will be partial, and of but little value. When this root is given in the stall, from its very succulent nature, it becomes necessary to employ as much dry food as possible during the use of it, in order to the expeditious fattening of cattle by such means.

It has also been practically remarked by a late writer, that the turnip is often employed in the fattening of sheep, somewhat in this way; and that in this application it is frequently advantageous, where the management is conducted with judgment. But to derive the greatest profit from this practice, it is probably the best method to only make use of them for such sheep as are in a considerable state of forwardness; as such as are poor, when turned to this sort of food, are seldom found to pay well for it. Every farmer who has applied turnip crops in this way, must, it is said, have found this to be the case. Where the soils are sufficiently dry, the best method of consuming them may be on the lands, by means of hurdling; but under the contrary circumstances, they may be drawn and eaten upon a dry piece of sward.

Turnips, as well as potatoes, have been steamed for this purpose. See *STEAMING of Cattle-Food*.

As to the use of brewers' grains, they can only be had recourse to in this way in particular situations, as near large towns, or other places where they can be had at a reasonable rate, and in sufficient quantity: and of this sort of

food, that which is the produce of large distilleries is found the most beneficial in this sort of feeding. The quantity made use of for moderate sized beasts is usually from a bushel to a bushel and a half, three times in the course of the day; hay or cut dry food being given between the periods of feeding with these matters. But this sort of substance seems to be much less powerful in its fattening properties, than any of those articles that have been mentioned above. Still, with good hay, it is probable that these matters may be made to fatten animals in a tolerably expeditious manner.

But besides these different substances, there are others of a less succulent quality employed in this practice: the first, perhaps, in respect to the properties of feeding, is that of *oil-cake*, that is, the refuse material left after expressing the oil from linseed. See *OIL-Cake*.

It is asserted that these cakes have a very extraordinary effect on cows before calving, causing their milk to flow more copiously, and preparing the animal in a good manner for the period of calving. But as the fat of beasts, fattened on oil-cake, is not supposed by some so good for food, and to be of a less firm texture, it has been advised to substitute linseed jelly, which is infinitely superior, and which, when mixed with a due proportion of hay or meal, affords an excellent composition for stall-feeding and fattening. This jelly is prepared in the following manner: to seven parts of water one part of linseed is only put, for 48 hours; then boil it slowly for two hours, gently stirring the whole, lest it should burn; afterwards it should be cooled, and mixed with meal, bran, or cut chaff. In the experiment of Mr. Moody, an eminent grazier, two quarts of this jelly were used *per* day to every large bullock, which proportion amounts to little more than one quart of feed in four days, and produced a great saving in the article of food in this process. And in America, experiments have been made with *linseed-oil*, mixed with the meal of Indian corn. The stall-fed steer, to which this composition was given, was observed to thrive rapidly, and to sweat most profusely; but, through inattention, too large a proportion of oil was given at one time with the food, which disgusted the beast, and occasioned the experiment to be discontinued. There can, however, be no doubt but that linseed or flax-feed jelly is more agreeable to cattle than cake, while it renders them less liable to surfeit, in case an extra quantity should be accidentally given; and is less liable to affect the meat with a peculiar taste than either oil or cake, and consequently it merits a further trial. To each bullock, or fattening animal, about half a gallon of jelly may be given every day, mixed with meal and cut straw; but it will be requisite to change this food about a month before the beast is killed, to prevent, if possible, the flesh from retaining the flavour of the oil-cake or jelly, as they, each of them, may be liable to affect it in some measure.

Further, where sheep are fattened with oil-cake, they require it to be brought into a much finer state than for cattle in general, and which may then be mixed with bran, or other similar substances, and put in the troughs or cribs for the animals to feed at.

Also, on the same principle as that of oil-cake, the use of linseed-oil and bran has been attempted, but probably with less success in the application. The consumption in this mode, for beasts of the smaller size, is something more than half a peck of bran three times in the day, with a third of a pint of linseed-oil well stirred into it: with this, good hay or cut chaff is usually given. But it is a mode attended with more trouble than that of cake-feeding, without any
great

great superiority in the effect that is produced; and it can only be employed where the oil is cheap, and to be had with convenience.

Linseed and barley mixed and ground together, in the proportion of two pecks of the former to two bushels and a half of the latter, have been found very beneficial in stall-feeding, in Suffex, when given to summer-soiled or pastured animals in the yards, in the beginning of the winter season. Of this mixture each ox has two bushels in the week given him, besides wheat-chaff and hay. They fatten rapidly, it is said, in this way.

And another article, equal, if not superior, to any of these last kinds, in this sort of fattening, is that of oats, which may be given either in the straw or when threshed; for neat cattle it is probably best given in the former state, but for sheep in the latter, in shallow troughs or cribs made for the purpose, so as to prevent its being blown out of them. The consumption, in this sort of food by sheep, is usually from two or three to four or more pounds each *per* day, according to the size and kind which are fattened; but with neat cattle it must be proportioned to the animals in different respects.

Where barley or other meals are employed, they are best made use of in their dry states for sheep, in mixture with the cut or other matters that are given at the same time in their cribs or bins; but for neat cattle they are sometimes mixed up and blended with liquid materials in different forms. These substances have much effect in promoting the fattening of the animals; but they can seldom be made use of with much profit, except for the best sort of cattle or sheep. Where sheep are fattening on the turnips, these sorts of food are also excellent in correcting the watery properties of that root. Several other substances of the dry kind have likewise been employed in the stall-feeding of different sorts of animals, such as the dust and combs of malt, cut pea and bean-haulm, and other similar matters, which have been found highly beneficial.

Also, in this practice, the use of food in a sour state has been advised by some; as in this condition, it is said, experience has shewn it to be useful in the keeping and fattening of swine. But experiments are still wanting on this subject. And on the same principle, it has been recommended as a food for large cattle, which has been done by fermenting rye, flour, and water, into a kind of paste, and then diluting it with water; and also, when thickened with hay, cut small, it is said to fatten quickly. This practice chiefly prevails in France, whence it was introduced into this country. But concerning the efficacy of acid food in stall-fattening animals, there is much difference of opinion.

It may be stated, that it is now found that the wash or refuse of malt, remaining after distillation, which was formerly applied exclusively to the feeding of swine, may be used in this way with profit; and that it has, of late years, been applied with much success. The cattle fed in this manner are asserted, not only to repay the expence of their keeping, by fattening speedily, but also to yield a large quantity of valuable manure. This substance has been extensively and successfully applied in stall-feeding by Messrs. Hodgson and Co., the proprietors of Bolingbroke-House distillery, Battersea, near London, where the proprietors have erected stalls for fattening about 350 head of cattle at one time, with wash and grains, and a certain portion of hay *per diem*, with the view of enabling them to chew the cud. They are said, between October and April, which is their regular working season in the distillery, to fatten about 600 bullocks; having generally about 300

in the house tied up at one time, and about 100 in an adjoining orchard to take in, to replace such as are sold off, or in consequence of any expectation of an approaching advance in meat. They have no stated period for fattening these bullocks, being regulated entirely by the state of the markets; but from ten to sixteen weeks are about the usual time, and the cattle are found to gain, upon an average, from three to four stone *per* week.

Another substance has been employed in this way with equal success, which is that of molasses or treacle; though the expence incurred by the use of this article will probably prevent its general application. It was first used in the West Indies by Mr. Millington, who found it, in combination with farinaceous substances, and, when these could not be procured, with cane-tops, oil-cake, and other articles of dry food, together with a little hay, or not too green fodder, greatly to expedite the fattening of cattle in general, and of old and decayed oxen in particular. He gave from half a pint to a pint of molasses twice in the day to very starving animals, which had been exhausted by continual and severe labour for a series of years. In adopting this article, a gallon of oats, or other damaged grain, roughly ground, or the same quantity of potatoes, should be boiled in a sufficient proportion of water to form a thick wash. It must be well stirred while on the fire, to prevent it from burning or sticking to the sides of the vessel; and when it becomes cool, the mixture is to be formed into balls of about one pound weight each. These balls are divided into two equal portions, which, being previously immersed in the treacle, are given to the beasts morning and evening. They will devour them with eagerness, and will speedily thrive and fatten by the addition of a little hay, or any green fodder, that is not too succulent. Farther, one or two spoonfuls of salt may be dissolved in the composition, which will contribute to preserve the health of the animals; and in case corn cannot be conveniently procured and ground, pulverized oil-cake, diluted in water, and seasoned with a small quantity of salt, with the same proportion of molasses, may be advantageously substituted. And there are probably many other refuse saccharine or sweet substances, formed in different manufactures, that might be employed in the fattening of cattle in this way.

Where this sort of business is conducted on an extensive scale, it is of the greatest utility to have a machine for the occasional weighing of the cattle, as they advance in their fattening; as, without such assistance, there are but few persons who are capable of judging whether they go on in a profitable manner or not. But by weighing them from time to time, at the distance of every eight or ten days, in the morning before they are fed, this may be correctly ascertained; and where they fall off, or do not advance in a sufficient degree to the preceding weighing, such changes may be made in their food, water, and management, as are the most likely to promote their fattening in the most perfect manner, and with the greatest profit.

STALLAGE, **STALLAGIUM**, in our *Old Writers*, the liberty, or right of pitching and erecting stalls in fairs and markets, or the money paid for the same.

STALLATI, in *Geography*, a town of Naples, in Calabria Ultra; 1 mile E.S.E. of Squillace.

STALLED, in *Rural Economy*, a term signifying tired with eating in animals, or a kind of loathing of food in them. It also signifies set fast in a slough or bad road with carts or waggons.

STALLING, in *Agriculture*, a term applied to the practice of foddering, feeding, and fattening neat cattle

in stalls, or the tying or binding them up in them for any other purpose.

STALLION, in the *Manege*, in French *etalon*, a stone-horse kept to breed. See *HORSE*, and *Breeding of HORSES*.

In the reign of Henry VII. a large number of mares, as well as geldings, were turned after harvest into the common pastures, and no stoned horses were allowed to mix with them; and it is at this day contrary to law to turn a stoned horse into a common pasture. Those horses which were kept to cover mares were always confined in safe and inclosed grounds, but more frequently in the stable, and were called "equi ad stabulum," by contraction, *stallum*. Hence were derived the Italian term "stalloni," the French "etalon," the English "stallion," or "stalled" horse; which expression prevails, and is in use at present with regard to the ox, which sometimes being kept from the pasture in order to be fattened, is called "the stall-fed" and "stalled" ox. In the reign of the succeeding prince, particular regard was paid to the raising of a breed of good and strong horses, and laws were made for the more certain attainment of this end. The only method of securing strength and size in the progeny, is to select the fires and dams of a certain proportion, size, and mould, and to permit no mare or stallion to breed, but under these restrictions. In order further to secure a breed of large horses, a singular kind of law was passed, which obliged every archbishop and duke, under penalties, to keep seven trotting stoned horses for the saddle, each of which was to be fourteen hands high at the age of three years. Afterwards minute directions were issued, with regard to the number of horses of the same kind, which were to be kept by other ranks and degrees, each in proportion to their circumstances and station.

The reasons for enjoining stone-horses to be kept must have been for the sake of breeding, and for the superior labour they were thought to be able to undergo; and as they were more expensive to maintain than mares or geldings, it being necessary to separate and keep them apart, the rich and noble only were required to keep them in numbers proportioned to their rank and ability; while the lower people used geldings, for the advantage of turning them to grass. Brood-mares, two at least, were ordered to be kept by those who had parks, inclosures, and other conveniences. Berenger's *Horsefanship*, vol. i.

STALLUPONEN, or **STALLUPEIONEN**, in *Geography*, a town of Prussian Lithuania, the principal trade of which consists in cattle; 33 miles S.E. of Tilsit. N. lat. 54° 33'. E. long. 22° 58'.

STALOWITZ, a town of Lithuania; 10 miles from Pinsk.

STALTWASSER, a river of Wurtemberg, which runs into the Lein, 2 miles S. of Welzen.

STAMBACH, a town of Germany, in the principality of Culmbach; 12 miles E. of Culmbach.

STAMEN, in *Botany* and *Vegetable Physiology*, the ancient Latin name for the part in question, now become English in the place of its old appellation, *chive*. The stamens are organs of impregnation, essential to every flower, either in the same individual with the pistils, or in a corresponding one of the same species. (See *PISTILLUM*, and *FECUNDATION of Plants*.) They are seated externally with respect to the pistil, internally with respect to the calyx and corolla. They are inserted either into the calyx, the corolla, or the receptacle, rarely either upon the germen, or the style. Their number differs in different genera or species of flowers, from one to an hundred or more.

Each *Stamen* commonly consists of two parts, the *FILA*-
VOL. XXXIII.

MENT and **ANTHER**; see those articles. The latter only is essential, being of a capfular texture, containing the *POLLEN*, whose nature and office will be found explained in its proper place. The *Anther*, when arrived at maturity, either bursts by the contraction of its membranous coat, or opens by appropriate cells for the discharge of the pollen, of which last circumstance the genus *Erica* affords beautiful examples. In *Laurus* and *Leontice*, even in some species of *Solanum*, each cell of the anther has a proper lid. These cells are usually two; but in *Tetratheca* and *Vatica* they are four. Sometimes the anther is ornamented with a crest, or with a pair of bristles, of both which various *Erica* exhibit specimens. In *Pinus* the crests of the anthers prove useful for specific discrimination.

The *Stamens*, according to their number, situation, and proportion, furnish the leading principles of distinction in the artificial, or sexual, system of Linnæus; see *CLASSIFICATION*.—These organs are liable to be changed into petals, in what are termed double flowers; and if that change be complete, they can no longer serve the purpose of impregnation.

STAMFORD, in *Geography*. See *STANFORD*.

STAMFORD, a township of Upper Canada, in the county of Lincoln, lying on the W. side of Niagara river, and S. of Newark. A port of entry and clearance is established in this township, on the N. bank of Chippawa river, near the bridge.—Also, a township of Vermont, in Bennington county; containing 378 inhabitants.—Also, a post-town of Connecticut, in Fairfield county, on a small stream called Mill-river, which discharges itself into Long Island sound; containing a congregational and episcopal church, and 4440 inhabitants; 10 miles S.W. of Norwalk, and 44 N.E. of New York. This township was formerly called "Rippowanns," and was settled in 1641.—Also, a post-town of New York, in Delaware county, taken from Woodstock, and incorporated in 1792, containing 284 families, and 1658 inhabitants; 60 miles S.W. from Albany.—Also, a post-town in Lincoln county, Kentucky; 628 miles from Washington.

STAMFORD Islands, a cluster of small islands near the coast of North Carolina. N. lat. 34° 37'. W. long. 77° 10'.

STAMINA. See *STAMEN*.

STAMINA, in the *Animal Body*, are those simple, original parts, which existed first in the embryo, or even in the seed; and by whose distinction, augmentation, and accretion by additional juices, the human body, at its utmost bulk, is supposed to be formed.

All that is essential to the animal, are the stamina, which exist *in ovo*; the rest being foreign, additional, and even accidental.

The stamina seem to coincide with the solids, which are surprisingly small in quantity.

STAMITZ, JOHN, in *Biography*, the illustrious father of a renowned musical family, concert-master and director of the chamber music, or court concerts of the elector palatine at Manheim, in 1756, was born at Teutechebrodt, in Bohemia, where his father was cantor in the principal church. It was during his time, and by his example, that German symphonics, in a style different from the overtures of Lulli, Handel, and the Italian opera composers, began to be cultivated and in favour all over Europe. It was under him that the late earl of Kelly placed himself as a scholar on the violin, and a student in composition; and it was also under him that the Manheim band, by its experiments and new effects, became, during thirty years, the most celebrated in the musical world.

The genius of Stamitz was truly original, bold, and

nervous: invention, fire, and contrast, in his quick movements; a tender, graceful, and insinuating melody, in the slow; together with the ingenuity and richness of the accompaniments; characterize his productions, all replete with great effects, produced by an enthusiasm of genius, refined, but not repressed, by cultivation.

The following is a list of his principal works, which we advise true lovers and judges of good music to purchase wherever they can find them: as, though more than forty years old, in spite of fashion and a rage for novelty, they will long continue to be good music; "VI Sonate da Camera à 2 Violini e Basso," Noremb. 1761. "VI Sonate à Violino Solo e Basso, Op. 6," Paris. "VI Sonate choisies pour le Clavecin avec Violon, Op. 1ma." Paris. In MS. he left unpublished, six symphonies, twenty-one violin concertos, two harpsichord concertos, and nine violin solos.

STAMITZ, CHARLES, the worthy son of so great a father, was born at Manheim in 1746, and studied under Canabich. In 1767 he was admitted into the elector palatine's chapel, as principal second violin. He has travelled since all over Europe, and given specimens of his spirited compositions and performance, particularly on the tenor. He was in England about the year 1780, and performed at Bach and Abel's concerts. He composed a duet for a violin and tenor, which Cramer and himself performed to the wonder and delight of all hearers. This duet has often been played since by great performers on the tenor, violin, and violoncello. On this instrument, we believe Linley was the last.

In 1770 Charles Stamitz went to Paris, where he gained great applause by his compositions and performance on the tenor and viol d'amour. In 1785 he returned to his own country, and exercised his skill and talents at Berlin, Dresden, and Helle Cassel; in all which places he continued writing for almost all kinds of instruments.

STAMITZ, ANTHONY, the younger brother of Charles, was born in 1753, and became eminent likewise by his compositions and performance.

STAMMERING, in *Physiology*, an hesitation or interruption of speech, which seems generally to arise from fear, eagerness, or some violent passion, that prevents a child's articulating rightly, by the confusion which it occasions in the vibrations that descend into the muscular system, so that, finding himself wrong, he attempts again and again, till he hits upon the true sound. It does not therefore begin, in general, till children are of an age to distinguish right from wrong in respect of pronunciation, and to articulate with tolerable propriety. A nervous disorder of the muscles of speech may have a like effect. When the trick of stammering has once begun to take place in a few words, it will extend itself to more and more from very slight resemblances, and particularly to all the first words of sentences, because then the organs pass in an instant from inactivity to action, whereas the subsequent parts of words and sentences may follow the foregoing from association; just as in repeating *memoriter*, one is most apt to hesitate at the first word in each sentence. A defect of memory from passion, natural weakness, &c. so that the proper word does not occur readily, also occasions stammering, and, like all other modes of speaking, it is caught, in some cases, by imitation.

Sometimes stammering takes place only in the utterance of such words as begin with certain letters, which are generally some of the labial or guttural consonants, as *b, p, m, c, g*, &c. Some persons, on the contrary, stammer in the utterance of all words indiscriminately, with whatever letter they begin, whether they be vowel or consonant, at certain

times only; as *e. g.* when the speaker is placed in any situation that occasions hurry or embarrassment. Agreeably to the observations already made, we find that persons of great nervous irritability, and lively consciousness, are most liable to stammering. This sort of impediment is a bad habit, founded upon this constitutional susceptibility: and in attempting to remove stammering, while every attention should be paid to such means as physical and medical science will point out for the strengthening of the corporeal system, it is of the utmost importance to induce the persons affected with it to reason on the subject. Let them practise the formation of the component parts of words, (that is, simple vocal sounds and the powers of the consonants,) singly, and in combination, alternately, till a facility and habit of subjecting the muscles concerned in speech to the will be acquired or regained. They should be accustomed to consider that which is true in fact, that the organs of speech are moved by muscles which, from the laws of animal economy, are the instruments of the will; though we are conscious of an act of the will only at the commencement of such actions.

To counteract stammering, therefore, we must appeal to the understanding, and endeavour to arouse the will into vigilant and vigorous controul of the muscles. When a hesitation happens, let a volition or direct act of this power take place: first to cease muscular motion altogether, and then to commence a new series. The greatest deliberation and recollection should be used in ordinary conversation; and the act of speaking, as such should be constantly present to the mind, till the wrong habit be overcome, and the right so confirmed as to leave no room to apprehend a relapse. The voice should be carefully pitched at that tone which nature in the individual points out as easiest to the organs, and most agreeable to the ear; and by no means should a hurried pronunciation, or fictitious voice, be resorted to. It should be studiously remembered, that we are accountable to no one for the innocent and decorous exercise of our muscular powers—that over them we ourselves alone ought to have controul—that speech, on proper occasions, is not only an innocent and a decorous, but, in the eyes of others, a necessary and an agreeable exercise of our muscles. Why then be thrown into perturbation and confusion, when we are to perform an action, confessedly in our power; and which others have not only no right to prevent, but are desirous that we should perform? If this train of reasoning be fairly entered upon, many other arguments will suggest themselves, and must inevitably produce good.

The following directions, with variations according to circumstances, will be found to be attended with advantage, if duly and perseveringly complied with.

In order to raise a voice, or that material of which speech is formed, let the vowels be practised in a natural key, but with firmness and strength, for ten minutes or a quarter of an hour, at least, every morning. Then let the powers of the consonants be formed, in their order, singly, and variously combined with the vowels.

After a little rest, if imagination supply a subject, by all means let an imaginary conversation take place for twenty minutes, half an hour, or even an hour, in a firm and natural tone of voice, using every effort of fancy, to suppose it directed to persons indiscriminately; that is, sometimes to servants, sometimes to equals in age and rank, and sometimes to elders, or those considered as superior in consequence and rank in society, from whatever cause. But if imagination do not furnish a topic, then let the time be spent in reading, in a tone as nearly approaching to the ease of familiar conversation as possible, taking care to manage the
fancy

fancy as above. This will furnish the lesson:—and after an interval of a few hours, the same sort of conversation or reading should be repeated, two or three times more in the course of a day. And on mixing with real auditors, every exertion should be made to associate the ideas of their imaginary, with their actual presence.

These directions, it will be perceived, are founded upon the principle of the association of ideas; than which a more powerful principle, in the formation of human habits, cannot be conceived.

An ingenious writer, whose observations we are now citing, is of opinion, that it may be laid down as an incontrovertible position, that persons possessing an ordinary mental capacity, with an adequate share of industry and strength, may *certainly* overcome the habit of stammering, by means such as here pointed out. See “*Instruction of the Deaf and Dumb,*” &c. by Joseph Watson, LL.D. 2 vols. 8vo. 1809.

STAMNOS, an urn, or vessel for holding water. Some authors have made it signify the bucket-head, as it is called, of those alembics which have no worm, but are cooled about the head by this means.

STAMP, a term used in some places for a weir, or waterfall.

STAMP-Duties, are a tax imposed upon all parchment and paper, on which any legal proceedings, or private instruments of almost any nature whatsoever are written; and also upon licences for retailing wines of all denominations; upon all almanacs, newspapers, advertisements, cards, dice, and pamphlets containing less than six sheets of paper. These imposts are very various, according to the nature of the thing stamped.

This tax, though in many instances very burdensome, is of service to the public in general, by authenticating instruments, rendering it much more difficult than formerly to forge deeds of any standing; since, as the officers of this branch of the revenue vary their stamps frequently, by marks perceptible to none but themselves, a man that would forge a deed of king William’s time must know, and be able to counterfeit the stamp of that date also.

The first institution of the stamp-duties was by statute 5 & 6 Will. and Mar. c. 21; and they have since, in many instances, been increased by subsequent statutes very far above their original amount. It would far exceed the limits of this work to recite all the duties of this kind that already exist; but it may not be improper to mention some of those that are most common.

By 44 Geo. III. c. 98. the several stamp-duties granted by any act of parliament then in force were repealed, and upon every almanac or calendar, for any time not exceeding one year, was imposed the duty of 1s.; for each and every year for which almanacs or calendars for several years shall be made, published, or intended, 1s.; and for a perpetual almanac or calendar, 10s. The calendar or perpetual almanac in any bible or common prayer book is specially exempted. Books or pamphlets serving the purpose of an almanac or calendar are subject to the same duty respectively, and to the same exemptions. (See ALMANAC.) For the stamp-duty on newspapers and pamphlets, see NEWSPAPERS.

By 44 Geo. III. c. 98. the several duties before imposed upon cards and dice made in Great Britain were repealed, and a new duty was imposed upon such cards and dice, *viz.* upon every pack of cards which shall be made fit for sale or use in Great Britain, 2s. 6d.; and upon every pair of dice fit for sale or use in Great Britain, 1l. See CARDS.

In one of the acts, *viz.* 10 Ann. c. 19. relating to the

stamp-duties, which are become in process of time very numerous and intricate, there is a clause which brings all the rest within the jurisdiction of the justices of the peace, and it is as follows: Two justices residing near the place where any pecuniary forfeitures not exceeding 20l., or any act touching any of the duties under the management of the commissioners of the duties on stamped vellum, parchment, and paper, shall be incurred, or any offence against any of the same acts shall be committed in any wise relating to the same duties, by which any sum of money only may be forfeited, may hear and determine the same; who shall, on information or complaint, within a year after the seizure made or offence committed, summon the party accused, and witnesses; and may issue warrants for levying the penalties by distress and sale, if not redeemed in six days. The said justices may at pleasure mitigate the penalties, the charges being first allowed; so that they do not reduce the penalty to less than double duty, over and above the said charges. The justice, before whom the offending person is convicted, shall levy the penalty, and apply the same as the act directs; and in default of sufficient direction, the same shall be applied, half to the king, and half to the person who shall prosecute for the same, if within six months after the offence is committed; but if after six months, the whole shall go to the king (26 Geo. III. c. 82.); which conviction shall be filed by the clerk of the peace, and shall not be removable by certiorari into any other court; but nevertheless subject to appeal to the quarter-sessions, in such manner as by any former act is directed. But now by the stat. 44 Geo. III. c. 98. s. 10. no action or information shall be commenced or filed in any court, or before any justice or justices of the peace, for any penalty or forfeiture under any of the stamp acts, but in the name of the attorney-general, or in the name of the solicitor or some other officer of the stamp-duties. And all penalties and forfeitures under the stamp-acts are to be applied to the use of the king, &c.; but the commissioners of the stamps may give such part of the penalty to the informer as they may think expedient.

By the 44 Geo. III. c. 98. all the duties and drawbacks under the care of the commissioners of the stamps shall cease from October 10, 1804, except as to the recovering of any penalties incurred previously thereto; and after that time certain duties are made payable, as specified in the schedules to that act annexed. By the 48 Geo. III. c. 149. the several duties in the schedule (A) to the former act annexed are repealed, excepting in certain cases.

By 55 Geo. III. c. 184. the duties granted by 48 Geo. III. c. 149. are repealed, together with the duties on pawn-brokers’ licences (44 Geo. III. c. 98.), and those on policies of insurance in the West Indies, or elsewhere beyond the seas, granted in the 50th year of his majesty’s reign, and the per-centage duty on insurances against fire, granted by 44 Geo. III. c. 98. all arrears excepted. The duties specified in the schedule annexed to 55 Geo. III. c. 184. are to be levied, and are committed to the management of the commissioners of stamps, who are to provide proper stamps, &c. By the same act, any person actually forging stamps, &c. and his aider or abettor, being lawfully convicted, shall suffer death as a felon, without benefit of clergy. It is further enacted, that all powers and provisions of former acts, together with fines, forfeitures, &c. shall extend to this act. The provisions of former acts respecting agreements shall be applied only to those that are charged with 1l.; and it is enacted, that the agreements charged with a duty of 1l. 15s. shall be subject to the same regulations as deeds hereby charged with a like duty. This act provides, that instruments having wrong stamps, but of

STAMP-DUTIES.

sufficient value, shall be valid; except in cases where the stamps used on such instruments shall have been specially appropriated to any other instrument, by having its name on the face thereof. It is further enacted, that the penalty for making, accepting, or paying bills of exchange, &c. without being duly stamped, shall be the forfeiture of 50*l.*; and the penalty of post-dating bills of exchange, &c. shall be the forfeiture of 100*l.* The penalty for issuing unstamped drafts on bankers, without specifying the place where issued, or if post-dated, is 100*l.* The penalty for receiving such drafts is 20*l.*, and on bankers for paying them, 100*l.* It is enacted, that promissory notes to bearer on demand, not exceeding 100*l.*, may be re-issued by the original makers, without further duty; nor shall such notes be liable to further duty, though re-issued by certain persons, not strictly the original makers. Notes re-issuable under 48 or 53 Geo. III. are to continue re-issuable till the end of three years from the date; the penalty on each fraud in the business being 50*l.* The penalty on issuing promissory notes for the payment of money to the bearer on demand, with printed dates, is 50*l.* Notes re-issuable for a limited period are to be cancelled, on payment afterwards; and notes not re-issuable are to be cancelled immediately on payment. The penalty for re-issuing notes, &c. contrary to law, and for not cancelling them, is 50*l.*: the penalty for taking notes, &c. re-issued contrary to law, is 20*l.* However, notes and bills of the bank of England are exempted from stamp-duty; and any such notes may be re-issued after payment, as often as it shall be thought fit. The composition annually payable by the governor and company of the bank of England, for the duties on their bills and notes, is the sum of 3500*l.* for every million, and after that rate for half a million, but not for a less sum than half a million, of the said averagement or value of their said notes and bank post-bills in circulation: but when the governor and company resume their payments in cash, a new averagement for the composition on account of stamp-duties shall be submitted to parliament. It is also enacted, that the bank of Scotland, and royal bank of Scotland, and British linen company, may issue small notes on unstamped paper, accounting for the duties.

It is further enacted, that re-issuable notes are not to be issued by bankers or others, without a licence; which licences are subject to certain regulations, specified in the act. But no banker shall take out more than four licences for any number of towns in Scotland. Several towns in England may, in certain cases, be included in one licence. Persons applying for licences are to deliver specimens of their notes; and the penalty for issuing notes without licence is 100*l.*

It is enacted, that promissory notes made out of Great Britain are not to be negociable, unless stamped; and the penalty on circulating such notes is 20*l.* for each.

The duty on fire-insurances is to be collected by the companies undertaking the same, who shall render to the commissioners of stamps quarterly accounts, making up such accounts to their own quarter-days. These companies have an allowance for collecting the duties of 4*l.* per cent. at the head office in London or Westminster, and of 5*l.* per cent. elsewhere.

The penalty, by this act, for not proving wills, or taking letters of administration within a given time, *viz.* six calendar months after the decease of any person, or two calendar months after the termination of any depending suit, is a forfeiture of 100*l.*, and 10*l.* per cent. on the duty. Ecclesiastical courts are forbidden to grant probates or letters of administration, without affidavit of the value of effects; and such affidavits are to be free of stamp-duty, and to be trans-

mitted to commissioners of stamps; the penalty for neglect being 50*l.* Provision is made for adjusting the stamp-duty, when it is either too high or too low. The penalty on executors, &c. for not paying the full duty on probates, &c. within a given time after discovery of a deficiency, is 100*l.*, and 10 per cent. on the deficient duty. The commissioners of stamps may give credit for the duty on probates and letters of administration, in certain circumstances; and may extend the credit, if necessary. A return of duty on probates, &c. is to be made in respect of debts, if claimed within three years.

Articles of confessionary are exempted from stamps, unless they be avowedly sold as medicines. The money accruing from all the duties arising from this act is to be paid to the receiver-general, and by him into the exchequer.

The schedule belonging to this act consists of three parts; the *first* containing the duties on admissions to offices, &c.; on instruments of conveyance, contract, obligation, and security for money; on deeds in general; and on other instruments not included under the following heads. The *second* part contains the duties on law proceedings. The *third* part contains the duties on probates of wills and letters of administration; on confirmations of testaments; on inventories to be exhibited in the commissary courts of Scotland; on legacies out of real or personal, heritable or moveable estates; and on successions to personal or moveable estates upon intestacy. Out of this mass of matter we shall content ourselves with selecting those articles that are most common and most interesting; referring for those of more rare occurrence, or of less general interest, to the act itself.

Under the *first* part we shall begin with the duty on the admission of any person to act as an advocate in any of the ecclesiastical courts, or in the high court of admiralty, or in any of the courts of justice in Scotland, which is 50*l.*; and the same sum on the admission of any person to the degree of barrister at law in either of the inns of court in England. On admission of any person to act as an attorney, solicitor, or proctor, in any court in England; or as a sworn clerk, clerk in court, or other clerk or officer in any court in England, whose business and emoluments depend, like those of an attorney or solicitor, on his being retained and employed by clients or suitors, the duty is 25*l.* These duties are subject to certain regulations, which we shall not detail. The same sum is also payable on the admission of any person to act as a writer to the signet, or as a solicitor, &c. in any court in Scotland. For the admission of any person to act as a solicitor, &c. in the court of session, judiciary, or commission of teinds in Scotland, who shall not have served a clerkship for five years, to a writer to the signet, or a solicitor, under regular articles, which shall have paid the stamp-duty payable by law, his admission shall be charged with a further duty of 60*l.*; and if any person be admitted to act as a procurator or solicitor in the high court of admiralty in Scotland, the commissary court, or any inferior court in Scotland, without having served a five years' clerkship or apprenticeship, &c. he shall be charged with a further duty of 30*l.* These payments are subject to certain exemptions. For admission of any person as a writer in ordinary in chancery, or as one of the six clerks, or one of the curators of the court of chancery in England, or as a sworn clerk, &c. in any court in Great Britain, the duty, where the salary, fees, &c. shall not amount to 50*l.* a year, is 2*l.*; between 50*l.* and 100*l.*, 4*l.*; from 100*l.* to 200*l.*, 6*l.*; from 200*l.* to 300*l.*, 12*l.*; from 300*l.* to 500*l.*, 25*l.*; from 500*l.* to 750*l.*, 35*l.*; from 750*l.* to 1000*l.*, 50*l.*; from 1000*l.* to 1500*l.*, 75*l.*; from 1500*l.* to 2000*l.*, 100*l.*; from 2000*l.* to 3000*l.*, 150*l.*; and from 3000*l.* upwards, 200*l.* The duty for admission

STAMP-DUTIES.

million as a notary public in England, is 3*l.*; and in Scotland, 2*l.*; for admission to be a member of either of the four inns of court in England, 25*l.*; into either of the societies called inns of chancery, 3*l.*; into the college of physicians in England or Scotland, 25*l.*; as a licentiate, 15*l.*; on matriculation in either of the English universities, 1*l.*; to the degree of a bachelor of arts in either English university, 3*l.* when conferred in ordinary course, and 5*l.* when conferred by special grace, or royal mandate, or by reason of nobility, or out of the ordinary course; to any other degree in either English university, for registry, in the ordinary course, 6*l.*, out of such course, 1*l.*; to the degree of doctor of medicine in either of the universities of Scotland, 1*l.*

For the admission of any person into any corporation, in respect of birth, apprenticeship, or marriage, the duty is 1*l.*; but upon any other ground, 3*l.* For an affidavit, the stamp-duty is 2*s.* 6*d.*, subject to various exemptions. For an agreement, or memorandum of the same, made in England under hand only, or in Scotland without any clause of registration, on a matter of the value of 2*l.*, or upwards, containing no more than 1080 words, 1*l.*; for more than 1080 words, 1*l.* 15*s.*; and for every quantity of 1080 words after the first, a progressive duty of 1*l.* 5*s.* This duty is subject to several general exemptions.

On the appointment of a chaplain, empowering to hold two ecclesiastical benefices in England, the duty is 2*l.*; on the appointment or deputation of a game-keeper, 1*l.* 15*s.* On the appraisement or valuation of any estate or effects, or any interest therein, or its annual value, or of any dilapidation, or of any repairs, &c. if the valuation shall not exceed 5*l.*, 2*s.* 6*d.*; from 5*l.* to 10*l.*, 5*s.*; from 10*l.* to 20*l.*, 10*s.*; from 20*l.* to 50*l.*, 15*s.*; and above 50*l.*, 1*l.* For the indenture of apprenticeship or clerkship (articles of clerkship to attorneys excepted), when the sum of money paid to the master or mistress shall not amount to 3*l.*, 1*l.*; from 3*l.* to 5*l.*, 2*l.*; from 5*l.* to 10*l.*, 3*l.*; from 10*l.* to 20*l.*, 6*l.*; from 20*l.* to 30*l.*, 12*l.*; from 30*l.* to 40*l.*, 20*l.*; from 40*l.* to 50*l.*, 25*l.*; from 50*l.* to 60*l.*, 30*l.*; from 60*l.* to 80*l.*, 40*l.*; from 80*l.* to 100*l.*, 50*l.*; from 100*l.* and upwards, 60*l.* For an indenture, without any consideration to the master or mistress, containing more than 1080 words, 1*l.*; and for more than that quantity, 1*l.* 15*s.* These indentures are subject to exemptions in favour of poor children apprenticed. For articles of clerkship, in order to admission as an attorney or solicitor in any of his majesty's courts at Westminster, 120*l.*; in any of the courts of the great sessions in Wales, or of the counties palatine of Chester, Lancaster, and Durham, or in any other court of record in England, holding pleas, in which the debt or damage amounts to 40*s.*, 60*l.*; and for any duplicate of such articles, 1*l.* 15*s.* With a view to admission as a sworn clerk in the office of the six clerks, or as a sworn clerk, &c. in the office of pleas, &c. in England, 120*l.*; and for any duplicate, 1*l.* 15*s.* For articles of clerkship, in order to admission as a proctor, 120*l.*; and for a duplicate, 1*l.* 15*s.* For indenture of clerkship, in order to admission as a writer to the signet, or solicitor in any of the courts of session, &c. in Scotland, 60*l.*; and for a duplicate, 1*l.* 15*s.* For indenture of clerkship, in order to admission to act as a procurator or solicitor in the high court of admiralty, the commissary court at Edinburgh, or any other inferior court in Scotland, 30*l.*; and for any duplicate, 1*l.* 15*s.*

For an inland bill of exchange, on demand or otherwise, not exceeding two months after date, or 60 days after sight, the duty for any sum amounting to 40*s.*, and not exceeding

5*l.* 5*s.*, is 1*s.*; from 5*l.* 5*s.* to 20*l.*, 1*s.* 6*d.*; from 20*l.* to 30*l.*, 2*s.*; from 30*l.* to 50*l.*, 2*s.* 6*d.*; from 50*l.* to 100*l.*, 3*s.* 6*d.*; from 100*l.* to 200*l.*, 4*s.* 6*d.*; from 200*l.* to 300*l.*, 5*s.*; from 300*l.* to 500*l.*, 6*s.*; from 500*l.* to 1000*l.*, 8*s.* 6*d.*; from 1000*l.* to 2000*l.*, 12*s.* 6*d.*; from 2000*l.* to 3000*l.*, 15*s.*; and exceeding 3000*l.*, 1*l.* 5*s.* For an inland bill of exchange, to bearer or order, exceeding two months after date, or 60 days after sight, for any sum from 40*s.* to 5*l.* 5*s.*, 1*s.*; from 5*l.* 5*s.* to 20*l.*, 2*s.*; from 20*l.* to 30*l.*, 2*s.* 6*d.*; from 30*l.* to 50*l.*, 3*s.* 6*d.*; from 50*l.* to 100*l.*, 4*s.* 6*d.*; from 100*l.* to 200*l.*, 5*s.*; from 200*l.* to 300*l.*, 6*s.*; from 300*l.* to 500*l.*, 8*s.* 6*d.*; from 500*l.* to 1000*l.*, 12*s.* 6*d.*; from 1000*l.* to 2000*l.*, 15*s.*; from 2000*l.* to 3000*l.*, 1*l.* 5*s.*; and above 3000*l.*, 1*l.* 10*s.* The duty for a foreign bill of exchange, drawn singly and not in a set, the same duty as on an inland bill of the same amount and tenor. The duty on foreign bills of exchange, drawn in sets according to the custom of merchants, is for every bill of each set, where the sum made payable doth not exceed 100*l.*, 1*s.* 6*d.*; from 100*l.* to 200*l.*, 3*s.*; from 200*l.* to 500*l.*, 4*s.*; from 500*l.* to 1000*l.*, 5*s.*; from 1000*l.* to 2000*l.*, 7*s.* 6*d.*; from 2000*l.* to 3000*l.*, 10*s.*; and for more than 3000*l.*, 15*s.* The bills exempt from the preceding and all other stamp-duties, are those issued by the governor and company of the bank of England, navy-bills, bills for the pay and allowances of his majesty's land forces, and some others. (See PROMISSORY Notes.) A bill of lading is chargeable with a duty of 3*s.* A bond in England, and personal bond in Scotland, given as a security for the payment of any definite sum of money, is chargeable, when the sum does not exceed 50*l.*, with a duty of 1*l.*; from 50*l.* to 100*l.*, 1*l.* 10*s.*; from 100*l.* to 200*l.*, 2*l.*; from 200*l.* to 300*l.*, 3*l.*; from 300*l.* to 500*l.*, 4*l.*; from 500*l.* to 1000*l.*, 5*l.*; from 1000*l.* to 2000*l.*, 6*l.*; from 2000*l.* to 3000*l.*, 7*l.*; from 3000*l.* to 4000*l.*, 8*l.*; from 4000*l.* to 5000*l.*, 9*l.*; from 5000*l.* to 10,000*l.*, 12*l.*; from 10,000*l.* to 15,000*l.*, 15*l.*; from 15,000*l.* to 20,000*l.*, 20*l.*; and exceeding 20,000*l.*, 25*l.* For a bond in England, and a personal bond in Scotland, given as a security for the transfer, or re-transfer of any share in any of the government parliamentary stocks or funds, or in the stock and funds of the bank of England, or East India company, or of the South-sea company, the duty is the same as on a bond for a sum of money, equal to the value of the stock or fund secured, according to its average price, on the day of the date of the bond, or on either of the ten days preceding.

