SOLANDRA, in *Botany*, was originally destined by the younger Linnæus, to preserve the memory of his friend Dr. Daniel Charles Solander, F.R.S., so well known in England as the companion of sir Joseph Banks, in his voyage round the world, and afterwards one of the librarians of the British Museum. He was intimately connected with the most eminent cultivators of natural science here in England, especially **ELLIS** (see that article); being no less esteemed for his polite and agreeable manners, than his extensive knowledge. He died of an apoplexy, in 1782, aged 46. His learned botanical manuscripts remain in the Banksian library; his premature decease having prevented his finishing, for publication, any considerable work, though his information enriched every thing that appeared in this country during his residence here. The great Linnæus, who justly considered Solander as one of his ablest pupils, had named a *Solandra* in the 6th edition of *Gen. Pl.* but this was subsequently referred to *Hydrocotyle*. The genus we are now to describe, must be considered as first published, by being represented on the honorary medal struck in Sweden soon after Dr. Solander's death; and thus it takes place of the less certain and ornamental *Solandra* of Murray, in Linn. Syst. Veg. ed. 14. 623, not published till 1784.—Swartz in Stock. Transf. for 1784.

VOL. XXXIII.

300. t. 11. Ind. Occ. v. 1. 386. Schreb. 793. Willd. Sp. Pl. v. 1. 936. Mart. Mill. Dict. v. 4. Salisb. Tr. of L. Soc. v. 6. 99. t. 6. Ait. Hort. Kew. v. 1. 388.—Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Luridæ*, Linn. *Solaneis affine*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, angular, with from three to five lanceolate, erect teeth, sub-frequently more deeply separated, permanent. *Cor.* of one petal, thrice the length of the calyx, funnel-shaped; tube inflated and bell-shaped in the upper part, five-ribbed; limb in five roundish, spreading, reflexed, wavy, partly doubly crenate, lobes. *Stam.* Filaments five, thread-shaped, declining, the length of the tube, inserted into its middle part; anthers terminal, versatile, somewhat pyramidal, of two cells. *Pist.* Germen superior, oval; style thread-shaped, declining, longer than the stamens; stigma obtuse, compressed, slightly two-lobed. *Peric.* Berry oval, pointed, smooth, of four cells. *Seeds* very numerous, kidney-shaped, imbedded in pulp, inserted into a four-branched receptacle.

Ess. Ch. Calyx tubular, splitting. Corolla funnel-shaped, inflated, irregular; limb in five rounded, reflexed, unequal segments. Berry of four cells, with many seeds.

1. *S. grandiflora*. Great-flowered Solandra. Willd. n. 1. Ait. n. 1. Jacq. Hort. Schonbr. v. 1. 21. t. 45.—Native of Jamaica, where, according to Swartz, it occupies the clefts of rocks, and the trunks of the largest trees, climbing, by roots thrown out of the stem, to their very summits, from whence its long, spreading, leafy, dependent *branches* hang down very far, flowering in January and February, and ripening fruit in August. The plant was introduced at Kew by Mr. Masson, in 1781, and long known by the extemporaneous name of *Portlandioides*, given by its finder; for being treated with the usual supplies of water, and a rich soil, it grew every year luxuriantly, but never flowered, till accidentally set aside and neglected, in the dry stove. By such management it has often flowered since, and Jacquin says it ripens fruit and seed at Schonbrun. The wood is spongy. *Stem* and *branches* round. *Leaves* scattered, most crowded about the ends of the branches, reflexed, stalked, obovate, or elliptic-oblong, acute, entire, somewhat undulated, single-ribbed, slightly succulent, more or less downy, from four to six inches long; paler beneath. *Footstalks* an inch long, round, downy. *Flowers* usually solitary, terminal, nearly sessile, very large, a span long, magnificent in appearance, and deliciously fragrant. The *corolla* is cream-coloured, with a tinge of yellow; the outside often purplish, and slightly downy; the segments of the limb flaccid, partly entire, partly crenate, and waved, in an elegant manner. *Fruit* sometimes as big as a hen's egg, white, red within, of a sweet subacid taste.—The inhabitants of Jamaica know this plant by the name of the Peach-coloured Trumpet-flower. Plumier is said to have left a sketch of it, among his drawings, by the name of *Stramonium scandens, flore luteo*.

SOLANÆÆ, the 41st natural order in Jussieu's system, the 8th of his 8th class. It is thus named from the Nightshade, (see **SOLANUM**,) which is one of the tribe, and the order is nearly equivalent to the Linnæan **LURIDÆ**, see that article. We refer the reader to **GENTIANÆ** for the character of Jussieu's 8th class; and to **LYSIMACHIÆ**, **PEDICULARES**, **SAPOTÆ**, and **SCROPHULARIÆ**, for some orders belonging to it.—The *Solaneæ* are thus defined.

Calyx generally in five segments, more or less deeply separated, for the most part permanent. *Corolla* generally regular, and five-cleft. *Stamens* mostly five, usually inserted into the lower part of the corolla. *Style* solitary. *Stigma* simple, or rarely cloven. *Fruit* mostly of two cells, with many

seeds; sometimes capsular, of two valves, with a partition parallel thereto, as in the *Scrophularia*; or more frequently pulpy, with central receptacles for the seeds attached to the middle of the partition, at each side, and usually prominent, so as to separate each principal cell of the berry internally into two parts, or, by a still further imperfect subdivision, into more. *Corculum* of the seed curved, lodged in a farinaceous albumen. *Stem* herbaceous or shrubby. *Leaves* alternate; in some instances there are two floral ones from the same point. *Flowers* variously disposed, often extra-axillary, that is, placed near the side of the insertion of the leaves, not springing from their bosoms.

The first section, with a capsular or dry fruit, consists of *Celsia*, *Verbascum*, *Hyoscyamus*, *Nicotiana*, and *Datura*.

The second, with a berry, of *Triguera* of Cavanilles, which we have recently discovered to be the very identical *Verbascum Osbeckii* of Linnæus, a plant that no subsequent botanist could ever make out; (see *VERBASCUM* and *TRIGUERA*;) *Jaborosa* of Jussieu; *Mandragora* of Tournefort; *Atropa*; *Nicandra* of Adanson, which is *Atropa physaloides* of Linnæus; *Physalis*; *Witheringia* of l'Heritier; *Aquartia*; *Solanum*; *Capsicum*; *Lycium*; and *Cestrum*.

Section third contains three genera, reckoned akin to the former; these are *Bontia*, *Brunfelsia*, and *Crescentia*. With these last the true *Solandra* is, as Jussieu suspected, to be associated. See *SOLANDRA*.

SOLANILLOS, in *Geography*, a town of Spain, in New Castile; 23 miles E. of Guadalaxara.

SOLANO, a small island near the coast of Peru. S. lat. 12° 20'.—Also, a river of Mexico, which runs into the Pacific ocean, N. lat. 10° 18'.

SOLANOIDES, in *Botany*, a name given by Tournefort to the *Rivina* of Linnæus, on account of its resemblance to *SOLANUM*; which see. See also *RIVINA*.

SOLANOS, in *Meteorology*, a name given to winds, which, blowing over an extensive tract of highly heated land, become so very drying, scorching, and suffocating, as to produce dreadful effects, and are often felt in the deserts of Arabia, in the vicinity of the Persian gulf, in the interior of Africa, and in some other places.

SOLANTA, in *Geography*, a town on the N. coast of the island of Sicily, which gives name to a cape and bay: 8 miles E. of Palermo. N. lat. 38° 9'. E. long. 13° 36'.

SOLANUM, in *Botany*, an ample genus, comprising various kinds of Nightshade, and other deadly plants, along with the esculent Tomato, Egg-plant, and even the valuable Potatoe, owes its name, according to some authors, to its comforting quality, such authors supposing the word to have originated from *solamen*. This indeed might apply to the potatoe, could that possibly have been in the contemplation of those who gave the name. The common derivation *a sole*, from the sun, carries no more conviction along with it; nor can we for a moment admit the true orthography to be *Sulanum*, from *Sus*, because the plant is useful to swine. It is far more prudent to leave *Solanum* among the few ancient names whose source cannot be traced.—Linn. Gen. 100. Schreb. 134. Willd. Sp. Pl. v. 1. 1025. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 256. Prodr. Fl. Græc. Sibth. v. 1. 154. Ait. Hort. Kew. v. 1. 396. Brown Prodr. Nov. Holl. v. 1. 444. Pursh v. 1. 156. Juss. 126. Tourn. t. 62. Lamarck Illustr. t. 115. Gært. t. 131. (Lycopericon; Tourn. t. 63. Melongena; ib. t. 65.)—Class and order, *Pentandria Monogynia*. Nat. Ord. *Lurideæ*, Linn. *Solanææ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, cut half way down into five, erect, acute, permanent segments. *Cor.* of one petal, wheel-shaped; tube very short; limb large,

plaited, spreading, somewhat reflexed, cut half way down into five acute segments. *Stam.* Filaments five, awl-shaped, very small; anthers large, erect, oblong, converging, slightly connected, of two cells, opening each by a terminal pore. *Pistl.* Germen superior, roundish; style thread-shaped, longer than the stamens; stigma obtuse. *Peric.* Berry roundish, smooth, marked with a dot-like scar at the summit, of two cells, divided by a fleshy receptacle, which is convex at each side. *Seeds* numerous, roundish, lodged in soft pulp.

Ess. Ch. Corolla wheel-shaped. Anthers slightly connected, opening by two terminal pores. Berry superior, of two cells.

Notwithstanding the rude and irregular habit of this genus, the flowers are often so handsome as to attract much notice, and the fruit is, in some cases, very striking and ornamental. The stem is branched, herbaceous or shrubby, smooth, hairy or prickly. Leaves alternate, simple or compound, lobed, cut or entire; sometimes prickly. Inflorescence often lateral, and extra-axillary. Corolla blue, purple, white, or yellow. Fruit yellow or red, rarely black or white. The herbage is foetid, narcotic, and dangerous. Flowers without scent. Fruit often very nauseous, and in no instance eatable without dressing.

The species are disposed in three sections. The fourteenth edition of Linn. Syst. Veg. contains forty-six; Willdenow has eighty-three. Some new ones are added by Brown, Pursh, Aiton, &c. We select the following, adding several unknown to the author whose arrangement we adopt.

Section 1. *Without prickles*. Forty-four species in Willdenow; two British.

S. laurifolium. Laurel-leaved Nightshade. Linn. Suppl. 148. Willd. n. 1.—Stem arboreous, unarmed. Leaves stalked, ovate-oblong; downy beneath. Panicle terminal, repeatedly forked, divaricated. Calyx brittle on the inner side.—Native of the vast forests of Surinam; unknown in the European gardens; nor has a figure of this species appeared. The branches are woody, round and smooth. Leaves near a span in length, entire, pointed, veiny; shining, and slightly downy, above; clothed with soft depressed hairs, spreading from all the finest veins, beneath. Footstalks an inch long, rather silky. Panicle repeatedly forked and racemose, widely spreading, composed of innumerable flowers, of which the calyx only remains on our specimens, which is small, with five acute spreading segments, most hairy or bristly within. Berries black, the size of a Black Currant.

S. verbasifolium. Mullein-leaved Nightshade. Linn. Sp. Pl. 263. Willd. n. 2. Ait. n. 1. Jacq. Hort. Vind. v. 1. 5. t. 13. (S. maximæ tomentosum, spms carens, virginianum; Pluk. Almag. 351. Phyt. t. 316. f. 1.)—Stem shrubby, unarmed. Leaves alternate, stalked, ovate, densely downy, entire. Corymbs terminal, divided. Calyx with five short teeth.—Native of the West Indies, from whence Catesby communicated it to Miller. The plant is preserved in some curious stoves, and flowers in summer. The branches, stalks, calyx, and both sides of the leaves, are hoary, densely clothed with close starry down. Flowers white, with yellow anthers, far inferior in size and beauty to the Potatoe-blossom. The shallow divisions of the calyx, and the close, not shaggy, hairs of the stalks and branches, distinguish it from the *auriculatum* hereafter described.

S. inæquale. Unequal-leaved Woolly Nightshade.—Stem shrubby, unarmed. Leaves in pairs, stalked, ovate, entire, densely downy; unequal at the base. Clusters lateral, divided. Calyx of the fruit in five deep segments.—Gathered in New Granada by Mutis. The younger Linnæus con-

founded the specimen with *S. verbascifolium*, from which it essentially differs in the inequality of the two sides of each leaf, at the base, and especially in the *inflorescence*. The twin racemose *flower-stalks* spring laterally from the intermediate spaces of the branches, between the *leaves*, and two of the latter always grow together, nearly from the same point. Whether the *calyx* of the *flower* be deeply divided, we cannot, because of its woolliness, determine; but that of the *fruit* is separated into five lanceolate segments, to the very base. *Berry* the size of a red currant, besprinkled with itary hairs.

S. auriculatum. Ear-leaved Nightshade. Ait. ed. 1. v. 1. 246. ed. 2. n. 2. Willd. n. 3. (*S. mauritanium*; Scop. Del. Infubr. v. 3. 16. t. 8.)—Stem shrubby, unarmed. Leaves stalked, ovate, pointed, entire; very soft above; acute at the base. Stipulas heart-shaped. Corymbs terminal, divided. Calyx cloven half way down.—Native of Madagascar, the Mauritius, and the East Indies. A tall *shrub*, with the habit of *S. verbascifolium*, but larger; the pubescence of the *stalks* usually more shaggy; the greener upper surface of the *leaves* remarkable for a velvet-like softness; the under white and woolly. *Calyx* separated half way down into five broad segments, which are not deeper in the *fruit* than in the *flower*. The *stipulas* are often wanting, but the species is sufficiently distinct.

S. Pseudocapsicum. Shrubby Winter-cherry Nightshade. Linn. Sp. Pl. 263. Willd. n. 6. Ait. n. 3. (*Amomum Plinii*; Lob. Ic. 265. Ger. Em. 361. *Pseudocapsicum*; Dod. Pempt. 718. *Strychnodendron*; Besl. Hort. Eyf. æt. arb. t. 14. f. 1.)—Stem shrubby, unarmed. Leaves lanceolate, wavy, smooth. Umbels lateral, sessile.—Native of Madeira. One of our popular hardy greenhouse plants from Gerard's time to this day. The *stem* is bushy, a yard high. *Leaves* stalked, ever-green, about two inches long. *Flowers* few together, drooping, white, with orange *anthers*. *Fruit* scarlet, globose, the size of a small cherry.

S. diphylum. Two-leaved Nightshade. Linn. Sp. Pl. 264. Willd. n. 10. Ait. n. 4. Jacq. Ic. Rar. t. 322. Coll. v. 2. 331. (*S. americanum*, *strychnodendro accedens*, fructu medio, antè maturitatem, quasi fisso; Pluk. Phyt. t. 111. f. 4.)—Stem shrubby, unarmed. Leaves in pairs, elliptic-oblong, smooth; one smaller than the other. Flowers cymose, opposite to the leaves.—Native of the West Indies, from whence it was brought early to this country; but is only occasionally kept in itoves, rather for curiosity's sake than otherwise, being less ornamental than the last, with smaller *flowers* and *fruit*, and much more tender.

S. Dulcamara. Woody Nightshade, or Bitter-sweet. Linn. Sp. Pl. 264. Willd. n. 15. Fl. Brit. n. 1. Engl. Bot. t. 565. Curt. Lond. fasc. 1. t. 14. Woodv. Med. Bot. t. 33. Fl. Dan. t. 607. (*Amara dulcis*; Ger. Em. 350.)—Stem shrubby, twining, unarmed. Upper leaves hastate. Clusters cymose, drooping, opposite to the leaves. *Fruit* elliptical.—Native of moist bushy places throughout Europe, from Norway to Greece, flowering in summer. The branching zigzag *stems* climb upon other shrubs, and display their elegant bunches of violet-coloured *flowers*, each of whose segments has two green dots at the base, in an elegant manner. The scarlet pellucid *berries* are also beautiful, though of a bitter and dangerous quality. The *leaves* are ovate, acute, usually smooth, on long stalks, some simple, others hastate, rarely distinctly auricled. The bark and roots are said to be bitter, with a subsequent sweetness. The young shoots have been recommended, in decoction, for rheumatic and scorbutic diseases. We have sometimes doubted whether this might not be the *κικλαμινος*; *βίση* of Dioscorides, a much disputed plant: but the flowers are

neither white, nor fragrant, as he describes them. We readily concur with Willdenow in believing the Linnæan β , figured in Dill. Elth. t. 273. f. 352, to be a distinct species, nor do we doubt its being the *quadrangulare*, hereafter mentioned.

S. Seaforthianum. Lord Seaforth's Nightshade. Andr. Repof. t. 504. Ait. Epit. 374.—Stem shrubby, twining, unarmed. Leaves simple or ternate, ovate, pointed, smooth. Panicles lateral, drooping, compound. Corolla without dots.—Native of the West Indies, from whence it was brought by the late earl of Seaforth. This beautiful species is said to succeed best in a conservatory. Its general appearance resembles the last, but the large pendulous *panicles* of numerous pale-purple *flowers*, destitute of green dots, are very different, and extremely ornamental on a trellis. The *inflorescence* often seems terminal, but is properly lateral. Of the *berries* we have no information.

S. scandens. Climbing Surinam Nightshade. Linn. Suppl. 147. Amoen. Acad. v. 8. 253. Willd. n. 17.—Stem twining, unarmed. Leaves ovate; heart-shaped at the base; downy beneath. Panicle terminal, cymose. Calyx smooth on the inside.—Native of Surinam. The *leaves* betray a considerable affinity to our first species, *laurifolium*, but the downiness of their under surface consists of little, forked or itary, scattered hairs, not of simple ones proceeding in double rows from each vein. The *branches* moreover are long and flaccid, apparently herbaceous; and the *calyx* is not brittle within, but nearly smooth on both sides. *Corolla* downy, divided almost to the bottom. Lower half of the *style* hairy. *Berries* the size of a cherry.

S. quercifolium. Oak-leaved Nightshade. Linn. Sp. Pl. 264. Willd. n. 20. Ait. n. 6. (*S. foliis quernis*; Feuill. Peruv. 722. t. 15.)—Stem somewhat herbaceous, angular, zig-zag, rough-edged, erect, unarmed. Leaves pinnatifid. Clusters cymose.—Gathered by Feuillé, on the mountains of Valparaiso, in Chili. Linnæus raised the plant at Upsal, from seeds sent by Jusſieu, but it has only lately found its way to the English gardens. The *root* is thick, fleshy, and perennial. *Stem* four or five feet high, branched, leafy, with several unequal angles, that are rough, with minute sharp tubercles. *Leaves* regularly pinnatifid, of five or seven bluntish, entire, rather distant lobes, nearly smooth; their long *footstalks* slightly winged. *Flowers* drooping, violet, with yellow *anthers*; their *corolla* broader than that of *S. Dulcamara*. *Berries* red, ovate.

S. radicans. Rooting Nightshade. Linn. Sp. Pl. 264. Willd. n. 22. Ait. n. 8. Linn. fil. Dec. 1. 19. t. 10.—Stem somewhat herbaceous, unarmed, roundish, prostrate, nearly smooth, taking root. Leaves pinnatifid. Clusters cymose.—Native of Peru. Very nearly related to the last, but differing in its prostrate creeping *stem*, whose angles are less marked, and almost smooth. The segments of the *leaves* are never more than five. *Clusters* simple. *Flowers* fewer and smaller, white; purplish beneath. *Berries* yellow, globose or two-lobed.

S. laciniatum. Cut-leaved Nightshade. Ait. ed. 1. v. 1. 247. ed. 2. n. 7. Willd. n. 21. Br. n. 4. Curt. Mag. t. 349. (*S. aviculare*; Forst. Prodr. 18. Pl. Escol. 42.)—Stem somewhat shrubby, unarmed, smooth. Leaves linear-lanceolate, undivided or pinnatifid, entire, smooth. Clusters lateral, corymbose. Calyx cloven half way down. Segments of the corolla emarginate. Stamens spreading. *Berry* oval.—Native of New Zealand, New South Wales, and Van Diemen's land. A greenhouse shrub, introduced by sir J. Banks in 1772. The *leaves* are dark green, nearly sessile; sometimes quite undivided, sometimes deeply pinnatifid, on the same or a different plant; their length from

four to eight inches. *Flowers* purple, large and handsome, with rounded notched segments. *Anthers* yellow, soon widely spreading from each other. *Fruit* yellow, the size of a large plum, acid, sweetish, but with a disagreeable flavour. Forster says the inhabitants, as well as the small birds, of New Zealand, greedily devour this fruit, nor did the European voyagers entirely reject it.

S. corymbosum. Corymbose Peruvian Nightshade. Ait. ed. 1. v. t. 248. ed. 2. n. 11. Willd. n. 26. Jacq. Ic. Rar. t. 40. Coll. v. 1. 78. Retz. Obs. fasc. 5. 22.—Stem unarmed, somewhat shrubby, smooth. Leaves ovato-lanceolate, entire; tapering at the base. Flower-stalks lateral, branched, corymbose.—Found by Dombey at Lima, growing near waters. M. Thouin sent seeds to Kew in 1786, when we saw the plant flowering in the stoves at Paris, in August. Its beauty scarcely exceeds our wild *S. nigrum*. The *flowers* are copious, small, purplish. *Clusters* several together, on a common corymbose stalk, opposite to each leaf. *Berries* scarlet, the size of a small pea.

S. quadrangulare. Quadrangular African Nightshade. Linn. Suppl. 147. Willd. n. 27. Thunb. Prodr. 36. (*S. Dulcamara* β; Linn. Sp. Pl. 264. *S. crassifolium*; Lamarck Dict. v. 4. 284. *S. dulcamara africanum*, foliis crassis hirsutis; Dill. Elth. 365. t. 273. t. 352.)—Stem shrubby, unarmed, angular, rough. Leaves ovate; undivided, or with angular lobes. Panicles terminal, cymose.—Found by Thunberg, at the Cape of Good Hope. Cultivated by Sherard at Eltham, and therefore entitled to a place in Mr. Aiton's work. The figure of Dillenius is very characteristic, as to the *foliage* and *flowers*, but does not express the remarkably angular *stem*, except towards the top of the specimen. Hence it has been overlooked with regard to this plant. The *branches* in Thunberg's two specimens before us are irregularly quadrangular, very rough, with callous points and bristly hairs. *Leaves* stalked, fleshy, smooth, except at the edges, an inch or inch and half long, obtuse, ovate; either quite entire, or on luxuriant shoots, furnished with one or two large, prominent, tooth-like lobes at each side. *Flowers* larger, paler, and less expanded than in our *Dulcamara*; the points of the *corolla* hairy.

S. bonariense. Tree Nightshade. Linn. Sp. Pl. 264. Mant. 205. Willd. n. 29. Ait. n. 12. (*S. bonariense arborescens*, papas floribus; Dill. Elth. 364. t. 272. f. 351.)—Stem shrubby, nearly unarmed. Leaves ovate-oblong, wavy and sinuated, rough. Fruit half the diameter of the flowers.—Native of Buenos Ayres. Raised from seed by Sherard in 1726, or thereabouts, and now a frequent greenhouse plant, of a tall bushy habit, esteemed for its copious large white *flowers*, with orange *anthers*. The *leaves* are from three to six inches long, besprinkled with little starry rigid hairs. *Flower-stalks* corymbose, opposite to the leaves. *Berries* yellow, scarcely half an inch broad. The young *stems* are prickly in the lower part, and indeed not unfrequently in the upper, so that this species would stand better in the second section.

S. macrocarpon. Large-fruited Nightshade. Linn. Mant. 205. Willd. n. 30. Ait. n. 13. (*S. caule inermi suffruticoso*, foliis oblongo-ovatis sinuatis utrinque glabris, floribus alaribus; Mill. Ic. v. 2. 196. t. 294. *Lycopersicum arborescens*, foliis angulatis, fructu aureo; Plum. Ic. 219. t. 224. f. 2.)—Stem shrubby, unarmed. Leaves wedge-shaped, wavy and sinuated, smooth. Fruit thrice the diameter of the flowers.—Native of Peru. A stove-plant, cultivated by Miller, and flowering in summer. This is of a larger size, and stouter habit, than the last, with which Linnæus long confounded it. The *flowers* are blue; their *corolla* smaller, with more pointed segments, and the *corymbs*

less compound, than in *S. bonariense*, but the *fruit* is ten times as large, supported by a short thick stalk.

S. tuberosum. Common Potatoe. Linn. Sp. Pl. 265. Willd. n. 31. Ait. n. 14. (*S. tuberosum esculentum*; Bauh. Prodr. 89. *Battata virginiana*; Ger. Em. 927. *Papas Peruanorum*; Besl. Hort. Eyst. autumn. t. 27. f. 1.)—Stem unarmed, herbaceous. Leaves interruptedly pinnate, entire. Flower-stalks subdivided.—Native of Peru. Gerarde says he received roots from Virginia, which succeeded well in his garden. No similar acquisition was ever more important to this country. The *herbage* is annual, impatient of cold, bushy, with copious roughish *leaves*, pinnate in a lyrate form, with very small intermediate leaflets. *Flowers* paniced, large, purplish or white, drooping, very handsome. *Fruit* globose, purplish.—For the different varieties, uses, and cultivation of this valuable plant, see POTATOE.

S. Lycopersicum. Tomato, or Love-apple. Linn. Sp. Pl. 265. Willd. n. 33. Ait. n. 15. (*Poma amoris*; Camer. Epit. 821. Ger. Em. 346. Besl. Hort. Eyst. autumn. t. 1, 2.)—Stem unarmed, herbaceous. Leaves interruptedly pinnate, cut. Clusters deeply divided, leaflets. Fruit smooth.—Native of South America. A tender annual, cultivated in England ever since Gerarde's time, for the sake of its large, variously-shaped, scarlet or orange *fruit*, which many people esteem a great luxury, either in soups; or broiled with pepper and salt, as an addition to roast-meat, or game. In the hotter parts of Europe, the Tomato has more acidity and briskness of flavour, and is therefore the more welcome in such climates. It has also the reputation of being stimulant, or aphrodisiac. The *root* is fibrous. *Herb* of rank growth, weak and decumbent, fœtid, glutinous, downy. *Leaflets* acute, coarsely cut and toothed, with a double series of small stalked intermediate ones. *Flowers* yellow, in large divided bunches. *Fruit* shining, pendulous, very ornamental.—Whether Jacquin's *Pseudo-lycopersicum*, with its simple *clusters*, and small globular *fruit*, be a distinct species, we greatly doubt; see his Hort. Vind. v. 1. t. 11. Linnæus did not distinguish it. Nor have we absolute confidence even in *S. peruvianum*, Linn. Sp. Pl. 265. Willd. n. 35. Jacq. Coll. v. 2. 284. Ic. Rar. t. 327, distinguished by its bracteated or leafy *clusters*, and somewhat downy *fruit*. Its *root* indeed is perennial, and the herbage more compact, neat, and hoary, than the common Love-apple.

S. multifidum. Ragwort-leaved Nightshade. Lamarck Dict. v. 4. 287. Illustr. t. 115. f. 3, not 2.—Stem herbaceous, unarmed, winged. Leaves doubly pinnatifid, obtuse. Panicle cymose.—Gathered by Dombey, in sandy ground at Lima. The *root* is fibrous, apparently annual. *Stem* twelve or eighteen inches high, branched, spreading, leafy, bordered at each side with an entire, uninterrupted wing. *Leaves* succulent, rather downy, elegantly subdivided, decurrent; all their lobes obtuse. *Flowers* white, or purplish, several together, in long-stalked, terminal, cymose or forked *panicles*. *Corolla* but slightly divided.

S. nigrum. Common or Garden Nightshade. Linn. Sp. Pl. 266. Willd. n. 39. Fl. Brit. n. 2. Engl. Bot. t. 566. Fl. Dan. t. 460. Curt. Lond. fasc. 2. t. 14. Woodv. Med. Bot. t. 226. (*S. hortense*; Ger. Em. 339. Camer. Epit. 812. Matth. Valgr. v. 2. 415.)—Stem herbaceous, unarmed, erect. Leaves ovate, with tooth-like angles. Umbels lateral, drooping.—Native of cultivated and waste ground in all parts of the world. *Root* annual. *Stem* bushy, more or less angular. *Leaves* scattered, stalked, ovate, slightly downy; elongated at the base; either entire, wavy, or coarsely toothed, at the margin. *Umbels* lateral, not

SOLANUM.

not quite opposite to the leaves, solitary, stalked, composed of numerous small white *flowers*, with yellow *anthers*. *Berries* the size of currants, usually black, but occasionally yellow, even in England, according to Hudson. Authors enumerate several varieties of this species, differing in the more or less angular, and somewhat crisped or toothed, *stem*, and more hairy or smoother *herbage*. Willdenow says these are permanent, but we can scarcely define the distinctive marks of each. Several of them are exhibited in Dill. Elth. t. 274 and 275.

S. angustifolium. Narrow-leaved Nightshade. Lamarck Dict. v. 4. 291.—Stem unarmed, somewhat herbaceous. Leaves stalked, linear-lanceolate, obtuse, entire, smooth. Clusters lateral, divided.—Gathered by Commerçon at Buenos Ayres. The *stem* is branched, leafy, somewhat angular, zig-zag, or perhaps rather twining. *Leaves* alternate, uniform, about two inches long, and a quarter or half an inch broad, with one rib, and a few lateral connected veins. *Flowers*, in our solitary specimen, certainly not terminal, but opposite to a leaf, in a divided *cluster*, not numerous, on long partial stalks. *Calyx* hemispherical, nearly or quite smooth, with very unequal broad segments. *Corolla* blue, half an inch wide, finely downy at the outside.

S. betaceum. Beet-leaved Nightshade. Cavan. Ic. v. 6. 15. t. 524. Ait. n. 18. Andr. Repof. t. 511.—Stem shrubby, round, unarmed. Leaves ovate, pointed, fleshy, smooth; heart-shaped at the base; wavy at the edges. Clusters lateral, stalked, divided, pendulous.—Probably a native of South America. Seeds were sent, in 1803, by Cavanilles, from the Madrid garden to the writer of this article. The plant is gigantic, twelve feet high or more, fleshy, very fœtid when touched or bruised, growing luxuriantly if turned out against a south wall in summer, but not of sufficient beauty to excite general notice. Some *leaves* measure twenty inches in length, and fifteen in breadth. The *flowers* are small in proportion, not quite so big as a potato-blossom, but more deeply divided, light purple with yellow *anthers*.

S. Melongena. Egg-plant Nightshade. Linn. Sp. Pl. 266. Willd. n. 41. Ait. n. 19. (Melongena; Camer. Epit. 820. Matth. Valgr. v. 2. 424. Mala insana; Ger. Em. 345. Fuchf. Hist. 533. Melauzana fructu pallido; Besl. Hort. Eyf. autumn. t. 3.)—Stem herbaceous, unarmed. Leaves ovate, wavy, clothed with starry down. Flower-stalks deflexed, swelling. *Calyx* mostly unarmed. Fruit ovate, smooth and even. Native of tropical climates; cultivated in various parts of the world by means of hot-beds or stoves, for the sake of its *fruit*, which resembles a large egg, and is usually of a pure polished white, though sometimes tinged with violet. It is eaten in Italy, Spain, and other warm countries, like the Tomato. We have under the article MELONGENA, traced the origin of that word, and ventured to derive from thence the frightful appellation of *Mala insana*, Mad-apples, given to the fruit in question, which it appears not particularly to deserve. The *herbage* is branched, clothed with starry, not very dense, pubescence. *Flowers* purplish, large, drooping, lateral or axillary, not many together. Segments of the *calyx* lanceolate, or nearly linear; sometimes prickly.—Gerarde says of these apples, “the people of Toledo eat them with great devotion, being boiled with fat flesh, putting to it some scraped cheese, which” (the apples) “they do keep in vinegar, honey, or salt pickle, to procure lust.”

Section 2. *Prickly*. Thirty-eight species in Willdenow; none British.

S. insanum. Prickly Mad-apples. Linn. Mant. 46. Willd. n. 45. (*S. pomiferum*, magno fructu ex albo et

atropurpureo nitente, foliis et calyce spinosis; Pluk. Phyt. t. 226. f. 3. *S. pomiferum*, fructu nigro spinoso; Morif. sect. 13. t. 2. f. 2.)—Stem prickly, herbaceous. Leaves ovate, sinuated, densely downy. Flower-stalks deflexed, swelling. *Calyx* armed with strong prickles. Fruit oblong, smooth, furrowed.—Native of tropical climates. Linnæus originally confounded this plant with *S. Melongena*, of which it may, after all, be only a thorny variety. *Troungum hortense*, Rumph. Amboin. v. 5. 238. t. 85, seems rather to belong to the *Melongena*.

S. mammosum. Nipple Nightshade or Bachelor's Pear. Linn. Sp. Pl. 267. Willd. n. 51. Ait. n. 24. Pursh n. 3. (*S. barbadense spinosum*, foliis villosis, fructu aureo rotundiore, pyri parvi inversi formâ et magnitudine; Pluk. Phyt. t. 226. f. 1. Pomum Sodomæ; Merian. Surin. 27. t. 27.)—Stem hairy, prickly, herbaceous. Leaves heart-shaped, lobed and angular; prickly and hairy on both sides. Fruit pointed.—Native of the West Indies. An annual stove-plant, which may perhaps have been frequently introduced, and soon again lost. The whole of the *herbage* is very villous, the *footstalks*, and ribs of the *leaves*, more especially, armed with formidable straight yellow thorns. *Flowers* pale blue, in small lateral clusters, with a hairy *calyx*, and large *anthers*. Fruit solitary, yellow, about two inches long, ovate with a point. Merian says it is very poisonous to men and beasts. Mr. Pursh found this species on the sea-coasts of Virginia and Carolina, its seeds, as we should suppose, having floated thither.

S. virginianum. Virginian Nightshade. Linn. Sp. Pl. 267. Willd. n. 55. Ait. n. 25. Pursh n. 4. (*S. americanum laciniatum spinosissimum*; Dill. Elth. 360. t. 267. *S. annuum nigricans virginianum spinosissimum latè se spargens*, flore cæruleo, glabrum; Pluk. Phyt. t. 62. f. 3.)—Leaves pinnatifid, with sinuated obtuse segments, ciliated, very prickly on both sides, as well as the herbaceous upright stem, the stalks, and the calyx. Fruit globose.—On road-sides, and in sandy fields, from Virginia to Carolina, flowering in July. *Pursh*. A tender biennial with us. The *root* is fibrous. *Stem* branched, erect, spreading. *Leaves* three or four inches long, deeply sinuated and cut, minutely fringed, but otherwise the whole plant is destitute of pubescence, though every where copiously armed with awl-shaped pale-yellowish thorns, sometimes near an inch long. *Flowers* lateral, distant from the leaves, simply racemose, blue. Fruit small, globose, variegated with green and white.

S. Jacquinii. Jacquin's Nightshade. Willd. n. 56. Ait. n. 26. (*S. virginianum*; Jacq. Coll. v. 2. 285. Ic. Rar. t. 332.)—Leaves pinnatifid, with sinuated obtuse segments, smooth, very prickly on both sides, as well as the decumbent, spreading, herbaceous stem, the stalks, and the calyx. Fruit globose.—Native of the East Indies, île de Bourbon, &c. Sent to Kew by sir Joseph Banks about 1804. A tender annual, flowering in September and October. Very nearly akin to the last, but the decumbent *stem*, and smooth edges of the *leaves*, are, in consideration of its oriental origin, supposed to indicate a specific difference. Some starry hairs occur on the young *leaves*, and extremities of the *branches*. The *fruit* is the size of a gooseberry, variegated with light and dark green. *S. xanthocarpum*, Schrad. Sert. Hannov. t. 2, is too nearly related to this to be considered as more than a variety.

S. fedomum. Dark-thorned Nightshade. Linn. Sp. Pl. 268. Willd. n. 63. Ait. n. 29. Sm. Fl. Græc. Sibth. t. 235, unpublished. (*S. pomiferum frutescens africanum spinosum nigricans, borraginis flore, foliis profundè laciniatis*; Herm. Lugd. Bat. 573. t. 575. Tourn. Inst.

Inft. 149. *S. pomiferum*, foliis quercus utrinque spinosis, flore borraginis; Morif. feft. 13. t. 1. f. 15.)—Stem shrubby, round, prickly. Leaves deeply pinnatifid, roundly lobed, roughish, with scattered thorns. Calyx prickly, much shorter than the fruit.—Native of Africa, and the south of Europe. A greenhouse shrub, flowering in June and July. The *stem* is erect, branched, brown or purplish, more or less roughish, like the rest of the herbage, with somewhat starry hairs, and bearing, like the ribs of the *leaves* above and below, and all the *stalks*, copious, strong, brownish, scarcely black, straight thorns, broad at the base. The *leaves* are green, very deeply, often doubly, pinnatifid, with wide sinuses, and blunt rounded lobes, like those of some American oaks. *Clusters* lateral, simple. *Flowers* large and handsome, purple, with shortish yellow *anthers*. *Calyx* very thorny. *Fruit* yellow, globose, pendulous, an inch or two in diameter.

S. Pyracantha. Orange-thorned Nightshade. Lamarck Dict. v. 4. 299. Ait. n. 30. Sm. Exot. Bot. v. 2. 9. t. 64.—Stem shrubby, very thorny, as well as the foliage and calyx. Leaves oblong, acute, pinnatifid, densely downy. *Clusters* lateral, woolly.—Native of Madagascar. Sent by M. Thouin, in 1789, to Mr. Aiton. It flowers in the stove in August and September, but, according to Mr. Lambert, succeeds well during autumn, if turned out under a south wall. The whole plant is rendered very brilliant by the copious, large, bright-orange thorns, and the downy ribs of the *leaves* are of the same rich hue. Each *leaf* is often a foot long, with spreading, parallel, acute, lanceolate, angular lobes, clothed on both sides with dense, white, starry pubescence. *Branches* and *stalks* woolly. *Clusters* simple. *Calyx* woolly, thorny at the base only; its segments linear-lanceolate. *Corolla* violet, with green branching veins. *Anthers* yellow, equal. *Stigma* simple. *Berry* globose, reddish.

S. fimbriifolium. Rocket-leaved Nightshade. Lamarck Dict. v. 4. 307.—Stem shrubby, thorny, as well as the foliage and calyx. Leaves doubly pinnatifid, acutely notched, hairy. *Clusters* lateral, with hairy stalks. *Stigma* two-lobed.—Gathered at Buenos Ayres, by Commerfon, whose specimen is before us. The *leaves* are not half so long as the last, but broader in proportion, and green, not white or hoary, their pubescence, and that of the whole herbage, being simply hairy, apparently viscid, not at all stellated. The *thorns* are slender, of a tawny or orange hue, and are extremely abundant about the base of the *calyx*. *Clusters* longer than the leaves, simple, of a few large, white, or bluish-coloured, *flowers*, whose *stigma* is capitate, of two downy lobes.

S. argentatum. Silvery-coated Nightshade.—Stem shrubby, prickly, as well as the foliage and calyx. Leaves oblong, obtuse, bluntly sinuated, clothed, like the stalks, calyx, and back of the corolla, with depressed, starry scales.—Native of Buenos Ayres. We presume this may be the supposed variety, mentioned by M. Poiret in Lamarck, with simply pinnatifid *leaves*. Probably that able botanist viewed it but slightly, for nothing can be more distinct than our plant, gathered by Commerfon, nor are many of its genus more elegant. The *leaves*, on long spinous *stalks*, are pretty exactly of the size and figure of our Common Oak, but thickly clothed on both sides with curious starry scales, rather than hairs, more dense and hoary on the under surface, and more silvery on the *flower-stalks*, *calyx*, and even the back of the *corolla* itself. The *thorns* of the whole plant are slender, and orange-coloured. The *calyx* is bell-shaped, angular, with short slender teeth; its base prickly.

S. cornutum. Horn-flowered Nightshade. Lamarck

Dict. v. 4. 308. “Juss. Annal. du Mus. d’Hist. Nat. v. 3. 120. t. 9;” *Pursh*.—Stem herbaceous, thorny, as well as the foliage and calyx. Leaves doubly pinnatifid, lyrate, nearly smooth. *Anthers* declining; the lower one much the largest.—Native of Vera Cruz, from whence Thierry de Menonville brought seeds to the Paris garden. We know not whether the *root* or *stem* be perennial or no, but the plant seems of luxuriant growth, with copious, long, slender, pale-yellow thorns. The *leaves* are green, not hairy, but roughish with minute points, at least in a dry state; the whole leaf, as well as each division, particularly the terminal one, elegantly lyrate; the ribs beset with fine bristly thorns. *Clusters* lateral, dense, with slightly downy stalks. *Flowers* large, yellow, remarkable for the great size of their lowermost *anther*.

S. heterandrum. North American Horned Nightshade. Pursh n. 6.—Stem herbaceous, thorny, as well as the foliage and calyx. Leaves doubly pinnatifid, hairy and downy on both sides; their segments obtuse. *Anthers* spreading; the lower one as long as the corolla. *Berry* enclosed in the armed calyx.—Found by Mr. Nuttall, on the banks of the Missouri, flowering in July. Annual, with large yellow *flowers*. Nearly allied to the last. *Pursh*.

S. capense. Thorny Cape Nightshade. Linn. Suppl. 147. Willd. n. 64. Thunb. Prodr. 37.—Stem shrubby, round, thorny, as well as the foliage and calyx. Prickles crowded, straight. Leaves bluntly pinnatifid, rough with starry hairs. *Fruit-stalks* lateral, in pairs, unarmed, recurved.—Brought by Thunberg from the Cape of Good Hope. The *stem* is woody, very much branched, knotty, rigid, apparently of humble stature, armed with plentiful, sharp, straight, tawny prickles, from a quarter to half an inch long; the young *branches*, and *stalks*, clothed with lax starry hairs. The *leaves* are stalked, barely an inch long, sinuated like an oak-leaf, with two rounded lobes at each side, bearing a few large prickles, and clothed all over with the same starry pubescence as the stalks, though described by the younger Linnæus and Thunberg as naked. The *flowers* we know nothing of. *Berries* globose, orange-coloured, polished, naked, the size of Black Currants, two or three together, on strong recurved *stalks*, shorter than the leaves, and almost entirely destitute of prickles, though the deeply-divided calyx bears several large ones. No figure, nor, till now, any full description, of this species has been published.

S. marginatum. White-margined Nightshade. Linn. Suppl. 147. Willd. n. 65. Ait. n. 31. Jacq. Coll. v. 1. 50. Ic. Rar. t. 45.—Stem shrubby, woolly, prickly, as well as the foliage and stalks. Leaves heart-shaped, waved or sinuated, white-edged; densely woolly beneath.—Said to have been brought by Mr. Bruce, the celebrated traveller, from Abyssinia, or at least from Africa, and introduced at Kew in 1775. Jacquin gives Palestine as its native country. This is a handsome greenhouse shrub, flowering most part of the summer, and distinguished by the pure-white margin of its rather large *leaves*, on the upper side, especially when young. The snowy, granulated, minutely starry pubescence of the whole plant, very dense on the backs of the *leaves*, is also striking. The *prickles* are small and few. *Flowers* the size of a potatoe-blossom, cymose, with purple ribs. *Calyx* woolly, unarmed, splitting unequally. *Fruit* ovate, of a dirty yellow.

S. Vespertilio. Bat-flowered, or Canary, Nightshade. Ait. ed. 1. v. 1. 252. ed. 2. n. 33. Willd. n. 67. Wendl. Hort. Herrenh. fasc. 4. 5. t. 21. (Nyctærium cordifolium; Venten. Malmaif. t. 85.)—Stem shrubby, prickly. Prickles conical. Leaves heart-shaped, undivided; woolly beneath. *Corolla*

SOLANUM.

Corolla irregular. Lower anther greatly elongated.— Brought by Mr. Masson, from the Canary islands, in 1779. A greenhouse shrub, flowering in March and April. The upright branching stem is armed with abundance of short, straight, conical, brownish prickles. Leaves the shape and size of those of the *Catalpa*; green, besprinkled with minute starry hairs, above; densely downy, and hoary, beneath. Flowers about the size of the last, and in like manner lateral and cymose, often, if not always, four-cleft and tetrandrous, their stalks, unarmed calyx, and back of the purple irregular corolla, covered with starry down. Lowermost anther declining, ending in a long recurved beak, as in *S. cornutum* and *heterandrum*, already described, upon which character principally Ventenat founds his genus of *Nycterium*, so called from *νυκτερις*, a bat. Such a genus would differ from *Solanum* nearly as *Celsia* does from *Verbascum*, and if several more species should occur, it might, for convenience at least, be adopted.

S. tomentosum. Woolly Nightshade. Linn. Sp. Pl. 269. Willd. n. 70. Ait. n. 34. Thunb. Prodr. 36. (*S. coccineum*; Jacq. Misc. v. 2. 329. Ic. Rar. t. 43. *S. spinosum*, maximè *tomentosum*; Bocc. Sic. 8. t. 5. f. 1.)—Stem shrubby, with a few bristly prickles. Leaves heart-shaped, unarmed, wavy, clothed with dense starry wool on both sides.—Native of the Cape of Good Hope; introduced into the European greenhouses about the middle of the 17th century. A pretty species, with a zig-zag stem of no great elevation, its branches and whole herbage remarkably woolly and white, with a few scattered, minute, needle-like prickles, especially on the flower-stalks. The pubescence of the young budding leaves is usually tinged with violet. Calyx bell-shaped, cloven half way down, unarmed. Corolla purple or lilac, woolly at the outside. Fruit globose, of a beautiful scarlet, varying in size from that of a pea to a small gooseberry.

S. giganteum. Tall Snowy-leaved Nightshade. Jacq. Coll. v. 4. 125. Ic. Rar. t. 328. Willd. n. 74. Ait. n. 36. (*S. niveum*; Thunb. Prodr. 36. Vahl. Symb. v. 2. 41.)—Stem shrubby, armed with downy conical prickles. Leaves elliptic-lanceolate, acute, unarmed; smooth above; snow-white and downy beneath. Clusters terminal, forked, cymose. Fruit erect.—Native of the Cape of Good Hope. Introduced by Mr. Masson, in 1792. A greenhouse shrub, flowering in June and July, of a tall and striking habit, like that of some *Echium* or *Tournefortia*. The branches are thick and round. Prickles copious, short. Leaves numerous about the tops of the branches, from three to five inches long, stalked, recurved; dark green above; peculiarly white and soft beneath. Flowers numerous, purple, rather small, drooping, on corymbose stalks, which become entirely erect as the fruit advances.

S. rubiginosum. Rusty Nightshade.—Stem shrubby, armed, like the footstalks and ribs of the leaves, with hooked prickles. Leaves elliptical, acute; nearly naked above; downy and rusty beneath. Clusters terminal, forked, cymose. Corolla downy.—Gathered in Cayenne by Mr. Von Rohr, who sent it to Sir Joseph Banks as the *S. rubiginosum* of Richard. But we find no such name in the catalogue of Cayenne plants by this botanist, in the *Actes de la Soc. d'Hist. Nat. de Paris*, v. 1. 105. Aublet appears by his herbarium to have called this species *rhamnoides*, but it does not occur in his book. The dried specimen is distinguished by a peculiarly striking rusty tint, which may possibly not be so strong in the living plant. The branches are round, covered with brown, minutely starry, close down, and armed with numerous, small,

smooth, very sharp, strongly hooked prickles. Footstalks an inch long, angular, similarly clothed and armed. Leaves three or four inches in length, and an inch and a half in breadth, entire, with one rib, prickly in the lower part, and many interbranching veins; their upper surface green, shining, smooth and naked, except a few scattered, rigid, starry hairs, which cause a roughness to the touch; under surface marked with prominent veins, and densely covered with close, shining, rusty or whitish, soft, starry down. Inflorescence similar to the last, to which this fine species seems most akin, but the stalks, calyx, and under side of the corolla, are clothed with rusty starry pubescence. The branch is subsequently continued beyond the flowers.

S. polyacanthos. Many-thorned Nightshade. Lamarck Tabl. Encycl. v. 2. 23. n. 2377. Dict. v. 4. 304. Willd. n. 79. (*S. parviflorum*; Cavan. Ic. v. 3. 19. t. 236. *Phytolacca frutescens spinosissima, foliis angustis et crispis*; Plum. Ic. 218. t. 224. f. 1.)—Stem shrubby, very prickly as well as the foliage. Prickles long, straight, and slender. Leaves linear-lanceolate, obtuse, slightly waved, nearly sessile, hairy. Stalks axillary, single-flowered.—Native of Hispaniola, where our specimen was gathered by Thierry. The whole herbage is excessively prickly, with yellow needle-like thorns, green, rough with starry hairs, not hoary. Leaves copious, an inch and a half long, rather convex, all simple and undivided. Flowers very small, solitary, drooping, white. Berry globose, hardly bigger than a mustard-seed. Calyx unarmed.

S. igneum. Red-spined Nightshade. Linn. Sp. Pl. 270. Willd. n. 80. Ait. n. 37. Jacq. Hort. Vind. v. 1. 5. t. 14. (*S. spiniferum frutescens, spinis igneis, americanum*; Pluk. Phyt. t. 225. f. 5.)—Stem shrubby, prickly, as well as the footstalks and foliage. Prickles scattered, somewhat conical, shining. Leaves lanceolate, entire, slightly downy on both sides.—Native of South America. Cultivated for more than 100 years past in the stoves of this country, where it is most conspicuous for the little shining flame-coloured thorns, sometimes making the shrub look as if on fire. The branches are round. Leaves stalked, green, three or four inches long. Flowers white, often only four-cleft, in slender, simple, lateral clusters.

S. stelligerum. Starry Nightshade. Sm. Exot. Bot. v. 2. 57. t. 88. Brown. n. 8.—Stem shrubby, prickly, with taper thorns. Leaves lanceolate, entire, unarmed; smooth above; densely woolly and veiny beneath. Wool starry. Corymbs lateral.—Native of New South Wales, as well as of the tropical part of New Holland, in which last-mentioned country the prickles were observed by Mr. Brown to be more perfectly straight. This pretty species has not yet appeared in any garden. The stem is bushy, from three to five feet high, with round, downy, leafy, prickly branches, but every other part is unarmed. Leaves about three inches long, on woolly stalks; their upper side green, shining, quite smooth except the rib; under covered with dense white wool, composed of starry hairs, elevated on stalks. Flowers numerous, three-quarters of an inch broad, light blue, with orange anthers, each of whose terminal pores is closed by a separate lid. Berries scarlet, erect, the size of a currant, not longer than the lanceolate segments of their unarmed calyx.

S. Milleri. Miller's Nightshade. Jacq. Coll. v. 4. 209. Ic. Rar. t. 330. Willd. n. 81. Ait. Epit. 374. (*S. trilobatum, floribus parvis albis*; Linn. Sp. Pl. 270. *S. Schirnschuna*; Mill. Dict. ed. 8. n. 32.)—Stem shrubby, armed with hooked compressed prickles. Leaves sinuated or pinnatifid, obtuse, slightly prickly, smooth. Stalks mostly in pairs, single-flowered.—Native of the Cape
of

of Good Hope. Cultivated by Miller in 1762, but we know not whether it exists at present in any garden. The *branches* are irregular and spreading, bearing copious tawny prickles, shaped like those of a wild briar. *Leaves* stalked, an inch or inch and half long, green, sinuated like those of an oak. *Flowers* small, white, not unlike those of *S. nigrum*, but their *calyx* is thorny. *Berries* black, resembling the fruit of that species.

S. trilobatum. Three-lobed Nightshade. Linn. Sp. Pl. 270. Willd. n. 82. Ait. n. 38. Burm. Ind. 57. t. 22. f. 2. — Stem shrubby, armed with hooked compressed prickles. Leaves angular, somewhat three-lobed, obtuse, unarmed, smooth. Flowers racemose.—Native of the East Indies. Cultivated by Miller in 1759. A stove-plant, flowering in August. More slender than the last, with more distant, and less sinuated *leaves*, on longer *stalks*. But the much larger purple *flowers*, in double-branched lateral *clusters*, essentially distinguish the present plant, whose *branches* and *leaves*, the prickles excepted, might be thought to belong to some species of *Boerhavia*. Plukenet's t. 316. f. 5, is rather more like *S. Milleri*, but cannot be precisely determined, for want of the inflorescence.

Section 3. *Branches ending in thorns*. One species.

S. lycioides. Box-thorn Nightshade. Linn. Mant. 46. Willd. n. 83. Ait. n. 39. Jacq. Coll. v. 1. 96. Ic. Rar. t. 46.—Stem shrubby; branches with terminal thorns. Leaves elliptical. Flowers solitary.—Supposed to be a native of Peru. A stove-plant in England, flowering in May and June. Its habit is correctly compared by Linnæus to that of a *Lycium*. The *stem* is woody, with many long, trailing, slender, angular, smooth, leafy *branches*, finally becoming spinous at the extremity. *Leaves* stalked, about an inch long, smooth, entire. *Flowers* elegant, solitary, on lateral slender stalks, an inch in length. Segments of the *calyx* narrow, smooth. *Corolla* light-blue. *Anthers* short, orange. *Berry* scarlet, the size of a currant.

Notwithstanding our having here added twelve species to Willdenow's list, we are conscious that many still remain unsettled, of which we have only imperfect or uncertain specimens. The tropical regions of Africa probably possess several more. Besides those we have noticed, Mr. Brown defines fourteen new species in his *Prodromus* of the Flora of New Holland, under the following names. *S. tetrandrum*, *viride*, and *biflorum*, without prickles. *S. difcolor*, *violaceum*, *sulfuraceum*, *parvifolium*, *ellipticum*, *armatum*, *Hystrix*, *cinerum*, *pungetium*, *campanulatum*, and *echinatum*, with prickles on the stem, stalks, leaves or calyx. Among these the *Hystrix* is most remarkable for having prickles on the corolla itself.

SOLANUM, in *Gardening*, contains plants of the herbaceous, shrubby, and tuberous-rooted, esculent kinds, of which the species cultivated are: the love-apple, or tomato (*S. lycopersicum*); the Ethiopian nightshade (*S. æthiopicum*); the large-fruited nightshade, or egg-plant (*S. melongena*); the woody nightshade, or bitter-sweet (*S. dulcamara*); the mullein-leaved nightshade (*S. verbascifolium*); the shrubby nightshade, or winter cherry (*S. pseudocapsicum*); the oak-leaved nightshade (*S. quercifolium*); the dug-fruited nightshade (*S. mammosum*); the Indian nightshade (*S. indicum*); the Carolina nightshade (*S. carolinense*); the black-spined nightshade (*S. fodomeum*); the Palestine nightshade (*S. sanctum*); and the tuberous-rooted nightshade, or common potatoe (*S. tuberosum*).

In the first sort the fruit is smooth, but varies in form, size, and colour, from which Miller has formed two varieties; the first of which is commonly cultivated in the

south of Europe to put into soups and fauces, to which it imparts an agreeable acid flavour: the fruit is very large, compressed both at top and bottom, and deeply furrowed all over the sides, and of a red-yellow or yellowish colour. The latter is round, about the size of a large cherry, either yellow or red. It is a native of South America, flowering from July to September.

And in the third sort there are varieties with oblong violet-coloured fruit, with an oblong, white, large fruit, with a globular violet-coloured fruit, and with a globular white or variegated fruit. Some make other varieties, as red-fruited, yellow-fruited, prickly-fruited, &c.

Also in the fourth sort there are varieties with flesh-coloured, with white flowers, and with variegated leaves. Some have likewise gold striped-leaved, African thick-leaved, &c.

The sixth sort has also varieties with red and with yellowish fruit.

In the last sort, which is probably a native of Peru, or some part of that tract of continent, the principal varieties may be distinguished into two kinds, as the red-rooted and white-rooted sorts; the sub-varieties of which are extremely numerous; but for garden purposes, the following are the most useful kinds that are generally employed.

The early dwarf-red, the round-red, the oblong-red, the pale-red, the blood-red, the Irish red or painted lord, old winter-red, rough-red, and smooth-red.

Early forcing potatoe, the early dwarf-white, brown early, Cumberland early, early Scot, golden dun, early champion, white blossom, Manly white, kidney-white and red, red-nosed, true white, flat white, and superfine white early.

Many other kinds or varieties are made use of in gardens for raising the late as well as the early crops of this most useful root. In Lancashire, for the very early crops, they have principally recourse to the early kings, and foxes seedlings.

They also cultivate a small everlasting potatoe, as it is called, in the same situations, covering the beds with straw or some other material in the winter season, when necessary. A ready supply of the root may, it is said, be provided in this way by this sort of potatoe.

In the first volume of the Transactions of the Horticultural Society of London, sir Joseph Banks has given the following curious and interesting account of the introduction of this species of solanum, or the common potatoe, into this country and Europe. The notes from which this account has been principally taken, have, it is said, been some of them collected from authorities of difficult access by the learned and very intelligent Mr. Dryander.

It is stated, that the potatoe now in use was brought to England by the colonists sent out by sir Walter Raleigh, under the authority of his patent, granted by queen Elizabeth "for discovering and planting new countries, not possessed by Christians," which passed the great seal in 1584. Some of sir Walter's ships sailed in the same year, others, on board of one of which was Thomas Herriot, afterwards known as a mathematician, in 1585; the whole of them, however, returned, and probably brought with them the potatoe, on the 27th of July, 1586.

The said Thomas Herriot, who was probably sent out, as it is said, to examine the country, and report to those who employed him the nature and produce of the soil, wrote an account of them, which is printed in the first volume of De Bry's Collection of Voyages. In this account, under the article of roots, in p. 17, he describes a plant which is called Opanawk. "These roots are," he says, "round, some as large as a walnut, others much larger;

larger; they grow in damp soil, many hanging together, as if fixed on ropes: they are good food either boiled or roasted."

Gerarde in his *Herbal*, published in the year 1597, gives a figure of the potatoe, under the name of the potatoe of Virginia, and asserts, that he received the roots from Virginia, which are otherwise denominated Norembega.

The manuscript minutes of the Royal Society, 13th of December, 1693, assure us, that sir Robert Southwell, then president, informed the fellows, at a meeting, that his grandfather brought potatoes into Ireland, who first had them of sir Walter Raleigh.

This evidence, it is supposed by sir Joseph, proves, in no satisfactory manner, that the potatoe was first brought into England, either in the year 1586, or very soon after that period, and sent from thence to Ireland without delay, by sir Robert Southwell's ancestor, where it was cherished and cultivated for food before the good people of England knew its value; for Gerarde, who had this plant in his garden in 1597, recommends the roots to be eaten as a delicate dish, not as common food.

It appears, however, he says, that it first came into Europe at an earlier period, and by a different channel; for Clusius, who at that time resided at Vienna, first received the potatoe, in 1598, from the governor of Mons, in Hainault, who had procured it the year before from one of the attendants of the pope's legate, under the name of Taronoffi; and learned from him, that in Italy, where it was then in use, no one certainly knew whether it originally came from Spain, or from America.

Peter Cicca, in his *Chronicle*, which was printed in 1553, tells us, it is said, in chap. xl. p. 49, that the inhabitants of Quito, and its vicinity, have, besides mays, a tuberous root, which they eat, and call papas; this Clusius guesses to be the same sort of plant he received from Flanders, and this conjecture has, it is said, been confirmed by the accounts of travellers, who have since that period visited the country.

It is concluded that, from these details, it may fairly be inferred, that potatoes were brought into Europe from the mountainous parts of South America, in the neighbourhood of Quito; and that, as the Spaniards were the sole possessors of that country, there can be little doubt of their having been carried first into Spain, but that as it would take some time to introduce them into use in that country, and afterwards to make the Italians so well acquainted with them as to give them a name, there is every reason to believe, that they had been several years in Europe before they were sent to Clusius.

As the name of the root in South America is papas, and in Virginia that of opanawk; the name of potatoe was, it is said, evidently applied to it on account of its similarity in appearance to the battata, or sweet potatoe; and our potatoe appears to have been distinguished from that root, by the appellation of potatoe of Virginia, until the year 1640, if not longer.

It is added, that some authors have asserted, that potatoes were first discovered by sir Francis Drake in the South seas, and others, that they were introduced into England by sir John Hawkins; but in both instances, the plant alluded to is, it is said, clearly the sweet potatoe, which was used in England, as a delicacy, long before the introduction of our potatoes; it was imported, it is said, in considerable quantities, from Spain and the Canaries, and was supposed to possess the power of restoring decayed vigour. The kissing comfits of Falstaff, and other confections of similar imaginary qualities, with which our an-

celtors were duped, were, it is said, principally composed of these, and eringo roots.

It is also further noticed, that the potatoes themselves were sold by itinerant dealers, chiefly in the neighbourhood of the Royal Exchange, and purchased, at no inconsiderable cost, by those who had faith in their alleged properties. The allusions to this opinion are, it is observed, very frequent in the plays of that age.

Method of Culture.—These plants, from the great differences in their natures, habits of growth, and other qualities, must evidently require different modes of cultivation and management.

Culture in the Annual Kind.—The three first species, which are of this sort, may be raised from seed, which should be sown in the early spring on hot-beds, moulded over to the depth of six or seven inches with light rich mould, in drills or pots plunged into the beds. When the plants come up, they should be properly thinned, have a pretty free admission of air, and occasional waterings; and the love-apple kinds, when they have attained some growth, as five or six inches, and the weather becomes settled warm, should be removed into the open ground, planting them in a warm sheltered border, and placing them at a considerable distance. Some may be trained against a south fence, to have the advantage of the full sun: they should always be supported by some means or other to shew themselves, and ripen their fruit. But the egg-plants should be pricked out, when a few inches in height, into another hot-bed prepared for the purpose, at the distance of four or five inches; and some may be put in separate pots, and plunged in the bed, giving water and shade till they are fresh rooted; the waterings should be duly repeated, and fresh air freely admitted, when the weather is fine: it may also be requisite to remove them with balls about their roots to a third hot-bed, in order to have them very fine and strong: the frame should be raised as they advance in growth, and when the weather becomes fine and hot, they should be gradually hardened, and finally set out in the pots, &c. where they are wanted.

Culture in the Hardy Shrubby Kind.—The fourth sort, which is of this nature, may be increased by layers and cuttings, which may be laid down or planted out in the autumn or spring, where they will be well rooted by the following autumn, when they may be taken off and removed into nursery-rows, or where they are to grow for good.

Culture in the Shrubby Greenhouse Kind.—Likewise all the eight following sorts, which are of this description, may be increased by seeds, which should be sown thinly in rich light earth in the early spring in small pots, plunging them in the hot-bed under frames and glasses, watering them frequently, when the plants will soon come up, admitting fresh air daily; and when the plants are about two inches high, they should be pricked out upon another hot-bed, giving water and shade, till they are fresh rooted; and some may be put into pots, plunging them in the bed. As the warm weather advances, they should be gradually hardened to the open air, so as to be set out into it about the middle of the summer, when the weather is mild and fine.

And they should afterwards be managed as other shrubby exotic greenhouse plants.

There are also many of the tender shrubby hot-house or stove kinds, that are highly deserving of cultivation, such as the fiery-thorned American, Guinea, tomentose trilobate, and several other species.

These may all be increased by sowing the seeds of them, in the spring, in pots of light earth, to be plunged into a hot-bed;

hot-bed; when the plants are come up two or three inches in height, they should be pricked out separately into small pots, which are also to be plunged into the hot-bed or bark-bed of the stove, afterwards managing them as other shrubby exotics of the stove kind. The propagation and increase of them may likewise be tried, in some cases, by cuttings, which are to be set or planted in pots, and the whole plunged into the bark-bed, covering them close down by means of a hand-glass.

All these plants must be constantly kept in pots filled with light rich earth, and be retained, the most part of the year, in the stove, among collections of that sort, except for just a month or two in the height of the summer, when the heat is considerable. In this way they not unfrequently succeed very well.

These plants, in all the sorts, are very ornamental among other potted plants; and the first is cultivated likewise for the fruit as a pickle: the fourth is also ornamental in the borders, &c. of gardens and small pleasure-grounds.

Culture in the Potatoe Kind.—This last sort is highly valuable for its tuberosus esculent root, which is well known under the title of potatoe. These roots may be obtained for use plentifully almost the year round: the early sorts, being planted forward in the spring, often afford tolerable crops fit to take up in the beginning of June and in July following, especially in rich warm grounds; but the main crops are permitted to continue growing till autumn, as about the latter end of October or beginning of November, when the stalks or haulm begin to decay, at which time the roots will be arrived to full maturity: and being then taken out of the ground, and housed in some close dry apartment, keep in good perfection for eating all winter and spring, until the arrival of the new crops in the following summer.

With regard to the properties of the different sorts or varieties of this root, so far as they relate to their usefulness as food, or their nourishing qualities, there is probably no very material difference; but inasmuch as their agreeableness for the purpose of eating by man is concerned, there is considerable diversity, some sorts being naturally farinaceous and mealy, while other kinds are heavy and clayey, or waxy, the former of which are, for the most part, highly desirable and greatly relished, while the latter are disagreeable to and disrelished by many. The red sorts were formerly held in great esteem, and supposed the best; and though they are most probably in no respect inferior to those of the white kinds, these have of late, in general, been much preferred, especially the round, the oblong-white or whitish red, and the kidney sorts, as being more productive, more saleable in the markets, and the most desirable for eating.

This has caused the culture of the large red sort to be in a great degree overlooked and neglected, though some think that the potatoes of this kind are superior to those of the white sort in the richness of their flavour and some other qualities.

As both sorts, however, possess good qualities in different ways, the best and most useful varieties, in each kind, should be cultivated in sufficient and suitable proportions. The early sorts are, however, the most proper and suitable for being cultivated in gardens in most cases.

It is of importance in the garden, as well as the field, to have good-sized potatoes for sets, or for taking the sets from, whatever the sort may be, as the very small potatoes, or chats, as they are called, never answer well in this intention. And it is equally important to have a frequent change of the seed or sets which are employed for raising the crops, as every two or three years, new, or such potatoes as are fresh from other grounds, being found highly useful in pre-

venting degeneracy and promoting the goodness and abundance of the crops, as well as in obviating their tendency to the curl, which is so greatly injurious to them.

The potatoe is an annual plant, which leaves offsets, tubers, or roots, for its future propagation and increase.

All the varieties may be cultivated with success in any open situation. They delight in a moderately light rather dry soil and open situation, which should be rendered light with dung. The plants are increased by the root, either whole or cut in pieces, each cutting forming a proper set or plant. This is their general method of cultivation; but they may likewise be raised from seed to gain new varieties.

In most places the general season for planting this root is from about the middle or the latter end of February to the middle of April; the early sorts, for forward crops, being planted in the latter end of February or early in March; but for the general crops, March, and the first fortnight in April, is the most proper planting season, especially in moist land; as, if planted earlier, and much wet should succeed, it would rot the sets, more particularly if cuttings; though in cases of necessity, where the ground is not ready before, they may be planted any time in April, or even in May, and yield tolerable crops by October. And the ground for this purpose should always be dug over for the reception of the plants to one full spade deep.

But as to the planting, it may be performed by means of a dibble, by holeing in with a spade, or drilling in with a hoe, bedding in, &c. in rows at two feet asunder, eight, twelve, or fifteen inches distant in each row, and not more than four or five inches deep at the most.

Dibble-planting.—This is performed either with a common large garden dibble, blunted at the bottom, making holes four or five inches deep, at the distance before mentioned, dropping one set into each hole as you go on, and striking the earth in over them, or raking it afterwards, which is a better method.

The surface of the ground should, some time afterwards, be further raked, and left perfectly even and level.

Drill-planting.—In this mode the drills may be formed either with a large hoe, two feet asunder, and four or five inches deep, in which drop the sets a foot asunder, and cover them in with the earth equally the depth of the drill; or the drills may be made with a spade, and the sets covered in by means of a rake, the ground being left quite even on the surface.

Furrow-planting.—This is performed by the spade, by turning over or taking out a spit of earth all along, putting in the dung, and then dropping the sets in the furrow immediately upon it, and with the next spit turning the earth in upon the sets of the first; and in another furrow, two feet from this, putting in the dung and dropping another row of sets, which are covered in as above, and so on till the whole is finished.

Holeing-in planting.—This is performed with a spade. A man having a light handy spade, and beginning at one end of the line, takes out a spit of earth, forms a small aperture four or five inches deep, another person directly following after drops a set in the hole, the earth of the next spit immediately covers it up, and so on to the end of the work.

Trenching-in planting.—This is sometimes practised in light ground, and is effected as the person proceeds in digging or trenching the ground, being trenched in the common way, each trench two spades wide, and one spade deep, placing one row of potatoes in each trench: beginning at one end of the ground, opening a trench the proper width and depth, as above, then paring in the top of the next trench deeply, putting

putting it with some good dung in the bottom of the first, levelling it evenly, then digging along about half the width of the next or second trench, turning the earth into the first upon the dung, only two or three inches in depth, and upon which lay the potatoe-sets in a row along the middle eight or ten inches or a foot or more asunder; then digging along the rest or whole width of the said second trench a moderate spade deep, turning the earth of it into the first trench, over the sets, three or four inches deep; this done, dung the bottom of the open trench, and proceed with the digging and planting as before; and continue trench and trench to the end of the work.

Bedding-in planting.—This is sometimes done in low wet-tish land, for the sake of raising the beds, and sinking the alleys deep enough to drain off the too copious moisture, and is thus performed:—the ground is divided into four, five, or six-feet wide beds, with alleys two or three feet wide between bed and bed; and the beds being dug, the potatoe-sets are placed upon a little littery dung on the surface in rows lengthwise; and then the alleys dug out a spade deep, casting the earth over the sets about three or four inches thick; or the alleys may be first dug out to raise the beds, and the sets then planted with a dibble in the common method: thus, by either of these methods, in wet ground, the alleys being sunk, and the beds raised, the alleys drain off the redundant moisture, which might rot the sets before they begin to sprout out and grow.

And this method of planting is sometimes performed on grass or sward-land, marking out beds as above, with alleys between of proportionable width; then, without digging the beds, the potatoe-sets are placed immediately upon the sward at proper distances; the alleys being then dug and the spits turned grass-side downward upon the beds over the sets, covering them the proper depth as above, in which, if any additional depth is wanted, it may be supplied from the under earth of the alleys; and thus the sets being between two swards, grow, and often are productive of very good crops, if permitted to have full growth. This is a sort of lazy-bed mode of planting, that is not to be much practised in gardens.

In the after-management of the crops, where weeds begin to over-run the ground, two or three hoeings should be given to kill them and loosen the surface of the soil; and when the plants have some growth, some hoe up a ridge of earth close to each side of every row of plants in the first or second hoeing, to strengthen their growth more effectually, and render them more prolific, as the bottom of the stalks so landed up generally emits roots in the earth that become productive of potatoes the same as the principal roots.

In October, when the potatoes are full grown, they should in the general crops be wholly taken up before they are attacked by frost, and deposited in some dry apartment for keeping: some may however be taken up before for occasional use: this business is usually performed by a three-pronged fork, the ends of the prongs being a little blunted. The early crops are to be taken up as they are wanted for use, as seen below.

Before the potatoes are begun to be dug up, whether in the early or late crops, the haulm should be cut close to the ground and cleared away, in the former only to the extent of what is to be taken up at the time, but in the latter for the whole space which is to be dug up in the day, or other length of time, or for the quantity there may be. It is to be turned off in heaps on to the dug land, that the surface of the ground to be dug for potatoes may be rendered perfectly clear and convenient for the work. This is usually

done as the workman proceeds. In forking the crop up, the labour then goes on, by first opening a trench along one end of the ground to the depth and width of a good spit, proceeding in the same way with the rest, throwing the whole of the potatoes, as they are dug up, into large baskets placed for the purpose, carefully digging over all the land in a regular manner spit by spit, turning each clean upside down into the previous open trench. In this manner the whole is to be completed.

The early crops are best taken up as they are wanted, as they do not keep so good when dug up in large quantities.

The haulm is sometimes burnt, in the heaps as they lie upon the ground, but it is probably better to make use of it as litter, or to employ it for some garden purposes, which it may be made to answer.

When become perfectly dry and well freed from dirt and other matters, the potatoes may be put up and secured in the house, when for keeping, all the cut and bruised ones, as well as the chaps or very small ones, being previously sorted out and taken away. Towards the spring they may likewise be rubbed over to take off the sprouts and make them keep better.

When it is intended to raise new varieties from seed, some of the first flowering plants should be marked, the seed should be gathered in autumn when full ripe, and in the March or April following sown in some light soil, in an open situation, in shallow drills a foot asunder; and when the plants come up, they should be kept clear from weeds till autumn, when, about the end of October or beginning of November, the roots may be taken up, selecting the finest and largest, which preserve in sand till spring; then plant them in the common way, and by the autumn following they will have made proper increase, and attain full perfection; when their properties must be determined.

It is not improbable, from what has been written on the subject in the Transactions of the Horticultural Society of London, that much utility and advantage may be derived in the cultivation of the early or proper garden potatoe, from making use of new and more early varieties than such as have been usually employed. Formerly, the early varieties of this root were solely gained by accident from the seeds of the late sorts, and consequently not often produced; as the early sorts or varieties of this plant were well known to seldom or never afford either blossoms or seeds in the common methods of culture, they being only capable of being increased by portions of their tubers or roots. But by having recourse to such methods of management with them, as tend to prevent the preternaturally early forming of their tubers or roots, it has been found that seeds may be readily procured from the most early of the best early sorts, the seeds of which may, it is suggested, in successive crops, at last afford still more early and better varieties, than any which have hitherto been produced. This would be a great and important acquisition, especially in the garden culture of the potatoe. See POTATOE.

The manner of the cultivation of the potatoe in the preceding year, and the state which it is in from it, would seem also to have much influence on the produce of the succeeding year, as great benefit has, it is said, arisen from planting such potatoes as had grown late and not been fully matured in the preceding year. And in the early sorts it has been found, that the earliness likewise of the crops, to some extent, are dependent upon the state of the varieties; so that the success of the cultivator in raising an early crop of this kind, may be good or bad, according to the mode or manner of the culture, in the preceding year, of the tubers or plants. Such varieties as have the appearance of

being expended, worn out, and worthless, may also be restored, in some instances at least, to their original or primary vigour and importance by attention in this way.

Thus, by preparing proper tubers in the preceding year for planting out crops in the succeeding one, great utility may be produced in the garden cultivation of this root, as well as in the field.

In the same Transactions, in speaking of the preventing of the curl, the able president remarks, that the rough and uneven surface of the leaf in this plant, which, in excess, indicates, and indeed constitutes, the diseased state known by the above name, seems to exist in, and to form an essential characteristic, of every good variety of the potatoe; as he has never met with a single variety of the perfectly smooth polished-leaved kind that possessed any degree of excellence. And it is endeavoured to be proved, that this rough and crumpled state of the leaf probably originates in the preternaturally inspissated or thickened state of the fluid, in the firm and farinaceous potatoe. Such varieties, however, as have smooth and polished leaves, are, it is said, in general, the most productive, and grow in the most luxuriant manner, which, it is thought, partly shews, that the smooth leaf is a more perfect and efficient organ than the rough one; the latter indicating, it is supposed, some degree of approximation to disease.