For a bond in England, and personal and heritable bond in Scotland, given as a security for the payment of any annuity, except upon the original creation and sale thereof, or of any sum or sums of money at stated periods, not being interest for any principal sum, nor rent reserved or payable upon any lease or tack, for any definite and certain term, so that the total amount of the money to be paid can be previously ascertained, the same duty as on a bond of the like nature, for the payment of a sum of money equal to such total amount. For a similar bond, for the payment of an annuity, &c. for any indefinite period, or the term of life, so that the whole money to be paid cannot be previously ascertained, if the annuity, or sums secured, shall not amount to 1*l.* per annum, 1*l.*; from 1*l.* to 50*l.* per annum, 2*l.*; from 50*l.* to 100*l.*, 3*l.*; from 100*l.* to 200*l.*, 4*l.*; from 200*l.* to 300*l.*, 5*l.*; from 300*l.* to 400*l.*, 6*l.*; from 400*l.* to 500*l.*, 7*l.*; from 500*l.* to 750*l.*, 9*l.*; from 750*l.* to 1000*l.*, 12*l.*; from 1000*l.* to 1500*l.*, 15*l.*; from 1500*l.* to 2000*l.*, 20*l.*; and from 2000*l.* per annum and upwards, 25*l.* The duties on various kinds of bonds

STAMP-DUTIES.

are subject to various exemptions and regulations, for which we refer to the statute. For a yearly certificate taken out by every person admitted as an attorney or solicitor, and as a proctor, in England, and by every person admitted as a writer to the signet, solicitor, agent, attorney, or procurator, in any of the courts of Scotland; and by every sworn clerk, &c. and any other clerk or officer in any of the courts aforesaid, who shall act, in expectation of any fee or reward, as an attorney, solicitor, agent, proctor, procurator, or notary public, though not admitted or enrolled as such, if he shall reside in the city of London, or city of Westminster, or within the limits of the two-penny post in England, or within the city or shire of Edinburgh, who has been in possession of his office for three years or upwards, 12*l.*, or if he has not been in possession so long, 6*l.*; or if he shall reside elsewhere, in the first circumstance above stated, 8*l.*, and in the second, 4*l.* For a certificate taken out yearly by a member of one of the four inns of court in England, who acts as a conveyancer, special pleader, draftsman in equity, or otherwise, if he shall reside in the city of London, &c. as before stated, 12*l.*; or if he shall reside elsewhere, 8*l.* The exemptions comprehend sergeants at law and barristers; attorneys, solicitors, proctors, and notaries public; and other persons acting as such by virtue of any office or appointment, taking out certificates in these characters; and public officers preparing deeds, &c. by virtue of their office. A certificate of marriage, that of any common seaman, marine, or soldier excepted, is chargeable with a duty of 5*s.*; and so is the certificate of a person's having received the holy sacrament. The duty upon a charter-party is 1*l.* 15*s.*; that upon collation by an archbishop or bishop to any ecclesiastical benefice or promotion of 10*l.* or upwards yearly value in the king's books, is 20*l.*; that of collation to any other ecclesiastical benefice, &c. in England, is 10*l.*; that of collation, or admission by any presbytery or competent authority, to any ecclesiastical benefice in Scotland, is 2*l.* For the duties on different kinds and modes of conveyance, see the statute. The duty on a debenture or certificate for entitling a person to receive a drawback of duties in the customs or excise, or bounty payable out of the revenue of either, if the same shall not exceed 100*l.*, is 5*s.*; from 100*l.* to 200*l.*, 10*s.*; from 200*l.* to 500*l.*, 1*l.*; and above 500*l.*, 2*l.* For a declaration of trust, &c. the duty is 1*l.* 15*s.* For every skin or piece of vellum, &c. upon which shall be written the exemplification or constat under the great seal of the united kingdom of Great Britain and Ireland, of any letters patent or grant, the duty is 5*l.*

For a faculty from the archbishop of Canterbury, or the master of the faculties for the time being, or from the guardian of the spiritualities during a vacancy of the archbishop's see, not otherwise charged, the duty is 30*l.* For a grant or letters patent under the great seal, or the seal of the county palatine of Lancaster, or the seal kept and used in Scotland, of the honour or dignity of a duke, 350*l.*; of a marquis, 300*l.*; of an earl, 250*l.*; of a viscount, 200*l.*; of a baron, 150*l.*; of a baronet, 100*l.*; of a congé d'elire for any dean and chapter, for the election of an archbishop or bishop, 30*l.*; of the royal assent to or signification of such election, or of the nomination and presentation by his majesty, in default of such election, of any person to be an archbishop or bishop, 30*l.*; of or for the restitution of the temporalities to any archbishop or bishop, 30*l.*; of any other honour or franchise, &c. to any person or persons, body or bodies politic or corporate, 30*l.*; and if such grant or letters patent are contained in more than one skin, piece of

vellum, &c., then for every skin, sheet, or piece thereof, after the first, a progressive duty of 20*l.* For a grant or warrant of precedence to take rank among nobility, under his majesty's sign manual, 100*l.*; for a grant or licence, under the sign manual, to take and use a surname and arms, or a surname only, in compliance with any will or settlement, 50*l.*; for arms to the same, on voluntary application, 10*l.*; and for grant of arms, or armorial ensigns only, 10*l.* For a grant, under the great seal, &c. of any definite sum of money, not amounting to 100*l.*, 1*l.* 10*s.*; from 100*l.* to 250*l.*, 4*l.*; from 250*l.* to 500*l.*, 10*l.*; from 500*l.* to 750*l.*, 20*l.*; from 750*l.* to 1000*l.*, 30*l.*; from 1000*l.* and upwards, for every 500*l.*, 5*l.*

The duty on a grant of any annuity or pension, not amounting to 100*l.* per annum, is 1*l.* 10*s.*; from 100*l.* to 200*l.*, 4*l.*; from 200*l.* to 400*l.*, 10*l.*; from 400*l.* to 600*l.*, 20*l.*; from 600*l.* to 800*l.*, 30*l.*; from 800*l.* to 1000*l.*, 40*l.*; from 1000*l.* and upwards, 50*l.* For his majesty's grant of any office or employment, by letters patent, deed, or other writing, the profits of which do not amount to 50*l.* per annum, 2*l.*; from 50*l.* to 100*l.*, 4*l.*; from 100*l.* to 200*l.*, 6*l.*; from 200*l.* to 300*l.*, 12*l.*; from 300*l.* to 500*l.*, 25*l.*; from 500*l.* to 750*l.*, 35*l.*; from 750*l.* to 1000*l.*, 50*l.*; from 1000*l.* to 1500*l.*, 75*l.*; from 1500*l.* to 2000*l.*, 100*l.*; from 2000*l.* to 3000*l.*, 150*l.*; from 3000*l.* and upwards, 200*l.*

For institution to any ecclesiastical benefice in England upon presentation, 2*l.*; upon petition of the patron to be admitted, if the benefice or promotion be of the yearly value of 10*l.* and upwards in the king's books, 30*l.*; or if the same shall be of any other description, 15*l.*

The duty on a letter of attorney, made by a petty officer, seaman, marine, or soldier serving as a marine, for receiving prize money, is 1*s.*, for receiving wages, 1*l.* For a letter of attorney for the sale, transfer, acceptance, or receipt of dividends in any of the government stocks or funds, 1*l.*; for that of any other kind, or commission or factory, 1*l.* 10*s.*; and if more than 1080 words be used, a progressive duty for every 1080 words, after the first, of 1*l.* For a letter of licence from creditors to a debtor, the duty is 1*l.* 15*s.*; and a progressive duty for every 1080 words above the first number, of 1*l.* 5*s.*: for letters of marque and reprisal, 5*l.*: for licence for marriage in England, if special, 5*l.*; if not special, 10*s.*: for licence to use the occupation of an appraiser, taken out yearly, 10*s.*: for a banker or any other person who shall issue any promissory notes for money payable to the bearer on demand, and allowed to be re-issued, 30*l.*: for exercising the trade of a pawnbroker within the cities of London and Westminster, or within the limits of the two-penny post, 15*l.*; and elsewhere, 7*l.* 10*s.* For policy of assurance on life or lives, if the sum insured shall not amount to 500*l.*, 1*l.*; from 500*l.* to 1000*l.*, 2*l.*; from 1000*l.* to 3000*l.*, 3*l.*; from 3000*l.* to 5000*l.*, 4*l.*; from 5000*l.* and upwards, 5*l.* For policy of insurance from loss or damage by fire to goods, &c. 3*s.* per cent. per annum. For policy of insurance on any ship or vessel, or any goods on board, &c. where the premium shall not exceed the rate of 20*s.* per cent. on the sum insured, if the whole sum does not exceed 100*l.*, the stamp-duty is 1*s.* 3*d.*; if the whole sum shall exceed 100*l.*, then for every 100*l.*, and also for any fractional part of 100*l.*, 1*s.* 3*d.*; and where the premium shall exceed the rate of 20*s.* per cent. on the sum insured, if the whole sum insured shall not exceed 100*l.*, 2*s.* 6*d.*; if it shall exceed 100*l.*, then for every 100*l.*, and also for any fractional part of 100*l.*, 2*s.* 6*d.* If the insurance be made upon any ship or vessel, or goods, or freight, for any other voyage besides that above mentioned,

STAMP-DUTIES.

tioned, from any part in the united kingdom or the adjacent islands, to any other part in the said kingdom or islands, or for any certain term or period of time not exceeding twelve calendar months, if the premium be 20s. *per cent.* on the sum insured, and the whole sum do not exceed 100*l.*, the duty is 2*s.* 6*d.*; but if it shall exceed 100*l.*, then for every 100*l.*, and for any fractional part, 2*s.* 6*d.*: and if the premium exceed 20s. *per cent.* on the sum insured, if the whole sum shall not exceed 100*l.*, the duty is 5*s.*; and if it shall exceed 100*l.*, then for every 100*l.*, and any fractional part of 100*l.*, of which the same shall consist, 5*s.*

For a presentation by his majesty, or by any patron, to any ecclesiastical benefice, &c. of the yearly value of 10*l.* or upwards in the king's books, the duty is 20*l.*; and to any other ecclesiastical benefice or promotion in England, 10*l.* For a deed of procuration, 1*l.* 10*s.* Of PROMISSORY Notes we have already given an account under that article; but the act, the provisions of which we are now reciting, has repealed the 48th of Geo. III. and made some addition to the stamp-duties. The note for payment of any sum of money to the bearer on demand is chargeable, for 1*l.* 1*s.* with a duty of 5*d.*; from 1*l.* 1*s.* to 2*l.* 2*s.* with 10*d.*; from 2*l.* 2*s.* to 5*l.* 5*s.* with 1*s.* 3*d.*; from 5*l.* 5*s.* to 10*l.*, with 1*s.* 9*d.*; from 10*l.* to 20*l.*, with 2*s.*; from 20*l.* to 30*l.*, with 3*s.*; from 30*l.* to 50*l.*, with 5*s.*; from 50*l.* to 100*l.*, with 8*s.* 6*d.* The promissory note for payment in any other manner, &c. but not exceeding two months after date, or 60 days after sight, from 40*s.* to 5*l.* 5*s.*, is chargeable with a duty of 1*s.*; from 5*l.* 5*s.* to 20*l.*, 1*s.* 6*d.*; from 20*l.* to 30*l.*, 2*s.*; from 30*l.* to 50*l.*, with 2*s.* 6*d.*; from 50*l.* to 100*l.*, with 3*s.* 6*d.* Those notes either to the bearer on demand, or in any other manner, but not exceeding two months after date, or 60 days after sight, are chargeable, from 100*l.* to 200*l.*, with a duty of 4*s.* 6*d.*; from 200*l.* to 300*l.*, with 5*s.*; from 300*l.* to 500*l.*, 6*s.*; from 500*l.* to 1000*l.*, 8*s.* 6*d.*; from 1000*l.* to 2000*l.*, 12*s.* 6*d.*; from 2000*l.* to 3000*l.*, with 15*s.*; above 3000*l.* with 1*l.* 5*s.* Those payable at any time exceeding two months after date, or 60 days after sight, from 40*s.* to 5*l.* 5*s.*, are chargeable with a duty of 1*s.* 6*d.*; from 5*l.* 5*s.* to 20*l.*, 2*s.*; from 20*l.* to 30*l.*, 2*s.* 6*d.*; from 30*l.* to 50*l.*, 3*s.* 6*d.*; from 50*l.* to 100*l.*, 4*s.* 6*d.*; from 100*l.* to 200*l.*, 5*s.*; from 200*l.* to 300*l.*, 6*s.*; from 300*l.* to 500*l.*, 8*s.* 6*d.*; from 500*l.* to 1000*l.*, 12*s.* 6*d.*; from 1000*l.* to 2000*l.*, 15*s.*; from 2000*l.* to 3000*l.*, 1*l.* 5*s.*; exceeding 3000*l.*, 1*l.* 10*s.* (See PROMISSORY Notes.) For protest of a bill of exchange or promissory note, for any sum under 20*l.*, 2*s.*; from 20*l.* to 100*l.*, 3*s.*; from 100*l.* to 500*l.*, 5*s.*; from 500*l.* upwards, 10*s.* For every sheet on which a protest is written, after the first, a progressive duty of 5*s.* For receipts from 2*l.* to 5*l.*, 2*d.*; from 5*l.* to 10*l.*, 3*d.*; from 10*l.* to 20*l.*, 6*d.*; from 20*l.* to 50*l.*, 1*s.*; from 50*l.* to 100*l.*, 1*s.* 6*d.*; from 100*l.* to 200*l.*, 2*s.* 6*d.*; from 200*l.* to 300*l.*, 4*s.*; from 300*l.* to 500*l.*, 5*s.*; from 500*l.* to 1000*l.*, 7*s.* 6*d.*; from 1000*l.* upwards, 10*s.*; and in full of all demands, 10*s.* (See RECEIPT.) For settlement upon or for the benefit of any person or persons, in possession or reversion, if the sum shall not amount to 1000*l.*, the duty is 1*l.* 15*s.*; from 1000*l.* to 2000*l.*, 2*l.*; from 2000*l.* to 3000*l.*, 3*l.*; from 3000*l.* to 4000*l.*, 4*l.*; from 4000*l.* to 5000*l.*, 5*l.*; from 5000*l.* to 7000*l.*, 7*l.*; from 7000*l.* to 9000*l.*, 9*l.*; from 9000*l.* to 12,000*l.*, 12*l.*; from 12,000*l.* to 15,000*l.*, 15*l.*; from 15,000*l.* to 20,000*l.*, 20*l.*; from 20,000*l.* and upwards, 25*l.* For testimonial or certificate of the admission of any person to the degree of bachelor of arts, in either of the English universities, 3*l.*; to any other degree, 10*l.* For transfer of any share in

bank stock, or South-sea stock, 7*s.* 9*d.*; in the stock of the East India company, 1*l.* 10*s.*; in the stock of any other corporation, company, or society, 1*l.* 10*s.*

For an account of the second part of the schedule annexed to the 55th Geo. III. c. 184. containing the duties on law proceedings, we refer to the act itself.

The third part contains the duties on probates of wills and letters of administration, on confirmations of testaments, inventories, legacies, and successions. The duties on probates of a will, and letters of administration with a will annexed, to be granted in England, confirmation of any testament and inventory to be recorded in any commissary court in Scotland, by the 55th Geo. III. which alters the amounts stated from 48 Geo. III. under PROBATE, are shewn in the following table:

For an account of legacies and successions, as under the article RECEIPT, Schedule, part iii. with the following alteration agreeably to 55 Geo. III. c. 184; inserting instead of 10th October 1808, the 31st day of August 1815; inserting also in col. 2. line 13 from the bottom, after "deceased," or the father or mother, or any lineal ancestor of the deceased; instead of 2*l.* 10*s.* — 3*l.*; instead of 4*l.* — 5*l.*, and instead of 5*l.* — 6*l.*

STAMP-Office, an office under the direction of six commissioners, who are empowered to substitute inferior officers for the management of the stamp-duties. (5 Will. cap. 21.

9 & 10 Will. c. 25.) To this office belong a receiver-general, a comptroller, a secretary, and a number of clerks, &c. &c.

STAMPALIA, or STAMPALÆA, in *Geography*, formerly *Alypalea*, properly signifying the ancient city, and called also *Pyrrha*, *Pilea*, and at length *Theon Trabeza*, i. e. the table of the gods, because its soil is fertile, and it is almost every where enamelled with flowers, an island of the Archipelago, which, in the time of Pliny, was an independent country, and where Achilles had a temple, and that sort of worship that was paid to valour, contributed to maintain among its inhabitants the energy necessary for people who are not willing to submit to the yoke of a conqueror. From the irregular form of this island, it might be called the "Indented Island;" its shores presenting a variety of points, or sinuosities, that form so many coves and bays fit for the anchorage of ships or boats, though we can scarcely reckon more than two harbours, the one to the south, the other to the north. It is about six leagues in length, and only two in its greatest breadth; it is not very lofty, nor has it any high mountains that can be discovered at a great distance. Its soil, as we have already said, is fertile, being of that kind which is observed on plains and hills, and which does not extend to the tops of steep mountains. Stampalia is reckoned one of the most fertile islands of the Archipelago: its inhabitants experience the mildness of the climate and the goodness of the soil; and in these respects they differ in character from the rough islanders of Calamo and Lero, which are rugged countries. Its fertility, however, is checked by the empire of the Turks, to which it is subject; and the oppressive exactions to which its inhabitants are compelled to submit: the shores abound with a great variety of fish. N. lat. 36° 40'. E. long. 26° 16'.

STAMPE, or TEMPÉ, in *Commerce*, a small copper coin in the West India islands. In the English Leeward islands 1 stampe = 1½ dog = 2¼*d.* Leeward currency, and 8 dogs or 4 stamperes = 1 bit = 9*d.* of the same currency; the dollar in this currency being reckoned at 9*s.* In the French islands, the noir or dog is = 2 fols 6 deniers = 1½*d.* Leeward currency, and the tempé or stampe = 3 fols 9 deniers = 2¼*d.* Leeward currency.

STAMPERS and STAMPING, in *Coinage*. See COIN and COINAGE.

STAMPING-MILL, or *Knocking-Mill*, an engine used in the tin-works to bruise the ore small.

STAMPS, in *Metallurgy*, a sort of large pestles lifted up by water-wheels, and serving to beat to powder the ores, and refuse of ores of metals.

STAMSLO, in *Geography*, a town of Hungary; 15 miles N.E. of Gros Wardein.

STAMWOOD, in *Agriculture*, a term applied to the roots of trees grubbed up. Any sorts of root-wood are so termed in different situations and places.

STANCH, or STAUNCH, a name given by the country people of Northamptonshire, and some other counties, to a species of fossil called felenites, from its supposed virtue in stopping fluxes of blood. See PACHODECARHOMBS.

STANCHING of Blood, the stopping of blood in cases of wounds in horses or other animals. This is mostly best performed by means of dossels of lint and tow applied to the parts which are wounded.

STANCHIO, or STANCHO, in *Geography*, an island in the Grecian Archipelago, anciently known by the name of *Cos* (which see), and by some modern geographers called "Lango." Of the ancient magnificence of this island no traces now remain. The modern town of Stancho

is small; its buildings are not particularly remarkable; though its situation on the sea-shore is the same with that of the ancient city, and its environs are still agreeable. It is surrounded by orchards of lemon and orange-trees, the flowers and fruit of which are equally regaling and refreshing to its inhabitants, and afford them a valuable article of commerce. Cargoes of oranges and lemons are shipped here, and conveyed to different parts of Turkey, but principally to Smyrna and Constantinople. The harbour, which is defended by a castle, kept in bad order, though formerly safe and deep, can no longer receive any but small vessels: large ships remain without, in a road which has good holding-ground, but in winter it is open to the winds, and the swell from the north and west, and therefore avoided. The population of the town of Stancho is in a great measure composed of Turks: the Greeks occupy the remaining part of the island, but they are not numerous. The island, which is much longer than it is broad, is not very extensive; but the beauty of its climate and of its soil, its fecundity, and its natural allurements, would render the paucity of its inhabitants extraordinary, if we did not recollect that it is under the immediate command of the Turks. Some writers have asserted that Stancho is an island subject to epidemical diseases, and dangerous to be inhabited: but Sonnini says, that this assertion is ill-founded. Stancho retains the high character for mildness of climate, richness of soil, and salubrity of the air, given by the ancients to Cos. Some very high mountains command the fourth part of the island: and navigators, desirous of a shelter from the impetuous northerly winds, find a propitious retreat in that quarter in the little harbour of Safodino. The remainder of the island is a beautiful plain, abounding with various fruits, such as oranges, lemons, figs, grapes, &c. which are delicious. The wine drawn from its grapes is delicate and agreeable. Its excellent pastures formerly fed numerous flocks, that furnished wool, with which the inhabitants manufactured stuffs, held in high estimation for their fineness, and also for the brilliant colours with which they were dyed. But this kind of industry and its benefits are lost. Its silk has also failed; though the climate is favourable to mulberry-trees, and the worm which feeds on them. Stancho is famous for a plane-tree, which covers the little public square in which it is found with its antique and twisting branches, and cools it with its impervious shade. Its thick branches are supported by pillars, or rather fragments of pillars, of marble and granite; and these pillars are the only ancient monuments which the island affords, if we except a few medals of little value. Under the shade of the plane-tree is a fountain, which supplies the Turks with water, and a coffee-house, which furnishes a beverage that serves them in lieu of wine and every other fermented liquor. It is not improbable, that ten centuries have elapsed since this tree was planted. N. lat. $36^{\circ} 46'$. E. long. $26^{\circ} 56'$. The bay of Stancho lies on the S.W. coast of Natolia, opposite to the island. N. lat. $36^{\circ} 48'$ to $37^{\circ} 4'$. E. long. $27^{\circ} 14'$ to $27^{\circ} 44'$.

STANCHIONS, in *Building*. See **PUNCHION**.

STANCHIONS, in a *Ship*, those small pillars of wood or iron which are used for various purposes; as to support the decks, the quarter-rails, the nettings, the awnings, &c. The first of these are two ranges of small columns fixed under the beams, throughout the ship's length between decks; one range being on the starboard, and the other on the larboard side of the hatchways. They are chiefly intended to support the weight of the artillery.

STANCHIONS of the Nettings, are either slender bars of iron, whose lower ends are fixed in iron sockets at proper

distances; or square wooden pillars, let into the upper part of the ship's side. See **QUARTER-Netting**.

STAND, STABLESTAND. See **STABLESTAND**.

STAND, in *Commerce*, a weight from two hundred and a half to three hundred of pitch.

STAND of Arms. See **ARMS**.

STAND, Bee, in *Rural Economy*, is constructed in the form and manner of a slight shed, and made of good seasoned wood, so framed, that the fore-part of the shed or stand may be about six or seven feet high, and the hind-part five or six. The top, and also the ends and back, must be well covered with strong boards. The inside should, likewise, have a lining of very thin deal-boards, and be furnished with strong shelves, so proportioned, as to suit the number of hives, boxes, or glasses, that are to be placed on them. And to the front, which should be open, thin shades of wood should be so formed and fixed up, that they may be raised or lowered, as may be necessary for the protection of the bees against either heat or moisture. See **HIVE**.

STAND, Grain or Corn, in *Agriculture*, the name of such as are made of framed wood, stones, low walls, or other contrivances, and which are raised for placing grain upon, in making it into stacks.

The most ordinary mode of forming these stands is merely that of placing two or three pieces of large timber lengthways, and then putting smaller ones cross-ways at the ends, filling up the middle parts with smaller pieces of wood or other materials. This is, however, a mode by no means to be generally employed, as it provides no security for the bottom of the stack. But in other cases, a strong framing of good timber is put upon posts of wood, or what is better, of stones, about two feet high, provided with round caps of good flat stones, and on these the stacks rest in a very solid and secure manner, and it affords a good and secure support for the corn.

These stack-stands are, however, much better when constructed wholly of stone, being built to the same height as in the former case, in a rather slanting manner outwards, and covered on the tops with copings of oak-planking or flat stones, which project over the edges several inches, and in that way prevent the depredations of rats and mice on the grain, as well as their lodging in the stacks. In both these modes, pieces of timber are placed as a frame in the middle, to support the grain upon.

Further, in constructing these stands, the foundation should be sunk a considerable depth into the ground, and the bottoms be well laid, to prevent vermin getting to the grain of the stacks by working under them; and no sort of substances should ever be suffered to rest against them, or the loose corn to hang down during the time of building the stacks. It is obvious that the form of these stands must vary according to that in which the stacks are to be made, which is different in different districts. The circular and oblong forms are the most usual; but the long narrow shape is probably to be preferred, as it is said, in the Agricultural Report of Northumberland, to keep the corn better, more dry, and freer from heating.

It has been remarked, that on brick or stone stands, stacks of the parallelogrammical form may be built to any size; but that for small stacks, especially where wood is employed, the octagonal form of stand should rather be preferred to the circular one, as the copings may be cut with less waste, and from smaller timber; and it is just as easy to build a circular stack on an octagonal stand as on a circular one. But that where stone can be easily procured, it is without

doubt the most proper material for the bottoms; and brick, when properly made for the purpose, answers very well, especially if proper care be taken in the laying of it. Slate is also another material, where it can be had at a reasonable expence, that may be a very good substance for this use. Likewise flag-stones would answer extremely well; but neither slates nor flag-stones are necessary, if the foundations be laid sufficiently deep to prevent the vermin burrowing under them. The celebrated Mr. Bakewell made use of stands of this kind with much advantage; and other farmers, in the same district, probably employed them before his time.

Several different forms of stands of this sort are employed on the farms of the duke of Bedford, at Woburn, and in other places. See *STACK*.

STAND, Hay, may be formed in somewhat the same manner as that for grain or corn, only it is seldom necessary to have it made of such expensive materials. A simple frame of wood is mostly sufficient, with proper bearers laid across for the support of the stack. See *STACK* and *STACKING of Hay*.

STANDARD, in *Commerce*, is a weight, measure, or coin, of acknowledged authority, by which others of the same denomination are sized, compared, or adjusted. (See *COIN, MEASURE, and WEIGHT*.) We shall begin this important article with *Measures*, and conclude with *Coins*, including the new standard weight for silver, of 1816.

When a standard for linear measure is once established, that for measures of capacity is easily deduced, by determining their cubic or solid contents; and from the latter, standard weights may be derived, as a vessel of any certain dimensions filled with pure water, at a given temperature, will always weigh the same in the same latitude.

It is, however, to be remarked, that this systematic mode of obtaining standards has been seldom adopted, as they seem to have been generally established at the will of individuals, or by the agreement of governments. Such are therefore called *arbitrary standards*, to distinguish them from *invariable standards from nature*; that is, measures obtained from some unalterable property of nature; as the dimensions of the earth, the motions of the heavenly bodies, or the laws of gravitation. These standards have been anxiously sought after by the first mathematicians of modern times; but before their labours and researches are described, it will be proper to give an account of the past and present state of arbitrary standards, which are those universally adopted, except in France.

The standard measures of linear extension of all countries appear, from their names, to have been originally taken from some part of the human body, as the foot, the fathom, &c. But as such must constantly vary with the different sizes of men, standards of some durable substance became necessary; and it may be observed, that in country places where such are not at hand, natural measures are still occasionally used, as the arm, the pace, &c. Hence some account of their proportions to each other cannot be uninteresting or foreign to our subject. The fathom is reckoned to equal the height or stature of a well-proportioned man: the pace is supposed to equal half of the stature, the cubit one-fourth, the foot one-sixth, and the span one-eighth. The breadth of the hand is reckoned one-third of the foot, that of the thumb one-twelfth, and of the finger one-eighteenth. Other proportions are occasionally used, which, however, are not considered so regular as the above; such are the head, the arm, and the girth, &c. The head is particularly noticed by painters and statuaries, who

reckon the symmetry good when the whole height equals seven heads: but it has been made to equal more than seven and a half heads in ancient figures intended to represent dignity or strength. The proportion, however, varies considerably among different races of men, and in different countries. The average of the European stature is from six to seven heads; but that of the Kalmucks, Samoyedes, Laplanders, &c. is seldom more than five heads, and frequently less.

From such an extraordinary variety may be traced the diversity of standard measures throughout the world. It has, however, been the endeavour of all regular governments to correct this inconvenience; and hence established standards have been, from the earliest period of history, objects of peculiar care. They have been deposited in the sanctuary of the Jews, the temples of the heathens, and the churches of the primitive Christians; and distinguished officers were always appointed to distribute copies of the same, to examine those in use, and to correct or condemn such as were found erroneous.

The Jews called their original standard *seabac*, and those copied from it, *mesurah baddin*, or judged measures. We frequently read in scripture of "the weight of the sanctuary," "the measure of the sanctuary," and "the shekel of the sanctuary." Numerous texts and precepts likewise occur in the sacred volume to command uniformity.

The Greeks called their standards *archetype*, *prototype*, and *metreon tropos*; and it is said, that at a very remote period they had but two standards, namely, the *Pythic* and the *Olympic* measures. At Athens, fifteen officers were constantly employed for the regulation of their standards. The ancient Romans likewise paid strict attention to the same object, and are said to have established one standard, called *mensura*, in every city throughout their vast dominions; and each of those measures was an accurate copy of the original, kept in the temple of Jupiter in the Capitol, which standard was therefore called *capitolina*.

It is stated by several good authorities, that the Egyptians gave standards at a very early period to the neighbouring countries of Asia and Greece, from measurements made of an arc of the meridian. It is observed by Pausanias, in his "Metrologie," that the base of their largest pyramid was made the principal standard, which was the 500th part of a degree of the meridian, previously measured for that purpose; and Bailly, in his "Astronomie Ancienne," asserts that the Egyptian computation of the degree nearly corresponds with the modern measurement of the same arc. However this may be, there is little doubt but that uniformity of standard measures was more strictly established among the ancients than among the moderns. The extensive and arbitrary power possessed by many ancient sovereigns must have greatly contributed to this. Even the Christian emperors were very strict in promoting uniformity, inasmuch that in the time of Charlemagne there was but one weight and one measure throughout his empire. In succeeding ages, however, a great diversity was introduced in France by the abuses of manorial rights and feudal tenures; and to similar causes may be ascribed much of that variety which still prevails in the different states of Italy, Germany, Spain, and most other countries of Europe.

These remarks naturally lead us to the consideration of the standards of our own country.

Standards of English Weights and Measures.—The standards of English weights and measures are supposed to be chiefly of Saxon origin, but their early history is very imperfectly known.

STANDARD.

Bishop Fleetwood observes, in his "Chronicum Preciosum," that "there were good laws made on the standards of weights and measures before the Conquest, by Edgar and Canute, but that they were never well observed." The same remark will indeed apply to many laws on the subject subsequent to that period.

Henry I. is said to have paid much attention to the regulation of weights and measures, and to have adjusted the Saxon *gyrd*, or girth, the modern yard, to the length of his arm. This standard he deposited in the Exchequer at Westminster, where it is still preserved. As to the standards of weights, they have undergone several alterations since that time. The troy weight, which is supposed to have taken its name from Troyes, in France, was introduced by the Normans, and contained at first 7680 grains, but was afterwards reduced to its present weight of 5760 grains. Before the reign of Henry VIII., the Tower or moneyer's pound was mostly used for the precious metals, and was 15 dwt. less than the troy pound. About the same period the avoirdupois weight was established for heavy goods, in the room of the old commercial weight, which latter is still retained in Scotland under the name of the *Amsterdam weight*; and it is worthy of remark, that the assize of bread in England has been constantly fixed according to this ancient weight by the magistrates; the peck loaf newly baked being 16 lb. Amsterdam weight, which answers to 17 lb. 6 oz. avoirdupois.

Several standards of weights and measures were anciently kept at Winchester, from whence our corn-bushel derives its name; but in later times they have been chiefly kept in the Exchequer, at Guildhall, and at the Tower.

Present State of English Standards.—In the year 1758, the house of commons appointed a select committee to enquire into the original standards of weights and measures, and to report accordingly. They were assisted in their researches by several eminent mathematicians and mechanists, who pursued the enquiry with great system and ability. Their report, which is very elaborate, contains the results of numerous trials and comparisons made on the several standards kept at the Exchequer and at Guildhall, which results were by no means satisfactory, particularly with regard to measures of capacity. Their labours, however, were not merely confined to comparisons and researches; they adjusted with great accuracy two standards, namely, the yard, and the pound troy, which are still carefully preserved, and considered of the first authority. The methods taken for preparing these standards are detailed at considerable length in their report, and are well worthy of attention. On the question, whether the troy or the avoirdupois pound should be the standard, they determined on the former, for the following reasons. "Because troy weight is best known to our law; that which hath been longest in use; that which is best known to the rest of the world; that to which our learned countrymen have referred, in comparing ancient and modern weights; and the weight which hath been subdivided into the smallest parts. On the other hand, the avoirdupois weight is of doubtful authority; and though unfit to be made a standard, yet the frequent use of it renders it necessary to ascertain how many ounces, pennyweights, and grains troy, the pound avoirdupois ought to weigh."

The committee therefore obtained, with the utmost exactness, standard weights of the several parts of the pound troy, which were made by Mr. Harris, the king's assay-master, with great skill, and proved by a very curious apparatus, contrived by Mr. Bird, the celebrated optician, which was adapted to five different beams, and which ascertained the weights, from twelve ounces down to one grain

inclusive, and that with so much correctness, as to discern any error in the pound to the 230,400th of the weight, and to the 2000th part of a single grain. By this apparatus the several parts of the standard pound were examined and adjusted, in every progressive combination necessary to discover their proportions to each other; and upon all these trials the several weights appeared so exact, that, to use the words of the committee, "no greater degree of correctness could in the nature of things be expected."

A copy of this standard pound was delivered to the house of commons, and another deposited in the Mint, where it is still preserved, and also Mr. Bird's apparatus. With these some very accurate trials have been lately made by Mr. Bingley, the present assay-master. "One of those trials deserves particular notice, as tending to confirm the proportion between troy and avoirdupois weight, which has been differently stated in works of high authority, varying from 6998 to 7010 grains troy to the pound avoirdupois. It was, however, found by the trial above-mentioned, that the avoirdupois standard pound kept in the Mint weighs exactly 7000 grains troy; and it was further ascertained, that this pound of the Mint perfectly agrees with the bell standard pound at Guildhall, and also with that, of 1588, kept at the Exchequer; and the agreement was the more curious, as the Mint standard pound had always been kept carefully packed up in paper, while the other two were constantly in use, and exposed to the atmosphere." Universal Cambist, vol. i. p. xv.

The standard yard of 1758 is still carefully preserved, and was compared with several others by professor Picquet, in the year 1802. These trials were made in the temperature of 62°, by means of the microscopic beam-compass, constructed by Mr. Troughton, capable of ascertaining differences to the 10,000th part of an inch; and the following were the results, as compared with the standard yard made by the same ingenious artist, and agreed upon by the Royal Society as the most accurate in its divisions and the best medium of comparison.

	Inches.
Taking Mr. Troughton's standard at -	36.00000
The parliamentary standard of 1758, made by } Mr. Bird, was found to be - - -	36.00023

Tower standard - - -	36.00400
General Roy's standard for the Trigonom. Survey	36.00036

From the foregoing view it appears, that the present standards of weights and linear measures are in a respectable state of correctness; but it is to be observed, that measures of capacity are not so accurate, especially in their subdivisions; and the variations are greatly increased by local customs, particularly in corn measures; an evil which the power of parliament has been hitherto unable to correct, notwithstanding the severe penalties which have been enacted at different periods to enforce uniformity. The committee of 1758 seemed to despair of success in this respect, by the remark in their report, p. 460, "that the repeated endeavours of the legislature, ever since Magna Charta, to compel one weight and one measure throughout the realm, never having proved effectual, there seems little to be expected from reviving means which experience has shewn to be inadequate, and yet it was difficult to devise any thing entirely unattempted by former parliaments."

Since the above period, several publications have appeared on the subject of standards, among which the communications

munications of fir George Shuckburgh Evelyn, in the Philosophical Transactions, deserve particular notice, as very scientific and accurate. Plans too have been proposed in parliament, and though not adopted, are well worthy of being recorded, as such may prove useful on future occasions.

In 1789, fir John Riggs Miller moved for a committee of the house of commons "to investigate and report on the best means of adopting an uniformity of weights and measures." He suggested the propriety of adopting the pendulum as the standard of linear extension; but the subject was not resumed the next session. The plan, however, was strongly recommended by a publication of the Rev. George Skene Keith, who proposed the decimal system, which was soon after established in France.

In 1814, fir George Clerk moved for a select committee of the house of commons "to enquire into the original standards of weights and measures, &c." And, in order to obtain information as to what were the best means of comparing linear measures with some invariable natural standard, the committee examined professor Playfair and Dr. W. Hyde Wollaston. Their report on the occasion contains much useful and important information; and a bill founded on it was brought into parliament. The plan was well received, and in the beginning of the present year, (1816,) the bill passed the house of commons without opposition, but was lost on the second reading in the house of lords.

The chief object of this bill was to abolish all the present measures of capacity, except coal measure, and to adopt one only in their stead. The proposed standard gallon was to be ascertained by weight; that is, when filled with pure water at a temperature of 62°, it was to weigh 10 lb. avoirdupois, and this standard was deduced from the weight of a cubic foot of pure water, which had been found to weigh, at the same temperature, 1000 ounces avoirdupois. Hence the proposed gallon was to measure 276.48 cubic inches. It was likewise proposed to make the avoirdupois, instead of troy weight, the standard for regulating weights; and to adjust the long measures by the length of the pendulum. (Other particulars of this bill, as well as the report of the committee, may be seen in the Appendix to Kelly's Metrology.)

The committee, not seeming satisfied with the experiments hitherto made on the pendulum, referred the consideration of the subject to the Royal Society, who have ordered a new measurement of it to be made. This operation is now in progress, under the direction of a committee, who have selected three members for the performance: namely, Dr. Young, Dr. Wollaston, and Mr. Troughton. Since these experiments have commenced, the earl Stanhope has moved in the house of lords, that an address should be presented to the Prince Regent to appoint a committee of scientific men, to be selected from the universities and mathematical institutions, to determine on the best standards for an improved system of weights and measures.

From such a co-operation much may be expected, and we hope to have an opportunity of stating important results in our article WEIGHT. At present, we shall proceed to shew what has been hitherto effected in seeking invariable standards from nature, and as the purpose of those researches is of a popular nature, we shall endeavour to be as elementary and minute as the subject will admit.

Invariable Standards from Nature.—If arbitrary standards could be preserved uniform, they would answer all the useful purposes for which they are intended; but as all material substances are liable to decay, methods have been proposed for obtaining standards from some unalterable

property of nature, by which lost measures might be restored, or new systems established: but it is remarkable that, in deducing standards from nature, nature opposes many obstacles difficult to be surmounted. Among the different methods that have been suggested, two only have been pursued with any degree of success, namely, the length of a pendulum that vibrates seconds of mean time; and the length of an arc or portion of the meridian. If the earth had been a perfect sphere, those measures might be obtained without much difficulty; but it is a kind of oblate spheroid, having its equatorial diameter longer than its axis or polar diameter. Hence the gravity of bodies varies on its surface, in proportion to their distance from the centre of the earth; and, therefore, a pendulum must be longer at the poles than on the equator, in order to vibrate equal portions of time. From the spheroidal figure of the earth, too, the degrees of the meridian vary, increasing in length, like the pendulum, from the equator to the pole. In order to ascertain these variations, many calculations and measurements have been made by the greatest mathematicians; and yet, with all their accumulated labours, up to the present time, the solutions are unsatisfactory. "It appears," says Laplace, in his *Système du Monde*, "that the earth differs sensibly from an ellipsoid: there is also reason to believe that its two hemispheres are not equal on each side of the equator." Doubts are likewise entertained of the uniformity of gravitation in different longitudes, though in the same latitude; and also of the equality of degrees of the meridian in those situations. The ratio, therefore, of any portion of the meridian to the whole circle is uncertain.

According to fir Isaac Newton's theory, the equatorial diameter is to the polar as 230 to 229; or, in other words, the earth's ellipticity is $\frac{1}{33}$. This computation was made on the hypothesis, that the earth is an homogeneous ellipsoid; but on the supposition that it is heterogeneous, the ellipticity or oblateness is found to be less, as may be seen by the tables contained in this article.

The measurement of a degree of the meridian was attempted at a very remote period by the Egyptians, as already noticed; but from the rude and imperfect state of the mechanical arts in ancient times, great doubts must be entertained of the accuracy of such operations. With respect to the pendulum, it was not known to the ancients; but it has greatly engaged the attention of modern astronomers and mechanists, as well as the measurement of the meridian. For a particular account of both, see our articles DEGREE, EARTH, and PENDULUM.

Huygens was the first who proposed the pendulum as the standard for linear measure; that is, its length from the point of suspension to the centre of oscillation. The third part of this distance he termed the horary foot, which he recommended to be the universal standard: but the variations of its length in different latitudes, as well as the great difficulty of obtaining the exact measurement, above stated, seemed to condemn this plan as wholly impracticable. The same ingenious philosopher proposed the method of obtaining the length of the pendulum by means of a rectangular cone; which when suspended by its vertex, and made to vibrate, the centre of its base he demonstrated to be the centre of oscillation, and reciprocally, if suspended by the centre of its base, its vertex would be the centre of oscillation, supposing, in both cases, that the length of the isochronous simple pendulum was equal to the altitude of the cone, or the semidiameter of the base. He likewise suggested, as an invariable standard of length, the space that a heavy body would fall through in a second of time; but
this,

this, like the pendulum, must vary in different latitudes, and is, moreover, affected by the resistance of the atmosphere. The operation is, in many other respects, very difficult to be performed with any degree of accuracy.

About the year 1778, the public attention was particularly excited and directed to the subject of standards from nature, by the Society for the Encouragement of Arts, Manufactures, and Commerce, in London, who advertised a premium of 100 guineas, or a gold medal, as a reward to any person who would propose an improved means "for obtaining invariable standards for weights and measures, communicable at all times, and to all nations." Among the candidates for this reward was Mr. Hatton, who proposed the application of a moveable point of suspension to one and the same pendulum, by which he intended to accomplish the full effect of two pendulums; and the difference of their lengths was to be the required measure. Mr. Whitehurst improved upon his plan by means of two pendulums, the vibrations of which were in a ratio of two to one. By this method it was generally admitted, that the difference between the rods of two pendulums, whose vibrations are known, is a datum from which may be derived an invariable standard measure, as well as many other useful problems relative to gravitation, to falling bodies, and to the figure of the earth. By these experiments it was ascertained, that the length of a seconds' pendulum in the latitude of London, vibrating in a circular arc of $3^{\circ} 8'$, is very nearly 39.119 inches, but performing the same motion in the arc of a cycloid, the result would be 39.136.

Experiments, which were supposed to be still more accurate, were afterwards made by Mr. Graham; and a plan was proposed to parliament, as before noticed, for adopting the pendulum as the standard of length; but it was more warmly taken up in other countries. M. Talleyrand, then bishop of Autun, and Mr. Jefferson, the secretary of state in America, turned their thoughts very earnestly to the subject. Mr. Jefferson proposed, in the house of representatives, that the length of a pendulum in lat. 38° , which he reckoned the medium of the United States, should be adopted as a standard on which to found a new system of weights and measures, and his plans were approved, but never carried into effect.

It was first proposed in France, that the length of the pendulum should be made the standard, taken in the latitude of Paris ($48^{\circ} 50'$); but the latitude 45° was afterwards preferred, as most likely to be universally received, being the medium between the equator and the poles. A report to this effect was made to the National Assembly, in which it was agreed, that the measurement should be entrusted to a committee of six members of the Academy of Sciences in Paris, and to six members of the Royal Society of London. But this plan was afterwards rejected by the academicians Lagrange, Laplace, Lalande, Borda, Monge, and Condorcet, who recommended a standard from the measurement of an arc of the meridian. As this seems the most scientific operation, and important change that has ever been made in any system of weights and measures, we shall give a full account of it here, extracted from their constitutional code.

Extract from the constitutional laws of the new system of measures in France.

"By a decree of the 8th of May, 1790, sanctioned the 22d of August, the constituent assembly desiring that all France should enjoy for ever the advantage that must result from an uniformity of weights and measures, commissioned the Academy of Sciences to determine the length of the pen-

dulum, and thence to deduce an invariable standard for all weights and measures.

"The length of the pendulum, at first, appeared proper for the basis of the system of measures, being easy to determine, and consequently to verify, if it should be necessary by any accidents happening to the standards; but it was observed, that to take, as was proposed, for the unit of measures, the length of the simple pendulum vibrating seconds, was to employ, in order to determine a measure of length, not only an heterogeneous element,—time, but also an arbitrary division,—the 86,400th part of the day. A measure of length was therefore preferred that did not depend on any other quantity; and it will be seen afterwards (*Précis des Experiences, &c.*) that observations of the pendulum can nevertheless be employed as a means of verifying, and even of finding that unit of measure, although they have not served as the basis of its determination. An unit of measure, taken on the earth even, has the advantage of being perfectly analogous to most of the measures that are likewise taken on the earth, as the distances between points of its surface, or the extent of portions of this same surface: it is, in fact, more natural to compare the distance of one place to another to the quadrant of one of the terrestrial circles, than to the length of the pendulum. In short, it was observed, that as the 10,000,000th part of the quarter of the meridian, or the metre, differed only from the pendulum vibrating seconds at Paris about six millimetres, both units would have led to results almost exactly similar."

A second decree of the same day commissions the Academy to appoint the most convenient scale of division for weights and measures, and also for monies.

The decree of the 26th of March, 1791, sanctioned on the 30th, to fix an unit of measure, natural and invariable, and which, in its determination, contains nothing arbitrary or peculiar to the situation of any people on earth, adopted, according to the advice of the Academy of the 19th of the same month, the dimensions of the quadrant of the terrestrial meridian as the basis of the new system of measures.

"The quadrant of the meridian should be preferred to the quadrant of the equator, on account of the great difficulties that the necessary operations to determine this last element would have presented, and their verification, if it were ever wished to have recourse to it. The regularity of this circle is not better ascertained, than the similitude or regularity of meridians. The size of the celestial arc answering to the portion of the equator that would have been measured, is less susceptible of being determined with precision: in short, every nation belongs to one of the meridians of the earth; one part only is placed under the equator."

The new system of weights and measures, founded on the measure of the meridian of the earth, and on the decimal division, was adopted by the law of the 1st of August 1793, under a nomenclature and on a basis, both of which have since experienced changes.

"This nomenclature, modified by the law of the 30th Nivose an. 2, did not admit the decimal multiples *deca*, *hecto*, *kilo*, and *myria*, but only the sub-multiples *deci* and *centi*. In order to make up for this, several denominations in each class of measures had been adopted. Thus, the *miliare* expressed 1000 metres; the *grade*, 100,000; the *cadil* corresponded with the litre, the *cade* to the kilolitre, the *gravet* to the gramme, the *grave* to the kilogramme, the *bar* to 1000 kilogrammes; and the words *decadil*, *centricadil*, *decicade*, *centicade*, *decigravet*, *centigravet*, *decibar*, and *centibar*, expressed the tenth and hundredth parts of these different units. The name *are* was given to the measure at present called *hectare*: the *franc* should be of the weight of 10 gravets, that is to say, double

double what it now is." According to this simple sketch, it will be readily confessed that the nomenclature adopted by the law of 1795, is more methodical, more conformable to the principles of common numeration, and therefore more susceptible of all applications of the decimal calculation.

Some laws applied also the decimal scale to the division of the day and of the year, which did not require such a change; they have been successively repealed.

Extract from the law of the 18th Germinal, 1795, relative to weights and measures.

Art. II. There shall be but one standard of weights and measures,—it shall be a rod of platina, on which the metre, the fundamental unit of the whole system of measures, shall be traced.

The second article of the law of the 19th Frimaire, 1800, acknowledges also the kilogramme for the standard.

Art. V. Their nomenclature is definitively adopted as follows:

Metre, the measure of length, equal to the 10,000,000th part of the arc of the terrestrial meridian, contained between the north pole and the equator.

Are, the measure of superficies for land, equal to a square of ten metres each side.

Stère, the measure particularly intended for fire-wood, and which shall be equal to the cubic metre.

Litre, the measure of capacity, both for liquids and dry goods, the contents of which shall be equal to the cubic metre.

Gramme, the absolute weight of a volume of pure water, equal to the cube of the hundredth part of the metre, of the temperature of melted ice.

The unit of monies shall be called *franc*, to replace the name *livre*, used hitherto.

Art. VI. The tenth part of the metre shall be called *decimetre*, and its 100th part *centimetre*; what shall be called *decametre* is a measure equal to 10 metres, which supplies a convenient measure for surveying. *Hectometre* shall signify the length of 100 metres. *Kilometre* and *myriametre* shall be lengths of 1000 and 10,000 metres, and shall designate principally itinerary distances.

Art. VII. The denominations of the measures of other kinds shall be determined according to the same principles as those of the preceding article.

Thus, *decalitre* shall be a measure of capacity ten times smaller than the *litre*; *centigramme* shall be the 100th part of the weight of a gramme.

Decalitre shall likewise be used to designate a measure containing 10 litres; *hectolitre* for a measure equal to 100 litres; a *kilogramme* shall be a weight of 1000 grammes.

In a similar manner the names of all other measures shall be composed.

For a comparison of the French and English weights and measures, see our articles MEASURE and WEIGHT.

Present State of Standards of Weights and Measures in France.—The success of the metrical system adopted in France is a subject of interelling and important inquiry. The plan was originally considered so excellent, that hopes were entertained of other nations following the example. This expectation, however, has not been realized, nor has that beautiful and scientific theory been found unexceptionable in practice. On the contrary, it met with such opposition on account of the Greek and Latin terms, and the decimal divisions, that in 1801 the government allowed the people to use, for a limited time, their ancient vocabulary of names, applying them to the new standards, which are still retained. And in 1812, a further concession was made, by the imperial government, to the pre-

judices and habits of the people. They were allowed to continue the ancient vocabulary applied to the new standards, with the word *usuel* added to each: thus, two metres are the *toise usuelle*; half a kilogramme, the *livre usuelle*, &c.: and these units are not divided decimally, but into halves, quarters, and eighths: the long measures are also divided duodecimally.

Besides the binary divisions of weights, the *livre usuelle* is divided into ounces, gros, and grains, like the ancient *livre*, *poids de marc*. Hence, the new ounce and its divisions depart so widely from the gramme, that the proportion cannot be ascertained without a troublesome calculation.

Thus, after more than twenty years of troublesome experiment and trial of the metrical system, the only advantage that has been gained is that of establishing one common standard, the *metre*; but uniformity might as well have been obtained by making their ancient *toise*, (so universally known,) their standard. The chief recommendation of the metre, as stated in the foregoing decree, as well as by the authors on the metrical system, Brillat, Brisson, and Tarbé, is, that should it be ever altered or lost, it may be easily restored, not by a second measurement of the meridian, but by a comparison with the pendulum. Thus they allow the pendulum to be the regulator of linear measure as well as of time, and, in short, the ultimate criterion, and of course the principal standard.

The following tables shew at one view the labours of the greatest mathematicians and philosophers to determine the figure of the earth, and thence to deduce standard measures. But it may be proper first to premise, in addition to our account of experiments on the pendulum by the English and French astronomers, what those of Spain have recently done in different parts of the globe, in pursuit of the same important object.

About the year 1789, the Spanish government sent out an expedition of two frigates, the *Descubierta* and the *Atrevida*, under the command of Alexander Malaspina, in order to make experiments with the pendulum in different parts of the world, and particularly with a view to ascertain if the southern hemisphere differed from the northern, as was supposed, and indeed warranted, by the few measurements antecedently made on the south side of the equator by La Caille and Bouguer.

The new experiments were made with a deal rod pendulum, and other necessary apparatus, under the direction and management of M. Ciscar, who appears to have been well qualified for the undertaking. The particulars of his important labours are detailed by M. Mathieu, in the "Connoissance des Temps" of the present year (1816), who states that M. Ciscar made sixteen experiments, from N. lat. $59^{\circ} 2'$ to S. lat. $51^{\circ} 2'$, and in very different longitudes; and compared them with the theory which Laplace established in his "Mecanique Celeste," on fifteen measurements of the pendulum, which led, by one method of calculation to make the earth's ellipticity $\frac{1}{237}$, and by another $\frac{1}{337}$. The results deduced from M. Ciscar's experiments do not determine which is correct, but they tend to shew that the two hemispheres are nearly alike, as may be seen by the following table of ellipticities.

As to the lengths of the pendulum, they do not differ materially from those already computed, making allowance for its being lengthened, in order to make the same number of vibrations in a vacuum as it did in the air. The calculations given of these alterations, according to the variable state of the atmosphere, are very curious, and well worthy the attention of philosophers engaged in experiments on the pendulum.

Cifcar	$\frac{1}{323}$ $\frac{1}{317.6}$ $\frac{1}{317}$	

We have pursued this article to considerable length, as well on account of its general importance, as its peculiar interest at the present time, when plans are set on foot for establishing new standards, and improving the British system of weights and measures.

From the foregoing view of the subject it appears, that, however profound and accurate the labours of the learned have been in search of invariable standards from nature, weights and measures have hitherto derived but little practical advantage from their researches, except indeed what has been effected in France; and the utility of the alterations there is questionable, when balanced against the great inconvenience that has been experienced, and which is likely long to continue.

The chief use of standards from nature is to restore established measures, should they be ever lost; a supposition highly improbable, and of which there are few examples. In short, standards from nature can be only known by comparison with a scale of established arbitrary measures. The researches of the learned, however, should be encouraged, as they may likewise lead to other useful and important discoveries in arts and sciences.

The plan of assimilating the standards of different nations has been at all times a favourite subject with philosophers and statesmen. Such was the benevolent but Utopian wish of Budeus, an eminent author of the twelfth century, who thus expresses himself in his work, entitled "De Re Nummaria."

"Una fides, pondus, mensura, moneta sit una,
Et status illævus totius orbis erit."

"One faith, one weight, one measure, and one coin,
Would soon the jarring world in friendship join."

"Experience, indeed, shews (says a late writer on Metrology), that plans for assimilating the standards of different countries, are as impracticable and visionary as proposals for establishing an universal language. History likewise shews, that while governments change with great facility their money systems, their constitution, and even their religion,

weights and measures seem immovable. They are indeed so mixed, and, as it were, matted with every concern of property, that they cannot be essentially altered without violence and confusion; nor are those evils of a temporary nature. The habits, customs, and prejudices of the multitude are not to be speedily changed. It was computed in France, that in three generations their metrical system would be fully established; but now it seems to require more. In England, the constant vigilance of the legislature for 500 years has been employed in correcting abuses rather than in improving the system. In short it appears, that nothing has a greater tendency to grow worse, or more obstinately resist improvement, than weights and measures."

Standard of Bullion and Coins.—The standard for bullion is a certain proportion fixed by law between the weight of pure gold or silver in any quantity, and the weight of alloy, which proportion is called the *fineness*. Thus, the standard fineness of gold coins in England is 27 carats, or $\frac{27}{24} = \frac{9}{8}$; and the standard fineness of silver coins is 11 oz. 2 dwt., or $\frac{5}{16}$. See our articles ASSAY, BULLION, and COIN.

Wrought gold, however, has two legal standards; the one 22 carats, as above, and the other 18 carats; the latter began in 1798, and is chiefly used for watch-cases and rings.

Wrought silver has likewise two legal standards; the one 11 oz. 2 dwt., as above, and the other 8 dwt. better; that is, 11 oz. 10 dwt. The latter, which is called new sterling, is of ancient standing, but seldom used.

Standard of Coins.—Besides the legal fineness for coins, there is also a standard weight fixed by law. Thus in England, a pound troy of standard gold is coined into 44½ guineas, and of standard silver into 62s. A law, however, has been recently enacted (June 1816), by which the standard weight of silver is altered, but the fineness both of this metal and of gold remains unchanged.

The new standard Weight of English silver coin is, that one pound troy of standard fineness shall be coined into 66s. Thus the weight of the new shilling is to be 3 dwt. 13 $\frac{3}{4}$ gr. and the other new silver coins in proportion.

No alteration is to take place in the gold coins; but gold pounds are to be coined in proportion to the guinea. Each will therefore be $\frac{20}{17}$ of a guinea, and must weigh 5 dwt. 3 $\frac{2}{3}$ gr. of standard gold, and 115 gr. of pure gold, without any allowance for remedy. But according to the regulation which allows a guinea of 5 dwt. 8 gr. to be a legal tender, the gold pound weighing 5 dwt. 13 $\frac{3}{4}$ gr. will be also legal.

By the new law of 1816, gold is declared to be the standard of value, or the measure of property, by which the par of exchange, and the value of silver and all other commodities, should be estimated.

It has been long a question of doubt, whether gold or silver should be the standard of value. Locke and other authorities state it to be silver; but lord Liverpool, in his "Letter to the King on the Coins of the Realm," observes, that "coins, which are the principal measures of property, should be composed of one metal only, and that this should be gold."

By a law of 1799, the question was settled with respect to large payments, as it was then declared that silver should not be a legal tender for any sum above 25*l.*; but by the law of 1816, gold is the only legal tender that can be made for any sum exceeding 42 shillings.

Standardizing Bullion and Coins.—The precious metals in England, whether in bullion or foreign coins, are generally bought and sold at so much *per ounce* standard, which is calculated from the assay-master's report of weight and fineness.

STANDARD.

The following are the characters generally used in those reports.

j	is	1 dwt. or oz.
ij	—	2 ditto.
2	—	5 ditto.
e	—	10 ditto.
e2	—	15 ditto.
e2ij	—	18 ditto.
eje	—	19 ditto.
ob	(obolus)	$\frac{1}{2}$ ditto.

Rules for standarding Bullion and Coins.—The common method of finding the value of small quantities of gold and silver is by allowing, from the assay-master's report, at the rate of 4s. per carat, B. or W., in every ounce weight of gold; and at the rate of 6d. per ounce, B. or W., in every ounce weight of silver. But when silver is more than 10 dwt. worse, an allowance of 2d. per ounce must be made for refining.

The following are the scales of allowance.

Scale for Gold.	Scale for Silver.
1 car. (4s.)	1 oz. (6d.)
1 gr. (1s.)	15 dwt. ($4\frac{1}{2}d.$)
$\frac{1}{2}$ gr. (6d.)	10 dwt. (3d.)
$\frac{1}{4}$ gr. (3d.)	5 dwt. ($1\frac{1}{2}d.$)
	$2\frac{1}{2}$ dwt. ($\frac{3}{4}d.$)

Thus, to find the value of 2 oz. of gold B. 1 car. 1 gr. at 4l. per oz. To 8l. (for 2 oz.) add 10s. for better, which gives the value 8l. 10s. And to find the value of 12 oz. of silver, W. 10 dwt. at 5s. 6d. per oz. From 3l. 6s. (for 12 oz.) subtract 3s. for worse, which gives the value 3l. 3s.

Rules for standarding Gold.—As 22 carats are to the assay or report of fineness, so is the grofs weight to the quantity that is to be added or subtracted from this grofs weight, according as the report is better or worse. If better, the additional quantity is called (by the trade) *betternefs*, and if worse, the subtracted quantity is called *worsenefs*.

Example.—How much standard gold is there in an ingot of the following report, B. 1 car. $3\frac{1}{2}$ gr. weight, 67 oz. 15 dwt. 8 gr.?

As 22	:	1 $3\frac{1}{2}$::	oz. dwt. gr.	67 15 8
4	4	—		20	
88	7	—		1355	
4	4	—		24	
352	30	—		32528	gr.
				30	oz. dwt. gr.
				÷ 352	= 2772
				= 5 15 12	
				oz. dwt. gr.	
To	67	15	8	grofs weight	
Add	5	15	12	betternefs.	
	73	10	20	standard.	

The following method for standarding gold may be generally used with advantage.

	oz. dwt. gr.				
	67 15 8				grofs weight, B. or W. 1 car. $3\frac{1}{2}$ gr.
2 gr =	$\frac{1}{2}$	33 17 16			
1	=	$\frac{1}{2}$	16 18 20		
$\frac{1}{2}$	=	$\frac{1}{2}$	8 9 10		
		2) 127 1 6			
		—			
		11) 63 10 15			} divided by 22.
		—			
		5 15 12			betternefs or worsenefs, as above.

Rules for standarding Silver.—As 11 oz. 2 dwt. are to the assay, so is the grofs weight to the quantity that is to be added or subtracted.

Example.—In 287 oz. of silver, W. $12\frac{1}{2}$ dwt., how much standard?

As 11	2 :	12 $\frac{1}{2}$::	287	
20		—		20	
222		—		2840	
				12 $\frac{1}{2}$	
				dwt. gr.	oz. dwt. gr.
				222) 71750	(323 4 = 16 3 4
				oz. dwt. gr.	
				From 287 0 0	grofs weight
				Subtract 16 3 4	worsenefs.
				270 16 20	standard.

From the last example, the reason of the following rule for standarding silver is obvious, viz.

Multiply half the weight in ounces by the assay in pennyweights, and divide the product by 111, the quotient will be the betternefs or worsenefs in ounces.

Example.—How much standard silver in 160 ounces of B. $18\frac{1}{2}$ dwt.?

Half weight	80				
	18 $\frac{1}{2}$				
	111) 1480			(13 oz. 6 dwt. 16 gr.	
	370			To 160 0 0	grofs
	333			Add 13 6 16	betternefs.
	37			173 6 16	standard.
	20 &c.				

It should be observed, that there are tables constructed, and sometimes used, for standarding gold and silver, as may be seen in Pottlethwayt's Dictionary of Commerce, vol. i. p. 388—398. But from the simplicity and conciseness of the foregoing examples, it is manifest that such tables cannot much shorten the operation, though they may serve to check or prove the calculation. Universal Cambist, vol. ii. p. 193.

STANDARD, in *Botany and Vegetable Physiology*, *Vexillum*, is the solitary superior petal of papilionaceous flowers, generally of a larger size, and more conspicuous colour, than the other petals. See **PAPILIONACEOUS**.

STANDARD, in *War*, a sort of banner or flags borne as a signal

signal for joining together of the several troops belonging to the same body. See FLAG, &c.

The standards were originally large flags, fixed on the tops of towers or other elevated places; and from their being stationary, were called standards; though this term was afterwards given to moveable ensigns, as at present to those borne by the cavalry.

Du-Cange derives the word from *standarum* or *stantarum*, *standardum* or *standale*, words used, in the corrupt Latin, to signify the principal flag of an army. Menage derives it from the German, *stander*, or the English, *stand*.

The standard is usually a piece of silk, a foot and a half square, on which are embroidered the arms, device, or cypher of the prince, or of the colonel. It is fixed on a lance, eight or nine feet long, and is carried in the centre of the first rank of a squadron of horse by the cornet.

The standard is used for any martial ensign of horse; but more particularly for that of the general; or the royal standard. Those borne by the foot are rather called colours.

The ancient kings of France bore St. Martin's hood for their standard. The Turks preserve a green standard, borne by Mahomet, with a great deal of devotion, as believing it to have been brought down by the angel Gabriel. Every time it is displayed, all who profess the Mahometan faith are obliged to take arms; those who refuse are to be deemed as infidels.

STANDARD-Guard. See GUARD.

STANDARDS, for the Roman, see SIGNA.

STANDARD, *Royal*, in *Sea Language*, is a flag in which the imperial ensigns of Great Britain, and the arms of France and Ireland, together with the armorial bearings of Hanover, are united and quartered. This is never hoisted unless when the sovereign is aboard, and then it is displayed at the main-top-mast-head.

STANDARDS, in *Ship-Building*, large knees of oak or iron, fayed on the deck and against the side. The arm upon the deck stands upon a sole, and is bolted through the beams, and clenched underneath; and the other arm through the ship's side. There is also a standard fayed on the gun-deck, against the apron forward, and another against the transoms abaft; also one against each riding-bitt, and one in head upon the knee, when the piece against the stem does not run high enough for the hole of the main-stay collar. Standards are also large poles, set up endways, about ten feet asunder, round the edges of slips, to which the spars are hung to support the staging. They have cleats nailed up their foremast and after sides, at about two feet distance.

STANDARD *Trees*, in *Planting*, are all such as stand singly, with an upright stem, without being trained to any wall or other support. In *Gardening*, they are mostly distinguished into three sorts; as *full standards*, *half standards*, and *dwarf standards*, from their being occasionally trained in all these ways; but forest and tall ornamental trees rarely in any other than full standards; though in the shrub tribe they are occasionally formed into both half and dwarf standards, according to their natural growths.

Full standards are such trees as are trained with tall, straight, clean stems, six or seven feet high, or more, then suffered to branch out at that height all around, to form a head, as in common standard apple and pear-trees, some forest-trees, &c. These should be trained accordingly in their minor growth, by trimming off all the lower lateral branches gradually, as the stem advances in height; suffering the leader always to remain entire, especially in all forest-trees;

or, if it should happen to fork, taking off the worst, and leaving the straightest shoot to run up, to continue the prolongation of the stem to the height above-mentioned. In fruit-trees, the stem is often cut or topped at the height of six or seven feet, to force out a set of laterals in that part, so as to form a regular spreading head of a moderate height, for the greater convenience of gathering the fruit; but for all kinds of forest-tree standards, the tops should never be reduced, but the leaders be permitted to remain entire to run up in height; as the beauty and worth of such trees consist in their lofty growth.

Most sorts of fruit-trees may be trained for full standards, except vines; though some of them will not ripen their fruit effectually in this way, as peaches, nectarines, and figs: but, on the other hand, all sorts of apples, pears, plums, and cherries, ripen their fruit freely on standards of this kind.

And all sorts of fruit-trees for this purpose are mostly raised by grafting, &c. on the freest strong-shooting stocks, and trained with straight clean stems full five or six feet high, as above, either the stock trained up to that height, and then grafted or budded, the graft or bud branching out forming the head; or the stock grafted near the ground, and the first shoot from the graft or bud trained up for a stem to the proper height, then suffered to send forth branches: in either method, it is next to be considered whether it be intended the tree shall form a spreading open head, or assume a more erect and aspiring growth: in the former case, if the leading shoot of the graft or bud be topped at six or seven feet from the ground, it will force out lateral shoots at that height, and commence a spreading head, open in the middle, suffering, however, the whole afterwards to take their own growth; and in the latter, by permitting the leading shoot to remain entire, it will aspire in height, and the whole head will assume a more upright and lofty growth: in both methods the heads will afterwards naturally branch out abundantly, and furnish themselves sufficiently with bearing wood, producing fruit, in some sorts, in two or three years from the grafting and budding, as in cherries, apples, &c. but pears are sometimes four, five, or six years before they bear. See GRAFTING.

It is expedient to train most of the principal hardy fruit-trees as full standards, that, when planted in continued rows, either in gardens or orchards, by having tall stems, they may admit the influence of the sun and air more freely to the heads, and permit the obtaining crops of excellent plants, grass, &c. from the ground under them, over which their spreading branches extend.

In respect to the management of full standard fruit-trees, little is required, after the first training, to form the stem to the proper height, and the first shoots are advanced at top, to give the head its first formation; being allowed to advance nearly in their natural order, except reducing any very irregular growths, permitting the whole to shoot in length, and branch laterally in their own way; by which they naturally form fruit-spurs along their sides upwards for bearing. The irregular branches must, however, be removed, and the heads kept properly thinned, as well as the suckers rubbed off from the stems or other parts, and the dead wood be wholly taken away. See PRUNING.

Standard fruit-trees with high stems are sometimes planted against walls, and trained as wall-trees: this is practised for high walls, so as immediately to cover the upper parts of them, whilst dwarfs and half standards cover the bottom and middle parts, and thus every part of the wall is fully occupied at once: but in these cases the dwarf-trees

are to remain, the others being wholly destroyed after a time. See *WALL-Trees*.

These sorts of high standards are likewise occasionally placed against the ends of buildings; some choice sorts of pears in particular: also apricots in a southerly aspect, and other fruit-trees of the same kind.

Half standards are trained with stems only three or four feet high, and then suffered to branch out to form heads. It is a method of training practised for many sorts of fruit-trees, both as detached standards for variety, and the convenience of gathering the fruit, and with fanned spreading heads, as wall-trees for high walls, in order to cover certain parts of them.

The method of raising these is nearly the same as for full standards, only they are grafted or budded upon lower stocks, training them with upright single stems only three or four feet high, by the stocks on which they are grafted being trained up to that height for a stem; or by being grafted or budded low in the stock, and the first main shoot of the graft, &c. led up for a stem, and topped at that height to force out branches to form the head; suffering the heads, in those designed as detached standards, to branch out all around, and run up to a full spread, nearly according to their natural mode of growth, except just reforming any ill-growing branch, as shortening the branches should be sparingly practised, as it would force out numerous useless shoots, and prevent the formation of bearing wood, especially in the apple, pear, plum, and cherry kinds.

But when half standards are intended for walls, they should have the head trained in a somewhat fanned manner, to spread to the wall like a common wall-tree. And when it is necessary to have them to form heads of as moderate growth as possible, especially in the detached half standards for small compartments, they should be grafted or budded upon the more dwarfish sort of stocks, as apples upon codlins, and pears upon quinces, &c.; in which case the heads will always shoot moderately, and never ramble wide or grow high. See *STOCKS*.

But though a few of this sort of trees may be eligible as detached half standards for variety, they are not proper for the open quarters of the garden; as the branches coming out low may impede the growth of under-crops. A few might, however, be thinly ranged and planted along the sides or boundary parts of large wide compartments, particularly of those sorts that are wrought on dwarf-stocks, which commonly branch more moderately, and in a less spreading manner: as a good portion of the common codlin kind, which naturally shoot moderately, and are good bearers; the heads in which being, for the most part, suffered to run in their natural way of growth, except just a little occasional regulation and pruning of their branches, as suggested for full standards. For walls, however, that are eight or nine feet high, they are proper to plant between the dwarfs or principal residents, to cover the middle, or upper half of the wall, whilst the dwarfs occupy the lower space. See *WALL-Trees*.

Half-standard cherries, apricots, &c. are also proper to plant in forcing-frames, to produce early fruit. See *FORCING-Frames*.

The after-management of detached trees of this sort, in respect to pruning, is nearly the same as that of the full standards; as, after having shot out at top to form the head, they should be permitted to branch both in length and laterally nearly in their own way, except just pruning to order any considerable irregularity, crowding branches in the middle, or long rambles, and detaching all suckers from

the root, stem, and head, and cutting out casual dead wood; and thus the regular branches remaining, at length will emit fruit-spurs abundantly in every part for bearing. And the half standards against walls are to be pruned and managed as other wall-trees, each according to its nature and habits of growth.

Forest-trees, and the taller sorts of the ornamental tree kinds, are seldom or ever trained as half standards, but mostly suffered to run up in height to their full growths, unless some particular sort may be required to have the form of a bushy half standard for some special use or purpose.

Several plants of the shrub kind, in their natural growth, assume something of the appearance of half standards, though, in most instances, they are branchy to the bottom, or rise with different stems; but they might be mostly trained with a single clear stem to the height of three or four feet, and be then suffered to branch out into full heads, like half standards.

Dwarf Standards.—These are trained with low stems, only one or two feet high, and then topped, to force out branches to form the head. There are several sorts of choice fruit-trees which are trained as dwarf standards, with stems not more than one foot high, branching out at that height, forming proportionably low heads; they being occasionally planted round the borders of the kitchen or pleasure-garden, &c. instead of espaliers, and the heads either kept down low by close pruning, or suffered to branch upward nearly in their natural growth. These are raised by grafting, &c. upon the most dwarfish stocks, such as apples on codlin or paradise-stocks, and pears on quinces, &c. in order to dwarf them as much as possible in their growth; and as they shoot in height, each year's shoots either pruned short, to keep the head down, and confine it within a small compass; or the branches permitted to shoot in length, except just reducing casual rambles and disorderly growers. But by too severe pruning, too many useless shoots are forced out annually, and a sufficiency of bearing wood seldom produced, so that it rarely answers well, while by slight pruning, the trees mostly shoot more moderately, and sooner form themselves into plentiful bearers in better perfection. These kinds of dwarf standards are not so generally introduced now, since espalier fruit-trees have been brought to a proper degree of perfection in training and bearing. They might, however, be sparingly admitted, where necessary, in their different sorts, under proper moderate pruning, according to their nature.

Some have dwarf standard fruit-trees in pots, for the purpose of forcing in hot-houses, forcing-frames, hot-beds, &c. particularly early May and May-duke cherries, plums, peaches, nectarines, apricots, figs, vines, gooseberries, currants, &c. which being placed as above, in January, or early in February, often ripen a few fruit very early in tolerable perfection, some of which might be brought to table growing on the trees in the pots. Dwarf standard fruit-trees are also proper to plant out fully in the borders, in forcing-frames and houses. See *FORCING-Frames* and *DWARF-Trees*.

Also the different varieties of currants and gooseberries may be trained with a single stem a foot or more high, and then permitted to branch out into a regular head, keeping the internal part always tolerably open, and the branches moderately thin; and shortening them but sparingly, particularly the gooseberry, by which dwarf shrubby plants are formed, and which become very productive.

There are different shrubby plants of the evergreen and flowering upright one-stemmed kinds, too, which may be

trained as dwarf standards, though the greatest number of plants of the shrubby sort are the most ornamental when they rise in a bushy manner, with many stems from the bottom. These plants, when necessary, are to be trained with one stem, which is readily accomplished by retrenching and removing the superfluous parts, and trimming away all low straggling branches, so as to form a clear single stem for a small space at the bottom parts, as the nature of their growth may require, then suffering them to branch out into full heads.

Some of the low shrubs of the above sorts are supposed by some to appear to the best advantage when trained in this manner.

General Culture.—In regard to the management of standard trees of the fruit kind, when they are planted out in an irregular manner throughout the whole garden ground, which is never, or very rarely, an eligible practice, little is to be done in the way of suiting them to the nature and cultivation of the ground or soil, as they must necessarily give way in these respects to the sorts of crops which are to be raised upon the different quarters or parts of the ground. Mr. Loudon has, however, suggested, that the best way of employing standard fruit-trees and shrubs in gardens, or all which are unfastened, is either in rows, in the manner in which gooseberry plants or bushes are usually set along the sides of the beds or borders, in particular quarters of the ground by themselves; or in orchard-grounds. Standard trees of these kinds, for the borders in kitchen-gardens, should always, it is said, be kept low, in order that they may shade the crops on the different sides as little as possible. But it is thought to be perhaps the best way to have separate distinct quarters or parts for standards of these kinds; to have those of the apple and pear sorts grafted on paradise or quince-stocks, by which means they come sooner into a fruiting state; and by the time those in the orchards or on the walls are in a full bearing condition, such quarters are fit to be thrown out: and, if necessary, other quarters might be planted to succeed them. In this manner, when a new garden was wanted to be made, a tolerable supply of fruit might be had every year after the third; it being well known, it is said, that apple-trees raised on paradise-stocks, and pears on quince-stocks, will frequently bear the second year after grafting, and very generally the third: and as those to be planted in the quarters would be three or four years old before they were removed from the nursery, they would commence bearing immediately.

Standard apple-trees for orchards should generally be of the tall or high kind, and always grafted upon crab-stocks. See ORCHARD and STOCKS.

In standard small fruit-shrubs, as the different currant kinds, a great deal depends upon their being properly cut in, as they should be permitted only to produce from studs or spurs, and from these, after the shrubby bushes are four years old, the young wood being wholly cut away during winter. This method is, however, only necessary and applicable to standard currant-shrubs, where large fruit is wanted; as when currant-trees are grown against walls, and the design is to preserve fruit upon the trees from the period of the currant season until the middle of winter, as is the practice in some cases, the mode is to have the fruit rather smaller, and the tree larger, and so much covered with fruit as to allow of but few shoots. These purposes are excellently accomplished in this way in many places.

Standard forest-trees of all sorts, and deciduous and ever-green standard shrubs, should mostly, when for ornament, be planted out singly, or among clumps or groups of low plants,

so as to produce the best and most suitable effects, according to the nature of the situation or place, and the kind of tree or shrub which is employed for the purpose.

STANDARD Timber-Trees, all such deciduous and other trees as are raised in woods and other places, trained and left for the purpose of forming timber. See TIMBER.

STANDENHEIM, in *Geography*, a town of France, in the department of the Rhine and Moselle; 9 miles W.S.W. of Creutznach.

STANDIA, called also *Dia*, an island of the Mediterranean sea, situated three leagues N.E. by E. of Candia. It is about four miles long by two broad; its circumference is irregular; in its south parts are three natural harbours, where ships of burden, bound to Candia, cast anchor and unload a part of their cargo, because the harbour of that town is not deep enough to receive them when they are fully laden. On their departure they also go and wait at Dia till boats bring them commodities for completing their lading. The middle harbour, called "Porto della Madona," is the best of the three; a vessel may cast anchor there in from six or eight fathoms water up to a considerable depth. On doubling the E. point a fourth harbour occurs, by no means safe, rather shallow and open to the E. wind, but sheltered from the S.W. and N.W. Here a merchant vessel, caught in a gale of wind, might take refuge. This island is lofty, rugged, and entirely calcareous. The rock is naked, except towards the summit, where the soil seems to be fit for the culture of the vine and the olive-tree. In various places a whitish marble is found; and here are also veins, several feet thick, of streaked alabaster, which is thought to be of the greatest beauty. Rabbits are numerous in this island; and it has some wild goats, in places that are inaccessible, and also several cats of different colours, that probably belonged to vessels which have been cast away. N. lat. 35° 26'. E. long. 25° 9'. Olivier.

STANDIA, a town of European Turkey, in Macedonia, in a small bay of the gulf of Saloniki; 13 miles N. of Larissa.—Also, a town of Asiatic Turkey, in Natolia, on the W. coast. N. lat. 36° 54'. E. long. 27° 18'.

STANDING, in *Navigation*, denotes the movement by which a ship advances towards a certain object, or departs from it: as the enemy stands in shore, the English fleet are standing-off, &c.

STANDING, in *Ship-Building*, a term applied to a bevelling that is obtuse-angled, or without a square.

STANDING Army. See ARMY.

STANDING Coins. See COINS.

STANDING of Colours, is used by painters for their durability, in opposition to *flying*.

STANDING Fold, in *Agriculture*, a term applied to that sort of fold, made for containing and protecting sheep, which is of the fixed and immoveable kind, in contradistinction to those which are of a moveable nature on land of the arable or grass kind. See *FOLDING of Sheep*, and *SHEEP-Fold*.

In Suffex, the standing fold of the late general Murray is stated to have been well contrived and formed. It comprised an inclosed area of fifty-seven yards in length, and twenty in breadth, containing one thousand one hundred and forty square yards: more than seven hundred ewes were usually folded in it during the night, and for that number, it afforded a space of more than a yard and a half for each sheep. It had all around it a shed, nine or ten feet wide, and likewise across the middle part, which latter was open on both sides. There was also a rack for hay put up against the wall, which was boarded, and surrounded the whole of the

the fold: and another, which was double, to be eaten out of on both sides, was placed and stood all along the central shed; under which was a small trough or manger, in which the fine sorts of food given to the sheep were put. This was, of course, a most complete and perfect standing fold for managing and protecting these animals, the plan of which may probably in some measure be imitated by other sheep-farmers with considerable utility and benefit.

STANDING Marriage, in the *Law* of Scotland, is used to express one actually subsisting, though perhaps reducible for adultery, or liable to be declared void for impotency, or contingency of blood; that is, consanguinity. *Bayne's Crim. Law*.

STANDING Part of the Sheat, in a *Ship*, that part of it which is made fast to a ring at the ship's quarter. When they say, *over-hale the sheat*, they mean, *hale upon the standing part*; but when they say *hale the sheat* barely, they intend only of the running part.

STANDING Part of a Tackle, is the end of the rope where the block is seized or fastened; as the other which is haled is called *fall*.

STANDING Rigging, are those ropes which do not run in any block, but are set taught, or let slack occasionally, as the shrouds, stays, back-stays, &c.

STANDING Ropes. See *Standing Ropes*.

STANDISH, in *Geography*, a post-town of America, in the district of Maine, on the W. line of Cumberland county, between Presumpscot and Saco rivers; incorporated in 1785, and containing 1378 inhabitants; 18 miles N.W. of Portland.

STANDON, *STANTON*, or *Stancelow*, is a small market-town and parish in the hundred of Braughin, county of Hertford, England, at the distance of one mile S.E. from Puckeridge, and 26 N.N.E. from London. It is mentioned by Ingulphus as having been granted to Croyland abbey in the early part of the ninth century; and as the place where abbot Brithmere, about the year 1030, built a spacious house for the accommodation of himself and his retinue, during his journeys to London. In this parish also was a preceptory of knights hospitallers, built on lands given with the church to that order by Gilbert de Clare, in the reign of king Stephen: the house was designed for the residence of some of the sisters of that order, till they were all placed together at Buckland, in Somersetshire. The site, and some remains of the preceptory, are now connected with a farm-house called Friars. The manor, rectory, and advowson of the vicarage, as parcel of the possessions of St. John of Jerusalem, were granted 36 Henry VIII. to sir Ralph Sadler. A hermitage was founded at Standon by William, an Anchorite, temp. Henry I.; which Richard de Clare, earl of Hertford, gave to the monks of Stoke by Clare, in Suffolk, who are said to have had a cell here, which in after-times appears to have become a free secular chapel, and to have been the same with the chapel at Salburn in this parish. Standon church contains many monuments and sepulchral memorials. In the eastern part of the chancel are the tombs of sir Ralph Sadler and family: on sir Ralph's is his effigy in armour lying beneath a canopy, with his children kneeling below. He died in 1587, aged 80. The parish of Standon, according to the population return in 1811, contained 1889 inhabitants; the number of houses being 254. A fair is held annually, and a market weekly, on Fridays.

On Haven-End, an eminence in Standon lordship, are two large barrows, supposed by Salmon to have been raised by the Danes. In the neighbouring parish of Widford are two other barrows, which give name to the estate on which they

are raised. *Beauties of England and Wales*, vol. vii. Hertfordshire, by E. W. Brayley.

STANDS, in *Rural Economy*, a word applied to such young timber-trees as are under six inches timber girth, or twenty-four inches in circumference. These are mostly reserved in cutting over young timber and other woods.

STANERN, or *STANAROW*, in *Geography*, a town of Moravia, in the circle of Iglau; 10 miles S. of Iglau.

STANES. See *STAINES*.

STANESBY, THOMAS, in *Biography*, father and son, two ingenious and eminent flute-makers in London during the early part of the last century. The flute a bec, or common flute, was so much in fashion during the life-time of the eldest Stanesby, who died about the year 1734, that no single song was printed without being transposed into C, or F \sharp , for the flute, at the bottom of the page. The younger Stanesby, who died in 1754, lived long enough to see the common flute totally thrown aside, in favour of the German flute, a concert instrument, an honour which never had been conferred on the common flute, except now and then in the accompaniments of a song, such as, "Hush ye little warbling choir," on the octave flute, and perhaps two or three more may be found in Handel's works.

Stanesby, however, conformed to the taste of the times, and furnished practitioners on the flute traversiere, or German flute, with instruments, for which the scholars of Weidiman and Ballicourt, the two first public players on the German flute in our capital, frequently and loudly called.

Poor Stanesby did not enrich himself like Theodorus, a flute-maker at Athens, father of the orator Iocaterus, who acquired wealth sufficient by his employment, not only to educate his children in a liberal manner, but also to bear one of the heaviest public burdens to which an Athenian citizen was liable, that of furnishing a choir or chorus for his tribe, or ward, at festivals and religious ceremonies.

The second Stanesby was buried in the church-yard of St. Pancras, near London, and on his grave-stone there is a very honourable record of the virtues of his private character; a circumstance which biographers should never neglect to mention, as monumental praise is seldom lavished on persons of low station: "Why should the poor be flattered?"

STANFALIA, in *Geography*. See *STAMPALIA*.

STANFORD, or *STAMFORD*, is an ancient market and borough-town, situated at the south-western angle of the county of Lincoln, England, on the banks of the river Welland. One parish of the town is in the county of Northampton; but the chief portion of it is built on the side of a hill in Lincolnshire, and when approached from the south, presents an interesting and picturesque appearance. Several old buildings, with towers and steeples, are seen grouped together. The name of the town is supposed to be derived from the Saxon *Staan*, and *ford*. According to some antiquaries, Stanford was a place of note in the time of Bladud, a British king, many centuries before the Christian era. The earliest authority upon which we can depend, is that of Henry of Huntingdon, a writer of the twelfth century; who relates, that the ancient enemies of England, the Picts and Scots, having ravaged the country as far as Stanford to the south, were there met and defeated by the Saxons under the command of Hengist; and that king Vortigern, for such valour, gave to the Saxon leader certain portions of land in the county of Lincoln. Wulphere, king of Mercia, who finished the monastery of Medeshamsted, now Peterborough, in a charter of lands to that abbey in the year 664, assigned Stanford as one of its boundaries; and as it rose progressively in importance, so in the year 972, in another charter to the same

fame house by Edgar, it appears to have been more considerable than Peterborough. At that period it was a market-town, and is noticed by Leland as afterwards becoming a royal borough: under the Danish monarchy it appears still to have maintained the rank which it originally claimed. That it was encircled by walls, and secured by gates at an early period, is evident from the Saxon annals terming it *Byrnigh*; Florence of Worcester, *Arx*; and by Speed's plan, where each is named and delineated. A castle was probably erected here by the Danes, as the above-mentioned historian, Henry of Huntingdon, notices their loss of it in the year 942 to Edmund Ironside, and remarks, that it had then been a considerable time in their possession. Leland, who, on the other hand, adheres to Matthew of Westminster, states that it was rebuilt by Elfreda, sister of Edward the Elder, on the northern bank of the Welland, A.D. 914. Again being possessed by the Danes, they held it till the decease of their last Anglo monarch, A.D. 1041, when the Britons once more became its owners, till William the Norman overcoming the kingdom, in 1066, it devolved to the new monarch and his retainers. The Domesday survey informs us, that it contained one hundred and forty-one mansions, and twelve lagemen, or civil magistrates, who received the forfeitures arising from crimes, and held their powers within certain limits. The castle, in the time of king Stephen, was besieged by Henry of Anjou, afterwards the second monarch of that name, who upon taking it bestowed that and the town, with certain feudal reservations, on one of his followers, called Richard Humetz, to hold from the crown by homage, tenure, and other services. King John passed them to William, earl of Warren, in a similar manner: at his death they were granted by John, who was also earl, to Edward I., and passed by him again to that nobleman, to revert on his decease once more to the crown. Thus, after many grants and reversions through forfeiture or failure of male issue, it was given by queen Elizabeth to William Cecil, first lord Burleigh. Through the marriage of his coheirs and granddaughter, Anne, with William, earl of Exeter, it passed to Henry Grey, first lord Stamford, and after continuing in that family several descents, was sold again to the house of Cecil. In Richard III.'s time the castle was entirely demolished; and the hill, which was artificially formed by horizontal layers of earth, with the slight fragments of a stone wall, are all the vestiges that are now visible.

In William the Conqueror's reign, Stamford was governed by the lagemen, or aldermen. Edward IV. gave it a privilege it still retains, of sending two members to parliament, and a charter was granted in the first year of that king's reign, when its civic officers were incorporated under the names of the "aldermen and burgesses of the first and second bench." Other charters conferred different privileges in succeeding reigns, till Charles II. recalling the royal charters throughout the kingdom, gave a new one to Stamford, which was afterwards confirmed by James II. Again incorporated by that deed, it was made to consist of a mayor, thirteen aldermen, and twenty-four capital burgesses, by the name of the "mayor, aldermen, and capital burgesses, of the town or borough of Stamford."

For parochial and municipal purposes, Stamford appears to have been divided, at a remote period, into fourteen wards, or parishes; but in 1461, some of the churches and houses were consumed by fire, by the northern soldiers; and the religious edifices were not afterwards re-erected. In 1547, an act of parliament was obtained to divide the northern part of the town into five parishes, St. Martin's, or Stamford-Baron, being a distinct parish. According to the population report of 1811, the borough contained 832 houses,

and 4582 inhabitants; and the parish of St. Martin's 163 houses, and 937 inhabitants.

St. Michael's church, which stands near the centre of the town, is supposed to be the most ancient erection, part of it having existed antecedent to the year 1230. It has a nave and choir, with north and south aisles, and chancels which extend beyond the aisles. The eastern end of the choir, which had much decayed, was, about 1705, taken down and rebuilt by the parishioners: in the wall were discovered various sculptured stones, the remains of some more ancient religious building. At the western end of the nave was a wooden tower, which was taken down and replaced by another of stone in 1761. The windows of this building were decorated with figures and heraldic ornaments, but it is much to be regretted that they are in a lamentable state of mutilation.

The church of St. Mary appears to have been built towards the latter end of the thirteenth century, and possibly upon the site of one much earlier. The upper part of the chancel contains a monument without armorial ensigns, device, or inscription, but simply consisting of a statue in armour, lying by the side of a female figure. This was erected to the memory of sir David Phillips, who bravely distinguished himself in the battle of Bosworth Field.

St. George's church, a large plain building, consisting of a chancel, nave, north and south aisles, with a square embattled tower at the west end, was rebuilt, in 1450, by William Bruges, the first garter king of arms, who bequeathed many valuable presents to this building. The remains of David Cecil, high sheriff of Northamptonshire in 1542, grandfather of the first lord Burleigh, are here entombed.

All-Saints church is a structure well proportioned, and of large dimensions: it consists of a nave, two aisles, and chancels; one at the end of the south aisle, and the other at the east end of the nave. At the west end of the north aisle rises the steeple, a lofty, handsome structure, embattled, with octagonal turrets at the corners, and surmounted by a spire of a similar form, crocketed at the angles from the base to the summit. This church was built at the expence of a Mr. John Brown, merchant of the Staple at Calais, who, with his wife, are buried at the upper end of the north aisle. In the same church, where the altar formerly stood, are the effigies of William Browne and his wife, who built and endowed the bead-house in this town. Against the east window, a white marble monument preserves the memory of Mr. Thomas Truefsdale, who lived in the same dwelling with Mr. Brown, and emulated his example, by founding another alms-house.

The church of St. John the Baptist was rebuilt about 1452, the thirtieth year of the unfortunate Henry VI. It has a nave, and two aisles, with a chancel at the east end of the first, and separated from it by elegant screen-work. The roof has been highly decorated with figures carved both in wood and stone; and the windows contained some admirable specimens of stained glass.

Stamford formerly contained several monastic establishments; and it is traditionally related that it was, at one time, the seat of an university. Hardinge, in his Poetical Chronicles, and in "The Mirror of Magistrates," relates the latter circumstance; but this is not authenticated by better historians. The only circumstances which appear to support the idea of an university are, that in the year 1109, Joffrid, abbot of Croyland, deputed three monks from his monastery for that purpose. Camden remarks, that a violent dispute arose between the northern and southern scholars at Oxford, in 1333, when many of the masters and students

STANFORD.

retired to Stanford. Several of these, however, soon returned to Oxford; and some time afterwards, Edward III. issued a writ to the sheriff of Lincolnshire, commanding him to proclaim at Stanford a prohibition for any person to study or perform scholastic exercises, elsewhere than in the universities, on pain of certain forfeitures.

In the reign of Henry III. the Carmelites had a monastery here, and gave public lectures on divinity and the liberal arts, with disputations against the Judaic faith. Many of the clergy and higher orders of the people sent their sons here for education; and from this possibly arose a custom, which in succeeding centuries was greatly followed. Other religious houses also became schools of literature; and by these means Stanford became celebrated for liberal instruction. The other public institutions of learning, which were supposed to constitute part of the above-mentioned university, were the following:—Brazen-nose college or school, from which the college at Oxford is supposed to have derived its name, was built at a remote period, and certainly existed early in the reign of Edward III. In 1668 it was taken down, and a charity-school erected on the same spot:—Sempringham-hall, supposed to have been founded by Robert Luttrell, in 1262:—Black-hall was of great antiquity, and was taken down soon after 1705.

Of Peterborough-hall, Vaudey-hall, the free-school, and other buildings of the same nature, but slight information can now be gained, excepting that the former was taken down about 1705, and stood near All-Saints church; and that the latter was founded in the year 1548, by Mr. William Radcliffe.

The schools at present supported at this place are, the one last mentioned, now called Radcliffe's; another instituted by Edward Wells, in 1604, denominated Wells's or the petty school; and the blue-coat school.

The ancient and modern institutions for the support of the poor are many in number: the most prominent, is one founded by William Browne in the reign of Richard III., already mentioned, which has a chapel at the eastern end, consecrated in 1494; the revenues of which have, of late years, greatly increased. Another was erected by the will of Mr. Thomas Truefdale, in 1700, with endowments bequeathed to it for ever. And, in addition to these, are certain charities denominated callises; with various other foundations of the like nature.

The principal public building is the town-hall, where the civil business is transacted. It was built by trustees, under an act passed in 1776, near St. Mary's church, when the old hall was taken down. It consists of two handsome fronts, containing twenty apartments, a guard-room, house of correction, and a gaol. A small theatre, in St. Mary's street, was built here in 1768.

The river Welland, which runs to the south of the town, and parts it from Stanford-Baron, is navigable for boats and barges from the sea to this place. Stanford has a market on Monday and Friday, and seven annual fairs.

Stanford-Baron, already named, is separated from the town only by a stone bridge, yet it is both a distinct parish and liberty in the county of Northampton: hence its original name of Stanford beyond the bridge. In 1455 it was held by the abbot of Peterborough, *per baroniam*, and was then first denominated Stanford-Baron. In the reign of Athelstan it had the privilege of a mint, and succeeding kings also greatly favoured it. Although it cannot now be discovered that this parish was ever walled, yet it appears to have been defended by five gates and a castle, which stood on that part of the Roman road now called the nun's farm. This place is designated in the Domesday-book as

being the sixth ward belonging to Stanford, situate in Hantunescire. In the reign of Henry II. it contained a Benedictine nunnery, dedicated to God and St. Michael, by William, abbot of Peterborough: the annual revenues of this house were 7*l.* 18*s.* 10½*d.*

By a deed of the reign of Richard I. notice is taken of an hospital for lepers, under the patronage of St. Egidius; and a house for knights hospitallers: but their founders are now wholly unknown. Where the alms-house is now erected, an hospital formerly stood, dedicated to St. John the Baptist. The present church is a large, handsome building, dedicated to St. Martin, and founded by bishop Russell in the reign of Edward IV. It consists of a nave, two chancels, north and south aisles, and a square pinnacled tower at the west end of the former. At the upper end of the north chancel are deposited the remains of Richard Cecil and his wife, the immediate progenitors of the first lord Burleigh; as also those of William Cecil, baron of Burleigh, with his effigy in armour on a highly ornamented altar-tomb. In the north chancel is a stately and large marble monument, with statues, &c. to the memory of John, earl of Exeter, and his lady, both of whom died in the year 1709.

According to Camden, the custom of borough English prevails in this manor; by which the younger son inherits the lands and tenements possessed by the parent, when the latter dies intestate. Another more singular custom, characteristic of feudal and semi-barbarous times, is still continued at Stanford. On a certain day, annually, about six weeks before Christmas, a bull is provided, and destined to be hunted by dogs and the lowest class of persons through the streets of the town. On such occasions a vast concourse of people is assembled, many dogs are brought to the place, and the most cruel and wanton acts are resorted to, in order to irritate the poor animal, and thereby produce what is mis-termed sport. The bull-running, as it is called, commences early in the morning, after a proclamation is made to guard doors and windows, and warn travellers who are passing through the town. The animal is let loose in the streets, when dogs, men, women, and even children, commence a boisterous and irritating pursuit. This is sometimes continued for hours, till the bull is provoked to madness. At length he is killed, and the flesh sold. It is traditionally related, that this custom originated in the reign of king John, by the order of William, the fifth earl of Warren, who, having observed a bull worried through the town by dogs, was so much diverted, that he gave a meadow to the butchers of Stanford, on condition that they would provide a bull annually for the same purpose. A custom somewhat resembling this prevails at Tutbury, in Staffordshire. See TUBURY.

About one mile south-east of Stanford is Burleigh or Burghley-house, the magnificent seat of the Cecil family, and now the property of the marquis of Exeter. The park was inclosed and house chiefly built by lord-treasurer Burleigh, who, in a letter dated 1585, says, the "house is of my mother's inheritance; and for the building there, I have set my walls on the old foundations." On different parts of the edifice are the dates of 1577, 1585, and 1587, pointing out the times when such portions of the house were raised; but many additions and alterations have been made at subsequent periods. The whole presents a palace-like appearance, and may be said to consist of a mass of building surrounding a square court 110 by 70 feet. In various rooms is preserved a large collection of pictures by different old masters, with some few paintings by modern artists.

The park is of great extent, of varied surface, is adorned with

with much fine timber, a large piece of water near the south front of the house; and at the western extremity, adjoining the great North road, is a stately lodge of entrance, which was erected in 1801, from the designs of Mr. Legg, architect. An interesting account of this seat, with a particular catalogue of the pictures, was published at Stanford, in 1815, entitled "A Guide to Burghley-House," &c.—Survey of the Town of Stanford, by Butcher, 8vo. 1717. An Essay on the ancient and present State of Stanford, by Howgrave, 4to. 1720. Antiquarian Annals of Stanford, by Peck, folio, 1727. The Antiquities of Stanford and St. Martin's, by W. Harrod, 2 vols. 12mo. 1785. An Account of the public Schools, Hospitals, and other charitable Foundations, in the Borough of Stanford, by Thomas Blore, 8vo. 1813. This is a very interesting and useful work, as calculated to preserve and give publicity to those benevolent institutions, which were originally intended to afford support to the aged poor, and instruction to the lower classes of youth.

STANFORD, a post-township of Duches county, New York, about 18 miles N.E. of Poughkeepsie; incorporated in 1793, and containing 2335 inhabitants. This township is well watered and cultivated; has many able farmers, several mills, three houses for worship, *viz.* for Quakers, Baptists, and Methodists. In 1810, its household looms produced 12,680 yards of cloth. Its sheep were 5564, horses 811, and cattle 2898.—Also, the capital of Lincoln county, Kentucky; situated on a fertile plain, about 10 miles S.S.E. of Danville, containing a stone court-house, a gaol, and about 40 houses.

STANG, a river of Sweden, which runs into lake Roxan, near Linkioping.—Also, a town of Norway; 24 miles N. of Berga.

STANG, in *Rural Economy*, a word provincially signifying a long pole, or other piece of wood in the same form. Stangs are useful for a variety of different purposes in the practice of farming.

STANG-Cart, in *Agriculture*, that sort of stang which constitutes the shafts of a cart, or the poles between which the horse draws. See CART.

STANGENBERG, in *Geography*, a town of Prussia, in Pomerelia; 15 miles S.E. of Marienburg.

STANGENGRUN, a town of Saxony, in the circle of Erzgebirg; 9 miles S.W. of Zwickau.

STANGENROD, a town of Westphalia, in the county of Mansfeld; 13 miles N.N.W. of Eifzleben.

STANGSKAR, a small island in the gulf of Finland. N. lat. 59° 45'. E. long. 26° 15'.

STANGWYK, a town of Norway, in the province of Drontheim; 80 miles S.W. of Drontheim.

STANHOPE, GEORGE, in *Biography*, an eminent divine of the church of England, was born at Hartshorn, in Derbyshire, in 1660. He was educated at Eton, and King's college, Cambridge; and after taking his degrees, and bearing some offices in the university, he was presented by lord Dartmouth, in whose family he had been chaplain and tutor, to the rectory of Lewisham, in Kent. He was appointed one of the chaplains to king William and queen Mary, and retained the same office in the following reign. In 1697 he proceeded doctor in divinity, and being at the same time distinguished for his pulpit eloquence, he was chosen, in 1701, to preach Boyle's lecture; and in 1703 he was promoted to the deanery of Canterbury. He sometimes preached the lecture at St. Laurence Jewry, in which he attained to great eminence, though he followed many persons of much celebrity. In 1705 he preached the Latin sermon before the convocation, of which body he was thrice

chosen prolocutor. He died in 1728, at the age of 68. Of the publications of this learned divine, some were translations: these were "Thomas à Kempis de Imitatione Christi;" "Charron de la Sagesse;" "The Meditations of Marcus Antoninus;" "Epictetus, with the Commentary of Simplicius;" "Rochefoucault's Maxims;" "St. Augustine's Meditations." His most considerable original work was "A Paraphrase on the Epistles and Gospels," 4 vols. 8vo. several times reprinted. He also published three sets of "Sermons on several Occasions;" besides "Sixteen Sermons preached at Boyle's Lectures."

STANHOPE, PHILIP DORMER, earl of Chesterfield, a nobleman celebrated as a great wit, statesman, and a man of letters, was the eldest son of Philip, third earl of Chesterfield, by lady Elizabeth Saville, daughter of George, marquis of Halifax. He was born in London, in September, 1694. He had the misfortune to lose his mother while he was very young, and being neglected by his father, he was educated under the care of his grandmother, lady Halifax, who proved herself quite adequate to the task. His elementary instructions were received at home from able masters, who had the advantage of finding in their pupil admirable qualities, and an ardent desire of excelling in whatever he undertook, and a resolution to persevere in the tract in which he entered, without any regard to the obstacles that might oppose themselves to his progress. It is said that lord Galway, discerning in him, when very young, a strong inclination for political distinction, and at the same time a great love of pleasure, with a propensity to sauntering, gave him a friendly lesson on the absolute necessity of rising early, in order that he might become a man of business. The admonition produced such an effect on his mind, that he immediately adopted the practice recommended, and adhered to it during the whole of his life. He was afterwards, by a trifling incident, permanently cured of an impatience of temper, which he was sensible would disqualify him for the character and duties of a statesman. In his 18th year he was entered of Trinity-hall, Cambridge, where he applied himself with great assiduity to the studies pursued in that seat of learning. He was particularly attentive to eloquence, which he was aware was a principal requisite in a free senate; and with the view of becoming a good and a forcible speaker, he marked down all the finest speeches of the ancients that came in his way, in the course of his reading, and formed his own style and manner by translating them; a practice which cannot be too warmly recommended to young men likely to come into public life. On quitting the university, this young nobleman made the usual tour of Europe; and it was at the Hague that he first began the cultivation of that enlarged acquaintance with mankind, which has been denominated seeing and knowing the world; but with this knowledge he acquired certain pernicious propensities, which adhered to him through life: among others was that of gaming. A visit of some length to Paris further contributed to fashion his manners, and to render him at length that model of true politeness, which he exhibited in after-life to his admiring countrymen. This was about the time of the demise of queen Anne, and he did himself high honour by the assertion of those principles of freedom which effected the succession of the house of Hanover, and which, during the whole of his political life, he steadily maintained. On his return to England in 1715, he was presented to the new sovereign, and appointed one of the gentlemen of the bed-chamber to the prince of Wales. He was elected member of parliament for one of the Cornish boroughs, in the first parliament of George I., and commenced a speaker in the debate respecting the impeachment of

of the persons concerned in the peace of Utrecht. Upon this occasion he manifested a juvenile violence, which produced an intimation from the opposite side, that advantage would be taken of his being under the lawful age for sitting in parliament. Upon this hint he immediately quitted the house, and set off for Paris. On his return, he was sometimes the defender and sometimes the opponent of ministerial measures; but his talents, at this time, do not appear to have made much impression on the house or the country. In reward, however, for his support of a motion for the augmentation of the army, he was, in 1723, made captain of the yeomen of the guards; and it was a proof of his disinterestedness, that when advised by his predecessor, lord Townshend, to make the post more profitable than he had done, by the sale of subordinate places, he replied, "I rather wish, in this instance, to follow your lordship's example than your advice." He was dismissed from this office in 1725; and in the following year, on the death of his father, with whom he had never been on terms of cordiality, he entered the house of lords, and joined the opposition. To this assembly his talents were better adapted than to the house of commons. His eloquence, the fruits of much study, was less characterized by force and compass than by elegance and perspicuity, and especially by good taste, and a vein of delicate irony, which, while it sometimes inflicted severe strokes, never passed the limits of decency and propriety. "It was that of a man, who, in the union of wit and good sense with politeness, had not a competitor." These qualities were matured by the advantage of a familiar acquaintance with almost all the eminent wits and writers of his time; many of whom had been the ornaments of the preceding age of literature, while others were destined to become those of a later period. He knew how to appreciate genius and talents, and was the friend of Pope, and received him in almost all his select parties at Twickenham, where he met the first nobility in association with the most distinguished votaries of the muses.