It is stated, that by planting potatoe of an early variety in the same soil from which a crop of the same variety had been taken in the month of July, a second crop was produced. But the tubers produced by those last planted, were found to be much more soft and watery, when boiled, than others of the same variety, and consequently greatly inferior in value for all culinary purposes; they were on that account kept for future planting. It was inferred, on the principles that had been laid down, that the organizable matter these contained, being in a less firm and concrete state, it would prove more disposable, and that in the succeeding season, plants of stronger growth, and more smooth and perfect foliage, might consequently be expected. The result proved the inference to be every way true: the plants presented the appearance of a different variety, and afforded a more abundant crop and larger tubers than had ever before been obtained from the same variety. This trial was, it is said, confined to a single very early kind, which had previously produced partially curled leaves; but, it is supposed, the same method of management will prove equally advantageous with other varieties, which shew similar indications of incipient disease.

If this reasoning and mode of culture should turn out to be correct and well founded, they may be of great use in bettering and promoting the growth of this sort of valuable root.

By other writers this disease in the potatoe plant has, however, been supposed to arise in other ways, and to be of a very different kind; and it is stated, that Mr. Dickson, in the Transactions of the Caledonian Horticultural Society, conceives it to originate in debility, arising from the too great ripeness of the tubers, and in the parent plant having too much expended itself in affording blossoms and seeds, as well as tubers. In proof of which, the very curious fact is related, that a cutting taken from the extremity, which is most firm and farinaceous, of a long or kidney-shaped potatoe, will afford diseased plants, while another cutting taken from the opposite end of the same potatoe, will produce perfectly healthy plants.

But it is thought by Mr. Knight, that this opinion cannot be acceded to, as it is not to be supposed, that a plant which is a native of such a climate as the potatoe, can ever

be over-ripened in so northern a situation; besides, those varieties which never afforded either blossoms or seeds, have in his garden been quite as subject to the disease as others. Nor is it believed that the buds of the firm farinaceous extremity have greater maturity than those at the contrary end, as those nearest the parent plant are in reality the oldest, the tuber being formed by a branch, which has expanded itself in a lateral manner, instead of having extended itself in a longitudinal direction. Consequently the buds of it are arranged as they would have been upon the elongated branch; and every tuber, in its incipient state of formation, will extend itself into a branch, provided the plant, to which it belongs, be cut off close to the ground, and the current of ascending sap be in consequence diverted into, and through the tubers.

It is however found, by both the above inquirers, that a tuber, or part of one, which is soft and aqueous, affords a better plant than one which is firm and farinaceous, or in the mealy state.

It is said, in the corrected Agricultural Survey of Cornwall, that a gardener of Penzance, in that district, can ascertain when a potatoe chosen for a set will produce the curl; as a healthy potatoe will always, in his opinion, be largest, and rounded at its nose-end, while a diseased potatoe runs smaller at its nose-end than at the tail-end, and will produce the curl, if planted. It is noticed, that the form of the diseased potatoe here described is very easily distinguishable in the kidney sort, or in any long-shaped potatoe, but not so readily, or with such facility, in the round kind; yet it is supposed to be capable of being distinguished by attention, and a little practice, in all.

In regard to sets, as whole potatoes do not always answer well for the purpose, and as those of certain large sizes are better than small ones; the best mode of forming them is supposed to be that of taking off the sprout or nose-end, and the umbilical or tail-end of the potatoe, leaving the middle part entirely for the set. The worst mode of cutting the potatoe, in this intention, is, it is said, that of dividing it down the middle, from the nose to the tail, though a method much too commonly practised.

The preparing the sets beforehand, as in the preceding winter, from the fairest and best potatoes, and placing them in such dry situations, as that they may become inculted with their juice, and thereby bleed less before sprouting, than if fresh cut in the spring at the time of planting, is a practice adopted in Ireland with advantage. The set is, of course, stronger, and it puts forth a more vigorous shoot soon after being planted. The planting of small whole potatoes, or sets having more than two strong eyes or buds, is with reason commonly avoided; and those potatoes with a number of eyes, on what is termed the crown of the potatoe, are invariably rejected, with the small potatoes, both being found to produce languid shoots, and a number of small bad potatoes of no value. In all these states they are thought to be improper for planting as sets.

These hints, statements, and conclusions, may serve to extend and improve our knowledge of the nature of a disease which has long been so injurious to potatoe crops. See CURL.

SOLANUM Dulcamara, in the *Materia Medica*. See *Woody NIGHTSHADE*.

SOLANUM Nigrum. See *Garden NIGHTSHADE*.

SOLANUM Pomiferum, *Apple-bearing Nightshade*, in *Botany*, a name given by writers to the nightshades, and plants of several genera allied to those, and bearing large fruits. See *MELONGENA* and *LYCOPERSICON*.

SOLANUM Somniferum, *Sleepy Nightshade*, a name given by

by Caspar Bauhin, and some others, to a species of winter-cherry, the whorled alkekengi with small fruit.

SOLAR, something belonging to the sun.

Thus, we say *solar* fire in contradistinction to *culinary* fire.

SOLAR *Civil Month*. See MONTH.

SOLAR *Cycle*. See CYCLE.

SOLAR *Comet*. See DISCUS.

SOLAR *Eclipse*, is a privation of the light of the sun, by the interposition of the opaque body of the moon. See ECLIPSE.

SOLAR *Month, Rising, Spots*. See the substantives.

SOLAR *System*, the order and disposition of the several heavenly bodies, which revolve round the sun as the centre of their motion; *viz.* the planets, primary and secondary, and the comets. For a scheme of the solar system, see SYSTEM.

SOLAR *Year*. See YEAR.

SOLARI, ANDREA, in *Biography*, a native of Milan, called also del Gobbo. Vafari says he flourished in the time of Correggio; and praises him as a pleasing colourist, and a graceful designer. He is one of those artists whose figures of the Virgin, &c. are constantly sold as Lionardo da Vinci's productions. He died about 1530.

SOLAROSA, in *Geography*, a town of the island of Sardinia; 9 miles N.E. of Oristagni.

SOLARS, three small islands in the East Indian sea, subject to the Dutch, furnished with every kind of provisions: the middlemost is said to have a good harbour for shipping, situated to the E. of Ende island.

SOLATRUM, in *Botany*. See NIGHTSHADE.

SOLCI, in *Ancient Geography*, a port on the southern coast of the isle of Sardinia, between Cherfonnesus and Populum. Ptol.

SOLCK, in *Geography*, a town of the duchy of Stiria; 16 miles W.N.W. of Oberwoltz.

SOLDAN. See SULTAN.

SOLDANELLA, in *Botany*, from *solidus*, a piece of money, a name given to the Sea Bindweed, (see CONVULVULUS,) and to the plant of which we are about to speak, because of the thick orbicular form of their leaves. In like manner *Nummularia* was named, from *nummus*, in allusion to its round flat yellow flowers. (See LYSIMACHIA.)—Linn. Gen. 81. Schreb. 106. Willd. Sp. Pl. v. 1. 808. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 1. 310. Julf. 97. Tourn. t. 16. Lamarck Illustr. t. 99.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Preciæ*, Linn. *Lysimachiz*, Julf. *Primulacæ*, Ventenat, Brown.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five deep, erect, lanceolate, permanent segments. *Cor.* of one petal, bell-shaped, gradually dilated upwards, divided into numerous, linear, straight segments. *Stam.* Filaments five, thread-shaped, very short; anthers simple, arrow-shaped, pointed, converging, shorter than the corolla. *Pist.* Germen superior, roundish; style thread-shaped, about the length of the corolla, permanent; stigma obtuse, notched, downy. *Peric.* Capsule nearly cylindrical, slightly curved, obliquely striated, of one cell, opening with five abrupt notched teeth at the summit. *Seeds* numerous, minute, pointed, attached to a central, columnar, unconnected *receptacle*.

Ess. Ch. Corolla bell-shaped, in many linear segments. Anthers beaked. Capsule cylindrical, of one cell, with several teeth at the summit.

1. *S. alpina*. Alpine Soldanella. Linn. Sp. Pl. 206. Willd. n. 1. Ait. n. 1. Curt. Mag. t. 49. Jacq. Austr. t. 13. Camer. Epit. 254. (*S. alpina*, major et minor; Clus. Hist. v. 1. 308, 309. Ger. Em. 838, 839.)—Na-

tive of the alps of Austria and Switzerland, and the Pyrenean mountains, flowering in spring. With us it is usually reckoned a hardy perennial, but succeeds best in a pot, sheltered in a frame in winter. Few, even of its alpine companions, are more singularly elegant. The root is fibrous. *Stem* none. *Leaves* several, stalked, spreading, round, smooth, convex, nearly or quite entire; somewhat heart-shaped at the base; paler underneath. *Flower-stalks* several, radical, erect, four or five inches high, smooth, each bearing one, two, or three drooping *flowers*, of a delicate purplish blue, occasionally white, with a red *calyx*, and two or three lanceolate *bractæas* at the base of the partial stalks. *Capsule* near an inch long. *Style* various in length.

SOLDANELLA, in *Gardening*, contains a plant of the low, herbaceous, perennial kind, of which the species cultivated is the alpine soldanella (*S. alpina*).

In this sort there is a variety which has all the parts smaller; the petiole is shorter and more slender, and the leaves are not so much rounded, but gradually widen from the petiole.

Method of Culture.—This is increased by parting the roots in autumn, about September, planting them in pots, or in a cool shady situation, where the soil is of a moist loamy kind, being frequently watered when the season is dry, and kept from the sun.

The seeds, soon after they become ripe, may also be sown in pots or boxes, filled with the above sort of mould, being placed in the shade, and frequently watered. The plants rise in the spring, and in the autumn following should be removed into separate pots, to have the protection of a frame in winter. They succeed best in a northern aspect.

These plants afford variety among other potted plants, in different situations about the house.

SOLDAU, or DZIADOREF, in *Geography*, a town of Prussia, in the province of Oberland; 100 miles S. of Konigsberg. N. lat. 53° 2'. E. long. 20° 4'.

SOLDER, SODDER, or Soder, formed from the French *soudure*, of the Latin *solidare*, to strengthen: is a metallic composition, used in foldering or joining together other metals.

For this purpose, it is required that folders melt sooner than the metal to be foldered, that they adhere firmly to its surface, and that they approach as near as may be to the metal foldered in hardness and colour.

The different folders are made of gold, silver, copper, tin, bismuth, and lead; usually observing, that in the composition there be some of the metal to be foldered mixed with some higher and finer metals.

The folder for gold is composed of fine gold, with one-fourth or one-half its weight of fine silver, accurately mixed together by fusion, and afterwards beat out into leaves, somewhat thinner than card-paper, and rendered as soft as possible by annealing. For the method of applying it, see SOLDERING.

Goldsmiths are said to make four kinds of folder; *viz.* folder of eight, where, to seven parts of silver, there is one of brass or copper; folder of six, where only a sixth part is copper; folder of four, and folder of three. It is the mixture of copper in the folder that makes raised plate always come cheaper than flat.

As mixtures of gold with a little copper are found to melt with less heat than pure gold itself, these mixtures serve as folders for gold; two pieces of fine gold are foldered by gold that has a small admixture of copper; and gold alloyed with copper is foldered by such as is alloyed with more copper: the workmen add a little silver as well as copper, and vary the proportions of the two to one another, so

as to make the colour of the folder correspond, as nearly as may be, to that of the piece. A mixture of gold and copper is also a folder for fine copper as well as for fine gold.

Gold being particularly disposed to unite with iron, this metal, with a high alloy of copper, proves an excellent folder for the finer kinds of steel instruments.

For larger works in iron and steel, copper, or an alloy composed of equal parts of tin and iron, is employed.

The folder used by plumbers is made of two pounds of lead to one of block-tin. Its goodness is tried by melting it, and pouring the bigness of a crown-piece on a table; for, if good, there will arise little, bright, shining stars in it.

For silver, two kinds of folder, *viz.* the hard and soft, are used and applied like the gold folder. The hard folder is composed of equal parts of silver and fine brass, and the soft is prepared by fusing the hard folder with $\frac{1}{3}$ th its weight of pure zinc. Another folder for silver may be formed of two parts of fine silver and one part of brass, taking care that these are not long kept in fusion, lest the brass fly off in fumes. For coarser silver, a folder is prepared by melting four parts of fine silver and three of brass, throwing in a little borax, and pouring it out as soon as it is melted.

The folder for copper is made like that of the plumbers; only with copper and tin; and for very nice works, instead of tin, they sometimes use a quantity of silver.

For copper, brass, and the hard alloys of copper, the best hard folder, says Aikin (*Dict.*), is composed of brass and zinc, in the proportion of from eight to sixteen of the former to one of the latter, according to the required hardness. The soft folder is composed of three parts of zinc and one of lead, and is applied by means of a common foldering iron, made red-hot.

Solder for tin is made of two-thirds of tin and one of lead, or of equal parts of each; but where the work is any thing delicate, as in organ-pipes, where the juncture is scarcely discernible, it is made of one part of bismuth, and three parts of pewter.

The pewterers use a kind of folder made with two parts of tin and one of bismuth: this composition melts with the least heat of any of the folders.

The folder for tin, pewter, and lead (or the plumber's folder), says Aikin (*ubi supra*), is of two kinds: the least fusible is composed of equal parts of tin and lead; the more fusible contains, besides, bismuth in various proportions. A very good soft folder is prepared by melting together sixteen parts of tin, eight of lead, and four of bismuth.

Spelter folder is made of one part of brass and two of spelter, and is used by the braziers and copper-smiths for foldering brass, copper, and iron. This folder is improved by adding to each ounce of it one pennyweight of silver. But as this folder does not melt without a considerable degree of heat, it cannot be used when it is inconvenient to heat the work red-hot; and therefore, in this case, copper and brass are foldered with silver.

Though spelter folder be much cheaper than silver folder, yet workmen in many cases prefer the latter. And Mr. Boyle informs us, that he has found it run with so moderate a heat, as not much to endanger the melting of the delicate parts of the work to be foldered; and if well made, this silver folder will lie even upon the ordinary kind itself; and so fill up those little cavities that may chance to be left in the first operation, which is not easily done without a folder more easily fusible than the first made use of. *Works Abridged*, vol. i. p. 135.

As to iron, it is sufficient that it be heated red-hot, and

the two extremities, in this state, be hammered together. By this means they become incorporated one with the other: when it is foldered it is usually done with brass; good tough brass, with borax applied, mixed with water to the consistence of paste.

The duke of Florence's nail, anciently so much admired, as being half iron and half gold, whereas those two metals were deemed irreconcilable, was joined by a kind of folder made by Turneisser, an ingenious chemist of Venice; the secret of which was never discovered till published by Tachenius. This folder is nothing but a little copper, or cyprus vitriol, put between the gold and the iron. For, naturally, the great acidity of the gold reduces the iron into a scoria or rust, when the two are applied over one another; but this inconvenience is removed, by the interposition of a little copper, be it in the smallest quantity imaginable. See the next article.

SOLDERING, or **SODDERING**, among *Mechanics*, the joining and fastening together of two pieces of the same metal, or of two different metals, by the fusion and application of some metallic composition on the extremities of the metals to be joined.

In foldering, some artifice is necessary to make the folder and metals adhere. All the metals, except silver and gold, upon melting, or before, are covered with dross: and all the folders have some of these metals in them: this dross hinders the folder and metal from uniting, and it is necessary to remove it. This is not performed in every kind of foldering by the same materials. The plumbers effect this by greasing the lead, laying on the folder, and melting it with a hot iron, and thus the dross, generated in fusion, unites with the grease, and flows away from the melted metal. The glaziers and tin-men use rosin in powder for the same purpose; for all inflammable substances that will melt are equally conducive to this use. When copper and brass are foldered with pewter, the work is first washed with a solution of sal ammoniac in water, then heated just hot enough to melt the pewter, and the pewter applied to the joint to be foldered. In foldering that requires a greater heat, borax is used.

Thus, in foldering gold, and also silver, take a piece of folder of the proper size and shape, and lay it on the part to be cemented, and sprinkle it over with pulverized borax; then apply the flame of a blow-pipe, which will cause both the borax and folder to fuse, the latter incorporating with, and adhering firmly to, the gold. When the juncture is complete, the piece is left to cool, and the borax is removed by boiling water, or, what is still better, a little dilute sulphuric or muriatic acid. It is observed, that the folder will, in this case, appear considerably paler than the other part, both on account of the silver with which it is alloyed, and of the borax, which always lowers the colour of the gold. This defect, however, may be remedied by melting on the surface of the folder a mixture of two parts of nitre and one of burnt alum, and afterwards washing it off with a soft brush and hot water; by which the natural colour of the gold will be restored, and even heightened. Others direct this operation to be performed by joining together the pieces proposed to be united with fine soft iron wire, and touching the joint to be foldered with a camel's hair pencil, dipped in borax finely powdered, and well moistened with water; and then placing a little folder upon the joint, and applying upon it a large piece of charcoal, and, with a blow-pipe and lamp, blowing upon it through the flame, until it melts the folder; and thus the work is finished. In order to cleanse silver or gold, after it is foldered, make it just red-hot, and let it cool; then boil it in alum-water, in

an earthen vessel, and it will be as clean as when new. If it be gold, boil it in urine and sal ammoniac.

For a method of foldering, particularly useful to optical and mathematical instrument-makers, see GRINDING of *Metallic Specula*.

SOLDIDO, a name given to the samoata.

SOLDIER, a military man, listed to serve a prince or state, in consideration of a certain daily pay.

The word is formed from the Italian, *foldato*, and that from the Latin, *solida*, or *solidata*, of *solidus*, the *solde* or *pay*; though Paquier chooses to derive it from the old Gaulish *foldoyer*, a foldier; and Nicod from *foldurius*.

The foldier is a person who takes pay; the vassal is one who is obliged to serve at his own expence: the volunteer serves at his own expence, and of his own accord.

Du-Cange observes, that the ancient soldiers were not to be short of five feet and a half; and that this measure was called *incoma* or *incommia*.

Every member of a society, capable of bearing arms, is obliged to serve and defend the state; and, therefore, should be disposed to take them up, at the first order of him who has the power of making war. In England this is the prerogative of the king, for to him belongs the right of granting commissions for raising troops; but he cannot compel any person to enlist, nor, without the concurrence of the parliament, keep an army on foot. In ancient times, especially in small states, every member, on a declaration of war, was a foldier: the whole community took up arms, and followed to the war. Soon after a choice was made, and armies formed of select men, whilst the rest of the people pursued their common occupations. At present the use of regular troops is almost every where adopted, especially in powerful states. The public authority raises foldiers, distributes them into different bodies, under the command of generals and other officers, and keeps them on foot as long as it thinks necessary. As every citizen or subject is obliged to serve the state, the sovereign has a right, in case of necessity, to enlist whom he pleases; but he should choose only such as are proper for the occupation of war: and it is highly proper to take, as far as possible, only volunteers, who enlist cheerfully without compulsion. See ENLISTING, IMPRESSING, and VOLUNTEERS.

No person is naturally exempt from taking up arms in defence of the state; the obligation of every member of the society being the same. Those only are excepted, who are incapable of handling arms, and supporting the fatigues of war. This is the reason why old men, children, and women, are excepted. Nevertheless, unless government is compelled by necessity, it should exempt from military service all who are employed in stations useful or necessary to society. Magistrates are, therefore, usually excepted; their whole time not being too much for the administration of justice, and the maintenance of order. The clergy, says Vattel, cannot naturally, and by any right, arrogate to themselves a particular exemption. To defend one's country is an action not unworthy of the most sacred hands. However, the reasons alleged in favour of magistrates may be urged also in behalf of that part of the clergy who are truly useful; such as teach religion, govern the church, and celebrate the public worship. But as for those immense multitudes of useless religious, who, under pretence of dedicating themselves to God, in effect spend their lives in an effeminate idleness, they have no right to claim a privilege that is pernicious to the state; and whilst the prince exempts them from military service, he injures the other members of the community, by throwing on them the whole burden. "I do not pretend," says Vattel, "to advise a prince to fill his

armies with monks, but gradually to diminish a useless class of men, by taking from it injurious and ill-grounded privileges." There is another class of idle persons, the exemption of whom is still more culpable; that useless class of footmen, who fill the houses of the great and wealthy: a class who by their calling corrupt themselves, by displaying the luxury of their master.

Among the Romans, while all the people served alternately in war, their service was gratuitous; but when a choice is made, and standing armies are formed, the state is to pay them; no man owing more than his quota of the public service; and if the ordinary revenues are not sufficient, it must be provided for by imposts. It is just that they who do not serve should pay their defenders. When the foldier is not in the field, there is a necessity of quartering him; and this burden naturally falls on housekeepers: but as it is attended with many inconveniences to the people, it becomes a good prince, or a wise and equitable government, to ease them of it as far as possible. Moreover, the asylums prepared for foldiers and reduced officers, who are grown old in the service, or whom fatigues or the enemy have rendered incapable of providing subsistence for themselves, may be considered as part of the military pay. The ease of these unfortunate victims of war is the indispensable duty of every state, in proportion to its ability. It is contrary, not only to humanity, but to the strictest justice, that generous citizens, heroes who have shed their blood for the safety of their country, should be left to perish with want, or unworthily forced to beg for subsistence.

Mercenary foldiers are foreigners voluntarily engaging to serve the state for money, or a stipulated pay. As they owe no service to a sovereign, whose subjects they are not, the prospect of advantage is their sole motive. It has been a question, however, whether the profession of a mercenary foldier be lawful, or not? or whether individuals may for money, or any other reward, engage to serve a foreign prince in his wars? This question, says Vattel, does not to me appear very difficult to be solved. They who enter into such engagements, without the express or tacit consent of their sovereigns, offend against their duty as subjects. But if their sovereign leaves them at liberty to follow their inclination for a military life, they are absolutely free. Now, every free man may join himself to whatever society he pleases, and which to him appears most advantageous. He may make its cause his own, and espouse its quarrels. He becomes in some measure, at least for a time, a member of the state in the service of which he engages: and as an officer is commonly at liberty to quit the service when he thinks proper, and the foldier at the term of his engagement; if, therefore, this state embark in a war, manifestly unjust, the foreigners may quit its service. And this mercenary foldier having now learnt the art of war, has rendered himself capable of serving his country, whenever it requires his assistance. The last consideration will furnish us with an answer to a question proposed on this head: whether the sovereign may, with equity and decency, permit his subjects to serve foreign powers indiscriminately for money? He may, because his subjects will by this means learn an art, the thorough knowledge of which is both useful and necessary. The tranquillity, the profound peace, which Switzerland has so long enjoyed, in the midst of all the commotions and wars which have agitated Europe; this long repose, it is said, would soon become fatal to it, did not the citizens, by serving foreign princes, qualify themselves for the operations of war, and support their martial spirit.

Mercenary foldiers engage themselves, and enlist voluntarily. The sovereign has no right to compel foreigners;

he is not even to make use of artifice or surprize, for inducing them to engage in a contract, which, like all others, should be founded on candour and probity.

As the right of levying soldiers belongs solely to the nation, so no person is to enlist soldiers in a foreign country, without the permission of the sovereign; and even with this permission, none but volunteers are to be enlisted: for the service of their country is out of the question here, and no sovereign has a right to give or sell his subjects to another. They who undertake to enlist soldiers in a foreign country, without the sovereign's permission; and, in general, whoever alienates the subjects of another, violates one of the most sacred rights both of the prince and the state. It is the crime distinguished by the name of *plagiat*, or man-stealing, and accordingly is punished with the utmost severity in every politic state.

All soldiers, natives or foreigners, are to take an oath to act faithfully, and not desert the service. This is no more than what they are already obliged to, the one as subjects, the other by their engagement; but their fidelity is of so great importance to the state, that too many precautions cannot be taken for rendering it secure. Deserters should be severely punished, and the sovereign, where he judges it necessary, may inflict capital punishment on them. The emissaries, who solicit them to desert, are far more guilty than the recruiters above mentioned.

Good order and subordination, so useful in all places, are no where so necessary as in an army. The sovereign should exactly specify and determine the functions, duties, and rights of military persons, as soldiers, officers, commanders of parties, and generals. He should regulate and fix the authority of commanders of all degrees, the punishments to be inflicted on offences, the form of trials, &c. The laws and orders relative to these several particulars form the military code.

These regulations, the particular end of which is to maintain order in the troops, and to render them capable of performing the best service, constitute what is called military discipline.

Judge Blackstone observes, that in a land of liberty it is extremely dangerous to make a distinct order of the profession of arms. In absolute monarchies this is necessary for the safety of the prince, and arises from the main principle of their constitution, which is that of governing by fear; but in free states, the profession of a soldier, taken singly and merely as a profession, is justly an object of jealousy. In these no man should take up arms but with a view to defend his country and its laws: he puts not off the citizen when he enters the camp; but it is because he is a citizen, and would wish to continue so, that he makes himself for a while a soldier. The laws, therefore, and constitution of these kingdoms, know no such state as that of a perpetual standing soldier, bred up to no other profession than that of war; and it was not till the reign of Henry VII. that the kings of England had so much as a guard about their persons.

The present regulations concerning the regular military force of our country, as contradistinguished from the militia, &c. and for regulating the royal marine forces when on shore, are chiefly contained in the yearly acts against mutiny and desertion. These comprehend the articles of war, enlisting of soldiers, including foreign soldiers, the number of whom allowed to be at one time in the united kingdom is extended by 46 Geo. III. c. 23. to 16,000, muster, the provision of carriages, billeting of soldiers, or quartering them by constables or other magistrates of cities, towns, villages, &c. in livery stables, ale-houses, victualling houses, the houses of sellers of wine by retail, and all houses

of persons selling brandy, strong waters, cyder, or methueglin, by retail; but in no private houses whatsoever; and the rates of subsistence to be paid to innkeepers, &c. for soldiers' quarters; the removal of soldiers in times of election of members of parliament; the mode of apprehending and punishing of deserters; maintenance and setting up trades after their discharge; the probate of their wills, &c. &c. Most of these particulars occur under their respective heads; and for others our limits require us to refer to the acts themselves.

As soldiers, by the annual act of mutiny, are put in a worse condition than any other subjects, so, by the humanity of our standing laws, they are in some cases put in a much better. By stat. 43 Eliz. cap. 3. a weekly allowance is to be raised in every county for the relief of soldiers that are sick, hurt, and maimed; and besides, the royal hospital at Chelsea is established for such as are worn out in their duty. Moreover, officers and soldiers, that have been in the king's service, are by several statutes, enacted at the close of several wars, at liberty to use any trade or occupation they are fit for in any town in the kingdom, (except the two universities,) notwithstanding any statute, custom, or charter to the contrary. And soldiers in actual military service, may make noncupative wills, and dispose of their goods, wages, and other personal chattels, without those forms, solemnities, and expences, which the law requires in other cases. Blackst. Comm. book i. cap. 13.

The profits attending the profession of a soldier, among the Romans, were very considerable. 1. Booty and plunder, with which they frequently returned home loaded, especially after taking any cities or towns; for these were generally given up to be plundered. 2. The subdued countries, which were often divided among the soldiers. 3. Their pay. 4. Clothes. 5. Provisions. 6. Farms and houses in provinces were also given them. 7. Many privileges and immunities, as that none could touch his goods in his absence in the camp. 8. Legacies, which the emperors left to be distributed among them. 9. Donatives. 10. Promotions to military honours lay open to every brave man, though of the meanest birth.

Not only humanity but interest require that great care should be taken of the health of soldiers. Much instruction may be drawn for this purpose from Dr. Pringle's excellent treatise, called "Observations on the Diseases of the Army." He there remarks, that the circumstances of soldiers in time of war differ from those of other people, in that they are more exposed to the injuries of the weather, and always crowded together, whether in camp, barracks, or hospitals: wherefore the most general division of these distempers may be into such as arise from the intemperature of the weather, and those from infection.

Military diseases depending on the weather, are reducible to two sorts, *viz.* to those of summer, and to those of winter. However, as expositions to cold are unavoidable upon the first encampment, as also for some time before the army usually goes into winter-quarters, the winter disorders, beginning about the end of autumn, will not entirely cease before the summer is well advanced; and, on the other hand, as the heats of summer and damps of autumn dispose the body to sickness, the camp-distempers are never quite over with the campaign, but continue some time after the troops retire into winter-quarters.

The summer diseases are all of a bilious or putrid nature, as those of winter are inflammatory. See FEVER, and the articles referred to under that subject.

SOLDIERS, Band of. See *BAND.*

SOLDIERS, Fresh-water, in Botany, a name given in several parts of England to the *fratiotes*, a distinct genus of plants, called by Boerhaave *aloides*.

SOLDIER-Wood. See *MIMOSA.*

SOLDIER'S Gut, in Geography, a cove on the north-east coast of the island of St. Christophers.

SOLDIN, a town of Brandenburg, the capital of a circle, and formerly the capital of the New Mark, situated on a lake of the same name, about six miles long, noted for its lampreys. The town contains about 200 houses, and two churches, and has some manufactures of cloth; 32 miles N. of Francfort on the Oder. N. lat. 53° 2'. E. long. 14° 59'.

SOLDO, in Commerce, a money of account and copper coin in Italy. Ferrara keeps accounts in lire of 20 soldi, or 240 denari correnti. The lira also contains 2 giuli or paoli; and the soldo, 6 quattrini. The feudo di Cambio is reckoned at 4 lire, or 80 soldi. At Florence, accounts are kept in feudo d'oro, ducati, or lire; each of these is divided into 20 soldi, or 240 denari, and distinguished by the names of soldi d'oro, soldi di ducato, soldi di lira; also in paoli of 13½ soldi di lira. Accounts of certain sales of goods are likewise kept in Pezze da otto reali, or livornine of 5¼ lire, which are likewise divided into 20 soldi, or 240 denari di Pezza. The copper coins at Florence are soldi, dueti or pieces of quattrini, single quattrini, and denari or piccioli. At Bologna, accounts are kept in lire of 20 soldi; the soldo, also called Bajocco or Bolognino, is divided into 12 denari, or 5 quattrini. At Rome, the feudo di stampa d'oro is divided into 20 soldi, or 240 denari. The coins at Bologna are of the same denomination, weight, and value, as those at Rome. The bolognini in silver is a single soldi; the copper soldi is its half, and quattrini the fifth part of a soldo. Kelly's Cambist.

SOLDURII, in Antiquity, a kind of military clients, or retainers to the great men in Gaul, particularly in Aquitania, mentioned by Cæsar.

The soldurii were people that shared all the good and ill fortune of their patrons; to whom, if any disaster happened, they either underwent the very same, or killed themselves; and Cæsar assures us, that no one had ever been known to refuse the alternative. Lib. iii. de Bell. Gall.

Vigenere takes them to have been more than common soldiers; and even gentlemen in pension, or appointment. Athenæus calls them *συναποθνησκοντες*, *q. d.* dying together, or with their masters.

SOLE, in Geography, a town of Norway; 6 miles S. of Stavanger.

SOLE, in Ship-Building, a sort of lining, to prevent wearing or tearing away the main part to which it may be attached; as to the rudder, bilgeways, &c.

SOLE is also a name sometimes given to the lower side of a gun-port, which, however, is more properly called the port-ill.

SOLE of a Horse, that plate of horn which, encompassing the fleshy sole, covers the whole bottom of the foot. The sole ought to be thick and strong, and the shoe of a horse so set upon the hoof as not to bear upon it, for otherwise the sole would be hurt, and not only make the horse lame, but destroy the flesh that separates it from the coffin-bone. It has been an absurd practice with some to take out the

sole. It is done without touching the outside of the hoof, as taking off the crust makes a *hoof-cast*. And a horse that has been unsoled, it is said, will recover in a few weeks. But this custom of *drawing* horses' soles, in order to relieve the inflammation of the part, and to promote a free perspiration, is not in the least beneficial, as it leaves such a weakness and tenderness behind, that the poor creatures mostly ever afterwards labour under an incurable lameness. And La Fosse, though he has recommended the practice, has not produced a single instance of its success. In lieu, therefore, of tearing the sole up by the roots, Mr. Wood advises the following method; in the first place, to take off from the tension of the vessels and lessen the inflammation, to draw away blood at the toe and above the hoof; after which, a poultice, composed as below, may be applied. This consists of linseed boiled in water to a pulp, then adding goose-grease, tar, and cow-dung to it; boiling them all together to the proper consistence.

The composition may be put to the foot, and all round the hoof; and a cold charge applied above the coronet. Where there is no great inflammation, the addition of a little soap to the poultice, may assist much in removing any coagulation of blood in that quarter.

When the foot is shaped like the back part of an oyster-shell, and the sole higher than the hoof, so that the whole foot is quite filled up on the lower part, it is called a *crowned sole*.

SOLE Corporation. See *CORPORATION.*

SOLEA, in Geography, a town of Italy, in the department of Panaro; 8 miles N. of Modena.

SOLEA, or Soli, a town of the island of Cyprus, formerly the see of a bishop, and in more ancient times called "Epea;" 30 miles N.N.E. of Bassa.

SOLEA, in Ichthyology, the *sole-fish*, a well-known fish, and much esteemed at table. See *SOAL*.

SOLEÆ, among the Romans, were a kind of sandals or slippers, which covered only the sole of the feet, and were bound on with thongs of leather; instead of which the women, and effeminate persons of the other sex, tied them on with purple-coloured ribbands, or such as were variously adorned with gold and silver.

SOLEBAY, in Geography. See *SOUTHWOLD*.

SOLEBURY, a township of Pennsylvania, in the county of Bucks, containing 1669 inhabitants; 30 miles N. of Philadelphia.

SOLECISM, SOLOECISMUS, in Grammar, a gross impropriety in speech, contrary to the use of language, and the rules of grammar, either in respect of declension, conjugation, or syntax. See *PURITY*.

The word is Greek, *σολοικισμός*, derived from the *Soli*, a people of Attica, who, being transplanted to Cilicia, lost the purity of their ancient tongue, and became ridiculous to the Athenians for their improprieties in it.

An actor on the Roman theatre having made a false gesture, the audience immediately cried out, he had committed a solecism with his hand.

Cicero, ad Herenn. lib. iv. cap. 12. distinguishes in the following manner between *barbarism* and *solecism*. "Latinitas est quæ sermonem purum conservat, ab omni vitio remotum. Vitia in sermone, quominus is latinus sit, duo pollutant esse; solecismus et barbarismus. Solecismus est, cum verbis plurimis consequens verbum superiori non accommodatur. Barbarismus est, cum verbum aliquod vitiose effertur."

Solecism is accounted by grammarians a much greater fault than barbarism, (see *PURITY*,) as it displays a greater ignorance

ignorance of the fundamental rules of the language. However, when solecisms are not very glaring, where they do not darken the sense, or suggest some ridiculous idea, the rhetorician regards them as much more excusable than barbarisms; because the former is accounted solely the effect of negligence, the latter of affectation. Negligence in expression, often the consequence of a noble ardour in regard to the sentiments, is, at the worst, a venial trespass; sometimes it is not even without energy; affectation is always a deadly sin against the laws of rhetoric. It ought also to be observed, that in the article of solecisms, much greater indulgence is given to the speaker than to the writer; and to the writer, who proposes to persuade or move, greater allowances are made, than to him who proposes barely to instruct or please. The more vehemence is required by the nature of the subject, the less correctness is exacted in the manner of treating it. Nay, a remarkable deficiency in this respect is not nearly so prejudicial to the scope of the orator, as a scrupulous accuracy, which bears in it the symptoms of study and art. Æschines is said to have remarked, that the orations of his rival and antagonist, Demosthenes, smelt of the lamp, thereby intimating that their style and composition were too elaborate. If this remark be just, it conveys the greatest censure that was ever passed on that eminent orator. But, as the intermediate degrees between the two extremes are innumerable, both doubtless ought to be avoided. Grammatical inaccuracies ought to be avoided by a writer, for two reasons; one is, that a reader will much sooner discover them than a hearer, however attentive he may be; the other is, as writing implies more leisure and greater coolness than is implied in speaking, defects of this kind, when discovered in the former, will be less excused than they would be in the latter. To enumerate all the kinds of solecism to which writers and speakers are subject, would be both an useless and endless task. The transgression of any of the rules of syntax is a solecism; and almost every rule may be transgressed in a variety of ways. Some of the more flagrant solecisms are those which betray an ignorance of the rudiments of the tongue; and others, which are more the effects of inattention, may be distinguished by the softer name of inaccuracies. For examples of both kinds we refer to Lowth, Priestley, Murray, and other grammarians. See also Campbell's *Philosophy of Rhetoric*, vol. i. b. 2. ch. 3.

SOLEDA, in *Geography*, a town of the island of Cuba; 56 miles S.S.E. of Havana.

SOLEFTA, a town of Sweden, in Angermanland; 40 miles N.N.W. of Hernösand.

SOLEIL. *Ombre de Soleil*. See OMBRE.

SOLEIL *de Mer*, in *Ichthyology*, a name given by the French writers, and by Rondeletius, to a peculiar species of star-fish, of a small size, the legs of which resemble very much the tails of lizards, and are very brittle.

Gesner describes also a species under the name of the sea-moon, *luna marina*, which, he says, is remarkably fragile, and which, from what else he has said of it in its description, appears also to be the same creature. The great character, however, of the creature's legs resembling, both in colour and figure, the end of the common brown land-newt's tail, is so expressive, that it cannot but be always known by it.

These rays are so extremely friable, that it is scarcely possible to touch them without their breaking, and they are not beset with points in the manner of the common rays of the creatures of this kind.

The other rays of star-fishes being furnished with many hundred legs, and these wanting them entirely, it follows,

that in this species the rays themselves must supply the place of legs, and assist the creature in walking; and thence its manner of walking must necessarily be different from that of any other kind. These rays are five in number, and are inserted very near the mouth of the creature, which is always placed in the centre of the star: the part where this aperture is situated, and which may be called the body of the animal, is of a roundish figure; the diameter of it is about a third part of the length of the rays; its under surface is flat, and its upper convex; and it is covered, both above and below, with scales, but they are arranged in different manners.

The common habitations of the sea-stars, on the rough shores of the sea, is no place for these tender creatures, every dash of a wave against a stone, if they were in the way, would break off their limbs; they have the caution, therefore, to fix their residence only in calm places, and where the shore is covered entirely with a deep smooth sand. When the water has forsaken them, they are often seen walking slowly on the shore; and in this case they use their rays as so many legs. As they divide the body of the fish into two equal parts, there is no ray before or behind any where, so that the creature goes with equal ease to any side that it likes. The best motion they are able to make is, however, very slow, and the ground on which they march ought to be very even; for if they attempt to hasten their pace, or if they find any thing uneven in their passage, one or more of their legs usually breaks; and this is the reason why this species is seldom found with its rays perfect. They never bury themselves deep in the sand, but just get under it, so as to be covered; and this they do by advancing two of the rays together, and burrowing carefully with them, and then following them with the rest of the rays and the body. *Mem. Acad. Par.* 1712.

SOLEISSEL, JAMES DE, in *Biography*, a celebrated master of horsemanship, was born in 1617, in the province of Forez. He was educated among the Jesuits, but followed, during his studies, a propensity which he had felt when very young, of attending to the manage, with which, when he arrived at man's estate, he joined the study of the diseases of horses. When he had made himself tolerably perfect in both branches of the science, he commenced teacher of horsemanship to the young noblesse of his province. The reputation which he soon acquired caused him to be invited to assist in the academy for the manage in Paris, where he published a work, entitled "Le Parfait Marechal," which became very popular, and was translated into several languages. He was likewise author of a treatise entitled "Le Marechal methodique," and of a Dictionary of the terms of horsemanship. He was a man of a very respectable private character, and possessed all the accomplishments that were necessary to his profession. He died in 1680.

SOLEK, in *Geography*, a town of Austrian Poland, in the palatinate of Sandomirs; 30 miles N. of Sandomirs.

SOLEMCO, a town of Hungary; 13 miles E.N.E. of Gros Wardein.

SOLEMN, SOLENNIS, something performed with much pomp, ceremony, and expence. Thus we say, solemn feasts, solemn funerals, solemn games, &c.

SOLEMN, in *Law*, signifies something authentic, or that is clothed in all its formalities.

SOLEMN *Acceptance*. See ACCEPTANCE.

SOLEMN *Testament*, in the *Civil Law*, is to be attested by seven persons, and sealed with their seals.

SOLEMN *Marriage*, is that performed in one's own parish-church, after publication of the banns, and in presence of witnesses.

SOLENS, or *Razor-Sheath*, in *Natural History*, a genus of the Vermes Testacea class and order, of which the generic character is as follows. The animal is an ascidia; its shield is bivalve, oblong and open at both ends; the hinge has a subulate reflected tooth; it is often double, and not inserted in the opposite valve. It had its name, *solen*, from the Greek, in which language that word expresses a pipe or tube; this fish, when the shells are closed, very aptly resembling a tube. The Latin writers have called it *unguis*, from its resemblance in colour and consistence to the human nail. The common people in many parts of France call it *couteiller*, and in Italy it is commonly called *cannolicchio*. (See SHELLS.) There are twenty-three species enumerated by Gmelin, which are as follow.

Species.

* **VAGINA**. The specific character of this is, that the shell is linear, straight, roundish, one end emarginated; the hinge is marked with a single opposite tooth in each valve. There is a variety that inhabits the European and Indian seas: it is six or seven inches broad, and only one inch long. The shell is yellowish, divided diagonally into two triangles, one of which is striate longitudinally, the other transversely, and marked with curved bands. This species, and all the others that are found in this genus belonging to this country, are figured by Barbut, Lister, Donovan, and other naturalists.

* **SILIQUA**. The shell of this species is linear, and straight; it has one hinge, which is two-toothed. There is a variety with rosy lunules. The former is found in most European seas, and on our own coasts. The latter is to be met with in the Indian seas. It is seven or eight inches broad, and not more than one and a half inch long. The shell is equally broad and compressed, with a double tooth at the hinge, receiving another opposite, and on one side there is another sharp tooth directed downwards: the colour is of an olive-brown, with a limpid ash-coloured mark dividing the shells diagonally: one part is striate longitudinally, the other transversely.

* **ENSIS**. Shell linear, a little bowed, like a scymitar: it has one hinge, which is two-toothed. It inhabits European seas. The shell is coloured, and marked like that of the siliqua; it is rounded at both ends; the two teeth of one valve are inserted into a triangular hollow of the other.

* **PELLUCIDUS**. Shell sub-arched, sub-oval, pellucid; one hinge two-toothed. This is found on the shores of Anglesea; the shell is thin and pellucid, about an inch broad, with a double sharp tooth in one valve, receiving a single one from the opposite, with a process in each shell pointing towards the cartilage of the hinge.

* **LEGUMEN**. Shell linear, oval, straight; hinges placed in the middle, and two-toothed; one of them bifid. It is found in the European and the Atlantic seas; is two inches and a half broad. The shell is sub-pellucid, radiate, from the hinge to the margin; it is rounded at both ends.

* **CULTELLUS**. The shell of this species is shaped something like a kidney, with a single tooth in one valve and two in the other. It inhabits European and Indian seas, and is more than two inches broad. The shell is fragile, covered with a rough cuticle, under which it is dirty-white, with tawny marks; both ends are rounded.

RADIATUS. Shell oval, straight and smooth, with a transverse depressed rib growing on one side. This is found in India, and is very thin and brittle. The shell is of a violet colour, with four transverse white rays, growing larger towards the thinner margin; the depressed rib run-

ning nearly the length of the shell; the hinge is callous on each side; both valves are two-toothed.

STRIGILATUS. Shell oval, obliquely striate. There is a variety which inhabits the Mediterranean, Atlantic, and Indian seas. The shell is rosy, with two white rays, strong and ventricose; the hinge is a little prominent at the margin, with a thin reflected tooth.

ANATINUS. The shell of this is ovate, membranaceous, and hairy, with a falcate rib at the hinge. It inhabits the Indian ocean, on a sandy bottom. The shell is pellucid, white, thin, like paper; one end rounded and closed, the other gaping, like the beak of a bird: there is a tooth in each valve resembling an ear-picker.

MACHA. Shell oval, oblong, truncate before; one hinge is two-toothed. It is found in the Pacific ocean. It is about six or seven inches long; in colour it is brown, varied with blue; it produces pearl.

BULLATUS. Shell roundish, inflated, sub-striate; the fore-part is gaping, in consequence of its crenatures. This is found in the American and Indian seas; brittle, white spotted or clouded with purple, longitudinally striate, sub-pellucid; hinge with a single tooth, marginal ones remote, compressed, and inserted in a hollow of the other valve.

MINUTUS. Shell oval, angles of the valves serrate. It is found in the northern parts of Europe, among zoophytes; is the size of a cucumber-seed; longitudinally striate, truncate at the top, with acute ferrate ridges, diverging from the hinge towards the top.

VIRENS. The shell of this is ovate-oblong, with tumid bosses. It inhabits Java; is very brittle, diaphanous, white, outwardly greenish, valves unequal, resembling in its shape the *Mya pictorum*; the tip and base hardly closed, with two approximate teeth in one hinge, and none in the opposite.

DIPHOS. Shell oval, straight, smooth, with prominent membranes. It inhabits the Indian ocean, and resembles the *S. radiatus*. It is two inches and a half long, and five broad; covered with a greenish cuticle, under which it is violet, with numerous rays; two of these are more distinct. The hinge has two teeth in one valve, and one in another.

MINIMUS. Shell linear-oval, straight; the hinges are lateral and two-toothed; one of them is bifid. It inhabits Tranquebar; resembles the *S. legumen*, but is much less; the cuticle is yellowish, under which it is clear white; the inner rib runs down the whole shell.

MAXIMUS. Shell linear, oval, straight, with arched striz; hinges lateral, two-toothed. It inhabits the shores of Nicobar; it is a very rare species. The shell is thin and pellucid, white, covered with a yellowish cuticle; it is four inches broad, one and a half long, gaping at both ends; the teeth of the hinge not receiving one another.

COARCTATUS. The shell of this is transversely wrinkled, contracted in the middle, rounded at both ends; hinge in the middle, with sometimes one, and sometimes two teeth in either valve. This is found on the shores of Nicobar, is about three-fourths of an inch long, and two and a half broad. The shell is of a dirty white, and gaping at both ends.

ROSEUS. Shell rosy, equivalve; the tooth of the hinge is rose-bifid, and inserted in a hollow of the opposite valve. It inhabits the Red sea, resembles the *Telina radiata*, but is open at both ends.

SANGUINOLENTUS. Shell oval, quite smooth; the hinge is callous, and two-toothed. It inhabits Jamaica; the beaks are rosy without and within.

STRIATUS. Shell equivalve, transversely striate; hinge with a single tooth. It is also found near the shores of

Nicobar, and is middle-sized. * The shell is thin, rosy, with white rays.

OCCIDENS. The shell of this species is transversely striate, smooth at the protuberant parts, radiate with white and reddish; both the hinges are two-toothed, with a hollow in the middle. Its residence is not known. The shell is marked with white and reddish spots scattered about; is more than four inches broad, and two long; both ends are gaping; the hinge is lateral.

* **CRISPUS.** The shell, in this species, is partly smooth, partly rough with undulate crimped lines; the hinge has a long narrow tooth. It is found in the river Tees, and resembles the *S. anatinus*, though it is thought by some naturalists not to be a distinct species.

SPENGLERI. Protuberances or beaks of the shell two-parted; primary tooth of the hinge rounded, accessory ones long and narrow; one of them is curved. The shell is hardly an inch long, but two and a half broad; it is rounded at both ends.

Rondeletius observes, that there are, among the solens of the same species, males and females, which are easily distinguishable from one another; and that the females are larger, have no variegations on the shells, and are much better tasted than the males. Rumphius has described a very remarkable species of solen, which always remains buried in sand, and which is not properly a bivalve, consisting only of one piece, though of the shape of the solen; he calls this *solen arenarius*. Litter has called the crooked species *solenes curvi*, and some call them the *scymitar* solens.

We have several species of the straight solens, though but few of the crooked ones.

Of the crooked solens, two are the only known species.

1. The *scymitar* solen. 2. The *solen arenarius*, always found in sand.

The shell of this fish is composed of two pieces, which are the two halves of a hollowed cylinder, with an elliptic base, divided in a longitudinal direction. These two pieces are fastened together near one end by a ligament, like that which joins the shells of the muscle or the oyster. From the place where this ligament is fixed, quite to the other end of the shell, there is a membrane fastened to each edge of the shell, and this increases in breadth in proportion to its distance from the place of its origin; so that, viewed externally, it forms a sort of isosceles triangle, the base of which was about two lines in breadth. The colour and consistence of this membrane give it very much the appearance of a piece of parchment; it has a considerable spring in it, and serves on occasion to open, or draw together, the two sides of the shell.

There is another membrane, of the same kind with this, fastened to the other side of the fish, there adhering to each shell, but this is of an equal breadth all the way down: this serves also to shut or open the edges of the shell. When the solen shuts its shell, it folds itself into several longitudinal wrinkles, which open again when the sides of the shells separate.

Hence it is to be observed, that though this shell has a power of opening and shutting, yet the body of the fish is always secured, and is no more exposed to sight at one time than at another, and there is no part where the fish can be seen but at the ends.

This fish lives in the sand on the sea-shore, where it buries itself often a foot and a half, or two feet deep; the length of the shell is, at this time, nearly in a vertical position, and the fish has a power of raising itself at pleasure up to the surface, and sinking down again, while the shell remains all the time buried in its place. Almost all

other animals have a horizontal motion, and the shell-fish of the sea crawl along upon its bottom under water, as the common land animals do on dry ground; but this creature's progressive motion is only vertical, and that confined to a very small compass; all that it is able to do for itself being only to raise itself higher or lower, and sink deeper or rise higher in the sand, within the narrow compass of about two feet at the utmost, as the going beyond that must occasion its destruction. Where these shell-fish are buried in the sand, there is a hole reaching from every one of them to the surface, by means of which they have a free communication with the water: these holes generally are placed in great numbers near one another, and are easily distinguished at a time when the tide has left the shore uncovered. They are not round, but oblong, and somewhat resemble the key-hole of a lock, but that they have a roundness at each end, whereas that usually is rounded only at one.

When it has occasion to ascend out of its hole, nothing more is required than the putting out the end of the leg, swelling it, and thus thrusting itself up to the length of that leg; then retracting it into the shell again, and thrusting out and inflating its end for a second movement of the same kind. These motions may be all perceived in the creature when out of the sand, particularly that by which it buries itself; for if held up in the fingers, it thrusts out the leg, and performs all the motions as if in the sand, making a fruitless attempt to save itself in its old way. Mem. Acad. Par. 1712.

Klein, and some others, have given the name solen to the several species of *tubuli marini*.

SOLENS, in *Geography*, a town of Westphalia; 6 miles S.S.W. of Magdeburg.

SOLENA, in *Botany*, so called by Willdenow, from *σωληνη*, a tube, or pipe, in allusion to the long tube of the flower. For the same reason, Schreber had named this same genus *Cyrtanthus*, but the latter appellation is now bestowed on a very different one. (See **CYRTANTHUS**.) Willd. Sp. Pl. v. 1. 961. (*Cyrtanthus*; Schreb. Gen. 122. Pofqueraia; Aubl. Guian. v. 1. 133. Juss. 201. Lamarck Illustr. t. 163.)—Class and order, *Pentandria Monogynia*. Nat. Ord. *Rubiaceae*, Juss.

Gen. Ch. Cal. Perianth superior, of one leaf, turbinate, in five acute, erect, permanent segments. Cor. of one petal; tube very long, cylindrical, recurved, dilated at the summit, its orifice fringed with hairs; limb in five deep, oblong, obtuse, reflexed segments. Stam. Filaments five, capillary, very short, incurved, somewhat unequal, inserted into the mouth of the tube, between the segments of the limb; anthers oblong, acute at each end, attached by their base. Pist. Germen inferior, elliptical; style capillary, as long as the tube; stigma minute, three-cleft. Peric. Berry elliptical, large, of one cell, full of pulp, and crowned with the calyx. Seeds about twelve, angular, imbedded in the pulp.

Ess. Ch. Calyx five-cleft, superior, permanent. Corolla salver-shaped, with a very long, incurved tube, hairy at the mouth. Stamens inserted into the rim of the tube. Style thread-shaped. Stigma three-cleft. Berry of one cell, with many angular seeds.

1. *S. longiflora*. Guiana Pipe-flower. Willd. n. 1. — (*Pofqueraia longiflora*; Aubl. Guian. v. 1. 134. t. 51.) — Found by Aublet, on the banks of the great rivers of Guiana, flowering in November, and bearing fruit in January. The Galibis call it *Aymara-pofqueri*, because a fish named *aymara* feeds on the berries. The stem is shrubby, five or six feet high, with a hard white wood, and slender, knotty,

knotty, smooth, opposite *branches*. *Leaves* opposite, stalked, elliptical, pointed, entire, veiny, smooth, about four inches long, each pair crossing the next. *Stipulas* in pairs between the footstalks, broad at the base, taper-pointed. *Flowers* about six, in a terminal *corymb*, white, drooping, slender, the tube of each about four inches long. *Fruit* yellow, succulent, sweet, and pleasant, the size of a guinea-hen's egg; the pulp red.

SOLENA is also the name of a genus, of the order of *Cucurbitaceæ*, in Loureiro's *Fl. Cochinch.* 514, which he thus denominates on account of the filaments forming a sort of sheath. The only species is *S. heterophylla*, a native of woods in China and Cochinchina, with which we are unacquainted, but which seems nearly related to *Bryonia*; only the *filaments* are monadelphous, and in the same flower with the *pistil*. The *berries* are scarlet. *Root* tuberous, of many white, oblong, farinaceous knobs, eatable, and, according to the author we follow, useful in consumptions and dysenteries, as well as the seeds.

SOLENANDRIA, so called by Ventenat, in his *Jardin de la Malmaison*, from *σάλω*, a tube, because of the union of the filaments. See GALAX.

SOLENHOFEN, in *Geography*, a town of Germany, in the principality of Anspach; 29 miles S. of Anspach.

SOLENIA, in *Botany*, a third generic name, (see SOLENA and SOLENANDRIA,) derived from *σάλω*, a tube, or pipe, is used in Hoffmann's *Flora Germanica*, v. 2. t. 8, for a minute genus of *Fungi*, whose tubular form it expresses. The species composing this supposed genus are, however, sunk in *Peziza*, by Perfoon in his *Synopsis Fungorum*, 675, of which they constitute the seventh section, being in all four species. See PEZIZA.

SOLENOE, in *Geography*, a town of Russia, in the government of Kolivan; 104 miles S. of Kolivan. N. lat. 52° 45'. E. long. 80° 54'.

SOLENOV, a lake of Russia, 60 miles long and 20 broad, with two islands, between lake Aral and the Caspian sea. N. lat. 43° 50' to 44° 50'. E. long. 56° 14'.

SOLES, in *Ancient Geography*, a town of Asia, in Cilicia, on the sea-coast, afterwards called Pompeiopolis.—Also, a town of the island of Cyprus, in which was a temple of Venus. See SOLOE.

SOLESMES, in *Geography*, a town of France, in the department of the North, and chief place of a canton, in the district of Cambrai; 9 miles E.N.E. of Cambrai. The town contains 3849, and the canton 16,419 inhabitants, on a territory of 140 kilometres, in 17 communes.—Also, a town of France, in the department of the Sarthe; 3 miles N. of Sable.

SOLE-TENANT, in *Law*, he or she who holds lands only in his or her own right, without any other person joined.

E. gr. If a man and his wife hold lands for their lives, the remainder to their son: here, the man dying, the lord shall not have heriot, because he dies not sole-tenant.

SOLEURE, in *Geography*, a canton of Switzerland, holding the eleventh rank in the Helvetic confederacy, stretches partly through the plain, and partly along the chains of the Jura, and contains about 50,000 souls, including the inhabitants of the capital. The soil is, for the most part, fertile in corn; and those districts which lie within the Jura abound in excellent pastures. The trade both of the town and canton is of little value, although the situation is commodious for an extensive commerce. It is divided into eleven districts or bailliages, called interior and exterior; the former are governed by bailiffs, who are senators, and remain in the towns; the latter by bailiffs selected

from the members of the great council, who reside in their bailliages. The inhabitants of the canton are Catholics, excepting those in the bailliage of Buckegberg, who profess the reformed religion. In spiritual offices, the Catholics depend on three bishops; but neither of these bishops can issue any ordinance, or even visit their dioceses, without the approbation of the senate. In this canton are two chapters; also an abbey of Benedictines, four convents, and three nunneries. Its principal charitable institutions are, an hospital at Soleure, and another at Olten, for the reception of burghers, subjects, and foreigners; the foundation of Thurigan, for old persons of both sexes belonging to the burghership; a founding hospital for orphans, and for children of poor burghers; and the hospital of St. Catharine, for the insane and incurables. In ecclesiastical affairs, the inhabitants of Buckegberg, who profess the reformed religion, though subject to Soleure, are under the protection of Bern: and though formerly this complication of political and religious interests created frequent misunderstandings between the two cantons, yet matters were amicably and finally adjusted on the 18th of November, 1618, at the treaty of Winingen. The inhabitants take the oath of fidelity, every third year, to the government of Soleure; but if aggrieved in their religious establishment, can have recourse to Bern. The senate of Bern nominates to the vacant benefices, but the priests are under the necessity of obtaining the confirmation of the chapter of Soleure. Bern also possesses supreme jurisdiction in criminal affairs. Soleure enjoys all the other rights of sovereignty; such as the power of levying taxes, appeals in the last resort, and the decision of all matrimonial and ecclesiastical concerns, with this proviso, that the decision shall be regulated according to the articles of the treaty of Winingen. With respect to the militia, all the males, from the age of 15 to 60, are formed into six regiments, consisting of about 8000 men, exclusive of 240 dragoons, and the corps of artillery, amounting to 600. The colonel of each regiment is always a senator, and the major a member, of the great council. The sovereign power resides in the great council, consisting of 102 members, chosen by the senate, in equal proportion, from the eleven tribes or companies into which the ancient burghers are distributed. The prerogatives of the great council are to enact and abrogate laws; to explain obscure parts of the constitution, and make alterations in the form of government; to levy taxes, declare war, and conclude peace; to contract alliances, receive appeals in criminal cases from the burghers of the capital, and in civil processes above the sum of two Swiss livres, or 6l. 3s.; to confer the new burghership, elect the treasurer, or fourth chief of the republic, from the ancient eleven senators, nominate to the seven exterior bailliages, &c. &c. To be qualified for admission into the great council, the candidate must be twenty years of age, an ancient burgher, and a member of the same tribe in which the vacancy happens. The great council assembles ordinarily once every month; and extraordinarily, when convened by the senate.

The senate, or little council, a constituent part of the great council, is composed of the two advocates or chiefs of the public, who annually alternate; the chancellor, or secretary of state, who has no vote; and 33 senators, drawn from the remaining 61 members of the great council, divided into 11 seniors and 22 juniors. The senate examines and digests all affairs, before they are submitted to the great council; is entrusted with the executive power, and care of the police; receives all appeals in the first instance from the inferior courts of justice; gives judgment in all civil processes, not exceeding

the value of 100 Swiss livres; and possesses supreme and final jurisdiction in criminal causes, except those in which a burgher of the capital is concerned, who may appeal to the great council. The senate also nominates, directly or indirectly, to most of the important charges of the republic; and confers the principal ecclesiastical benefices; it assembles regularly three times a week, and is convoked on extraordinary occasions by the reigning advoyer. A senator must be 24 years of age, a member of the great council, and drawn from the same company to which the last senator belonged.

Government draws its principal revenues, which do not exceed 12,500*l.* *per annum*, from the following sources: *viz.* a tax, called the tax for fortifications, laid on the funds of the tribes and monasteries in the town, and on those of parishes in the baillages; tythes and "rentes foncieres" belonging to the state; tolls; excise on wine; interest of money placed out in the canton and in foreign countries; monopoly of salt; revenues from the baillages; subsidy from France, about 1108*l.*; and sundry small sources, as demesnes, estates, salaries of vacant benefices, &c. The principal departments of government are the tribunals, comprising the inferior courts of justice, and the secret council of seven members; the boards of war; of rights, called "droits regaliens;" of finances, agriculture, and public buildings; of the police; and of ecclesiastical affairs, charitable institutions, and schools. The burghers are divided into ancient and new, the origin of the distinction being dated from 1681. About eighty-five families possess the right of burghership, and of these about thirty-four of the most illustrious supply the members of the great council, and fill the various departments of government. The burghers, both ancient and new, are distributed into eleven tribes or companies, each of which furnishes three senators and six members of the great council. The general assembly of ancient and new burghers, called "Rosengarten," or garden of roses, is held in the church of the Cordeliers on the day of St. John the Baptist, for the purpose of electing or confirming the charges of advoyer, banneret, and grand sautier; and the business of this meeting is conducted with great pomp and ceremony. From the manner of its proceeding, we may justly infer, that the government of Soleure is a most complete aristocracy. The government, however, is said to be mild and equitable; and the people are tranquil and contented. When Switzerland felt the effect of the French revolution, Soleure was one of the eighteen Swiss departments or cantons acceding to the division of 1798, and it formed one of the seventeen departments or cantons, acceding to the constitution of the 29th of May, 1801, and the number of its representatives was three. Soleure contains 288 square miles: its population, before the revolution, was 45,000; its contingent 600; and the era of its reception into the Helvetic confederacy A.D. 1481.

SOLEURE, the capital of the above-described canton, is pleasantly situated upon the Aar, which here expands its banks, and opens into a fine level river. This is a very ancient town; and though we reject the fabulous tradition of its having been built by the patriarch Abraham, it may be allowed that it was one of the twelve towns which were destroyed upon the emigration of the original inhabitants into Gaul. From a number of inscriptions, medals, and other ancient remains, found in its neighbourhood, it appears probable, that it was re-peopled by a Roman colony; and it was certainly a Roman station, as its ancient appellation, "Castrium Solodurense," implies. During the period of barbarism that succeeded the downfall of the Roman empire, it was

facked and destroyed by those northern nations which overran the greatest part of Europe. From the time of its re-establishment to that of its admission into the Helvetic confederacy in 1481, its state resembled that of many other imperial towns, which acquired a gradual accession of territory, and, after various struggles, finally secured independence.

Soleure is a small but very neat town, surrounded by regular stone fortifications, erected in the beginning of the last century; the walls enclose scarcely more than fifty square acres, and, including the suburbs, contain about 4000 souls. The new church, begun in 1762, and finished in 1772, is a noble edifice of whitish-grey stone, drawn from the neighbouring quarries, which is a species of marble, and admits a good polish. The lower part of the building is of the Corinthian, the upper of the Composite order; the façade, which consists of a portico, surrounded by an elegant tower, presents itself finely at the extremity of the principal street. Pizoni was the architect, and the expence amounted at least to 80,000*l.* Amongst the paintings in the interior, which is simple but elegant, the most esteemed is the Last Supper, by Corvi, a Roman artist. The town-house, though not worthy of any particular notice, is the place of meeting for the great council and senate. The public prison is a solid edifice of stone, well adapted to the purpose: the prisoners being confined in separate cells. The public library is of recent origin, and was formed by the Abbé Herman, canon of the cathedral; by whose assiduity and zeal it now contains more than 11,000 volumes. The circumjacent country is pleasing and diversified, and exhibits several points of view, which are as agreeable as wild, and as beautiful as romantic. N. lat. 47° 14'. E. long. 7° 19'. Coxe's Travels in Switzerland, vol. i.

SOLEURE, a town of France, in the department of the Forests; 4 miles N.E. of Longwy.

SOLEUS, in *Anatomy*, a muscle of the calf of the leg. See GASTROCNEMIUS.

SOLEUTINAN, in *Geography*, a small island in the lake of Nicaragua, near the south coast, with a town. N. lat. 11° 23'. W. long. 85° 36'.

SOLFACH, or SOLVA, a small sea-port town in the cwmwd of Mynyw, cantref of Pybidiog, (now called the hundred of Dewifland,) county of Pembroke, South Wales, is seated on the bank, and close to the mouth of the river Solfach, at the distance of 3¼ miles from the city of St. David's. "The estuary," says Mr. Fenton, "forms a curious inlet between two high hills, where a clear trout stream discharges itself, that has its source in Gwayn y Barry, and running by Lanrithan, receives a tributary stream near Llechmeylir, and so by Kerbyd and Carvoriog; then turning southward, after a course of six or seven miles, discharges itself here." The harbour at this place, forming part of St. Bride's bay, is safe and commodious; but the entrance to it is rendered dangerous by a large mass of rock in the mid of the channel. About 30 vessels of different descriptions belong to this port, from 20 to 250 tons.

Solfach may be said to be divided into an upper and lower town, both of which have progressively augmented in houses and inhabitants within the last four years. Historical Tour through Pembrokeshire, by Richard Fenton, esq. F.S.A. 4to. 1811.

SOL-FA-ING, in *Music*, the naming and pronouncing of the several notes of a song, by the syllables *sol, fa, la,* &c. in learning to sing it.

For a view of the origin of these syllables, see *Harmonical HAND*.

Though this system of solmification does not appear to have

have been wholly developed in the writings of Guido, to whom the invention of the gammut and harmonical hand has been commonly ascribed; yet Dr. Burney observes, that writers very near the period in which he lived give him the honour of its discovery; and particularly Sigebert, a monk of Gemblours, in the diocese of Namur, in Brabant, in his Chronicle under the year 1028. John Cotton also, who lived about a century after Guido, says that solmification by the six syllables, *ut, re, mi, fa, &c.* was practised by the English, French, and Germans; but the Italians, he adds, made use of other syllables; and by a passage from the Chronicle of Tours, under the year 1033, cited by Carpentier, in his Supplement to the Latin Glossary of Du-Cange, art. *Gamma*, Guido is put in full possession of the scale and solmification. About the end of the 17th century, the additional syllable *fi* was universally received in France for the seventh of the key of C. The earliest English writer, mentioned by Dr. Burney, who takes notice of the omission of *ut* and *re* in solmification, is Mr. Charles Butler, in his Principles of Music, published in 1636, and after his time the *ut* and *re* were rejected by all the English singing-masters; Dr. Holder, Dr. Wallis, and every writer on music in this kingdom, were unanimous in excommunicating these two syllables, till Dr. Pepusch endeavoured, and not unsuccessfully, to have them again restored.

An ingenious member of the Academy of Arcadia, in Rome, published a pamphlet in 1746, recommending a new method of solmification by twelve syllables, formed into twelve ideal words, *viz. utparè, bomisa, tufoldè, lanosì*, and comprehending the whole scale of semitones, from C to c exclusive. This method is approved by the celebrated composer Hasse, and by signor Giambattista Mancini, singing-master to the imperial family at Vienna. Signor Serra, in a treatise published at Rome in 1775, proposes to name the notes in singing by the seven first letters of the alphabet, distinguishing the flat, natural, and sharp notes by the addition of the three first vowels to the seven letters, as *ca*, *c* flat, *ce*, *c* natural, and *ci*, for *c* sharp, by which means the student is disembarrassed from all the mutations, and every found in the scale has a specific and invariable name appropriated to it. This method has been approved by several of the best masters in Rome.

Of the seven notes in the scale, *ut, re, mi, fa, sol, la, si*, only four are in use among us, *viz. fa, sol, la, mi*. Their office is principally in singing, that by applying them to every note in the scale, it may not only be pronounced more easily, but chiefly that, by them, the tones and semitones of the natural scale may be better marked out and distinguished.

The design is obtained by the four syllables, *fa, sol, la, mi*: thus, from *fa* to *sol* is a tone; as also from *sol* to *la*, and from *la* to *mi*, without distinguishing the greater or less tone; but from *la* to *fa*, also from *mi* to *fa*, is a semitone.

If then these be applied in this order, *fa, sol, la, fa, sol, la, mi, fa, &c.* they express the natural series from *c*; and if that be to be repeated to a second or third octave, we see by them how to express all the different orders of tones and semitones in the diatonic scale; and still above *mi* will stand *fa, sol, la*; and below it, the same reversed, *la, sol, fa*; and one *mi* is always distant from another by an octave; which cannot be said of any of the rest, because after *mi* ascending, comes always *fa, sol, la, fa, sol, la*, which are repeated invertedly, descending.

To conceive the use of this: it is to be remembered, that the first thing in teaching to sing, is to make one raise a scale of notes by tones and semitones to an octave, and descend again by the same notes, and then to rise and fall by greater

intervals, at a leap, as a third, fourth, fifth, &c. and to do all this by beginning at notes of different pitch. Then these notes are represented by lines and spaces, to which those syllables are applied; and the learner is taught to name each line and space by its respective syllable, which makes what we call *sol-fa-ing*; the use of which is, that while they are learning to tune the degrees and intervals of sound, expressed by notes set on lines and spaces, or learning a song to which no words are applied, they may do it the better by means of an articulate sound; but chiefly, that by knowing the degrees and intervals expressed by these syllables, they may more readily know the true distance of notes.

Mr. Malcolm observes, that the practice of *sol-fa-ing*, common as it is, is very useless and insignificant, either as to the understanding or practicing of music, yet exceedingly perplexing; the various applications of the several names, according to the various signatures of the clef, are enough to perplex any learner; there being no less than seventy-two different ways of applying the names, *sol, fa, &c.* to the lines and spaces of a particular system.

SOLFATARA, in *Geography*, a volcanic mountain, styled by the ancients the "Court of Vulcan," situated to the S. of the city of Naples. Its form is circular, and it is environed by hills of moderate elevation; and notwithstanding the vicinity of the fire, vines and fruit-trees grow very well on the outer declivity. The floor of the crater is white as chalk, composed of various materials, which, from the steam that rises, have been converted into a marly clay; or, perhaps, this was their original state, before they were acted upon by fire. Tiles placed over vent-holes, and serving as retorts, collect condensed alum, sal ammoniac, and sulphur: the air is very hot, and discolours paper and metals. Mr. Swinburne says, that the ground quaked and rebounded under his feet; and others conjecture that the hollow beneath is connected with mount Vesuvius: by laying his ear close to the ground, he could distinguish the bubbling and hissing of boiling water; and yet upon part of this crust or floor, chestnut-trees flourish in perfect vigour, and a variety of shrubs shoot up along the banks, where they find level ground into which to strike root, and are out of the blasting smoke. These hidden waters have their issue on the N. side of the mountain, where, in a dark valley, a fetid burning stream breaks out, and pursues its course among rocks and bushes, to the lake of Agnano. The Solfatara has not emitted flames within the memory of man, so that it is a kind of half extinct volcano; but wet weather increases the quantity of its smoke. Here are manufactures of sulphur, alum, and vitriol.

SOLFATARA, or *Lago di Bagni*, a lake of Italy, in the Campagna di Roma, containing several moveable islands of matted sedge and herbage, which may be pushed about by poles. The water is chalky and sulphureous; towards the surface hardly lukewarm, but at a greater depth, hot and continually boiling. Bathing in this water is recommended for cutaneous diseases: from the lake a river issues, which runs into the Tiber, 11 miles S.E. of Rome.

SOLFEGGIAMENTO, in the *Italian Music*, compositions, of which the syllables, *ut, or do, re, mi, fa, &c.* are the subject. See the next article.

SOLFEGGIARE, Ital. *Solfier*, Fr. is what the vulgar in England call *sol-fa-ing*. All these expressions imply the same thing,—naming the intervals in the first lessons of singing; for which, among regular bred musicians, the proper term in English is *solmification*; which see.

The *solfeggios*, or exercises for the voice, composed by Lco for the vocal students in the conservatories of Naples, were

were used, during the chief part of the last century, by all finging-masters unable to write to the wants and abilities of their scholars. But the passages in these, though excellent in their day, being now worn out and common, are generally superseded by the *solfeggii* of Aprile.

SOLFERINA, in *Geography*, a town of Italy, in the duchy of Mantua; 17 miles N.W. of Mantua.

SOLFWITZBURG, **SOLVESBORG**, or *Sylvisborg*, a seaport town of Sweden, in the province of Blekingen. This town, formerly more flourishing than it is at present, is almost furrounded by the Baltic sea. It has a harbour, and a castle in a ruined state. It is said to be the place where the Lombards assembled when they left their country, and migrated in search of new habitations; 35 miles W.S.W. of Carlscrona. N. lat. $56^{\circ} 9'$. E. long. $14^{\circ} 26'$.

SOLI, or *Asbaja Tuffa*, a town of Bosnia; 20 miles W.N.W. of Zwornick.

SOLI, or *Jokari Tuffa*, a town of Bosnia; 16 miles W.N.W. of Zwornick.

SOLIANOI, a fortrefs of Russia, in the government of Kolivan, on the Irtsch. N. lat. $54^{\circ} 20'$. E. long. $75^{\circ} 14'$.—Also, a town of Russia, in the government of Irkutsk; 20 miles N.N.W. of Selenginsk.

SOLIANSKOI STANITZ, a town of Russia, in the government of Irkutsk, on the Lena; 16 miles N.E. of Olekminsk.

SOLICITATION of Gravity. See **PARACENTRIC**.

SOLICITOR, or **SOLLICITOR**, *Solicitor*, a person employed to follow, and take care of, other persons' suits depending in courts of law or equity; formerly allowed only to nobility, whose menial servants they were; but now regularly admitted to practise in the court of chancery. See **ATTORNEY**.

The king has a solicitor-general, who holds his office by patent, during the king's pleasure. The attorney-general and he had anciently a right to their writs of summons, to sit in the lords house on special occasions, till the 13 Car. II. since which time, they have almost constantly been chosen members of the house of commons.

The solicitor-general has the care and concern of managing the king's affairs, and hath fees for pleading, besides other fees arising by patents, &c. He hath his attendance on the privy-council; and the attorney-general and he were anciently reckoned among the officers of the exchequer: they have audience, and come within the bar in all other courts.

To the queen's household there belongs also an officer with this appellation. See **PRECIDENCE**.

SOLID, in *Physics*, a body whose minute parts are connected together, so as not to give way or slip from each other, upon the smallest impression.

The word is used in this sense, in contradistinction to *fluid*.

SOLID Bodies, Atmosphere of. See **ATMOSPHERE**.

For the laws of gravitation of solids, immersed in fluids specifically, either lighter or heavier than the solids, see **GRAVITY and FLUID**.

To find the specific gravity of solids, and its ratio to that of fluids, see *Specific GRAVITY*.

For the laws of the resistance of solids moving in fluids, see **RESISTANCE**.

SOLID, in *Geometry*, is a magnitude endued with three dimensions, or extended in length, breadth, and depth. Hence, as all bodies have these three dimensions, and nothing but bodies, solid and body are frequently used indiscriminately.

A solid is terminated, or contained, under one or more

planes or surfaces, as a surface is under one or more lines. From the circumstances of the terminating lines, solids become divided into *regular* and *irregular*.

SOLIDS, Regular, are those terminated by regular and equal planes.

Under this class come the tetraëdron, hexaëdron or cube, octaëdron, dodecaëdron, and icoëdron. See **TETRAEDRON, CUBE, &c.**; and for the measure of these bodies, see **MENSURATION**.

SOLIDS, Irregular, are all such as do not come under the definition of regular ones. Such are the sphere, cylinder, cone, parallelogram, prism, pyramid, parallelepiped, &c.

For the ratio of geometrical solids, all prisms, parallelepipeds, cylinders, pyramids, and cones, are in a compound ratio of their bases and altitudes; so that if the bases be equal, they are in the simple ratio of the altitudes; or, if the altitudes be equal, they are as their bases: and as the bases of cylinders and cones are circles, and circles are in the duplicate ratio of their diameters, it follows that all cones and cylinders are in a ratio compounded of the direct ratio of their altitudes, and the duplicate ratio of their diameters.

The geneses, properties, ratios, constructions, dimensions, &c. of the several solids, regular and irregular, spherical, elliptical, conical, &c. see under each respective article. See also **MENSURATION**.

SOLID, Measure of a. See **MEASURE**.

SOLID, Cubature or Cubing of a. See **CUBATURE and SOLIDITY**.

SOLIDS, To find the Surfaces of. See **AREA, SUPERFICIES, and MENSURATION**.

SOLID of the least Resistance. See **RESISTANCE and ISOPERIMETRY**.

SOLID Angle, is that formed by three or more plain angles meeting in a point. (See **ANGLE**.) Or, more strictly, a solid angle, as B (*Plate XIV. Geometry, fig. 1.*), is the inclination of more than two lines, A B, B C, B F, which concur in the same point B, and are in the same planes.

Hence, for solid angles to be equal, it is necessary they be contained under an equal number of equal planes, disposed in the same manner.

And as solid angles are only distinguishable by the planes under which they are contained, and as planes thus equal are only distinguishable by comprence, they are similar; and consequently similar solid angles are equal, and *vice versa*.

The sum of all the plane angles constituting a solid angle, is always less than 360° ; otherwise they would constitute the plane of a circle, and not a solid.

The theory of solid angles is, perhaps, rather a subject of curiosity than utility; yet as it has given rise to much discussion amongst mathematicians, it may not be amiss to bestow a few lines in explanation of what we consider to be the most scientific method of considering this subject.

Euclid defines a solid angle to be that which is made by the meeting of more than two plane angles, which are not in the same plane, in one point; but a more general definition is, that "a solid angle is the angular space included between several plane surfaces, or one or more curve surfaces, meeting in the point which forms the summit of the angle."

According to this definition, solid angles bear just the same relation to the surfaces which comprise them, as plane angles do to the lines by which they are included; so that, as in the latter, it is not the magnitude of the lines, but their mutual inclination, which determines the angle; just so, in the former, it is not the magnitude of the planes, but their mutual inclinations which determines the angles. And

hence,

SOLID ANGLE.

hence, all those geometers, from the time of Euclid, who have confined their attention principally to the magnitude of the plane angles, instead of their relative positions, have never been able to develop the properties of this class of geometrical quantities; but have affirmed, that no solid angle can be said to be half or double of another; and have spoken of the bisection, trisection, &c. of solid angles, even in the simplest cases, as impossible problems. But all this supposed difficulty vanishes, and the doctrine of solid angles becomes simple and universal in its application, by assuming *spherical surfaces* for their measure, just as circular arcs are assumed for the measure of plane angles. This idea seems to have first occurred to Albert Girard, and published by him in his "Inventions Nouvelles en l'Algebra," an account of which is given at p. 7, vol. iii. Montucla's History of Mathematics. The principle of this method, however, seems to have escaped the attention of geometers, till it was recently brought forward again in vol. iii. of Hutton's Course of Mathematics, the writer of which, it should be observed, was not aware of the subject having been previously treated on the same principles by Girard. We shall, in what follows, avail ourselves of the latter article.

Imagine, then, that from the summit of a solid angle, (formed by the meeting of three planes,) as a centre, any sphere be described, and that those planes are produced till they cut the surface of the sphere; then will the surface of the spherical triangle, included between those planes, be a proper measure of the solid angle, made by the planes at their common point of meeting, for no change can be conceived in the relative position of those planes, without a corresponding and proportional mutation in the surface of the spherical triangle. If, in like manner, the three or more surfaces, which by their meeting constitute another solid angle, be produced till they cut the surface of the same, or an equal sphere, whose centre coincides with the summit of the angle; the surface of the spheric triangle, or polygon, included between the planes which determine the angle, will be a correct measure of that angle. And the ratio which subsists between the areas of the spheric triangles, polygons, or other surfaces thus formed, will be accurately the ratio that subsists between the solid angles, constituted by the meeting of the several planes or surfaces at the centre of the sphere.

Hence the comparison of solid angles becomes a matter of great ease and simplicity; for, since the areas of spherical triangles are measured by the excess of the sums of their angles, each above two right angles, and the areas of spherical polygons, of n sides, by the excess of the sum of their angles above $(2n - 4)$ right angles, it follows, that the magnitude of a trilateral solid angle will be measured by the excess of the sum of the three angles, made respectively by its bounding planes above two right angles; and the magnitude of solid angles, formed by n bounding planes, by the excess of the sum of the angles of inclination of the several planes above $(2n - 4)$ right angles.

As to solid angles, limited by curve surfaces, such as the angles at the vertex of cones; they will manifestly be measured by the spheric surface, in the same manner as angles determined by plane surfaces, are measured by the triangles or polygons they mark out upon the same, or an equal sphere. In all cases, the maximum limit of solid angles will be the plane towards which various planes determining such angles approach, as they diverge farther from each other about the same summit; the same as a right line is the maximum limit of plane angles, being formed by the two bounding-lines, when they make an angle of 180° . The maximum limit of solid angles is measured by the surface of the hemisphere, in

like manner as the maximum limit of plane angles is measured by the arc of a semicircle. The solid right angle (the angle, for example, of a cube) is $\frac{1}{4} = (\frac{1}{2})^2$ of the maximum solid angle; while the plane right angle is half the maximum plane angle.

The analogy between plane and solid angles being thus traced, we may proceed to exemplify this theory by a few instances; assuming 1000 as the numeral measure of the maximum solid angle = 4 times 90° solid = 360° solid.

1. The solid angles of right prisms are compared with great facility. For of the three angles made by the three planes, which by their meeting constitute every such solid angle, two are right angles, and the third is the same as the corresponding plane angle of the polygonal base; on which, therefore, the measure of the solid angle depends. Thus, with respect to the right prism with an equilateral triangular base, each solid angle is formed by planes, which respectively make angles of 90° , 90° , and 60° . Consequently, $90^\circ + 90^\circ + 60^\circ - 180^\circ = 60^\circ$, is the measure of such angle, compared with 360° , the maximum angle, and is therefore one-sixth of the maximum angle.

A right prism, with a square base, has, in like manner, each solid angle = $90^\circ + 90^\circ + 90^\circ - 180^\circ = 90^\circ$, which is one-fourth of the maximum angle; and thus it may be found that each solid angle of a right prism, with an equilateral

triangular base	=	$\frac{1}{6}$ max. angle	=	$\frac{1}{6}$.1000
square base	=	$\frac{1}{4}$	=	$\frac{1}{4}$.1000
pentagonal base	=	$\frac{1}{10}$	=	$\frac{1}{10}$.1000
hexagonal	=	$\frac{1}{6}$	=	$\frac{1}{6}$.1000
heptagonal	=	$\frac{1}{14}$	=	$\frac{1}{14}$.1000
octagonal	=	$\frac{1}{8}$	=	$\frac{1}{8}$.1000
nonagonal	=	$\frac{1}{18}$	=	$\frac{1}{18}$.1000
decagonal	=	$\frac{1}{10}$	=	$\frac{1}{10}$.1000
undecagonal	=	$\frac{1}{22}$	=	$\frac{1}{22}$.1000
duodecagonal	=	$\frac{1}{12}$	=	$\frac{1}{12}$.1000
m -gonal	=	$\frac{m-2}{2m}$	=	$\frac{m-2}{2m}$.1000

Hence it may be shewn, that each solid angle of a regular prism with triangular base, is *half* each solid angle of a prism of an hexagonal base. Each with regular

square base	=	$\frac{2}{3}$ of each with regular octagonal base.
pentagonal	=	$\frac{3}{4}$ - - - decagonal.
hexagonal	=	$\frac{4}{5}$ - - - duodecagonal.
$\frac{1}{2}$ m -gonal	=	$\frac{m-4}{m-2}$ - - - m -gonal.

Hence, again, we may infer, that the sum of all the solid angles of any prism of triangular base, whether that base be regular or irregular, is half the sum of the solid angles of a prism of quadrangular base, regular or irregular; and the sum of the solid angles of any prism of

tetragonal base	=	$\frac{3}{4}$ sum of angles of pentagonal base.
pentagonal base	=	$\frac{4}{5}$ - - - hexagonal.
hexagonal base	=	$\frac{5}{6}$ - - - heptagonal.
m -gonal base	=	$\frac{m-2}{m-1}$ - - - $(m+1)$ -gonal.

2. Let us now compare the solid angles of the five regular bodies. In these bodies, if m be the number of sides of each face; n the number of planes which meet at each

solid angle; $\pi = \frac{1}{2}$ circumference, or 180° ; and A the plane angle made by two adjacent faces; then we have

$$\sin. \frac{1}{2} A = \frac{\text{cof. } \frac{\pi}{n}}{\text{fin. } \frac{\pi}{m}}$$

This theorem gives for the plane angle formed by every two contiguous faces of the tetraëdron, $70^\circ 31' 42''$; of the hexaëdron, 90° ; of the octaëdron, $109^\circ 28' 18''$; of the dodecaëdron, $116^\circ 33' 54''$; of the icosaëdron, $138^\circ 11' 23''$. But in these polyedra, the number of faces meeting about each solid angle are 3, 3, 4, 3, 5, respectively. Consequently the solid angles will be determined by the subjoined proportions.

$$360^\circ : 1000 :: \begin{cases} 3 (70^\circ 31' 42'') - 180^\circ : 87.736 \text{ tetraë.} \\ 3 (90^\circ) - 180^\circ : 250 \text{ hexaë.} \\ 4 (109^\circ 28' 18'') - 180^\circ : 216.351 \text{ octaë.} \\ 3 (116^\circ 33' 54'') - 180^\circ : 471.395 \text{ dodecaë.} \\ 5 (138^\circ 11' 23'') - 180^\circ : 419.301 \text{ icosaë.} \end{cases}$$

3. Solid angles at the vertices of cones, will be determined by means of the spheric segments cut off at the bases of those cones; that is, if right cones, instead of having plane bases, had bases formed of the segments of equal spheres, whose centres were the vertices of cones, the surface of those segments would be the measures of the solid angles at the respective vertices. Now the surface of spheric segments, is to the surface of the hemisphere, as the altitudes to the radius of the sphere; and, therefore, the solid angle at the vertices of right cones, will be to the maximum solid angle, as the excess of the slant side above the axis of the cone, to the slant side of the cone. Thus, if we wish to ascertain the solid angles at the vertices of the equilateral and right-angled cones; the axis of the former is $\frac{1}{2} \sqrt{3}$, and of the latter $\frac{1}{2} \sqrt{2}$, the slant side of each being unity. Hence,

$$1 : 1 - \frac{1}{2} \sqrt{3} :: 1000 : 133.97 \text{ angle at vertex equilateral cone.}$$

$$1 : 1 - \frac{1}{2} \sqrt{2} :: 1000 : 292.98 \text{ - - - right-angled.}$$

4. From what has been said, the mode of determining the solid angles at the vertices of pyramids will be sufficiently obvious. If the pyramids be regular ones, and N represent the number of faces meeting about the vertical angle in one, and A the angle of inclination of each two of its plane faces; also n the number of planes meeting about the vertex of another, and a the angle of inclination of each two of its faces; then will the vertical angle of the former, be to the vertical angle of the latter, as

$$NA - (N - 2) 180^\circ, \text{ to } na - (n - 2) 180^\circ.$$

If a cube be cut by diagonal planes into six equal pyramids, with square bases, their vertices all meeting in the centre of the circumscribing sphere; then each of the solid angles made by the four planes meeting at each vertex, will be $\frac{1}{3}$ d of the maximum solid angle; and each of the solid angles at the bases of the pyramids will be $\frac{1}{2}$ th of the maximum solid angle. Therefore, each solid angle at the base of such pyramid is $\frac{1}{3}$ th of the solid angle at its vertex, and if the angle at the vertex be bisected, either of the solid angles arising from the bisection will be double of either solid angle at the base; hence also each solid angle of a prism with equilateral triangular base, will be half each vertical angle of these pyramids, and double each solid angle at their base.

SOLID Figures, Like. See LIKE.

SOLID Bastion. See BASTION.

SOLID Place. See LOCUS.

SOLID Foot. See FOOT.

SOLID Numbers, are those which arise from the multiplication of a plain number, by any other whatsoever.

Thus, 18 is a solid number made of 6 (which is plain) multiplied by 3; or of 9 multiplied by 2.

SOLID Problem, in Mathematics, is one which cannot be geometrically solved, but by the intersection of a circle and a conic section; or by the intersection of two other conic sections besides the circle.

Thus, to describe an isosceles triangle on a given right line, whose angle at the base shall be triple to that at the vertex, is a solid problem, resolved by the intersection of a parabola and a circle.

SOLID Root, among Botanists, expresses the whole root to be one uniform lump of matter.

SOLID Square, in Military Language, a body of foot where both ranks and files are equal.

SOLID Theorem. See THEOREM.

SOLID Celery, in Gardening, that sort which is of a firm crisp nature, without any kind of opening or hollowness in the middle part of the stems. There is a sort of this kind, which has a very slight reddish tinge, that is greatly esteemed in some places. Solid celery commonly eats in a more crisp and agreeable manner than the hollow sort, and on that account is, for the most part, cultivated in the gardens of those who do not raise the plant for sale; but in the market-gardens, where sale is the great object, the common hollow kind is the sort that is the most in cultivation, as it grows much more quickly, and of course becomes sooner ready to be disposed of in the market, nor does the solid sort stand the frost so well in the winter. Celery being ready at an early period is a matter of very great importance and consideration in these situations, in consequence of the difference in price being often so great, as that which is early will not unfrequently fetch double the price, and more, of that which is late. See APIUM.

Neither this solid sort, nor the tall or giant celery, as it is called, are commonly thought so fit for winter crops. This solid kind was not known until long after the hollow sort had been in use, and the above variety is but lately known and cultivated.

SOLIDAGO, in Botany, from *solido*, to make firm, and, particularly, to heal a wound; an old name, synonymous with the English word Confound, and intended to express the reputed vulnerary powers of the plants which bore it.—Linn. Gen. 425. Schreb. 556. Willd. Sp. Pl. v. 3. 2053. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 64. Sm. Fl. Brit. 889. Prodr. Fl. Græc. Sibth. v. 2. 179. Pursh 535. Juss. 181. Lamarck Illustr. t. 680. Gærtn. t. 170. (Virga aurea; Tourn. t. 275.) Class and order, *Syngenesis Polygamia-superflua*. Nat. Ord. *Composita discoidææ*, Linn. *Corymbifera*, Juss.

Gen. Ch. *Common Calyx* oblong, imbricated, with oblong, narrow, pointed, straight, converging scales. *Cor.* compound, radiated. Florets of the disk numerous, perfect, tubular, funnel-shaped, with a five-cleft spreading limb; those of the radius fewer than ten, usually five, ligulate, lanceolate, three-toothed, female. *Stam.* in the perfect florets, Filaments five, capillary, very short; anthers united into a cylindrical tube. *Pist.* in the same florets, Germen oblong; style thread-shaped, the length of the stamens; stigma cloven, spreading; in the female ones, Germen and style as in the former; stigmas two, revolute. *Peric.* none, the calyx remaining scarcely changed. *Seeds* solitary to each floret of the disk, obovate-oblong. Down capillary.

capillary. Those of the radius much the same. *Recept.* flattish, dotted, naked.

Eff. Ch. Receptacle dotted, naked. Down simple. Calyx imbricated, with converging scales. Florets of the radius about five.

The species of this genus, almost entirely American, vie with those of *Aster* in difficulty of determination. They are all perennial, mostly herbaceous, with simple undivided leaves, and paniced or spiked, almost always yellow, small flowers, and are known by the name of Golden Rods. Several are cultivated for ornament, more for curiosity. The *Hortus Kewensis*, enriched from Dr. Solander's manuscripts, has thrown great light on the present genus, as well as on *Aster*. Linnæus in *Sylt. Veg.* ed. 14, has only fourteen species of *Solidago*; Willdenow, profiting by Mr. Aiton's work, enumerates forty. Mr. Pursh reckons up fifty-one North American species alone. One only, subject to many varieties, is found in Britain.

So great a number of species now require to be added to Willdenow's catalogue, that it is necessary to take a compendious view of the whole, especially as we are furnished with more authentic specimens than most writers have had at their command.

Section 1. *Arborescent.*

1. *S. spuria*. Battard Tree Golden-rod. "Forst. *Comm. Gott.* v. 9. 68." Willd. n. 1. (*Conyza rugosa*; Ait. *Hort. Kew.* v. 5. 30.)—Stem arboreous. Panicle corymbose. Leaves oblong, wedge-shaped, serrated.—Native of St. Helena. Brought by sir Joseph Banks, in 1772, to Kew garden, where it flowers in the greenhouse in November. A spreading irregular small tree, with thick rugged branches, leafy at the ends. Leaves stalked, rugose, bright green, from a span to a foot long. Panicles large, level-topped. Flowers white, half an inch in diameter, with ten florets in the radius. *Forster.*

2. *S. Leucadendron*. White Tree Golden-rod. "Forst. *ibid.* 69." Willd. n. 2.—"Stem arboreous. Cymes level-topped. Leaves oblong-obovate, crenate, nearly sessile."—Native of woods in St. Helena. A tree, two or three fathoms in height. Branches dark brown, tuberculated, rather level-topped; leafy at the summit. Leaves smooth, spreading, three inches long, tapering at the base.—Flower-stalks cymose, smooth and slender. Flowers in every part like the preceding. *Forster.*

3. *S. arborescens*. New Zealand Tree Golden-rod. Forst. *Prodr.* 56. Willd. n. 3.—"Stem arboreous. Panicles corymbose, close, terminal. Leaves roundish-ovate, acute, wavy, stalked."—Native of New Zealand. Young branches downy. Leaves bluntly and distantly toothed; downy beneath. *Willd.*

Section 2. *Herbaceous.* Flowers unilateral. Leaves with three combined ribs.

4. *S. canadensis*. Canadian Golden-rod. Linn. *Sp. Pl.* 1233. Willd. n. 4. Ait. n. 1. Pursh n. 1. (*Virga aurea angulifolia*, panicula speciosa, canadensis; Pluk. *Almag.* 389. t. 236. f. 1.)—Stem downy. Leaves lanceolate, serrated, triple-ribbed, rough. Clusters copious, paniced, unilateral, recurved. Radius hardly exceeding the disk.—In hedges, old fields, and along fences, from Canada to Pennsylvania, flowering from July to September. From eighteen inches to five feet high. *Pursh.* The stem is angular, terminated by an ample downy panicle, of innumerable very small yellow flowers. Leaves sessile, three inches long, sometimes nearly entire, and occasionally downy. Pursh and, of course, Willdenow, copy the erroneous reference to Plukenet; a practice which overturns all confidence in the synonyms of authors who use it, as they cannot have judged of the description or figure cited.

5. *S. procera*. Great Golden-rod. Ait. n. 2. Willd. n. 5. Pursh n. 2.—"Stem villous, erect. Leaves lanceolate, serrated, triple-ribbed, rough; villous beneath. Clusters spiked, erect, drooping before flowering. Radius short."—In swamps, hedges, and about fences, from Canada to Virginia, flowering from July to September. From four to seven feet high. *Pursh.*

6. *S. serotina*. Upright Smooth Golden-rod. Ait. n. 3. Willd. n. 6. Pursh n. 3.—Stem erect, round, very smooth. Leaves linear-lanceolate, smooth, triple-ribbed, serrated, rough-edged. Clusters paniced, unilateral. Stalks downy.—In woods and hedges, from New England to Pennsylvania, flowering in September and October. Young leaves edged with copious little white rigid hairs.

7. *S. gigantea*. Gigantic Golden-rod. Ait. n. 4. Willd. n. 7. Pursh n. 4.—Stem erect, smooth. Leaves lanceolate, smooth, serrated, rough-edged, obscurely triple-ribbed. Clusters paniced, unilateral. Stalks hairy. Radius short.—In open low places, on the sides of fertile hills, from New England to Virginia, flowering from August to October. From four to seven feet high. *Pursh.*

8. *S. ciliaris*. Fringed Golden-rod. Willd. n. 8. Pursh n. 5.—Stem erect, smooth. Leaves lanceolate, somewhat triple-ribbed, smooth, rough-edged, slightly serrated. Clusters paniced, unilateral. Stalks smooth. Bractæas fringed. Radius short.—Sent from Pennsylvania, by the late Rev. Dr. Muhlenberg. The stem is angular. Radical leaves stalked, elliptical, pointed, veiny, serrated, rough, near a foot long. Branches of the panicle spreading. Bractæas minute. *Willd.*

9. *S. reflexa*. Hanging-leaved Golden-rod. Ait. n. 5. Willd. n. 9. Pursh n. 6.—Stem erect, villous. Leaves lanceolate, somewhat serrated, triple-ribbed, rough, reflexed. Clusters paniced, slightly unilateral.—In pine woods and old fields, from New Jersey to Carolina, flowering in August and September.

10. *S. lateriflora*. Lateral-flowered Golden-rod. Ait. n. 6. Willd. n. 10. Pursh n. 7. *Winn. Sp. Pl.* 1234? —Stem erect, rather hairy. Leaves lanceolate, obscurely triple-ribbed, smooth, rough-edged; the lower ones slightly serrated. Clusters paniced, unilateral, somewhat recurved.—In old fields and dry woods, from Canada to Carolina, flowering from August to October. The stem is from two to three feet high, striated, often purplish, furnished with numerous lateral flowering branches, as well as a principal terminal one. Leaves very smooth in the disk. Radius much longer than the calyx. This is probably the Linnæan plant, but some obscurity attends that question.

Section 3. *Clusters unilateral. Leaves veiny.*

11. *S. aspera*. Rough-leaved Golden-rod. Ait. n. 7. Willd. n. 11. Pursh n. 8. (*Virga aurea americana aspera*, foliis brevibus serratis; Dill. *Elth.* 411. t. 305.)—Stem erect, round, hairy. Leaves ovate, rather elliptical, very rough, rugged, serrated, without lateral ribs. Clusters paniced, unilateral.—In barren dry fields and woods, from New York to Carolina, flowering from September to November. *Pursh.* About a yard high. Leaves from one to two inches long, acute. Clusters dense, in some degree conical. Flowers small, yellow, the radius twice as long as the calyx.

12. *S. altissima*. Tall Variable Golden-rod. Linn. *Sp. Pl.* 1233. Willd. n. 12. Ait. n. 8. Pursh n. 9. (*Virga aurea altissima serotina*, panicula speciosa patula; Mart. *Cent.* 14. t. 14; and probably *V. aurea marilandica*, spicis florum racemosis, foliis integris scabris; *ibid.* 13. t. 13.)—Stem erect, hairy. Leaves lanceolate; the lower ones deeply serrated, very rough, rugose. Panicles unilateral.—

SOLIDAGO.

In hedges and fields of North America, common, flowering from August to October. A very variable species, scarcely two individuals look alike. *Pursh*. The numerous paniced clusters spread horizontally, in a graceful manner, and all the flowers are turned upward. They are twice the size of *S. canadensis*, with a prominent radius, half as long again as the calyx.

13. *S. rugosa*. Wrinkle-leaved Golden-rod. Mill. Dict. ed. 8. n. 25. Willd. n. 13. Ait. n. 9. Pursh n. 10. (*Virga aurea novæ anglæ, rugosis foliis crenatis*; Dill. Elth. 416. t. 308.)—Stem erect, hairy. Leaves ovato-lanceolate; the lower ones closely ferrated, rugged, very rough. Clusters paniced, compound, widely spreading, unilateral.—In a dry barren soil, from Canada to Virginia, flowering from August to October. *Pursh*. The leaves are shorter and broader than in the foregoing. Flowers rather smaller.

14. *S. villosa*. Soft-leaved Golden-rod. Pursh n. 11. (*S. altissima* β ; Ait. ed. 1. v. 3. 212. ed. 2. n. 8. Willd. n. 12. *S. pilosa*; Mill. Dict. ed. 8. n. 9.)—"Stem erect, villous. Leaves lanceolate, rather soft, ferrated, without lateral ribs. Clusters paniced, unilateral."—In fields and woods of North America frequent, flowering from August to October. From eighteen inches to three feet high. *Pursh*.

15. *S. scabra*. Harsh-leaved Golden-rod. Willd. n. 14. Pursh n. 12.—"Stem erect, hairy. Leaves oblong, pointed; smooth above; rugged and rough beneath. Clusters unilateral."—In old fields and about fences, from Pennsylvania to Virginia, flowering from August to October. *Pursh*. Stem furrowed. Leaves tapering at each end, pointed, with equal, short, close-pressed ferratures about the middle.

16. *S. pyramidata*. Pyramidal Golden-rod. Pursh n. 13.—"Stem erect, round, hairy. Leaves oblong, acute, sessile, somewhat clasping the stem, smooth, rough-edged, sparingly and slightly toothed. Panicle naked, unilateral, pyramidal; its branches reflexed. Flower-stalks smooth."—Gathered by Mr. Enslin, in the "pine-barrens" of Georgia, flowering in August and September. About two feet high. The leaves decrease toward the beginning of the panicle, which consists of lively yellow very small flowers. *Pursh*.

17. *S. nemoralis*. Woolly-stalked Golden-rod. Ait. ed. 1. v. 3. 213. ed. 2. n. 10. Willd. n. 15. Pursh n. 14.—"Stem erect, downy. Stem-leaves lanceolate, hispid, entire; radical ones somewhat wedge-shaped, ferrated. Clusters paniced, unilateral."—In sandy and barren fields common, from Canada to Carolina, flowering from August to October. The whole plant has a grey aspect, and is about a foot, or sometimes two, high. *Pursh*.

18. *S. patula*. Short-spreading-branched Golden-rod. Willd. n. 16. Pursh n. 15.—Stem erect, smooth, angular. Leaves elliptical, ferrated, smooth; the radical ones oblong-spatulate. Clusters paniced, unilateral, spreading. Flower-stalks downy.—In shady woods, on a fertile soil, from New York to Virginia, flowering in September and October. Our specimen was sent by the discoverer of this species, the Rev. Dr. Muhlenberg, from Lancaster, Pennsylvania. Its stems are upright and wand-like, two feet high, angular and striated. Stem-leaves sessile, an inch long, pointed; the radical ones are said by Willdenow to resemble exactly those of *Chrysanthemum Leucanthemum*. The flowers are larger than most of the foregoing, but each cluster is hardly above an inch in length.

19. *S. ulmifolia*. Elm-leaved Golden-rod. Willd. n. 17. Pursh n. 16.—"Stem erect, striated, smooth. Leaves elliptical, pointed, deeply ferrated; villous beneath; radical ones obovate. Clusters paniced, unilateral. Flower-stalks

villous. Rays short."—In swamps and shady woods, from New York to Virginia, flowering from August to October. *Pursh*. Radical leaves almost the same as the last, but more deeply ferrated, covered with hairs on both sides; the rest elliptical or ovate-oblong; smooth above; villous about the veins beneath. Flower-stalks villous; the partial ones clothed with scattered hairs, and accompanied by bractæas.

20. *S. arguta*. Sharp-notched Golden-rod. Ait. ed. 1. v. 3. 213. ed. 2. n. 11. Willd. n. 18. Pursh n. 17.—"Stem erect, smooth. Leaves smooth, sharply and unequally ferrated; those of the stem elliptical; radical ones ovate-oblong. Clusters paniced, unilateral. Rays elongated."—In woods and meadows, from Canada to Virginia, flowering from September to November. *Pursh*.

21. *S. juncea*. Rushy-stalked Golden-rod. Ait. ed. 1. v. 3. 213. ed. 2. n. 12. Willd. n. 19. Pursh n. 18.—Stem erect, smooth. Leaves lanceolate, smooth, rough-edged; the lower ones ferrated. Clusters paniced, unilateral.—In sandy fields and woods, from New Jersey to Carolina, flowering from August to October. The stem is brownish, somewhat angular and striated, leafy, copiously paniced at the top, with spreading, recurved, dense, oblong, compound clusters, a finger's length or more, whose partial stalks are roughish, bearing many small, lanceolate, obtuse bractæas. Florets of the radius twice as long as the calyx.

22. *S. elliptica*. Oval-leaved Golden-rod. Ait. ed. 1. v. 3. 214. ed. 2. n. 13. Willd. n. 20. Pursh n. 19. (*S. latissimifolia*; Mill. Dict. ed. 8. n. 14. *Virga aurea canadensis, latissimo folio glabro*; Tourn. Inf. 485.)—Stem erect, smooth. Leaves elliptical, smooth, ferrated. Clusters paniced, unilateral. Rays of a middling length.—In shady woods among rocks, from New York to Virginia, flowering from August to October. *Pursh*.

23. *S. dubia*. Lanceolate-leaved Golden-rod. Scopoli Del. Infubr. v. 2. 19. t. 10.—Stem erect, striated, slightly hairy. Leaves lanceolate, smooth, distantly toothed. Clusters paniced, unilateral, rather hairy; the lower ones axillary. Bractæas lanceolate, smooth.—Cultivated in the botanic garden of Pavia, from whence we obtained a specimen in June, 1787. The plant was supposed by professor Scopoli to be a native of North America, but we cannot refer it to any described species. The late Mr. Dryander, at that time intent on preparing the *Hortus Kewensis* for the press, considered our specimen as coming nearest to *S. elliptica*, but its leaves are narrower, and bractæas much less. Most of the clusters are axillary, composing a leafy panicle, and about as long as their corresponding leaves. Florets of the radius rather numerous. The foliage is rigid, entirely smooth, finely toothed, not ferrated, somewhat triple-ribbed; indeed more so than in *lateriflora*, n. 10, next to which species, in the first section, we should have placed the present, but for its alleged affinity to *elliptica*.

24. *S. asperata*. File-leaved Golden-rod. "Bankf. MSS." Pursh n. 20.—"Stem paniced, corymbose. Clusters nearly erect. Flowers ascending. Leaves lanceolate, ferrated, rough."—In Canada, according to the Bankfian herbarium. *Pursh*.

25. *S. recurvata*. Recurved Golden-rod. Willd. Enum. 889. Pursh n. 21.—Stem erect, downy. Leaves lanceolate, ferrated, rough-edged. Clusters elongated, unilateral, recurved, paniced. In shady woods, from Pennsylvania to Virginia, flowering from September to November. *Pursh*. Leaves lanceolate, pointed, deeply ferrated, nearly smooth, except at the edges. Willdenow.

26. *S. sempervirens*. Narrow-leaved Evergreen Golden-rod. Linn. Sp. Pl. 1232. Willd. n. 21. Ait. n. 14. Pursh

SOLIDAGO.

Pursh n. 22. (*S. maxima americana*; Cornut. Canad. 168. t. 169. *Virga aurea*, five *Solidago procerior americana*, caule multiplici; Pluk. Phyt. t. 235. f. 5.)—Stem erect, smooth. Leaves linear-lanceolate, rather fleshy, smooth, entire, rough-edged. Clusters panicled, unilateral. Flower-stalks roughish.—In swamps, and on the banks of rivers, from Canada to Pennsylvania, flowering from September to November. *Pursh*. A tall, smooth, purplish and somewhat glaucous species, with copious, long, narrow leaves, and dense oblong panicles, of unilateral clusters. Radiant florets long, narrow, rather numerous.

27. *S. virgata*. Slender Wand-like Golden-rod. Michaux Boreal-Amer. v. 2. 117. Pursh n. 23.—“Stem smooth, quite simple. Leaves lanceolate, somewhat wedge-shaped, obtuse, entire, very smooth, close-pressed; the upper ones gradually smaller. Branches of the panicle elongated, with terminal clusters. Flower-stalks smooth, unilateral.”—In shady wet woods of Lower Carolina and Georgia, flowering from August to October. About two feet high, extremely smooth and slender. *Pursh*.

28. *S. odora*. Sweet-scented Golden-rod. Ait. ed. 1. v. 3. 214. ed. 2. n. 15. Willd. n. 22. Pursh n. 24. (*Virga aurea americana*, tarraconis facie et sapore, paniculâ speciosissimâ; Pluk. Phyt. t. 116. f. 6.)—Stem erect, downy, striated. Leaves linear-lanceolate, entire, smooth, rough-edged. Clusters panicled, unilateral, nearly simple.—In dry sunny situations, on fertile woodlands, from Canada to Carolina, principally throughout the Allegany mountains, flowering from August to October. This is most generally and principally known among the inhabitants by the name of Golden-rod, and used as a wholesome tea. The flowers, gathered when fully expanded, and carefully dried, afford a most agreeable substitute for tea, which for some time has been an article of exportation to China, where it fetches a high price. *Pursh*. The upper part of the stem is regularly furrowed. Clusters two or three inches long, spreading horizontally, each mostly accompanied by a leaf; their stalks angular and rough. Bractæas oblong, smooth.

29. *S. retrorsa*. Reflexed Golden-rod. Michaux Boreal-Amer. v. 2. 117. Pursh n. 25.—“Stem erect, round, rough. Leaves closely sessile, reflexed, linear-lanceolate, pointed, rough-edged; somewhat keeled beneath. Clusters of the panicle recurved.”—In open swamps of Virginia and Carolina, flowering in August and September. *Pursh*. Said by Michaux to be akin to the last. We have had no opportunity of comparing them.

Section 3. Clusters erect.

30. *S. pauciflorescens*. Starved-flowered Golden-rod. Michaux Boreal-Amer. v. 2. 116. Pursh n. 26.—“Smooth, somewhat shrubby. Leaves lanceolate, obtuse, without ribs. Panicle compound, many-flowered; tufts of flowers erect. Calyx narrow-oblong, with five florets in the disk, and one in the radius.”—In the “sand-barrens” of Virginia and Carolina, flowering from August to October. *Pursh*.

31. *S. bicolor*. Two-coloured Golden-rod. Linn. Mant. 114. Willd. n. 23. Ait. n. 16. Pursh n. 27. (*Virga aurea*, flore albo spicato; Pluk. Phyt. t. 114. f. 8, not 3, as Willdenow and Pursh have it.)—Stem hairy. Leaves elliptical, hairy; the lower ones serrated; those on the flower-branches entire, numerous, and small. Clusters erect. Scales of the calyx obtuse.—In woods and on dry hills, from Canada to Carolina, flowering from August to October. Distinguished by its short close clusters, and white rays, which are not long, but rather numerous. The florets of the disk are also plentiful.

32. *S. petiolaris*. Latc-flowered Golden-rod. Ait. ed. 1.

v. 3. 216. ed. 2. n. 17. Willd. n. 24. Pursh n. 28.—Stem erect, villous. Leaves elliptical, roughish, stalked. Clusters erect. Rays twice the length of the calyx.—In dry sandy soil, from New Jersey to Carolina, flowering from September to November.—The stem is branched, round, hoary like the leaves, especially their ribs. The larger leaves are rather above an inch in length; those which plentifully clothe the flower-branches are much smaller; all are nearly entire. Clusters numerous, erect, short, of few, but rather large, flowers, with a conspicuous yellow radius.

33. *S. stricta*. Willow-leaved Golden-rod. Ait. ed. 1. v. 3. 216. ed. 2. n. 18. Willd. n. 25. Pursh n. 29.—“Stem erect, smooth. Stem-leaves lanceolate, entire, smooth, rough-edged; radical ones serrated. Clusters panicled, erect. Flower-stalks smooth.”—In sandy woods, from New Jersey to Carolina, flowering from August to November.—About two feet high, very smooth. *Pursh*. Panicle with erect, simple, close branches. *Willd*.

34. *S. lanceolata*. Grass-leaved Golden-rod. Linn. Mant. 114. Willd. n. 26. Ait. n. 19. Pursh n. 30. (*Chrysocoma graminifolia*; Linn. Sp. Pl. 1178.)—Stem smoothish, furrowed, much branched. Leaves almost linear, entire, roughish, nearly erect, with three or five rough ribs. Corymbs terminal, level-topped. Flowers capitate. Rays not longer than the disk.—In fields and meadows, by the sides of woods and rivers, from Canada to Pennsylvania, flowering from September to November. This plant has been found in Scotland, on the banks of the Esk, a mile above Musselburgh, among willows, alders, &c. by Mr. E. J. Maughan of Edinburgh, in September 1809. Still we have not ventured to admit into the British list, a plant often met with in gardens, and very rapid in propagation, though many have been admitted on far less sufficient grounds. The stems are four or five feet high, branched in a corymbose manner, leafy, angular or furrowed, slightly rough, or quite smooth. Leaves sessile, grass-green, two inches or more in length, a quarter of an inch in breadth, roughish, especially at the edges and ribs. Flowers numerous, rather small, densely corymbose, yellow. Calyx ovate, smooth, shining, with tumid green-tipped scales.

35. *S. tenuifolia*. Narrow-leaved Golden-rod. Pursh n. 31. (*S. lanceolata* β , minor; Michaux Boreal-Amer. v. 2. 116.)—“Stem rough, angular, branched, corymbose. Leaves spreading, linear, very narrow, slightly three-ribbed, rough, with axillary tufts of smaller ones. Corymbs terminal, level-topped. Flowers capitate. Rays scarcely exceeding the disk.”—In “pine-barrens,” from New Jersey to Carolina, flowering in September and October. Not above a foot high. Leaves very small and narrow. *Pursh*.

36. *S. Sarothræ*. Close-leaved Dwarf Golden-rod. Pursh n. 32.—“Stem angular, rough; naked in the lower part; corymbose above. Branches with a few terminal flowers. Leaves linear, close-pressed, obscurely three-ribbed, rough on both sides, without axillary tufts. Rays twice the length of the disk.”—Gathered by governor Lewis, on the plains of the Missouri, flowering in September.—About a span high, resembling the *Sarothra gentianoides* of Linnæus, *Hypericum Sarothra* of Pursh, very much in general habit. This and the two preceding have a great affinity to one another, but Mr. Pursh considers them good and permanent species, as there are no intermediate varieties, which might lead to a suspicion that all belong to one genuine species. We have seen neither of the two last.

37. *S. cæsia*. Maryland Golden-rod. Linn. Sp. Pl. 1234. Willd. n. 27. Ait. n. 20. Pursh n. 33. (*Virga aurea marilandica cæsia glabra*; Dill. Elth. 414. t. 307. f. 395.)—Stem nearly erect, very smooth and even. Leaves lanceolate, smooth, with roughish edges and ribs. Clusters erect.

Rays

Rays rather longer than the disk.—In woods and low fields, from New England to Carolina, flowering from August to October. *Pursh.* The *stem* is upright, but somewhat zig-zag, branched, leafy, destitute of any furrows or other inequalities. *Leaves* about two inches long, pointed, nearly or quite entire, rather glaucous; paler beneath. *Clusters* numerous, short, with rough stalks, and small, smooth, awl-shaped *bracteas*.

38. *S. livida*. Livid Golden-rod. Willd. Enum. 891. Pursh n. 34.—“Stem smooth, panicled. Leaves lanceolate, ferrated, smooth, rough-edged. Branches racemose at the extremity. Rays elongated.”—In sandy fields and woods, from New York to Virginia, flowering in September and October. *Pursh.* *Stem* branched, dark purple, smooth. *Leaves* tapering at each end. Akin to *S. cæsia* in the colour of the *stem*, but different in having a panicled *stem*, whose *branches* are racemose at the summit. Willdenow. We are unacquainted with any thing answering to this description.

39. *S. hispida*. Hispid Golden-rod. Willd. n. 28. Pursh n. 35.—“Stem erect, rough with bristles. Leaves lanceolate, rough, entire; the radical ones ferrated. Clusters erect. Rays of a middling length.”—In grassy fields and woods, from New Jersey to Virginia, flowering in October and November.—Resembles *S. cæsia*. *Pursh.*

40. *S. hirta*. Hairy Golden-rod. Willd. Enum. 891. Pursh n. 36.—“Stem panicled, hairy. Leaves lanceolate, rough on both sides; those of the stem ferrated; of the branches entire. Clusters erect. Rays elongated.”—Native of North America, according to Willdenow, on whose authority alone it finds a place in the work of Mr. Pursh. It is said to be sufficiently distinguished by the hairy *stem*, and rough *leaves*, of which such as grow on the principal stem are deeply and sharply ferrated.

41. *S. lithospermifolia*. Gromwell-leaved Golden-rod. Willd. Enum. 892. Pursh n. 37.—“Stem branched, downy. Leaves lanceolate, rough on both sides, tapering, three-ribbed, entire. Clusters erect. Rays elongated.”—In sandy barren woods, from New Jersey to Carolina, flowering from August to October. *Pursh.* Willdenow says the *leaves* are much like *Lithospermum officinale*.

42. *S. levigata*. Flethy-leaved Golden-rod. Ait. ed. 1. v. 3. 215. ed. 2. n. 21. Willd. n. 29. Pursh n. 38.—Stem erect, smooth. Leaves lanceolate, fleshy, entire, smooth in every part. Clusters panicled, erect. Flower-stalks scaly, hairy. Radius twice the length of the calyx.—In salt-marshes, from Canada to Virginia, flowering from September to November.—A tall robust species, resembling the following one very much, and probably nothing more than a variety. *Pursh.* This opinion seems to us very correct, there being really no difference between the two plants, except the hairiness of the *flower-stalks* in the present, and its flowering about three months later than *S. mexicana*.

43. *S. mexicana*. Mexican Golden-rod. Linn. Sp. Pl. 1234. Willd. n. 30. Ait. n. 22. Pursh n. 39. (*Virga aurea mexicana*; Bauh. Pin. 517. *V. aurea mexicana*, *limonii folio*; Dodart. Mem. ed. Amst. 629. t. 36.)—Stem oblique, smooth. Leaves lanceolate, somewhat fleshy, entire, smooth in every part. Clusters panicled, erect. Flower-stalks scaly, smooth. Rays longer than the calyx.—On the banks of rivers and ditches in North America, near salt-water, flowering from July to September.—Tall; *flowers* large. *Pursh.* This is smooth and even in every part, and of a rather fleshy, somewhat glaucous habit, approaching to our *Aster Tripolium*, whose place it occupies in America. The radical *leaves* are large, obovate, on long stalks. *Bracteas* numerous, lanceolate, keeled, recurved, of a thin, scaly, or squarrose, aspect, smooth, exactly like the last, but the

flower-stalks are equally smooth, which in that are very rough with short hairs. *Flowers* rather large.

44. *S. viminea*. Twiggy Golden-rod. Ait. ed. 1. v. 3. 215. ed. 2. n. 23. Willd. n. 31. Pursh n. 40. (*S. integerrima*; Mill. Dict. ed. 8. n. 24.)—Stem erect, slightly downy. Leaves linear-lanceolate, smooth, rough-edged; tapering at the base: the lower ones somewhat ferrated. Clusters erect. Rays elongated.—On the banks of rivers and ditches, from Canada to Virginia, flowering from August to October. *Pursh.*—Akin to the two last, but the *leaves* are thin or membranous, not succulent; their margin furnished with little inflexed rigid bristles. *Flower-stalks* and *branches* angular and very rough. *Bracteas* lanceolate, recurved, smooth. *Flowers* numerous, the size of the preceding.

45. *S. erecta*. Erect Golden-rod. “Bank. MSS.” Pursh n. 41.—“Stem rather villous. Leaves lanceolate, veiny, smooth, entire, somewhat stalked.”—Native of North America. *Herb. Banks. Pursh.*

46. *S. macrophylla*. Long-leaved Golden-rod. “Bank. MSS.” Pursh n. 42.—“Lower leaves ovate, pointed, tapering, unequally and sharply ferrated, smooth; those of the stem lanceolate, tapering at each end, ferrated, nearly sessile. Clusters axillary, stalked, leafy, the length of the leaves. Calyx oblong, turgid, many-flowered. Rays somewhat elongated.”—In Canada. About three feet high. Intermediate between this genus and *Aster*. *Pursh.*

47. *S. glomerata*. Round-headed Golden-rod. Michaux Boreal-Amer. v. 2. 117. Pursh n. 43.—“Stem low, quite simple. Leaves smooth, oblong-lanceolate, ferrated. Cluster simple, formed of round axillary heads; the uppermost crowded. Calyx turgid, many-flowered.”—Found by Michaux on the mountains of Carolina. No other botanist seems acquainted with this species, nor is it easy to understand his definition of the leaves; (“*foliis longè latèque lanceolatis*.”)

48. *S. flexicaulis*. Crooked-stalked Golden-rod. Linn. Sp. Pl. 1234. Willd. n. 32, α . Ait. n. 24, α . Pursh n. 44, α . (*Virga aurea montana*, *scrophulariæ folio*; Pluk. Phyt. t. 235. f. 3.)—Stem zig-zag, roundish, smooth. Leaves lanceolate, pointed, ferrated, smooth, nearly sessile. Clusters axillary, erect.—In woods and fields, from Canada to Carolina, flowering from August to October. *Pursh.* The *stem* is slender, zig-zag, purplish, smooth and even; mostly round; occasionally somewhat angular. *Leaves* numerous, alternate, on very short broad *stalks*, lanceolate, from one and a half to two inches long, half an inch wide, ferrated, rough-edged, very smooth on both sides; paler beneath, somewhat contracted and entire in their lower half; the upper ones sometimes nearly entire. *Clusters* much shorter than the leaves, oblong, with hairy *stalks*, and ovate, smooth, veiny *bracteas*; the upper ones very short, and nearly capitate. *Radius* pale yellow, half as long again as the calyx.

49. *S. latifolia*. Broad-leaved Axillary Golden-rod. Linn. Sp. Pl. 1234. (*S. flexicaulis* β ; Willd. n. 32. Ait. n. 24. Pursh n. 44. *Virga aurea canadensis asterifci folio*; Herm. Parad. 244. t. 244.)—Stem somewhat zig-zag, angular, smooth. Leaves ovate, pointed, strongly ferrated, smooth; tapering into a winged footstalk. Clusters axillary, erect.—In woods and fields from Canada to Carolina, flowering from August to October. *Pursh.* Very different in appearance from the last, to which it is united by various authors, on the authority of the *Hortus Kewensis*. But we suspect the real *flexicaulis* is not much understood in England, what we have under that name from Kew garden, as well as the Bankian herbarium, being really the *latifolia*, which latter species was not known, as such, to the botanists here,

here, till the Linnæan herbarium came among them. How far it may be specifically distinct, we cannot be certain. We have specimens of both from the late Rev. Dr. Muhlenberg, whose *leaves* differ greatly. Those of *latifolia* are two inches broad, with very copious, deep, acute serratures, and contract at the base, more or less suddenly, into a winged *footstalk*, near an inch long. Their rib, and under side, are sometimes hairy. Nothing like this is seen in *flexicaulis*. We suspect Plukenet's t. 235. f. 4, as well as f. 3, may belong to this last; see the following. Hermann's plate is certainly *latifolia*. Mr. Pursh speaks of these species collectively, as the most common *Solidago* in North America. We know not to which of the two this is most applicable.

50. *S. ambigua*. Angular-stalked Golden-rod. Ait. ed. 1. v. 3. 217. ed. 2. n. 25. Willd. n. 33. (*Virga aurea latissimo folio, canadensis, glabra*; Pluk. Phyt. t. 235. f. 4?)—Stem slightly zig-zag, smooth, angular, branched. Leaves ovato-lanceolate, pointed, densely serrated, rather hairy beneath; tapering into a winged footstalk; upper ones entire. Clusters axillary, erect; the upper ones much longer than the leaves.—Cultivated by Miller, and communicated from Kew garden to the younger Linnæus. It is said to flower in July and August, but its native country is unknown, nor has Mr. Pursh met with this plant in America. It may be a variety of *latifolia*, from which it differs in having somewhat narrower leaves, and in the much greater length of the upper clusters of flowers, which combine to form a close panicle. Plukenet's figure, cited here with doubt, does not quite enough express this, nor are so many of the leaves entire, though several of the upper ones are so in our specimen.

51. *S. alpestris*. Alpine Golden-rod. "Waldst. and Kitaib. Hung." Willd. n. 34.—"Stem erect, smooth. Leaves elliptic-lanceolate; the lower ones serrated. Clusters erect, close, shorter than the leaves. Rays elongated."—Native of the Carpathian, Austrian, and Bohemian alps. Very like the following, but the *stem-leaves* are elliptic-lanceolate, nearly entire, and the *stem* is smooth. It varies greatly by culture, becoming two feet, instead of one, in height, and branched, instead of quite simple. The leaves of the wild plant measure from half an inch to an inch and a half, (we presume in length); those of the garden one from one and a half to three inches. The upper clusters of the former are crowded into a sort of spike; those of the latter are axillary, and composed of few flowers. Willdenow.

52. *S. Virgaurea*. Common Golden-rod. Linn. Sp. Pl. 1235. Willd. n. 35. Ait. n. 26. Pursh n. 46. Fl. Brit. n. 1. Engl. Bot. t. 301. Fl. Dan. t. 663. (*S.* n. 69; Hall. Hist. v. 1. 29. *Virga aurea*; Ger. Em. 430. Camer. Epit. 748, 749. Matth. Valgr. v. 2. 354.)

β. *Virga aurea, longo, molli, et lanceolato folio, alpina*; Bocc. Mus. 34. t. 30.

γ. *Virga aurea montana minor*; Bocc. Mus. 169. t. 118. Barrel. Ic. t. 783.

δ. *Solidago cambrica*; Hudf. 367. Ait. n. 27. Willd. n. 36. (*Virga aurea cambrica, floribus conglomeratis*; Dill. Elth. 413. t. 306. f. 393.)

ε. *S. minuta*; Linn. Sp. Pl. 1235. Willd. n. 38. Ait. n. 29. (*Virga aurea omnium minima, floribus maximis*; Herm. Parad. 245. t. 245. *V. aurea montana biuncialis pumila, foliis acuminatis*; Pluk. Phyt. t. 235. f. 7; and *foliorum apicibus obtusis*; f. 8.)

Stem somewhat zig-zag, angular, hairy. Leaves more or less serrated, roughish; tapering at the base. Clusters paniced, erect, close. Rays twice the length of the calyx.—Native of bushy, heathy, mountainous, and alpine situ-

ations throughout Europe, as well as at Labrador, and even China, flowering in the latter part of summer. The root is perennial, consisting of long simple fibres. Stem very variable in height and luxuriance, mostly from one to three feet high, and branched in a paniced manner, more or less zig-zag, never quite straight, leafy, angular, covered more or less with short hairs, especially the upper part; rounder, and frequently purplish, at the base. Leaves elliptic-lanceolate, or nearly ovate, roughish, firm and rather rigid; the lower ones stalked; the rest variously elongated at the base; all extremely variable in size, and especially in their serratures, which, though commonly close and shallow, are sometimes very coarse and tooth-like, sometimes nearly wanting; the margin is always rough with minute bristly hairs; the surface smooth or rough; the under side rather paler; sometimes the upper leaves are recurved, or drooping, and the uppermost of all gradually diminish into bracteas. Panicle terminal, many-flowered, attended by small leaves; its lower branches often axillary; all downy, racemose, or corymbose; now and then simple and single-flowered. Scales of the calyx at length spreading, but all straight, imbricated, lanceolate, fringed, membranous at the edges; sometimes rough at the back. Florets of the radius from five to nine or ten, of a golden yellow, spreading, elliptic-oblong, toothed at the end, their limb the length of the calyx.—We scarcely know a plant more difficult to define or to understand than this, nor can we limit even the varieties so as to make them intelligible; much less elevate them to the rank of species. *β*, sent from Italy by Arduino to Linnæus, is more downy, with more pliant leaves, than our common kind, with numerous axillary clusters, and a more leafy panicle. The flowers are considerably larger than usual.

γ has equally large flowers, but much fewer, so that the panicle is nearly simply racemose, and the leaves are coarsely serrated. We have Swiss specimens of Haller's n. 69, which combine these two varieties, and whose herbage connects them with the common state of the species.

δ is equally simple in its panicle, and its growth is more humble, but the most authentic specimens prove it a mere variety. It is impossible to say what Willdenow had for *S. cambrica*, which he asserts to remain unchanged by culture; but his authority falls to the ground, since he persists in quoting Petiver's t. 16. f. 11, which we have pointed out in Fl. Brit. as a copy of Camerarius, t. 748, done for the common *Virgaurea*!

ε is the most puzzling of all. The flowers in Hermann's plate nearly equal those of our *β*; while in the Linnæan specimen, evidently, as Linnæus judged it, a variety of *Virgaurea*, they are but half as large, and paniced. This specimen was sent by Arduino for Boccone's t. 118, (see variety *γ*;) which it very little resembles. Plukenet's figures have the chiefly axillary inflorescence of our *β*, only each stalk is simple, not racemose.—If any of these varieties are to be established as species, it must be from far better materials than have fallen in our way, and by widely different characters than have as yet been given. We must observe that Grew's t. 59, cited by Haller, is evidently one of the garden American species, totally unlike *Virgaurea*.

53. *S. multiradiata*. Labrador Golden-rod. Ait. ed. 1. v. 3. 218. ed. 2. n. 28. Willd. n. 37. Pursh n. 47.—"Stem rather villous. Leaves sessile, lanceolate, smooth, fringed; the lower ones serrated at the end. Cluster terminal, erect. Rays numerous, elongated."—Found at Labrador and Hudson's Bay, flowering from August to October.—Pursh. —Stem a span high, downy, erect, quite simple. Leaves narrow, nearly entire. Cluster dense. Radius narrow, copious. Willdenow.

54. *S. humilis*. Humble Golden-rod. Pursh n. 48.—“Stem simple, erect, smooth. Leaves lanceolate, ferrated, smooth; tapering and elongated at the base. Clusters erect.”—Native of North America, according to the Banksian herbarium. *Pursh*.

55. *S. elata*. Lofty Golden-rod. Pursh n. 49.—“Stem hairy, round. Leaves lanceolate; rather hairy beneath. Clusters erect. Rays elongated.”—Native of North America, according to the same authority. *Pursh*.

56. *S. rigida*. Hard-leaved Golden-rod. Linn. Sp. Pl. 1235. Willd. n. 39. Ait. n. 30. Pursh n. 50. (*Virga aurea* Novæ Angliæ, lato rigido folio; Herm. Parad. 243. t. 243.)—Leaves ovate-oblong, rough, like the corymbose stem, with minute rigid hairs; the lowermost ferrated; upper entire. Clusters compact. Rays twice the length of the obtuse calyx.—In the tract of mountains from New Jersey to Carolina, flowering from August to October. *Pursh*. The stem is four or five feet high, round, striated, leafy, rough with copious rigid pubescence, and branched copiously, in a corymbose manner, at the top. Leaves rough like a file, somewhat hoary; the radical ones stalked, a foot long, broad, pointed, ribbed, more or less ferrated; the rest from one to four inches long, either obtuse or somewhat pointed, entire, or occasionally crenate; those on the flowering branches numerous, small, and entire. Flowers rather large, but various in size. Scales of the calyx blunt, or rounded at the end, ribbed, membranous at the edge, variable in breadth.—A Pennsylvania specimen, sent by the late Dr. Muhlenberg, has crenate, exactly ovate, leaves on the stem, and flowers about half the usual size; but we dare not make it a distinct species.

57. *S. noveboracensis*. New York Golden-rod. Linn. Sp. Pl. 1235. Willd. n. 40. Pursh n. 51.—Radical leaves elliptic-oblong, stalked, rough. Stem almost naked, branched, furrowed, level-topped. Rays twice as long as the taper-pointed calyx.—In sandy fields and woods of North America, flowering in September and October. *Pursh*. The root is thick and somewhat woody. Stem one and a half or two feet high, stout, rough, round, plentifully furrowed, quite erect, bearing two or three oblong-lanceolate leaves at the origin of the flowering branches, but otherwise naked. Leaves chiefly radical, on long, erect stalks, elliptical, tapering at each end, three inches long, rough like a file with minute tubercles, the margin furnished with shallow serratures. Flowers large, not numerous, on corymbose hairy stalks, with a few rough lanceolate bracteas. Calyx-scales narrow, purplish, downy, with long tapering points. The radiant florets appear to be sometimes more than ten. The seeds are hairy; their down long, very slender, minutely rough. This species appears to be a stranger in our gardens. Its habit is that of an *Aster*.

SOLIDAGO, in *Gardening*, contains plants of the tall, herbaceous, flowering, perennial kind, of which the species cultivated are; the common golden-rod (*S. virgaurea*); the Canadian golden-rod (*S. canadensis*); the tall golden-rod (*S. altissima*); the Mexican golden-rod (*S. mexicana*); the twiggly golden-rod (*S. viminea*); the two-coloured golden-rod (*S. bicolor*); the hard-leaved golden-rod (*S. rigida*); the Maryland golden-rod (*S. cæsia*); the crooked-stalked golden-rod (*S. flexicaulis*); and the narrow-leaved evergreen golden-rod (*S. sempervirens*).

The first sort has sometimes the names of Wound-wort and Aaron's rod. There are several varieties of it, as the purple-stalked broad-leaved, which has the stalks stiff, purplish-brown, two feet high; the panicles axillary and terminating; each flower on a long slender footstalk, pale yellow, appearing at the beginning of August; the leaves

lanceolate, almost four inches long, and a quarter of an inch broad, deeply ferrate, pale green beneath.

The common golden-rod, which has the lower leaves ovate-lanceolate, two inches long and an inch broad, slightly ferrate, on pretty long footstalks; the stems slender, a foot and a half high; with small, narrow, entire, sessile leaves; the flowers in panicked bunches, clustered together, forming a thick erect spike, appearing in August and September. The narrow-leaved, which has the stalk round, smooth, a foot and a half high; the leaves narrow-lanceolate, an inch and a quarter long, and an eighth of an inch broad, almost entire, sessile; the flowers in small clustered bunches from the axils, to which they fit very close; and the stalk is terminated by a roundish bunch. The dwarf golden-rod, which has the lower leaves indented; the stalk seldom more than a foot high, branching out almost from the bottom; the branches terminated by short, clustered, erect spikes; the leaves on the stem and branches very narrow, acute-pointed, and entire. The Welsh golden-rod, which has the lower leaves narrow-lanceolate, an inch and half long, and a quarter of an inch broad, smooth, slightly ferrate, a little hoary on the under side; the stalk about six inches high, with the same sort of leaves on it, only smaller; the flowers in roundish clustered terminating spikes, much larger than those of the common sort, and appearing five or six weeks earlier in the season.

In the third sort there are several varieties; as the tallest golden-rod, the hairy golden-rod, the recurved golden-rod, the Virginia golden-rod.

Method of Culture.—These plants are all readily increased by slipping or parting the roots, and planting them out in the autumn or winter soon after their stems decay, or very early in the spring before they begin to shoot, but the former is the better season, in the places where they are to grow; they succeed in almost any soil or situation, and afterwards require only to be kept clean from weeds, and to have the decayed stems cut down when they begin to decay in the autumn. When they have increased considerably in the roots, they should always be slipped as above.

These plants are very hardy and durable in their roots, by which most of them soon become large, the small slips not unfrequently growing into large bunches in one season, many of them, of course, require to be well cut in with a sharp spade all round about their roots annually, or nearly so, to prevent their spreading too greatly and having an improper appearance, as well as being injurious to other neighbouring plants of small growth.

In planting out they require much room, as they spread considerably. But they afford considerable variety and ornament in larger borders and clumps, on all pleasure-grounds towards the autumnal season.

SOLIDAGO, in the *Materia Medica*. The flowers and the leaves of the common golden-rod, or *virga aurea*, have a slightly aromatic odour, and a subastrigent somewhat aromatic taste. Boiling water extracts the active matter. The infusion changes slightly to green syrup of violets, and precipitates sulphate of iron black. Golden-rod is astrigent, and has been regarded as lithontriptic. It may be, says Thomson (*Disp.*), of some use in a weakened state of the viscera, and, like other tonics, beneficial in calculous habits, but it is not entitled to much notice. The dose of the powdered leaves and flowers may be from grs. x to 3j or more.

SOLIDAR, in *Geography*, a town of Bengal; 26 miles S.S.W. of Ragonatpour.

SOLIDITY, in *Physics*, a property of matter or body,

SOLIDITY.

by which it excludes every other body from that place which itself possesses.

Solidity, in this sense, is a property common to all bodies, whether solid or fluid. It is usually called *impenetrability*; but solidity expresses it best, as carrying somewhat more of positive with it than the other, which is a negative idea.

The idea of solidity, Mr. Locke observes, arises from the resistance we find one body make to the entrance of another into its own place. Solidity, he adds, seems the most extensive property of body, as being that by which we conceive it to fill space; it is distinguished from mere *space*, by this latter not being capable of resistance or motion.

It is distinguished from *hardness*, which is only a firm cohesion of the solid parts, so as they may not easily change their situation.

The difficulty of changing situation gives no more solidity to the hardest body than to the softest; nor is a diamond properly a jot more solid than water. By this we distinguish the idea of the extension of body from that of the extension of space: that of body is the continuity or cohesion of solid, separable, moveable parts; that of space, the continuity of unsoft, inseparable, immoveable parts.

The Cartesians, however, will, by all means, deduce solidity, or, as they call it, *impenetrability*, from the nature of extension; they contend that the idea of the former is contained in that of the latter; and hence they argue against a vacuum. Thus, say they, one cubic foot of extension cannot be added to another, without having two cubic feet of extension; for each has in itself all that is required to constitute that magnitude. And hence they conclude, that every part of space is solid, or impenetrable, inasmuch as of its own nature it excludes all others. But the conclusion is false, and the instance they give follows from this, that the parts of space are immoveable, not from their being impenetrable or solid.

For an account of a late controversy concerning the solidity of matter, see MATTER.

SOLIDITY, in *Geometry*, the quantity of space contained in a solid body; called also the *solid content*, and the cube of it.

The solidity of a cube, prism, cylinder, or parallelepiped, is had by multiplying its basis into its height.

The solidity of a pyramid or cone is had by multiplying either the whole base into a third part of the height, or the whole height into a third part of the base.

SOLIDITY of any irregular Body, To find the. Put the body in a hollow parallelepiped, and pour water or sand upon it, and note the height of the water or sand AB (*Plate XIV. Geometry, fig. 2.*); then taking out the body, observe at what height the water (or sand, when levelled) stands, as AC. Subtract AC from AB, the remainder will be BC. Thus is the irregular body reduced to a parallelepiped, whose base is FCGE, and its altitude BC. To find the solidity of which, see PARALLELEPIPED.

Suppose, *e. gr.* AB to be 8, and AC, 5; then will BC be 3: suppose, again, DB, 12, DE, 4; then will the solidity of the irregular body be found 144.

If the body be such as that it cannot be well laid in such a kind of channel, *e. gr.* if it be required to measure the solidity of a statue, as it stands; a quadrangular prism or parallelepiped is to be framed over it; the rest as before.

SOLIDITY of a hollow Body, To find the. If the body be not comprised in the number of regular bodies, its solidity is found as in the preceding problem. If it be a parallelepiped, prism, cylinder, sphere, pyramid, or cone, the solidity first of the whole body, including the cavity, then that of the cavity, which is supposed to have the same figure

with the body itself, is to be found, according to the respective methods delivered under PARALLELEPIPED, PRISM, &c. For the latter being subtracted out of the former, the remainder is the solidity of the hollow body required.

For the centrobaryc method of measuring the solidity of bodies, see CENTROBARYC Method.

To find the Solidity of Bodies by the Method of Fluxions. Let ABC (*Plate XIV. Analysis, fig. 1.*) represent any solid conceived to be generated by a plane PQ, passing over it with a parallel motion: let Hh, perpendicular to PQ, be taken to express the fluxion of AH (*x*), or the velocity with which the generating plane is carried: also let the area of the part EmFn be denoted by A: then it follows, from the definition of a fluxion, that the fluxion of the solid AEF will be expressed by A \dot{x} . Whence, by expounding A in terms of *x* (according to the nature of the figure), and then taking the fluent, the contents of the solid, which we may represent by *s*, will be given. But, when the proposed solid is that arising from the revolution of any given curve AEB about AHD, as an axis, the fluxion (*s*) of the solidity may be exhibited in a manner more convenient for practice; for, putting the area (3.141592, &c.) of the circle, whose radius is unity, = *p*, and the ordinate EH = *y*, it will be $1^2 : y^2 :: p : py^2$, the area of the circle EmFn, which being substituted for A, we have $\dot{s} = py^2 \dot{x}$.

Ex. 1. To find the Content of a Cone ABC (*fig. 2.*) Let the given altitude AD be = *a*, and the semidiameter of its base BD = *b*, and the distance AF of the circle EG from the vertex A, = *x*; then we shall have, by

similar triangles, $a : b :: x : EF (y) = \frac{bx}{a}$. Whence

$\dot{s} (= py^2 \dot{x}) = \frac{pb^2 x^2 \dot{x}}{a^2}$; and, consequently, by the inverse method of fluxions, $s = \frac{pb^2 x^3}{3a^2}$; which, when $x = a$

(= AD), gives $\frac{pb^2 a}{3} = p \times BD^2 \times \frac{1}{3} AD$ for the

content of the whole cone ABC; which appears, from hence, to be just $\frac{1}{3}$ d of a cylinder of the same base and altitude. See CONE.

Ex. 2. To find the Content of a Spheroid AFBH (*fig. 3.*) and also of a Sphere. Let the axis AB, about which the solid is generated, be = *a*, and the other axis FH of the generating ellipse = *b*; it follows, from the property of the ellipse, that $a^2 : b^2 :: x (a - x) (AD \times BD) : y^2 (DE^2) = \frac{b^2}{a^2} (ax - xv)$: whence we have

$s (= py^2 \dot{x}) = \frac{pb^2}{a^2} (ax \dot{x} - x^2 \dot{x})$, and $s = \frac{pb^2}{a^2} (\frac{1}{2} axx$

$- \frac{1}{3} x^3) =$ the segment AIE. Which, when AD (*x*)

= AB (*a*), becomes $\frac{pb^2}{a^2} (\frac{1}{2} a^3 - \frac{1}{3} a^3) = \frac{pb^2}{a^2} \times \frac{a^3}{6} =$

$\frac{1}{6} p a b^2 =$ the content of the whole spheroid. Where, if *b* (FH) be taken = *a* (AB), we shall obtain $\frac{1}{6} p a^3$ for the true content of a sphere whose diameter is *a*. Hence, a sphere, or a spheroid, is $\frac{1}{6}$ ds of its circumscribing cylinder;

for the area of the circle FH being expressed by $\frac{pb^2}{4}$, the

content of the cylinder, whose diameter is FH, and altitude

side AB, will, therefore, be $\frac{pb^2a}{4}$, of which $\frac{1}{2}pab^2$ is evidently two third parts. See SPHERE and SPHEROID.

Ex. 3. To find the Content of a parabolic Conoid. From the equation $a^{m-n}x^n = y^m$ of the generating curve, we

obtain $y = a^{\frac{m-n}{m}} \times x^{\frac{n}{m}}$, and $\dot{s} (= py^2\dot{x}) = pa^{\frac{2m-2n}{m}} \times x^{\frac{2n}{m}+1}$;
 and, therefore, $s = pa^{\frac{2m-2n}{m}} \times \frac{x^{\frac{2n}{m}+1}}{\frac{2n}{m}+1} = pa^{\frac{2m-2n}{m}} \times \frac{mx^{\frac{2n}{m}+1}}{2n+m}$
 $= py^2 \times \frac{mx}{2n+m} =$ the content of the solid; which,

therefore, is to py^2x , the content of the circumscribing cylinder, as m to $2n + m$. Whence the solid generated by the conical parabola (in which $m = 2$, and $n = 1$) appears to be just half of its circumscribing cylinder. See PARABOLIC Conoid.

Ex. 4. To find the Content of an hyperbolic Conoid. From the equation $y^2 = \frac{b^2}{a^2}(ax + xx)$ of the generating hyper-

bola, we have $\dot{s}(py^2\dot{x}) = \frac{pb^2}{a^2}(ax\dot{x} + x^2\dot{x})$, and consequently $s = \frac{pb^2}{a^2}(\frac{1}{2}ax^2 + \frac{1}{3}x^3) =$ the content of the conoid; which, therefore, is to $(\frac{pb^2}{a^2}(ax + x^2)x)$ that of

a cylinder of the same base and altitude, as $\frac{1}{2}a + \frac{1}{3}x$ to $a + x$. This ratio, if x be very small, will become as 1 to 2 very nearly: whence it may be inferred, that the content of a very small part of any solid generated by a curve, whose radius of curvature at the vertex is a finite quantity, is half that of a cylinder of the same base and altitude very nearly; because any such curve, for a small distance, will differ insensibly from an hyperbola, whose radius of curvature, at the vertex, is the same.

Ex. 5. To find the Content of a parabolic Spindle, generated by the Rotation of a given Parabola ACB (fig. 4.) about its Ordinate AB. Put CM, the abscisse of the given parabola, = a , and the femi-ordinate AM (or BM) = b ; and supposing ENF to be any section of the solid parallel to DC, let its distance MN or EP from DC be denoted by ω : then, by the property of the curve, we shall have

$AM^2 (b^2) : EP^2 (\omega^2) :: CM (a) : CP = \frac{a\omega^2}{b^2}$: therefore EN (= CM - CP) = $a - \frac{a\omega^2}{b^2} = \frac{a(b^2 - \omega^2)}{b^2}$,

and consequently $p \times EN^2 = \frac{pa^2}{b^4}(b^4 - 2b^2\omega^2 + \omega^4)$

= the area of the section EF: which, multiplied by $\dot{\omega}$, the fluxion of MN, gives $\frac{pa^2}{b^4}(b^4\dot{\omega} - 2b^2\omega^2\dot{\omega} + \omega^4\dot{\omega})$ for the fluxion of the solidity, whose fluent $\frac{pa^2}{b^4}(b^4\omega - \frac{2}{3}b^2\omega^3 + \frac{1}{5}\omega^5)$, when ω becomes = b , is $(\frac{8pa^2b}{15})$ half the content of the solid. See PYRAMOID.

For other examples of a similar kind, see Simpson's Fluxions, vol. i. sect. 9, and other elementary treatises on that subject.

SOLIDITY, in *Architecture*, is applied both to the consistence of the ground on which the foundation of a building is laid, and to a mass of masonry of extraordinary thickness, without any cavity within. The solidity of the Egyptian pyramids is inconceivable.

SOLIDS, in *Anatomy*, &c. denote all the continuous and continent parts of the body; thus called, in opposition to the fluids, or parts contained in them.

Of the solid kind, are the bones, cartilages, ligaments, membranes, fibres, muscles, tendons, arteries, veins, nerves, glands, lympheducts, and lacteals.

SOLIDUS, in *Ancient Coinage*. (See AUREUS.) According to Pliny's account, gold was coined at Rome sixty-two years after silver, *i. e.* 547 U. C. or B. C. 204; and then the seruple passed, as he informs us, for 20 sesterces. It was afterwards thought proper to coin 40 pieces out of the pound of gold; and, as he says, our princes have, by degrees, diminished their weight to 45 in the pound. The pieces that now remain confirm Pliny's account. In the first coinage, the aurei were 48 in the pound; afterwards, as Pliny says, there were 40 in the pound, and the aureus was raised from 106 grains, the weight of the didrachm of this coinage, to 126 grains. From Pliny and the coins it appears, that in the first coinage, the seruple of gold passed for 20 sesterces; the drachm of three seruples was 60 sesterterii, or 15 silver denarii; and the didrachm, or aureus, the common Roman gold coin, was worth 30 silver denarii, equal to 1*l.* sterling; gold being 10 silver as 17*½* to 1. The aureus seems to have continued at 30 silver denarii till Sylla's time; but about the year of Rome 675, B. C. 77, the aureus fell to the rate of 40 in the pound, as Pliny informs us, and being reduced near the scale of the Greek χρυσος, passed for 20 denarii, as the later for 20 drachmas, being in currency 13*s.* 4*d.* English. This is the more probable, because we know from Suetonius, that the great Cæsar brought so much gold from Gaul, that it sold at 3000 nummi a pound, that is, nine times its weight in silver; but the Gallic gold was of a very base sort. However, in the reign of Claudius, the aureus passed for 100 sesterterii, or 25 silver denarii; at which rate it remained. This was 16*s.* 8*d.* English in currency; but valuing gold at 4*l.* an ounce, the intrinsic value of the aureus is about 1*l.* The aureus fell by degrees, as Pliny says, to 45 in the pound. From the coins it is clear, that it was in the time of the civil wars of Otho and Vitellius, that the aureus fell from 40 in the pound, or about 125 troy grains at a medium, to 45 in the pound, or about 110 grains of medial weight each. It continued of this standard till the time of Elagabalus, when it fell to about 92 grains at an average, or near 55 in the pound. That the aureus passed for 25 silver denarii down to Alexander Severus, is clear; and supposing that standard to remain, as we have no authority for a change till the time of Constantine I., the double aureus will have borne 50 silver denarii, and the aureus 25. The "triens" must have had eight silver denarii, and two denarii aurei; and the double triens, 16 silver denarii or argentei, and four denarii aurei. The denarius was not then worth above 14*s.* English. The only change Aurelian made in the money, was probably restricted to the gold; for it is certain that under him, and his successor Probus, the common gold piece, or aureus, is of 100 grains, a size confined to these two emperors. There are also halves of about 50 grains; and double aurei, commonly of very fine workmanship, of upward of 200 grains. Down to Constantine

Constantine I., the aureus stands at between 80 and 70 grains. This prince, who seems not to have altered the size of the coin, instead of the "aureus," gave the "solidus" of six in the ounce of gold, and caused it to pass for 14 of his new silver coins, called "Milliarenfes," and 25 denarii, as before; gold being to silver as about 14 to 1. The solidus, or chief gold coin, continued of the same standard to the very close of the Byzantine empire; for gold was common in Constantinople, while silver became more and more scarce. The solidus was worth 12s. sterling. In the days of the first emperors the aureus was worth 25 denarii, and gold to silver about 13½ to 1. The medial aureus was 110 grains, the denarius 60. That standard remained the same till the time of Alexander Severus, after which we have no data; but it is probable that Constantine took the value as he found it, and that from Alexander Severus to Constantine, if we except the short interval of the end of Aurelian's reign, and beginning of that of Probus, gold was rising in value till it exceeded 14 to 1. The gold coins, called "Bezants" in Europe, because they were sent from Byzantium, or Constantinople, were solidi of the old scale, six to the ounce. In Byzantine writers, the solidus is also called "Nomisma," or *the coin*; "Crysinos," because of gold; "Hyperperos," from its being refined with fire, or from its being of bright gold flaming like fire. The solidi also, like the aurei formerly, received names from the princes whose portraits they bore; as "Michelati," "Manuelati." Solidus is a term used for the aureus by Apuleius (*Met. lib. 10.*) who lived in the time of Antoninus the philosopher; nay, so early as in the Prætorian edicts of the time of Trajan; being thus distinguished from the semissis or half. In the time of Valerian, when aurei of different sizes had been introduced, it became necessary to distinguish the particular aurei that were meant.