Soon after the accession of George II. lord Chesterfield was nominated ambassador at the Hague. Scarcely was any man ever better adapted than his lordship to fill a diplomatic situation, as well on account of his natural acuteness, and of his conciliating manners, as his familiarity with the modes and usages of general society. He was, however, at this time but little acquainted with public business; but possessing the laudable ambition of rendering himself fully master of whatever he undertook, he spared no pains to acquire the knowledge for the post in which he was placed, and which at that time was a very important one; the Hague being, in fact, the centre of the principal political negotiations carrying on throughout Europe. In the year 1730 he was appointed high steward of the household, and he was, at the same time, decorated with the order of the garter. He now returned to Holland, and was instrumental in forming an important treaty between the courts of London and Vienna, and the States-general. In 1732 he obtained his recall; and on his return, he supported the plans of the prime minister, though there does not appear to have been any cordiality between them; and when sir Robert Walpole introduced his famous excise measure, the earl spoke against him with all his force, and thereby gave so much offence that he was deprived of his offices, and he again joined the party in opposition. He married, in 1733, the countess of Walsingham, niece or probably daughter to the duchess of Kendal, who had been mistress to George I. She was a lady of great merit and accomplishments, and by her prudence contributed very much to retrieve the deranged affairs of her lord. The noble earl did not neglect to pay his

court to the prince of Wales, who attached himself to the opposers of his father's government. Of his oratorical exertions, none was more generally admired than his speech against the bill for granting to the lord chamberlain the power of licensing dramatic performances. In 1741, his health being much impaired, he was advised to make the tour of the continent. In his way to the Spa, he saw, at Brussels, Voltaire, with whom he had contracted a friendship in England. At Spa his reputation, and the urbanity of his manners, drew upon him much flattering notice from persons of distinction; and the manner in which he spoke of the rising Frederick of Prussia to the envoy of that monarch, procured for him a pressing invitation to the court of Berlin, which he would gladly have accepted, had he not been prevented by other engagements. A short stay at Paris introduced him to the most distinguished of both sexes for rank and talents in that capital, where he was equally gratified and admired.

His stay in the south of France was shortened by the state of political affairs at home. The attempts of France to ruin the house of Austria were threatening destruction to what was denominated the balance of power in Europe; and the miscarriages of the English ministers in their political measures spread discontent through the nation. This at length produced the fall of that statesman, who had so long ruled the public councils; and a new administration was formed, in which lord Chesterfield had no place. This omission was probably owing, in great part, to the personal dislike of the king, who could not forget the severe things he had said with respect to the royal partiality to the interests of Hanover, and the sacrifices made of the interests of Great Britain to those of the electorate. He took an active and most decided part in opposition to the measures of the ministry, and was said to be particularly happy in his speech against the gin-licence bill, and against that for continuing attainders upon the posterity of persons convicted of high treason. This last bill was introduced in consequence of the prospect of a new rebellion, promoted by France, and which soon after took place. This event produced a change in the ministry, and lord Chesterfield was sent out as ambassador to the United Provinces; a station which he had before occupied with much reputation. He effected the purpose for which he was sent, *viz.* that of engaging the Dutch to concur in earnest in the war against France; and returned in 1745, at the time of the breaking out of the rebellion in Scotland. He was immediately nominated to the high station of lord lieutenant of Ireland; an office of great importance at this period, when there was cause of apprehension from the prevalence of the Roman Catholic religion in that island. He set off for his government in the end of August, taking with him a secretary, who had not enjoyed any advantage from experience, and to whom he said in a tone of decision, "Sir, you will receive the emoluments of your place, but I will do the business myself, being determined to have no first minister." In a similar spirit he openly declared, that if any one, during his stay in Ireland, should make a successful application for a place in the king's gift through any channel but his own, he would immediately throw up the lieutenancy. With these resolutions he began his administration; and by vigour on the one hand, and conciliation on the other, by strict integrity, and a frank undisguised system of policy, he kept every thing quiet in that kingdom, while the sister island was over-run with terror and commotion. Instead of abridging the Catholics of their religious liberty, he favoured and augmented it; wisely judging, that the more openly they shewed themselves in attendance at their own

places of worship, the less their secret machinations were to be regarded. He, however, kept a vigilant eye upon all their proceedings, but discouraged idle suspicions and malicious informations. A zealous Protestant once came, very officiously, as the noble lord thought, to inform him that one of his coachmen went privately to mass. "Does he?" said the lord lieutenant: "I will take care that he never drives me thither." Such, says his biographer, was lord Chesterfield's conduct in his vice-royalty, that he quitted it with the regret of all parties; and that, to this day, the spirit of his administration is regarded as a model for all who are entrusted with that important station. He returned to England in April, 1746, when the rebellion was terminated by the victory gained at the battle of Culloden.

He now accepted the office of secretary of state, with the duke of Newcastle as his colleague. Never approving, in his own mind, of the war in which the nation was engaged, and constantly wishing for peace upon reasonable terms, he was nevertheless carried away, by a superior influence in the cabinet, to concur in the measures of the court, till their ill success induced him to draw up a strong memorial, which being disregarded, he resigned his place in February, 1748, and never afterwards joined in any administration. From this period till his death he lived as a private nobleman, attached to the arts and to letters, and was looked up to throughout Europe as inferior to none of his high rank for brilliancy of wit, and the polish of cultivated society. Being seized with a deafness in 1752, that incapacitated him, in a measure, for the pleasures of society, he led a retired life, amusing himself with his books and his pen. He engaged rather largely as a volunteer in a periodical work, entitled "The World," in which his contributions have a distinguished degree of excellence. His lordship maintained a character for wit and talents that has few equals. He rendered himself illustrious, as we have seen, by his eloquence in parliament, on many important occasions, of which there is a characteristic instance of his own relating. He was an active promoter of the bill for altering the style; on which occasion, as he himself relates in one of his letters to his son, he made so eloquent a speech in the house, that every one was pleased, and said he had made the whole very clear to them; "which," says he, "God knows, I never attempted. I could just as soon have talked Celtic or Slavonian to them as astronomy, and they would have understood me just as well." The high character which lord Chesterfield had supported through life received no small injury, soon after his death, from a full display of it by his own hand. He left no issue by his lady, but had a natural son, named Philip Stanhope, whose education was, for many years, a close object of his attention; and who was afterwards envoy extraordinary at the court of Dresden, but who died before his father. After the death of the earl of Chesterfield, Mr. Stanhope's widow published a course of letters, written by the father to the son, filled with instructions suitable to the different gradations of the young man's life to whom they were particularly addressed. These letters have been highly applauded, and as loudly condemned. They contain many admirable observations on mankind, and rules of conduct; but the author lays a greater stress on exterior accomplishments and address than on intellectual qualifications and sincerity, and allows a much greater latitude to fashionable pleasures than sound morality will admit. It has been urged in excuse for the author; that he never intended these letters for publication: they contained instructions for a particular individual, and they do not pretend to touch upon the more weighty points

of morals, these being left to the inculcation of a selected tutor: nevertheless, there is some occasional advice coming under this head, contained in the later letters, when the son was already launched upon the world, which have justly subjected the writer to severe animadversion. Of these, such as relate to truth in the commerce of society, under the distinctions simulation and dissimulation, have been defended and justified by politicians, as absolutely necessary for one who was to be trained to diplomatic habits. But the same apology cannot be made for a father's attempts to fashion his son to politeness, by recommending connections with married women, which, however lightly regarded in the licentious courts and capitals at which he himself had been a visitor and resident, must ever be considered as a most serious violation, not only of the laws of God, but of private friendship, and of the most sacred bond of social life. These obnoxious parts would, in all probability, have been suppressed, had the author revised and published his own letters. On the other hand, there are, in the course of the volumes and the other works of lord Chesterfield, many examples of his useful and efficacious endeavours to serve the cause of morality. His lordship died in March, 1773, in the 79th year of his age. He had for some time been extremely infirm, and having outlived most of his friends and contemporaries, he was in fact reduced to a state in which he rather patiently endured life than enjoyed it. "It is unnecessary," says his biographer, "to add any thing to the view already given of his moral character: if it was very far from faultless, it certainly exhibited many excellencies, which enabled him to perform important services to his friends and country. In his literary capacity, he possessed wit, good sense, and a fine taste, in an uncommon degree. His style is of the purest English." Of his works, which, besides those already referred to, contain papers in some of the political journals of the day, speeches, state papers, and letters, French and English, a Collection, in 2 vols. 4to. with memoirs of his life, by Dr. Maty, was published in the year 1777, to which the reader is referred for more minute information relating to the character, exertions, and works of the earl of Chesterfield.

STANHOPE, JAMES, earl, a celebrated English nobleman, statesman, and general, descended from a very ancient family in the county of Nottingham, eldest son of Alexander Stanhope, only son of Philip, the first earl of Chesterfield, was born in the year 1673. He entered at a very early period into the army, and served under king William in the war against France, during which, and particularly at the siege of Namur, he distinguished himself so much to the king's satisfaction, as to receive from his majesty a company of foot, and soon after a commission as colonel of the 33d regiment. In the war which was undertaken for the purpose of placing Charles II., son of the emperor Leopold, on the throne of Spain, colonel Stanhope, while commanding a regiment of foot, in 1704, at Porta Legra, in Portugal, was surrounded by king Philip's army, and he and his whole regiment were made prisoners of war. Being exchanged, he was in the following year promoted to the rank of brigadier-general, and in the next campaign he gained very considerable reputation at the siege of Barcelona, under the command of lord Peterborough. General Stanhope planned and completed the conquest of the island of Minorca. Having landed about ten miles from St. Philip's fort, on the 26th of August, with 3000 men, the general caused batteries to be erected, and ordered a number of arrows to be shot into the place, in which papers were stuck, written in the Spanish and French languages, containing threats that the whole garrison should be sent to

the mines, if they did not immediately surrender. The garrison consisted of 1600 men, commanded by colonel La Jonquiere. So artfully had general Stanhope drawn up his men, as to impress the minds of the enemy with the idea, that they were besieged by an army of at least 10,000 soldiers. The stratagem had the desired effect. On the third day the garrison capitulated; and so completely mortified was the Spanish governor when he learned the real number of the besiegers, that he threw himself out of a window in despair, and was killed on the spot. La Jonquiere was imprisoned for life, and the other French officers incurred their monarch's displeasure. In 1710, general Stanhope headed the allied troops, killed the Spanish commander with his own hand, and placed the victorious banners of England upon the walls of Madrid; but before the end of the year the general experienced a reverse of fortune, and he, with 2000 choice British troops, were made prisoners of war at the town of Brihuega. On this account he incurred the censure of the house of lords. Soon after the arrival of king George I. general Stanhope was appointed one of the principal secretaries of state, and a member of the privy council. He was also employed in several highly important negotiations. In the year 1717 he was appointed first lord of the treasury, and chancellor of the exchequer; and in a very short time afterwards, he was raised to the peerage of Great Britain. On the 13th of December, 1718, earl Stanhope brought into the house of peers a bill for the repeal of some clauses in the Corporation and Test acts, which, after a violent opposition, was carried through both houses, and received the royal sanction. This nobleman, distinguished in the several capacities of general, statesman, and senator, died in the year 1721, deeply regretted by the king, whose favourite minister he had been, and greatly respected by the nation at large, for whose interests he had ever manifested an unwearied and truly disinterested zeal.

STANHOPE, PHILIP, brother of the foregoing, was brought up to the sea-service, and in 1704 was promoted to the command of the *Hastings* frigate, as successor to captain Charles Parsons. After this he was appointed captain of the *Milford*, in which ship he was serving under sir Stafford Fairborne at the siege of Ollend, and chosen by that commander to bear to England the news of its surrender. Not long after he was sent to the Mediterranean, where he was employed under the command of captain Coney. He continued in the same command during the remainder of his life; which, says his biographer, excessive gallantry, added to a degree of fraternal love almost unequalled, rendered, alas! too short. Frequent mention is made of him in history, and the private journals of officers more particularly connected with him in service and command, as an active, diligent, and intelligent officer. In August, 1708, being left under the command of captain Hubbard, it was determined at a council of war, held on board the *Elizabeth* at the request of the king of Spain, that the *York* and *Milford* should assist in conveying the transports, which had on board lieutenant-general Stanhope and a strong body of troops, from Catalonia to Minorca. The reduction of this island was not only become a very favourite object with the king of Spain, but was regarded as likely to be extremely conducive to the success of the allied cause. General Stanhope, who commanded the land forces destined for this expedition, was, as has been intimated, the elder brother of this gentleman, and the ties of consanguinity appeared to increase the thirst of glory, and stimulated the latter to share with the former in danger, as, though a younger, he appeared a scarcely less ambitious candidate for fame and military glory. Attending the

land-forces as a volunteer at the assault of the Spanish lines at Fort Mahon, he there fell in the moment of victory, on the 17th of September, 1708. Campbell's Admirals.

STANHOPE, PHILIP, earl, son of the foregoing, born the 15th of August, 1714, succeeded to his father's titles when he was only seven years old. He was, by the will of his father, confided to the guardianship of Philip Dormer, the celebrated earl of Chesterfield, of whom we have already spoken. This nobleman, as we have seen, was so strongly attached to the study of the belles-lettres and classical pursuits, as to hold very cheap every other species of learning; and in conformity with this disposition, he absolutely prohibited his young relation and ward from mathematical studies, for which he manifested, while very young, a natural and strong attachment. Notwithstanding this injunction, the young lord, when advanced to more mature years, applied himself to his favourite study with so much avidity, as to become one of the first mathematicians of the age. His predilection, however, for the sciences, properly so called, did not prevent him from attaining the most profound and extensive knowledge of the ancient classics. At no very advanced period of his life, he was a complete master of the Latin and Greek languages, and could, without the smallest hesitation, repeat the whole of the *Iliad*, and the *Odyssey* of Homer, in the original language. He diligently cultivated an acquaintance with the poets and historians of antiquity through the whole of his life, spending several hours of each day either in classical reading, or in the investigation of theorems in the higher and more sublime branches of geometry. Earl Stanhope acquired, likewise, a complete knowledge of many modern languages, in which he could maintain a conversation with as much fluency, as if they had been his vernacular tongue.

A person so formed for the pursuits of literature and science in all its various branches, would, it may be easily conceived, have no great ambition to be distinguished as a politician and statesman. He was, in truth, a man of the most undeviating integrity, and his principles could in no instance be brought to bend to circumstances, nor be swayed by any motives from the strict line of rectitude. In the year 1742 we find him in his place in the senate, when the several estimates of the expence occasioned by foreign troops in the pay of Great Britain were taken into consideration. His lordship then, at the close of an excellent and pathetic speech, moved for an address to advise and beseech his majesty, "that, in compassion to his people, already loaded with such numerous and heavy taxes, such large and growing debts, and greater annual expences than the nation at any time before had ever sustained, he would exonerate his subjects of the charge and burthen of those mercenaries, who were taken into the service last year without the advice or consent of parliament."

Earl Stanhope's name is likewise enrolled among those of many other patriotic noblemen in several protests against measures, which appeared to his mind hostile to the constitution of his country, and the real interests of public liberty. It was either in the earlier attempts made by the ministers of his present majesty to subjugate America, or on the question of the Middlesex election, that this nobleman travelled from Geneva, where he resided several years, to give his vote against the measure, and finding his exertion of no avail, he soon after returned to the continent, to enjoy domestic privacy among his family and his books. At this period his lordship, whose dress always corresponded to the simplicity of his manners, was once rather rudely prevented from going into the house of peers by a door-keeper, who was unacquainted with his person. Lord

Stanhope persisted in endeavouring to get into the house, without stopping to explain who he was: and the door-keeper, determined also on his part, made use of these words: "*Honest man*, you have no business here:—"*Honest man*, you can have no business in this place."

In 1774, earl Stanhope took his leave of Geneva, where he had spent about ten years, greatly respected and beloved by all the respectable people of that city. His lordship's extensive hospitality and beneficence are still remembered with affection and gratitude by many of the inhabitants of that small republic. From this period his lordship took but a very small share in the public transactions of the country. He divided his time between his town residence and his seat at Chevening, in Kent, devoting himself closely for several hours in the day to classical and mathematical studies, which had long become his habitual amusement.

It is to be deeply regretted, that learning so profound and talents so rare should have been applied almost entirely to his own gratification, and that he had not consecrated part of his time to the publication of the result of those researches, which engaged his attention for more than half a century. To his lordship's munificence, however, the public are indebted for the posthumous works of Dr. Robert Simson (see his article); which were printed at his own expence, and a copy or copies of which were sent to every learned society in Europe, and also to many of the most distinguished mathematicians both of his own and foreign countries. It appears, likewise, that Dr. Simson was indebted to this nobleman for the ninety-eighth proposition of Euclid's data. To him also the public are under considerable obligations for the most complete and magnificent edition of the works of the illustrious Archimedes, which was prepared for the press by the learned Joseph Torelli of Verona, and which was printed in 1792, at the Clarendon press, Oxford.

From the circumstance of many valuable works of science being dedicated to earl Stanhope, the subject of this article, among which were Dodson's Logarithms, and the third volume of Dr. Priestley's Experiments on Air, and other branches of Natural Philosophy, we may infer that he was the patron of several learned men. His lordship died the 7th of March, 1786, leaving behind him a son, the present earl, well known in the political as well as the scientific world, and a widow, with whom he had lived forty-one years. This lady, who survived the earl twenty-three years, was Grizel, the daughter of viscount Binning, sister of the late, and aunt to the present earl of Haddington. She was endowed with a fine understanding, which she had cultivated and improved by the constant perusal of the best authors in the English and French languages. She died, in the full possession of her faculties, at the advanced age of ninety-six. It is a remarkable fact, that a year or two previous to her decease, she cut a set of new teeth, and had her hair renewed. She devoted much of her long life to acts of benevolence. The writer of this article was honoured with her acquaintance, and he hopes he may add with her friendship, during ten years of his life, and he will never cease, while in possession of his mental faculties, to reverence her memory, and to hold in high estimation her talents and virtues.

STANHOPE, in *Geography*, a market-town and extensive parish in the N.W. division of Darlington ward, in the county palatine of Durham, England, is situated on the northern banks of the river Wear, 21 miles W. from Durham, and 264 N.N.W. from London. The privilege of a market was granted by cardinal Langley in the year 1421, and having fallen into disuse, was revived by letters patent

in 1669, through the influence of Dr. Bafire, the then rector, and is now held on Fridays. Here were two annual fairs, but they are discontinued. The church is an ancient, plain structure, standing on a rising ground to the north of the town. The rectory is worth about 2000*l.* per annum. On the west side of the town is an eminence, called Cattle-Hill, which rises from the Wear to the height of 108 feet. The summit is of an oblong figure, thirty paces in width, divided by a ditch: another ditch defends the acclivity to the north and east, where the ascent is easiest. It is traditionally said to have been a fortress of remote origin, demolished during the incursions of the Scots. The parish of Stanhope, besides the town, includes the districts of Stanhope-Forest Quarter, and Stanhope-Park Quarter, as also the township of Newlandside. The whole, according to the population returns of the year 1811, contained 1011 houses, occupied by 6376 persons, most of whom are employed in the neighbouring lead-mines. Near the town, on the north, is a cavern, extending under ground nearly a mile, and said to abound with stalactites.

At a short distance west of the town is a spacious old fabric, called Stanhope Hall, formerly the manor-house of the ancient family of Featherstonehaugh, the last of whom was slain at the battle of Hockley.

Stanhope park, a large tract of elevated land, about twelve miles in circumference, is an appendage to the see of Durham, where the bishop anciently held his great forest-hunts, and had his master of the forest, his bow-bearer, and other subordinate officers. Leland mentions this park as being "rudely inclosed with stone."

St. John's Weardale is only a chapelry to Stanhope, but has the privilege of a market, established for the benefit of the workmen employed in the lead-mines. It is seated in a narrow part of the vale, on the south of the Wear. Beauties of England and Wales, vol. v. by John Britton, F.S.A. and E. W. Brayley.

STANHOPE *Presb.* See PRINTING.

STANIHURST, RICHARD, in *Biography*, a divine and historian, was born at Dublin about the year 1545, of which city his father was recorder. He was educated at the University college, Oxford, after which he came to London, and studied the law in Furnival's Inn, and then at Lincoln's Inn. Returning to Ireland, he practised some time at the bar; but having abandoned the Protestant for the Roman Catholic religion, he thought it necessary to remove to the continent, for the purpose of obtaining a freer exercise of the duties which he owed to his Maker. After this he entered into orders, and became chaplain at Brussels to Albert, archduke of Aultria. He died in 1618, having obtained a very high reputation for learning. His writings are enumerated as follow: "Harmonia, seu Catena dialectica in Porphyrium;" "Descriptio Hibernicæ," inserted in Holinghed's Chronicle; "De Rebus in Hibernia gestis. Lib. IV." In this work we are told he took Giraldus Cambrensis for his guide, and he is said to have adopted freely the erroneous statements of that writer, though in some places he has corrected him from other writers. He published likewise "A Life of St. Patrick," and several Catholic works: of these, one was entitled "Brevis Præmonitio profutura Concertatione cum Jacobo Ufferio." This was occasioned by a work of Dr. Usher, afterwards the celebrated primate of Ireland, who was a nephew of Stanihurst: our author did not, however, live to finish the reply thus announced. Mr. Stanihurst tried his powers as a poet, by a version of the four first books of Virgil's Æneid in English hexameters. It is remarkable for the uncouthness of its diction and version. It is mentioned by Warton, who acknowledges that Mr. Stanihurst, with

with all his foolish pedantry, was certainly a scholar. He had a son, who became a Jesuit, and wrote various moral and religious works.

STANISLAUS I., LEZIN-SKI, king of Poland, born at Leopold in 1677, was son of a distinguished Polish noble, who, after occupying several important posts, was raised to that of grand treasurer of the crown. His son, the subject of this article, displayed at a very early period talents and dispositions which announced a character equally amiable and estimable. "His countenance," says his biographer, "expressed courage joined with sweetness, together with that air of openness and sincerity which is more persuasive than eloquence itself. He was brave, and enured to hardship and fatigue. He slept on a straw mattress, required scarcely any personal services from his domestics, was temperate, economical, adored by his vassals, and beloved by his friends." When Charles XII. of Sweden entered Poland, for the purpose of dethroning Augustus, Stanislaus, then palatine of Pomerania, was deputed to that prince from the confederation of Warfaw. In the conference with the monarch, he appeared to him in so favourable a light, that the Swede immediately took the resolution of raising him to the crown of Poland, which was effected at an election held July 12, 1704, when Stanislaus was in his twenty-seventh year. The unexpected entrance of Augustus into Warfaw, when the king of Sweden was at a distance with his army, obliged Stanislaus to make a precipitate retreat: but by another change he was brought back, and crowned at Warfaw with his wife, in October 1705, and by a treaty in the following year, Augustus was compelled solemnly to abdicate the crown of Poland in favour of his rival. Stanislaus remained possessor of the kingdom till the fatal defeat of his patron Charles, at Pultowa, in July 1709. Being now unable to maintain himself in Poland, he withdrew with the Swedes into Pomerania, and thence crossed into Sweden, where he passed some time in retirement, while negotiations were carrying on to restore the peace of the north. As his abdication of the Polish crown seemed a necessary preliminary, he readily signified his own concurrence, and wrote to Charles at Bender to obtain his consent. Not being able, by letter, to persuade him, he resolved to try the effect of a personal conference; and accordingly assumed a feigned name, and, accompanied by two officers, proceeded for the frontiers of Turkey. On his arrival in Moldavia he was arrested, and brought before Hospodar, who discovered his true person, and sent him to Bender, where he was detained as a prisoner, but was extremely well treated. He was suffered to depart in 1714, when he went to Deux Ponts, where he was joined by his family. A Saxon officer made an attempt to assassinate him, but the design was discovered before it could be put into execution, and he pardoned and dismissed the conspirators. In 1719 he received intelligence of the death of Charles XII., and feeling himself now deprived of his protector, he applied to the court of France, which gave him a retreat in Alsace. Here he lived in a state of great obscurity, until his daughter, the princess Mary, was unexpectedly chosen as queen to Lewis XV. This was in the year 1725, when Stanislaus removed to the castle of Chambord. On the death of Augustus in 1733, an attempt was made by the French monarch to replace Stanislaus on the Polish throne, and he repaired to Dantzic, in order to support the party which actually proclaimed him; but his competitor, the son of Augustus, and elector of Saxony, favoured by Austria and Russia, was more successful, and Stanislaus was obliged to quit Dantzic in disguise, and through many dangers escaped to Konigsberg. He supported this reverse of fortune with philosophical resign-

ation, and at the peace of 1736 he formally abdicated all claim and pretensions to the kingdom, on condition of retaining the title, and being put into possession for life of the duchies of Lorraine and Bar. Thenceforth he lived as the sovereign of a small country, which he rendered happy by the exercise of virtues, that caused him to be named by the general voice of his subjects, "Stanislaus the Beneficent." Instead of imposing new and oppressive taxes, he relieved his people from the pressure of many which they had heretofore borne; yet he was able, by a prudent economy, to found many useful and charitable establishments, and to patronize the arts and sciences. He was himself attached to literature, and wrote various treatises on moral, philosophical, and political topics, which were published under the title of "Œuvres du Philosophe Bienfaisant," 4 vols. 8vo. These volumes were published in 1765, and the royal author of them died in the following year, universally lamented.

STANISLAUS-AUGUSTUS, PONIATOWSKI, king of Poland, was the son of count Poniatowski, a Lithuanian, who, after being in the service of Charles XII. of Sweden, and of Augustus, king of Poland, married the princess Czartorinska, a descendant of the great family of the Jagellons. Stanislaus possessed a fine person, and a graceful demeanour, and was well received in the various parts of Europe which he visited while he was young. From England he accompanied the ambassador to Russia, where he acquired the particular favour of Catharine, then grand duchess. When she came to the crown, she exhibited her attachment by resolving to raise him to the throne of Poland on the death of Augustus III., and by means of a body of Russian troops, his election was carried in the plain of Vola, on the 7th day of September, 1764, when Stanislaus was in his thirty-second year. His talents and excellent disposition gave promise of a reign happy to himself and prosperous to his country; but the overbearing influence by which he had been elected, and the radical vices of the Polish constitution, acted as perpetual causes of tumult and dissention, and thwarted all the expectations and hopes that had been formed of the government of Stanislaus. The first disorders in this reign arose from religious differences. The non-catholics, comprised under the general name of Dissidents, had been constantly opposed in their claims of equal civil rights by the Romanists, and had been obliged to apply for protection to the Protestant powers and the court of Russia, who were guaranties of the treaty of Olivia, by which their privileges had been ratified. In 1766, at a diet, the ministers of these powers had presented memoirs in favour of the Dissidents, and the king seemed inclined to support their cause, while the Catholic prelates and nobles violently opposed them. The empress of Russia interfered effectually by sending troops into Poland, which advanced to the gates of Warfaw. Confederacies started up to resist them, and the country was plunged into civil war. The king was quite unable to quell these disorders, being regarded as having been imposed on the nation by a Russian force, and in 1771 an extraordinary attempt was made on his person, of which a very interesting account is given in the first volume of Coxe's Travels into Poland, which is thus concluded: "So extraordinary an escape is scarcely to be paralleled in history, and affords ample matter of wonder and surprise. Scarcely could the nobility or people at Warfaw credit the evidence of their senses, when they saw him return. Certainly neither the escape of the king of France from Damien, nor of the king of Portugal from the conspiracy of the duke d'Aveiro, were equally amazing or improbable as that of the king of Poland."

This attempt on the life of his majesty was planned by a Polish

Polish nobleman named Pulaski, who engaged three other chiefs by a solemn oath, either to place the king alive in his hands, or to kill him in case of resistance. These persons, at the head of forty dragoons, entered Warsaw in disguise, attacked and seized the king, and after having wounded him in the head with a sabre, dragged him through the streets, and carried him out of the city. After a while the conspirators were alarmed at what they had done, and they all, except one, took advantage of the darkness of night to make their escape, and at day-break the king found himself alone with a person named Kosiński, and both of them on foot. Taking advantage of the perplexity in which he saw this man was involved, the king represented to him in such colours the atrocity of the attempt, to which he added the promises of pardon and even reward, that he entirely gained him over, and they proceeded together to a mill. From thence the king wrote the following letter. "Par une espèce de miracle je suis sauvé des mains des assassins. Je suis ici au petit moulin de Mariemont. Venez au plutôt me tirer d'ici. Je suis blessé, mais pas fort." He was accordingly conducted back to Warsaw, and received amidst the joyful acclamations of the people.

Stanislaus, though retaining his crown, was unable to quiet or direct the distractions of the country: nor could he make any effectual opposition to that truly infamous partition of a large portion of Poland between the plunderers of Russia, Prussia, and Austria, which took place in 1773, and which may be regarded as the first act of those open violations of every principle of national justice, which have so peculiarly stigmatized the times in which we live. The same powers enforced alterations in the Polish constitution, calculated to perpetuate its weakness, and which were in vain opposed by Stanislaus and the best patriots of the country. In 1789 he had an interview with Catharine, who deluded him with hopes of advantages for the Poles, which, of course, were never realized: and in 1792, the armies of Russia and Prussia entered Poland, destroyed the constitution which had been formed by the people, and completed that division of its territories which expunged its name from the map of Europe. In 1795 Stanislaus was obliged, by order of the empress Catharine, to resign, and abdicate the crown which she had hitherto allowed him to wear, and he retired to Grodno, contented to live a pensioner on her bounty. On the accession of Paul, Stanislaus was treated with great respect. He died at Petersburg in 1798, beloved and esteemed for his qualities in private society.

STANISLAUS, *Order of St.*, was instituted by Stanislaus, king of Poland, in the year 1765. The badge of the order is a gold cross, enamelled red; on the centre a medalion; on this the image of St. Stanislaus, enamelled in proper colours; on the reverse, the letters SS in a cypher. It is worn scarfwise, pendent to a broad watered ribband, edged with white. The star of the order is silver, in the centre of which is a cypher of three letters, viz. S.A.R. signifying Stanislaus Augustus Rex; within, the following motto, *PRÆMIANDO INCITAT.*

STANISLAW, in *Geography*, a town of Austrian Poland, in Galicia; 66 miles S.S.E. of Lemberg.

STANITZ, a town of Bohemia, in the circle of Chrudim; 13 miles N. of Chrudim.—Also, a town of Moravia, in the circle of Brunn; 18 miles S.E. of Brunn.

STANK, is a dam made with pile-planks, or otherwise, to pen water.

STANKAU, in *Geography*, a town of Bohemia, in the circle of Pilsen; 9 miles N.N.E. of Pilsen.

STANLEY, THOMAS, in *Biography*, born at Cumberland-Green, in Hertfordshire, was the son of sir Thomas

Stanley, knight. He received his early education at home, under Edward Fairfax, the translator of Tasso's Jerusalem, and was admitted a gentleman-commoner of Pembroke-hall, Cambridge, in 1639. Having taken his degree of M.A. at that university, he went abroad, but returning during the civil war, he took up his residence in the Middle Temple. He there pursued his studies with much eagerness, and in 1651 published a volume of original poems, and a number of translations in verse from the ancient and modern languages. Turning his attention to graver topics, in 1655 he published the first volume of the work by which he is chiefly known, "The History of Philosophy; containing the Lives, Opinions, Actions, and Discourses of the Philosophers of every Sect." This was followed by three other volumes; they were afterwards republished in one volume folio; and in 1743, a quarto edition was given to the public. After the favourable reception which this work met with, the author published an edition of Æschylus, which was published in London in 1663, the text of which was copied into De Pauw's edition of 1745. He died in London, April 12, 1678, leaving behind him farther monuments of his industry and erudition, in manuscript, consisting of "Commentaries on Æschylus," in 8 vols. fol.: "Adversaria; or Remarks on Passages in various ancient Authors;" "Prelections on the Characters of Theophrastus;" and a Latin treatise on the first-fruits and tenths of the spoils mentioned in the Epistle to the Hebrews. He had been married to a Northamptonshire lady, co-heiress to a good estate, and he left a son, who published, at an early age, a translation of Ælian's "Various Histories."

STANLEY, JOHN, bachelor in music, was born in 1713. At two years old he totally lost his sight, by falling on a marble hearth with a china basin in his hand. At the age of seven he first began to learn music, as an art that was likely to amuse him, but without his friends supposing it possible for him, circumstanced as he was, to make it his profession. His first master was Reading, a scholar of Dr. Blow, and organist of Hackney. But his father finding that he not only received great pleasure from music, but had made a rapid progress, placed him with Dr. Greene, under whom he studied with great diligence, and a success that was astonishing. At eleven years of age he obtained the place of organist of All-hallows, Bread-street, and in 1726, at the age of thirteen, was elected organist of St. Andrew's, Holborn, in preference to a great number of candidates. In 1734, the benchers of the honourable society of the Inner Temple elected him one of their organists. These two places he retained till the time of his death. Few professors have spent a more active life in every branch of his art than this extraordinary musician; having been not only a most neat, pleasing, and accurate performer, but a natural and agreeable composer, and an intelligent instructor. He was the conductor and soul of the Swan and Castle concerts in the city, as long as they subsisted. Upon the death of Handel, he and Mr. Smith undertook to superintend the performance of oratorios during Lent; and after Mr. Smith retired, he carried them on, in conjunction with Mr. Linley, till within two years of his death, in 1786. This ingenious and worthy professor, whose blindness excited the pity, and performance the admiration, of the public for so many years, will be long lamented by his surviving friends; for they have lost in him, exclusive of his musical talents, a most intelligent and agreeable companion, who contributed to the pleasures of society as much by his conversation in private, as by his professional merit in public. He was succeeded in his office as master of the king's band, by Mr., afterwards sir William Parsons. See PARADIS, *Mademoiselle.*

STANLEY,

STANLEY, in *Geography*, a township in the parish of Wakefield, Yorkshire. See WAKEFIELD.

STANMORE, GREAT, a parish in the hundred of Gore, and county of Middlesex, England, is 10 miles N.W. from London. It comprises 1400 acres of land, the greater part of which is occupied as meadow and pasture, but about 250 acres still remain in common. From the number of Roman antiquities found within this parish, it is conjectured by Camden, Stukeley, and Reynolds, that the station called Sulloniacæ was at Brockley-hill. During the Anglo-Roman dynasty, this part of Middlesex, and a great part of Hertfordshire, were covered with woods: indeed, at the time of compiling the Domesday survey, it appears to have been chiefly forest. Fitz-Stevens, who wrote about 1170, says that an immense forest extends itself to the north of London, "and is full of the lairs and coverts of beasts and game." The village of Stanmore is of considerable extent, and consists chiefly of houses erected on the sides of the great road from London to St. Albans. There are some handsome mansions and villas within the parish; the chief of which is Stanmore-house, the elegant seat of the countess of Aylesford. The house is seated in an extensive park, distinguished for its varied surface and fine woods. A villa called the Grove, the residence of Charles Poole, esq. was possessed by Aaron Capadoce in 1802, who died here in that year, at the age of 105.

The present church of Stanmore was completed in 1632, at the sole expence of sir John Wolstenholme, knt. It is built of brick, and among other monuments is one by Nicholas Stone, commemorating the builder of the church. It contains a statue of the deceased, finely executed, and cost 200*l.* (See Walpole's *Anecdotes of Painting*.) In the parish of Stanmore-Parva is Canons, an ancient and celebrated seat of the Brydges family. This estate was rendered noted by James Brydges, duke of Chandos, who was paymaster of the forces to queen Anne, and who, having accumulated great wealth, resolved to build two magnificent houses, to surpass any of the ducal residences in England. One was commenced in Cavendish-square, London, but never finished; the other at Canons. Three architects were employed, Gibbs, James, and Shepherd; and Vertue describes the house as "a noble square pile, all of stone;" ornamented with statues, busts, paintings, &c. Italian artists were employed to stucco and paint the walls and ceilings, and a profusion of marble was used in pillars, floors, &c. In the erection and decoration of this noble mansion, and in planting the ground, it is related that not less than 250,000*l.* were expended. Corresponding with the building were the domestic establishment and style of living within the house: all was grandeur and ostentation. The duke dined in public, and was attended by a band of music and a military guard. This parade excited the envy and satirical animadversions of Pope and some other poets. In Pope's satire on False Taste, the character of Timon is supposed to be intended for the duke. The splendid mansion just mentioned was taken down, and the materials sold by auction, in 1747; and a small but neat villa was afterwards built by Mr. Hallet, and which is now the property and residence of sir Thomas Plumer. *Beauties of England*, vol. x. pt. 4. Middlesex. By J. N. Brewer, 1816.

STANNARIES, STANNARIA, the mines and works where tin is dug and purified: as in Cornwall, Devonshire, &c. There are four courts of the stannaries in Devonshire, and as many in Cornwall, for the administration of justice among the tinners. See *Stannary-Courts*.

STANNEL, in *Ornithology*, an English name of a species of hawk, more commonly known by the names of the

kestrel, or the *windhover*; and called by Latin authors *tinnunculus* and *cenchris*.

STANNER-WORT, in *Agriculture*, the common name of a troublesome weed in arable as well as grafs-lands. See RAG-WORT.

STANNUM, TIN. See TIN.

STANOVAIA, in *Geography*, a fortress of Russia, in the government of Tobolsk; 8 miles S.W. of Ischim.

STANOVITZKOI, a town of Russia, in the government of Novgorod; 48 miles N.W. of Tcherapovetz.

STANSTEAD, a township of Lower Canada, bounded W. by lake Memphramagog, and S. by Vermont: settled by about 750 inhabitants, a promiscuous emigration from various parts of the United States.

STANSTED, a town of Virginia; 5 miles N. of Fal-mouth.

STANTONS, a town of North Carolina; 8 miles W. of Guildford.

STANTZ, a town of Switzerland, in the canton of Unterwalden, of which it was formerly the capital, on the lake of Lucerne; 8 miles S.E. of Lucerne. N. lat. 46° 51'. E. long. 8° 10'.—Also, a river of Stiria, which runs into the Muehr, 20 miles E.S.E. of Luttenberg.

STANZA, in *Poetry*, a certain stated number of grave verses, containing some perfect sense, terminated with a rest or pause.

The word is Italian, and literally signifies a stand or station, because of the pause to be made at the end of each stanza, or complete sense.

What the *couplet* is in songs, and the *strophe* in odes, the *stanza* is in the great and graver pieces, as epic poems, &c. Indeed, the Italians scarcely write any poems but they divide them into stanzas. There are stanzas of four, six, eight, ten, twelve, and fourteen verses, and sometimes of an uneven number of verses, as five, seven, &c. But these last are somewhat more difficult to execute, by reason of the three verses to one rhyme. The French lay it down as a rule, that if the first stanza begin with a masculine or feminine verse, the second is to begin and end with the same.

Every stanza ought not only to contain a perfect sense, but to be terminated with some lively and ingenious thought, or some just and pertinent reflection.

Stanzas were first introduced from the Italian into the French poetry about the year 1580, and thence they were transferred into the English.

The use of stanzas in tragedy, or comedy, is condemned by all the best critics; for though we speak verse on the stage, it is still presumed we are speaking prose. Stanzas shew a degree of ingenuity on the part of the poet, which has nothing of nature in it on the part of the actor. Add to this, that stanzas are not fit to express every thing: wrath, threatening, &c. fit very ill on a regular stanza; though irresolution, reveries, and every thing that leads the actor to think on what he is to resolve, agree well enough with the unequal cadence of the stanza.

STANZIONE, CAVALIERE MASSIMO, in *Biography*, was born at Naples in 1585, and was a disciple of G. B. Caracciolo: he also received instructions in fresco painting from Belisario Coferzio, one of the most eminent artists of his time, and indeed seems to have been exceedingly studious of the works of all the great painters of his day. He visited Rome, and in studying the works of Annibal Caracci, became intimate with Guido Rheni, into whose style he fell with so much success, that he obtained the name of *Il Guido Rheni di Napoli*.

It was in his native city that he principally exerted his ability in original productions, and was ranked among its ablest

ablest artists. Spagnoletto became jealous of him, and is said by Lanzi to have been guilty of a gross piece of perfidy to destroy the picture he had painted in competition with his Descend from the Cross, for the Certosa. The subject of his picture was Christ with the Maries, which having somewhat changed in tone, and become darker, Spagnoletto persuaded the monks to permit him to clean it; when he used some noxious preparation, which nearly destroyed the work. Upon application to Stanzione to remedy the mischief, he refused, declaring it should remain as it was, that the author of so disgraceful a procedure might reap the just fruits of his perfidy.

Among the considerable works executed by Stanzione at Naples, are the ceilings of the churches of St. Paolo and del Gesu Novo, and a large picture at the Certosa, representing St. Bruno presenting the regulations of his order to his monks. The small cabinet pictures by him are numerous, and much esteemed. He died at the age of 71, in the year 1656.

STAPEDIUS, or STAPIDÆUS, or *Stapidis Musculus*, in *Anatomy*, the smallest muscle in the body, situated in the tympanum of the ear. See EAR.

STAPELBURG, in *Geography*, a town of Germany, in the county of Wernigerode; 6 miles W. of Wernigerode.

STAPELIA, in *Botany*, an extensive and very singular genus of African plants, so named by Linnæus, in honour of Dr. John Bodæus a Stapel, the laborious and learned Dutch editor of Theophrastus. His edition of this ancient author, published in folio at Amsterdam, in 1644, is the best which has appeared.—Linn. Gen. 121. Schreb. 169. Willd. Sp. Pl. v. 1. 1277. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 2. 84. Brown Tr. of the Wernerian Society, v. 1. 23. Juss. 146. Lamarck Illustr. t. 178.—Class and order, *Pentandria Digynia*. Nat. Ord. *Contortæ*, Linn. *Apocineæ*, Juss. *Asclepiadææ*, Brown.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, small, in five acute segments, permanent. *Cor.* of one petal, large, thick, divided more than half way into five broad, flat, pointed segments, sometimes with intermediate teeth. Nectary (or Crown of the stamens) double; the outer in five segments or leaves, various in different species; inner of five leaves, alternate with the outer, undivided, sometimes obsolete; all much shorter than the petal. *Stam.* Filaments five, flat, short, more or less connected; anthers simple at the point; "masses of pollen attached by their base, cartilaginous and pellucid at one margin." *Br.* *Pist.* Germens two, ovate, flat on the inner side; styles none; common stigma pointless. *Peric.* Follicles two, nearly cylindrical, smooth, taper-pointed. *Seeds* numerous, imbricated, compressed, crowned with fine hairs.

Ess. Ch. Corolla of one petal, five-cleft. Nectary a double star, covering the organs of impregnation. Common stigma pointless. Follicles two, smooth. Seeds comose.

Such is the Linnæan genus of *Stapelia*, preserved entire by the late Mr. Dryander, in Ait. Hort. Kew., though Mr. Brown has separated some genera from it. (See HUERNIA and PIARANTHUS.) We have already, under those articles, ventured to express an opinion that the original genus, on account of its very distinct habit, and the varieties of structure in its nectary or crown, might best remain undisturbed. We shall therefore consider it under that point of view, giving examples of its various sections. Linnæus has, even in the fourteenth edition of Syst. Veg., but five *Stapeliæ*; Willdenow has forty-nine, mostly adopted from Mr. Masson's rich and splendid illustration of this genus, published

in 1796, with forty-one coloured folio plates. As this able collector sent most of his discoveries to Kew, forty-four species appear in Mr. Aiton's work. They are all natives of the deserts of Southern Africa, except three found by Forskall in Arabia Felix, and one by Roxburgh in India. Their habit is extremely succulent, toothed, angular, and gibbous, without leaves. *Flowers* lateral, stalked, various in size, parti-coloured, generally of a dark and speckled hue, often remarkable for an extraordinary fetor, resembling carrion, rotten cheese, corrupted water, or such delectable odours, and grateful perhaps to the Hottentots, to whose country these flowers belong. The *Stapeliæ* are easily cultivated in pots, in a dry stove, with very sparing supplies of water, and as much sun as our skies will afford. They blossom pretty freely, at various seasons, and if their odour can be tolerated, their beauty will amply repay the moderate care they require.

Section 1. *Corolla simple, five-cleft, its edges hairy*. Twenty species.

S. ciliata. Fringed Buff Stapelia. Willd. n. 1. Ait. n. 1. Masson Stap. 9. t. 1. Thunb. Prodr. 46.—Stem procumbent. Teeth of the branches spreading. Surface of the corolla papillary; its margin fringed; segments ovate, acute.—Native of very dry situations at the Cape of Good Hope, below the hill called *Bockland Berg*. It flowers in our gardens from October to December. The stem is branched, procumbent, taking root here and there, with short, erect branches, stained with brown, intermixed with a less glaucous green than in most other species; its length about a foot. The teeth of the branches are unusually large and spreading, somewhat unequal and irregular. *Flowers* solitary, near three inches wide, buff-coloured; violet in the centre. Hairs of their fringe minutely club-shaped.

S. hirsuta. Hairy Stapelia, or Carrion Flower. Linn. Sp. Pl. 316. Willd. n. 3. Ait. n. 3. Jacq. Misc. v. 1. 28. t. 3. (*Asclepias africana aizoides*, flore pulchre fimbriato; Commel. Rar. 19. t. 19.)—Branches ascending, quadrangular, with erect teeth; flowering at the base. Corolla hairy at the margin and centre; segments ovate, acute, transversely corrugated.—Native of the Cape. Introduced very early from thence, by the Dutch, into the gardens of Europe, where it has ever since been preserved. The flower is large and handsome, of a dark chocolate crimson, streaked across with yellow; the marginal fringe resembling grey fur. Its scent is so like carrion, that flesh-flies lay their eggs upon it, and the maggots are starved for want of their proper food. Sir John Hill asserted, in an express dissertation, that these flies are a peculiar species, whose maggots feed on the flower. For which falsehood he is stigmatized by the great entomologist Fabricius, as "*damnandæ memoriæ Johannes Hill*."

S. fororia, Masson, t. 39; *grandiflora*, t. 11; *ambigua*, t. 12; and *Asterias*, t. 14; are nearly related to *hirsuta*, in the size and general aspect of their flowers, but all sufficiently distinct.

S. pulvinata. Cushion-flowered Stapelia. Masson Stap. 13. t. 13. Willd. n. 7. Ait. n. 6. Curt. Mag. t. 1240.—Stem procumbent. Branches quadrangular, with erect teeth; flowering at the base. Corolla hairy at the margin; its rounded segments shorter than the diameter of the tumid shaggy centre.—Native of the Cape, in bushy places at *Camies berg*. Masson. The Dutch inhabitants call this species the Arabian Rose, notwithstanding its fetor. For size and beauty it is indeed conspicuous, and though akin to *hirsuta*, and to the other species we have just named, is distinguished by the very tumid, shaggy, cushion-like centre of the flower, and the short, rounded segments of the limb, each

each tipped with a sharp point, of a different colour from its disk.