In the first gold coinage at Rome, the aureus was divided into four inferior parts: the semissis, or half, of 60 sesterii; the tremissis, or third, of 40; the fourth, the name of which is not known, of 30; and the sixth, or scrupulum, of 20. But soon afterwards all these were dropped, except the semissis or half, which occurs in the times of the consuls, and of some emperors, but is extremely scarce, so that few must have been struck. This gold semissis, or half aureus, is termed "quinarius" by medallists with great propriety, and is very uncommon in all the consular and imperial times; but continued the only division of the aureus till the time of Alexander Severus. This prince, as Lampridius informs us, coined semisses and tremisses of gold; but none have yet been found. It is likely they were all recoined by his immediate successors, who again raised the tributes. He also proposed to issue quartarii, but did not live to accomplish his purpose. Trientes, or tremisses, of gold are, however, mentioned in rescripts of Valerian I., and actually exist, both of him and of his son Gallienus, weighing about 30 grains. The gold tremissis was the pattern of the early French and Spanish gold coins; as the silver denarius, in its diminished state, was that of the Gothic and Saxon penny. Pinkerton's Medals, vol. i.

SOLIEK ELSEID, in *Geography*, a town of Egypt, on the left bank of the Nile; 10 miles S. of Girgê.

SOLIFO, a town of Naples, in the province of Otranto; 9 miles E. of Nardo.

SOLIGNAC-*sur-Loire*, a town of France, in the department of the Upper Loire, and chief place of a canton, in the district of Le Puy; 13 miles S. of Le Puy. The town contains 880, and the canton 4455 inhabitants, on a territory of 150 kilometres, in 6 communes.

SOLIGNY, a town of France, in the department of the Orne; 6 miles N. of Mortagne.

SOLIGO, a town of Italy, in the Trevisan; 6 miles S.W. of Trevigio.

SOLIHULL, commonly pronounced *Silhill*, is situated in the division of the same name, in the hundred of Hemlingford, and county of Warwick, England. It is considered as a market-town, but the market is now in absolute disuse. Its distance from Birmingham is 7 miles, and from London 108 miles. Dugdale conjectures that the chief parts of the district, now included in the parish of Solihull, were known by the name of Ulverlei, at the time of the Norman survey. Here was formerly the principal seat of the barony of Limesie; and the residence of the barons he supposes to have occupied a spot at present called Olton, a small village about two miles north-west from Solihull. From the ruins of this baronial residence, and its dependent habitations, the town of Solihull is conjectured to have arisen. Grants for an annual fair and a weekly market were speedily procured; but the town does not appear to have obtained much distinction at any period. It bears the tranquil appearance of a large village, and contains little to attract the notice of travellers, except the church, which is a spacious edifice of the cruciform description. In the population return of the year 1811, the parish is stated to contain 528 houses, occupied by 2581 persons.

On an elevated site in the vicinity of Solihull, surrounded by spacious grounds, is Malvern-Hall, the mansion of Henry Grefwold Lewis, esq. Dugdale's Antiquities of Warwickshire. Beauties of England and Wales, vol. xv. Warwickshire, by J. N. Brewer.

SOLIKAMSK, a town of Russia, in the government of Perm, on the Kama, famous for its salt-works; 112 miles N. of Perm. N. lat. 59° 36'. E. long. 56° 13'.

SOLILOQUY, SOLILOQUIUM, a reasoning, or discourse, which a man holds with himself.

Papias says, that soliloquy is properly a discourse by way of answer to a question that a man has proposed to himself.

Soliloquies are become very common things on the modern stage; yet can nothing be more inartificial, or more unnatural, than an actor's making long speeches to himself, to convey his intentions, &c. to the audience.

Where such discoveries are necessary to be made, the poet should rather take care to give the dramatic persons such confidants, as may necessarily share their inmost thoughts; by which means, they will be more naturally conveyed to the audience. Yet is even this a shift an accurate poet would not be found to have occasion for.

The use and abuse of soliloquies is well delivered by the duke of Buckingham, in the following lines:

"Soliloquies had need be very few,
Extremely short, and spoke in passion too.
Our lovers talking to themselves, for want
Of others, make the pit their confidant:
Nor is the matter mended yet, if thus
They trust a friend, only to tell it us."—

SOLIMAGUE, in *Geography*, a small island near the west coast of Luçon. N. lat. 18° 3'. E. long. 120° 36'.

SOLIMAN, a country of Africa, near the source of the Gambia.—Also, a town of Tunis, the environs of which are inhabited by the descendants of the Moors, driven out of Spain, who preserve their ancient manners and language, and are more honest than other Africans; 20 miles E.S.E. of Tunis.

SOLIMAN, *Bay of*, a bay on the west coast of Africa, in the Strait of Babel-Mandeb. N. lat. 12° 3'.

SOLIMENE, FRANCESCO, called also *L'Abate Ciccio*, in *Biography*, was born at Nocera de Pagani, near Naples, in 1637. He was the son of a painter, Angelo Solimene, who at first educated him in literary pursuits, in which he was exceedingly assiduous, and made considerable progress; whilst at the same time he indulged himself in cultivating an inherent taste for design. By the advice of cardinal Orsini, Francesco was permitted by his father to change the object of his principal pursuit, and, instead of the law, to adopt the pencil, as the ground-work of his future fame. He became the disciple of Francesco Maria, and afterwards of Giacomo del Po; but soon left Naples, to go to Rome, where the freedom and brilliancy of Pietro da Cortona's execution and design attracted his admiration, and fixed his attention. To what he acquired of Cortona, he attempted to add the sweetness of Guido Rheni; and thus framed for himself a style remarkable for its ease and suavity, more than for its grace or truth. A very beautiful production of his is at Hampton Court, of the pool of Bethesda; but his most celebrated works are the sacrifice of S. Paulo Maggiore, and the Last Supper, in the refectory of the conventual at Assisi. Solimene possessed a vivid invention, and consequently a ready pencil; so much so, that his execution is always spirited and masterly, equally adapted to almost all kinds of subjects; and his colouring unites brilliancy and force. He died at Naples in 1747, aged 90.

SOLINGEN, in *Geography*, a town of the duchy of Berg, on the Wipper; 12 miles E.S.E. of Dusseldorf. N. lat. $51^{\circ} 8'$. E. long. $7^{\circ} 2'$.

SOLINUS, CAIUS JULIUS, in *Biography*, a Latin grammarian, but of what particular period is not known, though he is generally referred to the third century. He appears to have resided chiefly at Rome, but is known only as the author of a work, which he first entitled "Collectanea Rerum Memorabilium," afterwards "Polyhistor." This is a collection of the remarkable things in different countries, partly transcribed, without acknowledgment, from Pliny's Natural History; whence the author has been called the ape of Pliny. The work, however, of Solinus contains some things not to be found in Pliny, and it contains likewise an elucidation of some difficulties in the original; and on these accounts it has been deemed worthy of the notice of critics. Salmastius published an edition of it in two vols. folio, in which, however, the original is almost buried in the learning of the commentator. Solinus was author likewise of a poem, entitled "Ponticon," of which only a few verses remain. There have been many editions of the "Polyhistor," which were adapted to the taste of ages fond of wonders. The best modern ones are said to be the octavo of Salmastius, 2 vols. 1689; and Gesner's, printed at Leipzig in 1777.

SOLIO, in *Geography*, a river of Calabria, which runs into the Mediterranean, N. lat. $39^{\circ} 40'$. E. long. $16^{\circ} 6'$.

SOLIPUGA, or SOLIFEGA, in *Natural History*, the name given by the Romans to a small venomous insect of the spider-kind, called by the Greeks *heliocentros*; both words signifying an animal which flings most in the country, and seasons, where the sun is most hot.

Solinus makes this creature peculiar to Sardinia; but this is contrary to all the accounts given us by the ancients. It is common in Africa, and some parts of Europe.

Almost all the hot countries produce this venomous little creature. It lies under the sand, to seize other insects as they go by; and if it can meet with any uncovered part of a man, will bite him, and the wound will prove very painful and envenomed. It is said that the bite is absolutely mortal, but probably this is not true. Solinus writes the word *soli-*

fuga, and so do many others, erroneously deriving the name from its flying from the sun's rays, and burying itself in the sand.

SOLIS, ANTONIO DE, in *Biography*, a celebrated Spanish historian and poet, was born at Alcala de Henares. While he was very young, and a student, he wrote a comedy, which was extremely well received. It was followed by others, as well as by poems on different subjects, by which he raised a very high reputation. He was employed in the secretary of state's office, and the king, Philip IV., made him his own private secretary. In 1661 the queen nominated him historiographer for the Indies; and it was in this quality that he composed his "History of the Conquest of Mexico," a work which placed him among the most approved of the Spanish prose writers, and was greatly applauded both at home and abroad. De Solis took priests' orders when he was in the 57th year of his age, after which he renounced all connection with the theatre, and adopted a regularity of life conformable to his character as a priest. He died in the year 1686. The comedies of De Solis, which were printed collectively in 4to. Madrid, in 1661, are said by critics to be perplexed in their story, and rather romantic than comic; but they have afforded the foundation of many French plays. His poems are said to display more imagination than correct taste. His history is written with spirit and elegance, but there are occasional displays of the bombast and false taste, and frequently are to be met with great deviations from the truth. The object of De Solis is to make a perfect hero of Cortes, and on this account the history terminates with the conquest of Mexico, and does not touch upon subsequent cruelties. It has been translated into the French and English languages.

SOLIS, *Aquæ*, in *Ancient Geography*, a town of Albion, in the 14th route of Antonine's Itinerary, between Isca or Caerleon and Calleva or Silchester. *Aquæ Solis* was unquestionably Bath, which was much frequented by the Romans for its warm and medicinal springs.

SOLIS *Via*. See VIA.

SOLISTEN, in *Geography*, a town of Sweden, in the province of Angermanland; 42 miles N.W. of Hernofand.

SOLITAIRE ISLAND, a small island in the South Pacific ocean; 25 miles S. of Kerguelen's land. S. lat. $49^{\circ} 49'$. E. long. $68^{\circ} 6'$.

SOLITARIÆ GLANDULÆ, in *Anatomy*, those mucous glands of the intestines, which are arranged singly. See INTESTINE.

SOLITARY, SOLITARIUS, something retired, or in private; remote from the company or commerce of others of the same species. See HERMIT.

SOLITARIES, a denomination of the nuns of St. Peter of Alcantara, instituted in 1676, by cardinal Barberini, when abbot of Notre Dame de Faria, in that city.

The design of their institute is to imitate the severe, penitent life of St. Peter of Alcantara; to keep a continual silence; never open their mouths to any body but themselves; employ their time wholly in spiritual exercises; and leave the temporal concerns to a number of maids, who have a particular superior in a separate part of the monastery. They always go bare-footed, without sandals, gird themselves with a thick cord, and wear no linen.

SOLITARY Column, is a column that stands alone in any public place; as the Trajan column.

SOLITARY Worm, *Solum tania*, or *Lumbricus latus*, is a worm sometimes found in the intestines, and which is always the only one of the kind there; as commencing from the pylorus, and extending thence the whole length of the intestines;

intestines; so that there is no room for another. See TÆNIA and WORM.

SOLITARY Island, in *Geography*, an island in the South Pacific ocean, discovered by Mendana in the year 1595. It is low, round, and planted with trees; and the coast is surrounded with rocks. S. lat. $10^{\circ} 4'$. W. long. $178^{\circ} 20'$.

SOLITARY Islands, a cluster of small islands near the east coast of New Holland. S. lat. $30^{\circ} 8'$.

SOLITAUROLIA, in *Antiquity*. See SUOVETAUROLIA.

SOLIVA, in *Botany*, a genus in the *Flora Peruviana*, page 102, dedicated to Salvator Soliva, a Spanish physician and botanist. *De Theis*.

SOLIVE, Fr., among *Carpenters*, a joist, rafter, or piece of wood, either slit or sawed, with which the builders lay their ceilings.

SOLJURA, in *Geography*, a town of Bengal; 28 miles S.S.E. of Curruickpour.

SOLKIEV, or **ZOLKIEV**, a town of Austrian Poland, in Galicia; 10 miles N. of Lemberg.

SOLLAM MOSS. See *SOLWAY Moss*.

SOLLAPOUR, a circar of Hindoostan, in Vissiapour, between the rivers Kistnah and Beema, near their junction.—Also, a town of Hindoostan, and capital of the fore-mentioned circar, on the Kiltnah; 120 miles S.E. of Vissiapour. N. lat. $16^{\circ} 22'$. E. long. $77^{\circ} 10'$.

SOLLECITO, in *Italian Music*. This word has two acceptations: the one implies that a movement is to be performed with a mournful and forrowing expression; the other means carefully, and with accuracy.

SOLLERGUNGE, in *Geography*, a town of Hindoostan, in Oude; 9 miles E. of Lucknow.

SOLLERO, a town of Sweden, in Dalecarlia, on an island in lake Siljan; 48 miles N.W. of Fahlun.

SOLLIES LE PONT, a town of France, in the department of the Var; 13 miles S. of Brignole.

SOLMISATION, or naming the notes in the scale according to the hexachord of Guido. See *MUTATIONS* and *SERRA*.

SOLMISATION of the Greeks. The ancient Greeks had their solmisation in vocal music, as well as the moderns; having for that purpose used four monosyllables, ending with different vowels, for the exercise of the voice in singing; like our *mi, fa, sol, la*. These were, for the first note of each tetrachord, $\tau\acute{\alpha}$; for the second, $\tau\eta$; for the third, $\tau\omega$; and for the fourth, if it did not serve as the first of the adjoining and relative tetrachord, $\tau\epsilon$; but if it began a new tetrachord, it was called by the first name, $\tau\acute{\alpha}$.

The repetition of these monosyllables is a further proof that the *fourth*, in the ancient music, served as a boundary to a system of four sounds, in the same manner as a hexachord did in the Guido scale, and as an octave does for eight sounds in the more modern practice.

SOLMIZARE, in the *Italian Music*. See *SOLFEGGIARE*.

SOLMS, in *Geography*, a principality of Germany, situated in the Wetterau. The counts of Solms are supposed to be descended from the house of Nassau, and are divided into several branches, *viz.* Solms Braunfels, Solms Hohen-Solms, Solms Laubach, Solms Rodenheim, and Solms Lich.

SOLMS, Hohen. See *HOHEN-SOLMS*.

SOLMS, or Burg Solms, a town of Germany, in the principality of Solms Braunfels, having formerly a castle, which gave name to the county; 1 mile E. of Braunfels.

SOLMSBACH, a river of Germany, which runs into the Lahn, 2 miles N.E. of Braunfels.

SOLNAN, a river of France, which joins the Seille at Louhans, in the department of the Saone and Loire.

SOLNIZ, a town of Bohemia, in the circle of Konigingratz; 15 miles E. of Konigingratz.

SOLO, a mountain of Naples, in Lavora; 10 miles S.W. of Ponte Corvo.—Also, a town of Hindoostan, in Mewah; 30 miles N. of Dig.—Also, a town of South America, in the province of Cordova; 100 miles N.W. of Cordova.

SOLO, in *Italian Music*, used substantively, implies a composition for a single instrument, with a quiet and subdued accompaniment, to display the talents of a great performer; as a solo for a violin, German flute, or violoncello. In full pieces, *concertate*, each part is informed when it becomes principal, by the word *solo*; and when subordinate, by *tutti*, which implies the chorus, or full band.

In the concertos of Corelli, Geminiani, and Handel, chiefly composed *à deux cori*, or two orchestras, the principal parts are said to belong to the *concertini*, or solo parts; as *violino primo concertino*, *violino secondo del concertino*, &c.; and the inferior parts, that only play in the full chorus, are called *ripieni*; as *violino primo ripieno*, *violino secondo ripieno*, or *del concerto grosso*, or the great and full concert.

Solos, which used to afford the most exquisite delight to persons of refined taste, when composed and performed by great masters, are now wholly laid aside; and whoever attempts to perform one, is subjected to a penalty instead of a reward; a law instituted at the concert of ancient music, where a composition was never thought complete by the late earl of Sandwich, without a kettle-drum, nor with, unless he beat it himself. And at the Commemoration of Handel, the double drums, double cartels, tromboni, &c. augmented his lordship's pleasure, in proportion to the din and stenterophonic screams of these truly savage instruments; which, in so wide a building as Westminster Abbey, and softened by so powerful a chorus of voices and instruments as were assembled at the Commemoration, had, occasionally, a fine effect; but in a more confined space, the almost incessant use of the tromboni, and perpetual roll of the double drums, annihilate all the pleasing effects of mellifluous tones.

SOLOAYS, in *Geography*, a town of Pennsylvania; 24 miles N. of Easton.

SOLOE, in *Ancient Geography*, a town of the island of Cyprus, built, according to Strabo, by Acamas and Phalerus, both Athenians, but, as Plutarch says, by Demophon, on the banks of the river Clarius. It was situated on an eminence in a barren territory, and called "*Æpira*," denoting *high*, on account of its elevated position. Many ages afterwards, when Solon came to Cyprus and formed a league of friendship with Phylauptus, one of the kings of the island, he advised him to remove the town to a neighbouring plain, on the banks of a river with a port over-against Cilicia. This new city was called *Σολοι*, and in Latin *Solæ* or *Soli*, from the name of Solon. It is now "*Solin*." Another town of the same name in Cilicia, is called by Pliny "*Soloe Cilicij*," by way of distinction from the other. This was afterwards called "*Pompeipolis*."

SOLOE, a cape of Africa, on the Atlantic ocean, which the Periplus of Hannon places at the distance of three days' journey south of the promontory "*Hermeum*." Hannon built on the summit an altar consecrated to Neptune, and it was in process of time adorned with bas-relief works of art, which rendered it the most celebrated place on the coast.

SOLOEIS, a promontory of Libya, at the extremity of mount Atlas, now called Cape Cantin. It is mentioned by Herodotus.

SOLOENTIA, a promontory of interior Libya, between the mouth of the river Nunius and that of the river Maffa, according to Ptolemy.

SOLOFRA, in *Geography*, a town of Naples, in Principato Ultra; 18 miles S. of Benevento.

SOLOGNE, a district of the government of Orleanois, in France, before the revolution, about 60 miles in length, and 18 in breadth, of which Romorantin was the capital.

SOLOK, a town of Lithuania, in the palatinate of Troki, on a lake; 40 miles N.N.E. of Zytomiers.

SOLOMBO, GREAT, a small island in the East Indian sea. S. lat. $5^{\circ} 36'$. E. long. $114^{\circ} 45'$.

SOLOMBO, *Little*, a small island, a little N.E. of Great Solombo.

SOLOMBOL, an island of Russia, in the government of Archangel, situated on the river Dwina; which has a dock-yard for building ships, with a fort and garrison; 5 versts above Archangel.

SOLOMIAC, a town of France, in the department of the Gers; 14 miles S.E. of Lectoure.

SOLOMON, in *Biography*, a king of the Jews, eminently distinguished by his wisdom, wealth, and extent of territory, was the son of David by Bathsheba, formerly the wife of Uriah, and born in the year B.C. 1033. By the influence of Bathsheba, and the recommendation of Nathan, Zadok, and other friends, who thought it necessary to counteract the views and measures of Adonijah, David's eldest son, he was proclaimed the destined successor of his father before his death. When this event took place, B.C. 1015, he ascended the throne of all Israel, not only without opposition, but amidst the acclamations of the people. For his greater security, he ordered Adonijah, and Joab, who was attached to his interest, to be put to death. As soon as he was confirmed in his kingdom, he contracted an alliance with Pharaoh, king of Egypt, and married his daughter, whom he brought to Jerusalem, and for whom he afterwards built a sumptuous palace; receiving for her dowry the city of Gezer, which had been taken from the Canaanites. It was on occasion of this marriage, as some have thought, that he composed the Canticles, as a kind of epithalamium; and the 45th Psalm has been also referred to the same event. About this time he led his troops, and all Israel, to Gibeon, where he offered a thousand burnt-offerings upon the brazen altar. In the following night he is said to have been favoured with a vision, in which God promised to grant him whatsoever he desired: and as the object of his prayer was wisdom for discharging the duties of his high office, his request was fully granted. Upon his return to Jerusalem, he offered a great number of sacrifices on the altar, before the ark of the Lord, and made a great feast for his servants. As an instance of his wisdom, he decided a dispute between two mothers, who claimed the same child. (1 Kings, iii. 16—28.) In token of the acceptableness of his petition, he also obtained, more than he asked for, a gratuitous donation, on the part of God, of riches and honour: which were amply displayed in the magnificence of his court, the amount of his revenues, the multitude of his subjects, the number of his civil and military establishments, and a variety of other circumstances, which rendered him one of the most celebrated monarchs of the East. His reign was peaceful and prosperous. Judah and Israel were united and secure, and his neighbours either formed an alliance with him, or paid him tribute. His dominions extended from the Euphrates to the Nile; and his reputation for wisdom was spread through all nations.

As soon as Hiram, king of Tyre, heard of his accession to the throne of Israel, he deputed ambassadors to congratu-

tulate him; and with the acknowledgment of this message, he requested to be supplied with wood, and able artificers to assist in constructing the temple at Jerusalem, which, in deference to his father's vow, he had undertaken to execute. The completion of this magnificent edifice conferred singular celebrity on the reign of Solomon. It was begun in the 4th year of his reign, and the second after the death of David, B.C. 1012, and 480 years after the Exodus. In the various departments of this great work, he employed no less than 183,600 persons. This wonderful structure was completed in the 11th year of Solomon, or in the short space of seven years; and it was solemnly dedicated on Friday, Oct. 30, B.C. 1000 years. Solomon afterward built two palaces, one for himself and another for his queen; and the construction of the temple and palaces occupied a period of twenty years. He also built the walls of Jerusalem; and he repaired and fortified a great number of cities. The great expence which he thus incurred was defrayed by a commerce which he carried on from Ezion-geber and Elath, on the Red sea, to Ophir; for the situation of which see OPHIR.

Solomon, however, notwithstanding the wisdom which rendered him so famous, had not sufficient fortitude for resisting the temptations that accompanied his prosperity. He was betrayed, in the most culpable and disgraceful manner, into the vices attendant on luxury and sensuality. Besides 700 wives, he had 300 concubines; and in his declining age, though he had erected a temple to Jehovah the true God, and was thus implicitly pledged to preserve the religion of the Jews pure and uncorrupted, their influence caused him to degenerate into the most inexcusable idolatry, setting up as objects of worship, Ashtoreth, goddess of the Sidonians, Moloch, the idol of the Ammonites, and Chemosh, the god of the Moabites, and building for them temples on the mount of Olives, over-against, and east, of Jerusalem. As a just punishment of his culpable conduct, the sovereigns of Edom and Syria were excited against him, and he saw, before his death, the commencement of that revolt which terminated in the division of the kingdom.

Solomon closed his life and reign in the year B.C. 975, having reigned 40 years, at the age of 58. Such is the Scripture account, but Josephus assigns to him a reign of 80 years, and a life of 94 years. He was buried in the city of David, and succeeded by his son Rehoboam, who reigned only over part of the divided kingdom of Israel. Tradition ascribes to him a great number of books; but those only under his name admitted into the canon of Scriptures, are the "Proverbs," "Ecclesiastes," and the "Canticles." See each in its proper place.

SOLOMON'S *Seal*, in *Botany*, a plant called by authors *polygonatum*; which see. See also CONVALLARIA.

SOLOMON'S *Islands*, in *Geography*, a group of islands in the Pacific ocean, discovered by Mendana in 1565; and afterwards by M. Surville, in 1767, who called them *Artacides*, or *Assassins*; they were passed by Lieut. Shortland in 1788, and called by him *New Georgia*. See ARSACIDÆ and GEORGIA.

SOLON, in *Biography*, one of the sages of Greece, and the celebrated law-giver of the Athenians, was born in the seventh century before Christ. He was of a family descended from the ancient kings of Athens, but which, in the revolutions of time, had fallen into indigence, for he passed his early years in travelling on mercantile business. He shewed an early disposition for poetry, which he first exercised on the following occasion. The Athenians, in a war with the Megarensians, had been expelled from the isle of Salamis, and their efforts to recover it were attended with so

much

much loss, that a law passed to make it a capital offence for any one to propose a renewal of the attempt. Solon, feeling mortified at the disgrace attached to this decree, composed an elegy adapted to rouse the spirits of the people, and feigning himself to be under the influence of a temporary insanity, ran into the market-place, mounted the cryer's stool, and pronounced his verses with great vehemence. The crowd gathered round felt a rising ardour; which was farther excited by an harangue of Pisistratus, and they, without hesitation, decreed a war against the Megarensians. Salamis was recovered, and, according to a tradition which has been generally received, by a stratagem of Solon's. He afterwards increased his reputation by advising a war with the people of Cirrha, who had ravaged the sacred territory of Delphi, and contributed to the reduction of their city. Athens at this time was in a very unquiet state, arising as well from the contentions of different political factions, as from the oppressions of the superior classes, who had reduced a great part of the common people to slavery, in consequence of their debts. Solon, in this emergency, was looked up to by the citizens in general as the man who, by his wisdom and virtue, was best qualified to restore public tranquillity, and a large party was desirous of raising him to the sovereignty. This, however, he positively declined; but being chosen archon by acclamation in the year B.C. 594, he set himself to compose the dissensions by moderate measures. At first his plans were not well received, but reflection convinced all parties that his object was good, and they unanimously invested him with the high trust of new-modelling their laws and constitution. He abrogated the sanguinary laws of Draco, excepting such as related to homicide. Democracy being the form of government to which the Athenians were attached, he regarded it as the base of his new constitution, but studied to give it due checks and counterbalances. Hence he divided the citizens into four classes, three of which were formed upon different scales of property: the fourth included those of the lowest order, who were destitute of all property. These were excluded from public offices, but admitted to vote in the general assembly of the people. As this body was in possession of the supreme power, and judged causes in the last resort, the consequence, or at least the safety, of the meanest members of the state was sufficiently secured. To prevent inconsiderate resolutions in the democratic assembly, he instituted a senate of 400, which was to have a prior deliberation upon every proposal to be submitted to the general assembly. Solon revived the ancient Areopagus, and ordained that it should be composed only of those who had passed through the office of archon, the highest magistracy of the state; which conferred on it a splendour that rendered its decrees revered through the whole of Greece. The laws of Solon have been ranged under various heads, but it would not comport with our plan to enter at large into their nature. Their general spirit is mild and equitable. One of them has been the subject of much political discussion: this was, that in any case of civil contest, in which opposite parties take up arms, the citizen who remains neuter shall be punished with exile and confiscation of goods: another regulation, very salutary in its effects, and well adapted to a small state, was, that the Areopagus should have full power to enquire how every citizen supported himself, with the view of inflicting penalties on the idle.

As an apology for any imperfection that might be found in his code, Solon was accustomed to say, "I have given to the Athenians not the best possible laws, but the best they were capable of receiving." The code given by Solon was intended by the author to be in force a century, and then to

be revised and amended, as occasion might seem to demand. After the promulgation of his code, Solon was continually molested by persons who came to him, either for explanation of obscure passages, or with proposals for improvements of which they imagined it capable. To avoid their importunities he resolved to travel; and having obtained leave of absence for ten years, and exacted an oath from the citizens, that nothing should be altered till his return, he sailed to Egypt. He there procured instructions in philosophy from the priests of Heliopolis and Sais, one of whom, it is said, in the pride of Egyptian antiquity, said to him, "Solon, Solon, you Greeks are children, you have not a grey-headed man among you." From Egypt he went to Cyprus, where he suggested to one of the petty princes the erection of a new city, which was called after his name. About this time also he held a conference with Thales, the Milesian, recorded by Plutarch, and it was about this period that he visited the court of Cræsus, king of Lydia.

On his return to Athens, he found the state in great confusion from the contests of different factions. Pisistratus had placed himself at the head of the popular party, and was aiming, through its favour, at the sovereignty. Solon attempted to oppose the current, but in vain: he appeared with his arms in the assembly, and harangued the people, but he had lost his influence, and being wholly unable to rouse the people, he withdrew from Athens never more to return. The place and time of his death have never been accurately ascertained, but it is generally believed that he died at Cyprus, at the age of eighty. The Athenians held his memory in such high reverence, that they erected a statue of brass to his memory in the forum: the opinion of mankind at large has, however, survived the brazen memorial, and he is still regarded as among the greatest benefactors of mankind.

Solon was one of those early Greek philosophers who were distinguished by the appellation of the seven wise men. Philosophy had in that age attained to no systematic cultivation, and the only monuments of the wisdom of most of those ancient sages which have come down to us, are some short moral and prudential maxims, which seem to require for their discovery little depth of penetration or extent of observation. They have, however, been consecrated to perpetual remembrance by the gratitude and admiration of Greece. That the laws of Solon might be open to the inspection of the people, they were inscribed on wooden tablets, turning on axes, and said to have been of different forms, according as the laws which they contained related to private or public affairs. The mode of writing is that which is termed in the Greek language *βασίλειος*, that is, from the right to the left, and then from left to right; the term is taken from the method used in ploughing, which was always done in ancient times by means of oxen. The fragments of Solon's laws have been collected by various writers, but with very great care by Samuel Petit, in a learned work, which is, however, not free from inaccuracies, and conjectures that will not bear the test of criticism. This work was published at Paris, in folio, in the year 1635, under the title of "Leges Atticæ." It was republished by Wesseling, with many improvements, and the additions of his own remarks and those of other critics, in 1742. Diogenes Laërtius has annexed to his life of Solon four epistles, which he ascribes to that philosopher, addressed to Periander, Epimenides, Pisistratus, and Cræsus. Of his sayings or maxims, the following have come down to us. "Laws are like cobwebs, that entangle the weak, but are broken through by the strong:" "He who has learned to obey, will know how to command:" "In every thing you do, consider the object and end:" "In

all things let reason be your guide:" " Diligently contemplate excellent things." Of the poetical talents of Solon, time has left us little opportunity of judging. Thirty-one fragments, collected from Stobæus and other writers, have been printed by Brunk. They are written in various measures, but chiefly in the elegiac. Many of them, in a style resembling that of Theognis, the poet of Megara, are employed in the illustration of useful maxims relative to the conduct of life and formation of manners. The scanty fragments of the Salaminian elegy, to which we have already referred, manifest considerable animation, so that we can easily give credit to what is said of the effect which it produced.

SOLON, in *Geography*, a military township of America, in the state of New York and county of Cortland, bounded N. by Troxton, E. by Chenango county, S. by Cincinnati, and W. by Homer; 10 miles E. of Homer, and 132 miles W. of Albany. It is 12 miles square, and an excellent tract of land. The timber in this township is maple, beech, elm, ash, butternut, bass, together with some pine and hemlock. The soil is principally a warm gravelly loam, well adapted for farming, and the inhabitants are farmers. The population in 1810 consisted of 1270 persons. The roads in this township are in good order; and great numbers of lean cattle are driven from hence every year to Philadelphia, West Chester and Duches counties. —Also, a town of Maine, in the county of Somers, containing 312 inhabitants.

SOLONIUM, in *Ancient Geography*, a town of Italy, in Etruria, according to Dionysius Halicarnassus.

SOLOOKUPA, in *Geography*, a town of Bengal; 15 miles N.N.E. of Nuldingah.

SOLOON, a small island in the East Indian sea; 25 miles from Samar. N. lat. 10° 55'. E. long. 125° 42'.

SOLOR, an island in the East Indian sea, S. of Celebes, about 70 miles in circuit, separated from the E. coast of the island of Flores by a narrow channel, called the Straits of Flores. S. lat. 8° 33'. E. long. 125° 42'.

SOLOS, Σολος, in *Antiquity, an instrument with which the exercise of the quoit was performed, which some will have to be distinguished from the discus, because that was of iron, this of stone; but others, with more reason, report that the difference consisted in this, viz. that the σολος was of a spherical figure, and the discus broad.*

SOLOT, in *Geography*, a small island in the Indian sea, near the coast of Africa. S. lat. 12° 8'.

SOLOTHURN. See **SOLEURE**.

SOLOTKOVA, a town of Russia, in the government of Irkutsk, on the Ilmin; 60 miles S.W. of Orlenga.

SOLOTNICK, in *Commerce*, a weight in Russia, which expresses the fineness both of gold and silver; the pound or other weight being divided into 96 such parts: so that the solotnick is also the $\frac{1}{96}$ th part of a Russian pound weight. According to the mint regulations established in the reign of the emperor Paul, and confirmed by an edict of the emperor Alexander, in 1801, 22 $\frac{3}{4}$ rubles are to contain a Russian pound of fine silver; and they are to be 83 $\frac{1}{2}$ solotnicks (or 10 oz. 8 dwts.) fine; so that each ruble should weigh 320 $\frac{1}{4}$ English grains, and contain 277 $\frac{1}{2}$ grains of fine silver. It was declared that no gold coin should be hereafter struck in Russia, except the imperial and half-imperial, the standard of which was raised to 94 $\frac{1}{2}$ solotnicks, or 188 $\frac{1}{2}$ English grains. Accordingly,

	£	s.	d.	
The imperial is worth	1	12	9 $\frac{1}{2}$	} valued in English gold.
The ducat	0	9	1	
The ruble of 1763	0	3	3	} valued in English silver.
— of 1801	0	3	2 $\frac{1}{2}$	

By an assay lately made on a number of rubles at the London Mint, by order of the Bank of England:—

Rubles of 1763, weight from 14 dwts. 21 grs. to 15 dwts. 20 grs.; average 15 dwts. 8 $\frac{1}{2}$ grs.; fineness 44 dwts. worse than English, that is, 8 oz. 18 dwts.

Rubles of 1801, weight from 13 dwts. 2 grs. to 13 dwts. 12 grs.; average 13 dwts. 7 grs.; fineness 14 dwts. worse than English, that is, 10 oz. 8 dwts. Thus we have the value of the old ruble 3s. 2d. sterling, and of the new, 3s. 2 $\frac{1}{2}$ d.

The Russian weights are as follow, viz. the berquet or berkowitz contains 10 poods; the pood, 40lbs.; the pound, 32 loths; and the loth, 3 solotnicks. The Russian pound weighs 28 loths, Cologne weight, or 6314 troy grains. Hence 500lbs. Russian = 451lbs. avoirdupois. The ordinary computation among merchants is, that 36lbs. avoirdupois = the pood of 40lbs. Russian; and that 63 poods = 1 ton avoirdupois. Kelly's Cambil.

SOLOVETZKOI, in *Geography*, a small island of Russia, in the White sea. N. lat. 64° 55'. E. long. 30° 14'.

SOLRE-LIBRE (*Le Chateau*), a town of France, in the department of the North, and chief place of a canton, in the district of Avesnes; 6 miles N.E. of Avesnes. The place contains 1525, and the canton 7134 inhabitants, on a territory of 212 $\frac{1}{2}$ kilometres, in 23 communes.

SOLSEQUIUM, a word used by some chemical writers as a name for sulphur.

SOLSOGAN BAY, in *Geography*, a bay on the S. coast of the island of Luzon. N. lat. 13° 12'. E. long. 123° 50'.

SOLSONA, or **SALSONA**, a town of Spain, in Catalonia, the see of a bishop, suffragan of Tarragona; 97 miles E. of Saragossa. N. lat. 42° 2'. E. long. 1° 22'.

SOLSTICE, **SOLSTITIUM**, in *Astronomy*, the time when the sun is in one of the solstitial points; that is, when he is at his greatest distance from the equator, which is 23° 28': thus called, because he then appears to stand still, and not to change his place in the degrees of the zodiac, any way: an appearance owing to the obliquity of our sphere, and to which those who live under the equator are strangers.

The solstices are two in each year; the *æstival* or *summer* solstice, and the *hyemal* or *winter* solstice.

The summer solstice is when the sun is in the tropic of Cancer; which is on the 21st of June; when he makes the longest day.

The winter solstice is when he enters the first degree of Capricorn; which is on the 22d of December; when he begins to return towards us, and makes the shortest day.

This is to be understood as in our northern hemisphere; for in the southern, the sun's entrance into Capricorn makes the summer solstice, and that into Cancer the winter solstice.

Mr. Pond, the astronomer royal, from observations made on the summer and winter solstice, deduces the mean obliquity of the ecliptic for January 1, 1813, as 23° 27' 51".50 from the former, and from the latter 23° 27' 47".35.

SOLSTITIAL POINTS, are those points of the ecliptic, by which the sun's ascent above the equator, and his descent below it, are terminated.

The first point, which is in the beginning of the first degree of Cancer, is called the *æstival* or *summer* point; and the latter, which is in the beginning of the first point of Capricorn, the *winter* point. The solstitial points are diametrically opposite to each other.

SOLSTITIAL Colure, is that which passes through the solstitial points. See **COLURE**.

SOLTAU, in *Geography*, a town of Westphalia, in the principality of Luneburg Zelle. The inhabitants are for the most part clothiers; 29 miles N.N.W. of Zell. N. lat. $53^{\circ} 4'$. E. long. $9^{\circ} 55'$.

SOLTCAMP, a town of Holland; 13 miles N.W. of Groningen.

SOLTE, a river of Germany, which runs near Klopensburg in Munster, and joining the Vehnne, takes the name of Soelt, on the borders of Friesland.

SOLTENHAGEN, a town of Hinder Pomerania; 8 miles E. of Zachan.

SOLTKOTT, a town of Westphalia, in the bishopric of Paderborn, famous for its salt-works; 6 miles S.W. of Paderborn.

SOLTZ, a town of Germany, in the county of Henneberg; 4 miles N.W. of Meinungen.

SOLVA, a river of South Wales, in the county of Pembroke, northward of Milford Haven, which forms the port and harbour of the little town of the same name. This small town is situated in a deep valley, pervaded by the above-mentioned river. Most of the houses are of modern erection, and exhibit a neat appearance. They lie principally on the western side of the vale, forming one street in the direction of the river, but scattered without plan or order on the steep acclivity above. Solva is a sea-port, and carries on a small commercial intercourse with the adjacent parts of the coast, chiefly with Milford. Its rapid increase in size, of late years, is an evidence of its prosperity.

SOLVACH BAY, a creek of South Wales, on the N. side of St. Bride's bay; 3 miles E. of St. David's.

SOLUBILITY of Salts, in *Chemistry*, denotes their capacity to unite with, and remain suspended in water; and the different salts possess different degrees of solubility, requiring more or less of this fluid for their solution. See **SALTS**.

SOLUBLE, in *Medicine*, loose, or apt to go to stool. In chemistry it signifies easily dissolvable.

SOLUBLE Tartar. See **TARTAR**, and *Tartrate of Potash*, under **SALTS**.

SOLUBLE Matter of Plants, in *Agriculture*, the soluble parts of them, or the portion of vegetable matter which they contain, and which is capable of solution and of being employed as the food and nourishment of man and animals. The quantities or proportions of this matter, which different plants or vegetable substances possess, is very different. It is consequently not improbable, but that the difference in the nutrient powers of different plants and substances of the vegetable kind may, in a great measure, depend upon this difference in the quantities or relative proportions of the soluble matter which they may contain, but their utility and importance as food do not appear to be wholly dependent upon this circumstance.

SOLUBLE Matter of Soils, the resolvable matter in them, or the quantity and proportion of this sort of matter which they contain in different cases, and which is capable of being converted to use as food for the support and growth of plants as crops. Some soils abound much with materials of this nature, while others are almost wholly deficient of them. This, in some degree, constitutes the difference of fertility in lands, though it is influenced by a great variety of other causes. See **SOIL**.

The rich black soils are, for the most part, the most abundantly provided with this kind of matter, though many others possess it in a considerable proportion.

SOLUE, in *Geography*, a town of Africa, in the country of Barca; 10 miles S.W. of Curen.

SOLVENT, the same with *dissolvent*. See **SOLUTION**.

SOLVENT, *Universal*, in *Alchemy*. See **ALKAHEST**.

SOLVESBORG, in *Geography*. See **SOLFWITZBURG**.

SOLUMBERE, a town of Hindoostan, in the circuit of Oudipour; 35 miles S. of Afawully.

SOLUMBERGA, a town of Italy, in Friuli; 7 miles N. of Aviano.

SOLUS, in *Ancient Geography*, a town of Sicily, according to Pliny; marked in the Itinerary of Antonine as the route from the Lilybæan promontory to the Tyndaris, between Panormus and Thermæ.—Also, a promontory of Libya, on the coast of the Atlantic sea, according to the Periplus of Scylax. A temple, dedicated to Vengeance and Neptune, was erected on the summit of this promontory.

SOLUSAPRA, a town of Sicily, on the route from Tyndaris to the Lilybæan promontory, according to the Itinerary of Antonine.

SOLUTIO CONTINUI, or *Solution of Continuity*, a term used by physicians, &c. to express a disorder common to the solid parts of the body, in which their natural cohesion is separated: as by a wound, or other cause.

If this happen to a simple, similar part of the body, it is called simply *solutio continui*: if to a compound or organical part, it acquires a particular denomination, from the nature of the part, the difference of the cause, or the manner of application; as a *wound, rupture, fracture, puncture, fissure, contusion, ulcer, corrosion, dilaceration, exfoliation, caries*, &c.

SOLUTION, **SOLUTIO**, in *Algebra and Geometry*, is the answering of a question; or resolving any problem proposed. See **RESOLUTION** and **REDUCTION of Equations**.

The solution of the problem of the quadrature of the circle, and that of the duplicature of the cube, by right lines, are held impossible.

SOLUTION of Continuity, in *Surgery*. See **SOLUTIO CONTINUI**.

SOLUTION, in *Physics*, the reduction of a solid or firm body into a fluid state, by means of some menstruum.

Solution is frequently confounded with what we otherwise call *dissolution*, but there is a difference.

SOLUTION, in *Chemistry*, is sometimes used for the analysis, or reduction, of a natural body into its chemical principles.

In this sense, solution is the same with what we otherwise call resolution.

Solution, as the term is commonly used by chemical writers, consists in an union formed by the integrant parts of one body with those of another body of a different nature; and this cannot be effected till the aggregation of one, at least, of the two bodies is broken. And as bodies, whose aggregation is broken, are necessarily in a state of fluidity, or of vapours, an axiom has been formed, *corpora non agunt nisi sint fluida*, i. e. bodies do not act unless they be fluid.

The two bodies which unite in solution, are commonly distinguished by two different names. That body is generally called the *solvent*, which, by its fluidity or acrimony, appears to be active; and the body which, from its want of taste, or from its solidity, appears to be altogether passive, is said to be *dissolved*. E. g. When metal or marble is dissolved in aqua fortis, the solid bodies are considered as being dissolved, and aqua fortis as the solvent. Nevertheless, it must be remembered, that two bodies, which unite together in solution, act reciprocally upon one another, and their union is the effect of their mutual affinity or tendency to each other: and thus the marble and metal act as much upon the nitrous acid as this does upon them.

That a solid may be dissolved in a fluid, it is necessary that the force of affinity between the two should be sufficient to overcome the force of cohesion between the particles of the solid; and hence it is, that heat so much assists solution by lessening the force of cohesion between all particles of matter.

M. Gellert, however, represents as solvents, the bodies which are generally considered as dissolved, and hence, he says, that sand dissolves alkali. If, indeed, we allow the action of the combining bodies to be mutual, it signifies little which we call the solvent, and which the body dissolved; though it seems more clear and accurate to call that body the solvent, whose integrant parts are already separated before the solution, and that the body dissolved, whose integrant parts are only disunited during the act of solution. The solution of bodies may be effected either by the humid, or by the dry way; of the former kind are those solutions, in which the integrant parts of one or both of the two bodies are distributed in an aqueous fluid, *e. g.* of acids; and those solutions, in which one or both bodies are rendered fluid by fire, as in vitrification, and in alloys of metals with each other, are of the latter kind. A perfect solution requires, that each of the integrant parts of one body be united to one of the integrant parts of another: hence, if one of them be transparent, we ought to have, after the mutual solution, a transparent compound, such as occurs in the solutions of calcareous stones and acids, and those of earths by alkalis: whereas the solution of soap in water is incomplete; and the same may be said of glasses that are not perfectly transparent.

As the solution of two bodies can only be effected by the mutual attraction of their parts to each other, these parts, after the solution, are found to adhere together: so that heavy bodies, *e. g.* corrosive sublimate, may be suspended in the thinnest and lightest liquids, *e. g.* spirit of wine, when they are truly dissolved by each other.

In all cases of solution at a common temperature, it generally happens, that the mixture in the act of solution becomes either warmer or colder than the ingredients were before the mixture. This is owing to an evolution or absorption of free caloric, from the mixtures having a less or greater capacity for caloric, than the mean capacity of the two substances taken separately. See CALORIC.

It happens also, in the greater number of cases of solution, that the mixture has a greater specific gravity than the mean gravity of the ingredients, relatively to their respective quantities. Hence they occupy less space than before, which may be seen by putting into a bottle any soluble salt (*e. g.* sulphate of soda), and filling it to the brim with water; after the solution is effected, the liquor will appear to have sunk through a certain interval below the first level, without any loss of the ingredients. See AFFINITY.

When solutions of salts are congealed, the ice often affords very pretty figures; but it is to be observed, that the same salt does not always give the same figures. Thus, the same solution of verdigris, frozen by means of snow and salt, affords a different figure, from what is produced by the natural cold of the air. And the former ice being thawed, and left to freeze in the same phial, did not give the same figures as at first. See Boyle's Works Abridged, p. 168.

SOLUTION, in *Metallurgy*, is distinguished into dry and moist. The dry solution is the blending imperceptibly a small quantity of a metal or mineral, with a very large one of some other body, dry, hard, and not fluid when cold. The moist solution is the distributing a body through the

very minutest parts of an aqueous, or in great part aqueous fluid, in such manner, that both may turn into a fluid, to appearance homogeneous, which goes through all filters, without being detained or separated by them, and the smallest part of which contains in it a proportionable quantity of both the menstruum or dissolvent, and of the dissolved body. The solution of gold in aqua regia, and of silver in aqua fortis, as also that of any of the salts in water, are solutions of this kind. Cramer's Art of Assaying, p. 194.

In the making of the several metallic resolutions, for the necessary processes in chemistry, the operator is subject to great danger in his health, from the noxious vapours. This has been an accident complained of indeed by many, but scarcely attempted to be remedied or obviated by any, in a rational way, till M. Geoffroy, whose experiments subjected him greatly to the mischief, employed his thoughts, for his own sake, as well as that of the world in general, to the effectual prevention of it.

The dissolution of the metals in the corrosive acid spirits are those, which send out the most copious and most dangerous vapours. The exhalation of quicksilver, of antimony, and of lead and copper, are all in themselves greatly hurtful, as well as the fiery vapours of spirit of nitre, sea-salt, or vitriol; and if either of these is singly so, how pernicious must they need be in those cases, where two of them are joined together in such a manner, as that this union sends up infinitely more vapours than would otherwise arise; in this case the utmost care is necessary to prevent the chemist from falling a sacrifice to his zeal for his discoveries.

The common way of avoiding this danger, is by making the solution either abroad in the open air, or in a chimney; but sometimes these cautions cannot be used, and under some circumstances they are ineffectual. This gave occasion to M. Geoffroy to use a method, which he afterwards proposed to the public, of stopping the rise of the vapours entirely, or at least of diminishing them so greatly, that they shall be harmless and unperceived. All that was necessary to this, seemed to him to be the contriving to cover the surface of the fluid with some body, capable of retaining those vapours, yet not capable of disturbing the operation of the menstruum on the metal; and the common expressed oils of fruits, as the oil of olives, almonds, or the like, were found capable of happily performing this effect; and that particularly, as they would easily receive into themselves the acid salts which arise in the conflict. The thing which gave this gentleman the hint of the discovery was, that in the boiling of sugars, honey, or the like substances, when there is any danger of their boiling over the vessel, the pouring in a little oil stops the swelling. In the metallic solutions it has the same effect; and that heightened by this good consequence, that by keeping in the fiery vapours of the acid, it returns them back upon the metal, and by this means does, in effect, add greatly to the power of the menstruum.

This method of using oil has indeed three advantages. 1. The preserving the operator from the injuries of the vapours. 2. The greatly moderating of that violent rarefaction, which is often of ill consequence. And 3. The same quantity of the menstruum, by this means, dissolves more of the metal. The best method of making solutions with this advantage is this: first, wet the surface of the metal to be dissolved with water, or spirit of wine; then pour a little water, or spirit of wine, into the glass in which the solution is to be made, this will prevent the oil from sticking to the surfaces of either; then put the metal into the glass, and pour

pour in the oil upon it; last of all, pour on the menstruum: this, being greatly heavier than the oil, will sink to the bottom and work upon the metal, while the oil perfectly covers the whole surface. There is no need to be exact as to the quantity of the oil, but more or less is to be used, in proportion to the greater or less ebullition which the mixture is expected to make.

The air-bubbles, which arise to the surface with great impetuosity in the making of these solutions, are here seen to break by degrees as they enter the covering of oil, and generally are quite dissipated before they arise to the surface of it. The few of them which retain their figure till they arrive at the surface, there burst and give a slight exhalation; and one may continually see the drops of the menstruum falling back again out of the oil into it, after being deserted by the bubbles of the air which had raised them so far. On the contrary, in the common way of making solutions, the air-bubbles push one another up to the surface, where they form a sort of scum, which continually thickens by their fresh rising and supporting one another, till it often rises over the top of the vessel. These bubbles of air seem to be formed of small particles of air extremely condensed in the pores of the metal, which, when the particles of it are separated for solution, find themselves at liberty to dilate and expand, and arise to the surface in their proper form.

If it be thought necessary, in any solution which raises a more than ordinary quantity of vapours, to prevent the flying off of that small quantity which may escape through the oil, there is nothing more necessary than to pour a little spirit of wine upon the oil; for the acid vapours which pass the oil will then be received in the spirit, and will be dulcified in it, and instead of a disagreeable odour, will yield only a very sweet and safe one. Spirit of wine alone, used instead of oil, and poured gently on the solution, has very great effects; inasmuch, that if used to the solutions in spirit of nitre, which usually send up very noxious and coarse red vapours, they by this means are made to send up only very fine light white ones, and these of a very agreeable smell: the bubbles raised in this case are very small, and usually burst before they arrive at the surface of the spirit. The only objection to this method is, that the spirit of wine soon mixes itself with the menstruum, and there are some cases in which this may be of ill consequence to the process. Mem. Acad. Par. 1719.

SOLUTIVE, LOOSENING, or Laxative. See LAXATIVE.

SOLWAY FRITH, in *Geography*, an arm of the sea, branching off from the Irish sea, and forming a considerable part of the boundary between England and North Britain. Reckoning it to commence at Salterns Point, the S.E. corner of Galloway, its breadth to the nearest land in Cumberland is about eight miles, and its length, inland, to the east, 22 miles. As its outline, however, is rather irregular, it may be considered as comprehending an extent of 80 miles of sea-coast, of which 36 miles are on the Scottish shore and the remainder on the English side. This frith opens to the west, and is rather a troublesome navigation, as it abounds with shoals. The tides here are extremely regular, spring tides rising 20 feet above low water-mark, and ordinary tides about 10 or 12. Numerous rivers pour their waters into the Solway, of which the principal are the Nith, the Annan, the Esk, and the Leven, in Scotland, and the Eden and Wampool, in England. The Solway abounds with fish of various kinds, but particularly with salmon, which are caught in great quantities, and either sold in the neighbourhood, or sent pickled to London and other parts

of England. The modes of taking this valuable fish here are so singular as to deserve a particular detail. They are four in number, first with leisters, a kind of four-pronged fork, with the prongs turned a little to one side, having a shaft from 20 to 24 feet long; these the fishermen run along the sand on the edge, or throw them when they see any fish; in this manner they kill or wound great numbers. Some of the people are very dexterous at this exercise; inasmuch that, according to Mr. Pennant, they will on horseback, at full gallop, throw a leister, and kill at a great distance. 2. By *beaving* and *hauling*, that is, by standing in the current of the tide with small hand-nets. 3. By fixing small pock-nets to stakes in the currents. These nets are made with wide meshes, and the fish that come rapidly down with the stream, instantly run their heads into the meshes, from whence they are unable to disengage themselves. The other method is the common one used in other parts for catching salmon. Sinclair's Statistical Account of Scotland, 8vo. 1796. General Report of Scotland, 8vo. 1814. History and Antiquities of the Counties of Westmoreland and Cumberland, 4to. by Joseph Nicholson, esq. and Richard Burn, LL.D.

SOLWAY MOSS, a tract of land in Cumberland, England, is entitled to some notice in this place on account of the extraordinary effects of its eruption in the year 1771. Mr. Gilpin, in his "Observations on the Mountains and Lakes of Cumberland," &c. two vols. 1781, thus describes the nature of the place and the particulars of the inundation. "Solway Moss is a flat area, about seven miles in circumference. The substance of it is a gross fluid, composed of mud, and the putrid fibres of heath, diluted by internal springs, which arise in every part. The surface is a dry crust, covered with moss and rushes; offering a fair appearance over an unsound bottom, shaking with the least pressure. Cattle, by instinct, know and avoid it. Where rushes grow the bottom is soundest: the adventurous passenger, therefore, who sometimes, in dry seasons, traverses this perilous waste, to save a few miles, picks his cautious way over the rushy tussocks, as they appear before him. If his foot slips, or if he ventures to desert this mark of security, it is possible he may never more be heard of. On the south, Solway Moss is bounded by a cultivated plain, which declines gently through the space of a mile to the river Esk. This plain is lower than the moss, being separated from it by a breast-work formed by digging peat, which makes an irregular though perpendicular line of low black boundary. It was the bursting of the moss through this peat breast-work, over the plain between it and the Esk, that occasioned the dreadful inundation which destroyed so large a district. The more remarkable circumstances relating to this calamitous event were these: On the 13th of November, 1771, in a dark tempestuous night, the inhabitants of the plain were alarmed with a dreadful crash, which they could no way account for: many of them were then in the fields watching their cattle, lest the Esk, which was then rising violently in the storm, should carry them off. In the mean time, the enormous mass of fluid substance, which had burst from the moss, moved slowly on, spreading itself more and more, as it got possession of the plain. Some of the inhabitants, through the terror of the night, could plainly discover it advancing like a moving hill. This was in fact the case; for the gush of mud carried before it through the first two or three hundred yards of its course a part of the breast-work; which, though low, was yet several feet in perpendicular height; but it soon deposited this solid mass, and became a heavy fluid. One house after another it spread round, filled and crushed into ruin, just giving time to the terrified inhabitants to escape. Scarcely

any thing was saved except their lives; nothing of their furniture, few of their cattle. Some people were even surprised in their beds, and had the additional distress of flying naked from the ruin. The morning light explained the cause of this amazing scene of terror, and shewed the calamity in its full extent: and yet, among all the conjectures of that dreadful night, the mischief which really happened had never been supposed. Lands which in the evening would have let for twenty shillings an acre, in the morning were not worth sixpence. On this well-cultivated plain twenty-eight families had their dwellings and little farms; every one of which, except perhaps a few who lived near the skirts of it, had the world totally to begin again. Who could have imagined, that a breast-work, which had stood for ages, should at length give way? or that those subterranean floods which had been bedded in darkness since the memory of man, should have ever burst from their black abode? This dreadful inundation, though the first shock of it was most tremendous, continued still spreading for many weeks, till it covered the whole plain, an area of five hundred acres; and, like molten lead poured into a mould, filled all the hollows of it, lying in some parts thirty or forty feet deep, reducing the whole to one level surface." The plain that was covered with this Stygian torrent, has, however, since been restored to fertility by the exertions of a Yorkshireman named Wilson, whose self-taught genius at once conceived a novel plan, and directed its execution.

This plan was simple and easily executed. Wilson had two large reservoirs formed in the higher grounds, filled them with water, and directed the whole body and force of it, first against a large knoll in front of Netherby house, and afterwards against the masses of accumulated moss, all of which were progressively carried away into the channel of the river Elk. Further particulars may be seen in Gilpin's work, already referred to. Pennant's Tour to Scotland.

The vicinity of Solway Moss became celebrated from the defeat of the Scottish army under the command of Oliver Sinclair, in the reign of Henry VIII. The whole army was either taken or dispersed; and a few fugitives are said to have perished in the moss, into which they had plunged to escape the sword.

SOLYHULL. See **SOLIMULL.**

SOLYMA, in *Ancient Geography*, a name sometimes given to *Jerusalem*; which see.

SOLYMAN, in *Geography*. See **SOLIMAN**.

SOLYMANIA, a district of that portion of the pachalic of Bagdad beyond the Tigris, which comprehends almost the whole of ancient Assyria proper, and is now denominated the Lower Kurdistan; extending from Armenia and the territories of the chief of Julamerick to the district of Mendeli, which is its frontier, towards Kuzistan or Chufistan. Each of the eight districts into which this province is divided has a separate hakem, or governor; but he who resides at Solymania rules over the greatest portion of territory; and as he must, by birth, be a Kurd, he usually assumes the title of pasha of Kurdistan. The town of "Solymania a Shehr e Zour," designated in the retreat of Heraclius by the appellation of Siazuros, is distant 18 leagues E. of Kerkook. It is the residence of Solyman, pasha of Kurdistan, a distinguished warrior, who, in 1810, at the instigation of the Porte, took arms against his master, the pasha of Bagdad, whom he defeated and put to death. Shehr e Zour, having fallen into decay, was some years ago rebuilt by Solyman, pasha of Bagdad, and since that time has assumed his name. It is situated in a delightful country, close to the foot of mount Zagros, and contains about 6000

inhabitants. Not far from Solymania was the city of Holwan, the retreat of Yezdejird, after the battle of Cadesia, and to which the caliphs of Bagdad were accustomed to retire during the heats of summer. It was ruined by Holaku, and has never since recovered its consequence.

SOLYME, in *Ancient Geography*, a town beyond Jordan, in the district of Gaulon. Josephus.

SOLYMI, an ancient and venerable people, mentioned by Homer, and the poet Chœrilus, who spoke Phœnician, cut their hair round, and inhabited the Solymean mountains, near a large lake. These marks, according to Josephus and Tacitus, agree with the Jews, called Solymi, on account of their capital city Jerusalem:—a nation remarkable for the singularity of their laws and of their actions, speaking Phœnician or Hebrew, dwelling in a mountainous country near Jerusalem, situated in the mountains and near the Asphaltite lake. These tokens, according to other learned men, do not designate Jews. Hence some think, that they were Moabites, or Midianites, bordering on the Asphaltite lake, and reckoned among the Arabians, who cut their hair round in a circle. Others think that the Solymean mountains were in Pisidia, near Lycia; and that we must here seek the Solymi of Homer and Chœrilus.

SOMA, in *Commerce*, a corn measure at Bergamo in Italy, which is divided into 8 setari, and contains 4½ bushels, English measure. In the island of Corsica, it is a wine measure; the barile being = 2 fomme = 12 zucchi = 108 pinte = 432 quarti.

SOMA, in *Hindoo Mythology*, is the regent of the moon, being in India a male deity, like the Mouna of the Saxons, and the Lunus among some of the nations who settled in Italy. The Hindoos have however a female moon, as the consort of Soma or Chandra: she is named Chandri, being, in their style of personification, the fakti, or energy of her lord. (See **SAKTI**.) Chandra is a name as often used as Soma, perhaps oftener, and is the common name of the moon in several dialects of India. Chandri is sometimes identified with the goddess Parvati, consort of Siva, and in pictures of that god she is often seen in the form of a crescent ornamenting his head; he is thence named Chandrasekra, or moon-crowned. In the Hindoo theogonies, Soma is stated to be the son of a Rishi named Atri, son of Brahma: and Boodh, or Mercury, is the son of Chandra; Boodh, or Budha, was married to Ila, daughter of the seventh Menu, named Satyavrata. Soma is sometimes said to be the son of Surya, or the sun, having sprung from a ray of that glorious luminary. According to another legend, it was a flash of light from the eye of Atri that impregnated a goddess, who is found to be a personification of the via lactea, or space, who thence bore Soma. So that the Hindoo Soma is both husband, wife, and offspring of the sun. See **ILA**.

Soma is often invoked in the religious ceremonies of the Brahmans, and receives a share in the offerings with which such ceremonies often are accompanied. He is sometimes styled lord of plants, especially of medicinal plants. We may notice here, as connected with some supposed coincidences in Irish and Indian mythology, that *Som* in the former is the deity presiding over plants, the same as in India; for the Sanscrit has merely a grammatical termination: the names are radically alike. (See **SURYA** and **TRIVENI**.) One very mysterious vegetable is peculiarly sacred to the Hindoo Soma: it is called *Somalata*. Soma, like the moon of western mythologists, presides in India over Monday, which day is called Somvar in many dialects. See **ZODIAC**.

The lunar deity of the East is usually portrayed in a car
drawn

drawn by a pied antelope, his head encircled by a silver crescent, and sometimes with a rabbit on his banner. He is commonly seen four-handed, sometimes holding a lotos, a club, a discus, and shell, the usual attributes of Vishnu; though he seems in a greater degree connected with *Siva*, which see. He is also frequently seen with Chandra's emblem, the antelope, in his hand, which emblem is called *Safin*. (See *SASIN*.) A crescent on his forehead, and on the foreheads of his consort and offspring, is also a Sivean family distinction. The idea of a male and female moon has given birth to many poetical fancies and allegories. *Ifa* and *Ifi*, under their names of *Chandra* and *Chandri*, undergo several sexual and other metamorphoses. *Chandra*, or *Deus Lunus*, is the moon when in opposition to the sun; and *Chandri*, or *Dea Luna*, when in conjunction.

In the sol-lunar legends of the Hindoos, the sun is, as we have shewn, sometimes male, sometimes female; and both wife and husband of *Lunus* and *Luna*, under their several names of *Surya*, *Savitri*, *Chandra* and *Chandri*.

Chandri, who concealing herself in *Somagiri*, or the mountain of the moon, was there visited by *Surya*, the sun; from which conjunction arose a numerous family called *Pulinda*. See *ILA* and *ROHINI*.

The Hindoos have a fable that the moon is a vase of nectar, and draw many pleasing figures from this poetical source; hence nectar-beaming is an epithet or name of *Soma*. (See *SASIN*.) Other names or titles of *Soma* are *Himanfu*, *Indu*, *Saganka*, *Safanka*, and *Sushumna*. A similar idea of deriving ambrosia, or inspiration from the moon, is traceable in the poetics of Greece. The Hindoos call this immortal beverage *Umrita*; which see.

Images of *Chandra* are not often seen. He has been noticed among the sculptures in the cavern temple on *Elephanta*, and pictures of him are not rare. He is represented young and handsome; and it is very common for poets, both Hindoo and Mahometan, to compare their mistresses to the full moon; this is perhaps common to almost all nations.

In Hindoo histories and theogonies, mention is made of numerous races, offspring of the sun and moon, and severally called *Suryavanfa* and *Chandra-vanfa*. (See *SURYAVANSA*.) It is common in works of antiquity to see it noticed whether the heroes be of the solar or lunar race, but such distinctions are little regarded in modern times. Austerities are common to Hindoo devotees, in expiation of offences, or as security from evil. (See *TAPAS*.) One species of it is named *Chandrayana*, or the lunar penance. It consists in the sinner or devotee "eating for a whole month no more than thrice eighty mouthfuls of wild grains, as he happen to meet with them, keeping his organs in subjection." The reward, according to *Menu*, is attaining the same abode as the regent of the moon; and it absolves a Brahman from the sin of slaughtering a thousand small animals which have bones, or of boneless animals as many as will fill a cart: and it is also the expiation for killing a *Sudra*, an individual of the fourth or servile class. See *SUDRA*.

SOMADEVA, a name of the Hindoo regent of the moon, who is called also *Chandra*, *Soma*, and by several other names. (See the preceding article.) It is likewise the poetical appellation of a celebrated Indian writer, mention of whom is briefly made under the article *TRIVENI*.

SOMAINPOUR, in *Geography*, a town of Hindooftan, in the circar of *Gohud*; 25 miles S.E. of *Calpy*.

SOMAISSON, a town of Hindooftan, in *Myfore*; 22 miles W. of *Bangalore*.

SOMALATA, in *Botany*, is the Sanscrit name of the *Asclepias acida*, or *cynanchum viminale*, of our systems; a

vegetable highly venerated by the Hindoos. The name means *moon-plant*: it is sacred to *Soma*, or the moon, and is of such profound and mysterious allusion, that none but Brahmans may presume to taste its juice. It is gathered, expressed, and drank, with many superstitious ceremonies; and allusions to it are frequent in the writings of the Hindoos, who are said to consider it as typical of the *umrita* or ambrosia, obtained in so poetical a manner by the gods, and quaffed by them as the beverage of immortality. (See *UMRITA*.) "O thou who quaff the invigorating juice of the fomalata," is an invocation to Brahmans, met with in Sanscrit books; a farther examination of which would perhaps lead to a surmise, if not to a conclusion, that the mysteries connected with this holy vegetable in India are nearly similar to those related of our druids with their mysterious mistletoe. It is noticed under the article *SOMA*, that the Hindoos believe the moon to have great influence on vegetation in general, especially on the fomalata, or moon-plant, of which he is the particular lord; as well as generally of all vegetables.

SOMALPET, in *Geography*, a town of Hindooftan, in *Berar*; 55 miles N.N.E. of *Mahur*.

SOMANAPILLY, a town of Hindooftan, in *Myfore*; 18 miles S. of *Bangalore*.

SOMANOOR, a town of Hindooftan, in *Coimbatore*; 15 miles N.E. of *Coimbatore*.

SOMASQUO, *Fathers of*. See *FATHERS*.

SOMBAR, in *Geography*, a town of Persia, in the province of *Irak*; 114 miles S.W. of *Hamadan*.

SOMBERNON, a town of France, in the department of the *Cote d'Or*, and chief place of a canton, in the district of *Dijon*; 13 miles W. of *Dijon*. The place contains 755, and the canton 7770 inhabitants, on a territory of 235 kilometres, in 28 communes.

SOMBOR, a town of Austrian Poland, in *Galicia*; 6 miles W. of *Halicz*.

SOMBRERA, a small island in the West Indies, about 13 miles N. of *Anguilla*, dependent on *Barbuda*. N. lat. 18° 40'. W. long. 63° 25'.

SOMBRERE CHANNEL, a channel between the *Nicarbar* islands. N. lat. 7° 32' to 7° 50'. E. long. 94°.

SOMBRERETE, a town of Mexico, in the province of *Zacatecas*; 55 miles N. of *Zacatecas*. N. lat. 23° 40'. W. long. 4° 2'.

SOMBRERO, a river of Africa, which runs into the Atlantic, N. lat. 4° 40'. E. long. 5° 52'.—Also, a rock in the sea of *Mindoro*. N. lat. 10° 49'. E. long. 121° 27'.

SOM-CHAN, a town of Chinese Tartary. N. lat. 41° 2'. E. long. 120° 42'.

SOMEBODY KNOWS WHAT, a name given to the extremity of the arm of *Dusky bay*, which captain *Cook* calls "Nobody knows what." This name was given by captain *Vancouver*, who examined and found two inlets, or at least a large branch, divided by a ridge of land through its whole length.

SOMEER, a town of Hindooftan, in the circar of *Gohud*; 10 miles S.E. of *Lahaar*.

SOMEGILL, a river of Wales, which runs into the *Lug* below *Presteign*, in *Radnorshire*.

SOMENSHAR, a town of *Little Bucharja*; 15 miles N.W. of *Hami*.

SOMERA, a town of Sweden, in *Tavastland*; 33 miles S.W. of *Tavasthus*.

SOMERFELT, a town of Prussia, in *Oberland*, W. of *Liebstadt*.

SOMERGEM, or *SOMMERGEN*, a town of France, in the department of the *Scheldt*, and chief place of a canton, in

in the district of Gand or Ghent; 9 miles N.W. of Ghent. The place contains 6221, and the canton 18,800 inhabitants, on a territory of 125 kilometres, in 7 communes.

SOMERS, JOHN, *Lord*, in *Biography*, a distinguished lawyer and statesman, born at Worcester, in 1652, was the son of a respectable attorney of that city. He received his early education at the public school of his native city; and, at a proper age, he was entered a gentleman-commoner of Trinity college, Oxford. He quitted the university without a degree, but he had attained a good taste for polite literature, and being destined by his father for the legal profession, he spent some time as a clerk to sir Francis Winnington, an eminent lawyer, after which he removed to the Middle Temple. When called to the bar, he displayed those talents which ensured his arriving at professional distinction: at the same time, though extremely diligent in his legal studies, he did not abandon his classical pursuits, but translated the history of the life of Alcibiades, and Ovid's Epistle of Ariadne to Theseus.

He was an ardent friend of liberty, and in the latter part of the reign of Charles II. he wrote some political tracts; which, though they appeared without his name, were ascertained to be from his pen.

A piece entitled "The Security of Englishmen's Lives; or the Trust, Power, and Duty of the Grand Juries of England, explained according to the Fundamentals of the English Government," was attributed to him by Mr. Walpole, and is thought to be the same with one alluded to by bishop Burnet, written in consequence of the grand juries return of *ignoramus* to the bill against lord Shaftesbury. He was moreover the reputed author of "A brief History of the Succession of the Crown of England, collected out of the Records," the object of which was to prove the right of parliament to regulate the descent of the crown, with the view of supporting the intended exclusion of the duke of York, on account of his religion. In 1681 he took part in publishing "A just and modest Vindication of the Proceedings of the two last Parliaments," originally written by Algernon Sidney, but new-modelled by him. He was counsel, in 1683, for the sheriffs of London, and for other persons who were prosecuted for a riot in the city at the election of sheriffs. After the accession of James II. he continued the firm opposer of the arbitrary measures of the court, and obtained great credit as one of the counsel for the seven bishops. He most heartily concurred in the event of the revolution, and was one of the confidential advisers of the measure for bringing over the prince of Orange. He sat as representative of his native city in the convention-parliament, and was appointed one of the managers for the house of commons, in the conference held with the lords concerning the word *abdicate*, and his acute and sensible observations on the subject were greatly admired. In 1689 he was knighted, and made solicitor-general, and while he held that high post, delivered a spirited and seasonable speech in favour of the act of convention for recognizing William and Mary, the legality of which had been called in question by a member of the house of commons. In 1692, the office of attorney-general was conferred upon him, and in the following year that of lord-keeper of the great seal. When advanced to the bench, his behaviour was that of an able and upright magistrate, whose love of justice was tempered with singular mildness and condescension. At the same time he was in the highest credit with the sovereign, and he made use of his influence to serve persons of merit. He was a patron to Mr. Addison, and obtained for him an allowance to enable him to make that tour in Italy, of which he has printed an account. In 1695 he was advanced to the lord

chancellorship of England, and was raised to the peerage by the title of lord Somers, baron Evesham. At the same time he obtained certain grants from the crown, a circumstance which has drawn upon him some censure; though, without this addition, his advancement to the peerage would have been a punishment instead of reward, inasmuch as it would have been impossible for him to have maintained his rank in the peerage.

Lord Somers was now regarded as the head of the Whigs, and it was his aim to moderate the heat and jealousy of that party, and conciliate to it both the king and nation; hence it has been averred that he was too compliant in some points to the royal pleasure; which, however, did not prevent his being made a sacrifice when the Tories came into power. His acquiescence in the first partition treaty in 1699, with other ministerial measures, produced great complaints against him in parliament, and an address was moved in the house of commons, praying the king that lord Somers might for ever be removed from his majesty's presence and council. This motion was, however, defeated by a large majority; but the king, soon after, to quiet the discontents, desired him voluntarily to resign his seals. This he refused; and he was accordingly dismissed from his office. In 1701 the house of commons sent up to the lords an impeachment of lord Somers, which, however, was dismissed by the peers, and the prosecution was not resumed. Very shortly after this the king died, and the new reign not being favourable to the principles of lord Somers, he spent his time in literary retirement, and during this period of leisure he was elected president of the Royal Society. He was not, however, inattentive to public concerns, and vigorously opposed the bill brought into parliament by the high church party, to prevent occasional conformity. In 1706 he drew up a plan for effecting an union between England and Scotland, which was so much approved, that queen Anne nominated him one of the managers for carrying that measure into execution. He is also said to have had a considerable share in the bill of regency, by which the Protestant succession to the crown was extended and secured. Upon a change of ministry in 1708, lord Somers was nominated to the post of president of the council, from which he was dismissed in 1710; and though he continued for some time to take an active part in the business of the house of peers, it was not very long before a decline in the state of his health and faculties rendered him unfit for public business. He died in 1716, at the age of 64. The memory of lord Somers is still held in high veneration by the friends of constitutional liberty; to the establishment of which, by means of the revolution and Protestant succession, no individual contributed more than he. His abilities were very considerable, his manners highly ingratiating, and, notwithstanding the opposition which he had occasionally to encounter, few statesmen have passed through life with a purer character. He made a large collection of scarce and curious pamphlets, of which there has been published a selection in four parts, each consisting of four volumes, 4to. His collection of original papers and letters was unfortunately destroyed by a fire, which happened in the chambers of the Hon. Charles Yorke, on the 27th of Jan. 1752. *Biog. Brit.*

SOMERS, in *Geography*, a township of America, in Connecticut, and county of Tolland, containing 1210 inhabitants; 24 miles N.E. of Hartford.—Also, a post-township of New York, on the N. line of West Chester county, 50 miles N. of New York, and 120 from Albany; bounded N. by Dutchess county, E. by North Salem and South Salem, S. by Bedford and New-Castle, and W. by York or Yorktown. Its name, which was formerly Stephentown, was changed in

1808. Here are four grain-mills, five or six saw-mills, two fulling-mills, a paper-mill, and several fine scites still occupied. The soil of this township is generally very good, and adapted to produce a great variety of agricultural products. Here are also a printing establishment, that issues a weekly paper, the post-office, and a small collection of houses. This village is the principal market of lean stock of cattle and sheep, brought hither from distant parts of the country, for the supply of the sales of fattened cattle and sheep to the butchers of New York. The farmers of this country carry on an extensive traffic in this way, and droves are annually and almost constantly arriving from the inland regions, at the distance of 100, 200, and even 300 miles, to replace the consumption. The whole population consists of 1782 persons.—Also, a township of Prebble county, in the state of Ohio, containing 719 inhabitants.

SOMERS *Islands*. See BERMUDAS.

SOMERSDORF, a town of Germany, in the margraviate of Anspach; 5 miles S. of Anspach.

SOMERSET, *Duke of*, in *Biography*, according to Kircher (tom. i. lib. vi. p. 486.) and Printz, in his *Germ. Hist.* Mus. invented in 1649 a new species of violin, with eight strings; which contained all the most excellent secrets of music, and ravished every hearer.

SOMERSET, in *Geography*, a well-cultivated county of New Jersey, in America, on the N. side of the great road from New York to Philadelphia. The soil, especially on Rariton river and its branches, is good, and produces good crops of wheat, of which great quantities are annually exported. It is divided into seven townships, and contains 14,728 inhabitants, including 1968 slaves. The capital of the above county is situated on the W. side of Millstone river, and contains a court-house, gaol, and about 20 houses; 13 miles N. of New Brunswick.

SOMERSET, a county of Maryland, bounded E. by the state of Delaware and Worcester county, and W. by the waters of Chesapeake bay. It contains 17,195 inhabitants, including 6975 slaves. Washington Academy, in this county, was instituted by law in 1779: it was founded and is supported by voluntary subscriptions and donations, and is authorized to receive gifts and legacies, and to hold 2000 acres of land.

SOMERSET, a county of Pennsylvania, bounded N. by Huntingdon, and S. by Alleghany county, in Maryland; it is divided into 15 townships, and contains 11,284 inhabitants.

SOMERSET, a township of the above county, containing 1548 inhabitants; and also a borough, containing 489 inhabitants.

SOMERSET, a county of the state of Maine, containing 12,910 inhabitants.—Also, a township of Washington county, in Pennsylvania, containing 1500 inhabitants.—Also, a township of Windham county, in Vermont, containing 199 inhabitants; 10 or 12 miles N.E. of Bennington.

SOMERSET, or *Sommersett*, a post-town of Bristol county, in Massachusetts, on Taunton river; incorporated in 1790, and containing 1199 inhabitants; 49 miles S.E. of Boston.

SOMERSETSHIRE, one of the maritime counties of England, is situated in the south-western part of the kingdom, and is bounded by the Bristol Channel and Gloucestershire on the north, by Wiltshire on the east, by Devonshire on the south-west, and by Dorsetshire on the south-east. It is of an oblong form, and extends in length from north-east to south-west about 80 miles, and in breadth, in an opposite direction, about 36 miles; the circumference is something more than

200 miles, and the superficial contents about one million of acres.

Ancient Inhabitants, and historical Events.—This district, as well as its borders, is said to have been, in early times, inhabited by the Belgæ, a people of Celtic origin, who migrated hither from Gaul about three centuries prior to the Christian era. They are described as having established colonies, cultivated lands, and instructed such of the natives as chose to associate with them in the arts of industry. Their dominion was greatly extended about 250 years after their first settlement, when Divitiacus, king of the Suevones, brought over from the continent a considerable number of their countrymen. To appease the hostilities which had subsisted between these settlers and the native inhabitants, a treaty was now concluded, and a line or boundary made, to determine their respective territories. This line was perpetuated by a large and deep fosse, called, from the circumstances of its origin, Wanfdike; parts of which are still conspicuous in Wiltshire, &c. It is said to commence near Andover, in Hampshire, and terminate at the Severn sea, at Portishead, in this county; being an extent of about 80 miles. On Marlborough Downs this singular dike appears nearly in its pristine state, being exceedingly deep, and flanked by a lofty mound, or rampart, on its south side. According to this demarcation, the Belgæ occupied a great part of this county: and of their chief cities, Ivelcheiter, Bath, and Winchester, the two former are within its limits. Their contentions with the people, whose possessions they had usurped, lasted till the arrival of the Romans in Britain, when the oppressors, in their turn, became the oppressed. The Cangi, a tribe of those Belgæ who migrated hither under Divitiacus, were nearly annihilated by the Romans, nine years after their invasion. Many remains within this district bear testimony to the characteristic activity of the Romans, in establishing stations, marking out camps, and founding colonies. Besides their cities of Aquæ Solis or Bath, and Icalis or Ilchester, there are many places which, though their ancient names are lost, bear evident marks of a Roman origin, in the foundation of walls, and in various remains that have from time to time been discovered. Their principal road through this county was the Fosse, which extended from Bath, in a south-westerly direction, to Perry-street, on the confines of Devonshire. In a direction nearly parallel to it another road passed from the forest of Exmoor, through Taunton, Bridgewater, and Axbridge, to Portishead; whence there was a trajectus across the Bristol Channel, to the city of Ica Silurum, now Caerleon. A third road, called Via Julia, extended from Bath to Bristol and the Severn; and a fourth communicated from the former station to Portishead. Upwards of twenty-three Roman encampments are enumerated in this county. During the dominion of the Romans, it formed part of the province of Britannia Prima. On the decline of their power, and their evacuation of the country, in the fifth century, it became subject to the Saxons, who incorporated it with their kingdom of Wessex. It is noted as being one of the districts in which the Christian doctrines were propagated at an early period; and, according to ancient authors, king Ina, who began his reign over the West Saxons in 688, built a college at Wells. His successor, Kenulph, converted it into an episcopal see, and built the celebrated abbey of Glastonbury. But in those obscure and barbarous times, the progress of Christianity was necessarily slow and uncertain; for it was not only opposed by superstition, but thwarted by sanguinary wars. The incursions of the Danes kept the country in a state of continual alarm, and threatened its total subjugation. In the reign of Alfred, they desolated almost

SOMERSETSHIRE.

almost every province of Britain, and at length carried their ravages into the counties of Somerset, Wilts, and Hants; which had hitherto remained safe against their encroachments. The young king was constrained to relinquish his throne, and to preserve himself by disguise and concealment. He retired to an obscure part of this county, and lived in the house of a neatherd. During his residence here an incident occurred, which, though trivial in itself, has been thought sufficiently interesting to be recorded in history, and has been given in this work under ALFRED. At the general division of the kingdom into shires and hundreds, this province retained the name of Somersetshire, which the Saxons had given it; and which was probably derived from Somerton, at that time the chief town.

In the Saxon times, this county was subject to certain officary carls, who had authority to try and decide causes, and punish malefactors, within their jurisdiction. The first earl of Somerset was a warlike chief, named Hun, who attended king Egbert in his war with Beornulf, king of Mercia, and was slain in the battle of Ellendune, A.D. 823. At the period of the Norman conquest, when the Saxon nobles were, for the most part, deprived of their honours and estates, this county was bestowed on several chiefs who assisted William in his enterprise, either with troops or money. In this distribution, sir William Mohun obtained by far the greatest share; for, besides the castle of Dunster, he held sixty-one lordships, and had forty-seven knights in his retinue. He likewise received the title of earl of Somerset, which devolved on his descendant, sir Reginald de Mohun. In the sanguinary contests between the houses of York and Lancaster, the inhabitants of Somersetshire were particularly active in behalf of the latter; in consequence of which, it is said, that after Henry VII. was advanced to the throne, he encouraged and patronized the erection of some splendid towers and churches in this county. During the civil war in the reign of Charles I., Somersetshire had its full share of dissention and calamity. Various skirmishes were fought, but no general engagement took place, except one at Lansdown, near Bath, between the parliament's army, under sir William Waller, and the king's forces, under the marquis of Hertford. In this action, out of two thousand horse the marquis lost fifteen hundred, by a regiment of cuirassiers, commanded by sir Arthur Hazlerig, which was so completely armed, that they were called the regiment of lobsters. The marquis, however, drove sir William from his post, and compelled him to retire into Bath. Somersetshire was also the principal theatre of the rebellion of the duke of Monmouth, in 1685.

Surface, Marshes, Soil, &c.—The sea-coast of Somersetshire is very irregular, in some places projecting into lofty and rocky promontories, and in others receding into fine bays, with flat and level shores. From Stert-Point northward the coast is flat, and composed of vast sand-banks repelling the inundation of the sea, which, in ancient times, washed over these shoals, and flowed up into the country, covering with its waters that extensive tract of land, now called Brent-Marsh. The sea, after its general retirement, however, frequently overflowed these parts; and it was found necessary, for the security of the country, to establish a commission of sewers, the members of which were required to examine the sea-banks, ditches, gutters, and sewers, connected with the sea, and order the requisite cleanings and reparations. The first commission of this kind upon record, was in 1304; and similar offices are extended to this day. For fertility of soil and general produce, this county stands eminently high in reputation. The plains are remarkable for their luxuriant herbage, which furnishes not only a suf-

ficiency for home consumption, but also a considerable surplus for other markets. London, Bristol, Salisbury, and other cities and towns of the kingdom, are annually supplied from Somersetshire, with fat oxen, sheep, and hogs, together with cyder, cheese, butter, and many other articles in great abundance. Nor are the hills deficient in arable productions; yet the vicinity of the Bristol Channel, which fills the air with watery vapours unfavourable to the ripening of corn, particularly in the western parts, induces a preference of grazing and dairy husbandry; and, in consequence, vast quantities of grain are purchased from the adjacent counties of Wilts and Dorset, to the amount of at least one hundred thousand quarters annually. The surface of the inland parts is varied by lofty hills, rich level plains, and aspiring woods. The principal hills are the Quantock, between Taunton and the Bristol Channel; Brendon, near Quantock; Poulton, near Bridgewater; Mendip, between Frome and the coast; Broadfield-Down, between Bristol and Wrington; Leigh-Down, in the hundred of Portherry; Dundry, near Bristol; Lansdown, near Bath; White-Down, near Chard; and Black-Down, on the borders of Devonshire. The respective soils of these may be thus stated: Quantock, a thin variable soil, covering a loose shelly rock, interspersed with occasional limestone; Poulton, a strong surface, covering a bed of clay or marl; Mendip, Broadfield, and Leigh-Down, a gravelly loam on a limestone rock; Lansdown, a thin soil on a freestone grit; White-Down, variable; Black-Down, a thin surface of black earth on a bed of sand or gravel. Almost every species of soil (chalk excepted, of which there is only a small portion in the eastern division) may be found in different parts of the county, and of a quality highly fertile and productive.

Forests and Moors.—The ancient forests of Somersetshire were, Selwood, near Frome; Mendip, between Frome and the Bristol Channel; Exmoor, between the port of Watchet and the north-west part of Devonshire; but most of these formerly wooded tracts of country are now deprived of their ancient timber-trees, and inclosed. The principal moors are, King's-Sedgemoor, near Bridgewater; East-Sedgemoor, between Wells and Glastonbury; West-Sedgemoor, between Taunton and Langport; North-moor and Stanmoor, near the isle of Athelney; Common-moor, near Langport; West-moor, Curry and Hay-moor, near North-Curry; King's-moor, between Ilchester and Somerton; Ile-moor, on the river Ivel; Brent-Marsh, on the rivers Brue and Ax; Weston-moor, near Uphill; Banwell and Smeathmoors, near Churchill; Kenn-moor, near Yatton; Nailsea-moor, north of Kenn; Clapton-moor, between Clapton and Wirton. Of these, many have been inclosed, drained, and improved within the course of the last forty years.

Minerals, &c.—This county produces lead, copper, iron, lapis calaminaris, manganese, coal, limestone, paving-stone, tiling-stone, freestone, fullers'-earth, marle, and ochre. The Mendip hills are noted for their mines, particularly of lead and lapis calaminaris. The former seem nearly exhausted, or at least the deep working is so incumbered with water, that little can be done, and in all probability millions in value may remain concealed in the bowels of this mountain. In times past many thousand pounds have been paid to the fee of Wells for the lord's share (that is one-tenth) of the lead dug on the forest within the parish of Wells only.

Coal is abundant in the north-eastern part of the county. In the northern collieries, the strata of coal form an inclination in the plane of about nine inches in the yard. In thickness, it varies from ten inches to upwards of three feet; if

SOMERSETSHIRE.

less than fifteen inches they are seldom worked. Coal is now working generally from seventy to eighty fathom in depth: in a few places deeper; and by the late introduction of machinery to raise it by the steam-engine, a much greater depth of working will be obtained. The coal is of prime quality; pure and durable in burning; firm, large, and of a strong grain; which ensures its conveyance to almost any distance, without injury to its appearance or quality, which cannot be exceeded in any part of the kingdom. Bath is the principal market for sale and place of consumption; to which may be added, the western parts of Wiltshire, and the next adjacent parts of Somersetshire. The quantity raised is from fifteen hundred to two thousand tons weekly: a much greater can be supplied, if an increased demand requires it. Men and boys, to the number of fifteen hundred, are employed in the workings, with wages sufficiently adequate for a comfortable subsistence. The owners of the freehold whence the coal is raised generally receive an eighth of the gross receipt of sale. The average price of coal is five-pence *per* bushel at the pit, nine gallon measure. The collieries in the southern part of this district are on a more limited scale: the strata of coal form an inclination of the plane from eighteen to thirty inches in the yard; in some the plane is annihilated, and the shafts descend in a perpendicular direction. The south-western parts of Wiltshire, the northern district of Dorsetshire, and the east and southern parts of Somersetshire, are the markets for consumption. The quantity raised is from eight hundred to a thousand tons weekly, and capable of extension. Men and boys are employed to the amount of from five to six hundred. Average price three-pence three farthings *per* bushel. At Clapton, a village to the north-west of Leigh-Down, is a coal-work, which possesses the advantage of a land level of forty-four fathoms: about two hundred and forty bushels are landed daily. The best coal is sold at three-pence halfpenny *per* bushel, and the small is shipped at Portishead for Wales, where it is used for burning lime.

Rivers and Canals.—The principal rivers are the Avon, Ax, Brue, Parret, Yow, Cole, Chew, Tone, Frome, Ivel, Ex, and Barl. Of these, four only are navigable, *viz.* the Avon, from Bath to Bristol, 16 miles; the Brue, from the Bristol Channel to Highbridge, two miles; the Parret, from Stert-Point to Langport, about 20 miles; and the Tone, from Taunton to Boroughbridge, eight miles. The chief canals are, the Somersetshire coal canal, which has two branches, one commencing at Paulton, the other at Radstock, and both communicating with that of the Kennet and Avon; the Dorset and Somerset canal, commencing near Nettlebridge, and extending to Frome and thence to the county of Dorset; the Ilchester canal; the Grand Western canal, extending 35 miles from Taunton into Dorsetshire. For a particular account of these, see CANAL, in a former volume of this work.

Climate, &c.—Mr. Billingsley, who in the year 1795 drew up a general view of the agriculture of this county, divides it into three districts, the north-east, the middle, and the south-west. The first comprehending the tract between the ports of Uphill and Kingroad on the west, and the towns of Bath and Frome on the east; the second embracing that portion which is bounded by the Mendip hills on the north, Bridgewater-bay on the west, and the town of Chard on the south; the third occupying the remainder of the county. The north-east district being very irregular in surface, and intermixed with lofty hills and rich fertile plains, the climate is in consequence exceedingly varied. On the western side, including the hundred of Winter-Stoke and Porthury, the soil is, for the most part, a deep and rich mixture of clay

and sand; being originally a deposit by the sea, which, in ancient times, flowed up a considerable way into that part of the country. These moor-lands, as they are called, are subject to frequent inundation; and sometimes in rainy seasons are covered with water for four or five successive months. The middle district of the county, which is the largest, possesses a climate, for the most part, mild and temperate; but on so varied a surface that uniformity of soil cannot be expected.

The south-west district has nearly an equal portion of rough mountainous country, and rich fertile slopes and plains. The climate, particularly of that part which is called the Vale of Taunton-Dean, is peculiarly mild and serene, and the soil highly fertile and productive: and the eye is agreeably relieved by a judicious mixture of arable and pasture lands. There are, however, certain parts north-west of the vale which are mountainous, and subject to that mutability of weather, and moisture of air, generally found on elevated situations.

Civil and Ecclesiastical Divisions.—Somersetshire is divided into forty-three hundreds, and seven liberties. It contains two cities, Bath and Wells, with a part of Bristol, seven boroughs, twenty-two market-towns, one bishopric, three archdeaconries, thirteen deaneries, and four hundred and eighty-two parishes. Of the three archdeaconries, that of Bath contains two deaneries, Wells seven, and Taunton four.

Church History.—Although the inhabitants of this county, as has been observed, embraced Christianity in the seventh century, the ecclesiastical history commences only with the installation of Athelm, a monk of Glastonbury, to the see of Wells, in the reign of Edward the Elder, in the early part of the tenth century. During this reign, pope Formosus, for some unknown reason, excommunicated the whole kingdom, which continued under this sentence seven years, by which several sees were vacant; at length, the degraded monarch called a synod to consider the state of the church, and sent archbishop Plegmund to procure the removal of the interdict, and have new bishops confirmed. Having succeeded in his mission, seven bishops were consecrated in one day, among whom was Athelm, above-mentioned.

Political Economy.—Somersetshire is stated to contain 991,360 acres of land; of which 330,000 are arable, 534,500 pasture, 126,860 of commons, heaths, woods, wastes, roads, &c. The population, according to the return to parliament in the year 1811, amounted to 303,180, of which 141,449 were males, 161,731 females; 23,732 families being stated to be employed in trade and manufactures, and 27,472 families chiefly in agriculture. The number of houses were 54,787. The representatives in parliament are, for the county, two; Bath, two; Bridgewater, two; Ilchester, two; Melborne-Port, two; Minthead, two; Taunton, two; Wells, two: in the whole sixteen members. The county is included in the western circuit; it is in the province of Canterbury; and in the diocese of Bath and Wells.—“The History and Antiquities of the County of Somerset,” by Edm. Rack and the Rev. John Collinson, 3 vols. 4to. 1791. “General View of the Agriculture of the County of Somerset, by John Billingsley, *cfq.*” 8vo. 1798.

SOMERSHAM, a considerable village and parish in the hundred of Hurstington, and county of Huntingdon, England, is situated 6 miles distant from St. Ives, and 68 miles N. from London. It principally consists of one street, about three-quarters of a mile in length from E. to W.; with a second, but much shorter street, crossing the former at right angles. The church is a spacious structure, and consists of a nave, chancel, and aisles, with a substantial embattled tower at the west end. Near the church-yard is a

free school, with a large school-house recently built, 54 feet in length. The rich rectory of Somersham is annexed to the Regius professorship of divinity at Cambridge, and now held by the venerable bishop of Llandaff. Weever says, "William Weller (or Wolfere), parson of Somersham, was master of the rolls, serving Edward III. in the chancery, forty years and more." The bishops of Ely had formerly a palace here: the site is now partly built on; but the adjacent grounds still retain vestiges of their ancient appropriation. The population of Somersham, according to the return to parliament in the year 1811, was 1032; the number of houses 152. A mineral spring was discovered here by the late Dr. Layard, who published a small treatise concerning it in 1759, and whose experiments, with those of Dr. Morris, on its waters, were printed in the fifty-sixth volume of the *Philosophical Transactions*: its virtues are now but little noticed.

About the year 1731, near the road leading from Somersham to Chatteris, in a piece of fen-land belonging to William Thompson, esq. the plough turned up and broke a small urn, containing several Roman coins: and Mr. Thompson and the Rev. Mr. Ramfey, digging near the spot, found another, which contained about sixty coins, mostly copper, and of the late emperors. Camden's *Britannia*, by Gough, vol. ii. *Beauties of England and Wales*, vol. vii. by E. W. Brayley.

SOMERSWORTH, a township of America, in Strafford county, New Hampshire, taken from Dover, and incorporated in 1754, containing 878 inhabitants.

SOMERTON, a small market-town in the hundred of the same name, Somersetshire, England, is situated near the centre of the county, to which it is said to have originally given name, and is 125 miles W.S.W. from London. Somerton is said to have been a Roman citadel: but we have no authentic account of it previous to the Heptarchy, when it appears to have been a town of considerable extent, and strongly fortified. It was at one time a royal residence. Ina, and several other West Saxon kings, held their courts here. In the year 877 it was plundered and laid waste by the Danes, under the conduct of Inguar and Ubba; but was rebuilt, and recovered its importance, both for population and strength. John, king of France, was confined in the castle of Somerton, after his removal from that of Hertford. In the time of Leland this castle was converted into a prison: a part of the town-wall and a round tower still remain, but in a very ruinous condition. The town now consists principally of five streets: it is governed by a bailiff and constables, elected annually by the inhabitants: a weekly market is held on Tuesdays, and four fairs annually. The church is an ancient structure, consisting of a nave, chancel, and side-aisles: at the south end is an octangular embattled tower, 63 feet high. Near the church is an excellent free-school; and a well-endowed alms-house for eight poor women. In the centre of the town is a hall for holding the petty sessions. Adjoining to the town is the tything of Lower Somerton, or Somerton Erleigh; and about a mile eastward is the tything of Hurco: both are included in the parish; which, according to the population return of the year 1811, contained 338 houses, and 1478 inhabitants. Collinson's *History of Somersetshire*, vol. iii.

SOMERVILLE, WILLIAM, in *Biography*, son of Robert Somerville, was born at his father's house at Edilton, in Warwickshire. He was educated at Winchester school, from which he was elected to New college, Oxford. Here he made a good proficiency in classical literature, and cultivated a talent for poetry. His first piece, as far as is known to the public, was an ode to the duke of Marlbo-

rough, on his dismissal from his posts in 1710. He was strongly attached to the Whig party; and when Addison purchased an estate in Warwickshire, Somerville addressed a poem to him, which includes the following couplet, alluding to the papers in the several volumes of the *Spectator*, to which are annexed the letters C, L, I, O.

"When panting virtue her last efforts made
You brought your CLIO to the Virgin's aid."

Mr. Somerville inherited a considerable paternal estate, on which he chiefly lived, acting as a magistrate, and pursuing with vigour the amusements of a sportsman, varied by the studies of a man of letters. He was courteous and hospitable, but too much addicted to conviviality, and careless of economy. His mode of living threw him into embarrassments, which so preyed on his mind, that for the sake of relief, he fell into habits that shortened his life. He died in 1742, which Shentone thus notices to a friend and correspondent.

"Our old friend Somerville is dead! I did not imagine I could have been so sorry as I find myself on this occasion. I can excuse all his foibles, impute them to age and to distresses of circumstances: the last of these considerations wrings my very soul to think on. For a man of high spirit, conscientious of having, at least in one production, generally pleased the world, to be plagued and threatened by wretches that are low in every sense; to be forced to drink himself into pains of body, in order to get rid of pains of the mind, is a misery."

Somerville is chiefly known, as a poet, by his piece entitled "The Chase," which is written in blank verse, and which maintains a high rank in the didactic and descriptive class. It has the advantage of being composed by one who was perfectly acquainted with the sports which are its subject, and who entered into them with all the enthusiasm which they are calculated to inspire; hence his pictures, in exactness and animation, greatly excel the draughts of the same kind, attempted by poets by profession. Its language is free and nervous, and its versification generally denotes a nice and practised ear. He has another piece connected with this in subject; it is entitled "Field Sports," though it only describes that of hawking. His "Hobbinol, or Rural Games," is a kind of mock heroic, in which the burlesque is managed with tolerable success. Of his other pieces, serious and comic, there are few that can be said to add to his fame; but they make a part of the collection of British Poets.

SOMEVOIRE, in *Geography*, a town of France, in the department of the Upper Marne; 15 miles S. of St. Dizier.

SOMGHETIA, a province in the principality of Georgia, W. of Teflis.

SOMINO, a town of Africa, in Bambarra, on the Niger. N. lat. 13° 11'. W. long. 4° 48'.

SOMLYO, a town of Hungary; 29 miles S. of Zatmar.

SOMMA, a town of Naples, in Lavora, near which are annually produced between 7000 and 8000 pounds of silk of the best quality; 10 miles E. of Naples.—Also, a town of Italy, in the department of the Olona; 24 miles N.W. of Milan.—Also, a town of the Popedom, in Umbria; 4 miles S. of Spoleto.

SOMMARIVA del Bosco, a town of France, in the department of the Tanaro; 5 miles S.E. of Carmagnola.

SOMMARIVA di Perao, a town of France, in the department of the Tanaro; 7 miles E.S.E. of Carmagnola.

SOMMARNAS,

SOMMARNAS, a town of Sweden, in the province of Tavastland; 35 miles S.S.W. of Tavasthus.

SOMME, a river of France, which rises near Fontomme, in the department of the Aisne, passes by or near to St. Quentin, Ham, Peronne, Bray, Corbie, Amiens, Pequigny, Abbeville, St. Valery, &c. and runs into the English Channel, about 5 miles W.N.W. of St. Valery.

SOMME, one of the eleven departments of the northern region of France, composed of Amienois, Ponthieu, Vimeux, and Santerre, between Calais and Oise, in N. lat. $49^{\circ} 45'$, and bounded on the N. by the department of the Straits of Calais, on the E. by the department of the Aisne, on the S. by the department of the Oise, and on the W. by that of the Lower Seine, and the English Channel. Its territorial extent is $6512\frac{1}{2}$ kilometres, or in French leagues 34 in length, and 16 in breadth. It is divided into 5 circles or districts, 41 cantons, and 848 communes. The circles are Abbeville, containing 114,060 inhabitants; Doullans, with 45,627; Peronne, with 91,470; Montdidier, with 62,668; and Amiens, with 151,209 inhabitants: the whole population being 465,034. According to M. Haffenratz, it is divided into 5 circles and 72 cantons; and its population consists of 381,760 persons. The capital is Amiens. In the year 11 of the French era, the amount of its contributions was 5,650,664 fr., and its expences and charges 395,027 fr. 69 cents. This department is fertile in grain, fruits, hemp, flax, and pastures, and has some forests.

SOMMEIL, in *French Music*, an invocation to sleep; an old French movement of the lullaby kind, much in favour during the time of Merfennus; and continued in use, according to Blainville, in the reign of Louis XIV., when operas were first attempted at Paris.

SOMMERDA, or **SOMMERN**, in *Geography*, a town of Saxony, in the territory of Erfurt; 11 miles N.N.E. of Erfurt.

SOMMERDYCK, or **SOMMELSDYKE**, or *Zomerdyck*, a town of Holland, and chief town of the island of Overflakke; 20 miles W.S.W. of Dort.

SOMMEREUX, a town of France, in the department of the Oise; 3 miles N.E. of Grandvilliers.

SOMMERFELD, a town of the New Mark of Brandenburg; 15 miles S. of Crossen.

SOMMERGEM. See **SOMERGEM**.

SOMMERO, a small island in the gulf of Finland. N. lat. $60^{\circ} 8'$. E. long. $24^{\circ} 36'$.

SOMMERSET. See **SOMERSET**.

SOMMERSHAUSEN, a town of Germany, in the lordship of Speckfeld, on the Maine; 4 miles S. of Wurzburg. N. lat. $49^{\circ} 45'$. E. long. $10^{\circ} 3'$.

SOMMIER, Fr. the wind-cheft, or found-board of an organ. See **SOUND-BOARD**.

SOMMIERES, in *Geography*, a town of France, and principal place of a district, in the department of the Gard; 12 miles S.W. of Nismes. N. lat. $43^{\circ} 47'$. E. long. $4^{\circ} 11'$.

SOMMITE, in *Mineralogy*, *Nepbeline*, Haüy, a mineral which occurs in small crystals and crystalline grains, in the lava on the sides of mount Somma, a part of Vesuvius. The form of the crystal is a six-sided prism; the colour is greyish or greenish-white: the angles are sufficiently hard to scratch glass. The crystals are lamellar on the faces of the prism, but conchoidal, with a vitreous lustre, in the direction perpendicular to the axis of the crystal. It melts with difficulty before the blow-pipe, into a transparent homogeneous glass.

Its specific gravity is 3.3. According to Vauquelin, sommite contains

Silex	-	-	-	-	46
Alumine	-	-	-	-	49
Lime	-	-	-	-	2
Oxyd of iron	-	-	-	-	1

This mineral covers the cavities of lava, and is accompanied with hornblende, mica, and vesuvian.

SOMNAMBULISM, in *Medicine*, from *somnus*, *sleep*, and *ambulo*, *I walk*; sometimes also called *noctambulism*, or *night-walking*; is a singular condition of the body, in which a person performs many voluntary actions, implying a certain degree of perception of the presence of external objects, but without consciousness while the actions are performed, and without recollection of them when the consciousness returns.

This affection, as its name implies, is commonly considered as an imperfect degree of sleep; as it most frequently occurs after sleep, and seems to be but a more active exertion of volition than that which takes place in imperfect sleep, when we move, and even talk, and support ourselves in different postures. "There are many cases," says Mr. Stewart, "in which sleep seems to be partial; that is, when the mind loses its influence over some powers, and retains it over others. In the case of the *somnambuli*, it retains its power over the limbs, but it possesses no influence over its own thoughts, and scarcely any over the body; excepting those particular members of it which are employed in walking." (See his *Elements of the Philosophy of the Human Mind*, chap. 5, part i. § 5.) The subject is very obscure, in consequence perhaps of the rarity of these cases, which have not been sufficiently examined, since the physiology of the mind was rationally investigated. Dr. Cleghorn, however, in his excellent thesis "*De Somno*" (Edin. 1783), pointed out some circumstances which distinguish this condition from sleep; and Dr. Darwin has more recently considered it as belonging to *reverie*, and not to sleep, or as approximating rather to epilepsy or catalepsy, than to mere dreaming, or night-mare, to which it has also been referred.

Some of the most remarkable and best authenticated cases of somnambulism on record seem to favour this view of the subject. The older authors, Horst, Sennert, Schenck, Henry ab Heers, Willis, and many others, have related cases of somnambulism, in which various actions were unconsciously performed, such as opening doors and windows, crossing bridges, even walking on the tops of houses, and up precipitous paths, climbing to take a rook's nest, and various other feats. It is said, that if any sensation is excited sufficiently strong to awaken the somnambuli, they experience great surprize and terror, sometimes fall in syncope, and have no recollection of what has passed during the paroxysm. The essence of the disease, however, as Dr. Darwin observes, seems to "consist in the inaptitude of the mind to attend to external stimuli;" and they are not easily awakened. One of the cases most fully investigated, and reported to the Physical Society of Lausanne, while it exhibits the peculiarities of the malady, seems to prove that a slight and brief impression is actually made upon the senses, which excites afterwards so powerful a conception, or is so strongly fixed in the imagination, that the volition continues to direct the actions as accurately as if the impressions on the senses were repeated; which is also the character of *reverie*.

The somnambulist, in the case alluded to, was a lad thirteen years and a half old, of a good constitution, but of great sensibility and irritability, and very variable spirits.

His proceedings were watched by a committee of gentlemen, who reported the result to the society above-mentioned. His sleep was at all times unquiet, but the walking did not occur every night; sometimes several weeks past, during which he was free from it. The paroxysm commonly began about three or four o'clock in the morning, and the longest of them lasted from three to four hours. It was preceded by motions in every part of the body, with starting and palpitations; he then uttered broken words, and sometimes sat up in his bed, and afterwards lay down again. Then he began to pronounce words more distinctly, rose abruptly, and acted according to the instigation of his imagination. When he came out of the paroxysm, he did not recollect any of the actions he had been performing. It was dangerous, however, to awaken him during the continuance of it, especially if it were done suddenly; for he sometimes fell into convulsions. "Having risen one night with the intention of going to eat grapes, he left the house, passed through the town, and went to a vineyard, where he expected good cheer. He was followed by several persons, who kept at some distance from him, one of whom fired a pistol, the noise of which instantly awakened him, and he fell down without sense. He was carried home and brought to himself, when he recollected very well having been awakened in the vineyard, but nothing more, except the fright at being found in the vineyard alone, which had made him swoon."

The following statements shew how the impressions of external objects on the senses mingled with his reverie, as in the case of ordinary dreams. See DREAMS.

"Once he was observed dressing himself in perfect darkness. His clothes were on a large table, mixed with those of some other persons; he immediately perceived this, and complained of it much: at last a small light was brought, and then he dressed himself with sufficient precision. While his imagination was employed on various subjects, he heard a clock strike, which repeated at every stroke the note of the cuckoo. 'There are cuckoos here,' said he; and, upon being desired, he imitated the song of that bird immediately." Again, the reporters say, "If he is teased, or gently pinched, he is always sensible of it (unless he is at the time strongly impressed with some other thing), and wishes to strike the offender: however, he never attacks the person who has done the ill, but an ideal being, whom his imagination presents to him, and whom he pursues through the chamber without running against the furniture, nor can the persons whom he meets in his way divert him from the pursuit."

Other facts, which the reporters record, impressed them with a belief that the sleep-walker was capable of receiving certain impressions through the medium of the senses, when they accorded with the images which his imagination was occupied in forming; but that this faculty was predominant, and only admitted those perceptions which, on the principles of association, mingled with the reverie. They inferred, too, that he was obliged to open his eyes, in order to recognize objects; but that the impression, once made, although rapidly, was vivid enough to supersede the necessity of opening them again; that is, the same objects appeared to be afterwards represented by the conceptions of his imagination, with as much force and precision, as if he actually saw them. In the effort to open his eyes, however, when he wished to see an object, he could scarcely raise them a line or two, by drawing up his brows; and the iris appeared fixed, and the eye dim. He made this effort whenever any thing was presented to him, and he was told of it, always half

opening his eyes with great difficulty, and then shutting them after he had taken what was offered.

"Having engaged him to write a theme," the committee observe, "we saw him light a candle, take pen, ink, and paper from the drawer of his table, and begin to write, while his master dictated. As he was writing, we put a thick paper before his eyes, notwithstanding which he continued to write, and to form his letters very distinctly; shewing signs, however, that something incommoded him, which apparently proceeded from the obstruction which the paper gave to his respiration, being held too near his nose."

"An experiment was made by changing the place of the ink-standish, while Devaud was writing. He had a light beside him, and had certified himself of the place where his inkholder was standing by means of sight. From that time he continued to take ink with precision, without being obliged to open his eyes again: but the ink-standish being removed, his hand returned as usual to the place where he thought it was. It must be observed, that the motion of his hand was rapid, till it reached the height of the standish, and then he moved it slowly, till the pen gently touched the table, as he was seeking for the ink. He then perceived that a trick had been put upon him, and complained of it: he went in search of his ink-standish, and put it in its place."

This experiment, they affirm, was several times repeated, and was always attended with the same circumstances. And they put the following questions respecting the inferences to be drawn from it. "Does not what we have here stated prove, that the standish, the paper, the table, &c. are painted on his imagination in as lively a manner as if he really saw them; since he sought the real standish in the place where his imagination told him it ought to have been? Does it not prove that the same lively imagination is the cause of the most singular actions of this sleep-walker? And, lastly, does it not prove that a mere glance of his eye is sufficient to make his impressions as lively as durable?"

These conclusions appear to be legitimate; and the facts seem to shew how much more completely this condition of the somnambulist is allied to *reverie*, than to *sleep*, though commonly commencing from the latter. From the slightest degree of absence, or *brown study*, as it is popularly called, in which the conceptions of the imagination, upon subjects that interest the individual, are so vivid as to exclude for a time the perceptions excited by surrounding objects, up to this complete somnambulism, various degrees of the abstraction from external impressions may be traced. Most persons, perhaps, have been sensible, at times, when any subject of severe study, or any great gratification, anxiety, or distress strongly occupied their minds, how great the disposition to this abstraction has been. If engaged in reading, they have pursued every line with the eye, turned over leaf after leaf, and at length awoke from the reverie which had occupied the imagination, and found that not the smallest impression had been made on the mind by the pages which the eye had perused, and the hand had turned over. If walking in a crowded street, they have probably proceeded some way under the influence of reverie, moving the limbs as usual, directing the walking-tick, and performing other unconscious but voluntary acts, winding safely among the passing people, avoiding the posts and other obstacles, but so exclusively occupied by the conceptions of the mind, as to be totally insensible of all these actions of their own volition, and of the objects which they have passed, and which necessarily impress their senses so as to regulate those acts. From this state of the faculties in reverie, which we have so often experienced in our-

elves, and observed in others, as to suppose that the truth of the foregoing statement will be readily admitted, that condition of them which constitutes somnambulism seems to differ principally in two circumstances, *viz.* in commencing commonly in a disturbed sleep, and in requiring a stronger impression upon the senses to break the chain of mental conception; so that the lighter impressions only mingle with and modify the conceptions, according to the principle of association. The following singular example of the somnambulistic reverie is well authenticated, and is related of an amiable and distinguished poet. We quote it from the life of that writer in Anderfon's edition of the poets, vol. xi.

“Dr. Blacklock, one day, harassed by the censures of the populace, whereby not only his reputation, but his very subsistence was endangered, and fatigued with mental exertion, fell asleep after dinner. Some hours after, he was visited by a friend, answered his salutation, rose, and went with him into the dining-room, where some of his companions were met. He joined with two of them in a concert, singing, as usual, with taste and elegance, without missing a note, or forgetting a word. He then went to supper, and drank a glass or two of wine. His friends, however, observed him to be a little absent and inattentive: by and by he began to speak to himself, but in so slow and confused a manner, as to be unintelligible. At last, being more forcibly roused, he awoke with a certain start, unconscious of all that had happened; as till then he had continued fast asleep.”

Those who wish to investigate this curious subject farther, may consult the old writers mentioned in the beginning of this article; also Hoffmann's *Dissertatio de Somnambulismo*, in the third volume of the supplement to his works; the French *Encyclopédie*, article *Somnambulisme*; Darwin's *Zoonomia*, vol. i. sect. xix; Cleghorn de *Somno*, &c.

SOMNER, WILLIAM, in *Biography*, an able antiquary, was born at Canterbury in the year 1606. He received a good common education, after which he was taken as clerk by his father, who was register of the court of Canterbury. He was afterwards promoted by archbishop Laud to an office in the ecclesiastical court of that diocese, which naturally engaged him in the study of national antiquities. To pursue this to advantage, he applied with great diligence to the Saxon tongue, and having made himself master of that language, he drew up copious notes, and a glossary, to sir Roger Twissden's publication of the laws of Henry I. The antiquities of his own country engaged his particular attention, and he composed “A Treatise of the Roman Posts and Forts in Kent,” left by himself in MS. but which was printed at Oxford in 1693; and “A Treatise on Gavelkind,” completed in 1647, and published in 1660. He also wrote “A Discourse of *Portus Iccius*,” which was afterwards translated into Latin by bishop Gibson, and published with some other tracts. Having studied all the kindred dialects to the Saxon, he wrote observations on some old German words, collected by Lipsius, which were published by Meric Casaubon, and he drew up the Glossary annexed to the ten writers of English history, published by Twissden. This glossary being a key to replete and antiquated words, improved whatever of this nature had been done before. It is, indeed, a work of that extent as may serve as a key to all other historians, and to all records: “nevertheless,” says the writer of the life in the *Biographia Britannica*, “it might be greatly improved from our author's subsequent collections, which remain in the archives of Canterbury; from Junius's “*Etymologicum Anglicanum*,” and from Dr. Wilkin's Glossary, at the end of his edition of the Saxon laws. Mr.

Somner assisted Dugdale in compiling the “*Monasticon*.” In 1659 he published a Saxon dictionary, in folio, which has been styled the true and lasting monument of his praise; a work of incredible labour and himself, and of singular benefit to the world. The previous assistance of the like kind which came into Mr. Somner's hands were, 1. *Ælfrie's Glossary*, transcribed by Fr. Junius, from a very ancient copy in the library of sir Peter Paul Rubens, of Brussels; 2. The two ancient glossaries in the Cotton library; 3. Nowell's Saxon Vocabulary; 4. Joceline's Collections. From these and some other Saxon books then extant, Mr. Somner made immense collections, in two large volumes, for the compiling his dictionary. When it was finished, he sent it to Oxford, where it was printed, and it came out in the year already mentioned. During the composition of this dictionary, he was chiefly supported by the salary settled on the Saxon lecture, founded by sir Henry Spelman. Somner being a zealous royalist, he was arrested and imprisoned on account of the Kentish petition for a free parliament, in the same year that his dictionary was published; but was liberated on the restoration, and promoted to the mastership of St. John's hospital, in Canterbury. He died in 1669, and his books and manuscripts were purchased by the dean and chapter of Canterbury, and deposited in the cathedral library. *Biog. Brit.*

SOMNUS, in *Mythology*. See SLEEP.

SOMORROSTROW, in *Geography*, a town of Spain, in the province of Biscay, situated on a bay of the Atlantic; which, according to the opinion of baron Dillon, has all the appearance of being alluvial. Some of the workmen, as he says, assured him that they have often found broken pieces of pick-axes, mattocks, and other instruments, in places that had been worked centuries ago, and are now replete with new ore. Hence he infers that the mine increases. The ore is said to form an uninterrupted stratum, whose thickness varies from three to ten feet, and is covered with a coat of whitish calcareous rock, from two to six feet thick. Every one is at liberty to dig at pleasure, and transport it by land or water, without being subject to duties or any formalities. It is generally allowed, that no iron in Europe is so easy to fuse, or so soft, as that of Somorrostrow. When the ore is first taken out of this mine, it has the colour of bull's blood; and when wetted becomes purple. Great quantities are carried away by water to the neighbouring provinces, where they fuse it by itself, or mix it with ore of their own, which generally yields a harder iron. According to appearance, a quintal of ore will produce about 35 lbs. of good iron, and the residue about 30 lbs. of slag and dead earth. 13 miles N.W. of Bilbao. N. lat. 43° 19'. W. long. 3° 7'.

SOMOSIERRA, a town of Spain, in New Castile; 8 miles N. of Buytrago.

SOMOVNIA, a town of European Turkey, in Bulgaria; 10 miles W. of Nicopoli.

SOMPIL, a town of Thibet; 45 miles E.S.E. of Pa.

SOMPUINS, or SOMPY, a town of France, in the department of the Marne, and chief place of a canton, in the district of Vitry-sur-Marne; 18 miles N.W. of Menchould. The place contains 645, and the canton 4745 inhabitants, on a territory of 382½ kilometres, in 16 communes.

SOMSDORF, a town of Saxony, in the circle of Erzgebirg; 10 miles S. of Freyberg.

SON, a relative term, applied to a male child, considered in the relation he bears to his parents. See CHILD and PARENT.

The children of the king of England are called *sons* and *daughters of England*. The eldest son is born duke of Cornwall, and created prince of Wales. The younger sons are called *cadets*.

The king of France's children were anciently called *filz* and *filles de France*, *sons* and *daughters of France*; and the grand-children, *petits filz* and *petits filles de France*. At a later period, the daughters were called *mesdames*; and the grand-daughters *mesdemoiselles de France*.

SON, *Natural*. See BASTARD.

SON, *Adoptive*. See ADOPTIVE.

SON of God, is a term used in various senses in the holy scripture, as, 1. For Jesus Christ, or the Saviour of mankind; who is thus called, as some say, with respect to the manner of his generation, as being begotten of the Father.

This seems to have been the opinion of Dr. Clark, in his "Scripture Doctrine of the Trinity." Generation, says he, when applied to God, is but a figurative word, signifying only, in general, immediate derivation of being and life from God himself: and "only begotten" signifies being so derived from the Father, in a singular and inconceivable manner, as thereby to be distinguished from all other beings. Among men, a son does not, properly speaking, derive his being from his father; father, in this sense, signifying merely an instrumental, not an efficient, cause: but God, when he is styled father, must necessarily be understood to be (*αἰτία*) a true and proper cause, really and efficiently giving life. This consideration, he says, clearly removes the argument usually drawn from the equality between a father and son upon earth. It is observable, as our author proceeds, that St. John, in that passage, where he not only speaks of the Word before his incarnation, but carries his account of him farther back than any other place in the whole New Testament, gives not the least hint of the metaphysical manner how he derived his being from the Father; does not say, he was created, or emitted, or begotten, or was an emanation from him, but only that he *was*, that he *was in the beginning*, that he *was with God*, and that he was (*Θεός*) partaker of divine power and glory with and from the Father, not only before he was *made flesh* or *became man*, but also *before the world was*. As the scripture, says Dr. Clark, has no where distinctly declared in what particular metaphysical manner the Son derives his being from the Father, men ought not to presume to be able to define.

Some suppose, that this title of "son of God" belongs to Christ, on account of his possessing the same divine nature with the Father. Accordingly bishop Pearson says, the communication of the divine essence by the Father was the true and proper generation, by which he hath begotten a son. A son is nothing but another produced by his father, of the same nature with him. But God the Father hath communicated to the Word the same divine essence, by which he is God; and he says, the Father hath the essence or attributes of himself, and the Son by communication from the Father. But Dr. Waterland denies any literal generation of the son at all; for he supposes his being in the Father, before he was generated, to be the first and most proper filiation or generation; which he allows to be a mere co-existence with the Father, and not any derivation from him.

Whilst the Athanasians believed the Father and Son to be of the same substance, *i. e.* of the same *generical* substance, as two men are of the same substance; and the Pseudo-Athanasians believed them to be of the same identical *numerical* substance; the Arians, who believed the divine substance of the Father to be *ἀγέννητος*, unbegotten, and *ἀρχαῖος*, without beginning, concluded, that it was different

from the substance of the Son, who was begotten, and had a beginning. Moreover, as they believed the divine substance of the Father to be indivisible and un-compounded, they could not believe the Son to be generated in or from it, in any *literal* sense, either as being compounded with it, or divided from it; and, therefore, they concluded, that the generation of the Son was *figurative*, and was not a participation of substance, but a creation; as the word creation is frequently used in scripture with regard to mankind. They believed that Christ was the only begotten Son of God, because he only was created by the immediate act and power of God himself, and that all other beings, the Holy Ghost not excepted, were created by Christ; in which they agreed with Origen and Eusebius; and, therefore, they called him a creature, but not like other creatures; but they believed that he was generated or created before all ages.

Sonship, says Dr. Lardner, in his "Letter on the Logos," (Works, vol. x. vol. xi.) is a term of nearness, dearness, and affection; and Jesus is the Son of God, 1st, upon account of his miraculous conception and birth (Luke, i. 31—35); 2^{dly}, upon account of the especial commission given him by the Father, and the extraordinary qualifications bestowed upon him, in order to his fulfilling it (Matt. iii. 16. Mark, i. 10. Luke, iii. 21, 22. John, i. 32—34. iii. 34. If. xi. 1—3. xlii. 1—4. lxi. 1—3. and Matt. xii. 17. Luke, iv. 18, 19.); 3^{dly}, on account of his resurrection from the dead on the third day, to die no more (Rom. i. 3, 4. Heb. i. 6.); 4^{thly}, on account of his exaltation to God's right hand, and being invested with authority and dominion over all flesh, and constituted judge of the world, by whom God will pass sentence upon all mankind (John, iii. 35. v. 21, 22. Heb. i. 1, 2. iii. 5, 6.); 5^{thly}, on account of the pouring out of abundance of spiritual gifts, though in different degrees, upon his apostles, and those who believed in him after his resurrection (John, i. 32—34. Matt. iii. 1. Mark, i. 8. Luke, iii. 16. John, vii. 37—39. Acts, xi. 15, 16. i. 5. ii. 1—36. Gal. iv. 6. Eph. ix. 8—13.) Upon all these accounts, and not only upon account of his miraculous conception and birth, is Jesus "the Son of God." Our author suggests, that the passages which he has cited manifestly shew, that it is in respect to his humanity, and the dignity conferred upon it, that he has the title of the Son of God. This learned author rejects the opinion of those who understand by the "Son of God," an intelligent being or emanation, begotten by the Father, or proceeding from him, in an ineffable manner, from all eternity, and of the same essence or substance with the Father; and also of others, who understand by this appellation a mighty spirit, or angel, begotten or formed by the will of the Father, in time, before the creation of the world, and of a different substance from the Father; which son of God, as they say, became incarnate, that is, united himself, either to the human nature, consisting of soul and body, or to an human body, so as to supply the place of a human soul. These senses of the title, as he says, are not to be found in any of the books of the New Testament. The Jews, according to Whitby upon Rom. ix. 5. had no notion that their Messiah should be any thing more than mere man. See also Jortin's Discourses concerning the Christian Religion, p. 17. In the gospels, as Dr. Lardner observes, this title of the "Son of God" is given to our Lord, by many who took him to be a man specially favoured by God. (Matt. xvi. 16. and the parallel places. John, vi. 69. John, i. 34. iii. 35, 36. John, i. 49. xi. 27. Matt. xiv. 33. Luke, iv. 41.) Our blessed Lord likewise often takes it to himself, either directly or indirectly. (John, iii. 17, 18, v. 25. ix. 35—37. x. 36. xi. 4.) In the Jewish style,

style, and the language of scripture, all good men, and all people who are in a covenant relation to God, are his sons, and as such entitled to many privileges and blessings; but Jesus, as the Messiah, is "the Son of God," by way of eminence and distinction, and has in all things the pre-eminence. Accordingly, the Christ, or the Messiah, and the "Son of God," are equivalent in the New Testament. (Matt. xvi. 16. John, vi. 69. Mark, viii. 19. Luke, ix. 20.) And that, in the language of the Jews, the titles of Messiah and Son of God are the same, may be seen in Matt. xxvi. 63. and Luke, xxii. 66. 70. John, i. 34—49.

2. Several creatures are also called "sons of God," not as being so by nature and generation, but on divers other accounts. Thus, the angels are called sons of God by Job, in respect to their creation, adoption, &c. And great men are called sons of God in the Psalms, as being his lieutenants, or the depositories of his authority. Good men, and particularly the eminently pious, as we have clearly shewn, are also called sons of God, in various places of the sacred writings.

SON of Man, is frequently used, in scripture, to signify man; as expressing not only the nature of man, but his frailty.

The expression is very usual among the Hebrews and Chaldeans: Daniel, Ezekiel, and Jesus Christ, are particularly thus called; the first once, and the two latter frequently.

Some think, that the "son of man," when used by our Saviour, denotes his high dignity, or a man of distinction and eminence, and is equivalent to Messiah, or the Christ; and he thus intends to signify, that he is the great person spoken of by the prophets, who was to come for the benefit of mankind. (See Dan. vii. 13, 14. Matt. xxvi. 63, 64. Mark, xiv. 61, 62.) Against this sense Dr. Lardner has suggested some exceptions: and he observes, that man, and son of man, with the Hebrews, often denote a man of low condition. (Ps. xlix. 1, 2. Pl. cxliv. 3.) Our Lord, therefore, by this phrase or character, might represent that humbling of himself, which is spoken of by the apostle in the second chapter to the Philippians, and is the same with what is said in 11. liii. 3. "he is despised, and rejected of men," or is one of the lowest and meanest of men. Our Lord adopts this character in speaking of himself, in order to undeceive the Jews, and correct their false opinion concerning the kingdom of the Messiah; and to intimate, that he was not to arrive at glory, and the full possession of his kingdom, but through sufferings and humiliations. If son of man, then, be equivalent to Messiah, it is not used, as our author conceives, to denote his dignity, as the first and greatest of men, but rather to signify his humble form and low condition, in which he then lived; and is expressive of the scorn and contempt which were cast upon him, and in which he acquiesced.

Dr. Lardner further intimates, agreeably to his own opinion of the person of Christ, that he frequently makes use of this expression to denote his real humanity, and also that he was not made and created as Adam, but was a man born even of a woman. He adds also, that our Lord might assume this character as a modest way of speaking. Eminent and distinguished persons, who have many occasions to speak of themselves, especially if it be to their advantage, decline the too frequent use of the phrases *I* and *me*, and choose to speak in the third person, as of another, distinct from themselves. Works, vol. x.

Sometimes the phrase son of man is also used for the wicked and reprobate; in contradistinction to those called sons of God.

SON, Fr., a musical sound.

SON *Fondamental*. See FUNDAMENTAL.

SON *Fix*, Fr., a fixed and unalterable sound. To acquire such a sound, we must be certain that it will be the same at all times, and in all places. To be sure of this, it is not sufficient to have a pipe of a certain length or diameter in the fixed place; for though the pipe may always remain in the same state, the weight of the air will not always remain the same: the sound will become more grave or acute, as the air becomes more dense or rarefied. For the same reason, the sound of the same pipe will change with the column of the atmosphere, in proportion as this pipe shall be carried high or low, in the mountains or in the villages.

Secondly, this same pipe, of whatever materials it is made, will be subject to the variations which heat and cold occasion in all bodies. A pipe or string, if of metal, will lengthen or shorten; and its tone will be higher or lower, in proportion. If the pipe be of wood, it will swell or shrink, expand or contract; and from these causes combined, arises the difficulty of acquiring a fixed tone, and almost the impossibility of being sure of the same sound in two places at the same time, or twice in the same place.

SON, or *Sun-Plant*, the *crotalaria juncea* of Linnæus, in *Botany*, is cultivated in every part of Hindoostan with great assiduity, and applied to various uses. The seeds reduced to powder, and mixed with oil, form a kind of unguent, which the black ladies apply to their hair, in order to make it grow. The bark of this plant furnishes all kinds of rope, packing-cloths, nets, &c.; and from these, when old, most of the paper in that country is prepared. For this purpose they cut them into small pieces, macerate them in water for about five days, wash them in water, and then throw them into a vessel of water strongly impregnated with a lixivium composed of six parts of sedgi mutti, which is an earth containing a large portion of fossile alkali, and supposed to be the natron of the ancients, and seven parts of quick-lime. Here they remain eight or ten days, when they are again washed, broken into fibres by a stamping lever, and then exposed to the sun, and again steeped in a fresh lixivium, as before. When they have undergone three operations of this kind, they are fit for making coarse brown paper; and after seven or eight operations, they are prepared for making paper of a tolerable whiteness. For a farther account of the process, see Phil. Trans. vol. lxiv. p. 101, where it is minutely described and illustrated by figures.

SONABARYA, in *Geography*, a town of Bengal; 38 miles N.E. of Calcutta.

SONAH, a town of Hindoostan, in Bengal; 8 miles S.S.E. of Ghidore.

SONAN SUNDI, a town of Congo; 10 miles W. of Cundi.

SONAPURRA, a town of Hindoostan, in Bengal; 26 miles E.S.E. of Kishenagur.

SONATA, Ital. from *sonare*, to sound, or play on an instrument. Its use at present, in *Music*, is confined to solos for a single instrument: as Corelli's solos for the violin, Martini's solos for the German flute; and trios, or compositions in three parts, for two violins and a baste, &c. But which, in the body of these works, are all called *sonatas*.

In the last and 17th century, the Italians had distinct sonatas of two kinds: as *sonate da chiesa*, sonatas for the church; and *sonate da camera*, sonatas for the chamber, or private concerts, of a lighter kind. The first and third set of Corelli's sonatas are of the former kind, and the second and fourth of the latter. To the first and third set of Co-

relli's sonatas for the church, there are two bases, one for the base viol, or viol da gamba, and the other for the organ, arch lute or liarp, figured for thorough-bass.

In vocal music, *si suona* is written over the symphony or ritornelli, interstitial passages played by an instrument, either as an echo to the voice part, or to give the singer time to breathe. *Si canta*, "it is sung," to distinguish the vocal from the instrumental passages of songs written on one staff.

SONAUT, or SUNAT *Rupee*, in *Commerce*. See RUPEE.

SONAWRY, in *Geography*, a town of Hindoostan, in Oude; 20 miles S. of Bahraitch.

SONAX, a town of France, in the department of Mont Blanc; 4 miles N.N.E. of Chambéry.

SONCHUS, in *Botany*, *συνχος* of Dioscorides, supposed by some etymologists to be corrupted from *συνχος*, *hollow*, or *empty*, in allusion to its hollow stem. This seems scarcely satisfactory, and yet we meet with nothing else worth mentioning. In English it is named Sow-thistle, because swine are particularly fond of the plant.—Linn. Gen. 400. Schreb. 527. Willd. Sp. Pl. v. 3. 1509. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 4. 436. Sm. Fl. Brit. 815. Prodr. Fl. Græc. Sibth. v. 2. 124. Pursh 501. Juss. 169. Tourn. t. 268. Lamarek Illustr. t. 649. Gærtn. t. 158.—Class and order, *Syngenesia Polygamia-equalis*. Nat. Ord. *Compositæ semistrobiliferae*, Linn. *Cichoraceæ*, Juss.

Gen. Ch. *Common Calyx* imbricated, bellying, of numerous, linear, unequal scales. *Cor.* compound, imbricated, uniform; florets all perfect, numerous, equal, of one petal, ligulate, linear, abrupt, with five teeth. *Stam.* Filaments five, capillary, very short; anthers united into a cylindrical tube. *Pist.* Germen nearly ovate; style thread-shaped, the length of the filament; stigmas two, reflexed. *Peric.* none, except the calyx, closing into the form of a depressed globe, with a conical point. *Seeds* solitary, rather oblong; down capillary, sessile. *Recept.* naked.

Eff. Ch. Receptacle naked. Calyx imbricated, swelling at the base. Seed-down simple, sessile.

Having detailed at length the species of SCORZONERA, (see that article,) a genus which has been, in several instances, confounded with the present, we find it necessary to give a reformed view of *Sonchus*, following Willdenow in the distribution of the species.

1. *S. maritimus*. Sea Sow-thistle. Linn. Sp. Pl. 1116. Willd. n. 1. Ait. n. 1. Prodr. Fl. Græc. n. 1889. Allion. Pedem. v. 223. t. 16. f. 2. Cavan. Ic. v. 1. 38. t. 51.—Flower-stalks mostly solitary, terminal, naked. Leaves clasping the stem, lanceolate, undivided, with sharp reflexed teeth.—Native of maritime situations in the south of Europe, and north of Africa. Dr. Sibthorp met with it in Crete. Miller cultivated this plant in 1748, but it is hardly to be seen in any garden at present, either here or on the continent. The root is perennial. Stem herbaceous, about two feet high, slender, round, scarcely divided. Leaves near a foot long, narrow, smooth, glaucous, with a double set of small, sharp, recurved teeth; their base tapering, entire, clasping the stem at the bottom. Flowers sometimes two or three, on long, slightly bracteated, stalks, yellow, above an inch in diameter, with a smooth calyx.

2. *S. crassifolius*. Thick-leaved Sow-thistle. Willd. n. 2. Pourret MSS.—"Flower-stalks somewhat umbellate, scaly. Leaves lanceolate, with spreading pointed teeth; their base rounded, clasping the stem."—Native of Spain. Root perennial. This plant is intermediate between *S. maritimus* and *arvensis*, but most akin to the for-

mer. Stem simple, erect. Leaves thick and glaucous, unequally toothed; the teeth lanceolate, spreading at right angles. Flowers the size of the preceding, terminal, somewhat umbellate, with very short, solitary, single-flowered, axillary stalks, from the uppermost leaves. Each stalk is scaly, and shorter than its calyx.

3. *S. uliginosus*. Bog Sow-thistle. "Marschall von Bieberstein." Fischer MSS.—Flower-stalks somewhat umbellate, naked, much longer than the calyx. Leaves elliptic-oblong, with copious, spreading, pointed teeth; their base rounded, clasping the stem.—Native of mount Caucasus. Communicated under the above name, by Dr. Fischer of Moscow. This seems nearly related to the last. The stem is erect, stout, somewhat branched, three feet or more in height, round, smooth, leafy. Leaves four or five inches long, and above an inch broad, acute, smooth, veiny, rather thick or coriaceous, slightly glaucous, bordered with very numerous spinous teeth, projecting at right angles. Flowers resembling the last, four or five together in terminal umbels, whose stalks are quite naked and smooth, as well as the calyx.

4. *S. quercifolius*. Oak-leaved Shrubby Sow-thistle. Desfont. Atlant. v. 2. 225. t. 213. Willd. n. 3.—Flower-stalks somewhat corymbose, alternate, slightly scaly. Calyx-scales loosely imbricated. Leaves oblong, sinuated, toothed, somewhat three-pointed. Stem shrubby. On hills near Casia in Barbary. Stem from one to two feet high, branched, thick and fleshy. Leaves scattered, from four to eight inches long, very smooth and glaucous, rather succulent, evergreen, pinnatifid, with sharp lobes, directed forward rather than backward, their base tapering down into a short dilated footstalk. Flowers terminal, yellow, about an inch and a half broad, four or five together in a lax corymbose panicle. Scales of the calyx ovate, smooth, not close-pressed. Desfontaines.

5. *S. fruticosus*. Great Shrubby Sow-thistle. Linn. Suppl. 346. Willd. n. 4. Ait. n. 2. Jacq. Coll. v. 1. 83. Ic. Rar. t. 161. L'Herit. Stirp. t. 81.—Flower-stalks somewhat umbellate, bracteated. Calyx-scales loosely imbricated. Leaves oblong, sinuated, slightly runcinated, toothed. Stem shrubby.—Gathered by Mr. Masson on rocks in the islands of Teneriffe and Madeira, from whence it has found its way into the more curious greenhouses of this and other countries. The habit is much like the last, with a thick fleshy stem. The chief difference seems to consist in the more umbellate inflorescence, accompanied by leafy bractæas. The calyx is squarrose in a dried state only. Flowers like the common Dandelion in size and colour.

6. *S. acidus*. Sour Sow-thistle. Willd. n. 5.—"Flower-stalks branched, naked. Calyx-scales spreading. Leaves pinnatifid, with oblong-lanceolate, pointed, entire segments. Stem shrubby."—Gathered in Morocco by Mr. Schousboe. Leaves half a foot long, flaked, smooth. Flower-stalks very much branched, somewhat forked, and partly umbellate. Flowers the size of *S. arvensis*. Willdenow.

7. *S. pinnatus*. Wing-leaved Sow-thistle. Ait. ed. 1. v. 3. 116. ed. 2. n. 3. Willd. n. 6.—"Flower-stalks naked. Calyx smooth. Leaves pinnate; leaflets linear-lanceolate, slightly toothed. Stem shrubby."—Gathered by Mr. Masson in Madeira, from whence it was introduced into the greenhouse at Kew, in 1777, but it seems never to have flowered, and is now perhaps lost.

8. *S. radicans*. Long-rooted Sow-thistle. Ait. ed. 1. v. 3. 116. ed. 2. n. 4. Willd. n. 7.—"Flower-stalks naked, smooth like the calyx. Stem shrubby, almost naked. Radical leaves lyrate, smooth on both sides, with triangular

triangular ovate lobes. Brought by Mr. Masson from the Canary islands, in 1780. It flowers in the greenhouse in July. *Aiton*.

9. *S. taraxacifolius*. Dandelion-leaved Sow-thistle. Willd. n. 8.—Flower-stalks scaly, panicle. Leaves runcinate, with callous teeth; tapering at the base.—Native of Guinea. *Stem* as thick as a goose-quill, spongy. *Leaves* rather crowded, smooth, like Dandelion, but the tips of their teeth are white; the upper ones lanceolate, scarcely divided, though minutely toothed; the uppermost of all linear and entire. *Common flower-stalk* six inches, or more, in length, furnished with a few leaves, and dividing into a panicle at the top; *partial ones* very short, scaly, crowded at the terminations of the panicle. *Calyx* like the Garden Lettuce. *Willdenow*.

10. *S. palustris*. Tall Marsh Sow-thistle. Linn. Sp. Pl. 1116. Willd. n. 9. Fl. Brit. n. 2. Engl. Bot. t. 935. Curt. Lond. fasc. 5. t. 59. Fl. Dan. t. 606. (*S. laevior austriacus quintus altissimus*; Cluf. Hist. v. 2. 147. *S. arborecens* alter; Ger. Em. 294.)—Flower-stalks somewhat umbellate, bristly like the calyx. Leaves runcinate; arrow-shaped at the base; rough in the margin.—In low marshes, especially about the mouths of great rivers, in Holland, France, England, &c. as well as in Greece, flowering in July and August. It occurs in several places bordering on the Thames, below London, as well as in the isle of Ely. The *root* is perennial, fleshy, branched, but not creeping. *Stems* herbaceous, from six to eight feet high, leafy, angular, hollow, but little branched. *Leaves* runcinate, acute, smooth, finely toothed, not rounded, but acutely arrow-shaped, at the base. *Panicle* umbellate or cymose, of several yellow flowers, whose *calyx*, as well as the *flower-stalks*, is rough with dense, black, glandular hairs. Haller confounded this with the following, but Curtis has well distinguished them.

11. *S. arvensis*. Corn Sow-thistle. Linn. Sp. Pl. 1116. Willd. n. 10; (excluding the reference to Fl. Dan.) Fl. Brit. n. 3. Engl. Bot. t. 674. Curt. Lond. fasc. 4. t. 53. Pursh n. 1. (*S. arborecens*; Ger. Em. 294. *Hieracium majus*; Fuchf. Hist. 319.)—Flower-stalks somewhat umbellate, bristly like the calyx. Leaves runcinate, finely toothed; heart-shaped at the base. *Root* creeping.—In fields and about hedges, on a clay soil, in the middle or southern parts of Europe, as well as in Pennsylvania; frequent in England, especially towards the sea, flowering in August. The *root* is fleshy and milky, running deep into the ground, and difficult of extirpation. *Stem* but three or four feet high, nearly simple. *Leaves* rounded at the base. *Flowers* larger than in the last, and of a fuller golden hue, externally reddish; the tubes of their florets hairy. Dr. Sibthorp thought this the *σολυχος*; *ἄνερος* of Dioscorides.

12. *S. agrestis*. West Indian Sow-thistle. Swartz. Prodr. 110. Ind. Occ. 1289. Willd. n. 11. (*S. laevis*; Sloane Jam. v. 1. 255.)—Flower-stalks downy, many-flowered. *Calyx* smooth. *Stem* striated. *Leaves* sessile, deeply ferrated or cut.—Native of cultivated ground in the West Indies, along with *S. oleraceus*. *Root* annual. *Stem* two or three feet high, leafy, round, deeply striated, downy. *Lower leaves* scarcely divided. *Flowers* terminal and axillary, yellowish-white. *Calyx* elongated, sometimes slightly pubescent, but little tumid at the base, in which this species differs from the *oleraceus*, as well as in the remarkable shortness of its *florets*, which have not the appearance of being ligulate, but tubular. *Seeds* long, striated. *Swartz*.

13. *S. lacerus*. Jagged-leaved Sow-thistle. Willd.

n. 12.—“Flower-stalks umbellate, rather downy. *Calyx* smooth. *Leaves* pinnatifid, toothed; auricled and heart-shaped at the base.”—Native country unknown. *Root* annual. *Stem* two feet high, or more. *Leaves* with lanceolate, angular-toothed segments; their base dilated, clasping the stem, and coarsely toothed. *Flower-stalks* branched. *Flowers* the size of *S. oleraceus*. *Willdenow*. We have a mutilated specimen gathered by Thunberg at the Cape of Good Hope, which, as far as any judgment can be formed of it, answers to the above description; but it is very like the prickly varieties of the common *oleraceus*.

14. *S. angustifolius*. Narrow-leaved Sow-thistle. Defont. Atlant. v. 2. 225. Willd. n. 13.—“Leaves pinnate, glaucous, smooth; leaflets distant, linear, finely toothed. *Stem* scarcely any.”—Gathered near Casfa, in Barbary, by Desfontaines. *Root* perennial, long, spindle-shaped. *Stem* very short, or none. *Leaves* from four to eight inches long; their teeth withered and whitish. *Flower-stalks* slightly scaly, bearing one or more yellow flowers, the size of *S. arvensis*. *Calyx* smooth, ovate. *Desfont*.

15. *S. umbellifer*. Umbelliferous Cape Sow-thistle. Thunb. Prodr. 139. Willd. n. 14.—“Flower-stalks hispid, somewhat umbellate. *Leaves* oblong-heart-shaped, ferrated.”—Native of the Cape of Good Hope.

16. *S. glaber*. Smooth Cape Sow-thistle. Thunb. Prodr. 139. Willd. n. 15.—“Flower-stalks umbellate, smooth like the calyx. *Leaves* heart-shaped, runcinate.”—Native of the same country.

17. *S. gorænsis*. Scaly Goree Sow-thistle. Lamarck Dict. v. 3. 397. Willd. n. 16.—“Flower-stalks lateral, short, clothed with membranous scales. *Leaves* lyrate, with little spinous teeth.”—Native of the island of Goree, on the west coast of Africa. Sparrmann sent seeds to the Paris garden. The *root* is annual. *Stem* a foot high, round, smooth, with lax branches. *Leaves* distant, clasping the stem, scarcely more than two inches long, and one broad, smooth, green, somewhat runcinate. *Flowers* yellow, almost sessile along the branches. *Calyx* nearly cylindrical. *Flower-stalks* smooth, their scales with white membranous edges. *Lamarck*.

18. *S. oleraceus*. Common Sow-thistle. Linn. Sp. Pl. 1116. Willd. n. 17. Fl. Brit. n. 4. Engl. Bot. t. 843. Curt. Lond. fasc. 2. t. 58. (*S. laevis*; Ger. Em. 292. Camer. Epit. 279. Matth. Valgr. v. 1. 452.)

β. *S. oleraceus*; Fl. Dan. t. 682. (*S. laevis latifolius*; Ger. Em. 292.)

γ. *S. asperior*; Ger. Em. 291.

δ. *S. asper*; *ibid*.

ε. *S. subrotundo folio nostras*; Pluk. Phyt. t. 61. f. 5.

ζ. *S. aphyllocaulis, angusto et oblongo folio, nostras*; Pluk. Phyt. t. 62. f. 4. See also t. 61. f. 5.

Flower-stalks downy, imperfectly umbellate. *Calyx* smooth. *Leaves* runcinate, toothed.—A common weed in cultivated land throughout Europe, as well as in other parts of the world to which Europeans have had access, flowering in summer and autumn. The *root* is annual, spindle-shaped. *Herbage* smooth, brittle, milky, very various with respect to luxuriance, and the quantity of teeth, lobes, or prickles about the edges of its *leaves*; their segments, however, are almost always acute and runcinate. *Flower-stalks* axillary and terminal, rather cymose than umbellate, clothed when young with soft, white, dense, cobweb-like, deciduous down. *Corolla* lemon-coloured. *Seeds* angular, with erenate ribs.

19. *S. tenerrimus*. Clammy Sow-thistle. Linn. Sp. Pl. 1117. Willd. n. 18. Ait. n. 8. Sm. Fl. Græc. Sibth.

t. 790, unpublished. Tour on the Continent, v. 2. 313.— (*Hieracium foliis in tenues lacinias profundè sectis, flore luteo*; -Pluk. Phyt. t. 93. f. 3. *Chondrilla lutea*; Bauh. Hist. v. 2. 1020.)—Flower-stalks downy, somewhat umbellate. Calyx hairy. Leaves deeply pinnatifid, with parallel, oblong, toothed, bluntish segments; their base somewhat arrow-shaped.—Native of rocks and old walls, in Italy, Barbary, Crete, and Cyprus, as well as the south of France, flowering in spring. At Rome and Florence it is eaten in fallads, being of a more delicate, less bitter, flavour than *S. oleraceus*, from which it is also readily known, by the almost pectinate lobes of its leaves, hairy viscid calyx, and a much more elegant and slender aspect in the whole plant. The root is annual.

20. *S. chondrilloides*. Scaly Sow-thistle. Desfont. Atlant. v. 2. 226. Willd. n. 19. Sm. Fl. Græc. Sibth. t. 791, unpublished. (*Chondrilla ficula tragopogonoides maritima*; Bocc. Sic. 13. t. 7. f. 1.)—Flower-stalks elongated, scaly, single-flowered, somewhat corymbose. Calyx smooth; its outer scales heart-shaped. Radical leaves deeply pinnatifid, toothed: those of the stem oblong, toothed; heart-shaped at the base.—Native of sandy ground, in Barbary, Sicily, and Zante. Root perennial. Herb smooth, somewhat glaucous, with more radical, and fewer stem-leaves, than the last. Flowers large, yellow. Outer scales of the calyx, like those scattered over the flower-stalks, heart-shaped, pointed, with a broad, white, membranous border.

21. *S. hispanicus*. Spanish Sow-thistle. Jacq. Hort. Schoenbr. v. 2. 9. t. 143. Willd. n. 20.—Flower-stalks scaly, swelling upward, somewhat corymbose. Calyx-scales recurved. Leaves pinnatifid, toothed, clasping the stem, glaucous, with white downy dots. Found near Malaga, in Spain. An annual, milky herb, flowering from June to August. Jacquin. Stem a foot high, branching from the base, spreading, glaucous, and covered, like both sides of the leaves, with white dots, which prove, under a magnifier, tufts of down. Flowers smaller than the last, and more like the following, especially in their dark-purple central tint; but differing from both in the recurved points of their calyx-scales, whose white membranous margins, moreover, are crisped, or undulated.

22. *S. tingitanus*. Tangier Sow-thistle. Lamarck Dict. v. 3. 397. Willd. n. 21. Sm. Fl. Græc. Sibth. t. 792, unpublished. (*S. tingitanus, papaveris folio*; Tourn. Inf. 475. *Scorzonera tingitana*; Linn. Sp. Pl. 1114. Curt. Mag. t. 142. *S. orientalis*; Linn. Sp. Pl. 1113. Willd. Sp. Pl. v. 3. 1507. *Chondrilla tingitana, floribus luteis, papaveris hortensis folio*; Herm. Lugd-Bat. 657. t. 659.)—Flower-stalks swelling upward, slightly scaly. Calyx-scales erect, with membranous edges. Leaves pinnatifid, toothed, clasping the stem, glaucous, smooth.—Native of maritime rocks in Barbary and the Levant. Said to have been cultivated at Chelsea above 100 years ago, but it had long been lost, and its seeds were brought, by the writer of this, from Paris, to the garden of his worthy friend Dr. Gwyn of Ipswich, in 1787. The plant is annual, flowering in autumn, and its glaucous leaves, finely contrasted with the golden, purple-eyed flowers, make a striking appearance. The purple-tipped white-edged scales of the calyx also contribute to the beauty and singularity of the whole. That this plant is a *Sonchus*, not a *Scorzonera*, is evident to all who look at its seed-down, and the Linnæan herbarium proves *Scorzonera orientalis*, gathered by Hasselquist, to be the very same species.

23. *S. picroides*. Various-leaved Sow-thistle. Lamarck

Dict. v. 3. 398. Willd. n. 22. Allion. Pedem. v. 1. 223. t. 16. f. 1. Sm. Fl. Græc. Sibth. t. 793, unpublished. (*Scorzonera picroides*; Linn. Sp. Pl. 1114. *Crepis Dalechampi*; Dalech. Hist. 562.)—Flower-stalks swelling upward, scaly. Calyx-scales close-pressed, with slightly membranous edges. Leaves toothed; radical ones somewhat lyrate; the rest clasping the stem, obovate-oblong; uppermost linear, nearly entire. Native of the south of France, Barbary, Greece, Cyprus, and the Archipelago; sent by M. Richard to Kew, in 1773. It is a hardy annual, flowering in summer. The herb is smooth, rather glaucous, varying much in luxuriance, and the leaves of the same plant differ greatly in shape. The radical ones are runcinate and lyrate; being rarely obovate, and merely bordered with small teeth, like the rest. Flowers of a uniform yellow, above an inch broad, solitary, on a slightly scaly elongated stalk, at the end of each branch. The scales of the stalks, like the outer ones of the calyx, are heart-shaped, pointed, small, close and flat, with a narrow white edge. Although Plukenet's t. 61. f. 5, cited by Linnæus and Willdenow, bears some resemblance to the leaves of the species before us, yet that, being of English growth, can hardly be any thing else than a variety of *S. oleraceus*, to which we have often seen near approaches in that variable plant; see n. 18, §.