S. divaricata. Straddling Stapelia. Maffon Stap. 17. t. 22. Willd. n. 10. Ait. n. 9. Curt. Mag. t. 1007.—Branches bluntly quadrangular, tapering, spreading. Corolla very even; its segments lanceolate, pointed; revolute and distantly fringed at the margin.—Sent by Mr. Maffon, from the Cape, in 1793. The habit is slender, lax, and spreading. Flowers smaller than any of the foregoing, being but two inches wide, of a deep flesh-colour, polished, peculiarly smooth; their segments narrow, and so much reflexed, that the hairs on their edges may easily escape notice.

S. parviflora. Small-flowered Stapelia. Maffon Stap. 22. t. 35. Willd. n. 17. Ait. n. 16.—Branches acutely quadrangular, with recurved teeth; flowering in the upper part. Segments of the corolla lanceolate, fringed, shorter than the flower-stalk.—Native of bushy parts of Namaqua land. The branched stems are erect and stout, bright green, with large, compressed, hooked teeth. Flowers not half an inch broad, yellow, hairy, on deflexed purple stalks, scarcely an inch in length.

S. glanduliflora. Glandular-flowered Stapelia. Maffon Stap. 16. t. 19. Ait. n. 18. Sm. Exot. Bot. v. 2. 23. t. 71. (*S. glandulifera*; Willd. n. 20.)—Branches quadrangular, with upright teeth. Segments of the corolla ovate, acute, covered with club-shaped glands, and shorter than the flower-stalk.—Found in the deserts about *Nord Olifant's* river, by Mr. Maffon, who sent it to Kew in 1795. It flowers there late in autumn. The stems are green, erect, somewhat downy at the edges. Flowers above an inch broad, tawny or yellowish, clothed with erect club-shaped glands, of a very singular appearance. Crown of the stamens orange and black.

Section 2. *Corolla simply five-cleft, smooth-edged*. Twenty-two species, to which some are added in Hort. Kew. and Curt. Mag.

S. pedunculata. Long-stalked Stapelia. Maffon Stap. 17. t. 21. Willd. n. 21. Ait. n. 19. Curt. Mag. t. 793.—Branches bluntly angular, toothed at the top. Segments of the corolla lanceolate, acute, with tufts of pendulous glands at the base. Flower-stalks twice as long as the branches.—Native of dry places at *Camies berg*. Maffon. The branches are glaucous, tumid, with blunt, often obliterated angles, rather notched than toothed, except at the end. Flower-stalks five or six inches long. Flowers an inch and half, or two inches, wide, with narrow convex segments, of a more or less deep or variegated brown, accompanied at the base by pendulous tufts of trembling black glands. The centre of the flower is also black.

S. Gordoni. Gordon's Stapelia. Maffon Stap. 24. t. 40. Willd. n. 23.—Corolla orbicular, very slightly five-cleft. Stem branched, round, with copious spinous tubercles.—Gathered in *Groot Namaqua Land*, near Orange river, by Mr. Gordon, from whom Mr. Maffon received a drawing of this very singular species, it being the only one of the genus he had not himself seen and examined. The stem is represented erect, branched, a foot high, green, very thick and obtuse, beset all over with blunt tubercles, each bearing a prominent thorn. Flowers above two inches wide, of a pale nearly even brown, very smooth, convex, with five very shallow acute lobes, and a little blackish crown in the middle. The stalk is hardly an inch long.

S. pilifera. Hairy-tubercled Stapelia. Linn. Suppl. 171. Willd. n. 24. Ait. n. 21. Maffon Stap. 17. t. 23.—Branches erect, round, tumid, with copious tubercles, each

tipped with a bristle. Segments of the corolla ovate, pointed, smooth. Flowers sessile, scattered.—Native of very dry hills, in the deserts at the Cape of Good Hope. The Hottentots are said to eat it, knowing it by the name of *Guaap*. The habit of the plant is very like the last, only the tubercles are smaller in proportion, and bear bristles instead of thorns. The flowers are small, half an inch broad, smooth, of a dark purplish-brown, with a black and yellow crown, surrounded by a red circle. This species confirms the genus of the last, if there could be any doubt on that subject.

S. articulata. Jointed Stapelia. Maffon Stap. 20. t. 30. Willd. n. 26. Ait. n. 22.—Branches spreading, round, tessellated with pointed tubercles. Flowers nearly sessile; their segments triangular, papillary.—Native of the country of *Roggeveldt*, at the Cape of Good Hope. The Hottentots eat it raw; the Dutch settlers pickle it with vinegar. This is of a glaucous, often reddish, hue, and singularly tessellated, growing in a proliferous straggling form; its structure akin to the two last. Flowers very small; their parts not clearly intelligible from Maffon's figure, nor have we seen a recent specimen. They are scattered about the toothed summits of the branches.

S. mammillaris. Prickly Stapelia. Linn. Mant. 2. 216. Willd. n. 27. Ait. n. 23. (*S. aphyllus*, ad nodos mammillaris, stiloculo rubello, siliquis pendulis; Burm. Afric. 27. t. 11.)—Branches erect, roundish, with copious spinous tubercles. Flowers stalked; their segments lanceolate, smooth.—Native of the Cape, from whence it was sent to Kew, by Mr. Maffon, and having flowered there, proves very distinct from the last, to which he suspects, in his work, it might belong. The tubercles are prominent, and their spines very stout, even more so than in *S. Gordoni*, which this species nearly equals in stature. The flowers however are much smaller, and totally different in the form of their segments.

S. pulla. Black-flowered Stapelia. Maffon Stap. 21. t. 31. Willd. n. 30. Ait. n. 26.—Branches imperfectly hexagonal, erect, with spreading spinous teeth. Segments of the corolla lanceolate, revolute, smooth.—Native of the hot sandy deserts called *Karròs*, at the Cape of Good Hope. Brought to Kew by Mr. Maffon, in 1774. This is somewhat related to the last, being, though less tuberculated, and more angular, furnished with similar spines. The flowers also seem similarly formed. They grow, several together, on short aggregate stalks, and are pale externally, but almost black on the upper surface of their narrow, taper, almost erect, segments.

S. adscendens. East Indian Stapelia. Roxb. Corom. v. 1. 28. t. 30. Willd. n. 31. (*Caralluma*; Brown Tr. of the Wern. Soc. v. 1. 25.)—Branches quadrangular, ascending, toothed, flowering about the summit. Segments of the corolla ovato-lanceolate, pointed, revolute, smooth.—Found among bushes, on high dry barren ground in the East Indies, flowering in the wet season. The Telingas, according to Dr. Roxburgh, call it *Car-allum*, and eat the young tender branches raw, though they are bitter and salt to the taste. The stems are perennial, slender, a foot or two high, branched, their angles beset with ascending teeth. Flowers near an inch in diameter, scattered, on short stalks, towards the ends of the branches. Segments of the corolla green in the lower half; dark purple in the other part; pale beneath. We can form no idea of the structure of the crown, or neighbouring parts, from the figure, nor has Dr. Roxburgh ventured to explain them. Mr. Brown describes the crown as of ten leaflets, in a simple series;

five of them opposite to the anthers, and undivided; the last deeply divided, awl-shaped. With much respect for his opinion, we think the plant ought not to be separated from *Stapelia*, and therefore we need say nothing of his generic name.

S. incarnata. Flesh-coloured *Stapelia*. Linn. Suppl. 171. Willd. n. 33. Ait. n. 27. Masson Stap. 22. t. 34. (*Euphorbium erectum*, quadrangulare, spinolum, ramis lateralibus rotundis foliosis; Burm. Afric. 15. t. 7. f. 1.)—Branches quadrangular, erect, toothed, flowering about the summit. Segments of the corolla lanceolate, flat, pointless, smooth.—Found by Thunberg and Masson, in dry sandy fields at the Cape. About a foot high, glaucous, much flouter than the last. *Flowers* numerous, nearly sessile, scattered about the upper part of each branch, each half an inch broad, pale pink or white. The Hottentots are said to eat the branches.

S. punctata. Purple-dotted *Stapelia*. Masson Stap. 18. t. 24. Willd. n. 34. Ait. n. 28.—Stem proliferous, decumbent, with oblong, somewhat quadrangular, toothed joints. Corolla bell-shaped, with lanceolate acute segments; papillary on the upper surface.—Native of the *Namaqua lands*, in Southern Africa. Sent to Kew in 1795, where it flowers most part of the autumn. This is one of a tribe, of which Mr. Masson has described several more species, whose stems are composed of oblong or elliptical, proliferous joints, or branches, and whose flowers, supported by longish stalks, have lanceolate acute segments, dotted or glandular all over their upper surface. In the present instance the corolla, about an inch in diameter, has a bell-shaped tube, externally of a blueish-white. The upper side is pink, with purple dots. The flower-stalks, near two inches long, grow three or four together, and are of the same pink hue as the corolla.

S. geminata, Masson t. 25, and *decora*, t. 26, are, in habit and general character, allied to the last.

S. picta. Painted *Stapelia*. Sims in Curt. Mag. t. 1169. Ait. n. 34. (*S. variegata*; Jacq. Misc. v. 1. 27. t. 4.)—Branches simple, ascending, quadrangular, with spreading teeth. Segments of the corolla ovate, pointed, corrugated; the annular centre very rugged. Five leaflets of the crown cloven.—Native of the Cape of Good Hope, from whence Messrs. Loddiges are said to have introduced it into the English collections. The structure of the nectary however induces us to believe, with Dr. Sims, it is what Jacquin has figured as *S. variegata* of Linnæus, hereafter mentioned. This belongs, with the real *variegata*, to no less distinct a tribe of species than the last. Their stems, composed of numerous simple erect branches, have a tufted habit; their colour is less glaucous than in most others; the teeth of their branches are numerous, and strongly marked, spreading in four rows. *Flowers* about two inches wide, on deflexed solitary stalks, yellow, either transversely streaked or dotted with a chocolate-brown; their segments broad, rugged or warty. Crown of the flammens various in the different species. The colouring of the present flower is darker, and more blotched, than usual.

S. verrucosa. Warty-flowered *Stapelia*. Masson Stap. 11. t. 8. Willd. n. 39. Ait. n. 35. Curt. Mag. t. 786?—Branches simple, ascending, bluntly quadrangular, with spreading teeth. Segments of the corolla ovate, pointed, warty; the centre concave, with a rough pentagonal elevation.—Found in dry ground at the Cape. Akin to the last, but the corolla is warty, or tuberculated, not transversely corrugated. We cannot but have some doubts concerning the synonym of the Botanical Magazine, as the

representation there of the crown of the flower is not reconcilable to Mr. Masson's figure. One or the other must be incorrect. In the branches we see no important difference.

S. irrorata, Masson t. 9, is one of the same tribe, and perhaps nearer the plant of the Botanical Magazine.

S. variegata. Variegated *Stapelia*. Linn. Sp. Pl. 316. Willd. n. 42. Ait. n. 37. Curt. Mag. t. 26. (*Fritillaria crassa*, promontorii Bonæ Spei; Stapel. Theophr. 335.)—Stem branched upwards, quadrangular, with spreading teeth. Segments of the corolla ovate, pointed, corrugated; the annular centre concave, rugged. Leaflets of the crown all undivided.—Native of the Cape, from whence it was early brought to Europe. This is most akin to *S. picta*; but if the observations of our friend Dr. Sims be, as usual, correct, the leaflets of the crown, or nectary, being all undivided in the true *variegata*, essentially distinguish it. This flower smells like rotten cheese. It is prettily spotted with brown on a yellow ground. We dare not rely on all the old synonyms, the crown not being accurately expressed; especially as there are several species, so easily to be confounded with the present, which may have been cultivated, without being well distinguished.

S. busonis, Curt. Mag. t. 1676, is one of these uncertain species, nearly akin to the *picta*. They require to be all compared in a living state, particularly with regard to the structure of the crown.

Section 3. *Corolla with five intermediate teeth*. Six species, to which one is added in Hort. Kew. This section comprehends Mr. Brown's genus HUERNIA. See that article.

S. campanulata. Bell-shaped *Stapelia*. Masson Stap. 11. t. 6. Willd. n. 43. Ait. n. 38. Curt. Mag. t. 1227, and t. 1661!—Corolla bell-shaped, with ten teeth, rough; its tube internally bearded. Branches with four compressed toothed angles.—Native of dry ground at the Cape, from whence several collectors have received living plants. The branches are thick, ascending, somewhat tufted, with four, or more, very prominent, compressed angles, beset with large, acute, compressed, projecting teeth. *Flowers* two inches wide, with a perfectly bell-shaped tube, which is lined, and almost filled up, with converging, glandular, purple hairs; limb in five pointed shallow lobes, with as many very small intermediate ones, its inner surface cream-coloured or buff, dotted with purple. We cannot account for this species being given a second time in the Botanical Magazine without any reference to the former figure, which best agrees with Mr. Masson's, and with the specimens we have seen.

S. reticulata. Netted *Stapelia*. Masson Stap. 9. t. 2. Willd. n. 48. Ait. n. 43. Curt. Mag. t. 1662.—Corolla with ten teeth; its tube internally bearded, and surrounded with a tumid ring. Branches with five compressed angles, beset with hooked teeth.—Found in hollows of rocks, near north *Olifant's* river, at the Cape. The numerous, rather hooked teeth of the branches, differ somewhat from the last. Masson's figure of the flower is more striking, and more faithful, than that of the Magazine. The corolla, beautifully variegated with crimson and dark purple, is marked with a kind of net-work. The ring round its mouth, or tube, is singularly tumid; the latter is filled with purple hairs, as in *S. campanulata*.

S. lentiginosa. Freckled *Stapelia*. Sims in Curt. Mag. t. 506. Ait. n. 44.—Corolla with ten teeth; its tube bell-shaped, naked, surrounded with a tumid ring. Stem branched in the upper part, five-angled, with hooked teeth.

Brought

Brought by Mr. Masson from the Cape to Kew in 1795, though it does not occur in his work. The flower most agrees with his *guttata*, but the habit of the plant is very different.

Section 4: *Flowers not yet observed.* One species. Willdenow.

S. clavata. Club-shaped Stapelia. Willd. n. 49.—“Stem simple, thick, club-shaped, reticulated with obscure warts, flowering at the summit.”—Gathered by governor Patterfon, in sandy fields beyond *Kopperberg*, at the Cape. He has delineated the fruit only in his travels, tab. 8, according to the German edition, cited by Willdenow.

We beg leave to observe that the two first sections of the present genus are entirely artificial, the fringe of the *corolla* not leading to any natural affinities of species.

STAPELIA, in *Gardening*, contains plants of the succulent perennial kind, of which the species cultivated are, the hairy stapelia (*S. hirsuta*); and the variegated stapelia (*S. variegata*).

Method of Culture.—These sorts of plants are readily increased by cuttings or slips of the young branches, which should be exposed a few days in a dry covered place to heal over the cut part, and be then planted in pots, filled with light, poor, dry, fresh, sandy earth, with lime rubbish, plunging them in the tan-bed of the stove, where they soon strike root. When they are well rooted, they may be removed into separate pots, replunging them in the bed till fresh rooted, when they may be placed on the tops of the flues, or on the shelves in the hot-house. They are also capable of being preserved in the greenhouse. They have a fine effect in their leaflets, protuberant, warted appearance, and the beauty of their flowers, which are large, stellated, variegated, spotted, and differently striped.

STAPES, in *Anatomy*, one of the small bones of the ear, exactly resembling in shape the iron part of a stirrup. See EAR and CRANIUM.

STAPHISAGRIA, in *Botany and Gardening*. See DELPHINIUM.

STAPHISAGRIA, in the *Materia Medica*. See STAVES-ACRE.

STAPHYLÆA, in *Botany*, abridged by Linnæus from *Staphylodendrum* of Tournefort and of ancient authors, derived from *σταχυλῆ*, a bunch, or cluster, and *δένδρον*, a tree, because the clustered fruit of this shrub resembles a bunch of grapes in its mode of growth.—Linn. Gen. 148. Schreb. 198. Willd. Sp. Pl. v. 1. 1497. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 377. Prodr. Fl. Græc. Sibth. v. 1. 208. Ait. Hort. Kew. v. 2. 171. Pursh v. 1. 129. Jusl. 377. Tournef. t. 386. Lamarek Dict. v. 7. 391. Illultr. t. 210. Gært. t. 69.—Class and order, *Pentandria Trigynia*. Nat. Ord. *Tribilata*, Linn. *Rhamnii*, Jul. 1.

Gen. Ch. Cal. Perianth inferior, of one leaf, five-cleft, concave, roundish, coloured, the size of the corolla. Cor. Petals five, oblong, erect, like the segments of the calyx. Nectary at the receptacle of the fructification, in the base of the flower, concave, urn-shaped. Stam. Filaments five, oblong, erect, the length of the calyx; anthers simple. Pist. Germen superior, thickish, three-cleft; styles three, simple, a little longer than the stamens; stigmas obtuse, contiguous. Peric. Capsules three, inflated, flaccid, united longitudinally by a suture, pointed at the tip, bursting inwardly. Seeds two, bony, globular, with an oblique point, and an orbicular excavation at the side of the orifice.

Obs. In *S. pinnata* the germen, instead of being three-cleft, is mostly bifid, and there are generally but two capsules.

Ess. Ch. Calyx inferior, in five segments. Petals five.

Capsules inflated, joined together. Seeds two, globose, with a scar on one side.

1. *S. occidentalis.* Jamaica Bladder-nut. Willd. n. 1. Swartz Ind. Occ. v. 1. 566. (*Arbor jamaicensis fraxini alatis foliis, floribus pentapetalis corymbosis*; Pluk. Alm. 45. t. 269. f. 1.)—Leaves doubly pinnate. Capsules triangular. Seeds solitary. Stem arboreous.—Native of fields in the mountainous parts of Jamaica, flowering in the spring and autumn. A tree from twenty to thirty feet in height, with a smooth trunk, and round, smoothish, shining branches. Leaves alternate, stalked; leaflets two or three pair, ovate, pointed, serrated, smooth, shining. Stipulas two, between each pair of leaflets, small, incurved. Flowers in terminal, erect, lax clusters, white, fragrant, three on each stalk. Capsules scarcely inflated.

2. *S. pinnata.* Bladder-nut Tree. Linn. Sp. Pl. 386. Engl. Bot. t. 1560. “Schmidt. Arb. t. 80.”—Leaves pinnate. Styles and capsules but two.—Native of the south of Europe; but of such rare occurrence in this country as to be scarcely deemed indigenous, although it is admitted into the British Flora. It blossoms in May or June, and perfects fruit rather late in the autumn. Stem shrubby, five or six feet high, branched, smooth. Leaves unequally pinnate; leaflets five, opposite, ovate, serrated, acute. Stipulas large, membranous, brownish. Flowers in terminal, compound, drooping clusters, bell-shaped, pale yellow. Bractæas setaceous, membranous. Capsules two, rarely three, membranous, inflated, each containing two large, globular seeds, which when ripe are hard, light brown, and look as if varnished.

The general appearance of this shrub somewhat resembles that of the common Ash.

3. *S. trifolia.* Three-leaved Bladder-nut. Linn. Sp. Pl. 386. “Schmidt. Arb. t. 81.”—Leaves ternate.—Native of dry hills, in rocky situations from New York to Upper Carolina, flowering in May and June. Pursh. Stem stouter than in the last species; the older branches grey; the younger green, smooth. Leaves three together, ovate, pointed, serrated, the terminal one largest. Flowers produced from the sides of the branches, in longer clusters, but on shorter stalks, of a clearer white, and somewhat larger than in the last.

STAPHYLÆA, in *Gardening*, contains plants of the hardy, deciduous, flowering, shrubby kind, of which the species cultivated are, the five-leaved bladder-nut (*S. pinnata*); and the three-leaved bladder-nut (*S. trifolia*).

Method of Culture.—These plants may be increased by seeds, suckers, layers, and cuttings. The seeds should be sown as soon as they become ripe, in the autumn, in a bed of common earth, to the depth of an inch: they should be kept clear from weeds, and refreshed in dry weather with water frequently. In the following autumn or spring, the large plants should be removed into nursery-rows, at two feet apart, and one foot distant in the rows, to remain till of sufficient growth for the shrubbery. The suckers may be separated and taken up in autumn, or early in the spring, with root-fibres to them, and planted in nursery lines in the above manner. The layers may be put down from the young branches, being either slit or twisted; and, when properly rooted in the following autumn, be planted out in the nursery as above. The cuttings should be made from the lower parts of the young shoots of the preceding year, planting them in a shady border in the autumn, and watering them frequently during the spring and summer, when the weather is dry; and when well rooted, in the autumn following, planting them out in the nursery-rows as above, or where they are to remain. They afford ornament and

variety in the shrubby parts of pleasure-grounds, as well as in some other parts, by their long pendulous bunches of flowers, and bladder-shaped capsules, which have a singular appearance and effect in the autumnal season.

STAPHYLE, a word used by the old Greek writers, sometimes to express a grape, and sometimes a disorder of the uvula, which consists in an extenuation of its superior part, and a tumour of the inferior, whence it hangs down in the shape of a grape. The uvula, or gargareon, is also thus called by some writers.

STAPHYLEPARTES, the name of a surgical instrument, in use among the ancients for elevating the uvula. It is mentioned by Paulus Ægineta.

STAPHYLINUS, in *Anatomy*, the muscle of the uvula, commonly called *azygus*. See **DEGLUTITION**.

STAPHYLINUS, in *Botany*, a name given by some authors to the common *daucus sylvestris*, wild carrot, or bird's nest.

STAPHYLINUS, in *Entomology*, a genus of insects of the order *Coleoptera*. The generic character is as follows: Antennæ moniliform; four feelers; shell half as long as the body; wings folded up under the shells; tail not armed with a forceps, furnished with two exsertile vesicles. The insects of this genus are extremely rapacious, devouring not only the insects of other genera, but frequently each other. Many of them, when attempted to be caught, turn up the tail. The jaws are strong and exerted, with which they bite and pinch very hard: most of them are found in damp moist places, among substances, and a few upon flowers. There are about 180 species, separated into three sections, according as their feelers are filiform, hatchet-shaped, or clavate. Of these we shall notice but very few that are not to be found in this country.

Species.

A. *All the Feelers filiform.*

AUREUS. Head, thorax, and shells, covered with ferruginous down; the abdomen is black, with cinereous bands. It is found in Siam.

* **HIRTUS**. Hairy, black; thorax and hind-part of the abdomen yellow. Found in sandy situations, in this country, and other parts of Europe.

* **MURINUS**. Pubescent, cinereous, clouded; abdomen and legs deep black. It is found in this country, among decayed carcases and dung. The shells are blue, and polished beneath. The larva is six-footed, naked, and of a pale hue. The head and three first segments of the abdomen chestnut-brown; tail with two jointed bristles, and a cylindrical tubercle beneath.

* **OLENS**. Black, opaque, immaculate; head broader than the thorax. This is an English insect, but found likewise in many parts of the European continent.

* **MAXILLOSUS**. Pubescent, black, with cinereous bands. The jaws of this insect are as long as the head; the antennæ are still longer; the shell covers one third of the abdomen; the legs end in small tufts of hair.

* **ERYTHROPTERUS**. Black; shells, base of the antennæ, and legs, are red; the head and thorax are unpolished, black; shells with two triangular spots; each side is composed of a few gilded hairs.

* **POLITUS**. Black; thorax and shells polished; thorax with a line of impressed dots. This insect, when first caught, scatters a very fragrant odour.

* **BRUNNIPES**. Black; legs, base and tip of the antennæ, ferruginous; the antennæ are black, the first and two last joints are ferruginous; the eyes are white.

MARGINATUS. Black; sides of the thorax and legs are

yellow. It is something less than the *S. politus*, and of a glossy-black.

ALPINUS. Black; base of the antennæ, shells, and legs, livid. It inhabits the highest mountains of Lapland, on the birch. The body of this species is more depressed than is the case with regard to others; the antennæ are black, and pale at the base; the abdomen is black.

* **BI-PUSTULATUS**. Black; shells with a ferruginous dot behind.

BI-GUTTATUS. Black; shells with a whitish dot; the eyes are prominent. It inhabits the shores of the Baltic.

* **FUSCIPES**. Black; thorax roundish; shells and legs piceous; the body is small and thick; the edges a little blackish.

* **ATRICAPILLUS**. Thorax rufous; shells brown, with a white dot and hinder margin.

SANGUINEUS. Gibbous, black; shells sanguineous; antennæ thicker towards the top. This is found chiefly in France. The antennæ are as long as the body; the head is rough; the shells are striate at the base; legs yellowish; thighs brown; body sometimes chestnut-brown.

* **CARABOIDES**. Yellow, immaculate.

* **RUGOSUS**. Black; thorax and shells rugged. It is larger than the next. The head is flat; the thorax depressed, with longitudinal wrinkles.

* **PICEUS**. Black; thorax depressed, with three raised lines; the shells are piceous.

FLAVUS. Black; edges of the thorax and shells yellow; the latter with a brown fillet and outer margin; antennæ and legs yellow.

LITTOREUS. Black; shells grey on the fore-part; legs rufous. It inhabits the sea-shores.

B. *Hind-feelers hatchet-shaped.* **OXYPORUS.**

* **RUFUS**. Rufous; head and hind-part of the shells and abdomen are black. It is found chiefly on fungi, in this and other European countries.

* **LUNULATUS**. Yellow; shells black, pale at the base and tip. It inhabits Europe, on fungi. Head is black; the tip of the abdomen is marked with a white ring.

* **MERDARIUS**. Black; thorax and shells rufous. It is found in this and other European countries.

* **CHRYSOMELINUS**. Black; thorax rufous; shells testaceous, the margin at the base is black.

* **RUFIPES**. Glossy-black; legs rufous. It is found in the northern parts of Europe.

* **HYPNORUM**. Glossy-black; margin of the thorax, shells, and legs, testaceous; the body is black, glabrous, and polished.

* **MARGINELLUS**. Glossy-black; margins of the thorax and shells ferruginous. This is a very small insect.

C. *Fore-feelers clavate.* **PÆDERUS.**

* **RIPARIUS**. Rufous; shells blue; the head and end of the abdomen are blackish. This is figured in Donovan's English Insects.

* **FLONGATUS**. Hind-part of the shells and legs fulvous.

FULGESCENS. Glossy-black; shells and ends of the legs testaceous; head slightly punctured. The head is marked with numerous small impressed dots.

STAPHYLIS, a name given by some authors to a sort of cup, or boat, made for feeding young children, and contrived with a spout in form of a grape or nipple.

STAPHYLODENDRON. See **STAPHYLÆA**.

STAPHYLOMA, is the name given, in *Surgery*, to that disease of the eye, in which the cornea loses its natural transparency, rises above its proper level, and even projects between

tween the eye-lids, in the form of a whitish pearl-coloured tumour, which is attended with total loss of sight.

The malady commonly results from some violent species of ophthalmia, particularly that which is termed *purulent*, and affects children, and that which is consequent to the small-pox. As Scarpa observes, the staphyloma is one of the most serious dileates to which the eye-ball is subject; for, to the total and irremediable loss of sight, are added all the evils which necessarily result from the protuberance of the cornea in advanced cases. The inability of closing the eye-lids, the exposure of the eye-ball to the contact of the air and extraneous matter suspended in it, the friction of the eye-lashes against the tumour, the incessant flux of tears down the subjacent cheek, render the eye painful and inflamed; sympathetically induce ophthalmia in the sound one; and cause ulceration both on the diseased part of the eye, and on the lower eye-lid and cheek.

The opacity being irremediable, the only surgical object is to prevent the inconveniences arising from the protuberance of the diseased cornea. In recent cases, when the tumour does not project forward, it is best to do nothing. In inveterate cases, the prominent part of the cornea must be cut off. Scarpa recommends doing the operation as far from the conjunctiva as the case will allow. This eminent surgeon introduces a knife, like that used in the extraction of the cataract, completely across the staphyloma, at the distance of one line and a half, or two lines, from the centre of the tumour.

The lower half of the prominence is to be detached, by pushing the knife onward, till its edge comes out through the membrane below; then the flap is to be turned up with a pair of forceps, and the incision rendered completely circular with the same billoury. The aqueous humour, crystalline lens, and some of the vitreous humour, usually escape immediately after the operation, and the eye consequently becomes so diminished as to allow the eye-lids to be shut. Ophthalmia and suppuration of course succeed. Emollient poultices are now to be applied, until the violence of the inflammation has abated, the quantity of matter is diminished, and the wound manifests a disposition to heal: then they may be left off; and occasionally touching the sore with the *argentum nitratum*, and applying a pledget over the eye, will complete the cicatrization.

Mr. Ware thinks, that the portion of diseased cornea, taken away in the foregoing manner, is too diminutive to allow the crystalline lens to escape, without bruising the iris; and that it sometimes does not prevent the eye from becoming again distended with an aqueous fluid. He has, therefore, advised the circular incision of the cornea to be made about a quarter of an inch from the junction of that membrane with the sclerotic. Scarpa sulle Malattie principali degli Occhi. Ware in *Trans. of the Med. Society of London*, vol. i. art. 6. Cooper's First Lines of Surgery.

STAPHYLOSIS, a protuberance or protrusion of the choroid coat of the eye.

STAPIDACEUS MUSCULUS, in *Anatomy*, a name given by Duverney, Douglas, and many others, to the muscle of the stapes of the ear, called by others *stapidis musculus*, and by Albinus *stapidium*. See **STAPEDIUS** and **EAR**.

STAPLE, **STAPULA**, primarily signifies a public place, or market, whither merchants, &c. are obliged to bring their goods to be bought by the people; as the Greve, or the places along the Seine, for the wines and corns at Paris; whither the merchants of other parts are obliged to bring those commodities.

Vossius and Menage derive the word from *stapulus*, which is found in the Ripuary laws, signifying a place where jus-

tice is administered. Others derive it from the German *staple*, or Latin *stapula*, which Boxhornius derives farther from the German *stapelen*, to put in a heap. Others again have observed, that the English word staple is, in the civil law Latin style of former times, termed *stabile emporium*, i. e. a fixed port or mart for the importing of merchandize. And hence probably, they say, the contracted word *staple* (used, with some small variation in the orthography, all over Europe) had its derivation.

STAPLE also signifies a city or town, where merchants jointly agree to carry certain commodities, as wool, cloth, lead, tin, &c. in order to their being commodiously sold by the great. In England, staples were settled and appointed to be constantly kept in several towns, to which places merchants and traders were to carry goods to sell in those parts. See *Merchants of the STAPLE*.

The staple commodities of England were chiefly wool, leather, cloth, tin, lead, &c.; though by staple goods are now generally meant any proper saleable commodities, not easily subject to perish; or such wares and merchandize as are the natural and usual product or manufacture of any city or country.

The staples in the Levant, called by the French *eschelles*, i. e. *seales*, are such cities where the English, French, Dutch, Italians, &c. have consuls, factors, and magazines; and whither they send vessels regularly each year. The principal of these are Smyrna, Alexandretta, Aleppo, Seyda, Cyprus, Sallee, Alexandria, Cairo, Tunis, Algiers, Tripoli, the Morea, Candia, and the islands of the Archipelago. See **FACTORY**.

STAPLE, *Law of the*. See **LAW**.

STAPLE, *Merchants of the*, in the *History of English Commerce*, a denomination given to the first and most ancient commercial society in England, from their exporting the staple wares of the kingdom, which were wool, skins, lead, and tin, in their rough state for manufacture. This society is said to have had its rise in the year 1248; and it appears to have had the legal form of a corporation before the 12th year of Edward II. A.D. 1319; as there are records in the pipe-office of the Exchequer, which mention, that it was actually a corporation, with the title of the mayor and constables of the staple of England, who then had their staple at Antwerp, for conducting the sale of English staple wares, and the importation of such foreign goods as were wanted at home. However, in 1328, by 2 Edw. III. cap. 9. it was enacted, that the staples, on both sides of the sea, should cease, and that all merchant-strangers, &c. might go and come with their merchandize into England, after the tenor of the Great Charter. In 1336 the staple of wool was again fixed in Brabant; in 1341, at Bruges; and in 1348, at Calais; whither, and to no other place, all merchandize exported from England, Wales, and Ireland, either by denizens or aliens, were to be shipped from England and there landed. The customs from this staple are said to have then amounted to upwards of 60,000*l.* sterling yearly. In 1353, Edward III. removed the staple of wool from Bruges to Westminister, Canterbury, Chichester, Exeter, Winchester, Bristol, Lincoln, York, Norwich, Newcastle, and Hull, for England; and to Dublin, Cork, Waterford, and Drogheda, for Ireland. And it was enacted by 27 Edward III. called the *statute of the staple*, that all staple wares for exportation should be first brought to some of these places only, where the custom should be paid, and exported by merchant-strangers only, under an oath not to hold any staple thereof beyond sea; which privilege was extended by 31 Edward III. to denizens also. Calais, however, still remained a staple.

In these staple-towns, courts of *law-merchant* were established,

blished, by the said statute, for determining all mercantile affairs, and for punishing and amercing offenders. The principal matters under the cognizance of these courts were such as pertained to the five staple commodities of England, viz. wool and wool-fels or sheep-skins, leather, lead, and tin. From the year 1375, the staple of Westminster seems to have been removed to the place called Staple-Inn, in Holborn; when Calais, which had been for many years a principal staple-port for dispersing, in more early times, the English wool, lead, and tin, and, in later times, the English woollen manufactures, under the conduct of the Merchant-Adventurers, into the inland countries of the Netherlands, France, and Germany, was lost to this country. In 1588, the staple for wool, &c. was established at Bruges; and queen Elizabeth, in the third year of her reign, granted a new charter of confirmation to the corporation of the mayor and constables of the staple of England, of all such privileges as they did, might, or ought to have enjoyed before the loss of Calais. However, king James I., in 1604, granted a new charter to the Merchant-Adventurers, (which see,) and in 1617, confirmed all their former powers and privileges for trading to the Netherlands and to Germany, with the woollen manufactures of England, exclusively of all who were not free of their company; in consequence of which, the merchants of the staple, who had before been declining, by the manufacture and exportation of our woollen cloth, were brought to ruin. And when at length it was judged expedient to enact a total prohibition of the exportation of our wool, it is no wonder that the staplers' company should become extinct. At this day they exist only in name; though they maintain the form of a corporation by annually electing the officers of their company, according to the direction of their ancient charters. This nominal corporation is kept up by those who deal in wool (still called wool-staplers), and who, in their corporate capacity, possess a small sum in the public funds, the interest of which serves to defray the expence of their meetings and elections. But they never had a hall, or office of their own, within the city of London, like other trading companies, although the Inn of Chancery in Holborn is so denominated from their warehouses, which were formerly situated there; as was also an office and warehouse of theirs, which, since the erection of the new bridge at Westminster, has lost its place, as well as name of wool-staple, at the upper part of Cannon-Row. *Anderfon's Hist. Com. vol. i. See CUSTOMS.*

STAPLE, Statute. See **STATUTE**, and the preceding article.

STAPLE Articles of Food, in Agriculture, are all those which are of a firm and solid nature, texture, and quality, and which afford due support in the feeding and foddering of all sorts of domestic animals of the live-stock kind; in contradistinction to those which are of a watery and less firm structure and consistence, that supply nourishment and support to such animals in an inferior and less perfect manner; as corn, hay, tares, and some other similar sorts of food, in comparison with those of the more succulent root and grass kinds.

STAPLE of Land, a term signifying the particular nature and quality of it, in regard to the texture, consistence, and composition of its parts as a soil. In this way, there are heavy or strong stapled lands, those of a medium or middling staple, and light or thin stapled lands, according as the particles of the mouldy or powdery materials, of which they are constituted, may have more or less tenacity, adhesive firmness, and solidity among themselves, and more or less thickness. By this means, the differences in the staples of lands, as soils, become of very material importance to the farmer, as they shew and teach him not only the nature of the crops that may be grown upon them to the most

profit and advantage, and with the least danger, or greatest chance of success, but the manner in which they may be the most beneficially and effectually cultivated for the raising and producing of them. Besides, the differences in the staples of lands, as soils, are the chief or principal means by which the common farmer is able and capable of judging of, and deciding in respect to, the qualities of land as farms, as well as of their nature and values in the view of purchasing them. See **SOIL**.

STAPLE, Iron, in *Rural Economy*, a small piece of iron, in which the outward part is mostly either of the curved or square form, having two long sharp ends, points, or prongs; which are driven into wood or any other similar material. Staples of this sort are very useful for many different purposes about farms, as fastening gates, securing doors, and many others of the same nature.

STAPLES, or Keel-Staples, in *Ship-Building*, are generally made of copper, from six to twelve inches long, and about one and a quarter inch broad, with a jagged hook at each end, which are driven into the sides of the main and false keels to fasten them.

STAPLE-Rope, a term for ropes made of hemp not inferior to clean Petersburg.

STAPLETON, THOMAS, in *Biography*, was born of a good family at Henfield, in Sussex, in 1535. He was educated partly at Canterbury and partly at Winchester, and was then entered of New college, Oxford, of which he became a perpetual fellow. In the reign of queen Mary he obtained a prebend of Chichester, but on the accession of Elizabeth, his steady attachment to the Roman Catholic religion caused him and his family to remove to Louvain. Here he studied theology, and afterwards visited Paris and Rome. Returning to Louvain, he employed himself in writing books till 1572, when he was invited to Douay; where Philip II. had founded an university. After taking the degree of doctor in theology, he was presented to a canonry in that town, and was made royal professor of the holy scriptures. A distaste to the world induced him to enter among the Jesuits, who sent him to Louvain. This situation did not at all accord with his taste, and he returned to the canonry of Douay, whence, in 1590, he was called to occupy a royal professorship at Louvain: he was afterwards nominated to the deanery of Hilverbeck, near Bois-le-Duc, a preferment of considerable value, the profits of which placed him in good circumstances. He had now acquired a high reputation by his writings, which procured him an invitation to Rome from pope Clement VIII.; but he felt himself too old for such a change, and being beset with infirmities, he was led to decline the honour intended him. He died in 1598, at the age of sixty-three. He was a very voluminous writer, and his works, when collected, formed four volumes folio, which were printed at Paris in 1620. They all relate to the principles and controversies of the Romish religion, and the eulogies of its assertors. One of the most known was entitled "Propugnaculum Fidei primitivæ Anglorum," which was translated into English under the title of Stapleton's "Fortress of Faith." He gave an English version of Bede's Church History.

STAPLING of Wool, in *Rural Economy*, the art or process of sorting and adjusting its different properties and qualities in the same fleece, or in the whole quantity, so as that those of the same kind, and which are proper for the same use and intention in the manufactures, may be put together in the most useful and appropriate manner.

The Highland Society of Scotland has lately offered a premium for an essay on the best mode of executing the business, and the advantages that may be derived from it to that country. See **WOOL**.

STAPODIA, or *The Brothers*, in *Geography*, two islets in the Grecian Archipelago; 6 miles E. of Mycone. N. lat. $37^{\circ} 32'$. E. long. $36^{\circ} 42'$.

STAPPEN, a place of Iceland, farther along the coast towards the W. than Stadarfad (which see); situated on the brow of a range of curiously columnar rocks, large insulated masses of which stand in the sea, in various singular forms. Stappen, like Buderstad, is a trading station, and consists of a merchant's house, two or three store-houses, and a few cottages, inhabited by fishermen. The coast in the neighbourhood of Stappen is very remarkable; presenting, for an extent of about two miles, striking and beautiful columnar appearances, both in the cliffs which form the shore, and in the numerous insulated rocks which appear at different distances from the land. The ranges of columns, which in general are about 50 feet high, and perfectly regular in their forms, are variously broken, in consequence of their exposure to the action of the sea. In some places large caves have been formed; and in two of these the light is admitted by fissures in the roof, producing a very singular and striking effect. In general, the columns have a vertical position; but in different places they are disposed in bundles upon one another in all directions. In several instances they appear diverging from a centre; and they assume, in short, every form which such rocks can be imagined to take. About a mile and a half W. of Stappen, there is a curious perforated rock, forming a detached arch of considerable magnitude, the view through which is singularly picturesque, comprehending in the fore-ground many of the insulated masses of columnar rock, and in the distance, the fine range of mountains which stretches along the peninsula towards the east. On the beach at Stappen were several sharks, that had been taken for the sake of the oil of the liver, and the skin. Of the skin shoes were made; and some parts of the flesh were occasionally smoked, and used as food by the natives. But what they esteem a delicacy, presents a most horrible odour to strangers. Mackenzie's *Travel in Iceland*.

STAR, STELLA, in *Astronomy*, a general name for all the heavenly bodies.

The stars are distinguished, from the phenomena of their motion, &c. into *fixed* and *erratic*.

STARS, *Erratic*, or *Wandering*, are those whose distances and places, with regard to each other, are continually changing. These are what we properly call planets. Though to the same class may likewise be referred what we popularly call *blazing* stars, or comets.

STARS, *Fixed*, called also, by way of eminence, *stars*, are those which have been generally observed to keep the same distance with regard to each other, or because (except some few) they do not appear to have any proper motion of their own.

The principal points that have come under the consideration of astronomers concerning the fixed stars, are, their *distance*, *magnitude*, *number*, *nature*, and *motion*.

STARS, *Distance of the Fixed*. The fixed stars are bodies exceedingly remote from us; indeed so remote, that we have no distance in the planetary system to compare to them.

Their immense distance is argued hence, that they have no sensible parallax, that is, that the diameter of the earth's orbit bears no sensible proportion to it; but they are seen the very same in all the points of it. M. Huygens (*Cosmotheor. lib. iv.*) attempts to determine the distance of the stars, by making the aperture of a telescope so small, as that the sun through it appears no bigger than Sirius. In this state he found the sun's diameter to be as 1 to 27.664 of his diameter, when seen with the naked eye. Were the

sun's distance, then, 27.664 times as great as it is, it would be seen of the same diameter with Sirius; so that, allowing Sirius to be equal in magnitude with the sun (which is a very reasonable supposition), the distance of Sirius from the earth will be found to be to that of the sun from the earth, as 27.664 to 1. On which principle, Sirius will be 657,020,000 femidiameters of the earth distant from our earth.

Mr. James Gregory investigated the distance of Sirius, by supposing it of the same magnitude with the sun, and of the same diameter with Jupiter in opposition, as may be seen at large in Gregory's *Astr. lib. iii. prop. 47.*

Cassini (*Mém. de l'Acad. ann. 1717*), from comparing Jupiter and Sirius, when viewed through the same telescope, inferred, that the diameter of that planet was ten times as great as that of the star; and the diameter of Jupiter being 50", he concluded that the diameter of Sirius was about 5"; supposing then that Sirius is equal to the sun in magnitude, and the distance of the sun from us to be about 10,000 diameters of the earth, and the apparent diameter of Sirius being to that of the sun as 1 to 384, the distance of Sirius from the earth becomes equal to 3,840,000 diameters of the earth.

These methods of Gregory, Huygens, and Cassini, are conjectural and precarious, because they suppose that the sun and Sirius are equal in magnitude, and principally because they take it for granted, that the diameter of Sirius is determined with sufficient exactness.

Mr. Michell has proposed an enquiry into the probable parallax and magnitude of the fixed stars, from the quantity of light which they afford us, and the particular circumstances of their situation. With this view he supposes, that they are, at a medium, equal in magnitude and natural brightness to the sun; and then proceeds to enquire what would be the parallax of the sun, if he were to be removed so far from us, as to make the quantity of the light, which we should then receive from him, no more than equal to that of the fixed stars. Accordingly, he assumes Saturn in opposition, exclusively of his ring, (and when the earth and this planet are at their mean distances from the sun,) as equal, or nearly equal, in light to the most luminous fixed star. As the mean distance of Saturn from the sun is equal to about 2082 of the sun's femidiameters, the density of the sun's light at Saturn will consequently be less than at his own surface, in the proportion of the square of 2082 (or 4,334,724) to 1. If Saturn, therefore, was to reflect all the light that falls upon him, he would be less luminous in the same proportion; and, besides, his apparent diameter, in opposition, is at most but 105th part of that of the sun, and, consequently, the quantity of light which we receive from him, must be again diminished in the proportion of the square of 105 (or 11,025) to 1. By multiplying these two numbers together, we shall have the whole of the light of the sun to that of Saturn, as the square of nearly 220,000 (or 48,400,000,000) to 1; and removing the sun to 220,000 times its present distance, he would still appear at least as bright as Saturn, and his whole parallax upon the diameter of the earth's orbit would be less than 2"; and this must be allowed for the parallax of the brightest of the fixed stars, upon the supposition that their light does not exceed that of Saturn.

By a similar computation it may be found, that the distance at which the sun would afford us as much light as we receive from Jupiter, is not less than 46,000 times his present distance, and his whole parallax in that case, upon the diameter of the earth's orbit, would not be more than 9"; the light of Jupiter and Saturn, as seen from the earth,

earth, being in the ratio of about 22 to 1, when they are both in opposition, and supposing them to reflect equally in proportion to the whole of the light that falls upon them. But if Jupiter and Saturn, instead of reflecting the whole of the light that falls upon them, should really reflect only a part of it, *e. g.* a fourth or a sixth, which may be the case, their distances, computed above, must be increased in the proportion of 2 or $2\frac{1}{2}$ to 1, to make the sun's light no more than equal to their's; and his parallax would be less in the same proportion. Supposing, then, that the fixed stars are of the same magnitude and brightness with the sun, it is no wonder that their parallax should hitherto have escaped observation; since, if this is the case, it could hardly amount to 2", and probably not more than 1" in Sirius himself, though he had been placed in the pole of the ecliptic; and in those that appear much less luminous, *e. g.* γ Draconis, which is only of the third magnitude, it could hardly be expected to be sensible with such instruments as have hitherto been used. However, Mr. Michell suggests, that it is not impracticable to construct instruments, capable of distinguishing even to the 20th part of a second, provided the air will admit of that degree of exactness. This ingenious writer apprehends, that the quantity of light which we receive from Sirius, does not exceed the light which we receive from the least fixed stars of the sixth magnitude, in a greater proportion than that of 1000 to 1, nor in a less proportion than that of 400 to 1; and the smaller stars of the second magnitude seem to be about a mean proportional between the other two. Hence, the whole parallax of the least fixed stars of the sixth magnitude, supposing them of the same size and native bigness with the sun, should be from about 2" to 3", and their distance from about eight to twelve million times that of the sun: and the parallax of the smaller stars of the second magnitude, upon the same supposition, should be about 12", and their distance about two million times that of the sun.

This author farther suggests, that, from the apparent situation of the stars in the heavens, there is the highest probability (the odds against the contrary opinion being many million millions to one) that the stars are collected together in clusters in some places, where they form a kind of system, whilst in others there are either few or none of them, whether this disposition be owing to their mutual gravitation, or to some other law or appointment of the Creator. Hence it may be inferred, that such double stars, &c. as appear to consist of two or more stars placed very near together, do really consist of stars placed near together, and under the influence of some general law: and he proceeds to inquire, whether, if the stars are collected into systems, the sun does not likewise make one of some system, and which are those, among the fixed stars, that belong to the same system with himself.

Those stars, he apprehends, which are found in clusters, and surrounded by many others at a small distance from them, belong probably to other systems, and not to ours. And those stars which are surrounded with nebulae, are probably only very great stars, which, on account of their superior magnitude, are singly visible; while the others, which compose the remaining part of the same system, are so small as to escape our sight. And those nebulae in which we can discover either none or only a few stars, even with the assistance of the best telescopes, are probably systems that are still more distant than the rest.

For other particulars of this inquiry, we must refer to Phil. Transf. vol. lvii. art. 27. p. 234, &c.

As the distance of the fixed stars is best determined by their parallax, various methods have been pursued, hitherto

without success, for investigating it; and the result of the most accurate observations has given us little more than a distant approximation, from which we may conclude, that the nearest of the fixed stars cannot be less than 40,000 diameters of the whole annual orbit of the earth distant from us.