24. *S. crepioides*. Hawkweed Sow-thistle. (*Scorzonera crepioides*; Poiret in Lam. Dict. v. 7. 25.)—Flower-stalks naked, somewhat panicled. Stem much branched, rather downy as well as the calyx, whose outer scales are oval.—Gathered by M. Poiret, on the coasts of Barbary. His description of the fine, silky, simple seed-down, and naked receptacle, induces us to refer the plant to *Sonchus*. He describes it as having the aspect of *Crepis biennis*; but he knew not its leaves, nor the lower part of its herbage. Each division of the stem has, at its base, a little, clasping, linear-lanceolate, pointed, downy leaf. Flowers of a middle size, yellow. Calyx oval, close; its inner scales long, narrow, downy, or farinaceous; outer very short and oval.

25. *S. dichotomus*. Forked Sow-thistle. Willd. n. 23. (*Scorzonera dichotoma*; Vahl. Symb. v. 2. 89. Desfont. Atlant. v. 2. 450. *Lactuca flava*; Forsk. Ægypt-Arab. 143.)—"Flower-stalks scaly, of equal thickness throughout. Stem forked, almost leafless. Radical leaves runcinate."—Gathered by Forskall in the vale of Surdûd, in Arabia Felix, and by Vahl in the kingdom of Tunis. The herbage is smooth. Stems divided from the base into rigid forked branches, bearing in their lower part two lyrate leaves, like the radical ones, but otherwise only small, lanceolate, or ovate, entire ones under each subdivision. Flowers terminal, solitary, yellow. Calyx very smooth; its outer scales ovate, loose, with broad white edges.

26. *S. Plumieri*. Pyrenean Blue Sow-thistle. Linn. Sp. Pl. 1117. Willd. n. 24. Ait. n. 11.—Flower-stalks panicled, smooth, with clasping, long-pointed bractæas. Leaves pinnatifid, pointed, runcinate.—Native of the Pyrenees. It is also found, though rarely, on the Alps of Switzerland, having been observed by M. Favrod, on the mountain called Deut de Jamare, and above Queveisimen, in Teufelsgraben. We have seen this fine plant in some curious gardens, but cannot find it any where figured. The root is perennial. Stem often as tall as a man, round, branched, striated, leafy, smooth and glaucous like every other part of the herbage. Leaves one or two feet long, deeply pinnatifid, with numerous, pointed, opposite, parallel, sharp-toothed segments, and a terminal, pointed, triangular lobe; their base dilated, clasping the stem; under side most glaucous.

Flowers

Flowers numerous, large, pale blue, less vivid than those of the Wild Succory. *Braçteas* smooth, rounded at the base, with long, taper points. *Calyx* smooth. Its outer scales somewhat cordate.

27. *S. macrophyllus*. Large-leaved Hairy Blue Sow-thistle. Willd. n. 25. Pursh n. 3. (*S. canadensis*; Froelich in Uster's Annal. v. 1. 29. S. n. 1; Gronov. Virg. ed. 2. 115. "Chondrilla sylvestris alta, flore cæruleo specioso, foliis sinuatis longis acuminatis alternis, leviter hirsutis, caule ad cacumen ramoso, femine nigro, pappis albis et quasi argenteis instructo; Clayt. n. 139.")—*Flower-stalks* hairy, paniced. *Leaves* lyrate; heart-shaped at the base; hairy beneath.—In shady low grounds, near springs, from Pennsylvania to Carolina, flowering in August and September. From four to seven feet high. *Flowers* blue, the size of *Cichorium Intybus*. *Root* tuberous. *Pursh*. Mr. Froelich, above quoted, describes this species as having for some years been cultivated in the botanic garden at Erlang, with simple, spatulate radical *leaves* a foot long, which wither before the *flowers* come to perfection; their ribs and veins hairy beneath; the *stem-leaves* lyrate, toothed, somewhat fringed; much dilated, heart-shaped, rounded, and finely toothed, at the base; paler and hairy beneath; their terminal lobe very large, triangular, in some degree heart-shaped; the intermediate ones ovate, obtuse, unequal: *upper leaves* more simple, spatulate, very broad at their base, with scarcely any intermediate lobes. *Panicle* with alternate, hairy, subdivided, unequal branches; the upper ones longest and most compound. *Flower-stalks* unequal, erect, densely clothed with glutinous hairs, and bearing one or two scales. *Braçteas* lanceolate, pointed, hairy, much shorter than the partial stalks. *Calyx* half an inch long, cylindrical, pale violet; its inner scales about fourteen, linear, equal, thin at the edges; outer shorter, scattered, unequal, closely imbricated, a little hairy at the back. *Florets* from thirty-four to forty, of a purplish flesh-colour, with hairy tubes. *Seeds* ovate-oblong, triangular, striated. *Down* sessile, roughish, very white. *Odour* of the plant like opium, disagreeable, as well as the *taste*, which is bitter. Of this little-known species we suspect there is an imperfect specimen in the Linnæan herbarium, first marked as having been communicated by Kalm, and then by Gmelin, a reference to *Sonchus*, n. 12. Fl. Sibir. v. 2. 12. t. 4. f. 1, being at the back. This last is an error, the said figure answering best to *S. alpinus* of most authors, *cæruleus* of Fl. Brit. which we suspect to have been Gmelin's plant. He mentions having seen but a single specimen, or we should think it had been one of his, now also in our hands, which Linnæus, by a parallel error to the above, has marked as coming from Kalm, and described by the name of *canadensis*. At least, Linnæus's having confused himself about these two specimens, may account for his describing as a Canadian plant, what no one has ever found in that country; for Mr. Pursh evidently admits it on report only, by the name of *alpinus*.

28. *S. cæruleus*. Alpine Hairy Blue Sow-thistle. Camer. Epit. 281. Fl. Brit. n. 1. Engl. Bot. t. 2425. (*S. canadensis*; Linn. Sp. Pl. 1115. *S. montanus*; Lamarck Dict. v. 3. 401. *S. alpinus*; Willd. n. 26. Ait. n. 12, excluding the reference to Fl. Lapp. Pursh n. 4. Froelich in Ust. Annal. v. 1. 26. Fl. Dan. t. 182. *S. cæruleus latifolius*; Bauh. Hist. v. 2. 1005. *S. flore cæruleo*; Ger. Em. 294. S. n. 20; Hall. Hist. v. 1. 9.)—*Flower-stalks* hairy, racemose, with setaceous bractæas. *Leaves* somewhat lyrate; arrow-shaped at the base; their terminal lobe triangular, very large.—Native of alpine pastures in various parts of Europe, flowering in July and August. The late

Mr. G. Don found it on Lochnagore, Aberdeenshire, which is the only authority for retaining it in our Flora Britannica; *S. alpinus* of former British writers being only *Cichorium Intybus*, admitted on the word of a Northumberland writer, scarcely more correct than he who described the lemon, as growing on the bleak Welsh crag of Penmaen Mawr. This species has a fleshy, perennial, tufted root. *Stems* about a yard high only, simple, leafy. *Leaves* consisting chiefly of a large, triangular, toothed, sharply-pointed lobe, on a bordered, slightly pinnatifid, stalk, clasping the stem with an arrow-shaped base; the under side glaucous, with now and then a few hairs on the rib; the uppermost *leaves* are often quite linear, and merely fringed. *Cluster* terminal, solitary, erect, many-flowered, scarcely compound, its stalks, like the *calyx*, rough with copious, red, glutinous, prominent hairs. *Braçteas* linear or setaceous. *Corolla* of a fine blue. *Antlers* red. *Seed-down* roughish.

Linnæus originally confounded this with his true *S. alpinus*, which has given rise to much confusion and controversy; for authors, indolently following some of his synonyms, without regarding his definitions, have been thus led widely astray; nor can we screen their errors, by allowing them to change a fixed and primary Linnæan name. The learned and candid Mr. Froelich only has any claim to attention on this subject. He would call this plant *alpinus*, because Linnæus has, in *Philosophia Botanica*, p. 273 & 274, inadvertently spoken of his true *alpinus*, by the name of *lapponicus*. So has he there called his *oleraceus, levis*; his *palustris, belgicus*; and his *Cichorium Intybus, scanense*; all which errors he has corrected in his own copy of the work; nor did he dream of their misleading any body. Even Lamarck has used the name of *alpinus*, according to its original destination, and so we shall presume still to apply it; see the following species.

29. *S. alpinus*. Alpine Scaly Blue Sow-thistle. Linn. Sp. Pl. 1117. Fl. Suec. ed. 2. 269, excluding all, except Linnæan, synonyms. Fl. Lapp. ed. 2. 240. Lamarck Dict. v. 3. 400. Sm. Plant. Ic. t. 21. (*S. lapponicus*; Froelich in Ust. Annal. v. 1. 26. Willd. n. 27.)—*Flower-stalks* scaly, racemose, erect. *Leaves* pinnatifid, pointed, toothed, smooth; glaucous beneath. *Stem* simple.—Found by Linnæus on the sides of hills, and in valleys, among the Lapland alps, where it is extremely common, though not known in any other part of the world. The Laplanders peel the stalks, before flowering, and eat the fleshy part, which Linnæus thought too bitter, without the usual seasoning of a salad. He speaks of this plant as extremely handsome, the height of a man, or taller, with a straight, rigid, leafy stem. The *leaves* are smooth and shining, deeply pinnatifid, sharply toothed; rounded, but not dilated nor clasping, at the base; glaucous beneath. *Cluster* more or less compound, long, dense; its stalks not at all hairy or downy, but clothed with imbricated, concave, acute, sheathing scales. *Flowers* blue, about half the size of the last, but much more numerous. *Calyx* ovate, smooth. The late professor Willdenow informed us, in 1796, that this rare plant was then growing luxuriantly, in the garden of Mr. Krause, at Berlin. He favoured us with seeds, but they did not succeed. The root is marked as biennial.

30. *S. leucophæus*. Pale-blue American Sow-thistle. Willd. n. 28. Pursh n. 5. (*S. spicatus*; Lamarck Dict. v. 3. 401.)—*Flower-stalks* scaly, racemose, drooping. *Leaves* pinnatifid, toothed, smooth. *Stem* wand-like, paniced.—On the borders of woods, by road sides, from New England to Virginia, flowering from July to September. *Root* biennial. *Flowers* small, white tinged with blue. *Pursh*. Lamarck

says the *stem* is only two or three feet high. *Leaves* narrow; the upper ones small, linear, and entire.

31. *S. floridanus*. Small-flowered Florida Sow-thistle. Linn. Sp. Pl. 1118. Willd. n. 13. Pursh n. 6.—Flower-stalks panicled, distantly fealy. *Leaves* somewhat lyrate, minutely toothed, smooth, with a large, triangular, acute, terminal lobe.—On road sides, in the shady woods of Virginia and Carolina, flowering from July to September. *Root* biennial. *Leaves* a span long, of two large lobes, besides the much larger terminal one; narrow and linear at the base. *Panicle*, or *cluster*, doubly branched, spreading. *Flowers* very small, blue. Mr. Pursh says, this plant has been used for curing the bite of the rattle-snake, in the same manner as his *Prenanthes serpenticaria*, and is known by the name of Gail of the earth.

32. *S. acuminatus*. Pointed-leaved Sow-thistle. Willd. n. 30. (*Lactuca villosa*; Jacq. Hort. Schoenbr. v. 3. 62. t. 367?) —“Flower-stalks slightly fealy, panicled. Radical leaves somewhat runcinate; those of the stem ovate, pointed, stalked.”—In low shady places, from Pennsylvania to Virginia, flowering in August and September. Biennial. *Flowers* small, blue. *Pursh*. *Stem-leaves* tapering at each end, and furnished at each side, in the middle, with small pointed teeth. It differs from *S. floridanus* in these leaves being undivided. They are also slightly hairy beneath. The *panicle* was slender, composed of few *flowers*, in Willdenow's wild specimen, and the *seed-down* sessile. Jacquin's figure exhibits a triply-compound *panicle*, of innumerable small pale-blue *flowers*, and he unluckily does not mention the *seed-down*. We know nothing of this species, but from these authorities. It appears akin to the last, though sufficiently distinct.

33. *S. pallidus*. Pale-yellow Canadian Sow-thistle. Willd. n. 31. Ait. n. 14. Pursh n. 8. (*Lactuca canadensis*; Linn. Sp. Pl. 1119.)—Cluster compound, with fealy stalks. *Leaves* lanceolate, toothed, smooth, clasping the stem; the upper ones taper-pointed.—On road sides, and in woods, from Canada to New England, flowering from July to September. Perennial. *Flowers* small, yellow. *Pursh*. The scales of the *flower-stalks* are ovate, pointed, crowded and recurved. *Cluster* dense. *Calyx* very smooth. *Seed-down* quite sessile. The *leaves* are not properly sword-shaped. Mr. Pursh cites under this species Robert's *Icones* t. 148 and 151, which we have not been able to consult.

34. *S. pulchellus*. Beautiful Blue Sow-thistle. Pursh n. 9.—“Flower-stalks fealy, in a corymbose cluster. *Stem-leaves* ovate-oblong, acute, entire, smooth; with a clasping heart-shaped base.”—On the banks of the Missouri, flowering in September. Perennial. *Flowers* large, of a beautiful blue. *Pursh*.

35. *S. fliricus*. Willow-leaved Sow-thistle. Linn. Sp. Pl. 1118. Willd. n. 32. Ait. n. 15. (S. n. 11; Gmel. Sib. v. 2. 11. t. 3. *Lactuca falsis folio*, n. 211 and 212; Amm. Ruth. 150.)—Flower-stalks corymbose, with distant lanceolate scales. *Leaves* lanceolate, sessile; the upper ones entire; lower variously toothed.—Found throughout Siberia, as well as about the river Wolga, and in some parts of Russia and Finland. The *root* is perennial, creeping extensively. *Stem* from one to four feet high, leafy, wand-like; sometimes branched in the upper part. *Leaves* numerous, about four inches long, very smooth and even; rather glaucous at the back. *Flowers* blue, about an inch in diameter, composing a level-topped corymb.

36. *S. tataricus*. Tartarian Sow-thistle. Linn. Mant. 572, excluding the synonym. Willd. n. 33. Ait. n. 16.—Flower-stalks racemose, nearly naked. *Leaves* lanceolate,

runcinate.—Native of Siberia and Tartary. Perennial, flowering in June and July. A rather larger plant than the last; the teeth of its *leaves* large, pointing backward. *Flowers* blue, in compound clusters, terminating the stem and branches.

37. *S. prenanthoides*. Long-clustered Sow-thistle. “Marschall von Bieberstein.” Fischer MSS.—Flower-stalks racemose, lateral and terminal, fealy, downy. *Leaves* elliptic-oblong, toothed, somewhat fiddle-shaped.—Native of mount Caucasus. The *stem* is round, terminating in a long series of alternate, shortish, somewhat compound, *clusters*, whose partial stalks are cottony and fealy. The *flowers* seem to be blue or purplish. *Leaves* smooth, somewhat stalked, three or four inches long, an inch and half broad, finely toothed; the upper ones diminishing into lanceolate narrow *bractæas*.

SONCINO, in *Geography*, a town of Italy, on the Oglio; 8 miles E.N.E. of Crema.

SONDAU, a town of Brandenburg, in the duchy of Magdeburg; 50 miles N.N.E. of Magdeburg.

SONDELY, a town of Norway, in the province of Bergen; 30 miles S.S.W. of Romfald.

SONDERBORG, a sea-port town of Denmark, on the S. coast of the island of Alsén, with a royal palace, and one of the best harbours in Denmark. In this palace Christian II. king of Denmark, was confined as a prisoner for 13 years: the inhabitants are chiefly seamen: 16 miles E.N.E. of Flensborg. N. lat. 54° 57'. E. long. 9° 59'.

SONDERSHAUSEN, a town of Germany, in the county of Schwartzburg, situated on the Wipper. On an eminence without the town stands the palace, where the ruling prince of the Sondershausen line usually resides; 20 miles N.E. of Mulhausen. N. lat. 31° 22'. E. long. 10° 57'.

SONDERSITZ. See URSITZ.

SONDHEIM, a town of the duchy of Wurzburg; 7 miles N. of Bischofsheim.

SONDRE GRUND, or BOTTOMLESS, an island in the South Pacific ocean, discovered by Le Maire and Schouten, in 1616; about 20 leagues in circumference, long but not broad. It appeared covered with trees, among which were palm-trees and cocoa-nut trees. It had no anchoring ground. The inhabitants were naked, except a piece of mat round the middle, of a yellowish or reddish-brown colour, and black hair; their skin was marked with many figures: they were covetous of iron, and thieves. S. lat. 15°. W. long. 148°.

SONDRIO, or SONDERS, a town of Italy, and capital of the Valteline, partly on a plain and partly on the side of a rock, in a romantic situation, at the extremity of a narrow valley, on a small river which runs into the Adda; 15 miles E. of Chiavenna. N. lat. 46° 6'. E. long. 9° 50'.

SONE, a town of Bengal; 8 miles S.E. of Ramgur.

SONEGA, a town of Holland, in Friesland; 9 miles E. of Kuynder.

SONEGUERA, a town of Mexico, in the province of Honduras; 32 miles N. of St. Jorge de Olancho. N. lat. 15° 15'. W. long. 86° 40'.

SONEHUTCH, a town of Hindoostan, in Malwa; 30 miles N.E. of Indore.

SONENBERG, a town of Germany, in the county of Pludentz; 4 miles N. of Pludentz.—Also, a town of the New Mark of Brandenburg; 6 miles E. of Cultrin.

SONEPOUR, a town of Hindoostan, in Orissa, on the Mahanada; 38 miles S. of Sumbulpour. N. lat. 20° 47'. E. long. 83° 40'.

SONERGONG. See SUNERGONG.

SONEWALDT, a town of Lufatia; 8 miles S. of Luckau.

SONEY, a town of Hindooftan, in Malwa; 9 miles E. of Saurungpour.

SONG, a town of Africa, in Bambarra, on the Niger. N. lat. $13^{\circ} 54'$. W. long. $3^{\circ} 55'$.

SONG, a town of China, of the third rank, in Ho-nan; 37 miles S.S.W. of Ho-nan.

SONG SONG, a small island in the Indian sea, near the coast of Africa. S. lat. $8^{\circ} 12'$.

SONG, in *Poetry*, a little composition, consisting of simple, easy, natural verses, set to a tune, in order to be sung.

Each stanza of a song is called a *couplet*.

The song bears a great deal of resemblance to the madrigal, and more to the ode; which is, indeed, nothing but a song, according to the ancient rules.

Its object is usually either wine or love, whence M. le Brun defines a modern song, to be either a soft and amorous, or a brisk and Bacchic thought expressed in few words.

Indeed, this is to restrain it to too narrow bounds; for we have devout songs, satyrical songs, and panegyrical songs. But, be the song what it will, the verses are to be easy, natural, and flowing; and are to contain a certain harmony, which neither shocks the reason nor the ear; and which unites poetry and music agreeably together.

Anciently, the only way of preserving the memory of great and noble actions, was by recording them in songs; and, in America, there are still people who keep their whole history in songs.

Songs have at all times, and in all places, afforded amusement and consolation to mankind: every passion of the human breast has been vented in song; and the most savage as well as civilized inhabitants of the earth have encouraged these effusions. The natives of New Zealand, who seem to live as nearly in a state of nature as any animals that are merely gregarious, have their songs, and their *improvvisatori*; and the ancient Greeks, during every period of their history and refinement, had their *scolia* for almost every circumstance and occasion incident to society.

Singing was so common among the ancient Romans as to become proverbial. Phædrus, in the Phormio of Terence, begs Dorio to hear him, he has but one word to offer; when Dorio tells him he is always singing the same song. Horace speaks of the same affectation among the singers of his time as prevails with the present; never to sing when they are entreated, or to desist if no one wishes to hear them. And some idea of the cultivated state of music in Gaul, so early as the fifth century, may be acquired from a passage in one of the epistles of Sidonius Apollinari, who, in his character of king Theodoric the Goth, says, that "this prince was more delighted with the sweet and soothing sounds of a single instrument, which calmed his mind, and flattered his ear by its softness, than with hydraulic organs, or the noise and clangor of many voices and instruments in concert."

Clothaire II. in the seventh century, having gained a great victory over the Saxons, it was celebrated by a Latin song in rhyme, which the annalists tell us was sung with great vociferation all over the kingdom.

As the origin of songs and the formation of the language of every country are so nearly coeval, we hope the reader will allow us to bestow a few columns on a subject which, though it may not be thought absolutely necessary for a musical lexicographer, or even historian to trace, yet it lies so near his path, that he can hardly proceed on his way with-

out its being impressed on his mind fortuitously. For the songs of the ancient Greeks, see SCOLIA.

But in enquiring after the most ancient songs in modern languages, we shall not enter upon the merits of a question which has been much agitated in France during the middle of the last century, "Whether the present language of that country was first cultivated in the northern or southern provinces?" The origin of all inventions, after having been suffered by ignorance and idleness to sleep for many ages, is so difficult to ascertain, that if the inhabitants of the kingdoms which gave them birth, where information is most likely to be furnished, are unable to bring them to light, it would be arrogance in a foreigner to attempt it. The French critics and antiquaries all agree that the capital was the last place to cultivate the vulgar tongue, and to receive the first essays of those who made it the vehicle of their thoughts. Fontenelle says the first sparks of poetry appeared chiefly at the two extremities of the kingdom, in Provence and Picardy. "The Provençaux," says he, "warmed by a more genial sun, ought to have had the superiority; but the inhabitants of Picardy are their inferiors in nothing." M. de la Ravière gives the honour of priority to the writers of Normandy; and Fauchet and Pasquier, separating the French poetry from the Provençal, challenge the admirers of the Troubadours to produce verses of their writing of equal antiquity with the specimens of French poetry which they have exhibited. However, the Provençal bards have lately had many able champions, among whom M. de Lacurne de Sainte Palaye, and his faithful 'quire, M. Millot, have distinguished themselves. And though it cannot be denied but that fragments of songs subsist in the French language of higher antiquity than in the dialect of Provence, yet, as we have been able to find no melodies that have been set to a modern language more ancient than those that have been preserved in the Vatican library to the songs of the Troubadours, we shall begin our enquiries concerning the origin of vulgar dialects in Europe, by endeavouring to trace the first formation of the language of Provence.

Every refined and polished nation has a vulgar language in its remote provinces, and even in its capital, among the common people, in which there are innumerable words and phrases that have never been admitted into books. This must doubtless have been the case with the Romans; and it is the opinion of some persons of great eminence in literature, among whom may be numbered the learned cardinal Bembo, and the marquis Maffei, that the ancient Romans had at all times an oral vulgar language which was different from that of books; and that this colloquial language, less grammatical and elegant than that of the learned, was carried by the Romans into all the provinces under their dominion. It is therefore probable that this, and not the written language of Italy, was the mother of the Provençal, Sicilian, Italian, and Spanish dialects.

But supposing such a language as Cicero's was ever spoken, it could not be laid aside for another all at once; and when we are told of a particular period or century, during which the Latin tongue ceased to be spoken in France or Italy, and the Provençal, French, or Italian begun; credulity itself is staggered, and unable to reconcile it to probability. Every language is long spoken before it is written; and though the first poet of Italy or Provence, who committed his verses to writing in the vulgar tongue, could be named, no one would venture to tell us by whom it was first spoken.

The learned Maffei is of opinion that there was a vulgar language in Italy long before the irruptions of the Lombards, Goths,

Goths, or Franks; and has traced its use as early as the time of Quintilian, who tells us, that he had often heard the crowd in the Circus applaud, or demand something of the champions, in a barbarous language; that is, in a vulgar and plebeian dialect, different from pure Latin. Sammonicus, who lived in the time of Septimius Severus, names the vulgar language. And both Pliny and St. Jerome speak of the military language as of that kind; the latter even tells us that Fortunatianus, bishop of Aquileia, wrote a commentary on the Evangelists in this vulgar language, *ruffico sermone*, during the time of Constantine. But this was a singular instance, which was not imitated.

It appears, however, from the Dialogues of St. Gregory the Great, written 593, that there was then a language merely colloquial at Rome. For he tells us that a new convert, of whom he is speaking, was sent to a convent with two vessels of wine, which the vulgar call flasks.

And Gregory of Tours, so early as 572, complains of this vulgar or rustic tongue gaining ground in France, and being more in favour than Latin, the language of the learned.

It was therefore by degrees that Latin ceased to be understood by the common people, and the Romance language had admission into books. And in 813 it was ordered by a canon at the council of Tours, that the bishops should be employed in translating homilies into the Roman rustic tongue, that they might be the more easily understood by the common people. The same canon, we are told, was renewed in a council at Arles in 851.

In the ninth century historians tell us, that Charlemagne and his sons and successors spoke the Romance language, specimens of which may be seen in Fauchet, Pasquier, and several other writers on the French language. And in the twelfth century it began to be the general language of poets and polite writers. Some of the sermons written and preached by St. Bernard, about 1137, in this language, are still preserved among the MSS. of the convent of Feuillans, in the rue St. Honoré at Paris.

The colloquial language used only in familiar conversation was called by the Romans *sermo usualis, quotidianus, pedestris, vulgaris, miliaris, rufficus*, &c. It is supposed by M. Bonamy, as well as by others, that from this vulgar Latin not only the French language and its different dialects but the Spanish and Italian are derived. Indeed, it is most probable that the Latin tongue, in its periods of greatest purity, was only the language of the learned, in the Roman provinces remote from the capital; and that it was never so generally cultivated in other times as to exclude the vulgar dialect.

In the frequent revolutions and struggles for empire during these ages, the Roman language must have been debased and corrupted, while new tongues were forming, which, though not sufficiently fixed and grammatical to be used in books, were doubtless long the vulgar and colloquial dialects before the Latin ceased to be the common language of the learned.

It was about this time that the art of rhyming, or unisonous terminations of verses, stole into poetical composition, in a manner which the learned and judicious author of an Essay on the Language and Versification of Chaucer, seems to have traced to its source. Leonine verses, supposed to have been so called from a pope or monk Leo, their author, in the seventh century, are by some thought the first attempt at rhyme; while others imagine the hymn to St. John the Baptist, by Paul Diaconus, written about the latter end of the eighth century, to be not only rendered memorable by Guido's scale, but by having been the model of all other

monkish rhymes in Latin, as well as in modern languages. *Ut queant laxis*, &c.

But neither of these genealogies satisfies all enquirers. Gravina thinks it as absurd to ascribe the invention of rhyme to any one writer, as to attribute to an individual the propagation of the plague, which is caused by the universal contagion of the air.

The Arabs had rhyme, according to Don Calmet, before the time of Mahomet, who died 632, and in the second century used a kind of poetry in measures similar to the Greek, and set to music. See RHYME.

While the new languages were unsettled, and but partially known, even in the single kingdom or province where they were forming, it was not uncommon to write half a poem in Latin and half in a vulgar tongue. Indeed Dante has left a poem in three languages, Latin, Provençal, and Italian; and Rambaud de Vachieras, a Provençal poet, in five.

Petrarca and Muratori think that the Sicilians first composed and wrote songs in a vulgar language; that from them the custom went into Provence, and from Provence into Italy. Indeed Sicily and Provence were long under the dominion of the same princes, and the same language may have been cultivated at the courts of both countries; but as no vestiges remain of Sicilian poetry resembling the Provençal, the opinions of these authors, however eminent, and, on other accounts, respectable, while unsupported by reasons and facts, can have but little weight.

Cardinal Bembo, however, was of opinion that the first rhymers and poets who wrote in a modern language were of Provence; after them the Tuscans, who had more assistance from them in their poetry than from any other people. And both Crescembeni and Gravina make the same concession.

Nollradamus, in his lives of the Provençal poets, says that Provence was called the mother of Troubadours and Minstrels; and that Dante, Petrarca, Boccaccio, and other Tuscan poets, enriched both their language and fancy from the productions of his countrymen. However, as no *versi sciolti*, or poetical lines without rhymes, are to be found in the Provençal poets, though they abound among the Italians, it is natural to suppose that in these measures of blank verse the Italians imitated their ancestors the Romans, and that in rhyming, the Provençals were their models.

It was the opinion of Voltaire that this language began to be formed in the ninth century, out of Latin and Teutonic; that it was the mother of French, Spanish, and Italian; "continued in favour till the reign of the emperor Frederic II. and is still spoken in some villages of the Grisons, and near Switzerland."

Carpentier derives the word Troubadour from *Troba*, Provençal, *figmentum*. *Hinc Troubadours appellati poete Provinciales*.

It was in the eleventh century, during the first crusade, according to the abbé Millot, that Europe began to emerge from the barbarous stupidity and ignorance into which it had long been plunged. And while its inhabitants were exercising every species of rapine, plunder, and pious cruelty in Asia, art, ingenuity, and reason, insensibly civilized and softened their minds.

It was then that the poets and songsters known by the name of Troubadours were multiplied, and their profession honoured by the patronage and encouragement of the count of Poitou, and many other powerful princes and barons, who had themselves successfully cultivated poetry and music. At the courts of these munificent patrons they

were treated with the greatest consideration and respect. The ladies, whose charms they celebrated, gave them the most generous and flattering reception; and sometimes disdained not even to listen with compassion to tales of tenderness, and descriptions of the hawk which the irresistible charms of these sublunary divinities of chivalry had made in their hearts. The success of a few inspired the rest with hope, and excited exertions in the exercise of their art, which impelled them towards perfection with a rapidity that nothing but the united force of emulation and emolument could occasion.

As these founders of modern versification, these new poetical architects, constructed their poems upon plans of their own invention; and as all classical authority was laid aside, either through ignorance or design, each individual gave unlimited indulgence to fancy in the subject, form, and species of his composition. And it does not appear, during the cultivation and favour of Provençal literature, that any one Troubadour so far outstript his brethren in the approaches he made towards perfection, as to be considered as a model for his successors. We find, though military prowess, hospitality, Gothic gallantry, and a rage for feasts and revelry prevailed, that taste, refinement, and elegance, were never attained during this period, either in public or private amusements. The want of originality of composition is frequently lamented when licence is repressed by laws, and the wild effusions of an ardent imagination are bounded by authority; but the productions that have been preserved of the Provençal bards, which may be called the offspring of writers in a state of nature, seem to prove the necessity of rule, order, and example, even in the liberal arts as well as the government of a free state. For the progress of taste must ever be impeded by the ignorance and caprice of those who cultivate an art without science or principles.

During near two centuries after Guido's arrangement of the scale and invention of the time-table ascribed to Franco, no remnants or records of secular music can be found except those of the Troubadours, or Provençal poets. And though in the simple tunes which have been preserved of these bards, no time is marked, and but little variety of notation appears, yet it is not difficult to discover in them germs of the future melodies, as well as poetry, of France and Italy. Unluckily the poetry and music of the Troubadours of Provence were not for a long time called into notice by writers possessed of those blandishments of style or manner which fascinate, and render whatever subject they treat interesting to the generality of readers. Fauchet, Pasquier, and Noltradamus have written in a language that is now become so uncouth and difficult, that few have the courage to attempt acquiring information or amusement from it; and Muratori and Crescimbeni, who are respected for their diligence and exactitude, are certainly dry and dull narrators of facts which promise delight to every lover of literature; nor do we remember, in consulting their voluminous writings, ever to have found them guilty of hazarding a single reflection or conjecture that has embellished the subject, or rendered it amusing. But this censure must not be applied to Sainte-Palaye, Bonamy, la Raviere, and Barbazan, who, in the *Memoires de Litterature* and elsewhere, have not only embellished, but nearly exhausted the subject. Indeed, the period of Provençal poetry is interesting to literature, and the melody to which it was sung is a subject of curious enquiry to a musical historian; for it is generally allowed that the Troubadours, by singing and writing in a new tongue, occasioned a revolution not only in literature but the human mind. And as almost every species of Italian poetry is derived

from the Provençals, so air, the most captivating part of secular vocal melody, seems to have had the same origin. At least the most ancient strains that have been spared by time, are such as were set to the songs of the Troubadours. See TROUBADOURS.

Songs seem in a particular manner to belong to the language of Italy. The ancient Romans were no great songsters; and by what degrees the Latin language became Italian, would be a tedious and difficult enquiry. We know when the musical drama or opera was established, and consequently when opera airs, with instrumental accompaniments, began first to be cultivated; but these are not the subjects of our present research: but when national melodies, for such every country has, were first applied to songs in the Italian language, a dialect which has long been universally allowed to be more favourable to singing than any one which the numerous combinations of letters in all alphabets of modern times has produced, we are ignorant. And if the French, Provençal, and Spanish dialects can be deduced from the Latin, how much more easy is it to trace the Italian from that source? which is itself frequently so near pure and classical Latin, that no other change or arrangement of words seems to have been made, than what contributed to its sweetness and facility of utterance.

That the Italian tongue is derived from the vulgar language of the ancient Romans, seems the opinion of the best critics; but to discover and point out by what degrees it was smoothed and polished to the state in which Dante, Petrarca, and Boccaccio found it in the fourteenth century, would require more time, and occupy more space in this article, than the subject seems necessarily to require. However, as the Italian language has been truly allowed to be more musical in itself when merely spoken with purity, than any other in Europe, an enquiry into the causes of its natural melody and melliflence does not seem foreign to the subject of the present article.

Muratori (*Dissert.* 32.) has given innumerable passages from authors of the eighth and ninth centuries, to prove, that after the Franks and Germans were settled in Italy, articles were used in the Latin language instead of pronouns and changes of termination, in order to save the trouble of inflecting the cases in nouns; but pretends not to say what this vulgar language was, or whether the clergy preached to the common people, or merchants carried on their correspondence in Latin or Italian.

The learned Maffei allows the Provençal, French, Spanish, and Italian languages, to be descendants from the Latin, but denies that the ancient inhabitants of Italy adopted any words from the Goths or Huns who invaded them. The genius of the German, Francic, or Teutonic language, which was spoken by the Lombards, was so diametrically opposite to that of the Italians, that it seems incredible there should have been any exchange or union of dialects between them: the one being as remarkable for its numerous consonants and harsh terminations, as the other for its open vowels and mellifluous endings. As it is the opinion of this profound critic that the Romans had always a vulgar dialect, less grammatical and elegant than that of the senate and of books, he supposes the French, Spanish, and Italian languages to have been different modifications of this rustic, plebeian dialect. But it is as difficult to assign a reason for all these daughters of one common mother being so dissimilar, as it is to account for the little resemblance that is frequently found between other children of the same parents. And why the French language should have so many nasal endings, the Spanish so many syllabating, and the Italian alone have none but

vocal terminations, can only have been occasioned by some particular and radical tendency in the vulgar and plebeian language of each country from very high antiquity.

While this language was forming, no music seems to have been cultivated in Italy, except the *canto fermo* of the church; and, unluckily, no written melody can be found to the *Canzoni* of Dante, the sonnets of Petrarca, or the songs of Boccaccio, the three great founders of the Italian tongue. Yet these, we are told, were all set to some kind of music or other, and sung even in the streets. See the biographical articles of these lyric poets, particularly that of Boccaccio; whose "*Decamerone*" has always been regarded as a natural and faithful delineation of the manners and customs of Italy, at the time when it was written.

With respect to music, whether the personages which he assembles together after the plague at Florence 1348, and the stories they tell, are real or imaginary, the amusements he assigns them in his ritual must have been such as were usual to the Florentines, among whom he lived at that time; and indeed the poems that are pretended to have been sung, and the instruments with which they were accompanied, subsisted before this period, and still subsist.

Boccaccio tells us, at the end of his *prima giornata*, or first day, that "after supper the instruments were called in, when the queen, for the day, ordained that there should be a dance; and after one had been led off by Lauretta, Emilia sung a song, in which she was accompanied by Dion, a gentleman of the party, on the lute." There is nothing new or extraordinary in this quotation. But in Italy, whence all the liberal arts have travelled to the rest of Europe, it is curious to know in what rank music was held at this early period, and what use was made of it in polite assemblies, by the inhabitants. And here a writer, justly celebrated for the exactness with which he has described the customs of his contemporaries in all situations, tells us, that in an assembly of persons of birth and education, who passed ten days together during summer in a constant succession of innocent amusements, each evening was closed by dance and song; in which the whole company, consisting of seven ladies and three gentlemen, of different characters and acquirements, were able to perform their parts.

When we are told, that the lady who sang was accompanied by the lute, we know not of what this accompaniment consisted, whether it only fortified the voice-part by playing the same melody, or more elaborately furnished a base and a different treble, arising out of its harmony.

On the second day we find, that one of the company leading off a carol, a song was sung by another, which was answered in a kind of chorus by the rest.

At the close of the second day Boccaccio tells us, that after the song, of which he gives the words, had been performed, many others were sung, and many dances danced to different tunes, by which we may gather, that besides carols and ballads, the singing of which marked the steps of a dance, there were at this time songs without dances, and tunes without songs.

Whoever reads the history of the most ancient inhabitants of this island, the Cambre-Britons, will find innumerable instances of the reverence which they paid to their poet-musicians, the bards both of Pagan and Christian times; and songs of very high antiquity have been preserved in the Welsh language, though not all the tunes to which they were sung.

We are told (*Miscel. Antiq.* vol. ii. p. 8.) that sir Thomas Wyatt was the first who introduced Italian numbers into

English versification. This may have contributed to improve our lyric poetry; but to confess the truth, from the few parts of the first class throughout Europe, who, at the beginning of the sixteenth century, condescended to write madrigals and songs for music, it seems that the rage for canon, fugue, multiplied parts, and dissimilar melodies, moving at the same time, had so much employed the composers, and weaned the attention of the hearers of these learned, or, as some call them, Gothic contrivances, from poetry, that the words of a song seem to have been only a pretence for singing; and as the poets of the two or three last centuries were in little want of music, musicians, in their turn, manifested as little respect for poetry; for in these elaborate compositions, the words are rendered utterly unintelligible by repetitions of particular members of a verse; by each part singing different words at the same time; and by an utter inattention to accent.

In the "*Essays on Song-writing*," published with a collection of English songs (we need not name the author, whom he has not named himself, nor given the date of the publication) there are many judicious and excellent reflections; and the songs are admirably selected, and form the best collection in our language, under the three following heads: "On Song-writing in general;" "On Ballads and pastoral Songs;" "On passionate and descriptive Songs."

We can perceive, however, that the author of these ingenious essays loves poetry better than music; a personage whom he does not treat with common civility, when he says, "the heroine Poetry must give place to the *barlot Music*," notwithstanding her claim to the title of a *lady of fashion*. But we think the two ladies should *ride and tie*. There are songs where the poetry should be respected, and the music subordinate; and others, where music is entitled to pre-eminence.

We wish not fine poetry to have fine music, nor fine music to be manacled by laboured poetry. Lyric poetry cannot be too simple.

The author allows the primitive meaning of a song to signify something to be *sung*: and when he says, "a song, as a poetical composition, may be defined a short piece, divided into returning portions of measures, and formed upon a single incident, thought, or sentiment," we readily subscribe to the definition. Indeed it was our opinion, (see *Italian Tour*;) long before we had the pleasure to peruse these well written essays; and it is an opinion to which Metastasio has constantly adhered, in all his admirable musical dramas.

With regard to pastoral songs, though the Sicilian pastoral is not natural to our climate, yet we produce better fruit for the table in our hot-houses, than the southern continent of Europe can boast. An opera song is a *hot-house plant*. Pastoral songs may have pastoral music, as the Sicilian movement has been happily treated more frequently by Handel, and many of our best national composers, such as Arne and Boyce, than any other. And as for simple ballad tunes for historical and narrative songs, and common ditties, there can be no scarcity; as a collector of our acquaintance, many years ago, had amassed a sufficient number of songs set to music, and printed on a single folio half-sheet, from the latter end of the 17th century, to fill twelve volumes.

For descriptive and passionate songs, we have picturesque and passionate music; and we hope this intelligent and elegant writer will allow the *lady Music* to be tricked out a little in passionate and descriptive songs. Haydn, in his "*Seasons*," has described very happily, we think, rural sports

sports and occupations, and admirably displayed her imitative and picturesque powers, in awakening ideas of the several seasons, and the rustic employments of each.

SPRING.

The overture paints the departure of winter, and approach of spring; ploughing, sowing; a prayer to heaven for prosperity; the youths and virgins going a Maying; chorus of thanks to the Supreme Being, in which is an admirable fugue, equal to the best vocal fugues of Handel.

SUMMER.

The overture paints the dawn of day; the rising sun; choral hymn to that luminary; mowing, reaping; a shady retreat; rural employments, and evening sports.

AUTUMN.

The symphony indicates the husbandman's satisfaction at his plentiful harvest; chorus in praise of industry and labour; fruits gathered; duet between an innocent fond pair; field sports; hunting; vintage; dancing; romping; singing; revelling, and jubilation.

WINTER.

The overture paints thick fogs at the approach of winter; horrors of winter; distresses of travellers; evening domestic amusements; purring of the wheel; a narrative rustic song; moral reflections on winter, set to a fine air, cantabile; future rewards of a life well spent, in the *coro finale*.

Milton's *Allegro and Penferoso*, as set by Handel, which are all *description*, have not been injured by too elaborate music; but these are not the songs nor the music of which we meant to trace the history, when we began the present article. See AIR.

SONG of Birds, is defined by the Hon. Daines Barrington to be a succession of three or more different notes, which are continued without interruption, during the same interval, with a musical bar of four crotchets in an *adagio* movement, or whilst a pendulum swings four seconds.

It is observed that notes in birds are no more innate than language in man, and that they depend entirely upon the matter under which they are bred, as far as their organs will enable them to imitate the sounds which they have frequent opportunities of hearing; and their adhering so steadily, even in a wild state, to the same song, is owing entirely to the nestlings attending only to the instruction of the parent-bird, whilst it disregards the notes of all others that may perhaps be singing round him.

Birds in a wild state do not commonly sing above ten weeks in the year, whereas birds, that have plenty of food in a cage, sing the greatest part of the year: and we may add, that the female of no species of birds ever sings; and this is a wise provision of nature, because her song would discover her nest; and, in the same manner, we may rationally account for her inferiority in respect to plumage. The faculty of singing is confined to the cock birds; and accordingly Mr. Hunter, in dissecting birds of several species, found the muscles of the larynx to be stronger in the nightingale than in any other bird of the same size; and in all those instances, where he dissected both cock and hen, the same muscles were stronger in the cock. To the same purpose, it is an observation as ancient as the time of Pliny, that a capon does not crow.

Some have ascribed the singing of the cock-bird in the spring to the motive only of pleasing his mate, during incubation; nature, indeed, partly for this end, has given to the male the power of singing: but the singing of a bird in

the spring is more probably owing to the greater plenty of plants and insects, which, as well as seeds, are the proper food of singing birds, at that time of the year.

Mr. Barrington remarks, that there is no instance of any bird's singing, which exceeds our black-bird in size; and this, he supposes, may arise from the difficulty of its concealing itself, if it called the attention of its enemies, not only by bulk, but by the proportionable loudness of its notes. This writer farther observes, that some passages of the song, in a few kinds of birds, correspond with the intervals of our musical scale, of which the cuckoo is a striking and known instance; but much the greater part of such song is not capable of musical notations: partly, because the rapidity is often so great, and it is also so uncertain when they may stop, that we cannot reduce the passages to form a musical bar in any time whatsoever; partly also, because the pitch of most birds is considerably higher than the most shrill notes of those instruments which comprehend even the greatest compass; and principally, because the intervals used by birds are commonly so minute, that we cannot judge at all of them from the more gross intervals into which we divide our musical octave. This writer apprehends, that all birds sing in the same key; and in order to discover this key he informs us, that the following notes have been observed in different birds, A, B flat, C, D, F, and G; and, therefore, E only is wanting to complete the scale: now these intervals, he says, can only be found in the key of F with a sharp third, or that of G with a flat third; and he supposes it to be the latter, because, admitting that the first musical notes were learned from birds, those of the cuckoo, which have been most attended to, form a flat third; and most of our compositions are in a flat third, where music is simple, and consists merely of melody. As a farther evidence, that birds sing always in the same key, it has been found by attending to a nightingale, as well as a robin, which was educated under him, that the notes reducible to our intervals of the octave were always precisely the same.

Most people, who have not attended to the notes of birds, suppose, that those of every species sing exactly the same notes and passages, which is by no means true, though it is admitted that there is a general resemblance. Thus the London bird-catchers prefer the song of the Kentish goldfinches, and Essex chaffinches; but some of the nightingale-fanciers prefer a Surrey bird to those of Middlesex.

The nightingale has been almost universally reckoned the most capital of singing birds; and its superiority, deduced from a caged bird, consists in the following particulars: its tone is much more mellow than that of any other bird, though at the same time, by a proper exertion of its musical powers, it can be excellently brilliant. Another point of superiority is its continuance of song, without a pause, which is sometimes no less than twenty seconds; and when the respiration became necessary, it has been taken with as much judgment as by an opera-singer. The sky-lark in this particular, as well as in compass and variety, is only second to the nightingale. The nightingale also sings, if the expressions may be allowed, with superior judgment and taste. Mr. Barrington has observed, that his nightingale, which was a very capital bird, began softly like the ancient orators; reserving its breath to swell certain notes, which by this means had a most astonishing effect. This writer adds, that the notes of birds, which are annually imported from Asia, Africa, and America, both singly and in concert, are not to be compared to those of Europe.

The following table formed by Mr. Barrington, agreeably to the idea of M. de Piles in estimating the merits of

painters, is designed to exhibit the comparative merit of the British singing birds: in which twenty is supposed to be the point of absolute perfection.

	Melodious notes.	Sprightly notes.	Plaintive notes.	Comps.	Execution.

SONG, *Responsary*. See RESPONSARY.

SONGARI, in *Geography*, a river of Chinese Tartary, which joins the Amur at Saghalien.—Also, a town of Chinese Tartary; 10 miles N.W. of Foe Petouné Hotun.

SONGEONS, a town of France, in the department of the Oise, and chief place of a canton, in the district of Beauvais; 12 miles N.W. of Beauvais. The place contains 1041, and the canton 12,577 inhabitants, on a territory of 205 kilometres, in 29 communes.

SONG-HOA, a town of Corea; 50 miles S.W. of Hoang.

SONGI, a river of Malacca, which runs into the Chinese sea, N. lat. 2° 10'. E. long. 104° 10'.

SONGI *Tanjang*, a town on the west coast of the island of Sumatra. N. lat. 2° 35'. E. long. 97° 10'.

SONGIEU, a town of France, in the department of the Ain; 13 miles N. of Belley.

SONG-KI, a town of China, of the third rank, in Fokien; 40 miles N.N.E. of Kien-nhing.

SONG-KIANG, a city of China, of the first rank, in Kiang-nan, situated in the midst of several rivers or canals, near the sea, so that the Chinese junks approach it in every direction. It carries on a large trade in cotton cloth, which the inhabitants send to different parts of the empire. It has four towns in its jurisdiction; 560 miles S. of Peking. N. lat. 31°. E. long. 120° 44'.

SONG-MEN-CHAN, a small island, near the coast of China, in Tche-kiang. N. lat. 28° 22'. E. long. 121° 21'.

SONGO, or SANGO, a town of Africa, in the kingdom of Mandingo, near the coast of the Gambia.

SONGO. See SANKARI and SOGNO.

SONGOA, an island in the straits of Malacca, about 50 miles in circumference. N. lat. 2° 18'. E. long. 100° 30'.

SONGOO, a small island in the Indian sea, near the coast of Africa. S. lat. 7° 20'.—Also, a town on the east coast of the island of Banca. S. lat. 2° 12'. E. long. 106° 16'.

SONGORA. See SANGORA.

SONG-TCHOUI, a town of China, of the third rank, in Hou-quang; 40 miles N.E. of Ou-tchang.

SONG-TSI, a town of China, of the third rank, in Hou-quang; 27 miles W. of King-tcheou.

SONG-YANG, a town of China, of the third rank, in Tche-kiang; 22 miles W. of Tchu-tcheou.

SONGY-DAVAN, a town on the west coast of Sumatra. N. lat. 1° 18'. E. long. 98° 12'.

SONGY-LAMA, a town on the west coast of Sumatra. S. lat. 3° 40'. E. long. 101° 57'.

SONHO, Songo, or *Sogno*. See SOGNO.

SON-HOIT, a district of Chinese Tartary, in the territory of the Mongols. N. lat. 42° 45'. E. long. 114° 27'.

SONKOE, a town of Bengal; 15 miles W.N.W. of Moorshedabad.

SONMEANY, the principal sea-port in the district of Lus, and province of Mekran, in Persia. It is a small and mean town, and was destroyed in 1809 by the Jouaffimees. It is situated on an elevated bank, at the mouth of the river Pooralee, which forms a bar about a mile from the town, three fathoms deep at low-water, and boats can anchor close to the shore. The inhabitants, with the exception of a few Hindoo merchants, live chiefly by fishing. Fresh water is procured by digging in the sand: and it is necessary that the well be immediately filled up; for if it be suffered to remain open, the water becomes salt.

SONNA, a book, or collection of the Mahometan traditions, or of the sayings and actions of their prophet, which all the orthodox Mussulmen are required to believe. This is a kind of supplement to the Koran, directing the observance of several things omitted in that book, and in sense, as well as design, corresponding to the Mishna of the Jews. See MAHOMETANISM.

The word signifies, in Arabic, the same with *mishna* in the Hebrew, that is, *second law*; or, as the Jews call it, *oral law*.

The adherents to the Sonna are called *Sonnites*, or *Traditionaries*; and as, among the Jews, there is a sect of Caraites, who reject the traditions as fables invented by the rabbins; there are also sectaries among the Mahometans, called *Schiites*, (see the article,) who reject the traditions of the Sonnites, as being only founded on the authority of an apocryphal book, and not derived to them from their legislator.

There is the same enmity between the Sonnites and Schiites, as between the rabbinist Jews and the Caraites. The Schiites reproach the Sonnites, with obtruding the dreams of their doctors for the word of God; and the Sonnites, in their turn, treat the Schiites as heretics, who refuse to admit the divine precepts, and who have corrupted the Koran, &c.

The Sonnites are subdivided into four chief sects, which, notwithstanding some differences as to legal conclusions in their interpretations of the Koran, and matters of practice, are generally acknowledged to be orthodox in radicals or matters of faith, and capable of salvation; and have each of them their several stations or oratories in the temple of Mecca. The founders of these sects are regarded as the great masters of jurisprudence, and are said to have been men of great devotion and self-denial, well versed in the knowledge of those things which belong to a future life, and to man's right conduct in the present state, and directing all their knowledge to the glory of God. This is Al Ghazeli's encomium of them, who thinks it derogatory to their honour, that their names should be used by those who, neglecting to imitate the other virtues which form their character,

character, apply themselves merely to attain their skill, and follow their opinions in matters of legal practice.

The first of these orthodox sects is that of the "Hanefites," so named from their founder, Abu Hanifa al Nomen Ebn Thebet, who was born at Cufa, in the 80th year of the Hegira, and died in the 150th; ending his life in prison, at Bagdad. The reason of his confinement was his refusal to be called "Kadi," or judge; and when he was questioned concerning it, he is said to have replied, "If I speak the truth, I am unfit; but if I tell a lie, a liar is not fit to be a judge." It is reported, that, during his confinement in prison, he read over the Koran no less than 7000 times. An Arabian writer calls the Hanefites "the followers of reason," and those of the three other sects "followers of tradition;" the former being principally guided by their own judgment in their decisions, and the latter adhering more tenaciously to the traditions of Mahomet. This sect formerly obtained chiefly in Irak, but now generally prevails among the Turks and Tartars. The second orthodox sect is that of Malec Ebn Ans, who was born at Medina, in the year of the Hegira 90, 93, 94, or 95; and died there in 177, 178, or 179. This doctor is said to have paid great regard to the traditions of Mahomet. In his last illness, a friend who visited him, and found him in tears, and asking the reason of it, received for answer, "How should I not weep? and who has greater reason to weep than I? Would to God that for every question decided by me according to my opinion, I had received so many stripes! then would my account be more easy. Would to God I had never given any decision of my own!" The doctrine of Malec is chiefly favoured in Barbary, and other parts of Africa. The third orthodox sect was denominated "Shafeites." (See the article.) The founder of the fourth sect was Ahmed Ebn Hanbal. See HANBAL. Sale's Koran, Int.

SONNEBECK, in *Geography*, a town of France, in the department of the Lys; 5 miles N.E. of Ypres.

SONNEBERG, a town of Bohemia, in the circle of Saatz; 6 miles W. of Commotan.—Also, a town of Germany, in the principality of Coburg; 10 miles N.N.E. of Coburg. N. lat. 50° 23'. E. long. 11° 13'.—Also, a town of Austria; 12 miles S.S.W. of Laab. N. lat. 48° 29'. E. long. 16° 2'.—Also, a citadel of Austria, which gives name to a county vested in the house of Austria; 23 miles S. of Bregentz.

SONNEBORN, a town of Prussia, in the province of Oberland; 5 miles S. of Morungen.

SONNEBURG, a town of the Middle Mark of Brandenburg, on a small river, which runs into the Warta; in which is a commandery of the knights of Malta. The grand-master may create as many knights as he pleases, nor are Lutherans excluded, who are permitted to marry. The elector of Brandenburg is the grand-master of the order; 10 miles E.S.E. of Cultrin. N. lat. 52° 37'. E. long. 14° 58'.

SONNECQUE, a river of Brabant, which runs into the Senne, 5 miles above Halle.

SONNEG, a town of the duchy of Carinthia; 2 miles S. of Eberndorff.

SONNEN KOGEL, a mountain of Austria; 8 miles S. of Steyr.

SONNENBERG, a town of Germany, in the principality of Nassau Saarbruck Uffingen; 2 miles N.E. of Wisbaden.—Also, a town of Silesia, in the principality of Grotkau; 6 miles S.E. of Grotkau.—Also, a town of Prussia, in the province of Bartenland; 12 miles S.E. of

Bartenstein.—Also, a town of Prussia, in the province of Ermeland; 16 miles E.N.E. of Elbing.

SONNENBURG, a town of Brandenburg, in the New Mark, on the Lenza; 7 miles E. of Cultrin. N. lat. 52° 37'. E. long. 14° 58'.

SONNENSTEIN, a fortress of Saxony, in the margraviate of Meillen, near Pirna.

SONNERATIA, in *Botany*, was so named by the younger Linnæus, in honour of a distinguished French traveller and naturalist, M. Sonnerat, who published, in 1776, a Voyage to New Guinea, in one volume. 4to.; and in 1782, a Voyage to the East Indies and China, in two similar volumes. Both works are adorned with a multitude of engravings. They do honour to the author's character, as well as to his information. The latter publication is peculiarly instructive and correct, on the subject of Hindoo mythology, and has been made much use of by various succeeding writers. Botany does not make a prominent part of M. Sonnerat's performances; but he has described and figured several new or rare plants, particularly adverting to important articles of trade or medicine whose history was previously obscure, in his Voyages, and he is also the author of some expressly botanical treatises, of similar aim, which have been given to the world in periodical publications. He died, a short time since, at an advanced age, having just before paid a visit to England.—Linn. Suppl. 38. Schreb. Gen. 337. Willd. Sp. Pl. v. 2. 999. Mart. Mill. Dict. v. 4. Juss. 325. Lamarek Illustr. t. 420. (Aubletia; Gært. t. 78.)—Class and order, *Icosandria Monogynia*. Nat. Ord. *Myrti*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, coriaceous, somewhat bell-shaped at the base, with a tumid internal border; the limb in six or four ovate, acute, spreading, flat, permanent segments. *Cor.* Petals sometimes six, awl-shaped, spreading, inserted into the internal rim of the calyx, and about the same length; in some cases wanting. *Stam.* Filaments numerous, flattened, inserted likewise into the rim of the calyx, as long or longer than its segments; anthers roundish. *Pist.* Germen superior, globose, style thread-shaped, about the length of the stamens; stigma capitate. *Peric.* Berry large, globose, pointed, smooth, seated on the permanent calyx, of many cells, full of vesicular pulp. *Seeds* numerous, oblong, curved, gibbous and corrugated.

Ess. Ch. Calyx in four or six segments, coriaceous, inferior, permanent. Petals awl-shaped, or none. Berry of many cells. *Seeds* numerous, gibbous.

Obs. This genus is somewhat like a *Punica*, with its fruit turned out of the calyx. The younger Linnæus seems to have studied very superficially the only species which fell in his way, never perceiving it to be an old plant of his father's, described and figured by Rumphius.

1. *S. acida*. Red-flowered Sonneratia. Linn. Suppl. 252. Willd. n. 1. (Rhizophora caecolaris; Linn. Sp. Pl. 635. Aubletia caecolaris; Gært. v. 1. 379, excluding the synonym of Rumphius. Mangium caecolare rubrum; Rumph. Amboin. v. 3. 112. t. 74. Pagapate; Sonner. Nouv. Guin. 16. t. 10, 11.)—Flowers in six segments; with six petals. Leaves elliptic-oblong. Branches quadrangular.—Native of the muddy banks of large rivers in the Molucca islands; often planted about houses for the sake of its fruit. Sonnerat found it in moist parts of New Guinea. We have a specimen, gathered by Dr. Buchanan in Bengal, where, as he informs us, the natives know this plant by the name of *Duabanga*. The Malays call it *Brappat*, according to Rumphius, who describes it as a large tree, flowering in

October. The *branches*, as he justly observes, are square, not round. The heart of the *wood* is hard and durable. *Leaves* opposite, on very short stalks, elliptic-oblong, obtuse, with a small point, entire, somewhat succulent, a span long, smooth, with one rib, and numerous transverse veins; their under side glaucous. *Flowers* terminal, solitary, of a beautiful red. *Fruit* green, acid, smelling like rotten cheese, falling out of the *calyx* when quite ripe. The Malays, &c. eat it, as well as the young leaves, with fish and other food. The beautiful half-expanded *flowers* are worn as ornaments for the head, and are often imitated in gold. Rumphius says it is usual to depress the stamens with two little pegs, forced cross-wise through the pistil.

2. *S. alba*. White-flowered Sonneratia. (Mangium caseolare album; Rumph. Amboin. v. 3. 111. t. 73.)—*Flowers* in six, or more, segments, without petals? *Leaves* elliptical or roundish. *Branches* round.—Native of stony or rocky plains, overflowed by the tide, on the sea shore of the Molucca and neighbouring islands, flowering in August and September. Rumphius describes this as a large, thick and rugged tree, like an oak, with spreading and curved branches, commonly laden with various parasitical plants. The *branches* are round. *Leaves* smooth, brittle and succulent, with hardly any visible veins, and of a rounder broader shape than the foregoing. *Flowers* two or three together at the end of each branch. *Calyx* green, in six, seven or eight divisions. No mention is made of any *petals*. *Stamens* long, white, with brown *anthers*. *Style* very long, with a green *stigma*. *Fruit* depressed, as broad as the hand, internally dry, white, and granular, with an astringent, and slightly acid flavour, but no smell. It bursts at length into several portions, but does not fall off like the former, nor is it so generally eaten, except when dressed with fish. Rumphius so clearly distinguishes this species, which Gærtner mistook for the former, and Linnæus confounded therewith under his *Rhizophora caseolaris*, that though we have seen no specimen, we have ventured to describe it. What those horn-shaped excrescences are, which occupy the soil at some distance from the base of this tree, from a span to a foot in length, and of a corky substance, as described by Rumphius, we can offer no conjecture.

3. *S. apetala*. Small-flowered Sonneratia. Buchanan in Symes's Embassy to Ava, octavo, v. 3. 313. t. 25.—*Flowers* in four segments; without petals. *Leaves* ovato-lanceolate. *Branches* round, pendulous.—Native of the moist inundated sea-shores of the kingdom of Ava, near Rangoon, flowering in May. We have specimens communicated by Dr. Roxburgh to lord Valentia. This is described as a most beautiful tree, resembling our Weeping Willow, but taller, with scattered, pendulous, smooth, round, slender branches. *Leaves* few, opposite, stalked, ovato-lanceolate, entire, smooth, rather fleshy, about three inches long, mostly blunt, a little unequal at the base, hardly an inch broad. *Flowers* axillary and terminal, stalked, drooping, greenish, about an inch in diameter, with white stamens, the length of the *calyx*, but no *petals*. *Fruit* orbicular, depressed, of eight cells, with numerous angular seeds. The *stigma* is remarkable for its great size, and conical figure, hollow underneath, like a sort of cap. The want of *petals* in this species induces us the more readily to believe, that they may also be wanting in the last, and that the accurate Rumphius has not merely by accident omitted to mention them.

SONNERSKARET, in *Geography*, a small island on the E. side of the gulf of Bothnia. N. lat. 63° 25'. E. long. 21° 32'.

SONNET, SONETTO, in *Poetry*, a kind of composi-

tion properly contained in fourteen verses; viz. two stanzas, or measures, of four verses each, and two of three; the eight first verses being all in two rhymes.

The sonnet is of Italian origin, and Petrarch is allowed to be the father of it; it is held the most difficult and artful of all poetical compositions, as requiring the utmost accuracy and exactness. It is to end with some pretty ingenious thought: the close must be particularly beautiful, or the sonnet is defective.

In Malherb, and some other French poets, we meet with sonnets, where the two first stanzas are not in the same rhyme; but they are held irregular; and, in effect, great part of the merit of these pieces consists in a scrupulous observance of the rules.

Ronsard, Malherb, Maynard, and Gombaut, have composed abundance of sonnets; but, among two or three thousand, there are scarcely two or three worth much.

Pasquier observes, that Du Bellai was the first who introduced sonnets into France. But Du Bellai himself says, that Merlin de S. Gelais first converted the Italian sonnets into French.

Of twenty-three sonnets which were written by our great poet Milton, that addressed to Henry Laws is one of the best; and yet this shews how difficult and unnatural the construction of this species of poem is in the English language; whereas, from the great number of similar terminations in the Italian tongue, and the success of Petrarch, it has long been the favourite measure of Italy for short compositions. However, Muratori thinks it extremely difficult for his countrymen to make a good sonnet; and he compares this kind of poem to the bed of Procrustes, where the legs of those that were too short were stretched, and those too long were cut to the size of the bed.

Antonio a Tempo, a civilian at Padua, in his Treatise on Poetry, 1332, distinguishes sixteen different kinds of sonnet. Burney's Hist. Music, vol. ii. p. 324.

SONNEWALDE, in *Geography*, a town of Saxony; 10 miles S. of Luckau. N. lat. 51° 40'. E. long. 13° 38'.

SONNINO, a town of Campagna di Roma; 6 miles N. of Terracina.

SONNO, a town of Japan, in the island of Nippon; 18 miles N.W. of Iwata.

SONOKI, a town of Mingrelia; 45 miles S.E. of Anarghia.

SONORA, or SENORA, a province of New Spain, situated between 35° and 27° N. lat. and 110° and 117° W. long.; bounded N. by New Mexico, W. by California, S. by Sinaloa and the gulf, and E. by Biscay and New Mexico. Its greatest length from N. to S. is about 420 miles, and its breadth from E. to W. 380 miles. The air is dry and pure, and the climate generally healthy, though near the gulf the ground is marshy, and it is, in some of the districts, insalubrious. Sonora abounds in rich gold and silver-mines, particularly the former. Like Biscay, it is destitute of timber, but it has some rich soil near the gulf. Its rivers are the Rio de Pascension, which enters the gulf of California about N. lat. 31°, and the Rio Yaqui, which discharges itself into the same gulf at Guyamas, at N. lat. 28°. Its animals are the deer, cabrie, and bear, and large lizards, which are tamed by the inhabitants, and trained to catch mice. The population of Sonora may be estimated at 200,000 souls, consisting of Spaniards, Creoles, Metifs, and Indians. The capital of Sonora is Arispaa, situated in N. lat. 21° and W. long. 111°, near the head of the river Yaqui; celebrated for the urbanity and hospitality of its inhabitants,

habitants, and for the large quantity of gold table utensils used in their houses; and having a population of 3400 persons. The next cities in respect of magnitude are Sonora, S., and Terenate, N. of the capital. Sonora trades with New Mexico and Biscay for the productions of those different provinces, and with old Mexico, both by land and sea, through the gulf of California. It is famous for its cheese, horses, and sheep. The governor is a brigadier-general, and his salary is 7000 dollars, in addition to his pay in the line. The regular military force of this province consists of 900 dragoons, and 200 infantry, the latter being Indians called Opejas, and reckoned the best soldiers in New Spain. The professed religion is the Catholic, and it belongs to the diocese of the bishop of Durango. The seat of government is at Chihuahua.

SONORYA, a town of Hindoostan, in Benares; 10 miles S. of Merzapour.

SONS HARMONIQUES, or fluted sounds, a singular kind of sound produced on the violin, tenor, and violoncello, by touching the string slightly in its aliquot parts and harmonic divisions, without pressing the finger on the finger-board; by which means, that part of the string sounds, which is above the hand next to the nut, not the part touched by the bow. These sounds are very different in quality of tone from those which would be produced, if the finger were pressed down. As to the pitch of tone, the harmonics will give the fifth, when the third would be produced by the usual means; the third, when the sixth is expected, &c. The quality of tone acquired by this means is so much more sweet than the common tones of the instrument, that the French have entitled them *notes flutées*, fluted notes. Rousseau says, that to form an accurate idea of these sounds, it was necessary to hear Mondonville produce them on his violin, and Bernard on his violoncello, who could form a regular scale of these sweet tones, which very much astonished those who did not know the theory. But we have heard Salomon perform this feat, this trick of youth, with a dexterity and taste unknown to Mondonville.

As the principle on which this theory is founded depends on transferring the tone, produced by the bow, to that part of the string next the nut, instead of that next the bridge, of which the bow prevents the vibration, the long division of the string, when touched slightly by the finger, seems to produce the highest note; and *é contra*.

We shall give, in the *Musical Plates*, a table of harmonic sounds, which will facilitate the practice of this seemingly eccentric scale. The first line, or staff, will indicate the sounds which would be produced in the common way; and the second line, the correspondent fluted note, when the string is touched harmonically. All the sounds of the trumpet marine are harmonics, which renders it difficult to produce certain sounds upon that instrument. See NOISE.

SONSBECK, in *Geography*, a town of the duchy of Cleves; 11 miles S.S.E. of Cleves.

SONSECA, a town of Spain, in New Castile; 8 miles S. of Toledo.

SONSINO. See SONCINO.

SONSONATE. See *La TRINIDAD*.

SONTAG, a town of the duchy of Stiria; 3 miles N.W. of Fridau.

SONTAGBERG, a town of Austria, in which is a cloister of Benedictines; 5 miles N. of Bavarian Waidhoven.

SONTAGE, in our *Old Writers*, a tax of forty shillings laid upon every knight's fee, according to Stow, p. 284.

SONTHEIM, in *Geography*, a town of Germany, in

the lordship of Limburg; 15 miles S.E. of Hall in Swabia.

SONTHEIM, *Maine*, a town of the duchy of Wurzburg, on the Maine; 3 miles N. of Kitzingen.

SONTHOFEN, or SUNTHOFEN, a town of Bavaria, in the bishopric of Augsburg; 56 miles S. of Augsburg.

SONTHONNAX *de la Montagne*, a town of France, in the department of the Ain; 6 miles N.W. of Nantua.

SONTRA, a town of Germany, in the principality of Hesse Rhinens, on the Wohra; 28 miles S. of Cassel. N. lat. 51° 5'. E. long. 9° 58'.

SONVICO, a town of Italy; 5 miles N. of Lugano.

SONUS, or NUMADUS, in *Ancient Geography*, a river of India, on this side of the Ganges, which had its source in the mountains, ran towards the east, and bending its course towards the north-east, discharged itself into the Ganges, a little below Jomanas, after a course of about 200 leagues. M. d'Anville supposes that this river is the Audomatis of Arrian; but as this river had its rise among the Mondiadini, and ran into the Ganges, it could not be the same with the Sonus.

SONWARY, in *Geography*, a town of Hindoostan, in Guzerat; 21 miles S. of Surat.

SONZAY, a town of France, in the department of the Indre and Loire; 12 miles N. of Tours.

SOO, a town of Japan, in the island of Ximo; 25 miles N.W. of Uxumi.

SOOBARUM, a town of Hindoostan, in the circle of Cicacole; 10 miles N.W. of Visigapatam.

SOOBKA, a town of Bengal; 13 miles S. of Bogli-pour.

SOOBOO, a town of Africa, in Bambarra; 10 miles W. of Sego.

SOOBRUDOOKI, a town of Africa, in Bondou; 20 miles S.W. of Fatteconda.

SOO-CHOO. See SOU-TCHEOU.

SOOCOO, in *Commerce*, a money of account at Bencoolen; 4 soocoos being = a dollar = 32 fattalies, or fattellers: this dollar is reckoned at 5s. sterling.

SOODEREH, in *Geography*, a town of Hindoostan, in Lahore; 15 miles N.N.E. of Ameenabad.

SOOE, a town of Hindoostan, in Guzerat; 37 miles N.N.E. of Radunpour.

SOOHA, a town of Africa, in Bambarra, on the river Niger. N. lat. 13° 10'. W. long. 4° 52'.

SOOHAGEE, a town of Hindoostan, in Boggilcund; 30 miles N.N.E. of Rewah.

SOOINS, a name given in the North to a kind of rural food, that has been found very beneficial in the scurvy. This food is prepared by putting some oatmeal into a wooden vessel, and pouring hot water upon it, and continuing the infusion till the liquor begins to taste sourish, *i. e.* till a fermentation comes on, which in a place moderately warm may be in the space of two days. The water is then poured off from the grounds, and boiled down to the consistence of a jelly.

SOOKA, in *Geography*, a town of Bengal; 42 miles W. of Silhet.

SOOKANG, a town of Africa, in Fooladoo. N. lat. 13° 35'. W. long. 8° 5'.

SOOKAPOORA, a kingdom of Japan.

SOOKJURAH, a town of Bengal; 33 miles W. of Nagore.

SOOKSOR, a town of Bengal; 6 miles N. of Calcutta.

SOOLARAM, a town of Hindoostan, in the circle of Ellore.

SOOLOO,

SOOLOO, one of the Philippine islands, in the East Indian sea, about 30 miles long and 10 broad, and containing 60,000 inhabitants, who are Malays, governed by a king or sultan, with an aristocracy of about fifteen nobles, named "datoos," who form the greatest part of the legislature, whose title is hereditary to the eldest son, and who sit in council with the sultan. This island enjoys a perpetual summer, and produces a great variety of fruit: it abounds with the tree called teak. Many Chinese live on the island, and carry on great trade, sending to Canton black and white swallows, wax, pearls, teepye, or pearl oyster-shells, bird's-nests, tortoise-shell, sago, rattans, sandal, and various dyeing woods, cinnamon, or cassia, &c. At Sooloo, and many neighbouring islands, the pearl fishery has been carried on for ages, and is the principal source of their wealth. The dominions of Sooloo extend over the principal part of the archipelago of islands between Borneo and Mindanao, called the Sooloo Archipelago, and even on the north coast of the former island. Their religion is Mahometan, but in their morals they are faithless and cruel. The English East India company have an agent in this island. On the neighbouring sea are some excellent pearl fisheries; and abundance of edible bird-nests are found, especially in a small island, or rock, to the S.W. of Sooloo; but the principal production is sago. The situation is between Borneo and Mindanao, 42 miles S.W. from the latter. N. lat. 6°. E. long. 119°.

SOOLOO Archipelago, a part of the Eastern Indian sea, covered with a great number of small islands, extending from the S.W. coast of Mindanao to the N.E. coast of Borneo.

SOOMA, a town of Japan, in the island of Nippon; 45 miles E. of Jedo.

SOOMGONG, a town of Hindoostan, in Goondwana; 10 miles S. of Nagpour.

SOOMOONANG, a lofty range of mountains, which forms the boundary of Thibet on the south, and divides it from Bootan.

SOONABATTY, a town of Hindoostan, in Bahar; 40 miles E. of Doefa.

SOONAJURA, a town of Hindoostan, in Bengal; 50 miles W. of Silhet.

SOONAL, a town of Hindoostan, in the country of Malwa, of considerable extent, of a square form, and inclosed within a stone wall. Two wide streets cross one another, at right angles, in the middle of the town, which is the "Chowk." There are 32 villages in this pergunnah.

SOONAM, or SUNNAM, a town of Hindoostan, in the country of Delhi; 136 miles W.N.W. of Delhi. N. lat. 29° 57'. E. long. 75° 31'.

SOONAMOOKY, a town of Bengal; 13 miles N. of Bissunpour. N. lat. 23° 18'. E. long. 87° 33'.

SOONDA, a small country of Hindoostan, near the west coast, between Canara and Concan, about 40 miles from north to south, and 30 from east to west. After the death of Tippoo, sultan of Myfore, this country was assigned to the Mahrattas.

SOONGARES, a nation of Russia, which, at the separation of the Mongolian monarchy, formed one flock with the Derbetans, but afterwards parted, under two discordant brothers of their princely family. It was this horde which, in the 17th and 18th centuries, reduced to their subjection a great part of the other Kalmuck races, particularly the Khofshot, Derbet, and Kho-it; and waged bloody wars with the Mongoles, as well as with the Chinese empire itself, but which ended in their total subjugation and

dispersion. Previously to this unhappy period, they, together with the Derbets, numbered upwards of 50,000 bows, or fighting men, and passed in modern times for the bravest, richest, and most powerful horde. Their seat was formerly about the Balkhash lake, and its rivers Tschuy and Ily; and their most flourishing period was between the years 1696 and 1746. The towns of the eastern Bucharia and the great Kirghise horde were, about this time, tributary to them. They conquered Budala, the capital of the Dalai-lama, and raised contests in Siberia, where they made tributary some nations belonging to Russia. On the death of their khan Galdan Zeren, a dissolution of the horde ensued, occasioned by disputes concerning the succession; when the Torgots, the Khofshots, and Derbets, separated from it. Many of the Soongarians dispersed themselves in the interior parts of Asia, and quite into the Ubeck towns; some thousands of them fled into Siberia; when the generality accommodated themselves to the Chinese sovereignty: and from their own statements it appears, that scarcely 20,000 families of them and of the Derbetan nation are now remaining. The number of the Soongares, who at that time (1758) took refuge in Russia, amounted to about 20,000 persons. They were united with the Volgaic Kalmucks, but for the most part returned with them, in the year 1770, again into the Soongarey. Tooke's View of the Russ. Emp. vol. i.

SOONGEY PESANG Bay, a bay on the west coast of Sumatra. S. lat. 0° 57'. E. long. 99° 50'.

SOONKY, a town of Hindoostan, in Bahar; 15 miles W.N.W. of Arrah.

SOONWALLA, a town of Hindoostan, in Berar; 17 miles W. of Akoat.

SOONYGONG, a town of Hindoostan, in Goondwana; 60 miles N. of Ramteak.

SOOP. See SOUP.

SOOPA, in *Geography*, a town of Hindoostan, in Dow-latabad; 27 miles E. of Poorunder.

SOOPOUR, a town of Napaul, on the borders of Bahar; 120 miles N. of Patua.—Also, a town of Bengal; 30 miles S.E. of Nagore. N. lat. 23° 38'. E. long. 87° 48'.—Also, a town of Bengal; 45 miles N.W. of Midnapour.—Also, a town of Hindoostan; 5 miles N.W. of Benares.—Also, a town of Hindoostan, in Oude; 46 miles N.N.E. of Gooracpour. N. lat. 27° 20'. E. long. 84° 13'.

SOOPSUNDY, a town of Hindoostan, in the Carnatic; 10 miles S.S.E. of Tanjore.

SOOR, or SHOOR, a name given to the river Indus, between Attock and Moultan.

SOOR. See TSOR.

SOORANGUR, a town of Hindoostan, in the Orissa country, near the river Mahanada; the burial-place of an Englishman of the name of Elliot, who died on his way from Calcutta to Nagpour in the year 1778. Mr. Hallings caused a monument to be erected on the spot to his memory; 200 miles E. of Nagpour.

SOORAPATEE, a kingdom of the island of Java, on the south coast, east of Panaraga.

SOORAPETTA, a town of Hindoostan, in Golconda; 33 miles S. of Combamet.

SOORATPOUR, a town of Hindoostan, in Bahar; 10 miles N.N.E. of Arrah.

SOOREAH, a town of Hindoostan, in the circar of Ruttunpour; 28 miles S.S.E. of Ruttunpour.

SOORJEW, a name given to the Dewah, in Thibet.

SOORMA, a river of Asia, which rises in Meckley, and runs into the Burrampooter, near Sunerampour, in Bengal.

SOOROOT, an island in the Eastern Indian sea, about 25 miles in circumference. N. lat. $2^{\circ} 45'$. E. long. $108^{\circ} 36'$.

SOORORE, a circar of Bengal, bounded on the north, east, and south, by Cossimpour and Dinagepour; and on the west by Rajemal; about ten miles long, and from five to eight broad. Bydell seems the chief town.

SOORWALL, a town of Hindoostan, in Bundelcund; 35 miles W. of Allahabad.

SOORY, a town of Bengal; 7 miles E. of Nagore. N. lat. $23^{\circ} 55'$. E. long. $87^{\circ} 38'$.

SOOSELA, a town of Africa, in Kullo. N. lat. $12^{\circ} 21'$. W. long. $8^{\circ} 40'$.

SOOSNEER, a pretty large town of Hindoostan, in Malwa, belonging to Sindiah. See **OUGEIN**.

SOOSOOHOONAM, or **SOESOEHOONAM**, often called *Soefoehoonam Materam*, from the place of the residence of the emperor of Java, a kingdom or empire, being the fourth, of the island of Java. This empire formerly comprehended the greatest part of the island; that of "Cheribon" formed a part of it, and it was then very powerful; but since the Dutch established themselves there, it has lost much of its importance. Nevertheless it remained undivided till about the middle of the last century, when the emperor found himself so much embarrassed, in consequence of the rebellion of Manko Boeni, a prince of the blood, that he made a cession of his territories to the Company; who, in return, granted him half of it as their vassal, and promised him their protection; engaging, at the same time, never to make any one emperor of Java, who was not a prince of the imperial family. The empire being thus divided, the other half was, in the same manner, given to Manko Boeni, as the Company's vassal, under the title of sultan, with the like promise of protection, and the like engagement never to nominate any other than princes of his family, as successors to his dignity. This other half constitutes the fifth empire of Java. The capital of Soefoehoonam is Jolo.

SOOSWARGUR, a town of Hindoostan, in Sumbulpour; 32 miles W. of Sumbulpour.

SOOT, an earthy volatile matter, arising from wood, coals, and other fuel, along with the smoke, by the action of fire; or rather, it is the smoke itself, fixed and detained on the sides of the chimney.

Soot is a collection of substances formed by the matter in the flame of inflammable bodies, but which have escaped perfect combustion, from not having sufficient contact with the vital air. Hence it is that the soot may be burned over again, and hence likewise it is that when the combustion is very rapid and effectual, there is no perceptible smoke, because all the inflammable matter is then destroyed; as in the cylinder lamps, violent fires, &c. This matter is always of a black colour, more or less brownish, which colour it acquires from an oil that is burnt, and half reduced to the state of coal. Its different qualities and appearances are owing to the nature of the inflammable substances which produce it, and the different manner in which they are burnt.

Chimney soot is a compound of black carbonaceous matter with a considerable quantity of carbonated ammonia, and probably some other ammoniacal salts; and hence it gives a strong pungent smell of this alkali, when rubbed with quicklime. The analysis of soot exhibits an oil, which may be extracted by distillation; a resin, which may be taken up by alcohol, and which arises either from the imperfect alteration of the resin of the vegetable, or the combination of vital air with the volatile oil. It likewise affords an oil, which is often formed by the de-

composition of mucus; and it is this acid, of great utility in the arts, for which the academy of Stockholm have described a furnace proper for collecting it. Soot likewise affords volatile salts, such as the carbonate of ammonia, and others. A slight portion of fibrous matter is likewise volatilized by the force of the fire, and it is again found in the foot.

Soot is mostly formed from the combustion or burning of common or pit-coal, and in general contains some portion of matters derived from animal substances; it is consequently powerful, when applied as a manure. In the trials of sir Humphrey Davy, it was found to afford ammoniacal salts by distillation, and to yield a brown extractive matter, of a bitter taste, by means of hot water. It is likewise said to contain an empyreumatic oil, but that its great basis is charcoal, in a state in which it is capable of being rendered soluble by the action of oxygen and water.

The soot which is formed either from vegetables or from coal, is good both for corn and grass, especially on cold moist grounds, or lands apt to be over-run with moss. Many have found their account in sowing it early over their green wheat and barley crops; but Mr. Ellis says, neither of them ought to be sooted after the 25th of April, because the wheat, and generally the barley, have then done gathering and branching, and are upon the spindle. He likewise thinks it proper to be sown over young turnips, just after they have appeared. But care should always be taken not to sow it too thick, lest its hot nature should hurt the plants. Mr. Worlidge seems to think wood-soot the best; but Mr. Mortimer prefers that which is made from sea-coal, of which about 40 bushels are commonly allowed to an acre; though some grounds will require more: to which he adds, that it produces a very fine sweet grass, and destroys worms and weeds; and that it ought not to be sown upon wheat till Candlemas, because the long cold rains and snows are apt to wash it in too soon; nor is it safe to lay it on later, lest a drought succeed, and burn it up. See **MANURE** and **TOP-DRESSINGS**.

However, Mr. Donaldson observes, that this useful manure can be obtained in considerable quantities only from great cities, or large manufacturing towns. The price in London, whence great quantities are carried to the adjacent districts, is eight-pence the bushel. The ordinary allowance is from 25 to 35 bushels an acre. Soot is used in many parts of England, as Middlesex, Buckingham, Gloucester, Wilts, Lancashire, Yorkshire, &c. The mode of application is chiefly as top-dressings for young clover, sainfoin, and old worn-out meadows. The best season for laying it on is in February or March. It is carefully spread over the field with the hand, and always succeeds best, if rain immediately ensues. But Mr. Marshall recommends its being sown before rain, when a shower washes it in, and will be of obvious service; but that if it lie on the surface long without rain, there will be no benefit derived from it. A rich soil wants no soot, but a soil much out of heart wants 40 or 50 bushels. In his Rural Economy of Norfolk, he says, that the time of sowing it over the land is considered as very material. If it be sown early, and the frost catch it, its strength is thereby lowered; if late, and no rain falls to wash it in, it is thought to be rather injurious than beneficial to the crop of wheat. And it is not, in any case, found of much, if any, service to the succeeding crop of barley.

The method of sowing it is extremely simple; and, in the only instance he saw, the sowing of soot practised there, was very complete. A favourable opportunity being embraced, when the wind blew gently, and in the direction, or nearly

in the same direction, as the lands or ridges lie; the same waggon which brought it from Norwich, and which, until the opportunity offered, had stood safe under cover, was drawn in a furrow against the wind; while a man, standing on the outside of the waggon, spread the soot, with a shovel, several yards wide on either side of him; the height of his situation at once enabling him to spread it wide and even. As he reached the windward end of the lands, the team wheeled round under the hedges, and took a fresh width. The quantity set on was forty bushels an acre in this case.

Mr. Young, however, remarks, that, in general, thirty bushels are used for a complete dressing; that is, when dung or some other manure has not been previously applied to the same crop, which is very frequently the practice, and the quantity of top-dressing is then diminished to about one-half of a complete dressing. Of soot, a complete dressing, as above, costs from 30s. to 36s. per acre. Soot is found to answer best on wheat in April. It likewise succeeds on pease or clover in the same month, and has a good effect sown with barley, in the beginning of April, and harrowed in. A slight dressing of soot is used at any time in the spring, when grubs or worms appear to injure the young corn. The worms frequently make great havoc, by drawing the blades of young corn after them into their holes: this soot prevents best: soot thinly distributed on newly sown turnips, just before they come up, prevents the fly or grub from injuring them, provided no rain falls to wash it into the soil. Soot answers best on light, dry, chalky soils, and in moderately wet seasons. It does little good on strong or wet land, or in very dry seasons, unless sown earlier than usual. The London soot from coals is rarely bought unmixed with cork-dust, coal-ashes, or sweepings of the streets; yet, even in this adulterated state, it is found to answer much better than real country soot from wood.

And it is remarked, in the Agricultural Survey of Hertfordshire, that about Stevenage they spread from 20 to 40 bushels an acre, bringing it from London: it costs 8d., and the carriage 3d., in all 11d. per bushel. And Mr. Clarke of Sandridgebury, spreads from 35 to 40 bushels an acre on wheat. But about Beachwood they sow from 30 to 40 bushels on wheat, in February or March, bought at 1s. a bushel at London, and bring 160 bushels in a waggon with four horses. Around Hitchin, 40 bushels are sown on wheat. And a good deal is used at Watford, at the rate of 40 bushels an acre. Also, about Barkway they have a very high opinion of it; 50 bushels an acre, brought 30 miles from London, are seen on wheat to an inch. And it is stated, in addition, that the practice is universal through this country; inasmuch, that the question is, whether there is a parish in it in which some men are not in the habit of using this manure from London.

On cabbage crops that have been sown, it has been found that if, as soon as the plants appear distinctly above the ground, a furge of soot be drilled upon them, to the amount of from 10 to 12 bushels the acre, it affords much security against the fly. And it has been suggested that this business may be cheaply and conveniently executed by a hopper and round of cups, similar to Cook's, but larger, fixed to a frame similar to that of the Northumberland drill. When employed for preventing the fly in drilled turnips, it should be sprinkled along the rows, from a scuttle, by the hand, or some such mean, in the proportion of about twenty bushels the acre.

But in respect to the application of this sort of substance to land, it is remarked by Mr. Kiddle, in the fourth volume of Communications to the Board of Agriculture, that

all manures that are laid on the surface of land cannot be laid on too early in the season. Soot, for instance, is always recommended to be sown on wheats or clovers, and grass-lands, in the month of February, from a notion, that if sown sooner, they would exhaust themselves too soon. This, he thinks, absurd reasoning. No manure can be of any service to the crop, which it is meant to advantage, until it reaches the roots: and what contributes more to save it than the winter rains, and the dissolving of the snow? He has, in consequence, always sown the soot for wheat and clover, when he has been able to procure it, in the month of November or December, and always with satisfaction to himself. He last year sowed with soot an inclosure of wheat of eight acres, part of which was sown in the beginning of December, before the frost set in, and a heavy rain succeeded the sowing; on the remaining parts, owing to his not being able to procure more soot at that time, the sowing was postponed until after the frost was gone, in the month of February. The quantity sown on an acre, in both instances, was equal; but the superiority of the crop of wheat, where it was sown early, might be discerned by the eye. He had the curiosity to have it thrashed separately, and found its increase beyond the other considerable. If he could procure soot at the time of sowing wheat, he should be under no apprehension of its answering then, if the land was worked for the wheat. Some years since, having bought a small quantity of soot immediately after harvest, he had the desire to try its effects on the crop at that early season, and having a pea-stubble which had been ploughed twice, and was designed for wheat, after sowing as much of the land as he had soot for with wheat, he then had the soot sown, and ploughed both in together. He owns he was anxious to see the success of his experiment, as it was a novel one, as were his neighbours also who had seen it done. The remainder of the land was sown with soot, as he was able to procure it. The wheat, where the soot was sown with it, kept the lead during the first months: this he did not wonder at, but expected it from its forcing quality; but he was very much pleased to see it continue to do so during the remainder of the season, and at harvest the superiority in favour of it was easily to be seen.

Soot, in some districts, as where the soil is rather inclining to be strong and heavy, is far from being found a durable manure, though it commonly produces very strong crops for the first year. And it is in other places more commonly applied over the grass-lands than the tillage crops, being supposed more useful and proper in such a manner of application. But it is not improbable but that it is a sort of manure that may in general be the best fitted to be employed in its dry state by being thrown into the ground at the same time with the seed, somewhat in the manner of powdered rape-cake, having the advantage of requiring no sort of preparation when used in this way.

Some suppose that 20 bushels of soot to the acre are nearly equal to 50 of the ashes of either coals, wood, or peat. And the writer of the Middlesex corrected Agricultural Report remarks, that the smoke, consisting of the lightest particles of soot and coal, raised by the force of the ascending current of rarefied air arising from 300,000 fires in the metropolis and its vicinity, is daily deposited on the surrounding country; where the next rain washes it into the soil, and it promotes vegetation and the fertility of the land to a considerable degree.

The dyers make a considerable use of soot, for a kind of dun-colour; which, it is true, has no agreeable smell; but, in return, it has the property of saving clothes, and other stuffs, from moths.

Carbonated ammonia is extracted from it in the large way in several manufactories of this salt.

Soot of Frankincense, is the smallest and finest part of the incense called olibanum, or male incense; burnt after the manner of rosin, to make lamp-black.

Soot, Wood, was formerly regarded as a good medicine in many cases, but the principles upon which it acted as such were never well understood, till Boerhaave gave a regular analysis of it. The directions he gives for the process are these.

Choose the blackest and driest wood-foot from the chimney of an oven, where nothing is baked but bread, and nothing burnt but vegetables; gather this in a dry day, and fill with it a glass retort almost up to the neck; clean the neck of the retort, and luting on a receiver, give a fire of 150°, and keep it up equally, a large quantity of transparent water will come over with considerable violence. When no more water will come over, cleanse the receiver, and raising the fire to a little above 200°, there will then come over a whitish fat liquor; this also comes over with great violence, and the fire must be gradually increased, till no more of this will come. Change the receiver, and raise the fire to a yet greater degree, and a yellow, copious, volatile salt will come over, and stick all over the sides of the new receiver. When no more of this salt will arise, increase the fire to the utmost that sand can give, and with a heat of suppression there will arise a black thick oil; when this is all come over, and the vessels cooled, there will be found in the neck of the retort a salt, which could be raised no higher, even by that violent fire; and in the bottom of the retort there remains a black feculent matter, the upper surface of which is covered with a white saline crust, which, both in figure, colour, and the structure of its stræ, resembles the common sal ammoniac. If the milky liquor be rectified, it affords a very penetrating volatile spirit, and some sharp volatile salt.

Here we are taught what the agitation of an open fire can move, change, expel, and drive through the air by burning; first in the form of smoke, then of flame, and lastly of exhalation, and how high it is able to carry them; for a chimney is a kind of still-head, converging in an open top, and foot is often carried up thirty or forty feet, or more, to the top of these, and after this a black smoke is discharged out of the orifice, which disperses in the air, and finally seems to vanish.

From his accurate analysis of wood-foot, we may learn, says Boerhaave, that foot, which contains so many active principles, must be qualified for a powerful medicine. Pills of dry foot are found very beneficial in all cold distempers; the volatile salt of foot possesses the virtues of the volatile salts of animals. The salt which rises last is recommended greatly by Hartman for giving relief in cancers; and this is very probable, since sal ammoniac of the common kind, properly applied, is known to be of great use in cases of running cancers. Soots of different fuels are not all to be supposed to possess the same virtues; that of pit-coal is found to be a substance of a very different kind from that of wood; and that of the common turf or peat, and of the oak-wood, have also been found, on experiment, to be very different.

Boerhaave very justly observes, that the foot from kitchen-chimneys, where the smoke must have been impregnated with the effluvia of the victuals, must be very different from pure wood-foot. Boerhaave's Chemistry.

Wood-foot was formerly directed in hysterical cases, and in different nervous disorders, as an antispasmodic and corroborant. It was used chiefly in the form of a spirituous tincture,

in conjunction, commonly, with assa-fœtida, or other materials of similar intention: the officinal tincture was drawn from two ounces of foot, and one of assa-fœtida, with a quart of proof spirit.

The virtues of the foot are extracted almost equally by proof spirit, rectified spirit, and water, each of which, if the foot is of a good kind, dissolves about one-fourth of it.

The extracts, obtained by inspissating the filtered solutions, are very bitter, and the spirituous extract retains most perfectly the peculiar flavour of the foot. Lewis.

Dioscorides shews how to make a foot of butter, which was thought to have several uses in medicine. The foot found in furnaces of glass-houses is used by painters.

SOOTA, in *Geography*, a town of Japan, on the N. coast of the island of Sado.

SOOTEEAH, a town of Hindoostan, in Bahar; 15 miles N.N.E. of Chuprah.

SOOTEREE, a town of Bengal; 12 miles S.E. of Rangur.

SOOTICH, a town of Bengal; 15 miles N.N.E. of Kishenagur.

SOOTY, a town of Bengal; 30 miles N.E. of Calcutta. — Also, a town of Bengal; 27 miles N. of Moorshedabad. N. lat. 24° 25'. E. long. 88° 11'.

SOPE. See SOAP.

SOPEDIERO, in *Geography*, a town of Mexico, in New Biscay; 140 miles S.S.W. of Parral.

SOPETRAN, a town of Spain, in New Castile; 10 miles N. of Guadalaxara.

SOPHA, in *Ancient Geography*, a town of Palestine, in the tribe of Zebulon, according to Epiphanius.

SOPHANITÆ, a people of Arabia Felix, placed by Ptolemy in the southern part of that country.

SOPHAR, a town of Judea, in the tribe of Gad.

SOPHECLA, in *Geography*, a small island in the gulf of Engia; 5 miles N.W. of Engia.

SOPHENA, ZOPH, in *Ancient Geography*, a country of Asia, in the Greater Armenia, N. of Mesopotamia and Comagene, between the mountains Masius and Antitaurus, according to Strabo.

SOPHERA, in *Botany*. See CASSIA and SOPHORA.

SOPHI, or SORI, a title of quality, given to the emperor of Persia; importing as much as wise, sage, or philosopher.

The title is by some said to have taken its rise from a young shepherd thus named, who attained to the crown of Persia in 1370; others derive it from the *sophoi*, or *sages*, anciently called *magi*. Vossius gives a different account of the word: *sophi*, in Arabic, he observes, signifies wool; and he adds, that it was applied by the Turks out of derision to the kings of Persia, ever since Ismael's time; because, according to their scheme of religion, he is to wear no other covering on his head, but an ordinary, red, woolen stuff; whence the Persians are also called *hazalbaschs*, q. d. *red-heads*. But Bochart assures us, that *sophi*, in the original Persian language, signifies one that is pure in his religion, and who prefers the service of God in all things: and derives it from an order of religious called by the same name.

The *sophis* pride themselves, and with some reason, on their illustrious extraction; the race being second to none in the East. They are descended in a right line from Houssain, second son of Ali, Mahomet's cousin, and Fathima, Mahomet's daughter.

There is no prince in the world whose authority is more absolute than that of the *sophi* of Persia; his power is not even limited by any laws he himself can make; but he suspends, changes, and annuls them at pleasure. See SOHUS.

SOPHIA, or **SOFIA**, in *Geography*, a city of European Turkey, in Bulgaria, built by Justinian on the ruins of the ancient Sardica. This is the capital of Bulgaria, and a *sangiacat*; the see of a Greek archbishop, and of a Roman bishop. It is commercial, populous, and well-built, but without walls; and the streets are narrow, uneven, and dirty: 280 miles W.N.W. of Constantinople. N. lat. 42° 56'. E. long. 23° 14'.

SOPHIA Chirurgorum, in *Botany*, a name sometimes given to a species of water-crelles.

SOPHIAL, in *Geography*, a town of Russia, in the government of Petersburg; 16 miles S.S.E. of Peterburg. N. lat. 59° 40'. E. long. 13° 14'.

SOPHIANA, a town of Persia, in the government of Adirbeizan; or Azerbaijan; 24 miles N.W. of Tauris.

SOPHIENBERG, a town of Denmark, in the island of Zealand, near the coast of the Sound, with a royal palace; 13 miles N. of Copenhagen.

SOPHIENBURG, a town of Germany, in the principality of Culmbach; 5 miles S. of Bayreuth.

SOPHIENLUST, a town of Germany, in the county of Henneberg; 3 miles S. of Meinungen.

SOPHIS, or **SOFEEES**, denote a kind of order of religion among the Mahometans in Persia, answering to what are otherwise called *derwises*; and among the Arabs and Indians, *faqirs*.

Some will have them called *sophis*, from a kind of coarse camlet which they wear, called *souf*, from the city Souf, in Syria, where it is principally manufactured.

The more eminent of these *sophis* are complimented with the title *scheik*, that is, *reverend*; much as in Romish countries the religious are called *reverend fathers*.

Sheick Sophi, who laid the first foundation of the grandeur of the royal house of Persia, was the founder, or rather the restorer, of this order: *Ishmael*, who conquered Persia, was himself a *sophi*, and greatly valued himself on his being so. He chose all the guards of his person from among the religious of this order; and would have all the great lords of his court *sophis*.

The king of Persia is still guard-master of the order; and the lords continue to enter into it, though it be now fallen under some contempt.

The vulgar *sophis* are now chiefly employed as ushers and attendants of the court; and some even as executioners of justice; the emperor last reigning would not allow them, according to custom, to gird the sword on him.

This neglect into which the *sophis* are sunk, has occasioned the late emperor to disuse the title of *sophi*, or *sofi*: however, *M. de la Croix* is mistaken, when he says, that they never bore it.

SOPHIS, *Sofees*, or *Sufi's*, the denomination of a sect of modern philosophers among the Persians, whose name is derived either from the Greek word for a sage, or from the woollen mantle which they used to wear in some provinces of Persia. They seem, says sir William Jones (*Works*, vol. iii. p. 130. 8vo. ed.) to have adopted that metaphysical theology, which has been professed immemorially by a numerous sect of Persians and Hindoos, which was carried into Greece, and which prevails, even at this time, among the learned Mussulmans, who sometimes avow it without reserve. Their fundamental tenets are, that nothing exists absolutely but God: that the human soul is an emanation from his essence; and, though separated for a time from its heavenly source, will be finally reunited with it: that the highest possible happiness will arise from its reunion; and that the chief good of mankind, in this transitory world, consists in as perfect an union with the eternal Spirit, as the incumbrances

of a mortal frame will allow: that, for this purpose, they should break all connection with extrinsic objects, and pass through life without attachments, as a swimmer in the ocean strikes freely without the impediment of clothes: that they should be straight and free as the cypress, whose fruit is hardly perceptible; and not sink under a load, like fruit-trees attached to a trellis: that, if mere earthly charms have power to influence the soul, the idea of celestial beauty must overwhelm it in extatic delight: that, for want of apt words to express the divine perfections with the ardour of devotion, we must borrow such expressions as approach the nearest to our ideas, and speak of *beauty* and *love* in a transcendent and mystical sense: that, like a reed torn from its native bank, like *wax* separated from its delicious honey, the soul of man bewails its disunion with *melancholy music*, and sheds burning tears like the lighted taper, waiting passionately for the moment of its extinction, as a disengagement from earthly trammels, and the means of returning to its only Beloved.

Such, in part, is the wild and enthusiastic religion of the modern Persian poets, especially of the sweet *Hafiz*, and the great *Maulavi*. Such is the system of the *Vedanti* philosophers, and best lyric poets of India; and, as it was a system of the highest antiquity in both nations, it may be added to many other proofs of an immemorial affinity between them. The philosophy of the *Sofees* seems also, in early times, to have prevailed amongst the Jews, in Europe among the *Theosophists* (see that article), as well as among the disciples of the *Vedanti* school in India. Sir William Jones has expressed with great precision the tenets of the Indian school, nor do they differ from the doctrines maintained by the *Sofees* of the present day. The fundamental tenet of the *Vedanti* school, says sir W. Jones (*Works*, vol. iii. p. 239. 8vo. ed.) to which, in a more modern age, the incomparable *Sancara* was a firm and illustrious adherent, consisted not in denying the existence of matter; that is, of solidity, impenetrability, and extended figure; but in correcting the popular notion of it, and in contending that it has no essence independent of mental perception; that existence and perceptibility are convertible terms; that external appearances and sensations are illusory, and would vanish into nothing, if the divine energy, which alone sustains them, were suspended but for a moment, an opinion which *Epicharmus* and *Plato* seem to have adopted, and which has been maintained in the last century, and in our own country, with great elegance and acuteness by *Berkeley* and others. The *Sofees* consider themselves, as we have above stated, immersed in depravity by an union with matter, and in the figurative style of their poets, lament the separation from their beloved, and solicit, with impatient ardour, a release from a material and earthly bondage.

SOPHISM, Σοφισμα, in *Logic*, a captious and fallacious reasoning; or an argument, which, with some subtlety, carries much appearance of truth, but little solidity. See **FALLACY**.

A *sophism* is, properly, an argument false at bottom, and only invented to amuse and embarrass the person to whom it is used.

Logicians enumerate the following kinds of *sophism*, *viz.* *ignoratio elenchi*, or a mistake of the question, *i. e.* when something else is proved, which has neither any necessary connection nor inconsistency with the thing inquired, and consequently gives no determination to the inquiry, though at first sight it may seem to determine the question; *petitio principii*; a circle; *non causa pro causa*, or the assignation of a false cause; *fallacia accidentis*, which pronounces concerning the nature and essential properties of any subject, according

according to something which is merely accidental to it. *A dicto secundum quid ad dictum simpliciter*, arguing from that which is true in particular circumstances, to prove the same thing true absolutely, simply, and abstracted from all circumstances, and *vice versa*: the sophisms of composition and division, when we infer any thing concerning ideas in a compounded sense, which is only true in a divided sense, and *vice versa*: and the sophisms arising from an abuse of the ambiguity of words: to which may be added an imperfect enumeration, or false induction, when from a few experiments and observations, men infer general theorems and universal propositions. Watts's Logic, p. iii. c. 3. sect. 1.

These sophistical modes of reasoning, or logical quibbles, called by Aristotle Eristic syllogisms, were introduced into the Megaric school, founded by Euclid of Megara, (see his article,) by Eubulides of Miletus, who in that school succeeded Euclid; but as they furnished merely examples of egregious trifling, they deserve no farther notice. The Stoics also amused themselves with quibbles and fallacies of the same kind with those of the Megaric school, of which the following example will be sufficient. Protagoras the sophist (see PROTAGORAS) agreed to instruct a young man in eloquence for a large sum, one half of which was to be paid in hand, the other half upon his first successful pleading in the courts. Neglecting to plead for a long time after Protagoras had completely instructed him in the art of rhetoric, the sophist sued him for the remaining moiety of his stipend. Each pleaded his own cause. Protagoras urged, that which way soever the cause was determined, the young man must complete the payment: for if the cause was determined *against* the defendant, the payment would be granted him by judgment; if *for* him, the payment would be due according to agreement. The young man, on the contrary, pleaded, that if the cause was determined *in his favour*, he should be excused from the payment by the decision of the court; if *against* him, Protagoras, by his own agreement, could have no demand upon him. The subtlety of these pleas perplexed the judges; and, without coming to any determination, they dismissed the court.

SOPHISMS, or *Sophistical Arguments*, among *Logicians*, are more particularly such as are not in form, or are founded on equivocal.

As, *You have every thing you have not lost; but you have not lost horns, therefore you have horns.*

SOPHIST, Σοφιστής, formed from σοφός, *wise*, or rather from σοφιστής, *impollor, deceiver*, a person who frames sophisms; that is, uses subtle arguments, with design to deceive those whom he would persuade or convince.

The term *sophist*, which is now reproachful, was anciently honourable, and carried a very innocent idea. St. Augustine observes, it signifies a rhetor, or professor of eloquence: such as were Lucian, Athenæus, Libanius, &c. Suidas, and after him Olar. Celsius, in an express dissertation on the Greek sophists, tells us, that the appellation was applied indifferently to all who excelled in any art or science; whether divines, lawyers, physicians, poets, orators, or musicians.

However, as rhetoricians often employed their art rather to vindicate what was false and unjust, than to support truth and virtue, their conduct brought a discredit both upon themselves and their profession; and, therefore, the name *sophist*, sometimes confounded with that of *sophistler*, has been used in an ill sense, to signify a specious but false reasoner, one skilled rather in the arts of cavilling than qualified to speak well and accurately upon any subject.

Solon is the first who appears to have ever borne the ap-

pellation of *sophist*, which is given him by Isocrates; afterwards, it was scarcely ever given, except to philosophers and declaimers.

In the time of Socrates, there was in Athens a large body of professional preceptors of eloquence, distinguished by the appellation of *sophists*. By the mere pomp of words, these men made a magnificent display of wisdom, upon a slight foundation of real knowledge; and they taught an artificial structure of language, and a false method of reasoning; by means of which they were able, in argument, to make the worse appear the better cause. Whilst they arrogated to themselves the merit of every kind of learning, they publicly practised the art of disputing with plausibility on either side of any question, and professed to teach this art to the Athenian youth. By these imposing pretensions, they collected, in their schools, a numerous train of young men, who followed them in hope of acquiring those talents, which would give them influence and authority in popular assemblies. In such high repute were these *sophists*, that they were literally supported, not only by contributions from their pupils, but by a regular salary from the state; and were in many instances distinguished by public honours, and employed in offices of magistracy. Of their enmity to Socrates, we have given an account under his biographical article.

The title *sophista* was in great credit among the Latins in the twelfth century, and in the time of St. Bernard; but it began to lose ground in Greece as early as Plato's time; on account of Protagoras and Gorgias, who made a fordid traffic of it, by selling eloquence for money. Hence Seneca calls the *sophists* quacks, or empirics.

Cicero says, that the title *sophisti* was in his time given to such as professed philosophy with too much ostentation, in order to make a trade of it, by running from town to town, to retail their deceitful science. A *sophist*, therefore, was then, as now, a rhetor, or logician, who makes it his business to ensnare and perplex people, by frivolous distinctions, vain reasonings, and captious discourses.

Nothing has conduced more to the increasing of the number of *sophists* than the contentious school-philosophy: people are there taught to puzzle and obscure the truth, by barbarous unintelligible terms; as, antipredicaments, great and little logicals, quiddities, &c.

The title *sophist* was given to Rabanus Maurus, by way of eminence. John Hinton, a modern English scholastic writer, endeavoured also to procure the splendid title of *sophist*.

SOPHISTICATIO, in *Chemistry, Alchemy*, &c. a term particularly applied to the counterfeit works of fraudulent alchemists, who use indirect means of whitening copper, gilding silver, and giving other superficial tinctures to metals; as also of making augmentations, by divers mixtures, and other illegal operations, to delude those at whose expence they are employed.

Hence the term is also applied to merchandizes, and other goods adulterated, mixed, or altered, by the deceit of the seller.

SOPHOCLES, in *Biography*, a celebrated tragic poet, was born at Athens about the year 497 B.C. He received an education in every way suitable to his rank in life; and it appears that he was but a youth, when the monuments of the victory over Xerxes were fixed up at Salamis, and then he went at the head of a chorus of noble birth, whose song of triumph he led by the strains of his lyre. He first applied himself to lyric poetry; but the fame acquired by Æschylus, the author, or at least the great reformer, of Grecian tragedy, induced him to try his powers in that

species of composition; and in his 28th year he ventured to contend with that veteran for the theatrical prize. He obtained the victory, which was followed by the retreat of his rival, who left him the undisputed master of the tragic stage. The improvements introduced by Sophocles were so great, that he has generally and justly been regarded as the father of the regular tragedy. "He brought," says the critic, "a third interlocutor to the two who before alone appeared on the scene at once; he interested the chorus in the subject of the piece; he reduced the turgid and unnatural diction of Æschylus to the proper standard of heroic dignity; and invented that artful construction of fable and development of incidents, which contribute so much to the interest of a dramatic performance." In these points he was superior to his younger competitor Euripides; and upon the whole, he appears to have stood at the head of his class, in the judgment both of Greek and Roman critics. Cicero terms him a *divine poet*; and he is highly commended by Dionysius of Halicarnassus, for preserving the dignity of his characters, and dwelling rather on the more noble and generous affections, than on the mean and debasing passions. These praises shew that his works were regarded as the most perfect example of tragedy, in the highest sense of the word. Sophocles was a statesman, as well as a tragedian, and entrusted with very important civil and military employments. He retained his faculties to the last, and continued to write tragedies to an advanced age; and when his unnatural sons, on account of some neglect in his domestic affairs, applied to the magistrates to put him under their guardianship, as having outlived his understanding, he appeared in court, an advocate in his own cause, and reciting his *Œdipus at Colonus*, which he had just finished, appealed to the judges and auditors, if that were the work of the dotard described by his own children. The sentence was pronounced unanimously in his favour, and he was carried home with every mark of triumph. The benignity of his character acquired him a number of friends, his attachment to whom, and his moderate wishes, caused him to decline the invitations of the kings who were desirous of drawing him to their courts. He paid every token of respect to the memory of his rival Euripides, thus demonstrating that he was incapable of the meanness of jealousy. He lived to the great age of 90, and is said even at that age to have died with joy, on obtaining the prize for his last tragedy. Above a hundred pieces have been attributed to him by some ancient writers, of which, however, only seven have reached our times. Of these, both separately and collectively, many editions have been made. Among the most esteemed are Johnson's, 3 vols. 8vo. Oxon. et Lond.; Capperonier's, Par. 4to.; Brunck's, 2 vols. royal 8vo. 1786; and Mulgrave's, Oxon. 2 vols. 8vo.

SOPHONE, in *Ancient Geography*, a country of Asia, situated in the place where the Tigris re-appears, after having been under ground for the space of 25 miles, according to Justin.

SOPHORA, in *Botany*, a name of most whimsical origin. *Sophera* is, according to Prosper Alpinus, the Egyptian denomination of a species of *Cassia*, the Linnæan *C. Sophera*, nearly related to the genus before us. Linnæus, in his *Hortus Cliffortianus*, 156, spelling it *Sophora*, calls it a *genus Sopherum*, or of wise men; as teaching that separate stamens, in the papilionaceous family, if ever the limits of that family can be determined, afford so decisive a mark of discrimination, as almost to exclude the plants furnished with such, from the same natural class, or order, with those whose filaments are combined. The soundness of the doctrine may make us tolerate the conceit.—Linn. Gen.

204. Schreb. 275. Willd. Sp. Pl. v. 2. 499. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 3. 2. Juss. 351. Lamarck Illustr. t. 325. Gært. t. 149, tomentosa. (Edwardia; Salis. in Tr. of Linn. Soc. v. 9. 298. Ait. Hort. Kew. v. 3. 1.)—Class and order, *Decandria Monogynia*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, short, oblique; gibbous on the upper side; its tube turbinate, angular; limb bell-shaped, abrupt, with five teeth. *Cor.* papilionaceous, of five petals. Standard oblong, straight, dilated upwards, flexed at the sides, various in length. Wings two, as long as the standard, or longer, with a lobe at the base. Keel of two petals, similar to the wings and about the same length, their lower edges close together, boat-like. *Stam.* Filaments ten, inserted into the tube of the calyx, distinct, parallel, rigid, awl-shaped, about the length of the corolla, and lodged in its keel, deciduous; anthers small, oval, incumbent. *Pist.* Germen superior, oblong, slender, nearly cylindrical; style the size and shape of the stamens; stigma simple, obtuse. *Peric.* Legume very long and slender, of one cell, and two imperfect valves, swelling at each seed, so as to become beaded; often angular or winged. *Seeds* numerous, roundish, large, polished.

Ess. Ch. Calyx bell-shaped, oblique, five-toothed; turbinate at the base. Corolla papilionaceous. Legume beaded, scarcely bursting, with many seeds.

We have under EDWARDSIA (see that article) expressed an opinion unfavourable to the permanency of that genus of Mr. Salisbury's, though we have many reasons for wishing we could admit it; nor does our decision at all interfere with the propriety of the name. Our reasons will appear presently. The genus of *Sophora* is, nevertheless, commodiously divisible into two sections, by the situation of the inflorescence, but this can make no generic distinction, unless it were supported by some character in the fructification, such as the learned editors of the *Hortus Kewensis* thought they had found in the legume; but it is overset by a new species before us; see n. 5.

SECTION I. *Clusters terminal, elongated.*

1. *S. tomentosa*. Downy Sophora. Linn. Sp. Pl. 533. Willd. n. 5. Ait. n. 1. (*S. occidentalis*; Linn. Sp. Pl. 533. Willd. n. 6. *S. arborescens*, &c.; Trew's Ehret. 27. t. 59. *Colutea zeylanica argentea tota*; Herm. Lugd.-Bat. 169. t. 171. Galea? n. 1; Browne Jam. 289. t. 31. f. 1.)—Stem arboreous. Leaflets numerous, roundish-elliptical, very obtuse, downy as well as the calyx.—Native of the East and West Indies. Long cultivated in our stoves, but it has seldom flowered. The *branches, stalks, foliage*, and *inflorescence*, are more or less clothed with short, dense, hoary pubescence. *Leaves* a span long, of six or seven pair, with an odd one, of stalked, elliptical, coriaceous leaflets, all nearly equal and uniform, above an inch long; sometimes their upper surface is smooth, and the whole of the plant much less downy than usual. *Stipulas* none. *Clusters* terminal, solitary, stalked, simple, generally a foot long, composed of very numerous, large, elegant, pale-yellow flowers. *Legume* three or four inches in length, beaded, two-edged, slightly downy, often interrupted here and there by a failure in the impregnation of some of the seeds, which, when perfect, are the size of a large pea, globular, brown, discharged finally by the decay, and partial splitting of the valves.

2. *S. heptaphylla*. Seven-leaved Sophora. Linn. Sp. Pl. 533. Willd. n. 8. (*Anticholericæ*; Rumph. Amboin. v. 4. 60. t. 22.)—Stem shrubby. Leaflets about seven, elliptical, acute; downy beneath.—Native of the East

SOPHORA.

Indies, on sandy or rocky sea-coasts. Rumphius describes it as about the size of a Privet-bush, but with a thicker trunk. He says there are seven, eight, or nine pair of *leaflets*, besides an odd one; dark green above; downy and grey beneath; hardly two inches long, about one broad. Linnæus describes seven smooth *leaflets* in all. The *flowers* are yellowish. *Legumes* beaded. Having seen no specimen, we forbear all further description; only excluding, without hesitation, the *Fruticulus sinensis, senæ sylvestris folio*, &c. Pluk. Amalth. append. t. 451. f. 10. (See the next species.) The *root* and *seeds* of the plant of Rumphius are celebrated by him as inestimable remedies for dangerous bilious colics.

3. *S. japonica*. Japanese Sophora. Linn. Mant. 68. Willd. n. 7. Ait. n. 2. Thunb. Jap. 178. Andr. Repof. t. 585. Jacq. Hort. Schoenbr. v. 3. 55. t. 353.—Stem arborescent. *Leaflets* ovato-lanceolate, acute, smooth. *Clusters* compound, panicled.—Native of Japan and China. Introduced by the celebrated cultivator Mr. James Gordon, in 1753. It has been nearly as long cultivated about Paris, where it was called *l'arbre inconnu des Chinois*. This is a tall and handsome hardy deciduous tree, with elegant, smooth, pinnate *leaves*, whose *leaflets* are about an inch and a half long, and half an inch broad, acutely pointed. *Flowers* smaller than those of Laburnum, of a pale greenish-yellow, almost white, composing numerous, branched, spreading *clusters*, collected into large, terminal, upright *panicles*. *Legumes* pendulous, two or three inches long, turgid, smooth. By Jacquin's figure the withered *stamens* seem permanent. Perhaps Plukenet's Amalth. t. 451. f. 10, cited with doubt by Linnæus for *S. heptaphylla*, may belong to this.

4. *S. alopecuroides*. Fox-tail Sophora. Linn. Sp. Pl. 533. Willd. n. 4. Ait. n. 3. (Glycirrhiza filiquis nodosis, quasi articulatis; Buxb. Cent. 3. 25. t. 46. Ervum orientale alopecuroides perenne, fructu longissimo; Dill. Elth. 136. t. 112. f. 136.)—Stem herbaceous. *Leaflets* elliptic-oblong, obtuse; somewhat silky beneath, when full grown.—Native of the Levant, hardy in our gardens, where it was cultivated in the days of Miller and Sherard, flowering in July and August. The *root* is perennial, creeping extensively. *Stems* annual, herbaceous, simple, leafy, about two feet high. *Leaflets* numerous, about an inch long, green, sparingly pubescent. *Clusters* simple, solitary at the top of each stem, without much of an elongated stalk, composed of numerous, pale, greenish-white, sweet-scented *flowers*, larger than those of the common *Galega officinalis*. *Calyx* nearly smooth. *Legume* slender, somewhat silky. Dillenius noticed the ten distinct *stamens*; and he asserts that to make the plant flower freely, the roots must be confined in a pot.

5. *S. flavescens*. Siberian Sophora. Ait. ed. 1. v. 2. 43. ed. 2. n. 4. Willd. n. 3.—“Stem herbaceous. *Leaflets* ovate-oblong, nearly smooth.”—Native of Siberia; introduced here in 1785, by Mr. John Bell. A hardy perennial, flowering from May to July. We have seen no specimen. Willdenow says it is like the preceding, but entirely smooth. *Leaflets* six pair, with an odd one, ovato-lanceolate, bluntish. *Calyx* obscurely toothed. Mr. Salisbury recommends the separation of these two last from *Sophora*, on account of their permanent *stamens*; but it seems to us that *S. japonica* connects them with the original species, both by that character, and somewhat of habit, or aspect.

Section 2. *Clusters lateral, shorter than the leaves.*

6. *S. macrocarpa*. Great-seeded Sophora.—*Leaflets* elliptic-oblong, nearly smooth. *Clusters* axillary, very

short. *Legume* silky, two-edged, tumid, without wings.—Native of Chili, where it is commonly known by the name of *Mayo*. We received fine specimens from the late abbé Cavanilles, in 1804. The *stem* is arborescent. *Branches* roundish, knotty; silky when young. *Leaves* deciduous, about a finger's length, composed of from six to nine pair of, not exactly opposite, obtuse, rigid *leaflets*, three quarters of an inch long, besides an odd one, all green; shining, and sparingly downy, above; paler, and rather silky, beneath. *Clusters* towards the ends of the branches, axillary, simple, composed of four or five large yellow *flowers*, whose partial stalks are about the length of the common one, all silky, as well as the *calyx*. *Stamens* occasionally permanent. *Legume* from three to five inches long; when young compressed, two-edged, and finely silky; where the *seeds* ripen, they form large oval swellings, almost as big as a bullace plum, partly deprived of their downiness, and marked with a slight ridge along each side, as in *S. tomentosa*, but quite destitute of angles, wings, or other inequalities. In inflorescence, habit, and aspect of the *flowers*, this species accords exactly with all the following ones, while its *legume* is that of the original *Sophora*. We conceive, therefore, that it oversets the genus *Edwardia*, to which, if that genus exists at all, the present plant should belong, and yet its *legume* is neither quadrangular nor winged, nor is there any character in the fructification at all different from *Sophora*.

7. *S. nitida*. Silky-leaved Sophora.—*Leaflets* elliptic-oblong, silky on both sides. *Clusters* axillary, very short. *Legume* hairy, with four prominent angles.—Gathered by Commerson, in the isle de Bourbon. An elegant silky *shrub* or *tree*. *Leaves* two or three inches long, composed of from eight to twelve pair of *leaflets*, half the size of the last, beautifully silky, as well as their stalks; brighter beneath. The *flowers* are past in our specimen; their *stalks* are much like the last, but more hairy, with larger, more permanent, opposite *bractæas*. Half-ripe *legumes* about four inches long, rather slender, beaded, their four thick prominent angles much more hairy than the interstices, which should seem to become quite smooth as the oval parts, enclosing the *seeds*, are more enlarged.

8. *S. tetraptera*. Four-winged Sophora. Ait. ed. 1. v. 2. 43. Willd. n. 1. J. Mill. Ic. t. 1. Curt. Mag. t. 167. Lamarek f. 3. Roem. and Uft. Mag. fasc. 12. t. 1. (*Edwardia grandiflora*; Salis. Tr. of Linn. Soc. v. 9. 299. Ait. Hort. Kew. v. 3. 1.)—*Leaflets* elliptic-oblong, silky on both sides. *Clusters* lateral. *Legume* slightly hairy, with four membranous crenate wings.—Discovered in New Zealand, by sir Joseph Banks, and brought in 1772 to this country, where it thrives well against a fourth or west wall, in the open air, with only the protection of a mat in winter, flowering about May or June. Few shrubs are more ornamental. The silky *leaves* are much like the last, but rather larger. *Flowers* about six together, in silky-stalked, drooping clusters; each *flower* near two inches long. The brown *stalks* and *calyx* are strikingly contrasted with the golden *petals*, whose standard is shorter, and of a fuller yellow, than the rest. *Legume* three or four inches long, each tumid part, where a seed is lodged, bordered, at each side of the suture, with two parallel wings, the whole *legume* being somewhat compressed, and not uniformly winged in four directions, like that of *Lotus tetragonolobus*. The base or tube of the *calyx* is, in this species, broader, or more dilated, than in most of the rest, besides having ten ribs. But we find it precisely analogous to the same part in *S. tomentosa*, and others, where it always has a different colour, texture, or appearance, from the limb.

9. *S. chrysophylla*. Golden-leaved Sophora. (Edwardia chrysophylla; Salis. Tr. of Linn. Soc. v. 9. 299. t. 26. f. 1.)—Leaflets obovate, emarginate, silky. Clusters lateral. Legume—Gathered in the Sandwich islands, by Mr. Menzies. The leaflets are thrice as broad as in the foregoing; flowers yellow, about half the size of that species. Nothing is known respecting the legume.

10. *S. microphylla*. Small-leaved Sophora. Ait. ed. 1. v. 3. 43. Willd. n. 2. Lamarck f. 1. Jacq. Hort. Schoenbr. v. 3. 10. t. 269. (*S. tetraptera*; Forst. Prodr. 32. Linn. Suppl. 230.)—Leaflets numerous, roundish-obovate, somewhat silky. Clusters lateral. Legume with four membranous crevate wings.—Discovered by Banks, Forster, and others, in New Zealand. Introduced in 1772 to the notice of British cultivators. It is usually treated here as a greenhouse shrub, though marked as hardy by Mr. Aiton, flowering in May and June. The younger Linnæus, like Forster, confounded this with *S. tetraptera*, n. 8, though our native specimen, from the latter, is marked *microphylla*. It differs essentially from *tetraptera*, though their legumes are similar, in having flowers not above half so large, and especially in the rounded figure, and small size, of its numerous leaflets, whose silky pubescence, most conspicuous on their under side, is silvery, not of a tawny or golden hue, even after long keeping.

For other species, formerly referred to this genus, see ORMOSIA and PODALYRIA.

SOPHORA, in Gardening, contains plants of the herbaceous, flowery, perennial, and shrubby exotic kinds, of which the species (as some have reckoned them) cultivated are, the wing-podded sophora (*S. tetraptera*); the small-leaved shrubby sophora (*S. microphylla*); the fox-tail sophora (*S. alopecuroides*); the blue sophora (*S. australis*); the dyer's sophora (*S. tinctoria*); the white sophora (*S. alba*); the downy sophora (*S. tomentosa*); the occidental sophora (*S. occidentalis*); the thining-leaved sophora (*S. japonica*); the vetch-leaved sophora (*S. capensis*); the golden-flowered sophora (*S. aurea*); and the round-leaved sophora (*S. myrtillifolia*).

Method of Culture.—The first five sorts are hardy, and may be increased by seeds, or parting the roots. The seeds should be sown in the spring, in pots of fine mould; and when the plants are come up, they should be removed into separate pots, till they have obtained sufficient strength, when they may be planted out where they are to grow. The roots may likewise, in many of the sorts, be parted at the same season, and planted in pots, or where they are to remain. The first and second sorts may also be raised from cuttings and layers, planted or laid down at the same season. These, when planted against a wall, so as to be protected from the frost in winter, succeed very well.

But all the other sorts are tender, and require the protection of the hot-house or stove. They are increased by sowing the seed in the early spring, in pots filled with fine mellow light mould, and plunging them in the hot-bed under glasses, or in the bark-bed. When the plants have advanced a little in growth, they should be removed into separate pots, filled with soft loamy mould, being well watered, and replunged in the bark-bed till fresh rooted; being afterwards managed as other exotic stove plants, with but little water. They likewise sometimes succeed by layers and cuttings, treated in the same manner.

It may be noticed, that the first sorts afford variety in the borders, and among potted plants; and the latter in stove collections, where heat is required. Many of the tender sorts are very elegant plants, proper for affording ornament and curiosity in such situations.

SOPHRONISTÆ, σωφρονισται, among the Athenians,

were ten officers, appointed to take care that the young men behaved themselves with sobriety and moderation.

SOPHRONISTERIUM, σωφρονιστηριον, among the Athenians, a house of correction, like our Bridewell.

SOPIANÆ, in *Ancient Geography*, a town of the Lower Pannonia, upon the route from Sirmium to Carnuntum, between Antiana and Mansuetianus, according to the Itinerary of Antonine.

SOPIO, a name used by some of the old writers for opium, from its soporific virtue.

SOLOPO, in *Geography*, a town of Turkish Albania; 32 miles S.S.E. of Valona.

SOPORARIÆ ARTERIÆ, a name given by some authors to the carotid arteries.

SOPORIFIC, or SOPORIFEROUS, a medicine that has the faculty of procuring sleep. Such are opium, laudanum, &c.

The word is formed from the Latin *sopor*, sleep. The Greeks, in lieu of it, use the word *hypnotic*.

SOPOROUS, SLEEPY, or *Drowsy diseases*, a term by which medical writers express the lethargy and coma, and some others even the carus and apoplexy.

SOPPAU, in *Geography*, a town of Silesia, in the principality of Jagerndorf; 5 miles N. of Jagerndorf.

SOPPY, a town on the N.W. coast of the island of Mörty. N. lat. 2° 40'. E. long. 128° 15'.

SOPRA, Ital. above, upper: as *nelle parte di sopra*, in the upper parts; *di sopra*, above; *contrapunto sopra il soggetto*, counterpoint above the subject. See SOGGETTO.

SOPRANO, in *Italian Music*, means supreme, or the highest vocal part. Its clef is that of the tenor or C clef on the first line. Music for a soprano or treble voice in Italy, is always written in the C clef on the first line, thence called the soprano clef. The treble or G clef, in which we write vocal treble parts, is called by the Italians, *chiave di violino*, the violin clef, and only used for the highest parts of instrumental music.

SOPRON, in *Geography*. See EDENBURG.

SOQUA, a town of the duchy of Warfaw; 60 miles N. of Warfaw.

SOR, a river of France, which runs into the Agout, six miles below Castres.

SOR. See TSOR.

SORA, in *Botany*, the name given by the people of Guinea to a kind of shrub which they use in medicine, boiling it in water, and giving the decoction in cases of pain of any kind.

The leaves of this shrub are of the size and shape of those of fenna; they stand upon short footstalks, and are woolly underneath. *Philos. Trans.* No. 231.

SORA, in *Ancient Geography*, a town of Arabia Deserta, on the confines of Mesopotamia. Ptolemy.—Also, a town of India, on this side of the Ganges, according to Ptolemy, who gives it the title of "Arcati Regia."—Also, the name of a town of Phœnicia. *Steph. Byz.*—Also, a town of Italy, in Latium, towards the N.E., upon the Lixis. According to Livy, it belonged to the Samnites.

SORA, in *Geography*, a town of Naples, in Lavora, the see of a bishop, immediately under the pope; 31 miles N.N.W. of Sezza. N. lat. 41° 47'. E. long. 13° 36'.

SORACTES, in *Ancient Geography*, mountains of Italy, in Etruria, on the confines of the country of the Falisci, and in the vicinity of the Tiber.

SORÆ, a people of India, who dwelt in the vicinity of Carmania and Gedrosia, near the river Caberon, according to Pliny.—Also, a people of India, on this side of the Ganges, counted

counted among the Nomades by Ptolemy, who places them between the mountains Bitigus and Difathrus.

SORÆI, a people of Africa, in Mauritania Cæfariensis. Ptolemy.

SORAGNA, in *Geography*, a town of the duchy of Parma; 13 miles N.N.W. of Parma.

SORAMIA, in *Botany*, Aubl. Guian. t. 219. Juss. 433. See MAPPIA.

SORANUS, in *Medical History*, one of the most able of the physicians of the *methodic* sect, according to the opinion of Cælius Aurelianus, and the one who put the finishing hand to that system, was a native of Ephesus. His father's name was Menander, and that of his mother Phæbe. He studied medicine, and afterwards practised it at Alexandria, but at length he settled at Rome, and was in considerable repute in that metropolis in the reigns of Trajan and Adrian. His character, indeed, seems to have been highly estimated; for he was in favour with all parties. Even Galen, who was violent in his opposition to the *Methodists*, and abused Thesalus with some acrimony, speaks favourably of the knowledge of Soranus, and bears his testimony, from experience, to the efficacy of some of his remedies. Soranus composed several works, none of which have come down to us in their proper form; but as Cælius Aurelianus, in his treatise "De Morbis Acutis et Chronicis," every where acknowledges himself to be a translator from the Greek of Soranus, that work may be considered as in substance the production of the latter.

Some confusion prevails among medical writers, who mistake Soranus the Methodist for two other physicians of the same name. The first of these was also a native of Ephesus, but posterior to the Methodist. He was the author of a good treatise on the diseases and organs of generation of women, which was printed at Paris in 1556, under the title of "De Utero et Muliebri pudendo libellus," together with some pieces of Rufus, the Ephesian. This fragment is so accurate in point of anatomical description, as to leave a regret that the other writings of this physician are lost. The third of these physicians of the name of Soranus, was surnamed *Melotas*, from the town in Cilicia, where he was born. There is, however, no very authentic record of him extant; and the only work ascribed to him, which is entitled "Isagoge saluberrima in Artem medendi," and was printed at Basle, 1528, and Venice, 1547, is maintained by Vossius to be the work of a posterior Latin writer, and not of any of the three persons named Soranus. See Le Clerc, Hist. de la Med. Eloy Dict. Hist.

SORARUM, in *Geography*, a town of Hindooistan, in the circuit of Cicacole; 10 miles W. of Cossimcotta.

SORAS, a town and jurisdiction of Peru; 60 miles S. of Guamanga.—Also, a town of Italy, in the Feltrin; 8 miles W.S.W. of Feltri.

SORAU, or ZYORY, a town of Silesia, in the principality of Ratibor; 18 miles E. of Ratibor. N. lat. 50° 1'. E. long. 18° 40'.

SORAW, or ZAROW, a town of Lusatia, and one of the most ancient towns in the country, surrounded with walls in the year 1207. It has manufactures of cloth, and a considerable trade in linen and yarn; 25 miles S.S.E. of Guben. N. lat. 51° 37'. E. long. 15° 10'.

SORBA, a town of France, in the department of Jemappe, and chief place of a canton, in the district of Corté. The canton contains 2000 inhabitants.

SORBAIT, PAUL DE, in *Biography*, a physician of eminence, was a native of Hainault, in the Low Countries. Having finished his courses of classical and philosophical studies, he commenced that of medicine, which he appears

to have concluded by taking the degree of doctor in that faculty at Vienna, where he ultimately settled. He obtained a high reputation for medical skill and erudition; and, in 1655, was appointed to the principal professorship of medicine in the university of that metropolis, the duties of which he executed with considerable celebrity, until the year 1679. While he was engaged in his course of this year, he was honoured with the appointment of physician to the dowager empress Eleanor, and at the conclusion of it, relinquished altogether his academical avocations. His merits were still farther rewarded by the office of counsellor and superintendent of the public health, and by his elevation to the dignity of a knight of the kingdom of Hungary. He died in April 1691, at an advanced age. He left several works, namely, a body of medical practice, first published at Nuremberg, in 1672, folio, with the title of "Univerſa Medicina, tam Theorica quam Practica, nempe Isagoge Institutionum Medicarum et Anatomicarum, &c." This work was republished at Vienna in 1680, and again after his death, in 1701, with the new title of "Praxeos Medicæ auctæ, et a plurimis typi mendis ab ipſo Auſtore calligatæ, Tractatus VII. &c." "Nova et aucta Institutionum Medicarum Isagoge," 1678, 4to. "Commentaria et Controversiæ in omnes Libros Aphorismorum Hippocratis," 1680. In the preceding year he published an account of the plague, which had committed dreadful ravages in Vienna, having destroyed, he affirms, not less than 76,921 persons. Its title was "Consilium Medicum, sive Dialogus Loimicus de Peste Viennensi," 1697; and he published the same work, in German, in 1680. He was author also of "A Treatise on Midwifery," in the German language. Eloy Dict. Hist. de la Med.

SORBECKE, in *Geography*, a river which rises in Westphalia, and runs into the Rhur, about two miles S. of Neheim.

SORBELLONI, in *Biography*, a second rate Italian opera singer in *soprano*, who arrived here in 1761; and who, from the mere sweetness of his voice, free from vulgarity, was always much applauded. He was here at the same time as Paganini, and performed the part of serious man in the burlettas of the time.

SORBIERE, SAMUEL, was born in 1615, at St. Ambroix, in the diocese of Uzez. He was educated by his maternal uncle, an eminent Calvinist minister at Nismes. He came to Paris in 1639, and being disgusted, for some reasons not now known, with the study of theology, he took up that of medicine. In 1642 he went to Holland, where, besides pursuing his medical studies, he materially assisted in the translation of Camden's Britannia, and also More's Utopia. He married, in Holland, the daughter of one of his townsmen, and went to Leyden, with the intention of settling in his profession. In 1648 he published, under his own name, a French version of a treatise of Gallendi, entitling it "Discours sceptique sur le Passage du Chyle, et le Mouvement du Cœur." Returning to France in 1650, he was made principal of the college of Orange, and there printed a Discours on the true cause of the troubles of England, and a letter on the designs of Cromwell. He conformed to the Catholic religion in 1653, after which his life was chiefly spent as an author, with a view, it is said, of attempting to obtain pensions, in which he was very successful, having laid under contribution cardinal Mazarin, Lewis XIV., and the popes Alexander VII. and Clement IX. He visited England in 1664, and on his return he published an account of what he had observed, which was so free in its strictures, that he was for a time exiled by a *lettre de cachet*. Sorbier was likewise author of a work entitled "Lettres et Discours sur divers Matières curieuses,"

curieuses," which contributed to his temporary reputation. He died in 1670, and a *Sorberiana* was published after his death, containing sentiments supposed to have dropt from him in conversation. His writings exhibit a caustic and satirical spirit, and the learning which they display is neither original nor solid. He was intimately connected with Hobbes and Gaffendi, on whom he imposed himself as a profound thinker.

SORBIODUNUM, in *Ancient Geography*. See **SORVIDUNUM**.

SORBOE, in *Geography*, a small island in the North sea, near the coast of Norway. N. lat. 59° 5'.

SORBOLE, a town of Sweden, in West Bothnia; 10 miles S.W. of Umea.

SORBONNE, **ROBERT DE**, in *Biography*, founder of the famous theological college which bears his name, was born in 1201, of an obscure family at Sorbon, in the diocese of Rheims. Being educated at Paris, and having taken his degree of doctor, he devoted himself to preaching, in which he became so celebrated, that the king made him his chaplain and confessor. Having become a canon of Cambrai in 1251, the recollection of the difficulties which he had experienced in the course of his own studies, suggested to him a plan for facilitating to poor scholars the means of proceeding to graduation. This was to form a society of secular ecclesiastics, who, living in common, and provided with a regular maintenance, should read lectures gratuitously. With the assistance of his friends, he founded the college called the Sorbonne, which was particularly consecrated to the study of theology, and its constitution has served as a model for that of all colleges since erected in that country. Sorbonne afterwards added to this foundation a college for the languages and philosophy, under the name of the College of Calvi, or the Little Sorbonne. He was made canon of Paris in 1258, and rose to such a height of reputation, that princes looked to him on many important occasions as the arbitrator in their disputes. He died in 1274, at the age of 73, and left considerable property to his college. He was author of several works on theological subjects, which are preserved in MS. in the library of the great college of which he was the liberal founder.

SORBONNE, or **SORBON**, the house or college of the faculty of theology, established in the university of Paris.

It was founded in 1256, by St. Louis, or rather by Robert de Sorbonne, his confessor and almoner; first canon of Cambrai, and afterwards of the church of Paris; who gave his own name to it, which he himself took from the village of Sorbon, or Serbon, in the department of the Ardennes, near Sens, six miles N. of Rethel, where he was born.

The foundation was laid in 1250, afterwards the king gave him all the houses he had in the same place, in exchange for some others in another.

The college has been since magnificently rebuilt by the cardinal de Richelieu. The design of its institution was for the use of poor students in divinity.

There were lodgings in it for thirty-six doctors and bachelors of the house; who were said to be of the *society of the Sorbonne*. Those admitted into it without being doctors were said to be of the *hospitality of the Sorbonne*. Six regent doctors held lectures every day, for an hour and half each: three in the morning, and three in the afternoon.

SORBONNE has been also used in the general for the whole faculty of theology at Paris, because the assemblies of the whole body were held in the house of the Sorbonne: and because the bachelors of the other houses of the faculty, as the house of Navarre, &c. came thither to hold their *sorbonnique*, or act, for being admitted doctors of divinity.

SORBUS, in *Botany*, a word usually derived by critics from *forbeo*, to fuck in; because its fruit *Sorbum*, the Sorb-apple, or Service, see **SERVICE-TREE**, is not eatable till the pulp becomes quite soft, so as to be fucked rather than bitten. De Theis, however, goes to the recondite sources of Celtic learning for its origin; *Sornel*, the name of the fruit in that language, being, as he says, formed of *for*, harsh or rude, and *mel*, an apple.—Linn. Gen. 250. Schreb. 338. Willd. Sp. Pl. v. 2. 1008. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 3. 204. Juss. 335. Lamarck Illustr. t. 434.—Class and order, *Icosandria Trigynia*, Linn. Nat. Ord. *Pomacea*, Linn. *Rosacea*, Juss.

This genus, consisting, in most authors, of three species, *S. aucuparia*, *hybrida*, and *domestica*, we refer, without scruple, as in the *Flora Britannica*, to **PYRUS**; see that article, n. 24, 25, 26. See also **MESPILUS**.

SORBUS, in *Gardening*, contains plants of the ornamental tree kind, among which the species cultivated are, the mountain-service, mountain-ash, quicken-tree, roan-tree (*S. aucuparia*); the true service, or forb (*S. domestica*); and the battard service, or mountain-ash (*S. hybrida*).

In the first sort the leaves make a pretty variety, when mixed with other trees in plantations: it is also handsome when in flower, and in the autumn, when in fruit; but the blackbirds and thrushes are so fond of it, that they devour it before it is well ripe.

In the second sort there are varieties in the fruit; as with apple-shaped fruit; with pear-shaped fruit; with oval fruit; with turbinated fruit; and with compressed fruit.

Method of Culture.—These plants are all capable of being raised from seed, and also by layers; but the first is the best method. The seeds, when well ripened in the autumn, should be sown on small beds of light fine ground in the nursery, either in drills or over the surface, covering them in to the depth of about an inch. When the plants rise in the following or second spring, they should be kept clear from weeds, and when of a year's growth, be planted out in nursery rows, to remain till of a proper size for planting out. But the second sort is sometimes sown in large pots, and forwarded in a hot-bed, so as to be sooner fit for planting out in nursery rows, as in one year, or a short space of time.

In the layer method, some of the best trees should be cut down near to the ground while young, by which shoots will soon be made and sent off, which should be laid down in the usual way in the autumn or spring seasons, where they readily strike root, and become proper for being planted out in nursery rows in about one year.

In order to continue any particular variety, this method must constantly be adopted. Also, in cultivating the second sort, for the purpose of fruit, the best method is by grafting or budding upon stocks of any of the sorts raised as above, or upon pear-stocks.

These trees, in rearing, should be trained for standards, each with a single upright stem, in the nursery, till from three to six or eight feet high, when they are proper for any plantation, and may be transplanted as required. And they may be introduced in any large shrubbery or other ornamental plantation, and in those of forest-trees. Some of the domestic service-tree sort may also be introduced as fruit-trees in gardens and orchards, principally as standards, but occasionally in espaliers, &c. in both of which modes they should be planted and managed as apple and pear-trees, permitting the standards to shoot freely above into full heads; the others being regulated according to their order of training. They will produce plentiful crops of fruit annually, after
some

some time, to gather in autumn. In gathering of which for the table, it is proper to lay some in the fruitery, or other place, a little time, to mellow and become soft and tender; in which state it is eatable, and of an agreeable taste and flavour.

Some of these sorts of trees, as the first and last kinds, are very ornamental in pleasure-ground plantations, and large shrubberies, both in their leaves and fruit. The other sort may also be occasionally introduced with good effect in particular situations.

SORCERER'S ISLAND, in *Geography*, a small island in the Atlantic, near the coast of Africa, where the Negroes come yearly to sacrifice to their deities, near the mouth of the Rio Grande.

SORCERY, the crime of witchcraft, or divination, by the assistance of evil spirits. See **MAGIC** and **MAGICIAN**.

Some hold forcibly to be properly what the ancients call *forti-legium*, or divination by means of *fortes*, or *lots*. Lord Coke, 3d Inst. fol. 44, describes a forcerer, *qui utitur fortibus, et incantationibus demonum*.

Sorcery is pretended to have been a thing formerly very common; at least the credulity of those ages made it pass for such; and people suffered frequently for it.

This supposed crime was made felony by 33 Hen. VIII. c. 8, and 1 Jac. I. c. 12; but this absurd law was very properly repealed by an act of George II. See **CONJURATION**.

SORCY, in *Geography*, a town of France, in the department of the Meuse, situated on the Meuse; 3 miles S.E. of Commercy.

SORDE, or **SORDES**, a town of France, in the department of the Landes, on the gulf of Oleron; 9 miles E. of Bayonne.

SORDES, a term applied to the matter discharged from ulcers in horses, when it is rather viscid or glutinous. This matter is frequently of a brownish-red colour, somewhat resembling the grounds of coffee, or grumous blood mixed with water. *Sordes, sanies*, and *ichor*, are all of them terms which imply a discharge much more fetid than purulent matter, and none of them are altogether free from acrimony; but that which is generally termed *ichor* is by much the most acrid of them, being frequently so sharp and corrosive, as to destroy large quantities of the neighbouring parts.

SORDINO, Ital., **SOURDINE**, Fr., a mute, or little machine placed on the bridge of a violin or violoncello to enfeeble or deaden the tone, by impeding the vibration of the whole instrument. The French never use this machine, and the Italians but seldom, at present.

SORDITIES, in *Surgery*, putrid pus of bad quality.

SORDUN, in *Geography*, a town of France, in the department of the Seine and Marne; 3 miles S.E. of Provins.

SORE, a town of France, in the department of the Landes, and chief place of a canton, in the district of Mont-de-Marsan; 27 miles N. of Mont-de-Marsan. The place contains 1450, and the canton 3409 inhabitants, on a territory of 420 kilometres, in 4 communes.

SORE, among *Sportsmen*, denotes a buck of the fourth year.

SOREL, a buck of the third year.

SOREL, in *Botany*. See **SORREL**.

SOREL, in *Geography*, a cape on the N. coast of the island of Jersey; 7 miles N.E. of St. Helier.

SORELLE, a town of Lower Canada, situated at the mouth of a river of the same name, which runs from lake Champlain into the St. Lawrence. It was laid out about

the year 1787, and on an extensive plan, with very wide streets, and a large square; but at present it contains only 100 houses, which are all very indifferent, and widely separated from one another. This is the only town on the St. Lawrence, between Montreal and Quebec, in which English is the predominant language. The inhabitants consist principally of loyalists from the United States, who took refuge in Canada. The chief business carried on here is that of ship-building; several vessels are annually launched from 50 to 200 tons burthen, which are floated down to Quebec, and there rigged. The river of Sorelle is deep at its mouth, and affords good shelter for ships from the ice, at the breaking up of winter: it is not navigable far beyond the town, even in boats, on account of the rapids; 24 miles N.N.E. from Montreal. Weld's Travels, vol. i.

SORENTO, or **SORRENTO**, a sea-port town of Naples, in Principato Citra, situated on the brink of the steep rocks that overhang the bay of the same name, and presenting an enchanting aspect. The mountains of Vico and Massa, between which it lies, shelter it from the W. and S. winds. Its streets are narrow; but this is no inconvenience in a warm climate, where carriages are not used, nor any communication with the metropolis practicable by land. Of all the places in the kingdom, this enjoys the most delightful climate, for which it was renowned in ancient times. Silius Italicus extols its soft and wholesome zephyrs: "Zephyro Sorentum molle salubri." At present it enjoys shady groves, excellent water, fruit, fish, milk, butter, the finest veal, the best wine, and every necessary of life at an easy rate. Its population consists of about 15,000 inhabitants, being half the population of the whole plain. These are goldsmiths, mariners, or fishermen. The women are employed in breeding silk-worms, and weaving the silk which they draw from them. It is an archiepiscopal see, of which the bishops of Stabia, Vico, Equeuse, and Massa, are suffragans. Some abbies are also subservient to it.

According to Hyginus, it was built by the Greeks; and was called Syrenetum, or Surenetum, from its having been the residence of the Syrens Leucosia and Ligia. However this be, it was anciently the abode of the Ofci, Opici, and Picientini, whose capital it was, and afterwards a Roman colony, and a municipal city, as we may conclude from a multitude of antique marbles. Its numerous ruins of edifices shew that the town is much reduced from its ancient state. It was formerly adorned with several magnificent temples, among which were those of Juno and Diana; but the most splendid of them was that built by Pollius, in honour of Hercules, and which Statius has depicted in all the charms of poetry. The place where this temple stood is now called corruptly Polo, and some traces are still seen of those of Ceres, Neptune, and Apollo. Besides the fruits and wines for which Sorrento is famous, it was also celebrated among the ancients for its beautiful earthen vessels, especially as goblets or drinking cups. Pliny very much applauds them, and Martial prefers them to those of the most valuable materials, and of the most exquisite workmanship. Sorrento values itself upon having been the birth-place of the celebrated grammarian L. Crassitius Pasides, mentioned by Suetonius in his treatise "De illustribus Grammaticis;" of the learned Bernardin Rota; and of the renowned Torquato Tasso; 15 miles S. of Naples. N. lat. 40° 40'. E. long. 14° 24'.

The bay of Sorrento is three miles wide: a semicircular chain of woody mountains incloses a rich and beautiful plain, rather sloping towards the sea, full of white buildings peeping out of the groves. This crescent terminates in a straight line to the sea, by a bold coast of black perpendicular

cular rocks. This probably formed a portion of a circle, half of which broke off and sunk into the waves, and probably the whole was once the crater of a volcano. The whole foil of the plain is cineritious, and its rocks consist of a strong blue lava, except near the east end, where they are of a softer piperino kind. The encircling mountains are composed of regular calcareous layers; and the materials of the lower ground are without doubt volcanical.

SOREX, or **SHREW**, in *Natural History*, a genus of the Mammalia Feræ class and order, of which the following is the generic character: there are two upper fore-teeth, which are long and bifid; the lower fore-teeth are from two to four; the intermediate ones are shorter; there are several tusks on each side; the grinders cuspidate. (See the article **SHREW**.) Seventeen species are enumerated in Gmelin's last edition of the Linnæan genera, which are as follow.

Species.

CRISTATUS; Crested Shrew. The nostrils in this species are carunculate; the tail is short. It inhabits North America. The whole animal is four inches long, and the tail an inch and a quarter: it feeds on roots, and resembles the mole in its face and snout.

MINUTUS; Minute Shrew. The snout of this species is very long, and it has no tail. It inhabits Siberia, in moist woods, under the roots of trees: it makes its nest of lichen, collects seeds, runs and burrows quickly; it bites, has the voice of a bat, and weighs about a drachm.

AQUATICUS; Aquatic Shrew. In this species the hind-feet are palmate; fore-feet are white; the tail is short and white. It is an inhabitant of North America, and is the size of a mole.

MOSCHIATUS. Feet palmate, tail flattened, thickest in the middle. This is called the musky shrew; it inhabits about the lakes of Volga and Tanais; burrows under the banks, with an entrance into the water; feeds on flags and fish; the body of the animal is seven inches long, and the tail is eight.

* **BICOLOR**; Water Shrew. The tail of this species is of the mean length; it is nakedish; the body is blackish, beneath it is cinereous; the toes are fringed. It inhabits Europe and Siberia, near swamps and rivers; swims easily, often under water: the female has ten teats, and brings forth nine young at a time; it makes a noise like the chirp of a grasshopper; the body of the animal is four inches long, and the tail two.

MURINUS; Murine Shrew. The tail is of a middle length; the body is brown, feet and tail cinereous. It inhabits Java, and is the size of a mouse.

* **ARANEUS**; Fetid Shrew. The tail of this species is of the middle length; the body beneath is whitish. It inhabits almost every part of Europe, and in the northern climates of Asia; it lives in old walls, stables, yards, granaries, out-houses, swamps, and pools; it feeds on corn and insects; it smells of musk; is killed, but not eaten, by cats; the voice is shrill; it runs much slower than a mouse; brings five or six young ones in spring and summer; it is seldom so long as three inches. There are two varieties. 1. Head, and upper parts, dusky; sides brownish rusty. This is found in Hudson's Bay and Labrador. 2. The upper parts are of a dusky grey, and underneath the animal is of a yellowish-white.

SURINAMENSIS; Surinam Shrew. The tail of this species is half as long as the body; the body above is chestnut, beneath white and yellowish-grey. It is found, as its specific name denotes, at Surinam.

PUSILLUS; Timid Shrew. Ears rounded; tail short, a

little fringed at the sides. It inhabits the northern parts of Persia, in holes which it burrows; it is three inches and a half long; the body is of a dark grey above, and the belly is paler.

BRASILIENSIS. The body of this species is brown, the back is black, with three stripes. It inhabits Brazil, is about five inches long, with a tail of two inches in length.

EXILIS. The tail of this is very thick in the middle, tapering to each end. It inhabits Siberia; it is the smallest of quadrupeds, scarcely weighing half a drachm; it is like, though of a darker colour, the *S. araneus*.

CÆRULEUS; Blue Shrew. The tail is of a mean length; the upper parts are of a pale blue; the belly is lighter; the legs and feet are white. It inhabits Java, and the other East Indian islands, feeds on rice, smells strongly of musk, is eight inches long, with a tail about half that length.

MEXICANUS; Mexican Shrew. The tail is short; the fore-feet are three-toed; the hind-feet have four toes. It is found in New Spain; burrows in vast numbers, feeds on roots and seeds; the flesh is good; it is about nine inches long.