The method pointed out by Galileo, and first attempted by Hooke, Flamsteed, Molineux, and Bradley, of taking distances of stars from the zenith that pass very near it, has given us a much juster idea of the immense distance of the stars, and furnished us with an approximation to the knowledge of their parallax, that is much nearer the truth than we ever had before.

Dr. Bradley assures us (Phil. Transf. N^o 406, or Abr. vol. vi. p. 162.), that, if it had amounted to a single second, or two at most, he should have perceived it in the great number of observations which he made, especially upon γ Draconis; and that it seemed to him very probable, that the annual parallax of this star is not so great as a single second, and consequently, that it is above four hundred thousand times farther from us than the sun.

But Dr. Herschel, to whose ingenuity and industry in exploring the heavens astronomy is already much indebted, and from whom much more may be expected, remarks, that the instrument used on this occasion, being the same with the present zenith sectors, can hardly be allowed sufficient to shew an angle of one or even two seconds with accuracy: and besides, the star on which the observations were made, is only a bright star of the third or small star of the second magnitude; and, therefore, its parallax is probably considerably less than that of a star of the first magnitude: so that we are not warranted in inferring that the parallax of the stars in general does not exceed 1", whereas those of the first magnitude may have, notwithstanding the result of Dr. Bradley's observations, a parallax of several seconds.

Moreover, the method of zenith distances is liable to considerable errors, on account of refraction, the change of position of the earth's axis arising from nutation, precession of the equinoxes, and other causes, and the aberration of light.

Dr. Herschel has proposed another method, by means of double stars, which is free from these errors, and of such a nature, that the annual parallax, even if it should not exceed the tenth part of a second, may still become visible and be ascertained, at least to a much greater degree of approximation than it ever has been done. This method, which was first proposed in an imperfect manner by Galileo, and has been also mentioned by other authors, is capable of every improvement which the telescope and mechanism of micrometers can furnish. In order to obtain a general idea of it, let O, E, (*Plate XX. Astronomy, fig. 8.*) be two opposite points of the annual orbit, taken in the same plane with two stars *a, b*, of unequal magnitudes. Let the angle *aOb* be observed when the earth is at O, and *aEb* be observed when the earth is at E. From the difference of these angles, if there should be any, we may calculate the parallax of the stars, according to the theory subjoined. These two stars ought to be as near each other as possible, and also to differ as much in magnitude as we can find them.

Dr. Herschel's theory of the annual parallax of double stars, with the method of computing from thence what is generally called the parallax of the fixed stars, or of single stars of the first magnitude, such as are nearest to us, supposes, *first*, that the stars, one with another, are about the size of the sun: and, *secondly*, that the difference of their apparent magnitudes is owing to their different distances, so that the star of the second, third, or fourth magnitude, is two, three,

or four times as far off as one of the first. These principles, which he premises as postulata, have so great a probability in their favour, that they will hardly be objected to by those who are the least acquainted with the doctrine of chances. See Mr. Michell's Inquiry, &c. already cited. Phil. Transf. vol. vii. p. 234, 236, 237, 240. And Dr. Halley on the Number, Order, and Light of the Fixed Stars. Phil. Transf. vol. xxxi. or Abr. vol. vi. p. 148.

Accordingly, let OE (Plate XX. Astronomy, fig. 9.) be the whole diameter of the earth's annual orbit; and let a, b, c , be three stars situated in the ecliptic, in such a manner, that they may be seen all in one line $Oabc$, when the earth is at O . Let the line $Oabc$ be perpendicular to OE , and draw PE parallel to cO : then, if Oa, ab, bc , are equal to each other, a will be a star of the first magnitude, b of the second, and c of the third. Let us now suppose the angle OaE , or parallax of the whole orbit of the earth, to be $1''$ of a degree; then we have $PEa = OaE = 1''$; and because very small angles, having the same subtense OE , may be taken to be in the inverse ratio of the lines Oa, Ob, Oc , &c. we shall have $ObE = \frac{1}{2}''$, $OcE = \frac{1}{3}''$, &c. Now when the earth is removed to E , we shall have $PEb = EbO = \frac{1}{2}''$, and $PEa - PEb = aEb = \frac{1}{2}''$: i. e. the stars a, b , will appear to be $\frac{1}{2}''$ distant. We also have $PEc = EcO = \frac{1}{3}''$, and $PEa - PEc = aEc = \frac{2}{3}''$; i. e. the stars a, c , will appear to be $\frac{2}{3}''$ distant, when the earth is at E . Now, since we have $bEP = \frac{1}{2}''$, and $cEP = \frac{1}{3}''$, therefore $bEP - cEP = bEc = \frac{1}{6}'' - \frac{1}{9}'' = \frac{1}{18}''$; i. e. the stars b, c , will appear to be only $\frac{1}{18}''$ removed from each other, when the earth is at E . Whence we may deduce the following expression, to denote the parallax that will become visible in the change of distance between the two stars, by the removal of the earth from one extreme of its orbit to the other. Let P express the total parallax of a fixed star of the first magnitude, M the magnitude of the largest of the two stars, m the magnitude of the smallest, and p the partial parallax to be observed by the change in the distance of a double star;

then will $p = \frac{m - M}{M m} P$; and p , being found by observation, will give us $P = \frac{p M m}{m - M}$.

E. gr. Suppose a star of the first magnitude should have a small star of the twelfth magnitude near it: then will the partial parallax we are to expect to see be $\frac{12 \times 1 P}{12 - 1}$, or $\frac{1}{11}$ th of the total parallax of a fixed star of the first magnitude; and if we should, by observation, find the partial parallax between two such stars to amount to $1''$, we shall have the total parallax $P = \frac{1 \times 1 \times 12}{12 - 1} = 1''.0909$. If the stars are of the third and twenty-fourth magnitudes, the partial parallax will be $\frac{24 - 3}{3 \times 24} = \frac{21}{72} P$; and if, by observation, p is found to be a tenth of a second, the whole parallax will come out $\frac{1 \times 3 \times 24}{24 - 3} = 0''.3428$.

Farther, suppose the stars, being still in the ecliptic, to appear in one line, when the earth is in any other part of its orbit between O and E ; then will the parallax still be expressed by the same algebraic formula, and one of the maxima will still lie at O , the other at E : but the whole effect will be divided into two parts, which will be in proportion to each other as radius - sine to radius + sine of the stars' distance from the nearest conjunction or opposition.

When the stars are any where out of the ecliptic, situated so as to appear in one line $Oabc$ perpendicular to OE , the maximum of parallax will still be expressed by $\frac{m - M}{M m} P$;

but there will arise another additional parallax in the conjunction and opposition, which will be to that which is found 90° before or after the sun, as the sine (S) of the latitude of the stars seen at O is to the radius (R); and the effect of this parallax will be divided into two parts; half of it lying on one side of the large star, the other half on the other side of it. This latter parallax, moreover, will be compounded with the former, so that the distance of the stars in the conjunction and opposition will then be represented by the diagonal of a parallelogram, of which the two semi-parallaxes are the sides; a general expression for which

will be $\sqrt{\left(\frac{m - M}{2 m M} P\right)^2 \times \frac{S S}{R R} + 1}$; for the stars will ap-

parently describe two ellipses in the heavens, whose transverse axes will be to each other in the ratio of M to m (fig. 10.) and Aa, Bb, Cc, Dd , will be contemporary situations. Now, if bQ be drawn parallel to AC , and the parallelogram $bqBQ$ be completed, we shall have $bQ = \frac{1}{2} CA - \frac{1}{2} ca = \frac{1}{2} Cc = \frac{1}{2} p$, or semi-parallax 90° before or after the sun, and Bb may be resolved into, or is compounded of, bQ and bq ; but $bq = \frac{1}{2} BD - \frac{1}{2} bd =$ the semi-parallax in the conjunction or opposition. We also

have $R : S :: bQ : bq = \frac{p S}{2 R}$; therefore the distance Bb (or

Dd) = $\sqrt{\left(\frac{p}{2}\right)^2 + \left(\frac{p S}{2 R}\right)^2}$; and by substituting the value

of p into this expression, we obtain $\sqrt{\left(\frac{m - M}{2 M m} P\right)^2 \times \frac{S S}{R R} + 1}$,

as above. When the stars are in the pole of the ecliptic, bq will become equal to bQ , and Bb will be $.7071 P \frac{m - M}{M m}$. Again, let the stars be at some distance, *e. g.* $5''$, from each other, and let them both be in the ecliptic. This case is resolvable into the first; for imagine the star a (fig. 11.) to stand at x , and in that situation the stars x, b, c , will be in one line, and their parallax expressed by $\frac{m - M}{M m} P$.

But the angle aEx may be taken to be equal to aOx ; and as the foregoing formula gives us the angles xEb, xEc , we are to add aEx or $5''$ to xEb , and we shall have aEb . In general, let the distance of the stars be d , and let the observed distance at E be D ; then will $D = d + p$, and therefore the whole parallax of the annual orbit will be

expressed by $\frac{D M m - d M m}{m - M} = P$.

Suppose the two stars now to differ only in latitude, one being in the ecliptic, the other, *e. g.* $5''$ north, when seen at O . This case may also be resolved by the former; for imagine the stars b, c , (fig. 9.) to be elevated at right angles above the plane of the figure, so that aOb , or aOc , may make an angle of $5''$ at O ; then instead of the lines $Oabc, Ea, Eb, Ec, EP$, imagine them all to be planes at right angles to the figure; and it will appear, that the parallax of the stars in longitude must be the same as if the small star had been without latitude. And since the stars b, c , by the motion of the earth from O to E , will not change their latitude, we shall have the following construction for finding the

the distance of the stars ab, ac , at E , and from thence the parallax P . Let the triangle $ab\beta$ (Plate XX. *Astronomy*, fig. 12.) represent the situation of the stars; ab is the subtense of $5''$, the angle under which they are to be seen at O .

The quantity $b\beta$ by the former theorem is found $\frac{m-M}{Mm} P$,

which is the partial parallax that would have been seen by the earth's moving from O to E , if both stars had been in the ecliptic; but on account of the difference in latitude, it will be now represented by $a\beta$, the hypotenuse of the triangle $ab\beta$: therefore in general, putting $ab = d$, and $a\beta$

$= D$, we have $\sqrt{\frac{DD - dd \times Mm}{m - M}} = P$. Hence, D

being taken by observation, and d, M , and m , given, we obtain the total parallax.

If the situation of the stars differs in longitude as well as latitude, we may resolve this case by the following method. Let the triangle $ab\beta$ (Plate XX. *Astronomy*, fig. 13.) represent the situation of the stars, $ab = d$ being their distance seen at O , $a\beta = D$ their distance seen at E . That the change $b\beta$, which is produced by the earth's motion, will

be truly expressed by $\frac{m-M}{Mm} P$, may be proved as before,

by supposing the star a to have been placed at α . Now let the angle of position $ba\alpha$ be taken by a micrometer, or by any other method sufficiently exact; then, by solving the triangle $ab\alpha$, we shall have the longitudinal and latitudinal differences $a\alpha$ and $b\alpha$ of the two stars. Put $a\alpha = x$, $b\alpha = y$, and it will be $x + b\beta = a\alpha$, whence $D =$

$\sqrt{x + \frac{m-M}{Mm} P}^2 + yy$; and $\sqrt{\frac{D^2 - y^2 \times Mm - xMm}{M - m}} = P$.

If neither of the stars should be in the ecliptic, nor have the same longitude or latitude, the last theorem will still serve to calculate the total parallax whose maximum will lie in E . There will, moreover, arise another parallax, whose maximum will be in the conjunction and opposition, which will be divided, and lie on different sides of the large star; but as we know the whole parallax to be exceedingly small, it will not be necessary to investigate every particular case of this kind; for, by reason of the division of the parallax, which renders observations taken at any other time, except where it is greatest, very unfavourable, the formulæ would be of little use. Dr. Herschel closes his account of this theory with a general observation on the time and place where the maxima of parallax will happen.

When two unequal stars are both in the ecliptic, or, not being in the ecliptic, have equal latitudes, north or south, and the largest star has most longitude, the maximum of the apparent distance will be when the sun's longitude is 90° more than the stars, or when observed in the morning: and the minimum when the longitude of the sun is 90° less than that of the star, or when observed in the evening. When the small star has most longitude, the maximum and minimum, as well as the time of observation, will be the reverse of the former. When the stars differ in latitude, this makes no alteration in the place of the maximum or minimum, nor in the time of observation; *i. e.* it is immaterial whether the largest star has the least or the greatest latitude of the two stars. Phil. Transf. vol. lxxii. part i. art. 11.

The distance of the star γ Draconis appears by Dr. Bradley's observations, already recited, to be at least four hundred thousand times that of the sun, and the distance of the nearest fixed star not less than forty thousand diameters of

the earth's annual orbit: *i. e.* the former is distant from the earth at least 38,000,000,000,000 miles, and the latter not less than 7,600,000,000,000 miles. As these distances are immensely great, it may not be unamusing to compare them with the velocity of some moving body by which they may be measured.

The swiftest motion we know of is that of light, (see LIGHT,) which passes from the sun to the earth in eight minutes thirteen seconds, and yet this would be above six years traversing the first space, and nearly $1\frac{1}{4}$ year in passing from the nearest fixed star to the earth. A cannon-ball discharged from a twenty-four pounder, with two-thirds its weight of powder, which moves at the rate of about nineteen miles in a minute (see GUN), would be three million eight hundred thousand years passing from γ Draconis to the earth, and seven hundred and sixty thousand years passing from the nearest fixed star. Sound, which moves at the rate of about thirteen miles in a minute, would be five million six hundred thousand years traversing the former distance, and one million one hundred and twenty thousand passing through the latter.

The celebrated Huygens pursued speculations of this kind so far, as to believe it not impossible, that there may be stars at such inconceivable distances, that their light has not yet reached the earth since its creation.

Dr. Halley also advanced, what he says (Phil. Transf. No. 364. or Abr. vol. vi. p. 418.) seems to be a metaphysical paradox, *viz.* that the number of fixed stars must be more than any finite number, and some of them more than at a finite distance from others: and Mr. Addison has justly observed, that this thought is far from being extravagant, when we consider that the universe is the work of infinite power, prompted by infinite goodness, having an infinite space to exert itself in; so that our imagination can set no bounds to it.

STARS, *The Magnitudes of the Fixed*, appear to be very different, which difference may probably arise, not only from a diversity in their real magnitudes, but principally from their distances, which are different.

The stars appear of a sensible magnitude to the bare eye, because the retina is affected not only by the rays of light which are emitted directly from them, but by many thousands more, which, falling upon our eye-lids, and upon the aerial particles about us, are reflected into our eyes so strongly, as to excite vibrations, not only in those points of the retina where the real images of the stars are formed, but also in other points at some distance round about. This makes us imagine the stars to be much bigger than they would appear, if we saw them only by the few rays which come directly from them, so as to enter our eyes without being intermixed with others.

Any one may be sensible of this by looking at a star of the first magnitude through a long narrow tube, which, though it takes in as much of the sky as would hold a thousand such stars, scarcely renders that one visible.

The more a telescope magnifies, the less is the aperture through which the star is seen, and consequently the fewer rays it admits into the eye. Since, therefore, the stars appear less in a telescope which magnifies 200 times, than they do to the bare eye, inasmuch that they seem to be only indivisible points, we may infer that they are at immense distances from us, and also that they shine by their own proper light. If they shone by borrowed light, they would be as invisible without telescopes as the satellites of Jupiter are: for these satellites appear bigger when viewed with a good telescope than the largest fixed stars do.

The stars, on account of their apparently various magnitudes,

nitudes, have been distributed into several classes, called *magnitudes*.

The first class, or stars of the first magnitude, are those which appear largest, and may probably be nearest us. Next these, are those of the second magnitude, and so on to the sixth, which comprehends the smallest stars visible to the naked eye. All beyond these are called *telescopic* stars. Not that all the stars of each class appear justly of the same magnitude; there is great latitude in this respect; and those of the first magnitude appear almost all different in lustre and size. Other stars there are, of intermediate magnitudes, which astronomers cannot refer to one rather than another class, and therefore they place them between the two.

Procyon, for instance, which Ptolemy makes of the first magnitude, and Tycho of the second, Mr. Flamsteed lays down as between the first and second.

Thus, instead of six several magnitudes, we may say there are almost as many orders of stars as there are stars; such a difference being observable in the magnitude, colour, and brightness of them.

Whatever room there may be to hope, that we may some time or other be able to discover the parallax of a few among the fixed stars, yet at the same time it seems probable, that we shall never be able to discover any sensible magnitude in their apparent diameters, which, even in Sirius, if his native brightness is not less than that of the sun, must be considerably less, whatever be his parallax, than the hundredth, probably than the two hundredth part of a second; so that it could scarcely be distinguishable with a telescope, upon the former supposition, that should magnify six, or, upon the latter, with one that should magnify twelve thousand times. Nor can we well expect to find their apparent diameters from any occultation by the moon, since the diameter of a hundredth part of a second would be covered by the moon, if it entered directly, in less than the fiftieth part of a second of time, and, therefore, a star can hardly enter so obliquely, as to appear to vanish by degrees: no star, probably, which the moon can pass over, subtending an angle half so great. Nor is it likely there can any thing be determined from occultations by any of the planets. And, therefore, there seems to be little chance of discovering with certainty the real size of any of the fixed stars, and we must be content to deduce it from their parallax (if that should ever be found) and the quantity of light which they afford us, compared with that of the sun. Dr. Herschel, however, informs us, that with a magnifying power of 6450, and by means of his new micrometer, he found the apparent diameter of α Lyræ to be $0''.355$.

The stars are likewise distinguished, with regard to their situation, into *asterisms*, or *constellations*, which are nothing but assemblages of several neighbouring stars, considered as constituting some determinate figure, as of an animal, &c. and denominated from it; a division as ancient as the book of Job, in which we find mention of Orion, and the Pleiades, &c. See CONSTELLATION.

Besides the stars thus distinguished into magnitudes and constellations, there are others not reduced to either. Those not reduced into constellations, are called *informes*, (which see,) or *unformed stars*; of which kind several, so left at large by the ancients, have been since formed into new constellations by the modern astronomers; as *Cor Caroli*, by Dr. Halley; *Scutum Sobiesci*, by Hevelius, &c.

In describing the particular stars, it will be most convenient to begin with such as never set in our climates, and we may then refer the situations of others to their positions with respect to these.

The Great Bear is the most conspicuous of the constella-

tions which never set; it consists of seven stars, placed like the four wheels of a waggon, and its three horses, except that the horses are fixed to one of the wheels. The two hind-wheels are the pointers, which direct us to the pole-star, in the extremity of the tail of the Little Bear: and further on, to the constellation Cassiopeia, which is situated in the milky way, where it is nearest to the pole, and which consists of several stars, nearly in the form of the letter W. The two northernmost wheels of the Great Bear, or wain, point at the bright star Capella, the goat, in Auriga. Descending along the milky way from Cassiopeia, if we go towards Capella, we come to Algenib, in Perseus; and a little further from the pole we find Algol, or Medusa's head: but if we take the opposite direction, we arrive at Cygnus, the swan; and beyond it, a little out of the milky way, is the bright star Lyra. The Dragon consists of a chain of stars partly surrounding the Little Bear; and between Cassiopeia and the Swan is the constellation Cepheus.

Near Algenib, and pointing directly towards it, are two stars of Andromeda, and a third is a little beyond them. A line drawn through the Great Bear and Capella passes to the Pleiades, and then, turning at a right angle towards the milky way, reaches Aldebaran, or the bull's eye, and the shoulders of Orion, who is known by his belt, consisting of three stars, placed in the middle of a quadrangle. Aldebaran, the Pleiades, and Algol, make the upper, and Menkar, or the whale's jaw, with Aries, the lower points of a W. In Aries we observe two principal stars, one of them with a smaller attendant.

A line drawn from the pole, midway between the Great Bear and Capella, passes to the Twins and to Procyon; and then, in order to reach Sirius, it must bend across the milky way. Algol and the Twins point at Regulus, the lion's heart, which is situated at one end of an arch, with Denebola at the other end.

The pole-star and the middle horse of the wain direct us to Spica Virginis, considerably distant: the pole and the first horse nearly to Arcturus, in the waggoner, or Bootes. Much further southwards, and near the milky way, is Antares, in the Scorpion, forming, with Arcturus and Spica, a triangle, within which are the two stars of Libra. The Northern crown is nearly in a line between Lyra and Arcturus, and the heads of Hercules and Serpentarius are between Lyra and Scorpio.

In the milky way, below the part nearest to Lyra, and on a line drawn from Arcturus through the head of Hercules, is Aquila, making with Lyra and Cygnus a conspicuous triangle. The last of the three principal stars in Andromeda makes, with three of Pegafus, a square, of which one of the sides points to Fomalhaut, situated at a considerable distance in the southern fish, and in the neighbourhood of the whale, which has already been mentioned.

By means of these alineations, all the principal stars that are ever visible in Britain may be easily recognised. Of those which never rise above our horizon, there are several of the first magnitude; Canopus, in the ship Argo, and Achernar, in the river Eridanus, are the most brilliant of them; the feet of the Centaur, and the Croser are the next; and, according to Humboldt's observations, perhaps some others may require to be admitted into the same class.

Those stars not reduced to classes or magnitudes, are called *nebulous* stars, being such as only appear faintly in clusters, in form of little lucid nebulae, or clouds. See NEBULÆ.

Ptolemy sets down five cloudy stars, viz. one at the extremity of the right hand of Perseus, which appears, through the telescope, thickly set with stars; one in the middle of the Crab, called *Præsepe*, or the Manger, in which Galileo

counted above forty stars; one unformed near the sting of the Scorpion; the eye of Sagittarius, in which two stars may be seen in a clear sky with the naked eye, and several more with the telescope; and one in the head of Orion, in which Galileo counted twenty-one stars.

Flamsteed observed a cloudy star before the bow of Sagittarius, which consists of a great number of small stars, and the star *d* above Sagittarius's right shoulder is encompassed with several more.

Cassini and Flamsteed discovered one between the Great and Little Dog, which is very full of stars, visible only by the telescope.

But the most remarkable of all the cloudy stars is that in the middle of Orion's sword, in which Huygens, and since Dr. Long, observed twelve stars, seven of which (three of them, now known to be four, being very close together) seem to shine through a cloud, very lucid near the middle, but faint and ill-defined about the edges. (See GALAXY, MAGELLANIC Clouds, and Lucid SPOTS.) Cassini is of opinion, that the brightness of these proceeds from stars so minute, as not to be distinguished by the best glasses: others more probably think, they are large spaces in the ether through which a lucid medium is diffused. Although most of these spaces are but a few minutes of a degree in breadth, yet, since they are among the fixed stars, they are probably spaces not less than our whole solar system; in which there seems to be a perpetual uninterrupted day, which may furnish matter of speculation, as well to the curious naturalist, as to the astronomer.

There are also several stars which appear single to the naked eye, but are discovered by the telescope to be double, &c. Of these several have been observed by Cassini, Hooke, Long, Maskelyne, Hornsby, Pigott, Mayer, &c.; but Dr. Herschel has been much the most successful in observations of this kind. Besides the skill and industry by which he is no less distinguished than other astronomers who have been employed in celestial observations, his success has been chiefly owing to the very extraordinary magnifying powers of the Newtonian seven-foot reflector which he has used, and the advantage of an excellent micrometer of his own construction. The powers which he has used have been 146, 227, 278, 460, 754, 932, 1159, 1536, 2010, 3168, and even 6450. His observations appear to commence with the year 1776, but almost all of them were made in the years 1779, 1780, 1781; and they have been since continued with the same skill and general assiduity. For the result, we refer to the articles DOUBLE Stars, GALAXY, HEAVENS, NEBULA, NEBULOSITY, and the sequel of this article.

STAR, *Double*, or a *Binary Sidereal System*, is formed by two stars situated so near to each other, as to be kept together by their mutual gravitation. The two bodies may revolve round their common centre of gravity in circles, or in similar ellipses, the dimensions of their orbits being proportional to their relative quantities of matter. From a series of observations on double stars, Dr. Herschel has found that they have changed their situations with regard to each other, that the one performs a revolution round the other, and that the motion of some of them is direct, while that of others is retrograde. In the course of observations pursued for twenty-five years, he discovered that in more than fifty of the double stars, there is a change either in the distance of the two stars, or in the angle made by a line joining them with the direction of their daily motion, which he calls "the angle of position." The interesting observations that have been published (Phil. Transf. vol. lxxiii.) relate to six double stars, α Geminorum, γ Leonis, ϵ Bootes, ζ Herculis, δ Serpentis, and γ Virginis. In respect to the first

of these, Castor or α Geminorum, the angle of position was found to have diminished in the space of 43 years 142 days, $45^{\circ} 39'$; and from the regularity of its decrease, he thinks it highly probable that the orbits in which the two stars move round their common centre of gravity are nearly circular, and at right angles to the line in which we see them; and that the time of a whole apparent revolution of the small star round Castor will be nearly 342 years and 2 months, in a retrograde direction. From the year 1778 to 1803, he never could perceive any variation in the distance of the two stars, which was uniformly $1\frac{2}{3}$ of the diameter of the large one. The distance of the two stars which compose γ Leonis has undergone a decided change from February 16th, 1782, to March 26th, 1803. The diameters of the two stars were as 5 to 4. The angle of position had diminished in this time from $7^{\circ} 37' N.$ following, to $6^{\circ} 21' S.$ following. From the interval between the two stars, the ratio of their diameters, and the variation in the angle of position, Dr. Herschel has found that the apparent orbit of the small star is elliptical, and that it performs a whole revolution in about 1200 years, in a retrograde direction. The beautiful double star of ϵ Bootes is composed of two stars, one of which is of a light red, and the other of a fine blue, having the appearance of a planet and its satellite. The distance between the two stars, observed with a power of 460, and an aperture of 6.3 inches, in 1781, was $1\frac{1}{2}$ the diameter of the large star, and in 1803, the interval had increased to $1\frac{3}{4}$ of that diameter. The ratio of the size of the stars is as 3 to 2. The angle of position appeared to have suffered a change of $12^{\circ} 33'$, in the space of 22 years and 207 days. From these facts Dr. Herschel concludes that the orbit of the small star is elliptical, and performs its revolution, according to the order of the signs, in 1681 years. The double star ζ Hercules is composed of a greater and a lesser star; the former being of a beautiful blueish-white, and the latter of a fine ash-colour. On the 18th July, 1782, the interval between the two stars was one half the diameter of the smaller one, with a power of 460. On the 21st July of the same year, their distance remained the same, but with a power of 1987; they were one full diameter of the small star asunder. In 1795, Dr. Herschel found it difficult to perceive the small star. In the month of October 1795, however, he saw it distinctly with a power of 460. In 1802, he could no longer perceive the small star, but in a clear night in September of that year, with a power of 460, the apparent disc of ζ Hercules seemed to be a little lengthened in one direction. With the ten-foot telescope, and a power of 600, it had the appearance of a lengthened, or rather wedge-formed, star. With a power of 2140, he again examined it on the 11th of April, 1803, and found the disc a little distorted; but he was convinced that not more than three-eighths of the apparent diameter of the small star was wanting to a complete occultation. The angle of position, on the 21st July, 1782, was $20^{\circ} 42'$ north following.

The double star of δ Serpentis has, like ϵ Bootes, undergone a considerable change in the angle of position, without any variation in the distance between the two stars. On the 5th September, 1782, the angle of position was $42^{\circ} 48'$ south preceding; and on the 7th February 1802, it was $61^{\circ} 27'$ south preceding, having sustained a diminution of $18^{\circ} 39'$ in the space of 19 years and 155 days. Hence the period of a complete revolution of the smaller star will be about 375 years.

The double star of γ Virginis, which has long been known to astronomers, is composed of two stars, which Dr. Herschel at first considered as nearly equal, though he has since ascertained that the one is a little larger than the other. Their distance,

STARS.

distance, which is about $2\frac{1}{2}$ diameters, has continued the same for 21 years, while the angle of position has varied considerably. On the 21st November, 1781, the angle of position was $40^{\circ} 44'$ south following, or rather north preceding, since the other star was afterwards found to be the smaller of the two; and on the 15th April, 1803, the angle of position was $30^{\circ} 20'$ north preceding, having suffered a diminution of $10^{\circ} 24'$ in 21 years and 145 days. From an observation of Mayer's, however, in 1756, Dr. Herschel has found the angle of position for that year to be $54^{\circ} 21' 37''$ north preceding, which gives a motion of $24^{\circ} 2'$ in 47 years and 105 days. Hence he concludes, that a complete revolution is performed in about 708 years.

For a catalogue, such as our limits would allow, of the principal double stars, see the article *DOUBLE Stars*.

For an account of clustering stars, clusters of stars, and groups of stars, and also treble, quadruple, quintuple, and multiple systems of stars, we must refer to the articles *GALAXY* and *HEAVENS*; and for a more particular detail, and catalogues of them, to Dr. Herschel's papers, or to the 2d volume of Fergufon's *Astronomy*, by Dr. Brewster.

STARS, Insulated, a name applied by Dr. Herschel to those celestial bodies which are in a great degree out of the reach of the attractive force of other stars, such as our Sun, Arcturus, Capella, Lyra, Sirius, Canopus, Markab Bellatrix, Menkar, Shedir, Algorah, Propus, and probably many others. It is obvious that no two stars in the universe can be altogether out of the sphere of each other's attraction; but in the case of Sirius and our sun, which, upon the supposition that their masses are equal, and that the former has a parallax of $1''$, would take 33 millions of years to fall to one another by their mutual action, we are entitled to say that they are insulated. Insulated stars are considered by Dr. Herschel as the centres of extensive planetary systems like our own; an opinion which he deduces from analogy, and from the nature of other sidereal combinations. Instead of supposing, therefore, as has generally been done, that every star in the firmament is encircled with planets, satellites, and comets, Dr. Herschel believes that the insulated stars alone are surrounded with such numerous attendants.

STARS, called Nebulae. (See *NEBULÆ*, *NEBULOSITY*, and the articles to which we have above referred.) Mr. Michell has shewn, from the computation of probabilities, that it is many million million chances to one, that the stars, which appear to form double stars, &c. clusters and nebulae in the heavens, are really collected together into separate systems. In the case of the Pleiades, for example, he computes that it is 500,000 to 1, that no six stars out of the number of those that are equal to the faintest of them in splendour, scattered at random in the whole heavens, should be within so small a distance from each other as the Pleiades are.

A similar opinion was maintained by professor Kant and M. Lambert, who supposed that all the stars in the universe are collected into nebulae; and that all the insulated or scattered stars which appear in the heavens, belong to the particular nebula in which our system is placed. We are indebted, however, solely to the genius and industry of Dr. Herschel, for perfecting these sagacious views, and supporting them by a body of evidence amounting nearly to demonstration. He has observed the position, magnitude, and structure of no fewer than 2500 nebulae. He generally detected them in certain directions, rather than in others; and in many parts of the heavens there were vacant spaces, both preceding and following the nebulous strata. Dr. Herschel supposes the nebula in Cancer, and that of Coma Berenices, to belong to two strata which are nearest the nebula of the Milky Way.

The following catalogue of nebulae, copied from Dr. Brewster's edition of Fergufon's *Astronomy*, is founded chiefly on the observations of Messier, as given in the "*Connoissance des Temps*" for 1784, the more recent observations of Dr. Herschel being always added. The *first* column contains the number of the nebulae, and the time when the observation was made; the *second* and *third*, its right ascension and declination for that time, which are more convenient than their longitude and latitude for finding them on a celestial globe. The *fourth*, its diameter in degrees and minutes; and the last, some general remarks on its appearance. All the nebulae in this class may be seen with good telescopes of a moderate size.

Catalogue of 103 Nebulae, the Positions of which have been determined by Messier.

No. and Year when observed.	Position of the Nebulae.	Right Ascen. in Degrees.	Declination.	Diamet.	General Remarks.
1. 1758.	Above the Bull's south- ern horn, west of ζ - }	80 0 33	21 45 27 N.		{ A whitish light, elongated like the flame of a taper. It exhibited a mottled nebulousity to Dr. Herschel.
2. 1760.	In the head of Aquarius, } near the 24th star - }	320 17 0	1 47 0 S.	4'	{ It is like the nucleus of a comet, surrounded with a large round nebula. Dr. H. resolved it into stars.
3. 1764.	Between Arcturus and } Cor Caroli - }	202 51 19	29 32 57 N.	3'	{ It is round, bright in the centre, and fades away gradually. It exhibited a mottled nebulousity to Dr. H.
4.	Near Antares - - -	242 16 56	25 55 40 S.	$2\frac{1}{2}'$	A mass of small stars.
5.	Near 6 Serpent - - -	226 39 4	2 57 16 N.	3'	A round nebula. Resolved into stars by Dr. H.
6.	Between the bow of Sa- gittarius and the tail of } Scorpio - - - }	261 10 39	32 10 34 S.	15'	A mass of small stars.
7.	Near the preceding - - -	264 30 24	34 40 34 S.	30'	A mass of small stars.
8.	Between the bow of Sa- gittarius, and the right } foot of Ophiuchus - }	267 29 30	24 21 10 S.	30'	{ An elongated mass of stars. Near this mass is the 9th of Sagittarius, which is encircled with a faint light.

STARS.

No. and Year when observed.	Position of the Nebulae.	Right Ascen. in Degrees.	Declination.	Diamet.	General Remarks.
9.	In the right leg of Ophiuchus	256 20 36	18 13 26 S.	3'	{ Round and faint; but resolved by Dr. Herschel into stars.
10.	In the girdle near 30 Ophiuchus	251 12 6	3 42 18 S.	4'	{ A fine and round nebula. Resolved into stars by Dr. H.
11.	Near K. Antinous	279 35 43	6 31 1 S.	4'	{ A mass of many small stars, mixed with a faint light.
12.	Between the arm and the left side of Ophiuchus	248 43 10	2 30 28 S.	3'	{ Round and faint. Near it is a star of the 9th magn. Resolved by Dr. H. into stars.
13.	In the girdle of Hercules, between two stars of the 8th magnitude	248 18 48	36 54 44 N.	6'	{ Round and bright in the middle. Resolved by Dr. H. into stars.
14.	In the drapery over the R. arm of Ophiuchus	261 18 29	3 5 45 S.	7'	{ Round and faint. Near a star of the 9th magn. Resolved into stars by Dr. H.
15.	Between the head of Pegasus, and that of the Little Horse	319 40 19	10 40 3 N.	3'	{ Round and bright in the centre. Resolved into stars by Dr. H.
16.	Near the Serpent's tail	271 15 3	13 51 44 N.	8'	{ A mass of small stars, mixed with a faint light, resolved by Dr. H.
17.	North of the bow of Sagittarius	271 45 48	16 14 44 S.	5'	A train of faint light, with stars.
18.	Above the preceding	271 34 3	17 13 14 S.	5'	{ A mass of small stars surrounded with nebulosity.
19.	Between Scorpio and the R. foot of Ophiuchus	252 1 45	25 54 46 S.	3'	Round, and resolved into stars by Dr. H.
20.	Between the bow of Sagittarius and the right foot of Ophiuchus	267 4 5	22 59 10 S.		{ A mass of stars of the 8th and 9th magnitude, surrounded with nebulosity.
21.	Near 11 Sagittarius	267 31 35	22 31 25 S.		The same as the preceding.
22.	Near 25 Sagittarius	275 28 39	24 6 11 S.	6'	Round, and resolved into stars by Dr. H.
23.	Near 65 Ophiuchus	265 42 50	18 45 55 S.	15'	A mass of stars very near each other.
24.	Near the end of the bow of Sagittarius in the Milky Way	270 26 0	18 26 0 S.	10 30'	{ Great nebulosity, containing several stars. The light is divided into several parts. Resolved into stars by Dr. H.
25.	Near the preceding, near 21 Sagittarius	274 25 0	19 5 0 S.	10'	A mass of small stars.
26.	Near η and σ Antinous	278 5 25	9 38 14 S.	2'	A mass of small stars.
27.	Near 14 of the Fox	297 21 41	22 4 0 N.	4'	{ Oval. It exhibited a mottled nebulosity to Dr. H.
28.	A degree from λ Sagittarius	272 29 30	24 57 11 S.	2'	Round, and resolved into stars by Dr. H.
29.	Below γ Cygni	303 54 29	37 11 57 N.		A mass of 7 or 8 small stars.
30.	Near 41 Capricorn	321 46 18	24 19 4 S.	2'	Round, and resolved into stars by Dr. H.
31.	In Andromeda's girdle	7 26 32	39 9 32 N.	40'	{ It resembles two cones of light joined at their base, which is 15' broad. Resolved into stars by Dr. H.
32.	Below the preceding	7 27 32	38 45 34 N.	2'	Round, without stars, and with a faint light.
33.	Below the head of the N. Fish and the Great Triangle	20 9 17	29 32 23 N.	15'	{ Its light is uniform and whitish. It exhibited a mottled nebulosity to Dr. H.
34.	Between Medusa's head and the left foot of Andromeda	36 51 37	41 39 32 N.	15'	A mass of small stars.
35.	Near μ and ν Castor	88 40 9	24 33 30 N.	20'	A mass of small stars near Castor's left foot.
36.	Near ϕ Bootes	80 11 42	34 8 6 N.	9'	A mass of small stars.
37.	Near the preceding	84 15 12	32 11 51 N.	9'	{ A mass of small stars with a nebulosity, resolved into stars by Dr. H.
38.	Near σ Auriga	78 10 12	36 11 51 N.	15'	A square mass of small stars.
39.	Near the Swan's tail	320 57 10	47 25 0 N.	10 0'	A mass of small stars.
40.	At the root of the Great Bear's tail	182 45 30	59 23 50 N.		Two stars very near one another
41.	Below Sirius	98 58 12	20 33 0 S.		A mass of small stars.

STARS.

No. and Year when observed.	Position of the Nebulae.	Right Ascen. in Degrees.	Declination.	Diamet.	General Remarks.
1765. 42.	Between θ and ϵ in Orion's sword - - - }	80 59 40	5 34 6 S.	6'	{ A beautiful nebula, containing seven small stars.
1769. 43.	Above the preceding - - -	81 3 0	5 26 37 S.		A star surrounded with nebulosity.
44.	Between γ and δ Cancer - - -	126 50 30	20 31 38 N.		A mass of small stars.
45.	The Pleiades - - -	53 27 4	23 22 41 N.		Cluster of stars.
46. 1771.	{ Between the G. Dog's head and the hind feet of the Unicorn - - }	112 47 43	14 19 7 S.		A mass of stars, with a little nebulosity.
47.	Near the preceding - - -	116 3 58	14 50 8 S.		A mass of small stars.
48.	Near the three stars at the root of the Unicorn's tail - - - }	120 36 0	1 16 42 S.		A mass of small stars.
49.	Near ρ Virgo - - -	184 26 58	9 16 9 N.		See Mem. Acad. 1779.
50. 1772.	Above θ Great Dog - - -	102 57 28	7 57 42 S.		{ A mass of small stars below the Unicorn's right thigh.
51. 1774.	{ Below η Great Bear. Near the ear of the Northern Greyhound - }	200 5 48	48 24 24 N.		{ Double. The two atmospheres, whose centres are 4' 35" distant, touch one another, and are bright in the middle. The one is fainter than the other. Resolved into stars by Dr. Herschel.
52.	Below d Cassiopeia - - -	348 39 27	60 22 12 N.		{ Mass of stars, mixed with a nebulosity, according to Dr. H. This cluster appears like a solid ball, consisting of small stars, quite compressed into one blaze of light, with a great number of loose ones surrounding it.
53. 1777.	Near α Berenice's hair - - -	195 30 26	19 22 44 N.		Round, and resolved into stars by Dr. H.
54. 1778.	In Sagittarius - - -	280 12 55	30 44 1 S.	6'	Faint and bright in the centre.
55.	In Sagittarius - - -	291 30 25	31 26 27 S.		A white spot, resolved into stars by Dr. H.
56. 1779.	Near the Milky Way - - -	287 0 1	29 48 14 N.		Faint, and resolved into stars by Dr. H.
57.	Between γ and β Lyra - - -	281 20 8	32 46 3 N.		Round, and consisting of a mottled nebulosity.
58.	In Virgo - - -	186 37 23	13 2 42 N.		Very faint, without any star.
59.	Near the preceding - - -	187 41 38	12 52 36 N.		Very faint, without any star.
60.	In Virgo - - -	188 6 53	12 46 2 N.		Brighter than the two preceding.
61.	In Virgo - - -	182 41 5	5 42 5 N.		Very faint.
62.	In Scorpio - - -	251 48 24	29 45 30 S.		{ Like a comet, with a brilliant centre, surrounded with a faint light. Resolved into stars by Dr. H.
63.	In the Canes Venatici - - -	196 5 30	43 12 37 N.		Very faint.
64. 1780.	In Berenice's hair - - -	191 27 38	22 52 31 N.		Faint.
65.	In the Lion - - -	166 50 54	14 16 8 N.		Faint, but resolved into stars by Dr. H.
66.	Very near the preceding - - -	167 11 39	14 12 21 N.		Very faint, but resolved into stars by Dr. H.
67.	Below the southern claw of the Crab - - - }	129 6 57	12 36 38 N.		{ A mass of stars, with nebulosity. It is a cluster, pretty much compressed, in which Dr. H. has observed 200 stars at once, with a power of 157 in his great reflector.
68.	Below the Crow - - -	186 54 33	25 30 20 S.	2'	Very faint.
69.	Below the left arm of Sagittarius - - - }	274 11 46	32 31 45 S.	2'	Faint, like the nucleus of a small comet.
70.	Near the preceding - - -	277 13 16	32 31 7 S.	2'	Near four telescopic stars.
71.	Between γ and δ Arrow - - -	295 59 9	18 13 0 N.	3' 30"	Very faint, and resolved into stars by Dr. H.
72.	Above the tail of Capricorn - - -	310 20 49	13 20 51 S.	2'	Faint, but resolved into stars by Dr. H.
73.	Near the preceding - - -	311 43 4	13 28 40 S.		{ Three or four small stars, containing a little nebulosity.

STARS.

No. and Year when observed.	Position of the Nebulae.	Right Ascen. in Degrees.	Declination.	Diamet.	General Remarks.
74.	Near η in the string that connects the Fishes	21 14 9	14 39 35 N.		{ Very faint, but resolved into stars by Dr. Herschel.
75.	Between Sagittarius and the head of Capricorn	208 17 24	22 32 23 S.		{ Composed of small stars, with nebulosity. Mechain makes it only nebulous.
76.	In Andromeda's right foot	22 10 47	50 28 48 N.	2'	{ Composed of small stars, with nebulosity. Small and faint.
77.	In the Whale - - -	37 52 33	0 57 43 S.		{ A mass of small stars, containing nebulosity.
78.	In Orion - - -	83 53 35	0 1 23 S.	3'	{ A mass of stars, with two bright nuclei, surrounded with a nebulosity.
79.	Below the Hare - - -	78 49 2	24 42 57 S.		{ A fine nebula, bright in the centre, and a little diffused. Resolved into a mottled nebulosity by Dr. H.
80.	Between γ and δ Scorpio	240 59 48	22 25 13 S.	2'	{ Round and bright in the centre, like a comet.
1781. 81.	Near the ear of the Great Bear	144 27 44	70 7 24 N.		{ A little oval, bright in the centre, and exhibiting a mottled nebulosity to Dr. H.
82.	Near the preceding - - -	144 29 22	70 44 27 N.		{ Faint, and elongated, with a telescopic star at its extremity. It shewed a mottled nebulosity to Dr. H.
83.	Near the Centaur's head	201 8 13	28 42 27 S.		{ Very faint.
84.	In Virgo - - -	183 30 21	14 7 1 N.		{ Bright in the centre, and surrounded with nebulosity.
85.	Above and near Spica - - -	183 35 21	19 24 26 N.		{ Very faint.
86.	In Virgo - - -	183 46 21	14 9 52 N.		{ The same as N ^o 84, and near it.
87.	In Virgo - - -	184 57 6	13 38 1 N.		{ As luminous as the preceding.
88.	In Virgo - - -	185 15 49	15 37 51 N.		{ Very faint, and like N ^o 58.
89.	Near N ^o 87 - - -	186 9 36	13 46 49 N.		{ Very faint.
90.	In Virgo - - -	186 27 0	14 22 50 N.		{ Like the preceding.
91.	Above the preceding	186 37 0	14 57 6 N.		{ Fainter than the preceding.
92.	Between the knee and the left leg of Hercules	257 38 3	43 21 59 N.	5'	{ A beautiful nebula, bright in the centre, and surrounded with great nebulosity. Resolved into stars by Dr. H.
93.	Between the Great Dog and the Ship	113 48 35	23 19 45 S.	8'	{ A mass of small stars.
94.	Above Cor Caroli - - -	190 10 46	42 18 43 N.	2' 30''	{ Bright in the centre, with a diffused nebulosity.
95.	In the Lion, above ι - - -	158 3 5	12 50 21 N.		{ Very faint.
96.	Near the preceding - - -	158 46 20	12 58 9 N.		{ Fainter than the preceding.
97.	Near β Great Bear - - -	165 18 40	56 13 30 S.	2'	{ Very faint. Another near it, and another near γ .
98.	Above N. wing of Virgo	180 50 49	16 8 15 N.		{ Very faint.
99.	On the N. wing of Virgo	181 55 19	15 37 12 N.		{ Brighter than the preceding. Between two stars of the 7th and 8th magnitude.
100.	In the ear of corn in Virgo	182 59 19	16 59 21 N.		{ Like the preceding.
101.	Between the left hand of Bootes and the tail of the Great Bear	208 52 4	55 24 25 N.	7'	{ Very faint. Discovered by Mechain. Mottled nebulosity, according to Dr. H.
102.	Between α Bootes and ι Dragon	- - -	- - -		{ Very faint. Discovered by Mechain.
103.	Between ϵ and δ Cassiopeia	- - -	- - -		{ A mass of stars.

STAR, *Nebulous*, is a luminous point, surrounded with an immense visible atmosphere. Dr. Herschel thinks, that the central point is a star, from its complete resemblance to a star of equal magnitude. Allied to these are planetary nebulae, or circular spaces in the heavens, uniformly luminous, resembling a planetary disc. The light of one of these nebulae, 15" in diameter, was hardly equal to that of a star of the 8th or 9th magnitude. Hence Dr. Herschel supposes, that they can scarcely be bodies like our sun, as a part of the sun's disc, 15" in diameter, would exceed the greatest lustre of the full moon. If, on the other hand, he observes, we should suppose them to be groups or clusters

of stars, at a distance sufficiently great to reduce them to so small an apparent diameter, we shall be at a loss to account for their uniform light, if clusters; or for their circular forms, if mere groups of stars. Perhaps they may be rather allied to nebulous stars; for, should the planetary nebulae, with lucid centres, be an intermediate step between planetary nebulae and nebulous stars, the appearances of these different species, when all the individuals of them are fully examined, might throw a considerable light on the subject. The class of planetary nebulae with centres differs only from the last in having a bright central point. See NEBULOSITY.

STARS.

Catalogue of Two Hundred and Eighty-eight of the Class of Bright Nebulæ, according to the Observations of
Dr. Herschel:—F. signifying following, P. preceding, N. north, and S. south.

Number.	Stars by which the Nebulæ may be found.	Differ. of Right Ascension in Time between the Nebulæ and the Star.		Difference in Declination.		Number.	Stars by which the Nebulæ may be found.	Differ. of Right Ascension in Time between the Nebulæ and the Star.		Difference in Declination.

A table of nebulae in the southern hemisphere, by La Caille, may be seen in the "Connoissance des Temps" for 1784, p. 270.

STARS, *The Number of*, appears to be vastly great, almost infinite; yet have astronomers long ago ascertained the number of those visible to the eye, which are found much fewer than one might imagine. See *CATALOGUE of the Stars*.

Of the 3000 contained in the *Britannic Catalogue*, there are many only visible through a telescope; nor does a good eye scarcely ever see more than a thousand at the same time in the clearest heaven; the appearance of innumerable more, frequent in clear winter nights, arising from our sight's being deceived by their twinkling, and from our viewing them confusedly, and not reducing them to any order. Yet, for all this, the stars are really almost infinite. See Halley on the Number, Order, and Light of the fixed Stars, *Phil. Trans.* N^o 364, or *Abr.* vol. vi. p. 148.

Riccioli makes no scruple to affirm, in his *New Almagest*, that a man who should say there are above twenty thousand times twenty thousand, would say nothing improbable.

For a good telescope, directed to almost any point of the heavens, discovers numbers that are lost to the naked sight; particularly in the Milky Way, which Dr. Herschel has ascertained to be an assemblage of stars, too remote to be singly seen, but so closely disposed as to give a luminous appearance to that part of the heavens where they are. See *GALAXY*.

In the single constellation of the Pleiades, instead of 6, 7, or 8 stars seen by the best eye, Dr. Hooke, with a telescope 12 feet long, told 78, and with larger glasses many more of different magnitudes. And F. de Rhita, a Capuchin,

affirms, that he has observed above 2000 stars in the single constellation of Orion.

The same author found above 188 in the Pleiades. And Huygens, looking at the star in the middle of Orion's sword, instead of one found it to be twelve. Galileo found 80 in the space of the belt of Orion's sword, 21 in the nebulous star of his head, and above 500 in another part of him, within the compass of one or two degrees space, and more than 40 in the nebulous star *Præsepe*. See *Magnitudes of the Stars, supra*.

If an ordinary telescope, therefore, will, in several parts of the heavens, discover ten times as many stars as are visible to the naked eye, what may not be expected from the improved magnifying powers of modern times?

STARS, *The Changes that have happened in the*, are very considerable; contrary to the opinion of the ancients, who held, that the heavens and heavenly bodies were incapable of any change, the matter of which being permanent and eternal, infinitely exceeding the hardness of diamonds, and not susceptible of any different form. And, in effect, till the time of Aristotle, and even two hundred years afterwards, there had no change been observed. The first was above 120 years before the incarnation; when Hipparchus, discovering a new star to appear, was first induced to make a catalogue of the stars, that posterity might perceive any future changes of the like kind. (See *CATALOGUE*.) The number of stars which are ascertained to be variable, amounts only to 15; while those which are suspected to be variable, amount to 37.

In the year 1572, Cornelius Gemma and Tycho Brahe observed another new star in the constellation Cassiopeia, which

which was, likewise, the occasion of Tycho's making a new catalogue. Its magnitude and brightness, at first, exceeded that of the biggest of our stars, Sirius and Lyra; it even equalled that of Venus when nearest the earth, and was seen in fair day-light. It continued sixteen months; towards the latter end of which, it began to dwindle, and at last, *viz.* March, 1573, totally disappeared, without any change of place in all that time.

Leovicus tells us of another star appearing in the same constellation about the year 945, which resembled that of 1572, and quotes another ancient observation, by which it appears, that a new star was seen about the same place in 1264.

Dr. Keil takes those to have been all the same star: and he conjectures its period to be 150 years; but though it did not appear at the end of this period, this might be owing to its having different degrees of lustre at different periods. Right asc. in 1786, $0^h 13' 0''$. Declin. N. $62^\circ 58'$. Greatest and least magn. 1—0.

Fabricius, in 1596, discovered another new star, called the *stella mira*, or wonderful star, in the neck of the Whale, which has been since found to appear and disappear periodically, seven times in six years, continuing in the greatest lustre for fifteen days together; and is never quite extinguished. Its course and motion are described by Bullialdus, in a treatise printed at Paris in 1667. R. asc. in 1786, $2^h 8' 33''$. Decl. S. $3^\circ 37' 25''$. Greatest and least magn. 2—0. Period, determined by Cassini, 334 days: seen by Mr. Goodricke of the 2d magnitude, August 9th, 1782, and by Mr. Pigott of the 8.9 magn. Dec. 30, 1782.

Dr. Herschel has lately, *viz.* in the years 1777, 1778, 1779, 1780, made several observations on this star, an account of which may be seen in the Phil. Trans. vol. lxx. part ii. art. 21. He makes its period $331^d 10^h 19'$.

The variations of Algol, or β Perseus, were first observed by Montanari. In 1693, Maraldi could not perceive any change in its brightness; but in 1694 he saw its variation from the second to the fourth magnitude. Its period was first discovered by Mr. Goodricke to be $2^d 20^h 48' 56''$. He found that its brightness, at its minimum, is different in different periods; and Pigott perceived, that, at its maximum of brightness, it is sometimes more luminous than α Persei, and at other times less brilliant. R. asc. 1786, $2^h 54' 19''$. Decl. N. $40^\circ 6' 55''$. Greatest and least magn. 2—4.

The 420th star in Mayer's Catalogue, situated in the Lion, was found to be variable by M. Koch, being in February, 1782, of the seventh magnitude; in April, 1783, of the ninth; and in April, 1784, of the tenth. Mr. Pigott could not see it, and it must therefore have disappeared. R. asc. 1786, $9^h 36' 5''$. Decl. N. $12^\circ 25' 0''$. Greatest and least magn. 6—0.

Star in Hydra, as far east of π as ψ is west of γ , the 30th Hydra of Hevelius, and probably the 1st of the Balance, according to Flamsteed, was discovered to be variable, in 1784, by Maraldi; and he made its period two years. According to Pigott, it is of the fourth magnitude at its full brightness, and for a fortnight suffers no perceptible change. It takes about six months to increase from the tenth to the fourth magnitude, and about the same time to return to the tenth; so that it may be regarded as invisible to the naked eye during six months. R. asc. 1786, $13^h 18' 4''$. Decl. S. $22^\circ 9' 38''$. Greatest and least magn. 4—0. Period 494 days.

In the year 1604, 17th October, Kepler, and several of his friends, saw a new star near the heel of the right foot of Serpentarius, particularly bright and sparkling; and took notice, that it was every moment changing into some of the colours of the rainbow, except when it was near the horizon, at which time it was generally white. It surpassed

Jupiter in magnitude, but was easily distinguished from it by the steady light of that planet. It began to diminish, and ceased to be visible, October 18th, 1605, and has not been seen since that time; though Mr. Pigott has examined that part of the heavens with great care since the year 1782. R. asc. $17^h 18' 0''$. Decl. S. $21^\circ 10' 30''$. Greatest and least magn. 1—0.

Simon Marius discovered another in Andromeda's girdle, in 1612 and 1613; though Bullialdus says, it had been seen before in the 15th century.

The variations and period of β Lyrae were discovered by Mr. Goodricke. R. asc. $18^h 42' 11''$. Decl. N. $33^\circ 7' 46''$. Greatest and least magn. 3—4.5. Period, not accurately ascertained, $6^d 9^h$.

The new star discovered by Don Anthelme in the Swan's head, on the 20th of June, 1670, soon reached the third magnitude, and, after several variations, disappeared in 1672. It was observed of the sixth magnitude, by Hevelius, in the years 1671, 1672; but since that time has not been seen, though Mr. Pigott must have detected it, if it had been of the tenth or eleventh magnitude. R. asc. $19^h 38' 58''$. Decl. N. $26^\circ 48' 30''$. Greatest and least magn. 3—0.

The star α Antinoi was discovered to be variable by Mr. Pigott, who also determined its period. It continues 40^h at its greatest brightness, 30^h at its least, 66^h on its decrease, and 36^h on its increase. R. asc. $19^h 41' 34''$. Decl. N. $0^\circ 28' 14''$. Greatest and least magn. 3.4—5. Period $7^d 4^h 15'$.

The star χ in the Swan's neck was discovered to be variable by Kirch, in 1686. Maraldi, Cassini, and M. le Gentil, make its period 405 days; whence Pigott concludes that its period is variable, who states that it continues a fortnight at its full brightness. It takes about $3\frac{1}{2}$ months to increase from the eleventh magnitude to its maximum brightness, and to decrease to the eleventh again; so that it may be regarded as invisible for six months. At its greatest lustre, it is sometimes of the fifth, and, at other times, of the seventh magnitude. R. asc. $19^h 42' 21''$. Decl. N. $32^\circ 22' 58''$. Greatest and least magn. 5—0. Period $396^d 21^h$.

The changeable star near γ in the Swan's breast was observed by William Janfenius and Kepler in 1600: it became, in time, so small as to be thought to have entirely disappeared, until the years 1657, 1658, and 1659, when it recovered its former lustre and magnitude; but it soon decayed. Pigott concludes, from the observations of the 17th century, that it continues about five years at its full brightness; that its lustre decreases rapidly during two years; that it is invisible to the naked eye during four years; and that it increases slowly during seven years. At the end of the year 1663, it was at its minimum brightness. From November, 1781, to 1786, Pigott always saw it of the sixth magnitude; though he suspects, that in 1785, 1786, it had rather decreased. R. asc. $20^h 9' 54''$. Decl. N. $37^\circ 22' 37''$. Greatest and least magn. 3—0. Period 18 years.

The variation and period of δ Cephei were discovered by Mr. Goodricke, and the period has been confirmed by Mr. Pigott's observations. Its variations are not easily perceptible, unless at its minimum and maximum brightness. R. asc. $22^h 21' 0''$. Decl. N. $57^\circ 20' 0''$. Greatest and least magn. 4.3—4.5. Period $5^d 8^h 37\frac{1}{2}'$.

The variation and period of the star β or α Hercules were discovered by Dr. Herschel, by comparing it with α Ophiuchi. R. asc. $17^h 4' 54''$. Decl. N. $14^\circ 38'$. Period of variation $60\frac{2}{3}$ days.

The period and variations of a star in Sobieski's shield, having nearly the same right ascension as the star l , and situated

situated about a degree farther south, were discovered by Mr. Pigott, who has given the result of his observations in a table. R. asc. in 1796, $18^{\text{h}} 36' 38''$. Decl. S. $5^{\circ} 56'$. Greatest and least magn. 5—7.8. Period 62 days.

The star in the Northern Crown, ranked of the sixth magnitude by Bayer, but omitted in Flamsteed's Catalogue, was suspected by Mr. Pigott, in 1783, to be variable; and his suspicions were confirmed in the spring of 1795, when it became invisible. He saw it on the 20th of June in this year, of the 9.10th magnitude; and in six weeks afterwards, it attained its full brightness; and on the 11th of August, 1795, it was of the 6.7th magnitude, and so continued for about three weeks. In $3\frac{1}{2}$ weeks it decreased to the 9.10th magnitude, and a few days afterwards it disappeared. In April, 1796, it re-appeared; and on the 7th of May it reached the 9.10th magnitude, increasing as it had done on the 20th of June, 1795. At its maximum brightness, it exhibited great unsteadiness. It then increased, as before, till it reached the 7.8th magnitude; wavering between these two magnitudes till August, 1797. R. asc. in 1796, $15^{\text{h}} 40' 11''$. Decl. N. $28^{\circ} 49' 30''$. Greatest and least magn. 6.7—0. Period $10\frac{1}{2}$ months.

The stars that are supposed to be variable are the following: viz. Hevelius's δ Cassiopeæ; R. asc. $0^{\text{h}} 23' 16''$. Decl. N. $60^{\circ} 50'$. Greatest and least magn. 7—0:—46 or ξ Andromedæ, suspected to be different stars; R. asc. $1^{\text{h}} 9' 46''$. Decl. N. $44^{\circ} 24'$. Greatest and least magn. 4.5—5.6:—Flamsteed's 50 or ν Andromedæ; R. asc. $1^{\text{h}} 24' 16''$. Decl. N. $40^{\circ} 20' 15''$. Greatest and least magn. 4.5—0:—Hevelius's 41 Andromedæ, probably the same with Tycho's Andromedæ; also, Flamsteed's 50, of the 4.5th magnitude; Flamsteed's τ , of the fifth magnitude; Flamsteed's 49 and 52, and Hevelius's 41, all three of the same brightness, are of the 5.6th magnitude. A star between Hevelius's 41 and Flamsteed's 52 is rather less than the sixth magnitude:—Tycho's 20 Ceti, probably χ in the Whale's belly, of the 4.5th magnitude, and of the same brightness as the three \downarrow Aquarii, which disappeared in the time of Hevelius; R. asc. $1^{\text{h}} 39'$. Decl. S. $13^{\circ} 20'$. Greatest and least magn. 5—0:—Flamsteed's 55 Andromedæ, marked nebulous in his catalogue, observed to be a star of the sixth magnitude; R. asc. $1^{\text{h}} 40' 30''$. Decl. N. $39^{\circ} 40' 3''$. Greatest and least magn. 6—0:— σ or the 17th Eridani, according to Ptolemy and Ulugh Beigh, could not be seen by Flamsteed in 1691 and 1692; but in 1782, 1783, and 1784, Mr. Pigott observed in this place a star of the seventh magnitude, without any variation of brightness; R. asc. $2^{\text{h}} 42'$. Decl. S. $9^{\circ} 40'$. Greatest and least magn. 4—0:—Flamsteed's 41 Tauri, the 26th of Ulugh Beigh, and the 43d of Tycho, suspected by Cassini to be new and variable, was seen by Ulugh Beigh and Tycho, and found by Mr. Pigott, in 1784 and 1785, to be of the fifth magnitude, as Hevelius made it, but of the sixth magnitude, according to Flamsteed; R. asc. $3^{\text{h}} 53' 27''$. Decl. N. $27^{\circ} 0' 39''$. Greatest and least magn. 5—8:—The star $2^{\circ} 15'$ N. of 53 Eridani, was believed by Cassini to be a new star, and was not visible in 1664; but in 1784, Mr. Pigott observed it to be less than ω and d , brighter than Λ , and equal to \downarrow Eridani; R. asc. $4^{\text{h}} 29'$. Decl. S. $12^{\circ} 30'$. Greatest and least magn. 4—0:—Flamsteed's 47 Eridani was also supposed by Cassini to be a new one; but in 1784 it appeared to Mr. Pigott less than 46 Eridani. R. asc. $4^{\text{h}} 23' 54''$. Decl. S. $8^{\circ} 41' 40''$. Greatest and least magn. 4—0:—The star γ of the Great Dog is marked by Tycho, Bayer, Hevelius, and Flamsteed, as of the third magnitude: invisible in 1670, according to Maraldi and Montanari, but

in 1692 and 1693, it appeared of the fourth magnitude; observed by Mr. Pigott frequently since 1782, without the least variation; always of the fourth magnitude, a little brighter than θ , and decidedly brighter than ι ; made by La Caille of the fourth magnitude. R. asc. $6^{\text{h}} 54' 5''$. Decl. S. $15^{\circ} 19' 36''$. Greatest and least magn. 3—0:—Pollux, or β Gemini, was undoubtedly brighter in 1783, 1784, and 1785, than Castor; both made by Hevelius of the second magnitude: Flamsteed makes Castor of the first, and Pollux of the second magnitude: La Caille makes Castor of the 1.2d, and Pollux of the 2.3d magnitude: and Bradley makes them both of the first magnitude. R. asc. $7^{\text{h}} 32' 11''$. Decl. N. $28^{\circ} 31' 38''$. Greatest and least magn. 1—3:—The star ξ Leonis is marked by Tycho, Bayer, Flamsteed, Mayer, and Bradley, of the fourth magnitude; could scarcely be seen by Maraldi and Montanari in 1693; always seen in 1783, 1784, and 1785, of the fifth magnitude, less than Λ and π , and perhaps rather brighter than b and ω Leonis. R. asc. $9^{\text{h}} 20' 4''$. Decl. N. $12^{\circ} 14' 23''$. Greatest and least magn. 5.6—0:—The star \downarrow Leonis is said to have disappeared in 1667, when it was seen by Montanari; observed by Maraldi in 1691, when it was very small; from 1784 to 1786, always seen by Pigott of the 5.6th magnitude, less than ω , and brighter than i , Flamsteed's 46th; made by Hevelius of the fifth, and by Flamsteed of the sixth magnitude. R. asc. $9^{\text{h}} 32' 3''$. Decl. N. $14^{\circ} 59' 36''$. Greatest and least magn. 5.6—0:—The star 25 Leonis was found by Mr. Pigott to be missing in 1783, nor could he see it in 1784 and 1785. R. asc. $9^{\text{h}} 46' 8''$. Decl. N. $12^{\circ} 20' 36''$. Greatest and least magn. 6.7—0:—Bayer's i Leonis and Tycho's 16 Leonis was invisible in 1709; and could not be seen by Pigott in 1785; nor is it the i Leonis of other catalogues. R. asc. $9^{\text{h}} 52' 30''$. Decl. N. $15^{\circ} 30'$. Greatest and least magn. 6—0:— δ of the Great Bear is marked of the second magnitude by Tycho and the prince of Hesse; but Hevelius, La Caille, and Bradley, mark it of the third. From 1783 to 1786 it appeared to Pigott as a bright fourth magnitude, rather less than ι , equal to α , and rather brighter than α Draconis: Flamsteed makes it of the 2.3d magnitude. R. asc. $12^{\text{h}} 4' 45''$. Decl. N. $58^{\circ} 13' 24''$. Greatest and least magn. 2—4:—The star η Virginis, though not in the charts of Bayer, was observed by Ricciolus; was not seen by Flamsteed on the 27th of January, 1680, though he must have observed it on the 12th of May 1677, and some years afterwards, as it is in his catalogue; observed frequently in 1784 and 1785, by Pigott; but it always appeared of the sixth magnitude, as it is marked by Flamsteed; by Bradley it is of the fifth magnitude. R. asc. $12^{\text{h}} 7' 43''$. Decl. N. $0^{\circ} 24' 16''$. Greatest and least magn. 6—0:—Bayer's star of the sixth magnitude, 1° S. of γ Virginis, could not be seen by Maraldi, and looked for in vain by Pigott in May, 1785. R. asc. $12^{\text{h}} 53'$. Decl. S. 10° . Greatest and least magn. 6—0:—The star in the Virgin's northern thigh is marked by Ricciolus as of the 6th magnitude; could not be seen by Maraldi in 1709, nor by Pigott in 1785. R. asc. $13^{\circ} 29' +$. Decl. S. $0^{\circ} 30'$. Greatest and least magn. 6—0:— η 1 or η 2 Virginis, the first supposed by Pigott to be missing in 1785; the other is of the 6.7th magnitude. R. asc. $13^{\text{h}} 43' 43''$. Decl. N. $2^{\circ} 5' 50''$. Greatest and least magn. 6—0:—The star α Draconis is at present only of the 4th magnitude, though Hevelius, Flamsteed, and Bradley, mark it of the third; Pigott and Herschel think it to be variable; La Caille marks it of the third magnitude. R. asc. $13^{\text{h}} 58' 36''$. Decl. N. $65^{\circ} 24' 8''$. Greatest and least magn. 2—4:—Bayer's star in the Well Scales of Libra, could not be found by Maraldi, nor by Pigott in 1784 and 1785.

R. asc. $14^{\circ} 53' 30''$. Decl. S. $13^{\circ} 26'$. Greatest and least magn. 4—7:—Ptolemy's and Ulugh Beigh's ν 6 of the unformed stars in Libra, is marked of the fourth magnitude, and nevertheless does not appear in any modern catalogue; in 1785, Mr. Pigott often observed a star of the seventh magnitude very near its place, rather less than Flamsteed's 41. R. asc. $15^{\text{h}} 29' +$. Decl. S. $20^{\circ} 30'$. Greatest and least magn. 4—7:—The star κ Libræ is marked by Tycho and Bayer as of the fourth magnitude; Hevelius says that it had disappeared: in the years 1783, 1784, and 1785, Pigott always found it of the fifth magnitude; but Flamsteed marks it of the fourth. R. asc. $15^{\text{h}} 29' 39''$. Decl. S. $19^{\circ} 58' 27''$. Greatest and least magn. 4—5:—Tycho's 11 Libræ could not be found by Hevelius and Pigott; the latter thinks that it never existed, and that it is the κ , with an error of 2° in longitude. R. asc. $15^{\text{h}} 37' 30''$. Decl. S. $19^{\circ} 30'$. Greatest and least magn. 4—0:—The star 33 Serpentis was found to be missing in 1784 and 1785, by Pigott. R. asc. $15^{\text{h}} 38'$. Decl. N. $17^{\circ} 14'$. Greatest and least magn. 6—0:—Bayer's star, near ϵ of the Great Bear, could not be seen by Cassini; nor could Pigott find any star near the ϵ brighter than the 7.8th magnitude. R. asc. $16^{\text{h}} 15'$. Decl. N. $82^{\circ} 45'$. Greatest and least magn. 6—0:—The star ρ , or Ptolemy's and Ulugh Beigh's 14th of Ophiuchus, or Flamsteed's 36th, is said to have disappeared before 1695; could not be found by Hevelius; but Pigott found it in 1784 and 1785 of the 4.5th magnitude, much brighter than 39, rather brighter than 51 and 58, and less than 44. R. asc. $17^{\text{h}} 2' 14''$. Decl. S. $26^{\circ} 15' 37''$. Greatest and least magn. 4—0:—Ptolemy's 13th Ophiuchi. R. asc. $17^{\text{h}} 18' +$. Decl. S. $20^{\circ} 35'$. Greatest and least magn. 4—0:—Ptolemy's 18th Ophiuchi. R. asc. $17^{\text{h}} 22'$. Decl. S. $24^{\circ} 10'$. Greatest and least magn. 5—0. These two last-mentioned stars seem to have disappeared; however, Mr. Pigott thinks that the 13th Ophiuchi is Flamsteed's 40th, and that the 18th Ophiuchi should be marked with north instead of south latitude, which would make it coincide nearly with Flamsteed's 58th:—The star σ Sagittarii is thought by Dr. Herschel and Mr. Pigott to be variable; in 1783, 1784, and 1785, he observed it to be of the 2.8th magnitude, and brighter than π Sagittarii. Hevelius makes it of the fourth, and La Caille of the 2.3d magnitude. R. asc. $18^{\text{h}} 42'$. Decl. S. $26^{\circ} 32' 34''$. Greatest and least magn. 2—4:—The star θ Serpentis was observed by Tycho, Bayer, Hevelius, and Flamsteed, to be of the third magnitude; according to Montanari, it was of the fifth; it was frequently observed in 1783, 1784, and 1785, by Pigott, without any perceptible change of lustre, always of the fourth magnitude, less than δ Aquilæ and ρ Ophiuchi; La Caille makes it of the 4.3d magnitude. R. asc. $18^{\text{h}} 45' 35''$. Decl. N. $3^{\circ} 56' 36''$. Greatest and least magn. 4—5:—Tycho's 27 Capricorni could not be seen by Hevelius nor by Pigott. R. asc. $21^{\text{h}} 41' 0''$. Decl. S. $14^{\circ} 28' 0''$. Greatest and least magn. 6—0:—Tycho's 22 Andromedæ, at the end of the chain, was, as Cassini observes, so small, that it could scarcely be seen; Pigott could find no star in its place near the two π Cygni, in 1784 and 1785. R. asc. $21^{\text{h}} 43' 30''$. Decl. N. $49^{\circ} 15'$. Greatest and least magn. 4—0:—Tycho's 19th Aquarii was marked as missing by Hevelius, nor could Flamsteed see it with his naked eye; Pigott is confident that it is the same with Flamsteed's 56th, marked f by Bayer, from which it is only $1\frac{1}{2}^{\circ}$ distant. R. asc. $22^{\text{h}} 25'$. Decl. S. $15^{\circ} 55' 0''$. Greatest and least magn. 6—0:—The star σ Andromedæ, according to Pigott, less than σ Cephei, equal to ζ Cassiopeiæ, or perhaps brighter than it, and brighter than λ , κ , or ι Andromedæ. R. asc.

$22^{\text{h}} 52' 6''$. Decl. N. $41^{\circ} 10' 45''$. Greatest and least magn. 4—6:—La Caille's 483 Aquarii was found by Pigott missing in 1778, nor could he see it in 1783 or 1784. R. asc. $22^{\text{h}} 55' 40''$. Decl. S. $8^{\circ} 50' 45''$.

The following 13 stars are ranked by Dr. Herschel among those that are lost, or have undergone some great change; viz. 80 and 81 Hercules; 71 Hercules; 55 Hercules; 56 Cancer; 19 Perseus; 108 Pices; 73 and 74 Cancer; 8 Hydræ; 26 Cancer; 62 Orion; 34 Berenice's Hair; and 19 Berenice's Hair. The following are reckoned by Dr. Herschel among those that have undergone a change of magnitude since the time of Flamsteed: viz. α Draconis, α Ceti, ζ Serpentis, η in the Swan, the 2 of the Great Bear, ν Bootes, ι Dolphin, β Triangle, γ Eagle, σ Sagittarius, δ of the Great Dog, κ Serpent, κ Serpentarius, β of the Little Horse, δ Dolphin, ϵ Bootes, δ in the Arrow, δ in the Great Bear, α Great Bear, 1st and 2d Hydræ, γ Lyræ, 31st and 34th of the Dragon, 44 Cancer, 96 Tauri, 62 Aries, 12 and 14 Lynx, 38 Perseus, θ Perseus, δ Unicorn, 23 Gemini, 26 Orion, and ξ Lion. The following are marked by Dr. Herschel among the stars that have recently become visible; viz. a star in the end of the Lizard's tail, of the 4.5th magnitude; the star of the eighth magnitude following τ Perseus, probably new; a star near the head of Cepheus, not given by Flamsteed; a considerable star in a direction from the 68th to the 61st Gemini, not in Flamsteed's catalogue; a star of considerable brightness, preceding the first of the Little Horse, not given by Flamsteed; a considerable star, following the first of the Sextant, and another following the 7th, not in Flamsteed's catalogue; a remarkable star between β and δ Hydra, not given by Flamsteed; a star nearly $1^{\circ} 30'$ N. following δ Hercules, in the direction of δ and ν , and of the 4.5th magnitude, not given by Flamsteed; a star of the 6th magnitude, about 3° S. preceding γ Bootes, and another of the same size, preceding λ , not observed by Flamsteed. Phil. Trans. for 1783, vol. lxxiii. p. 247, &c.

From the old catalogues, it is certain that many of the ancient stars are not now visible: this has been particularly remarked with regard to the Pleiades: and it is equally certain, as we have now shewn, that some have become visible.

M. Montanari, in his letter to the Royal Society in 1670, observes, that there are now wanting in the heavens two stars of the second magnitude, in the stern of the ship Argo and its yard, which had been seen till the year 1664. When they first disappeared is not known; but he assures us there was not the least glimpse of them in 1668. He adds he has observed many more changes in the fixed stars, even to the number of a hundred.

Many other changes in the stars have been taken notice of by Cassini, Maraldi, and other observers. See Gregory's Astr. lib. ii. prop. 30, and the preceding part of this article.

As none of these stars could ever be perceived to have tails, it is plain they could not be comets; especially as they had no parallax, even when largest and brightest. It is not improbable that the periodical stars have vast clusters of dark spots, and very slow rotations on their axes, by which means they must disappear when the side covered with spots is turned towards us. And as for those which break out on a sudden with such lustre, these may, perhaps, be suns whose fuel is almost spent, and again supplied by some of their comets falling upon them, and occasioning an uncommon blaze and splendour for some time; which has been conjectured to be one use of the cometary part of any system.

M. Maupertuis, in his Dissertation on the Figures of the Celestial

Celestial Bodies (p. 61—63.), is of opinion, that some stars, by their prodigious swift rotation on their axes, may not only assume the figures of oblate spheroids, but that by the great centrifugal force arising from such rotations, they may become of the figures of mill-stones, or be reduced to flat circular planes, so thin, as to be quite invisible when their edges are turned towards us, as Saturn's ring is in such position. But when very eccentric planets or comets go round any flat star in orbits much inclined to its equator, the attraction of the planets or comets in their perihelions must alter the inclination of the axes of that star; on which account it will appear more or less large and luminous, as its broad side is more or less turned towards us. And thus he imagines we may account for the apparent changes of magnitude and lustre of those stars, and likewise for their appearing and disappearing.

Hevelius (Cometograph. p. 380.) apprehends, that the sun and stars are surrounded with atmospheres, and that, whirling round their axes with great rapidity, they throw off great quantities of matter into those atmospheres, and thereby cause great changes in them; and that thus it may come to pass, that a star, which when its atmosphere is clear, shines out with great lustre, may at another time, when it is full of clouds and thick vapours, appear greatly diminished in brightness and magnitude, or even become quite invisible.

The periodical variation in the light of the stars has also been ascribed to the interposition of the planets which circulate around them; but it is by no means probable, that these planets, even if they do exist, are sufficiently large to obstruct any large portion of their light. Even when seen from the earth, the light of our own sun is not sensibly impaired, when Mercury and Venus are passing over his disc.

The ingenious Mr. Pigott has ventured a step farther than any of his predecessors in this branch of astronomy. In his investigation of the phenomena exhibited by the variable star of Sobieski's shield, the periodical changes of which are affected by very singular anomalies, he supposes, that the greater part of its disc is unenlightened; and that a few luminous spots, placed at certain intervals, produce, by the rotation of the star, all the variations which have been observed. Mr. Pigott supposes, that the body of the stars is dark and solid; that their rotation on their axes is regular; and that the surrounding medium is occasionally generating and absorbing its luminous particles, by a process similar to what Dr. Herschel supposes is going on in the atmosphere of the sun. He imagines, that these luminous particles are sparingly dispersed in the atmosphere of the variable star of Sobieski, from the circumstance of its diminishing even to the ninth magnitude; and as the duration of its full lustre continues only about $9\frac{1}{2}$ days, while it performs a complete rotation in 62 days, he considers the luminous spots to be somewhat circular, and of no great extent. Since this small portion of light may naturally be supposed to diminish and finally disappear, Mr. Pigott imagines, that this may have been the cause of the disappearance of the new stars of 1572 and 1604. Hence he concludes, that there are others which have never shewn a glimpse of brightness; and that there are "primary invisible bodies, or unenlightened stars, that have ever remained in eternal darkness." Following out this notion, Mr. Pigott conceives, that clusters of these dark bodies may be found, and by intercepting "all more distant rays," may appear like dark spaces in the heavens, similar to what has been observed in the southern hemisphere.

STARS, *As for the Nature of the fixed,* their immense distance leaves us greatly at a loss about it. What we can gather for certain from their phenomena is as follows:

1. That the fixed stars are greater than our earth: be-

cause, if that was not the case, they could not be visible at such an immense distance.

2. The fixed stars are farther distant from the earth than the farthest of the planets. For we frequently find the fixed stars hid behind the most distant of the planets: and besides, they are supposed to have no parallax, which the planets have.

3. The fixed stars shine with their own light; for they are much farther from the sun than the remotest planet, and appear much smaller; but since, notwithstanding this, they are found to shine much brighter than such planet, it is evident they cannot borrow their light from the same source as that does, *viz.* the sun; but since we know of no other luminous body beside the sun, whence they might derive their light, it follows, that they shine with their own native light.

Besides, it is known, that the more a telescope magnifies, the less is the aperture through which the star is seen; and, consequently, the fewer rays it admits into the eye. Now since the stars appear less in a telescope which magnifies two hundred times, than they do to the naked eye, inasmuch that they seem to be only indivisible points, it proves at once that the stars are at immense distances from us, and that they shine by their own proper light. If they shone by borrowed light, they would be as invisible without telescopes as the satellites of Jupiter are; for these satellites appear bigger, when viewed with a good telescope, than the largest fixed stars do. Hence,

1. We deduce, that the fixed stars are so many suns; for they have all the characters of suns.

2. That, in all probability, the stars are not smaller than our sun.

3. That it is highly probable, that each star is the centre of a system, and has planets or earths revolving round it, in the same manner as round our sun, *i. e.* it has opaque bodies illuminated, warmed, and cherished by its light. As we have incomparably more light from the moon than from all the stars together, it is absurd to imagine that the stars were made for no other purpose than to cast a faint light upon the earth; especially since many more require the assistance of a good telescope to find them out than are visible without that instrument. Our sun is surrounded by a system of planets and comets, all which would be invisible from the nearest fixed star; and from what we already know of the immense distance of the stars, it is easy to prove, that the sun, seen from such a distance, would appear no bigger than a star of the first magnitude.

From all this it is highly probable, that each star is a sun to a system of worlds moving round it, though unseen by us; especially as the doctrine of a plurality of worlds is rational, and greatly manifests the power, wisdom, and goodness of the great Creator.

How immense, then, does the universe appear! Indeed, it must either be infinite, or infinitely near it.

Kepler, it is true, denies that each star can have its system of planets as our's has; and takes them all to be fixed in the same surface or sphere; urging, that were one twice or thrice as remote as another, it would appear twice or thrice as small, supposing their real magnitudes equal; whereas there is no difference in their apparent magnitudes, justly observed, at all. But to this we oppose, that Huygens has not only shewn that fires and flames are visible at distances where other bodies, comprehended under equal angles, disappear; but it should likewise seem, that the optic theorem about the apparent diameters of objects, being reciprocally proportional to their distances from the eye, does only hold while the diameter of the object has some sensible ratio to its distance.

As for periodical stars, &c. see *Changes, &c. of STARS, supra.*

STARS,

STARS, *Motion of the.* The fixed stars have two kinds of apparent motion; one called the *first, common, or diurnal* motion, arising from the earth's motion round its axis: by this they seem to be carried along with the sphere, or firmament, (in which they appear fixed,) round the earth, from east to west, in the space of twenty-four hours.

The other, called the *second, or proper* motion, is that by which they appear to go backwards from west to east, round the poles of the ecliptic, with such slowness, as not to describe above a degree of their circle in the space of 72 years, or 50 seconds in a year.

This apparent motion is owing to the recession of the equinoctial points, which is 50 seconds of a degree in a year backward, or contrary to the order of the signs of the zodiac.

Some have imagined, but it is unknown on what grounds, that when they are got round to the points whence they first departed, nature will have finished her course, and the stars having performed their career, the heavens will remain at rest; unless the Being, who first gave them motion, appoint them to begin another circuit.

On the footing of this calculation, the world should last about 30,000 years, according to Ptolemy; 25,816, according to Tycho; 25,920, according to Riccioli; and 24,800, according to Cassini.

In consequence of this second motion, the longitude of the stars will be always increasing.

Thus, *e. gr.* the longitude of Cor Leonis was found by Ptolemy, A.D. 138, to be $2^{\circ} 30'$; in 1115, it was observed by the Persians to be $17^{\circ} 30'$; in 1364, by Alphonsus, $20^{\circ} 40'$; in 1586, by the prince of Hesse, $24^{\circ} 11'$; in 1601, by Tycho, $24^{\circ} 17'$; and in 1690, by Mr. Flamsteed, $25^{\circ} 31' 20''$; whence the proper motion of the stars, according to the order of the signs in circles parallel to the ecliptic, is easily inferred.

It was Hipparchus who first suspected this motion, upon comparing the observations of Timocharis and Arilyllus with his own. Ptolemy, who lived three centuries after Hipparchus, demonstrated the same by undeniable arguments.

Tycho Brahe makes the increase of longitude in a century $1^{\circ} 25'$; Copernicus, $1^{\circ} 23' 40'' 12'''$; Flamsteed and Riccioli, $1^{\circ} 23' 20''$; Bullialdus, $1^{\circ} 24' 54''$; Hevelius, $1^{\circ} 24' 46'' 50'''$; whence, with Flamsteed, the annual increase of the longitudes of the fixed stars may be well fixed at $50''$.

From these data, the increase of the longitude of a star for any given time is easily had; and hence the longitude of a star for any given year being given, its longitude for any other year is readily found: *e. gr.* the longitude of Sirius, in Mr. Flamsteed's tables, for the year 1690, being $9^{\circ} 49' 1''$; its longitude for the year 1724 is found by multiplying the interval of time, *viz.* 34 years, by $50''$; the product $1700''$, or $28' 20''$, added to the given longitude, will give the longitude required, $10^{\circ} 17' 21''$. By means of this correction, applied as the case requires, the longitudes of the stars, transcribed from any tables, may be adapted to the present or any given time.

The principal phenomena of the fixed stars, arising from their common and proper motion, besides their longitude, are their altitudes, right ascensions, declinations, occultations, culminations, risings, and settings. See ALTITUDE, ASCENSION, DECLINATION, and OCCULTATION.

Some have supposed that the latitudes of the stars are invariable; but this supposition is founded on two assumptions, which are both controverted among astronomers; one is, that the orbit of the earth continues unalterably in the same plane, and consequently that the ecliptic is invariable, the contrary of which is now very generally allowed. See ECLIPTIC.

The other assumption is, that the stars are so fixed as

to keep their places immoveably. Ptolemy, Tycho, and others, comparing the observations of ancient astronomers with their own, have adopted this opinion. But from the result of the comparison of our best modern observations, with such as were formerly made with any tolerable degree of exactness, there appears to have been a real change in the position of some of the fixed stars, with respect to each other; and several stars of the first magnitude have already been observed, and others suspected to have a proper motion of their own.

Dr. Halley (Phil. Transf. N^o 355, or Jones's Abr. vol. iv. p. 225.) has observed, that the Bull's eye, Sirius, and Arcturus, are now found to be about half a degree more southerly than the ancients reckoned them: that this difference cannot arise from the errors of the transcribers, because the declination of the stars, set down by Ptolemy, as observed by Timocharis, Hipparchus, and himself, shew their latitudes given by him are such as those authors intended; and it is scarcely to be believed, that those three observers could be deceived in so plain a matter. To this he adds, that the bright star in the shoulder of Orion has, in Ptolemy, almost a whole degree more southerly latitude than at present: that an ancient observation, made A.D. 509, at Athens, as Bullialdus supposes, of an appulse of the moon to the Bull's eye, shews that star to have had less latitude at that time than it now has; that as to Sirius, it appears by Tycho's observations, that he found him $4\frac{1}{2}$ more northerly than he is at this time. All these observations, compared together, seem to favour an opinion, that some of the stars have a proper motion of their own, which changes their places in the sphere of heaven: this change of place, as Dr. Halley observes, may shew itself in so long a time as 1800 years, though it be entirely imperceptible in the space of one single century; and it is likely to be soonest discovered in such stars as those just now mentioned, because they are all of the first magnitude, and may, therefore, probably be some of the nearest to our solar system. Arcturus, in particular, affords a strong proof of this: for if its present declination be compared with its place as determined either by Tycho or Flamsteed, the difference will be found to be much greater than what can be suspected to arise from the uncertainty of their observations. See ARCTURUS, and Mr. Hornsby's Inquiry into the Quantity and Direction of the proper Motion of Arcturus, Phil. Transf. vol. lxxiii. part i. p. 93, &c.

Upon the whole, we have reason to conclude, that there is not, strictly speaking, any *fixed* star in the heavens; and to admit the general motion of all the starry systems, and consequently of the solar one among the rest.

For an account of Dr. Bradley's observations, see the sequel of this article.

Dr. Herschel has also lately observed, that the distance of the two stars forming the double star γ Draconis, Fl. 24 and 25, is $54'' 48'''$, and their position $44^{\circ} 19' N.$ preceding. Whereas, from the right ascension and declination of these stars in Flamsteed's Catalogue, their distance, in his time, appears to have been $1' 11''.418$, and their position $44^{\circ} 23' N.$ preceding. Hence he infers, that as the difference in the distance of these two stars is so considerable, we can hardly account for it, otherwise than by admitting a proper motion in one or the other of the stars, or in our solar system: most probably, he says, neither of the three is at rest. He also suspects a proper motion in one of the double stars in cauda Lyncis media, Fl. 38, and in \circ Ceti, Fl. 68. Phil. Transf. vol. lxxii. part i. p. 117. 143. 150.

It is reasonable to expect, that other instances of the like kind must also occur among the great number of visible stars, because their relative positions may be altered by various

various means. For if our own solar system be conceived to change its place with respect to absolute space, this might, in process of time, occasion an apparent change in the angular distances of the fixed stars; and in such a case, the places of the nearest stars being more affected than of those that are very remote, their relative position might seem to alter, though the stars themselves were really immoveable: and *vice versa*, we may surmise, from the observed motion of the stars, that our sun, with all his planets and comets, may have a motion towards some particular part of the heavens, on account of a greater quantity of matter collected in a number of stars and their surrounding planets there situated, which may perhaps occasion a gravitation of our whole solar system towards it. If this surmise should have any foundation, as Dr. Herschel observes, *ubi supra*, p. 103, it will shew itself in a series of some years; as from that motion will arise another kind of hitherto unknown parallax (suggested by Mr. Michell, *Phil. Transf. vol. lvii. p. 252.*), the investigation of which may account for some part of the motions already observed in some of the principal stars; and for the purpose of determining the direction and quantity of such a motion, accurate observations of the distance of stars that are near enough to be measured with a micrometer, and a very high power of telescopes, may be of considerable use, as they will undoubtedly give us the relative places of those stars to a much greater degree of accuracy than they can be had by transit instruments or sectors, and thereby much sooner enable us to discover any apparent change in their situation, occasioned by this new kind of systematical parallax, if we may so express the change arising from the motion of the whole solar system. For an account of Dr. Herschel's theory of the annual parallax of double stars, with the method of computing from thence what is generally called the parallax of the fixed stars, or of single stars of the first magnitude, such as are nearest to us, see the preceding part of this article, under *Distance of the STARS*.

On the other hand, if our system be at rest, and any of the stars really in motion, this might likewise vary their apparent positions; and the more so, the nearer they are to us, or the swifter their motions are, or the more proper the direction of the motion is to be rendered perceptible by us. Since then the relative places of the stars may be changed from such a variety of causes, considering the amazing distance at which it is certain some of them are placed, it may require the observations of many ages to determine the laws of the apparent changes even of a single star; much more difficult, therefore, must it be to settle the laws relating to all the most remarkable stars.

When the causes which affect the places of all the stars in general are known, such as the precession, aberration, and nutation; it may be of singular use to examine nicely the relative situations of particular stars, and especially of those of the greatest lustre, which, it may be presumed, lie nearest to us, and may therefore be subject to more sensible changes, either from their own motion, or from that of our system. And if at the same time that the brighter stars are compared with each other, we likewise determine the relative positions of some of the smallest that appear near them, whose places can be ascertained with sufficient exactness, we may perhaps be able to judge to what cause the change, if any be observable, is owing. The uncertainty that we are at present under, with respect to the degree of accuracy with which former astronomers could observe, makes us unable to determine several things relating to this subject; but the improvements which have of late years been made in the methods of taking the places of the heavenly bodies are so great, that a few years may hereafter be sufficient to settle

some points, which cannot now be settled, by comparing even the earliest observations with those of the present age.

The first person who pointed out the method of investigating the parallax of the stars, by taking the distances from the zenith of those that pass very near it, was Galileo. The execution of this method was also attempted by Hooke, Flamsteed, Molyneux, and Bradley. See *Distance of the STARS, supra*.

Dr. Hooke communicated several observations on the apparent motions of the fixed stars; and as this was a matter of great importance in astronomy, several of the learned were desirous of verifying and confirming his observations. An instrument was accordingly contrived by Mr. George Graham, and executed with surprising exactness.

With this instrument the star γ , in the constellation Draco, was frequently observed by Messrs. Molyneux, Bradley, and Graham, in the years 1725, 1726; and the observations were afterwards repeated by Dr. Bradley with an instrument contrived by the same ingenious person, Mr. Graham, and so exact, that it might be depended on to half a second. The result of these observations was, that the star did not always appear in the same place, but that its distance from the zenith varied; and that the difference of the apparent places of θ of Themis, the third satellite of Jupiter, amounted to 21 or 22 seconds. Similar observations were made on other stars, and a like apparent motion was found in them, proportional to the latitude of the star. This motion was by no means such as was to have been expected, as the effect of a parallax; and it was some time before any way could be found of accounting for this new phenomenon. At length Dr. Bradley resolved all its variety, in a satisfactory manner, by the motion of light and the motion of the earth compounded together. See LIGHT, and *Phil. Transf. N^o 406. p. 364, or Abr. vol. vi. p. 149, &c.*

Our excellent astronomer, Dr. Bradley, had no sooner discovered the cause, and settled the laws of the aberration of the fixed stars, than his attention was again excited by another new phenomenon, *viz.* an annual change of declination in some of the fixed stars, which appeared to be sensibly greater than a precession of the equinoctial points of 50" in a year, the mean quantity now usually allowed by astronomers, would have occasioned.

This apparent change of declination was observed in the stars near the equinoctial colure, and there appearing at the same time an effect of a quite contrary nature in some stars near the solstitial colure, which seemed to alter their declination less than a precession of 50" required, Dr. Bradley was thereby convinced, that all the phenomena in the different stars could not be accounted for merely by supposing that he had assumed a wrong quantity for the precession of the equinoctial points. He had also, after many trials, sufficient reason to conclude, that these second unexpected deviations of the stars were not owing to any imperfection of his instruments. At length, from repeated observations, he began to guess at the real cause of these phenomena.

It appeared from the doctor's observations, during his residence at Wanstead, from the year 1727 to 1732, that some of the stars near the solstitial colure had changed their declinations 9" or 10" less than a precession of 50" would have produced; and, at the same time, that others near the equinoctial colure had altered theirs about the same quantity more than a like precession would have occasioned; the north pole of the equator seeming to have approached the stars which come to the meridian with the sun about the vernal equinox and the winter solstice; and to have receded from those which come to the meridian with the sun about the autumnal equinox and the summer solstice.

From the consideration of these circumstances, and the

situation of the ascending node of the moon's orbit when he first began to make his observations, he suspected that the moon's action upon the equatorial parts of the earth might produce these effects. For if the precession of the equinox be, according to sir Isaac Newton's principles, caused by the actions of the sun and moon upon those parts; the plane of the moon's orbit being, at one time, above ten degrees more inclined to the plane of the equator than at another, it was reasonable to conclude, that the part of the whole annual precession which arises from her action, would, in different years, be varied in its quantity; whereas the plane of the ecliptic, in which the sun appears, keeping always nearly the same inclination to the equator, that part of the precession which is owing to the sun's action, may be the same every year; and from hence it would follow, that although the mean annual precession, proceeding from the joint actions of the sun and moon, were $50''$; yet the apparent annual precession might sometimes exceed, and sometimes fall short of that mean quantity, according to the various situations of the nodes of the moon's orbit.

In the year 1727, the moon's ascending node was near the beginning of Aries, and consequently her orbit was as much inclined to the equator as it can at any time be; and then the apparent annual precession was found, by the doctor's first year's observations, to be greater than the mean; which proved, that the stars near the equinoctial colure, whose declinations are most of all affected by the precession, had changed theirs above a tenth part more than a precession of $50''$ would have caused. The succeeding year's observations proved the same thing; and in three or four years time the difference became so considerable, as to leave no room to suspect it was owing to any imperfection either of the instrument or observation.

But some of the stars that were near the solstitial colure having appeared to move, during the same time, in a manner contrary to what they ought to have done, by an increase of the precession; and the deviations in them being as remarkable as in the others; it was evident that something more than a mere change in the quantity of the precession would be requisite to solve this part of the phenomenon. Upon comparing the observations of stars near the solstitial colure that were almost opposite to each other in right ascension, they were found to be equally affected by this cause. For whilst γ Draconis appeared to have moved northward, the small star, which is the 35th Camelopardali Hevelii in the British Catalogue, seemed to have gone as much towards the south; which shewed, that this apparent motion in both those stars might proceed from a nutation of the earth's axis; whereas the comparison of the doctor's observations of the same stars, formerly enabled him to draw a different conclusion with respect to the cause of the annual aberrations arising from the motion of light. For the apparent alteration in γ Draconis, from that cause, being as great again as in the other small star, proved that that did not proceed from a nutation of the earth's axis; as, on the contrary, this may. Upon making the like comparison between the observation of other stars that lie nearly opposite in right ascension, whatever their situations were with respect to the cardinal points of the equator, it appeared that their change of declination was nearly equal, but contrary; and such as a nutation or motion of the earth's axis would effect.

The moon's ascending node being got back towards the beginning of Capricorn in the year 1732, the stars near the equinoctial colure appeared about that time to change their declinations no more than a precession of $50''$ required; whilst some of those near the solstitial colure altered theirs above $2''$ in a year less than they ought. Soon after, the an-

nual change of declination of the former was perceived to be diminished, so as to become less than $50''$ of precession would cause; and it continued to diminish till the year 1736, when the moon's ascending node was about the beginning of Libra, and her orbit had the least inclination to the equator. But by this time, some of the stars near the solstitial colure had altered their declinations $18''$ less since the year 1727, than they ought to have done from a precession of $50''$. For γ Draconis, which in those nine years would have gone about $8''$ more southerly, was observed, in 1736, to appear $10''$ more northerly than it did in the year 1727.

As this appearance in γ Draconis indicated a diminution of the inclination of the earth's axis to the plane of the ecliptic, and as several astronomers have supposed that inclination to diminish regularly; if this phenomenon depended upon such a cause, and amounted to $18''$ in nine years, the obliquity of the ecliptic would, at that rate, alter a whole minute in thirty years; which is much faster than any observations before made would allow. The doctor had therefore reason to think, that some part of this motion at least, if not the whole, was owing to the moon's action upon the equatorial parts of the earth, which, he conceived, might cause a libratory motion of the earth's axis. But as he was unable to judge, from only nine years' observations, whether the axis would entirely recover the same position that it had in the year 1727, he found it necessary to continue his observations through a whole period of the moon's nodes; at the end of which he had the satisfaction to see, that the stars returned into the same positions again, as if there had been no alteration at all in the inclination of the earth's axis, which fully convinced him that he had guessed rightly as to the cause of the phenomenon. This circumstance proves likewise, that if there be a gradual diminution of the obliquity of the ecliptic, it does not arise only from an alteration in the position of the earth's axis, but rather from some change in the plane of the ecliptic itself; because the stars, at the end of the period of the moon's nodes, appeared in the same places, with respect to the equator, as they ought to have done if the earth's axis had retained the same inclination to an invariable plane.

The doctor having communicated these observations, and his suspicion of their cause, to the late Mr. Machin, that excellent geometer soon after sent him a table, containing the quantity of the annual precession in the various positions of the moon's nodes, as also the corresponding nutations of the earth's axis; which was computed upon the supposition that the mean annual precession is $50''$, and that the whole is governed by the pole of the moon's orbit only; and, therefore, Mr. Machin imagined, that the numbers in the table would be too large, as, in fact, they were found to be. But it appeared that the changes which Dr. Bradley had observed, both in the annual precession and nutation, kept the same law, as to increasing and decreasing, with the numbers of Mr. Machin's table. Those were calculated upon the supposition, that the pole of the equator, during a period of the moon's nodes, moved round in the periphery of a little circle, whose centre was $23^{\circ} 29'$ distant from the pole of the ecliptic; having itself also an angular motion of $50''$ in a year about the same pole. The north pole of the equator was conceived to be in that part of the small circle which is farthest from the north pole of the ecliptic, at the time when the moon's ascending node is in the beginning of Aries; and in the opposite point of it, when the same node is in Libra.

If the diameter of the little circle, in which the pole of the equator moves, be supposed equal to $18''$, which is the whole quantity of the *nutation*, (which see,) as collected from

Dr. Bradley's observations of the star γ Draconis, then all the phenomena of the several stars which he observed will be very nearly solved by his hypothesis. But for the particulars of his solution, and the application of his theory to the practice of astronomy, we must refer to the excellent author himself, our intention being only to give the history of the invention.

The corrections arising from the aberration of light, and from the nutation of the earth's axis, must not be neglected in astronomical observations; since such neglects might produce errors of near a minute in the polar distances of some stars.

As to the allowance to be made for the aberration of light, Dr. Bradley assures us, that having again examined those of his own observations, which were most proper to determine the transverse axis of the ellipsis which each star seems to describe, he found it to be nearest to $40''$; and this is the number he makes use of in his computations relating to the nutation.

Dr. Bradley says, in general, that experience has taught him, that the observations of such stars as lie nearest the zenith, generally agree best with one another, and are therefore the fittest to prove the truth of any hypothesis. Phil. Trans. No. 485. vol. xlv. p. 1, &c.

Monsieur d'Alembert has published a treatise, entitled "Recherches sur la Precession des Equinoxes et sur la Nutation de la Terre dans le Systeme Newtonien," 4to. Paris, 1749. The calculations of this learned gentleman agree, in general, with Dr. Bradley's observations. But Monsieur d'Alembert finds, that the pole of the equator describes an ellipsis in the heavens, the ratio of whose axes is as 4 to 3; whereas, according to Dr. Bradley, the curve described is either a circle or an ellipsis, the ratio of whose axes is as 18 to 16.

From this digression we shall return to the proper motion of the stars and solar system. This motion was first observed, as we have already suggested, by Dr. Halley, and afterwards by Le Monnier and Cassini. Tobias Mayer had the merit of giving the first explanation of this proper motion; he compared the places of about eighty stars, as determined by Roemer, with his own observations, and he found that the greater number of them had a proper motion. He was apprized that this change of place in the position of the stars might be explained by a progressive motion of the sun towards one quarter of the heavens; but the result of his observations not according with this hypothesis, he concluded, that many centuries might elapse before the true cause of this motion is explained. The possibility of a solar motion was suggested, upon theoretical principles, by the late Dr. Wilson of Glasgow; and M. de la Lande deduced the same opinion from the rotatory motion of the sun; but another kind of argument has completely confirmed these conjectures.

If the sun has a motion in absolute space, directed towards any quarter of the heavens, it is obvious that the stars in that quarter must appear to recede from each other, while those in the opposite region seem gradually approaching. The proper motion of the stars, therefore, in those opposite regions, as ascertained by a comparison of ancient with modern observations, ought to correspond with this hypothesis.

Dr. Herschel has examined this subject with his usual success, and he has certainly discovered the direction in which our system is gradually advancing. He found that the apparent proper motions of about forty-four stars out of fifty-six are very nearly in the direction which should result from a motion of the sun towards the constellation Hercules, or, more accurately, to a point in the heavens, whose right

ascension is $250^{\circ} 52' 30''$, and whose north polar distance is $40^{\circ} 22'$.

Dr. Herschel, in establishing this motion of the starry and solar systems, begins with principles drawn from the theory of attraction, which evidently oppose every idea of absolute rest in any one of the stars, when once it is known that some of them are in motion; for the change that must arise by such motion, in the value of a power which acts inversely as the squares of the distances, must be felt in all the neighbouring stars; and if these be influenced by the motion of the former, they will again affect those that are next to them, and so on till all are in motion. Now as we know that several stars, in divers parts of the heavens, do actually change their place, it will follow, that the motion of our solar system is not a mere hypothesis; and this consideration will be confirmed by the reasons that induce us to suppose, that most of those very stars which have been observed to move, to be such as are nearest to us; and, therefore, their influence on our situation would of itself be a powerful argument in favour of the proper motion of the sun, if it had been originally at rest. Moreover, it seems very natural, that the changes which are observed to take place among the stars; such as the increase of magnitude in many, and the gradual disappearance of others; the periods of some not before observed, and the distances of many that are actually changing, while many more are suspected to have a considerable motion; afford a strong suspicion that most probably every star in the heavens is more or less in motion. Allowing the proper motion of the stars, it must follow, that our system, with all its planets and comets, that is, the solar system, is not less liable to such a general agitation as is found to obtain among all the other celestial bodies. Astronomers have already observed what they call a proper motion in several of the fixed stars, and the same may be supposed of them all. We ought, therefore, to resolve that which is common to all the stars, which are found to have what has been called a proper motion, into a single real motion of the solar system, as far as that will answer the known facts, and only to attribute to the proper motion of each particular star the deviations from the general law the stars seem to follow in those movements.

By Dr. Maskelyne's account of the proper motion of some principal stars, we find that Sirius, Castor, Procyon, Pollux, Regulus, Arcturus, and α Aquilæ, appear to have respectively the following proper motions in right ascension; $-0''.63$; $-0''.28$; $-0''.80$; $-0''.93$; $-0''.41$; $-1''.40$; and $+0''.57$; and two of them, Sirius and Arcturus, in declination, *viz.* $1''.20$ and $2''.01$, both southward.

Since the apparent motions of these seven stars may be accounted for, either by supposing them to move just as they appear to do, or else by supposing the sun alone to have a motion in a direction such as Dr. Herschel assigns to it, we are no more authorised to suppose the sun at rest than we should be to deny the diurnal motion of the earth, except in this respect, that the proofs of the latter are very numerous, whereas the former rests only on a few though capital testimonies. Our author finds from other considerations, founded on a table by M. de la Lande of the proper motion of twelve stars, both in right ascension and declination, for fifty years, (Phil. Trans. vol. lxxiii. p. 270, &c.), that this motion of the sun, or solar system, is directed towards the star λ Herculis; and he mentions some very striking circumstances in the quantities of the real proper motions of the stars that deserve notice. First, Arcturus and Sirius being the largest of the stars, and therefore probably the nearest, ought to have the most apparent motion, both in right ascension and declination, which is agreeable to observation. Next, in regard to the right

ascension only, Arcturus being better situated to shew its motion, ought to have it much larger, which we find it has. Aldebaran, both badly situated and considerably smaller than the two former, ought to shew but little motion. Procyon, better situated than Sirius, though not quite so large, should have almost as much motion; for, on supposing it farther off because it appears smaller, the effect of the sun's motion will be lessened upon it; whereas, on the other hand, its better situation will partly compensate for its greater distance. ϵ Cygni, very favourably situated, though but a small star, should shew it considerably as well as α Aquilæ; whereas β Cygni should have but little motion; and γ Piscium, best situated of all, should have a great increase of right ascension.

In the last place, a very striking agreement with the hypothesis is displayed in Castor and Pollux. They are both pretty well situated; and we accordingly find that Pollux, for the size of the star, shews as much motion in right ascension as we could expect: but it is remarkable, and seemingly contrary to our hypothesis, that Castor, equally well placed, shews no more than one half of the motion of Pollux. Now, if we recollect that the former is a double star, consisting of two stars not much different in size, we can allow but about half the light to each of them, which affords a strong presumption of their being at a greater distance, and therefore their partial systematical parallax ought to be so much less than that of Pollux, which agrees wonderfully with observation. Not to mention the great difficulty in which we should be involved, were we to suppose the motion of Castor to be really in the star; for how extraordinary must appear the concurrence, that two stars, namely, those that make up this apparently single star, should both have a proper motion so exactly alike, that in all our observations hitherto they have not been found to disagree a single second, either in right ascension or declination, for fifty years together! Does not this seem strongly to point out the common cause, the motion of the solar system?

As to the quantity of the solar motion, Dr. Herschel suggests the following hints. From the annual parallax of the fixed stars, which, from observations, he finds much less than it has hitherto been proved to be, we may certainly admit, that the diameter of the earth's orbit, at the distance of Sirius or Arcturus, would not nearly subtend an angle of one second; but the apparent motion of Arcturus, if owing to a translation of the solar system, amounts to no less than $2''.7$ a-year, as will appear if we compound the two motions of $1' 11''$ in right ascension, and $1' 55''$ in declination, into one single motion, and reduce it to an annual quantity. Hence we may, in a general way, estimate, that the solar motion can certainly not be less than that which the earth has in her annual orbit.

By considering the motion of the satellites round their primary planets, and of the primary planets round the sun, Dr. Herschel is led to suppose that the proper motion of the sun is not rectilinear, but that it is performed round some distant and unknown centre. Although we may not acquiesce in the hypothesis, that there is any immense central body of sufficient magnitude to carry round it all the systems with which astronomers have filled the regions of space, yet we may suppose, with M. de la Lande, that there is a kind of equilibrium among all the systems of the world, and that they have all a periodical circulation round their common centre of gravity. See Phil. Transf. vol. xcvi. p. 233—256. Lalande's Astron. tom. iii.

The following table contains the proper motion of 36 of the principal fixed stars in right ascension and declination, according to the accurate observations of Dr. Maskelyne.

TABLE of the Annual Proper Motion of 36 Stars in Right Ascension and Declination.

Names of the Stars.	Magnitude.	Annual proper Motion in Right Ascension.	Annual proper Motion in Declination.
		Seconds.	Seconds.
γ Pegasi - -	2	- 0.09	- 0.15 N.
α Arietis - -	2.3	+ 0.10	+ 0.07 S.
α Ceti - - -	2	- 0.12	- 0.08 N.
Aldebaran - -	1	+ 0.03	+ 0.12 S.
Capella - - -	1	+ 0.21	+ 0.44 S.

To learn to know the several fixed stars by the globe, see **GLOBE**.

The parallax and distance of the fixed stars, see under **PARALLAX** and **DISTANCE**.

STARS, Circumpolar. See **CIRCUMPOLAR**.

STAR, Falling, in *Meteorology*, a meteor, the explication of which has puzzled all philosophers, till our modern discoveries in electricity have led to the most probable account of it. Signor Beccaria makes it pretty evident, that it is an electrical appearance, and in proof of this position he recites the following fact. About an hour after sunset, he, and some friends that were with him, observed a falling star directing its course towards them, and apparently growing larger and larger, but it disappeared not far from them; when it left their faces, hauds, and clothes, with the earth, and all the neighbouring objects, suddenly illuminated with a diffused and lambent light, attended with no noise at all. During their surprize at this appearance, a servant informed them that he had seen a light shine suddenly in the garden, and especially upon the stream which he was throwing to water it. All these appearances were evidently electrical; and S. Beccaria was confirmed in his conjecture, that electricity was the cause of them, by the quantity of electric matter which he had seen gradually advancing towards his kite, which had very much the appearance of a falling star. Sometimes also he saw a kind of glory round the kite, which followed it when it changed its place, but left some light, for a small space of time, in the place which it had quitted. Priestl. Elect. vol. i. p. 434. 8vo. See **IGNIS Fatuus**.

STAR, Morning. See **MORNING**.

STAR, Place of a. See **PLACE**.

STAR, Pole. See **POLE**.

STARS, Twinkling of the. See **TWINKLING**.

STARS, Unformed. See **INFORMES**.

STAR, in Electricity, denotes the appearance of the electric matter on a point into which it enters. Beccaria supposes that the star is occasioned by the difficulty with which the electric fluid is extricated from the air, which is an electric. See **BRUSH**.

STAR, in Fortification, a little fort, with five or more points, or salient and re-entering angles, flanking one another, and their faces 90 or 100 feet long.

Formerly, star-forts were frequently made in lines of circumvallation, after two or three redoubts. See **REDOUBT** and **SCONCE**.

STAR, in Heraldry, denotes a charge frequently borne on the shield, and the honourable ordinaries, in the figure of a star. It differs from the mullet, or spur-rowel, in that it is not pierced as this last is.

It usually consists of five rays or spokes. When it has six or eight, as among the Germans and Italians, particular mention must be made of them in blazoning.

STARS, on Medals, are marks of consecration and deification, being intended as symbols of eternity. F. Joubert says, they sometimes express the children of princes reigning, and sometimes the children dead; and placed in the rank of deities.

STAR, in the Manege. *White stars in the forehead* are esteemed good marks in all horses, except white and grey ones: where nature fails to produce this good criterion, our jockies have frequently recourse to art. See **HORSE**.

The method of making stars, practised among the Dutch, is to roast a large onion in hot ashes, and when near thoroughly done, to divide it in two, and dip it in scalding hot walnut-oil. This done, they immediately apply the flat side of it to the place the star is to be on, and keep it there half an hour. After taking it off, they anoint the

scalded place with ointment of roses; in a short time, the scurf-skin falls off, and white hair grows up in its room; but the middle always continues bare of hair, which is the certain characteristic of an artificial star.

The method most used among us is to shave the hair from the place it is to be made on; then to apply a little oil of vitriol with a feather, or the like, passing it lightly over the bald place. This eats away the roots of the former hair, which will be succeeded by white. The fore is healed up with copperas, and green ointment.

STAR, To make a Black, on a white or other coloured horse, wash the place to be changed frequently with fern-roots and sage, boiled in ley; and they say it will breed black hairs. The same may be done by beating four milk, galls, and rust, together, and anointing the part with it.

STAR, A Red, is made with an ounce of aqua fortis, a penny-worth of aqua vitæ, and silver to the value of eighteen-pence, all heated together in a glass, and the place anointed with it. This immediately turns the hair to a perfect red; but it lasts no longer than till the horse casts his coat.

STAR, or Starr, Starrum, in our *Old Writers*. All the deeds, obligations, &c. of the Jews, were called *starra*, and writ for the most part in Hebrew alone, or in Hebrew and Latin; one of which yet remains in the treasury of the exchequer, written in Hebrew without points, the substance of which is expressed in Latin just under it, like an English condition under a Latin obligation: this bears date in the reign of king John; and many starrs, as well of grant and release, as obligatory and by way of mortgage, are pleaded and recited at large in the Plea Rolls.

Before the banishment of the Jews under Edward I., their contracts and obligations were denominated *starra*, or *starrs*; which, by an ordinance of Richard I., preserved by Hoveden, were commanded to be enrolled and deposited in chests, under three keys, in certain places; one and the most considerable of which was in the king's exchequer, at Westminster; and no *starr* was allowed to be valid, unless it were found in some of the said repositories.

The word *starr* is a contraction from the Hebrew *schetar*; a deed or contract.

STAR, in Pyrotechny, a composition of combustible matters; which being borne, or thrown aloft into the air, exhibits the appearance of a real star.

Stars are generally used as appendages to rockets, a number of them being usually enclosed in a conical cap, or cover, at the head of the rocket, and carried up with it to its utmost altitude, where the stars taking fire, are spread around, and exhibit an agreeable spectacle. For their composition, see **PYROTECHNY**.

STAR is also a badge of the orders of the Garter and Bath.

STAR, Order of the, or *Our Lady of the Star*, an order of knighthood, instituted by king John II. of France in the year 1351, in imitation of the order of the Garter, not many years before established in England by king Edward III., so denominated from a star they wore on the stomach.

At first there were but thirty knights; but the order, in time, became depreciated by the multitude of persons admitted without any distinction. For which reason Charles VII. when grand-matter thereof, quitted it, and gave it the chevalier de Guet, knight of the watch at Paris, and his archers; who still wear a star on their coats. But this account is contradicted by others; who will have the order instituted by king Robert, in 1022, in honour of the Holy Virgin, and to have fallen in disregard during the wars of Philip de Valois.

Others say, that Lewis XI. having instituted the order

of St. Michael, this order was abolished by his son Charles VIII.

The ensign of this order was the four capital letters M. R. A. V., embroidered in gold within a square on the left breast of the knight's garment; between the letters a mullet of eight points, the point in base wavy, and larger than the other; over the mullet a crown, composed of fleurs-de-lis and balls. The collar was three rows of gold chains; thereon roses enamelled white and red, and placed alternately.

Justiniani mentions another order of the Star, at Messina, in Sicily, called also the *order of the Crescent*. This was instituted in the year 1268, by Charles of Anjou, brother of St. Louis, king of the Two Sicilies.

According to others, this order was instituted in 1351, when the princes of the house of Anjou being driven out of the kingdom of Naples, and Sicily falling again under the dominion of the kings of Aragon, this order, it is said, was established in lieu of that of the Crescent, which was then abolished, as is this order also. The badge of the order was a star of eight points, surmounted with a mullet of eight points.

Others will have it instituted in 1464, by Renato, duke of Anjou, who took the title of king of Sicily. At least it appears, from the arms of this prince, that he made some alteration in the collar of the order; for, instead of fleurs-de-lis, and stars, he only bore two chains, whence hung a crescent, with the old French word *loz*; which, in the language of rebus, signified *loz in a crescent*.

The order, being sunk into obscurity, was raised again by the people of Messina, under the name of the "Noble Academy of the Knights of the Star," reducing the ancient collar to a single star, placed on a forked cross; and the number of knights to sixty-two. Their device was MONSTRANT REGIBUS ASTRA VIAM: which they expressed by

MR

the four initial letters * with the star in the middle.

STAR-Hyacinth. See SCILLA.

STAR of Bethlehem. See ORNITHOGALUM.

STAR of the Earth, the name of a plant famous for its virtues in curing the bite of a mad dog. The original account of its nature and virtues seems to be this: king James sent to the Royal Society a dried specimen of a plant, which had been sent to him as the plant with which his dogs had been cured when bitten by a mad dog, and the name by which this was called was *star of the earth*.

This plant was so ill dried, that it was not easily distinguished; but at length Mr. Ray found it to be the *sesamoides salamanicum magnum*. It does not seem, however, clear, that this was the plant vulgarly known by that name, but rather that it was gathered by some ignorant person; neither the name star of the earth at all agreeing with it, nor any account having been given before of its having such virtues. Dr. Grey, in his Complete Farrier, greatly recommends the star of the earth in the cure of this bite, and the plant he means is plainly the coronopus, or buck's-horn-plantain; and, upon the whole, it seems that this last mentioned is the plant properly called by this name, as its virtues have always been celebrated even in this case, and its leaves always are disposed on the earth in the form of the rays of a star. It is to be added to this, that the countess of Suffolk's powder, so famous in many places for this terrible disease, and

by which several persons have been known to be cured, is principally composed of this plant. Phil. Trans. N^o 450. p. 155.

STAR-Fish called also the *Sea-star*, in *Ichthyology*, is the general name for the Linnæan genus *ASTERIAS*; under which term several species are enumerated without description. There are more than forty species, separated into sections, according as the individuals are lunate, stellate, or radiate.

A. Lunate.

Species.

NORLIS. Granulous, with a ridge round the margin, the disk of which is glabrous. It is found in the North seas.

PULVILLU. Lubricous, with an entire simple margin. This is found in the North seas. It is described as having a body convex above, covered with a smooth sanguineous skin transversely in particular parts; beset towards the margin with soft blunt white spines, about the size of a grain of millet-seed, and divided into ten areas; the margin is not articulate, but rough in the angles, with about ten acute papillæ; beneath, the body is concave, smooth, whitish, with a rosy tinge, and hollowed by five grooves each side, covered with horizontal batons. It tinges warm water with a tawny colour.

MILITARIS. Every where granulous, with a granulous margin. It is found in the North seas.

LUNA. Orbicular, entire. It inhabits India. The body is compressed, and every where sprinkled with raised dots.

B. Stellate.

* PAPPOSA. This species has from twelve to fourteen rays, the edges of which are surrounded with short fascicular processes; the surface is muricate. It inhabits the European and Asiatic seas. The body above is ferruginous, the disk spotted with white; the rays are paler at the ends; beneath whitish with paler papillæ and black grooves down the rays; the disk is tinged with red; the rays are from 11 to 15; it is lanceolate, and a little convex above.

SPONGIOSA. This species is roughish; with five femicylindrical obtuse rays, unarmed at the edges. It inhabits the Greenland seas, and is not three-quarters of an inch in diameter. The body is of a pale reddish, with a very minute and red central protuberance above, and rough, with minute crowded spines; the rays are inflexed at the edges.

* RUBENS. Lax, with five lanceolate, convex rays, covered above with single spines, disposed in rows. This is the *Asterias hispida* of Pennant. It inhabits the ocean, and is from nine to fourteen inches in diameter. The body above is red, pale orange, yellowish, cinereous or black, sometimes violet; it has from four to six rays, with four rows of papillæ beneath; the tubercles are sometimes scattered, or disposed in rows. In some of the individuals there are no prickles, and in some no bristles.

* SEPOSITA. With five round rays, reticulate beneath, and covered above with pectinate prickles. This is the *Asterias spinosa* of Pennant. It is very small, and found in the European seas.

ENDECA. With nine rays, every where covered with pectinate prickles. There is a variety of this species. It is found in the North seas; and the rays are from five to nine.

MINUTA. With six rays, the edges with distant, projecting, fascicular processes. It inhabits the Northern seas. The body is of a pale yellow; about two lines and a half in diameter; and flat on each side.

* **GLACIALIS.** With five angular rays, triangles with prickly protuberances. It inhabits the Ndh seas, and feeds on oysters. The rays are thick and lanolate. The body, when alive, is rufous, undulate with wlie, sometimes cinereous brown, or green; the disk above with tubercles disposed in a circle, beneath hollow: the tentacula are numerous, pellucid, with a row of small pinnules on each side; the back is marked with a round striate operculum or lid.

* **CLATHRATA.** With five short thick ray; hirsute beneath, and cancelled above. It inhabits the European seas; and is described and figured in Pennant's British Zoology.

ECHINITES. With twenty rays, each with two rows of suckers, and numerous large and small moveable spines. It inhabits Batavia. The disk as well as the rays are covered with small moveable spines.

RETICULATA. Rays four, reticulate with prickles. It is found in the Indian seas.

PHRYGIANA. This species is every where beset with papillæ, which are beneath of a rosy colour. It is found on the coasts of Norway.

NODOSA. With five convex rays, longitudinally elevated, and mucicate: it is met with on the coasts of the Indian seas.

* **VIOLACEA.** Lax, with a grey-brown surface, and violet tubercles; it has five rays. Inhabits the European and Northern seas. The body has sometimes a violet surface, and marked sometimes with violet tubercles only; these are either disposed in rows, or irregularly scattered; the disk is orbicular; the rays lanceolate and reddish at the tip; beneath yellowish in the grooves.

SANGUIOLENTA. Above sanguineous; the rays are tipped with white. It inhabits the North seas.

PERFORATA. Unarmed; with perforated dots on the back. This also is an inhabitant of the North seas.

ARANCIACA. Disk broad; rays five, sub-depressed, and prickly at the margins: in the Mediterranean and North seas.

* **EQUESTRIS.** Five rays; disk reticulate, and perforated with dots; tubercles five; margin sub-articulate; beneath a single row of tentacula: an European species.

LÆVIGATA. With five semi-cylindrical obtusely eight-angled, unarmed rays. It inhabits the Mediterranean and Indian seas. The rays are covered with obsolete warts, and between them, at the sides, are hollow dots; beneath, the warts are disposed in quincunx.

* **MEMBRANACEA.** With five broad membranaceous rays, extremely thin and flat. Inhabits the European and Mediterranean seas. The rays are rough, with tubercles; beneath with five elevated convex ribs.

GRANULOSA. Pentangular, unarmed, each side tessellate with granulations, the margin is jointed. It is found on the coasts of the island of Santa Cruz.

C. Radiate.

ROSEA. Rough, with reticulate granulations; rays round. This species is found in the Belgic and Norway seas, and is reckoned extremely elegant. Body above of a rich rose-colour, sometimes inclining to orange, with blackish dots between the granulations; beneath whitish, with dilated grooves; a quadruple row of tentaculæ, and five rows of divergent pinnules; rays white at the tip.

PERTUSA. Rough, rays round, with a narrow, gibbous base. This inhabits the North seas.

* **OPHIURA.** Disk scaly; scale of the angles serrate. It inhabits the ocean, is very small, and moves slowly. The body above is generally grey, reddish, or violet, rarely white; glabrous, with five rays; the disk is orbicular; the rays are four times as long as the body, slender, quadrangular, flexuous, and covered with a single row of scales. It

has been assumed, rather than proved, that the mischievous effects which at certain times of the year are produced by eating the common mussel, are occasioned by their having fed upon this species of asterias.

ACULEATA. With glabrous prickles; it is shorter than the diameter of the rays. It inhabits the ocean. It has five rays. The body varies in colour; it is in shape orbicular, with minute scales beneath, six of which resemble a corol.

CILIARIS. With rough spines, longer than the diameter of the rays. It inhabits the Indian and North seas.

* **SPILERULATA.** With five slender-jointed rays, hirsute on the sides; with a small globular head between the base of each ray. It inhabits the European seas. The body is pentangular, indented, smooth above the aperture, beneath it is five-pointed.

* **PENTAPHYLLA.** This species is known by five slender rays, hirsute at the sides, and tessellate above, and below green, sometimes with sky-blue. It inhabits the British coasts. The body is regularly pentangular.

* **VARIA.** With five hirsute rays, annulate with red; the body is circular, with ten radiate streaks; the ends are lozenge-form. This also is found on our own coasts, as are the four that follow.

* **ACULEARIS.** This species is known by its five slender, hirsute rays; the body is round, with alternately broad and narrow streaks from the centre.

* **HASTATA.** With five hirsute, jointed rays; the body is pentagonal and indented, brownish-red, with ten ochraceous streaks, five slender, with javelin-shaped extremities.

* **FISSA.** With five slender, hirsute rays; the body is circular, with five equidistant dents, penetrating deep into the sides, and five light-coloured streaks from the centre.

* **NIGRA.** This also has five hirsute olive rays, tessellate with deeper shades: the body is pentagonal, black, with five radiate streaks of white.

TENELLA. With ten pectinate rays above; and filiform ones beneath, which are thickened at the joints. It is found on the coasts of Santa Cruz. The body is white; the stem of the rays is longer.

* **PECTINATA.** With ten pectinate rays above, and fewer filiform ones beneath; the joints are equal; disk smooth above. It inhabits the European and Indian seas. The body is covered above with five unequal valves; the colour is of a deep red; the filiform rays beneath are terminated by an incurved claw.

MULTIRADIATA. This species has ten palmate, sub-quadrifid, pectinate rays above, and numerous filiform ones beneath; the disk is granulate: inhabits the Indian ocean.

* **CAPUT MEDUSÆ.** With five divided and sub-divided rays; disk and rays granulate; mouth depressed. This species inhabits most seas, and is an extremely curious sea-animal; the five rays dividing into two smaller ones, and each of these dividing again into two others; which mode of regular sub-division is continued to a vast extent, gradually decreasing in size, till at length the ramifications amount to many thousands, forming a beautiful net-work. Its colour is sometimes pale or reddish-white, sometimes brown.

EURYALI. Rays divided and sub-divided; disk papillous, and with the rays granulate; the mouth is a little raised. It inhabits the Cape of Good Hope.

OLIGETES. Rays very long and simple, with two acute moveable styles at each joint. Found near Curassoa, adhering to gorgoniæ. The body is pentangular, minute, ochraceous, and rather hard.

NIGRITA. With five jointed rays, covered with imbricate scales above, and lateral patulous ramifications; the disk is obtusely pentangular and granulate.

TRICOLOR. With five jointed rays, pectinate at the sides; the ramifications are rough; the disk is hispid. It is found on the coast of the Feroe islands.

FRAGILIS. Disk orbicular, muricate, spinous on the back: rays five, jointed and pectinate at the sides; the ramifications ferrato-muricate: found in the North seas.

The most frequent kind of star-fish is that which has five rays, which issue in the manner of so many vermiform, or worm-like processes: these therefore are called *stella vermiformes*, or the *worm-like* star-fish. Another kind, nearly approaching to the nature of these, has more than five rays, and from the sides of these other transverse processes are produced, which are covered with an extremely fine kind of down, or hairiness; these are called the *hairy* star-fish. A third kind is called the *astrophyta*, or *plant-like* star-fish: this is composed of a body from whence there arise a great number of branches, which divaricating more and more, are at length increased, or divided into a prodigious number; and these being cylindrical in figure, resemble very much the branches of plants. Several of the species of the star-fish are eatable, and some of them afford a very good nourishment. Some are prescribed by physicians as ingredients in plasters.

Every ray of the star-fish is furnished with so very large a number of legs, that they cover the whole surface: they are disposed in four ranges, each of which contains about seventy-four; so that the whole ray contains three hundred and four, and consequently the fish has, upon all five of its rays, no less than fifteen hundred and twenty legs. With all this numerous train of legs, however, the animal moves but very slowly; and indeed they are so soft and feeble, that they scarcely deserve the name of legs, and, more properly speaking, they are only a sort of horns, like those of our garden-snails, but they serve the animal to walk with, and are therefore called legs. Mem. Acad. Par. 1710.

The amazing property of reproducing the essential parts, when lost, extends to the star-fish. M. Reaumur, on the discovery of this property in the polype, observed these other animals, as they lay on the shores of Poitou and other places, and often found that species of star-fish which is very commonly known, and which has naturally five rays or arms, with only three or four, one or two being wanting; and on taking up and examining these mutilated ones, nature was always found reproducing the limb that was wanting; and on cutting and breaking other star-fish into several parts, it was but a very little while before the broken parts cicatrized, and every part remained alive. Phil. Transf. N° 464. Append.

The *arborescent* star-fish, *stella arborescens*, or *caput meduse* of Linnæus, is one of the curiosities of nature, found in several cabinets of natural rarities. See *MEDUSÆ Caput*, and *supra*. Grew, Mus. Reg. Societ. part i. sect. 5. cap. 4. p. 122.

This has been found in the north of Scotland, and on the coast of Cornwall. See *BASKET-Fish*.

STAR-Gazer, the English name of the uranoscopus.

STAR-Shot, the common name of a gelatinous substance often found lying on the surface of the earth, and called by some *star-jelly*, and *star-fallen*.

The vulgar have been always of opinion, that this was produced from that meteor which they call a falling-star; others have imagined it a vegetable substance, and supposed it grew out of the earth: but it is probably the half-digested food of herons, bitterns, crows, sea-mews, and caddy-moddies, principally when they have fed upon frogs or earth-worms.

The heads of frogs are found whole in masses of this matter, and also parts of worms: these birds, when shot,

disgorge a substance of the same kind. This is gelatinous, like a thick mucilage of gum tragacanth, and cold to the touch. In it are often yellow specks and small clots, like grumous blood. It smells like putrid flesh, when kept, and is principally found in misty mornings, and in wet weather, in autumn, winter, and spring. Moreton's Northampton, p. 353.

Mr. Boyle says, he has seen this jelly resolved, by digestion only, into a permanent liquor, and that a physician of his acquaintance extolled it as a specific, outwardly applied to wens. Works, Abr. vol. i. p. 310.

STAR-Shot, in *Artillery*, consists of four pieces of iron, whose bases, when separate, form the quadrant of a circle; so that the whole being joined forms a cylinder equal to the shot of the cannon. Each of these pieces is furnished with an iron bar, the extremity of which is attached to a sort of link, as keys are strung upon a ring. Being discharged from the gun, the four branches or arms extend every way from the link in the centre. These are used in the sea-service, and chiefly designed for destroying the sails and rigging; but their flight and execution are very precarious at any considerable distance.

STAR-Stone, *Asteria*, in *Natural History*, the name of a kind of extraneous fossil, of a very regular figure and structure, and approaching very much to the nature of the entrochi, having the same substance and inner structure, and being much of the same size, though different in form: it comprehends the *asteropodia* and the *appendiculæ*, or wires of the asteriæ. The asteriæ are by many affirmed to be the fossile radii of the star-fish of the decempede, or ten-rayed kind: others have thought that some species of them have been the remains of the common coriaceous kinds. The encrinos, or *lilium lapideum*, seems to be a part of one of the ten-rayed kinds; and the trochitæ, and entrochi, are plainly owing to the fragments of several of these kinds. Linkius, de Stellis Marin.

Mr. Ellis has particularly described, and illustrated by figures, fossils of this kind, as well as the animals or star-fish to which they belong; but as the stem of the animal, the specimen of which he examined, and from which his description is taken, was broke off short at the bottom, he is in doubt whether it moves about in the sea, or is fixed to rocks and shells by a base, like corals, sponges, and keratophytos. Phil. Transf. vol. lii. part i. art. 56.

The *asteropodia* (see *ASTEROPodium*), in substance and inner structure, agree perfectly with the shells of the echinitæ, found in our chalk-pits, and with the asteriæ and entrochi; these bodies being all composed of obliquely-arranged plates of a tabulated spar: the several parts of which they are composed are all convex on one side, and concave on the other; but they are of very different shapes, being sometimes roundish, sometimes oblong, often quadrangular, and not unfrequently of different numbers of angles. They have frequently two, sometimes more, ridges running across them, and sometimes they have tubercles, or small protuberances, standing either on their upper or under side: they are sometimes found single, but more frequently compound, or arranged into smaller or larger parcels, being placed over one another in the manner of the tiles of a house, and seem truly to have been originally part of an imbricated shell, or crust of some species of sea-fish. They are in these compound masses even very evidently fragments, and are usually of irregularly broken figures, though sometimes they resemble, in some degree, parts of the rays of one or other of the kinds of star-fish. They are usually found loose from the asteriæ, though lying among them; but sometimes the asteriæ are regularly fixed on them, just as

the entrochi on the modiola, and are plainly seen to have originally grown out of them.

The asteropodia seem properly the bases of the asteriæ, and the asteriæ themselves are branches of them. The asteriæ are short, and have commonly somewhat crooked angular columns, composed of several joints, each resembling the figure of a radiated star, with a greater or smaller number of rays in the different species: they are usually found of about an inch in length, and of the thickness of a goose-quill. Some of them have five angles or rays, and others only four, and in some the angles are equidistant, while in others they are irregularly so; in some also they are short and blunt, while in others they are long, narrow, and pointed; and some have their angles so very short and obtuse, that at first sight they may be taken for entrocho-asteriæ. The several joints in the same specimen are usually all of the same thickness; this, however, is not always the case, but in some they are larger at one end, and in others at the middle, than in any other part of the body; and some species have one of the rays bifid, so as to emulate the appearance of a six-rayed kind.

All the asteriæ are naturally fulcated between the angles, but this in a very different degree; some are very little so, while others are cut so deeply, that the single joints of them resemble the rowels of a spur. One end of the column is frequently found finely engraved along the edges of the angles, or rays, while the other end is smooth, or nearly so; and the same is often the case also in the single joints. Not unfrequently, also, one end of a column is indented, and the other has five striæ, running from a hollow centre to the fulci between the rays. They are found of various sizes and colours; the longest seldom arrive, however, at two inches; and they are found of all the intermediate bulk from this down to the length of a barley-corn: they are not unfrequently found, also, compressed and flattened, as is common to the fossils that have been formed in animal moulds.

They are usually bedded in strata of clay, though not unfrequently in those of a lax sort of quarry-stone, and sometimes in a harder. They usually have sea-shells, and other marine remains, lying about them; and sometimes these shells adhere to the asteriæ, and when separated from them, do no injury to the asteriæ, but themselves shew a mark of the figure of the body, or part of the column, when a part has been always wanting in the shell.

From the columns of the asteriæ there are sometimes propagated certain small branches, like those of the entrochi; these are called by authors *appendicule asteriarum*, or the wires of the asteriæ.

These are sometimes two inches long, and the largest or thickest joint always adheres to the alteria, all the succeeding ones growing smaller, and the branch more tapering toward the end. In their natural situation on the alteria, they stand in regular circles at different distances one above another: there is always one wire in each of the fulci, or channels of the body, and these stand evenly against one another.

These wires or appendiculæ are very seldom, however, found in this their native state, or fixed to the bodies of the asteriæ; they are commonly found broken off, and lying loose among them, either in fragments of different lengths, or in single joints, immersed in stone, or lying among the strata of clay.

The asteriæ may be reduced to two kinds; the first, those whose whole bodies make the form of a star; the second, those which in the whole are irregular, but which are adorned, as it were, with constellations in the parts.

Dr. Lister, for distinction sake, only gives the name *asteria* to the former sort, distinguishing the latter by the appellation of *astroites*; the other naturalists generally use the two indiscriminately. The asteria spoken of by the ancients appears to be of this latter kind.

The quality of moving in vinegar, as if animated, is scarcely perceivable in the astroites, but is signal in the asteria. The former must be broken in small pieces before it will move; but the latter will move, not only in a whole joint, but in two or three knit together. Plott, Nat. Hist. Oxford.

STAR-*Thistle*, in *Botany*. See *CENTAUREA Calcitropa*.

STAR-*Wort*. See *ASTER*.

STAR-*Wort*, *American*, or *Trailing*, of Vera Cruz. See *TRIDAX*.

STAR-*Wort*, *Basard*, a species of *Bupthalmum*; which see.

STAR-*Wort*, *Yellow*, a species of *Inula*; which see.

STAR-*Chamber*, *Court of*. See *COURT*.

STAR-*Fort*, or *Redoubt*, in *Fortification*. See *STAR*, *REDOUBT*; and *FORT*.

STARADI, in *Geography*, a town of Asiatic Turkey, in Natolia; 42 miles E. of Iznik.

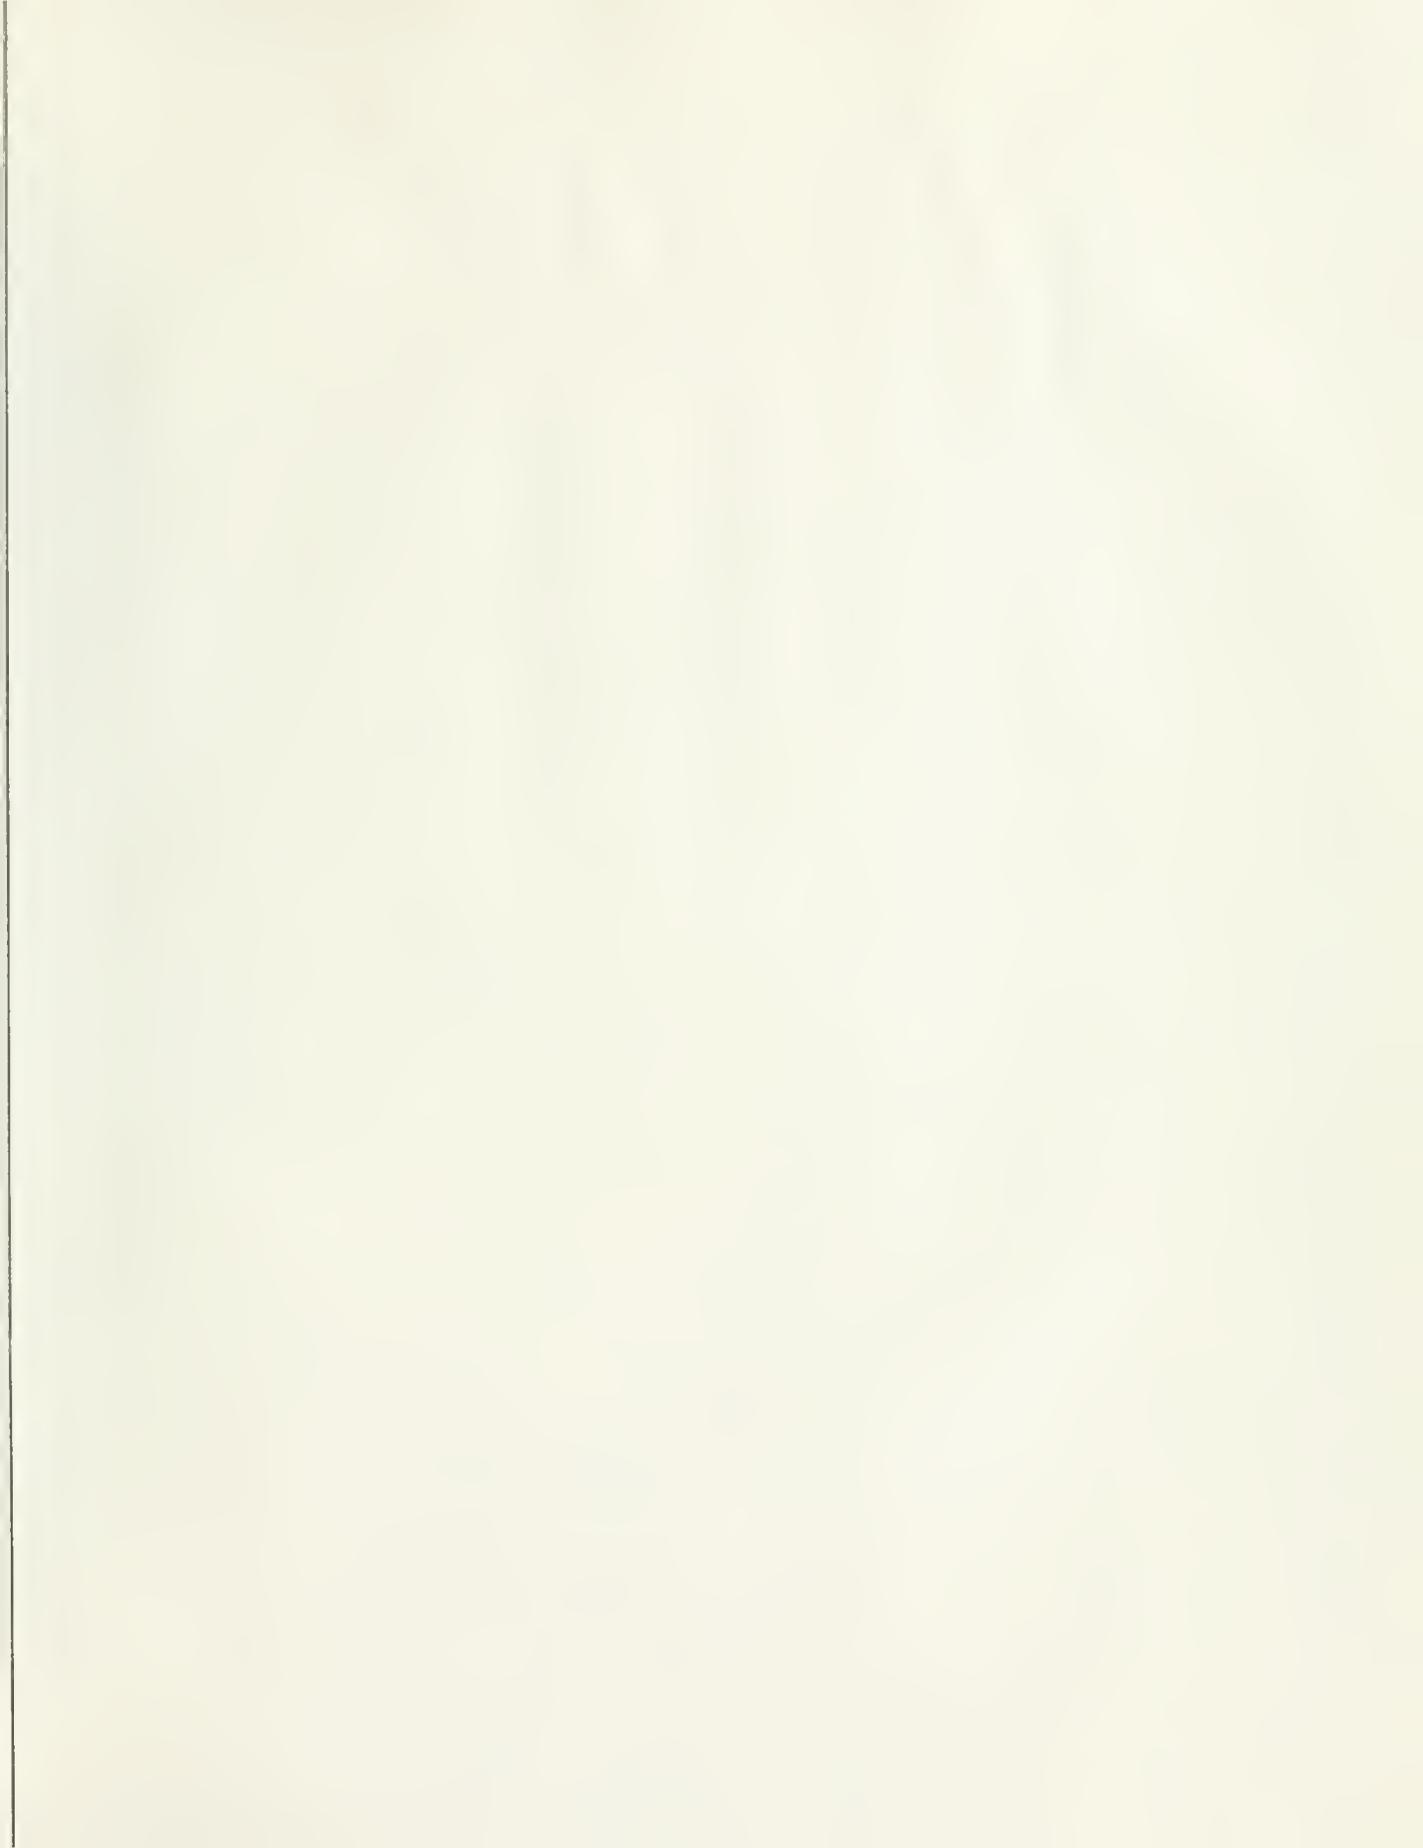

STARAPHAXAT, a name used by some of the old writers for any medicine that restrains fluxions from the eyes, nose, or fauces.

STARA-RUSA, in *Geography*, a town of Russia, in the government of Novgorod, near lake Ilmen; 56 miles S. of Novgorod. N. lat. 57° 40'. E. long. 31° 50'.

STARASELLA, a town of Italy; in Friuli; 8 miles N.E. of Friuli.

STARBOARD, in *Sea Language*, is the right-hand side of a ship, when looking forward from the stern.