ALBIPES; White-footed Shrew. Tail slender, hairy; upper parts dusky-ash; feet, belly, and teeth, white.

QUADRI-CAUDATUS; Square-tailed Shrew. The tail, as its specific name denotes, is squarish; the head and upper parts are of a dusky-ash; the belly is paler; the fore-teeth are brown.

LURI-CAUDATUS; Carinate Shrew. The tail is taper, keeled underneath; head and upper parts dusky-ash, belly whitish; fore-teeth brown, a white spot behind each eye.

UNICOLOR. The tail is compressed at the base; the body is of an uniform dusky-ash. It is observed by Gmelin, that the last four, described as distinct species, are probably only varieties of the *S. araneus*. They are all found near Strasburg.

SOREY, in *Geography*, a town of France, in the department of the Meuse; 3 miles S.S.E. of Commercy.

SOREZE, a town of France, in the department of the Tarn; 12 miles S.S.W. of Castres.

SORG, a town of Germany, in the principality of Anspach, on the Schwarzach; 8 miles E. of Schwabach.

SORGANO, a town of the island of Sardinia; 38 miles E. of Bofa.

SORGE, **GEORGE ANDREAS**, in *Biography*, a voluminous writer on music, and a composer, born in 1703, and who died in 1778. In Gerber there is a list of his works.

SORGENFREY, or **SANS SOUCI**, in *Geography*, a town of Denmark, in the island of Zealand, with a royal palace; 6 miles N. of Copenhagen.

SORGHUM, in *Botany*, a name of oriental or barbarous origin, but venerable for its antiquity.—“*Perf. Ench. v. 1. 101.*” *Pursh v. 1. 78.* (*Sorghum*; *Mich. Gen. 35.* *Mieg. Aët. Helvet. v. 8. 131.* *Holcus*; *Brown Prodr. Nov. Holl. v. 1. 198.*)—Class and order, *Triandria Digynia*. *Nat. Ord. Gramina.*

Gen. Ch. Cal. Glume of two ovate, concave, coriaceous, unequal valves, inflexed at the margin, single-flowered. *Cor.* of two membranous, ovato-lanceolate, rather unequal valves, hairy at the edges; the innermost rather the smallest, cloven, bearing from its fissure a twisted awn, twice the length of the glume itself. *Nectary* a thin, awl-shaped, villous scale. *Stam.* Filaments three, capillary; anthers cloven at each end, prominent. *Pist.* Germen ovate, polished; styles two, capillary, short, spreading; stigmas oblong, feathery. Some flowers, elevated on stalks, have neither awn nor pistil. *Peric.* none, except the permanent, hardened, closed calyx. *Seed* solitary,

solitary, oval, tumid, concealed in the hard polished calyx, out of which the awn of the corolla projects.

Eff. Ch. Calyx of two valves, single-flowered. Corolla of two valves; the inner one cloven and awned. Nectary villous. Seed enclosed in the hardened calyx. Some flowers male, stalked, without an awn.

We have under the article *HOLCUS* adverted to the present genus, which requires to be separated therefrom, and is in itself important, on account of its economical uses. What are its genuine species, we do not completely undertake to determine, nor how far those which are described are distinct, authors having been obliged to recur to *colour* in their definitions. "They are annual grasses, of quick growth, and of a very large bulk, abounding with saccharine juice, as much as the sugar-cane, at least in Italy." Professor Arduino shewed the writer of this, at Padua in 1787, good sugar and treacle procured from his *Holcus Cafer*, hereafter mentioned. See Sm. Tour on the Continent, ed. 2. v. 3. 10. The stalks of the ripe panicles of some of the species make brooms, or even carpet and clothes-brushes of a very good quality. The following will serve to exemplify the genus in question.

S. Dora. Common Indian-millet. (*Holcus Dora*; Mieg. Act. Helvet. v. 8. 125. t. 4. f. 3. *Holcus Sorghum*; Linn. Sp. Pl. 1484. Willd. Sp. Pl. v. 4. 929. Ait. Hort. Kew. v. 5. 430. Arduin. Olc. o Sorg. 19. t. 4. f. 1. *Milium indicum*; Matth. Valgr. v. 1. 370.)—Panicle ovate, compact, erect. Glumes downy. Seeds slightly compressed.—Native of the East Indies. Cultivated in the south of Europe. The root is annual, consisting of innumerable fibres. *Stem* erect, round, jointed, leafy, from six to ten feet high, as thick as the finger or thumb. *Leaves* sheathing, reed-like, lanceolate, smooth, with a strong mid-rib, and many fine lateral, oblique, parallel ones. *Panicle* terminal, from four to twelve inches long, very much branched, close, of innumerable downy flowers, on zig-zag or curved stalks. *Seeds* roundish, various in colour, usually yellow or reddish. This is the most general species, under which indeed many of the rest have been confounded; but some of them, by their superior merits, have superseded it in cultivation.

S. bicolor. Two-coloured Indian-millet. (*Holcus bicolor*; Linn. Mant. 301. Willd. Sp. Pl. v. 4. 929. Ait. Hort. Kew. v. 5. 430. Arduin. Olc. o Sorg. 29. t. 6. H. Sorghum; Mieg. Act. Helvet. v. 8. 129. t. 4. f. 4?)—Panicle erect, somewhat lobed. Glumes smooth, black. Seeds globose, white.—Said to be a native of Persia. Sufficiently distinct from the former, by the above characters.

S. cernuum. Drooping Indian-millet. (*Holcus cernuum*; Willd. Sp. Pl. v. 4. 930. Arduin. Olc. o Sorg. 14. t. 3. f. 1, 2.)—Panicle compact, curved downward as it ripens. Glumes downy. Seeds globose.—Cultivated in Arabia, Syria, and various parts of the Levant, being probably a native of India. It is remarkable for its deflexed, or pendulous panicle of seed, whose stalk cannot be made straight without breaking. The stem is five or six feet high. Leaves smooth. Seeds very white, scarcely compressed.

S. caffrorum. Caffres Indian-millet. (*Holcus caffrorum*; Thunb. Prodr. 20. Willd. Sp. Pl. v. 4. 930. H. Cafer; Arduin. Olc. o Sorg. 5. t. 1.)—Branches of the panicle spreading every way, deflexed. Glumes downy. Awns deciduous. Seeds globose.—Native of the Cape of Good Hope. Rather larger than most of the preceding, with a spreading, drooping-branched panicle. Seeds more exposed than in the others. Professor Arduino recommends this much for culture, on account of its abundant crop; the goodness of the grain for poultry; and the copious sac-

charine juices of the stems. We perfume his plant and Thunberg's to be the same, but have no proof.

S. saccharatum. Yellow-seeded Indian-millet. Pursh n. 1. (*Holcus saccharatus*; Linn. Sp. Pl. 1484. Willd. Sp. Pl. v. 4. 930. Ait. Hort. Kew. v. 5. 430. Arduin. Olc. o Sorg. 22. t. 4. f. 2. Mieg. Act. Helvet. v. 8. 119. t. 4. f. 1. Sorghum; Rumph. Amboin. v. 5. 194. t. 75. f. 1.)—Panicle erect, with slender, drooping, lax branches. Glumes hairy. Male flowers very few, withering.—Native of the East Indies. The more dispersed flowers, on the long, spreading, drooping, whorled branches of the panicle, readily mark this species.

S. nigrum. Coal-black Indian-millet. (*Holcus niger*; Arduin. Olc. o Sorg. 20. t. 9.)—Panicle ovate, erect, with spreading dense branches. Glumes and seeds black.—Nothing is said of the native country, or particular qualities, of this species, which is one of the largest of the genus. The leaves are long and broad, conspicuous for their white rib. Panicle somewhat pyramidal, not near so dense as that of the first species, but the flowers are thickly set on its spreading, slightly deflexed, branches.

SORGUE, or *Pont de Sorgue*, in *Geography*, a town of France, on the river Sorgue; 6 miles from Avignon.—Also, a river of France, which rises from the fountain of Vaucluse, and runs into the Rhone, by several mouths, at and near Avignon.

SORI, a town of the Ligurian republic; 9 miles S.E. of Genoa.

SORIA, a town of Spain, in Old Castile, near the source of the Duero, built near the ruins of the ancient Numantia. This town, which suffered much during the Moorish wars, was repopled in the beginning of the 12th century, by order of Alonso, king of Castile; 116 miles N.N.E. of Madrid. N. lat. 41° 47'. W. long. 2° 35'.

SORIAN, a river on the W. coast of the island of Celebes, which runs into the sea, S. lat. 3° 9'. E. long. 119° 48'.

SORIANO, FRANCESCO, in *Biography*, a great canonist, and critic of the music of his time, was maestro di cappella of St. Peter's church at Rome, and in 1610 published one hundred and ten canons upon the chant to the hymn "Ave Maris Stella," for three, four, five, six, seven, and eight voices. Refolutions of these canons in score, with remarks, by Zacconi, 1625, in manuscript, were in the possession of the late respectable theorist and historian, P. Martini, who, among his other musical curiosities, communicated to us this manuscript, which impressed us with a much higher opinion of the patience than the genius of Soriano. Few masters, except himself, could perhaps have composed these canons, but many must have thought that the loss to music would not have been very great, if they had never been composed. Baptist Doni, an enemy to learned music, and a great advocate for the recitative and melodies for a single voice, which were now advancing into favour, says (Tratt. della Mus. Scenica, Op. omn. tom. ii. p. 129.) that though Soriano was generally allowed by musicians to be a learned contrapuntist, he never had genius sufficient to invent a single air that was beautiful or pleasing; on which account he applied himself to the composition of elaborate fugues and canons: as in poetry, those who have no original ideas or invention can write acrostics and anagrams, by which they become only rhymers, not poets; so canonists should be called contrapuntists, not musicians.

SORIANO, in *Geography*, a town of the Patrimonio; 6 miles E.S.E. of Viterbo.—Also, a town of Naples, in Calabria Ultra; 6 miles E.S.E. of Mileto.

SORIBOA, a town of Peru, in the diocefe of Truxillo, and jurifdiction of Chacapoyas.

SORICINA, a town of Italy, in the department of the Upper Po; 12 miles N. of Cremona.

SORIGO, a town of Italy, in the department of the Lario; 27 miles N. of Como.

SORIN, a river of France, which runs into the Rhone, at Roanne.

SORITES, Σωρητις, formed from σωρη, *cumulus*, *heap*, in *Rhetoric*, &c. a kind of argument, in which feveral middle terms are chofen to connect one another fucceffively in feveral propofitions, till the laft propofition connects its predicate with the firft fubject. Whence Cicero calls it *fylogifmus acervatus*, an *accumulative fylogifm*.

Such was that merry argument of Themiftocles, to prove, that his little fon, under ten years old, governed the whole world. Thus: "My fon governs his mother; his mother me; I the Athenians; the Athenians the Greeks; Greece commands Europe; Europe the whole world: therefore my fon commands the whole world."

This method of difputing prevailed much among the Stoics; efpecially with Zeno and Chryfippus; but it is very fophiftical.

SORITO, in *Geography*, a town of Naples, in Calabria Ultra; 5 miles E.S.E. of Mileto.

SORIVA, a town of Italy, in the Feltrin; 6 miles W. of Feltri.

SORKEY, a town of Hindooftan, in Bahar; 15 miles W. of Rotafgur.

SORLECHEU, a town of France, in the department of the Jemappe; 6 miles E.N.E. of Avesnes.

SORNAC, a town of France, in the department of the Correze, and chief place of a canton, in the diftrict of Uffel. The place contains 1453, and the canton 5647 inhabitants, on a territory of 205 kilometres, in 8 communes.

SORNI, a name given by fome of the chemical writers to iron.

SORNZIG, in *Geography*, a town of Saxony, in the circle of Leipfic; 3 miles S. of Mugeln.

SORO, a river of Portugal, which runs into the Tagus, near Salvaterra, in the province of Eltremadura.

SOROCEPHALUS, in *Botany*, fo named by Mr. Brown, from σωρος, a *heap*, and κεφαλη, the *head*, alluding to the aggregate, or crowded, heads of flowers.—Brown Tr. of Linn. Soc. v. 10. 139. Ait. Hort. Kew. v. 1. 202.—Clafs and order, *Tetrandria Monogynia*. Nat. Ord. *Proteaceae*, Juff. Brown.

Eff. Ch. Corolla four-cleft, regular. Stamens in the concave tips of the fegments. Nectary four fcales beneath the germen. Stigma vertical. Nut fuperior. Involucrum of from three to fix leaves, permanent, containing one, or a very few, flowers. Common receptacle naked.

Shrubs, with wand-like branches. Leaves fcattered; either thread-shaped or flat, undivided; the loweft only being occasionally bipinnatifid. Involucrum nearly feffile, with a folitary braetea, collected into a capitate terminal fpike, fometimes fubtended by imbricated braeteas. Flowers purplifh. *Brown*.

Mr. Brown defcribes eight fpecies, all natives of fouthern Africa. Two are in the Englifh gardens.

Section 1. *Spike nearly naked. Involucrum from one to three-flowered. Nut entire at the bafe, on a very fhort falk. Leaves thread-shaped, undivided.*

1. *S. fetaceus*. Brittle-leaved Sorocephalus. Br. n. 1.—"Involucrum fingle-flowered. Leaves fetaceous, incurved, hairy, as well as the branches."—Gathered by Dr. Roxburgh, at the Cape of Good Hope. An erect *shrub*, with

ftaight umbellate *branches*. *Leaves* numerous, an inch, or rather more, in length, with a briftly faded point; the lower ones lefs incurved. *Head* terminal, feffile, ovate; the fize of a black cherry. Lower part of the *corolla* loofely downy; its fegments bearded. *Stigma* ovate, fomewhat conical.

2. *S. falfoloides*. Salt-wort Sorocephalus. Br. n. 2.—"Involucrum fingle-flowered. Leaves triangular-thread-shaped, incurved, fmoother."—From the fame country. *Roxburgh*. Erect, very much branched. Youngeft *branches* finely downy. *Leaves* half an inch long, furrowed above, with an acute point, nearly of their own colour. *Head* rather fmall than the former, accompanied underneath by a few minute lanceolate *braeteas*. *Corolla* bearded with fhort hairs. *Stigma* erect, or flightly inclined.

3. *S. imberbis*. Beardlefs Sorocephalus. Br. n. 3.—"Involucrum three-flowered. Segments of the corolla, as well as the points of the braeteas, fmoother."—Gathered by Mr. Niven, near the Cape of Good Hope. Much branched; the young *branches* downy. *Leaves* fmoother, an inch long, moderately fpreading, fcarcely incurved, fsharp-pointed; furrowed above. *Head* on a fhort falk, terminal, nearly globofe, the fize of the firft fpecies. *Braeteas* lanceolate, fringed, with a fmoother awl-shaped point. Lower part of the *corolla* bearded. *Style* ftraight. *Stigma* club-shaped, equal.

4. *S. spatuloides*. Curve-ftyled Sorocephalus. Br. n. 4.—"Involucrum three-flowered, fomewhat stalked. Segments of the corolla bearded."—Found by Mr. Niven, near Franche-hoek, at the Cape of Good Hope. An upright *shrub*, with umbellate, finely downy, *branches*. *Leaves* fcarcely an inch long, moderately fpreading; hairy when young. *Heads* either folitary, or two or three together, ovate or oblong, the fize of a hazel-nut, on fhort falks. *Braeteas* lanceolate, acute, downy; fometimes fmoother at the point. *Corolla* bearded with long hairs. *Style* generally incurved at the point, in which cafe the *stigma* is fomewhat unequal; but if the *style* be nearly ftraight, it is ovate and equilateral.

Section 2. *Spike with more or lefs of a general involucrum. Partial involucrum with from four to fix flowers. Nut emarginate at the bafe.*

5. *S. tenuifolius*. Slender-leaved Sorocephalus. Br. n. 5.—"Leaves thread-shaped, very fhort. Heads of few flowers. Corolla with a feathery beard; its innermoft fegment nearly naked."—Gathered by Mr. Niven, in moift fituations near Breed river, at the Cape of Good Hope. A *shrub* three or four feet high, with fmoother, reddifh, leafy *branches*; fomewhat villous when young. *Leaves* imbricated, roughifh, fsharp-pointed, not half an inch long; the younger ones hairy. Aggregate *head* terminal, feffile, the fize of a pea, compofed of from two to four partial *heads*. *Partial involucrum* fomewhat imbricated; their leaflets lanceolate, bearded, fmoother at the points. *Corolla* very deeply four-cleft, equal. *Style* ftraight. *Stigma* ovate, erect, equilateral.

6. *S. lanatus*. Woolly Sorocephalus. Br. n. 6. Ait. n. 1. (*Protea lanata*; Thunb. Diff. n. 30. t. 3. Willd. Sp. Pl. v. 1. 519.)—Leaves triangular-thread-shaped; furrowed above. Heads of many flowers. All the fegments of the corolla with feathery beards.—Native of Swartland, and other mountainous tracts, about the Cape of Good Hope. Sent to Kew garden, by Mr. Maffon, in 1790. It flowers from June to September. An upright *shrub*, with fomewhat umbellate, ftraight, leafy, minutely downy *branches*. *Leaves* imbricated, from five to eight lines long. *Head* the fize of a large hazel-nut, feffile, globofe, folitary; the partial ones very clofely crowded; each of from five to eight flowers.

flowers. *Involucrum* of from five to seven narrow-lanceolate bearded leaves. *Corolla* equal, deeply divided. *Style* straight, with a thick equilateral *stigma*. *Nut* finely downy, with a thin, brown, slightly rugged, shell; its stalk very short. The *leaves* are occasionally roughish or smooth, their keel rounded or acute.

7. *S. imbricatus*. Imbricated Sorocephalus. Br. n. 7. Ait. n. 2. (*Protea imbricata*; Thunb. Diss. n. 45. t. 5. Linn. Suppl. 116. Willd. Sp. Pl. v. 1. 527. Andr. Repof. t. 517.—Leaves lanceolate; rough underneath. Base of the corolla clothed with glandular hairs. *Stigma* club-shaped.—Found on hills at the Cape of Good Hope. Sent to Kew, by Mr. Masson, in 1794. Mr. Hibbert also obtained it from his collector there, Mr. Niven. This has the habit of the foregoing, but the *leaves* are lanceolate, near an inch long; hairy beneath, and at the edges; smooth above. *Head* sessile, ovate or oblong, either solitary, or composed of two or three crowded together; with a common *involucrum*, of many lanceolate coloured leaves. Each partial *involucrum*, of four lanceolate hairy leaves, usually contains four flowers. *Corolla* slender, purplish; its segments bearded, with a long dense tuft of white hairs, as is likewise the *germen*. *Style* straight. *Stigma* a little gibbous. *Nut* oblong, brown, very smooth and shining.

8. *S. diversifolius*. Various-leaved Sorocephalus. Br. n. 8.—“Leaves spatulate-lanceolate; smooth underneath; the lowermost doubly pinnatifid. *Corolla* bearded throughout. *Stigma* cylindrical.”—Gathered by Mr. Niven, on stony hills near *Goud Rivier*, at the Cape of Good Hope. A smooth *shrub*, whose *stem* is from two to six feet high, either simple or divided, straight, erect, as thick as a swan's quill; downy in the upper part. *Lower leaves* two inches long, twice three-cleft, channelled; the rest imbricated, bluntish, scarcely concave, hardly half an inch in length. *Head* sessile, solitary, ovate, obtuse, the size of a small plum.

SOROCHINSKAIA, in *Geography*, a fortress of Russia, in the government of Upha, on the Samara; 80 miles N.W. of Orenburg.

SOROE, a town of Denmark, in the island of Zealand, surrounded by three fresh-water lakes. In this place is a royal academy, endowed with the revenues of a rich convent, which was dissolved at the revolution; 35 miles S.W. of Copenhagen. N. lat. $55^{\circ} 27'$. E. long. $11^{\circ} 30'$.—Also, a small island in the North sea, near the coast of Norway. N. lat. $70^{\circ} 30'$.

SOROOMAN, a town of Arabia, in the province of Oman; 110 miles S.W. of Julfa.

SOROTO, a town of Thibet; 70 miles W.N.W. of Cha-tehou.

SORRANCES, among *Farriers*, signify two things; viz. either an ill state, or habit, of a horse's body, arising from some part diseased; or a loosening and solution of the continuity of the parts; which, according to the various circumstances of it, acquire new names, as fracture, wound, ulcer, rupture, convulsion, cramp, excoriation, &c.

SORRANCE-WATER, a name given by our farriers to a solution of vitriol, and some other ingredients, in vinegar; a medicine much esteemed in many of the diseases of horses. It is prepared in the following manner.

Take Roman vitriol, and roach-alum, of each an ounce and a half; verdigris, an ounce; copperas, two ounces: reduce all these to powder together, and put them into a two-quart bottle, into which pour a quart of the strongest and best wine-vinegar; this is to be set in balneo Mariæ. The short way of doing which by the farrier, is this: he

puts a wisp of hay into the bottom of the kettle, and then tying some pieces of lead or iron about the neck of the bottle, to make it heavy enough to sink in water, it is set upon the hay so, as to stand very upright; then three notches are cut lengthwise in the cork to give passage to some of the vapours when the bottle is heated, that it may not burst. When every thing is thus prepared, so much cold water is to be put into the kettle, that the neck of the bottle may stand two or three inches above it; the kettle is then to be set over the fire, and the water is to be made to boil, and kept boiling about half an hour, the bottle being at times taken out, and thoroughly shaken. When the salts are thus thoroughly dissolved in the vinegar, the whole is to be kept for use.

The method in which they use it is this: take an earthen pan, which will hold about twelve quarts; let this be filled with urine that has been made by sound, healthy, and young persons; the staler the urine is, the better it is for use, and it ought indeed always to stand, at least, three weeks before it is used. It is proper for the farrier, therefore, always to keep a quantity of this ready, and when the water is to be used, half a pint of it is to be mixed with a quart of the urine; or, if it be required stronger, more of the water is to be added: these are to be thoroughly mixed together, and the legs, or other affected part of the horse, bathed with it with soft rags twice a-day.

The virtues of this water are highly extolled: it is said to cure the malanders in two or three times dressing; it is also a sovereign remedy for the mange, either dry or wet, and for the rat-tails, scratches, goured or swelled legs and heels, and it also cures horses when the greafe is fallen into their heels, as the farriers express it. The farcy is also said to be often cured by a long continuance in the use of it, purging the horse two or three times, at different distances of time, during the time of his being under cure by the water. They also find it a good cleanser and healer of foul ulcers, and that it prevents the breeding of proud-flesh and worms in wounds, and drives away a flux of humours that were falling upon any part. They use it also in clefts and cracks of the heels, and in windgalls, especially in the prevention of the lall, by its repellent qualities. The green water alone is an excellent remedy for filulas, cankers, and the galled backs of horses; disposing such sores, as they are called, not to fester, rot, and grow worse, as all greasy and oily medicines do, but cleansing them, and preparing the way to a very sound and standing cure.

SORREL, ACETOSA, in *Botany*, *Gardening*, and the *Materia Medica*. See RUMEX.

SORRELS, *Indian Red*, and *Indian White*, or *Syrian Mal-low*, in *Botany*, are species of *Hibiscus*; which see.

SORREL, *Wood*, in *Botany*, *Gardening*, and the *Materia Medica*. See OXALIS.

SORREL, *Common* and *Curled*, in *Agriculture*, troublesome weeds in meadows and pasture lands; also the latter in cultivated arable ground, where neither horses nor neat cattle will eat it, which, of course, renders it necessary to be eradicated. This is mostly accomplished by rooting it out, or frequently cutting the stalks over just below the surface of the land. It has often the title of curled dock. See WEEDS.

SORREL, in the *Manege*, is used for a reddish colour. The mane ought to be red or white, in a horse of this colour. It is distinguished, according to the degrees of its deepness, into a *burnt sorrel*, and a *bright* or *light sorrel*. Generally speaking, it is a sign of a good horse.

SORREL, *Salt of*, in *Chemistry*, the native super-oxalat of potash,

potash, contained in the juice of this plant. See *OXALIC Acid*.

SORREL-Tree, in *Botany*. See *ANDROMEDA*.

SORRO, in *Geography*, a town of Africa, in Beeroo; 85 miles S.W. of Walet.

SORROINSU, a town of the department of Liamone, or island of Corfica; the canton of which contains 1528 inhabitants.

SORS, a town of the island of Sardinia; 10 miles N.N.E. of Saffari.

SORSELE, a town of Swedish Lapland, in the lap-mark of Pitea; 105 miles W. of Pitea. N. lat. $65^{\circ} 33'$. E. long. $17^{\circ} 20'$.

SORSOKEN, a sea-port town in the S.E. part of the island of Lugon.

SORT, a town of Spain, in the province of Catalonia; 18 miles W. of Urgel.—Also, a sea-port town of Africa, in the country of Tripoli, situated on the coast of the Mediterranean, in the gulf of Sidra. N. lat. $30^{\circ} 28'$. E. long. $16^{\circ} 55'$.

SORTES, *LOTS*, in *Antiquity*, a method of deciding dubious cases, where there appears no ground for a preference; by referring the decision to chance; as in casting of dice, drawing of tickets, &c.

The fortes, or lots, were of ancient use among the Jews; and in the books of the Old Testament we meet with divers standing and perpetual laws, and divers particular commands, prescribing and regulating the use of them. Thus, the Scripture informs us, that the lot fell on St. Matthias, when a successor to Judas in the apostolate was to be chosen. Our Saviour's garment itself was cast lots for.

The *SORTES Prænestinae* were famous among the Greeks. The method of these was to put a great number of letters, or even whole words, into an urn; to shake them together, and throw them out; and whatever should chance to be made out in the arrangement of the letters, &c. composed the answer of this oracle.

Cicero, de *Divin.* lib. ii. § 41, says, that a variety of predictions were inscribed on pieces of wood, which were kept in a box or chest; and one of these drawn out by a child, after the box was shaken, contained the answer sought. He also informs us, how these fragments of wood were first discovered; but he observes, "Tota res est inventa fallaciis, aut ad quæstum, aut ad superstitionem." In lieu of this, another kind of fortes was introduced into Greece and Italy; which was, to take some celebrated poet, as Homer, Euripides, or Virgil, to open the book, and whatever first presented itself to the eye upon opening, was taken for the ordinance of heaven. This made what they called the *fortes Homericae*, and *fortes Virgiliana*; which succeeded to the use of the *fortes Prænestinae*.

The bath *kol* among the Jews was much of the same kind, differing only in this circumstance, that the Jews took their oracle from the first words which they heard any body pronounce; the Heathen, from the first they cast their eyes upon, on opening Homer, &c. in which they endeavoured to discover a meaning suitable to the matter concerning which they inquired.

This superstition passed from Paganism into Christianity; and the Christians took their fortes out of the books of the Old and New Testament. The first passage that presented itself upon opening a book of Scripture, was esteemed the answer of God himself.

If the first passage did not happen to be any thing to the purpose for which the fortes were consulted, another book was opened; till a passage was met with that might be taken for an answer. This was called *fortes sanctorum*.

St. Augustine (Epist. ad. Jan. 109.) does not disapprove of this method of learning futurity, provided it be not used for worldly purposes.

Gregory of Tours adds, that the custom was first to lay the Bible on the altar, and to pray the Lord, that he would discover by it what was to come to pass. Instances of the use of the fortes sanctorum are very frequent in history. Heraclius, M. Fleury tells us, in his war against Chosroes, to learn where he should take up his winter-quarters, purified his army for three days, and then opened the Gospels, and found the place appointed for his winter-quarters was in Albania.

Gilbert of Nogent informs us, that, in his time, (that is, about the beginning of the 12th century,) the custom was, at the consecration of bishops, to consult the fortes sanctorum, to learn the success, fate, &c. of their episcopate.

The practice is founded on a supposition, that God presides over the fortes, and on Prov. xvi. 33. "The lot is cast into the lap; but the disposing thereof is of the Lord."

In effect, many divines hold that the lot is conducted in a particular manner by Providence; that it is an extraordinary manner in which God declares his will by a kind of immediate revelation. The fortes sanctorum, however, were condemned by the council of Agda, in 506, at the time they were beginning to take footing in France, &c.

SORTILEGE, *SORTILEGIUM*, a kind of divination by fortes, or lots.

SORTING Sheep-Stock, in *Agriculture*, the practice of carefully choosing, sorting, collecting, and putting together, those which are the most proper and best suited for the purpose of breeding, or any other use that may be in the contemplation of the grazing farmer. It is a practice which has hitherto, for the most part, only prevailed among the larger and better kinds of sheep-farmers, but which ought to be every where attended to where good sheep-stock is wanted, and good management with them to be pursued. It, however, requires great care and attention in the execution, in order to perform it in a proper manner; but, when well conducted, amply repays the judgment and skill of the stock-farmer. The proper introduction of new and approved breeds has done much in bettering this sort of stock, by promoting a more spirited attention to the subject, and inculcating the necessity of a more careful selection; as, since this has been the case, very evident improvements have taken place in the forms and dispositions of sheep, as well as in the quality of their wool.

The utmost care and attention are constantly demanded in the selection of such sheep as are to be bred from; and as it would require a great length of time to correct and remove the errors and bad consequences that might arise from any neglect in so important and essential a matter, the sheep-master should always himself be, as much as possible, employed in the business. He should take care that the ewe teags, or young ewes, be very fully and strictly examined in the mouths, to see that they are not chopped or defective in such parts; their make should be seen to be proper and handsome in all points, and their wool of a superior quality; the staple being well suited to the pasture or nature of the keep, rather short than long, as short wool is commonly thick, and kindly for the sheep; but when too long, it is apt to be thin, and to draw too much nourishment from the animal, without affording the necessary warmth and protection in the winter season. These sorts of sheep should in all cases be sorted down, or refused, as it is called, in a very close manner; and when there are not more than are wanting to put the ram to, and many of these are defective, all such should be fattened or sold, and their places supplied by the best

best of the old ewe-stock, which would otherwise be sent away. This is not generally practised, but it is evident that a well-formed or perfect old ewe must be better for breeding from, than such young ones as are ill-formed or imperfect in their shape.

There are different periods for the sorting or selecting of sheep-stock; as the time when the ewes are arranged and put into different classes for the rams, the season of lambing, &c.: in each of which, the defects and imperfections of them may be discovered without much difficulty. But the most proper time of all, according to some, is in the early spring, as about the beginning of March, as then the soft, the long, the coarse wool, and all other imperfections in the ewes, are the most conspicuous, and readily detected, and those of the best forms, qualities, and dispositions, may be the most fitly drawn off and preserved; as such sheep as are capable of supporting themselves, and of looking well under the difficulties of a severe winter season, must in general be the most deserving of the breeding sheep-farmer's attention; while such as have wintered badly will not unfrequently shew a good disposition in the summer season. In these cases, where imperfections are discovered, the sheep should either be drawn off, put out, and lambed by themselves, or a private mark set upon them; and the ewes and lambs sold or made fat. Thus, the number of bad ill-formed sheep, that ought not to be kept, are conveniently reduced and completely got rid of, which, if they or their lambs were suffered to blend and intermix with the well-formed sheep, the stock would be in danger of being contaminated. It is the common practice in most cases, to only select or sort the sheep once in the year; but with good managers they are had under hand two or three times in the same space of time; and whenever a sheep is seen with any sort of defect, it is immediately marked, and sent to be made fat.

Many make this sorting, or inspection, so late as the beginning of the autumn, but an earlier performance of the business is evidently preferable, in order that the defective stock may be put to fatten in proper time.

The manner of performing the business is commonly by pouncing the sheep in a small number at a time, so that the sheep-farmer may be able to examine them at once, without the danger of being distracted or confused by having too many exposed to his view, and consequently be incapable of distinguishing the properties of their forms, and other qualities which ought to be particularly attended to in forming his decision. In the execution of this work, the farmer, his shepherd, or looker, are provided with ochre, or some other material, for giving the defective sheep the usual private mark, in order that they may be known from the perfect part of the flock, and be disposed of accordingly. This marking, or *tivering*, as it is called in some places, is performed differently, according to circumstances, as the purposes the sheep are to be put to, and the number of lambs the ewes have had. It is well done sometimes also to have the sheep marked with pitch, according to their ages. See *TIVERING*.

The defects which are chiefly to be taken notice of in the sorting of sheep in this intention, are those of bad shape, as the head being thick or too long, the body too long and narrow, without sufficient roundness, the feet and bones too large, the chest too much confined, the want of straightness in the back, too great a length in the legs and neck, the sheep being too large for the pasture or keep, their not handling in a proper manner, the wool bad, as too coarse or too long and picky, or coming off, waxy, or hempy, the sheep being lousy, struck with the fly, gally,

thick pelted, and scurvy, their being hog-chopped, that is, having the lower jaw shorter than the upper one, by which their feeding properly is prevented, the mouths large, causing the loss of the cud in rechewing their food, &c. By sorting and selecting sheep as free as possible from defects of these kinds, the best sheep-stock may be procured, provided the true form be properly understood and constantly kept in mind, without suffering it to be injured in any way by the admission of improper qualities at any time, or under any circumstances.

The sorting or selection of sheep in this intention, may perhaps be a little different in different cases; but wherever a good stock is aimed at, the breeding sheep-farmer should of course select that breed, whatever it may be, which is most suited to his circumstances and purposes, and which the most nearly approaches towards the state of perfection in its form and other properties, or which possesses that particular kind of improvement which he is in want of, being constantly well aware what constitutes such states in the animal. The parts of his stock which are deficient, or do not fully come up to or possess such properties, are always to be sorted out and rejected, being sold or turned off for the purpose of fattening, both in the ewes and the lambs, as they might be in danger of accidentally injuring the flock. Good breeding sheep-farmers are also at all times closely on the watch to have none but those of superior qualities, and to take advantage of any accidental improved variety which may answer their intentions. The full proper culling or selecting and sorting of the younger part of the ewe-stock, is in all cases a material point in having good sheep-stock, and one which is never to be neglected. The careful breeder should indeed continually have his eyes upon his flock, to see that there are no faulty animals continued in it, especially in any material degree, as much may be effected in this way, and the trouble of sorting be considerably lessened. See *BREEDING, LIVE-STOCK, and SHEEP*.

The practice of sorting sheep is not, however, useful only for the purpose of breeding, but may be beneficially employed in other intentions. The sorting of sheep, according to their ages, sizes, kinds, and other qualities, is often highly important and advantageous in the stocking of pasture lands, as it enables the sheep-farmer to do it with greater propriety and correctness, as well as with a greater profit in the improvement of the stock. See *STOCKING Pasture Land*.

Sheep are likewise sorted with very much benefit for the different purposes of store-feeding, lambing, fattening, and other sorts of management with them.

But however beneficial the practice may be in these several intentions, as well as in some others, it is probable that it has hitherto been attempted only in a few instances, and in many of those in much too slight and inattentive a manner; it is, notwithstanding, of the utmost necessity and importance in the management of this sort of live-stock, and when once well understood and properly performed, cannot fail of producing very advantageous effects, and much improvement in the business of sheep-farming.

SORTINSKOL, in *Geography*, a town of Russia, in the government of Tobolsk; 72 miles S.S.W. of Berezov.

SORTOWITZ, a town of Prussia, in the palatinate of Culm; 10 miles N. of Culm.

SORVIODUNUM, or *SORBIODUNUM*, in *Ancient Geography*, a town of the isle of Albion, upon the route from Calleva to Vrioconium, in passing by Muridunum between Brige and Vindocladia, according to the Itinerary of Antonine; Calleva being Silchester, Muridunum, being Eggerton, Vrioconium being Wroxeter, Brige being Broughton, Vindo-

Vindocladia near Cranburn, and Sorbiodonum being Old Sarum.

SORUNDO, in *Geography*, a town of Sweden, in Sudermanland; 20 miles S.S.W. of Stockholm.

SORUS, in *Botany* and *Vegetable Physiology*, from *σρος*, a heap, is a term recently introduced, for the assemblage of capsules in Ferns, which had hitherto been called a dot, spot, or line, according to its particular figure. (See *FILICES*.) The *Sori* in many kinds of *Polypodium* and *Aspidium* are very much elevated, or prominent, well answering to this appellation, which is indeed, in every case, more correct and less exceptionable than the terms it supersedes. In an early state, the *Sori* are little more than spots, more or less opaque, or quite pellucid, in whose homogeneous substance nothing can be discerned of the mystery of impregnation, though certainly performed there. Whether that mystery takes place before the shape of each particular capsule is developed, we cannot determine, though it appears most probable; for if the *Sori* swell at all, they do not seem to fail afterwards. If they do not come to perfection, they remain in their original state, of a scarcely conspicuous dot.

SORUT, in *Geography*, a circar of Hindoostan, in Guzerat; 120 miles long, and 40 broad.

SORWY, a river of Monmouthshire, which runs into the Edwith.

SORY, in *Natural History*, the name of a fossile substance, much spoken of by the ancients, but erroneously supposed to be now lost.

It is a firm and not brittle substance, though of a spongy and cavernous structure, and is considerably heavy. It is found in masses of no regular shape or size, some being roundish, others angular or flatted, and some of the size of a walnut, others of many pounds weight. It feels very harsh and rough to the touch, and is covered with no investient coat or crust, but shews its natural surface, which is always corrugated or wrinkled, and usually full of small protuberances and cavities, and when broken, is found to be of a rugged and spongy structure within.

Its natural colour is a rusty black, but it is sometimes reddish, and sometimes blueish: and is commonly stained, in different places, with spots of a blueish or rust colour, when black; and of a greenish hue, when it is of a reddish colour: in the places where it is free from these, it is usually somewhat bright and sparkling. It is of an acrid and disagreeable taste, and of a strong and nauseous smell; put into the fire it burns to a deep purple; and if boiled in water a great part of it becomes dissolved in it; and this may again be separated from the water by evaporation and crystallization, and then appears in the form of pure blue vitriol, forming regular rhomboidal crystals, and tinging iron to a copper colour, on being first wetted, and then rubbed upon it.

It is found in many parts of the Turkish dominions, particularly in Gallo-Græcia; as also in some parts of Germany. In this country it is boiled for the blue vitriol it contains. In Turkey it is mixed with lime, and made into a paste with water, which is laid on such parts of the body as they would eradicate the hair from, and effects that purpose in a very few minutes. In the eastern nations, where it is thus used, it is known by the name of *rufma*.

The ancients used it externally to take off pimples, and put a piece of it into a hollow tooth, as a remedy for the tooth-ache. There can be no doubt of their sory being the same substance with this; since Dioscorides has described it to be blackish in colour, full of small cavities, moist on the

surface, (as ours always is in moist weather,) and of a disagreeable taste and smell.

This substance, as also the chalcitis, mify, and melanteria, are all properly ores of vitriol, the particles of those salts being so perfectly blended in them, as not to be at all distinguishable to the naked eye, yet being always regularly separable from them by water, which is to the saline ores what fire is to those of the metalline kind. Hill's Hist. of Foss. p. 606.

SORYGAZA, in *Ancient Geography*, a town of India, on the banks and on the other side of the Ganges, towards the eastern coast. Ptolemy.

SOS, in *Geography*, a town of France, in the department of the Lot and Garonne; 10 miles S.W. of Nerac.—Also, a town of Spain, in Aragon; 30 miles W. of Jaca.—Also, a river of Spain, in Aragon, which runs into the Sinca, near Monçon.

SOSA, a town of Saxony, in the circle of Erzgebirg; 22 miles S.S.W. of Chemnitz.

SOSE, a river of Germany, which runs into the Ruhme, 9 miles E. of Nordheim.

SOSES, a town of Spain, in Catalonia; 6 miles S.W. of Lerida.

SOSIBES, in *Ancient Geography*, a people who inhabited the environs of Asiatic Sarmatia, and who are comprehended, by Julius Capitolinus, in the number of those who had conspired against the Roman empire, under Marcus Antoninus the philosopher.

SOSIGENES, in *Biography*, a Peripatetic philosopher, and skilful astronomer, was brought from Egypt by Julius Cæsar, with the view expressly of assisting him in reforming the calendar. The philosopher, by tolerably accurate observations, discovered that the year was 365 days and 6 hours; and to make allowance for the odd hours, he invented the intercalation of one day in four years; and the duplication of the sixth day before the calends of March was the intercalary day: and hence the year in which this took place was called Bissextile. This was called the Julian year, the reckoning by which commenced in the 45th year B.C., and continued till it gave place to something more accurate, and a still farther reformation under pope Gregory XIII. Sosigenes was author of a commentary upon Aristotle's book "De Cælo."

SOSIPPUS PORTUS, in *Ancient Geography*, a port of Arabia Felix, on the coast of the Arabian gulf, between Musa Emporium and Pseudocelis, according to Ptolemy.

SOSNINSKAIA, in *Geography*, a town of Russia, in the province of Novgorod; 32 miles N. of Novgorod.

SOSNITZA, a town of Russia, in the government of Novgorod Sieverskoi; 32 miles S.S.W. of Novgorod Sieverskoi. N. lat. 51° 30'. E. long. 32° 46'.

SOSNOPA, a town of Russia, in the government of Perm; 48 miles S. of Ofa.

SOSNOVOI, an island of Russia, in the river Angara; 96 miles N.N.W. of Ilmsk.

SOSNOVSKOI, a town of Russia, in the government of Kolivan. N. lat. 55° 50'. E. long. 85° 44'.

SOSPELLO, a town of France, in the department of the Maritime Alps, and chief place of a canton, in the district of Monaco; divided by a small river into two parts. The town contains 2990, and the canton 5512 inhabitants, on a territory of 142½ kilometres, in 4 communes. It is the see of a bishop, united with Vintimiglia; containing four churches, one of which is a cathedral, and two convents; 10 miles N.E. of Nice.

SOSPIRO, Ital., *Soupir*, Fr., a crotchet rest in *Music*. See CHARACTERS and TIME-TABLE.

SOSPIRO, *Al Canone*. See *CANONE al Sospiro*.

SOSSINATI, in *Ancient Geography*, a name given to one of the four classes of mountaineers in the isle of Sardinia, who took up their abode in caverns. Strabo.

SOSSIUS, a river on the southern coast of Sicily, between the town Pintia and the mouth of the river Ibarus. Ptolemy.

SOSTENUTO, in *Italian Music*, *Soutenu*, Fr., sustained, continuing sounds and uniting them to each other, in opposition to *spiccato*, detached. See *LEGATO*.

SOSTI, in *Geography*, a town of Naples, in Calabria Ultra; 10 miles S. of Squillace.

SOSTRATUS, in *Biography*, the most eminent architect of his time, was a native of Gnidus, in Lesser Asia, and flourished in the third century before the Christian era. The patronage which he met with, caused him to be denominated the friend of kings; and he was particularly in favour with Ptolemy Philadelphus, sovereign of Egypt. He is celebrated in history likewise for the terraces, supported on arcades, which adorned his native city; and the famous *Pharos*, the light-house of Alexandria, which was reckoned one of the wonders of the world. He transmitted his name to posterity by an inscription on this light-house, in the Greek language, of which the translation is, "Sostratus of Gnidus, the son of Dexiphanes, dedicates this to the gods, the protectors of navigators."

SOSVA, in *Geography*, a river of Russia, which rises in the government of Tobolsk, N. lat. $61^{\circ} 10'$. E. long. $59^{\circ} 54'$, soon after enters into the province of Ekaterinburg, and takes a southern course to lat. 59° , then bends its course easterly, and loses itself in lake Phelim, in the government of Tobolsk, N. lat. $59^{\circ} 15'$. E. long. $63^{\circ} 54'$.—Also, a river of Russia, which runs into the Oby, 40 miles S. of Berezov.

SOSZNIZOWITZ, or *SASZINKOWITZ*, a town of Silesia, in the principality of Oppeln; 35 miles S.E. of Oppeln. N. lat. $50^{\circ} 14'$. E. long. $18^{\circ} 28'$.

SOTA DE PALANA, a town of the island of Cuba; 100 miles S.W. of Havana.

SOTCHEOU, a town of Corea; 403 miles E. of Peking. N. lat. $40^{\circ} 9'$. E. long. $124^{\circ} 34'$.

SOTELLO, a town of Spain, in Old Castile; 30 miles S. of Burgos.

SOTER, in *Biography*, pope, a native of Fondi, in the Campagna of Rome, was elected to the Roman see on the decease of Anicetus, in the year 168. During the period that he ruled the church, the heresy of the Montanists made its appearance, and he is said to have composed a book against their doctrines; but as the title is not known, the fact itself is liable to much doubt. Four decretals have been ascribed to him, but they are generally regarded as spurious. He died in 176, and he has been enrolled among the martyrs by modern writers, but no ancient one gives him that title. He is, however, generally commended for the contributions which he caused to be raised for the relief of the poor brethren in foreign countries, and particularly for those who were condemned to the mines, on account of their faith.

SOTERIA, formed from *σωτηρ*, *salvator*, in *Antiquity*, sacrifices offered to the gods, in gratitude for their having delivered a person from danger. See *SACRIFICE*.

The term is also applied to poetical pieces composed for the same end. Orpheus is the first who appears to have composed *soteria*.

Our Latin poets give the same name to poems in Latin verse, written to give thanks to God, or the saints, for having preserved them on any occasion. F. Petavius being

delivered from a dangerous disease, by the intercession, as he supposed, of St. Genevieve, composed that fine piece in honour of that saint, still extant under the title of "*Soteria*."

SOTERUS, in *Ancient Geography*, a port of the Arabian gulf, according to Diodorus Siculus.

SOTI, in *Geography*, a town of Africa, in the country of Whidah; 18 miles W. of Sabi.

SOTIRA, in *Ancient Geography*, a town of Asia, in Aria. Ptol.—Also, a town of Asia, in Cappadocia, Pliny.—Also, a town of Parthia. Arrian.

SOTIRELLA, a name given by some to a compound medicine, in form of a hard mass, and consisting of opium, and some other narcotics, with camphor, wood-foot, and nutmeg. It is described in the Augustan Dispensatory, and is intended to be put into hollow teeth, as a remedy for the tooth-ache.

SOTO, DOMINIC, in *Biography*, a learned Spanish ecclesiastic, was born at Segovia in 1494. His father was a gardener, and his circumstances being of a very humble nature, he destined his son for the same occupation; but having learned the elements of instruction, he officiated in the duties of sacristan in a village church, and at length rendered himself qualified to study philosophy at the university of Alcalá. He afterwards completed his studies at Paris; and on returning to Spain, entered into the Dominican order. He was employed as a professor in different universities, and published commentaries on the Aristotelian philosophy. In 1545 he was deputed as a theologian to the council of Trent, and was one of the persons to whom was committed the office of recording decisions of the assembly, and drawing up its decrees. He was a frequent and able speaker in the council, and maintained the proposition, "that the residence of bishops is of divine right." The emperor Charles V., in 1549, offered him the bishopric of Segovia, which he refused. He was, however, persuaded to take the office of judging between Las Casas and Sepulveda, in their contest respecting the Indians, which he determined in favour of the former. He then retired to Salamanca, where he died in 1560. His chief works are, "*De Justicia et Jure*;" "*De Tegendis Secretis*;" "*De Pauperum Causa*;" "*De Cavendo Juramentorum Abusu*."

SOTOVENTO, in *Geography, a name applied to the Lesser Antilles in the West Indies. Among these, the chief may be reckoned Trinidad, Margaretta, Curassoa, and Tortugas.*

SOTOVENTO Lobos, or *Leeward Island of Sea-Wolves or Seals*, an island on the coast of Peru; 7 leagues from Barvento Lobos, or Windward island of sea-wolves. It is about 6 miles in circuit, and 15 miles from Cape Aguja.

SOTTEGHEM, a town of France, in the department of the Scheldt, and chief place of a canton, in the district of Audenaerde. The place contains 1508, and the canton 14,603 inhabitants, on a territory of $77\frac{1}{2}$ kilometres, in 14 communes.

SOTTERN, a lake of Sweden, in the province of Nericia; 14 miles S.E. of Orebro.

SOTTEVAST, a town of France, in the department of the Channel; 9 miles W. of Valognes.

SOTTEVILLE, a town of France, on the south side of the Seine; 3 miles S. of Rouen.

SOTTO VOCE, in *Italian Music*, implies a degree of piano, or soft, and subdued voice; which is sometimes expressed by *mezzo forte*, and *mezza voce*, half piano.

SOU, in *Commerce*. See *Sol*.

SOV, or *So-tcheou*, in *Geography*, a town of China, of

the second rank, in Chen-fi. N. lat. 39° 38'. E. long. 98° 44'.

SOUADI, or SOUALLY, a town of Egypt, on the east side of the Nile; 23 miles S. of Abu Girgê. This burgh is governed by a cachef; and west of it are two Coptic monasteries, situated at the entrance of the desert. Their churches are ornamented with Corinthian pillars, with a cross in the middle of the capital; and they are paved with red granite, covered with hieroglyphics. Their architecture is said by Savary to indicate the decline of taste among the Greeks. They are thought to have been built by the empress Helena. On the space between them are strewed antique marbles. These remains point out the site of Crocodilopolis, or the sacred city of this name, which was far from the river, and which Ptolemy places after Aphroditopolis, or the city of Venus.

SOUADY, or SOHAR, a small island in the Arabian sea, near the coast of Oman. N. lat. 24° 14'.

SOVANA, a town of Etruria, the see of a bishop; 45 miles N.N.W. of Rome.

SOUANANPOUR, a town of Hindoostan, in Golconda; 10 miles S. of Hydrabad.

SOVANOCALCHI, in *Ancient Geography*, a people of Asiatic Sarmatia, upon the banks of the Euxine sea. Ptolemy.

SOUBES, in *Geography*, a town of France, in the department of the Herault; 3 miles N. of Lodeve.

SOUBIZE, a town of France, in the department of the Lower Charente; 3 miles W. of Rochefort.

SOUC, a town of Thibet; 360 miles N.N.E. of Lassa. N. lat. 33° 18'. E. long. 94° 24'.

SOUCTOU, a mountain of Thibet. N. lat. 32° 18'. E. long. 84° 19'.

SOUCY, a town of France, in the department of the Yonne; 19 miles S. of Provins.

SOUDAH, a rocky desert country of Africa, between Tripoli and Fezzan.

SOUDAN, from *Souda* or *Suda*, which signifies in Arabic *black*, a name given by the Moors and Arabs to Negroland, or Nigritia; and sometimes more particularly to the empire of Haussa, or Houssa. Abulfeda includes the whole lower part of Africa, south of the Great Desert and Egypt, under the denomination of Belad Soudan, or the country of Soudan. With him Soudan is the southern quarter of the globe; and d'Herbelot also allows it a wide range. See NEGROLAND.

SOUDE ST. CROIX, a town of France, in the department of the Marne; 10 miles W. of Vitry.

SOVEIB, a town of the Arabian Irak, on the Euphrates; 20 miles N.W. of Bassora.

SOUE-KI, a town of China, of the third rank, in Quang-tong; 30 miles S.W. of Hoa.

SOVEL, a small island in the Chinese sea, near the coast of Tonquin. N. lat. 11° 2'. E. long. 105° 25'.

SOUE-OUIE-CHAN, a town of Corea; 30 miles N.W. of Long-kouan.

SOVERDEM, a town of Italy; 3 miles N. of Belluno.

SOVEREIGN, SUPREME, the chief and highest Being, or the Almighty; a term, in strictness, only applicable to God.

The word is French, *soverein*; which Pasquier derives farther from the Latin *superior*, the first in any thing; or he who is superior to the rest. Hence,

In the ancient French customs we meet with sovereign master of the household; sovereign master of the forests; sovereign master of the treasury. Under Charles VI. the

title sovereign was given to bailiffs and seneschals, with regard to their superiority over prevots, and chatelains.

SOVEREIGN, with regard to subjects, is applied to kings and princes, who are supreme and independent.

The authority of a sovereign is only bounded by the law of God, of nature, and the fundamental laws of the state. See KING. See SOVEREIGNTY, *infra*.

SOVEREIGN is also a title given to such as are invested with certain rights and prerogatives, which belong only to sovereigns; as the power of coining money, sending agents to diets, to treat of war and peace, &c.

In which sense the feudatories of the empire, and the tributaries of the grand signior, are called sovereigns.

SOVEREIGN is also applied to courts and judges, who have a power from a prince to decide the processes of his subjects without appeal, or in the last resort.

At Paris, under the old regime, there were five sovereign companies: the parliament, the chamber of accounts, the court of aids, the grand council, and the court of monies.

In England we have but one sovereign court, which is the house of lords.

SOVEREIGN, in *English Coinage*, a gold coin of 20s. value, equal to the double ryal, which was coined by order of Henry VII. in the year 1485; and this was accompanied by the double sovereign of 40s. Henry VIII., in 1527, added to the gold denominations sovereigns of 22s. 6d., and ryals of 11s. 3d., angels of 7s. 6d., and nobles at their old value of 6s. 8d. In 1546 the same prince, after raising the value of silver, and making it to gold as 1 to 5, struck sovereigns of the former value of 20s., and half-sovereigns in proportion. Upon the union of the crowns, James I. of England gave the sovereign the name of unite, it being then of 20s. value. The sovereign, which had been commonly termed the "broad-piece," under the Commonwealth assumed the univindious name of the twenty-shilling piece, which it retained till supplanted by that of the guinea, which was proclaimed in 1663, and to pass for 20s. But it never went for less than 21s. by tacit and universal consent. Pinkerton's *Ess. on Medals*, vol. ii.

SOVEREIGNTY, in *Political Economy*, denotes that public authority, which commands in civil society, ordering and directing what each is to perform, in order to obtain the end of its institution. This authority belonged originally and essentially to the body of the society, to which each member submitted, and ceded the rights he received from nature, to conduct himself in every thing as he pleased, according to the dictates of his own understanding, and to do himself justice. But the body of this society does not always retain this sovereign authority: it frequently trusts it to a senate, or to a single person. This senate, or this person, is then the sovereign. (See SOVEREIGN, *supra*.) It is evident that men form a political society, and submit to laws, solely for their own safety and advantage. The sovereign authority is then established, only for the common good of all the citizens; and it would be absurd to think that it could change its nature, on its passing into the hands of a senate, or a monarch. Flattery, therefore, cannot disown, without rendering itself equally ridiculous and odious, that the sovereign is only established for the safety of the state, and the advantage of society.

A good prince, a wise conductor of society, ought to have his mind impressed with this great truth, that the sovereign power is only entrusted with him for the safety of the state, and for the happiness of all his people; that he is not permitted to seek himself in the administration of affairs, to propose his own satisfaction, or his private advantage; but that he ought to direct all his views, all his steps, to

SOVEREIGNTY.

the great advantage of the state and people who have submitted to him. How noble a sight is it, says the admirable Vattel, to see a king of England acquaint his parliament with all his principal operations; assure that body, the representatives of the nation, that he proposes no other end but the glory of the state, and the happiness of his people; and affectionately thank all who concur with him in such salutary views! Certainly a monarch, who makes use of this language, and proves his sincerity by his conduct, is, in the opinion of the wise, the only great man. But for a long time a base flattery has, in most kingdoms, caused these maxims to be forgotten. A crowd of fervent courtiers without difficulty persuade a proud monarch, that the nation was made for him, and not he for the nation. He soon considers the kingdom as his patrimony, and his people as a herd of cattle, from which he may obtain riches, and dispose of them so as best to answer his views, and gratify his passions. From thence arise those fatal wars, undertaken by ambition, selfishness, hatred, and pride: from thence those oppressive taxes, dissipated by luxury, or squandered upon mistresses and favourites: from thence, in fine, are important posts given by favour, while public merit is neglected, and every thing that does not immediately interest the prince, abandoned to ministers and subalterns. Who can observe, in this unhappy government, authority established for the public welfare? A great prince will be on his guard, even against his virtues. Let us not say, with some writers, that private virtues are not the virtues of kings; the maxim of superficial politicians, or of those who are very inaccurate in their expressions. Goodness, friendship, gratitude, are still virtues of the throne; and would to God they were to be always so! But a wise king does not, without discernment, give himself up to their impressions. He cherishes them, he cultivates them in his private life; but in state-affairs he listens only to justice and sound politics. And why? because he knows that the government was trusted to him only for the happiness of society; and that, therefore, he ought not to consult his own pleasure in the use he makes of his power. He tempers his goodness with wisdom. He gives to friendship his domestic and private favours; he distributes posts and employments according to merit; public rewards to services done to the state. In a word, he uses the public power only with a view to the public welfare. All this is comprehended in the fine saying of Lewis XII., "A king of France does not revenge the injuries of a duke of Orleans."

A political society is a moral person, as it has an understanding and a will, of which it makes use for the conduct of its affairs, and is capable of obligations and laws. When, therefore, a people confer the sovereignty on any one person, they invest him with their understanding and will; and make over to him their obligations and rights, so far as relates to the administration of the affairs of state, and the exercise of the public authority; thus the sovereign, or conductor of the state, becoming the subject, in which reside the obligations and rights relative to government, in him is found the moral person, who, without absolutely ceasing to exist in the nation, acts from thence forwards only in and by him. Such is the origin of the representative character attributed to the sovereign: He represents the nation in all the affairs it was capable of managing as sovereign. It does not debase the dignity of the greatest monarch to attribute to him this representative character; on the contrary, nothing can make him shine with greater lustre: for by this means the monarch unites, in his own person, all the majesty that belongs to the entire body of the nation.

The sovereign, thus clothed with the public authority, with every thing that constitutes the moral personality of the nation, is under the obligations of that nation, and invested with its rights.

Every thing that concerns the general duties of a nation towards itself, particularly regards the sovereign. He is the depositary of the empire, and of the power of commanding whatever relates to the public welfare: he ought, therefore, as a tender and wise father, and as a faithful administrator, to watch for the nation, to take care of preserving it, to render it more perfect, to better its state, and to secure it, as much as he is able, from every thing that threatens its safety, or its happiness.

The prince derives his authority from the nation; and it is exactly equal to what they have entrusted him with. If the nation has simply and strictly invested him with the sovereignty without limitation, or division, he is supposed to be invested with all the prerogatives, without which the sovereign command, or authority, could not be exerted in the manner most conducive to the public welfare. These are called *regal prerogatives*, or *the prerogatives of majesty*.

But the sovereign power is limited and regulated by the fundamental laws of the state: those laws shew the prince the extent and bounds of his power, and the manner in which it ought to be exerted. The prince is, therefore, strictly obliged not only to respect, but also to support them. The constitution and the fundamental laws are the plan on which the nation has resolved to endeavour the obtaining of happiness: the execution is entrusted to the prince. If he religiously follows this plan; if he regards the fundamental laws as inviolable and sacred rules, and knows that the moment he deviates from them, his commands become unjust, and are no less than a criminal abuse of the power with which he is entrusted. He is, in virtue of this power, the guardian and defender of the laws; and being obliged to punish any one who shall presume to violate them, he himself ought not to trample them under his feet.

While the laws of a society, over which a sovereign presides, subsist, he ought religiously to maintain and observe them. This is no less his true interest than his duty. But in explaining this submission of the prince to the laws, Vattel observes, that he is above all civil penal laws. The majesty of a sovereign will not suffer his being punished like a private person; and his employments are too sublime to admit of his being troubled, under the pretence of a fault that does not directly concern the government of the state. His person, therefore, should be regarded as inviolable. Nevertheless, this high attribute of sovereignty is no reason why a nation should not curb an insupportable tyrant, call him even to an account, respecting in his person the majesty of his rank, and withdraw itself from his obedience. To this indisputable right a powerful republic owes its birth. The tyranny exercised by Philip II. in the Netherlands, excited those provinces to rise: seven of them, closely confederated, bravely maintained their liberties, under the conduct of a hero of the house of Orange; and Spain, after several vain and destructive efforts, acknowledged them sovereign and independent states. If the authority of the prince is limited and regulated by the fundamental laws, the prince, on leaving the bounds prescribed him, commands without any right, and even without a just title: the nation, then, is not obliged to obey him, but may resist his unjust enterprizes. As soon as he attacks the constitution of the state, the prince breaks the contract which bound the people to him; the people became free by the act of the sovereign, and see nothing in him but an usurper who would load them with oppression. This truth is acknowledged by every sensible

writer, whose pen is not enslaved by fear, or rendered venal by interest. But some celebrated authors maintain, that if the prince is invested with the supreme command in a full and absolute manner, nobody has a right to resist him, much less to curb him, and that the nation has no resource left but to suffer and obey with patience. This is founded upon the supposition that such a sovereign need not give an account to any person of the manner in which he governs; and that if the nation might controul his actions and resist him, where they were found to be unjust, his authority would no longer be absolute; which would be contrary to this hypothesis. They say, that an absolute sovereign possesses completely all the political authority of the society, in which nobody can oppose him; if he abuses it, he does ill, indeed, and wounds his conscience, but that his commands are not the less obligatory, as being founded on a lawful right to command: that the nation, by giving him absolute authority, had reserved nothing to itself, and had submitted to his discretion, &c. We might satisfy ourselves with answering, that in this light there is not any sovereign who is completely and fully absolute. But in order to remove all these vain subtilties, let us remember the essential end of civil society: is it not to labour in concert for the common happiness of all? Is it not with this view that every citizen strips himself of his rights, and resigns his liberty? Was it in the power of the society to make such use of its authority as to deliver up itself, and all its members, without relief, to the discretion of a cruel tyrant? No, certainly, since it had no right itself, if it was disposed to it, to oppress a part of the citizens. When it, therefore, conferred the supreme and absolute government, without an express reserve, it was necessarily with the tacit reserve, that the sovereign should use it for the safety of the people, and not for their ruin. If he becomes the scourge of the state, he degrades himself; he is no more than a public enemy, against whom the nation may and ought to defend itself; and if he has carried his tyranny to the utmost height, why should even the life of so cruel and perfidious an enemy be spared? Who presumes to blame the Roman senate, that declared Nero an enemy to his country?

But it is of the utmost importance to observe, that this judgment can only be passed by the nation, or by the body by which it is represented; and that the nation itself cannot make any attempt on the person of the sovereign, but in cases of extreme necessity, and when the prince, by violating the laws, and threatening the safety of his people, puts them in a state of war against them. The person of the sovereign, the very interest of the nation declares sacred and inviolable; but not that of an unnatural tyrant, and an enemy of the public. We seldom see such monsters as Nero.

As soon as a nation acknowledges a prince for its lawful sovereign, all the citizens owe him a faithful obedience. He can neither govern the state, nor perform what the nation expects from him, if he is not punctually obeyed. Subjects then have no right, in doubtful cases, to question the wisdom or justice of their sovereign's commands; this examination belongs to the prince: his subjects ought to suppose, if there be a possibility of doing it, that all his orders are just and salutary: he alone is accountable for the evil that may result from them.

In the mean time, this ought not to be entirely a blind obedience. No engagement can oblige, or even authorize, a man to violate the laws of nature. All authors who have any regard to conscience, or modesty, agree, that a person ought not to obey such commands as are evidently contrary to the laws of God. Those governors of places,

who bravely refused to execute the barbarous orders of Charles IX. to the famous St. Bartholomew, have been universally praised; and the court did not dare to punish them, at least openly. "Sire," said the brave Orte, governor of Bayonne, in his letter, "I have communicated your majesty's command to your faithful inhabitants and warriors in the garrison; and I have found there only good citizens and brave soldiers: not one hangman; therefore, both they and I most humbly entreat your majesty, to be pleased to employ our arms and lives in things that are possible, however hazardous they may be, and we will exert ourselves to the last drop of our blood." The count de Tende, Charney, and others, replied to those who brought them the orders of the court, that they had too great a respect for the king, to believe that such barbarous orders came from him.

It is not easy to determine in what cases a subject may not only refuse to obey, but even resist a sovereign, and by force repel force. However, when the injuries, which society suffers, are manifest and atrocious; when a prince, without any apparent reason, is resolved to deprive us of life, or of those things, the loss of which would render life bitter, who can dispute our right to resist him? Self-preservation is not only a law of nature, but an obligation imposed by nature, and no man can entirely and absolutely give it up to another. And though he might give it up, can he be considered as having done it by his political engagements, when he entered into society only to establish his own safety upon a more solid basis? The welfare of society does not require such a sacrifice; and as Barbeyrac well observes in his notes on Grotius, "If the public interest requires, that those who obey should particularly suffer something; it is not less for the public interest that those who command, should be afraid of carrying their patience to the utmost extremity." The prince who violates all laws, who observes no measures, and who would in his transports of fury take away the life of an innocent person, strips himself of his royalty, and is no more than an unjust and outrageous mortal, against whom his people are allowed to defend themselves. But he who, after having lost all the sentiments of a sovereign, divests himself even of the appearances and exterior conduct of a monarch, degrades himself; he no longer retains the sacred person of a sovereign, and cannot retain the prerogatives attached to his sublime character. However, if this prince is not a monster, if he is furious only from a just passion, and is supportable to the rest of the nation; the respect we ought to pay to the tranquillity of the state is such, and the respect of sovereign majesty so powerful, that we are strictly obliged to seek every other means of preservation, rather than to put his person in danger. Every one knows the example set by David: he fled; he kept himself concealed, to secure himself from Saul's fury; and more than once saved the life of his persecutor. When the reason of Charles VI. of France was suddenly disordered by a fatal accident, he in his fury killed several of those who surrounded him: none of them thought of securing his own life, at the expence of that of the king; they only endeavoured to disarm him, and to make him master of himself: they did their duty like brave men and faithful subjects, in exposing their lives, to save that of this unfortunate monarch. We owe this sacrifice to the state and to sovereign majesty. Furious from the disorder of his organs, Charles was not guilty; he might recover his health, and again become a good king.

We shall here further observe, that a sovereign is undoubtedly allowed to take ministers, to ease him in the painful office of government; but he ought never to abandon

don his authority to them. Ministers ought only to be instruments in the hands of the prince; he ought constantly to direct them, and continually endeavour to know whether they follow his instructions. Ministers, however, who undertake this charge, become responsible to the state for their conduct; for the advice which they are supposed to give to the sovereign, and for the measures which they adopt and pursue. Vattel's Law of Nations, b. i. ch. 4.

SOVERICK, in *Geography*, formerly known by the name of *Sauro*, a town of the pachalic of Orfa, a pachalic which is almost entirely encircled by the windings of the Euphrates and the river Khabour, and occupying a considerable portion of the most barren part of Mesopotamia. The town is situated, according to Niebuhr, in N. lat. $37^{\circ} 48'$, and contains about 500 inhabitants, with three mosques, and a strong castle. The country to the south of the parallel of Soverick is, for the most part, flat, sandy, and uncultivated, and inhabited by tribes of wandering Arabs, who pitch their tents on the banks of the rivers, and in the vicinity of springs. From Soverick to Diarbekir it is more mountainous, and better inhabited.

SOUF, or VOSTANI, the middle district of Egypt, between the Bahira and Said.

SOUFFEL, a river of France, which runs into the Rhine, four miles below Strasburg.

SOUFFLEUR, Fr., the bellows-blower of an organ.

SOUFFLOT, JAMES-GERMAIN, in *Biography*, an eminent architect, was born in 1714 at Irancy, near Auxerre. His father, an advocate in parliament, destined him for his own profession, and sent him, while very young, to Paris for education; but he felt a taste and inclination for the science of architecture. Having been employed for some time in that art at Lyons, he went into Italy, where, by his talents and industry, he was admitted one of the king's pensioners. It being resolved that several public buildings should be erected at Lyons, he was recommended to undertake a part of the work, by the director of the French academy at Rome; and the construction of the exchange and the hospital was committed to him. The noble simplicity of the hospital, together with its excellent adaptation to the object for which it was intended, were universally admired, and raised him to high reputation as an artist. He was, after this, employed to build the concert-room and theatre of the same city. He next travelled into Italy, and on his return he settled at Paris, where he was successively made controller of the buildings at Marly and the Tuilleries, member of the academies of architecture and painting, knight of St. Michael, and intendant of the royal buildings. In 1757 he laid the foundation of the church of St. Genevieve, of which he was able only to finish the portal, the nave, and the towers. In this business he subjected himself to some severe criticism, especially with respect to the possibility of erecting the intended dome upon the bases designed to bear it; though some exact calculations justified his plan. The criticisms and unfriendly remarks of his rivals were more than his temper, naturally irritable, could bear; and he died, partly of chagrin, in the year 1780, at the age of 67. Besides the public works already mentioned, he executed many others, which display the powers of a great artist; and after his death, M. Dumont, professor of architecture, published a book of Designs, which he had left behind him, under the title of "Elevations et Coupes de quelques Edifices de France et d'Italie, dessinées par feu M. Soufflot, Architecte du Roi, et gravées par ses Ordres." Though Soufflot was rough and hasty in his manners, he was kind and friendly; whence he obtained the name of *le Bourru Bienfaisant*.

SOUFFRIERE BAY, in *Geography*, a bay on the east coast of the island of Dominica. N. lat. $15^{\circ} 31'$. W. long. $61^{\circ} 17'$.

SOU-FONG, a town of China, of the third rank, in Kiang-nan; 47 miles S.W. of Ngan-king.

SOUGH, in *Agriculture*, a covered drain of any size, but commonly of the more large kind. Sough drains are most commonly employed in the business of spring-draining, though occasionally in other modes. See *SPRING-Drain* and *SPRING-Draining*.

SOUGH, otherwise called an *Adit*, in *Mineralogy*, is a passage like a vault cut out under the earth, to drain the water from the mines.

In a canal, it denotes a small culvert or leading.

SOUHAITOU, in *Geography*, a town of Thibet; 28 miles W.N.W. of Yolotou Hotun.

SOUI, a city of China, of the second rank, in Hou-quang; 527 miles S. of Peking. N. lat. $31^{\circ} 48'$. E. long. $112^{\circ} 40'$.

SOU-CHONTO, a town of Chinese Tartary, in the country of Hami. N. lat. $41^{\circ} 8'$. E. long. $94^{\circ} 37'$.

SOVIESE, a town of European Turkey, in Moldavia; 44 miles W. of Birlat.

SOU-KI, a town of China, of the third rank, in Quang-tong; 30 miles N. of Louy.

SOULLAC, a town of France, in the department of the Lot, and chief place of a canton, in the district of Gourdon. The place contains 1654, and the canton 8158 inhabitants, on a territory of $182\frac{1}{2}$ kilometres, in 10 communes.

SOUILLY, a town of France, in the department of the Meuse, and chief place of a canton, in the district of Verdun. The place contains 792, and the canton 7528 inhabitants, on a territory of 230 kilometres, in 21 communes.

SOUIN-HING, a town of China, of the third rank, in Hou-quang; 20 miles E.S.E. of Tsin.

SOU-PIING, a town of China, of the third rank, in Ho-nan; 17 miles W.N.W. of Yun-hing.

SOU-TCHEOU, a city of China, of the first rank, in Se-tchuen, at the conflux of the rivers Yan and Kincha; 850 miles S.W. of Peking. N. lat. $28^{\circ} 40'$. E. long. $104^{\circ} 23'$.

SOU-TE, a city of China, of the second rank, in the province of Chen-si, on the Voutin river; 337 miles W.S.W. of Peking. N. lat. $37^{\circ} 38'$. E. long. $109^{\circ} 34'$.

SOU-YANG, a town of China, of the third rank, in Se-tchuen; 20 miles N.N.E. of Tfun-y.

SOUKAPURA, a kingdom on the south coast of the island of Java.

SOUKENE, a town of Africa; 130 miles S. of Tripoli.

SOUKERKE, a town of France, in the department of the Lys; 5 miles N.W. of Bruges.

SOUKETON, a river of New Hampshire, which runs into the Merrimack, N. lat. $42^{\circ} 48'$. W. long. $71^{\circ} 30'$.

SOU-KISE, a town of China, in Hou-quang, on the river Lo; 55 miles N.N.W. of Pao-king.

SOUL, ANIMA, a spirit adapted to an organized body. See *SPIRIT* and *BODY*.

Many of the ancient philosophers asserted an *ANIMA Mundi* (which see), a soul which moved and animated the machine of the universe, and gave action to all natural causes. This doctrine Plato handles very fully in his *Timæus*. (See *PLATONISM*.) For the doctrine of the Stoics on this subject, see *STOICS*. See also *PHERECYDES*.

The ancient Indians, who possibly derived their notions of

of God and providence from the Persian Zoroaster, conceived God to be the soul of the world, a rational and intellectual light, from which all good is derived, and the chief feat of whose divinity is the sun. Their notion of divine providence, deduced from that of the soul of the world, probably extended no farther than that this principle is necessarily the first spring of all motion, life, and enjoyment; and fell far short of that wise and gracious voluntary superintendance, which is the Christian idea of Providence.

Others have given particular souls to all the heavenly bodies, the sun, stars, earth, &c. to regulate their motions. The philosophers, many of them, allow of two, and others of three, kinds of souls; *viz.* a

SOUL, Rational, which they hold to be divine, and infused by the breath of God. This they call the spirit, and in this they suppose the intellect and will to be seated.

SOUL, Sensitive, or Irrational, which man has in common with brutes; which is formed out of the elements, and in which they apprehend the passions and appetites are seated.

SOUL, Vegetative, which we have in common with plants; and, as the first is the principle of reason and understanding, or that in us which thinks and understands; and the second, the principle of life; this is the principle of growth, nutrition, and vegetation.

The first ancient philosopher who taught the immortality of the soul, is said to have been Pherecydes. (See his article.) The human mind, according to the doctrine of the ancient Indians (see BRACHMANS), is of celestial origin, and has a near relation to God. When it departs from the body, it returns to its parent, who expects to receive back the souls which he has sent forth. The human soul they represented as of divine original, because, with all the other eastern nations, they conceived it to be a particle, or an emanation, of that intellectual fire, by which they believed the universe to be animated. Their doctrine of the return of the soul to God, which some have confounded with the Christian doctrine of the resurrection, seems to have meant nothing more than that the soul, after being disengaged from the grosser material body, would be reunited to the fountain of all being, the soul of the world. For the opinion of the Egyptians concerning the human soul, we refer to the article EGYPT.

Among the northern nations it was a generally received opinion, that the human soul was of divine original, rational and immortal. That this was the universal doctrine of the Celts, whether Gauls, Britons, Germans, or other nations, is unanimously attested by the Greek and Roman writers, and by the remains of northern antiquities. Cæsar informs us (Bell. Gall. lib. vi. c. 14.), that the first doctrine of the Gallic Druids was, that the soul of man is immortal; and Pomponius Mela (lib. iii. c. 2.) says, that one of their doctrines, which was divulged among the people in order to inspire them with martial courage, was, that the soul is immortal. This account is confirmed by Valerius Maximus (l. ii. c. 6.), Strabo (l. iv.), and other historians. And the fables every where received among the Celts concerning a future state, leave no room to doubt, that the doctrine of the immortality of the soul was generally received among them.

“ Without or breath, or reasoning pow’rs, or speech,
Or vital blood, or the fair human face,
Askus and Emla lay: till Odin bade
Them live, Hænerus kindled in their breast
The lamp of mind, and Lædur through their veins
Pour’d forth the purple stream; thus man arose,
Graceful in youth, an animated form.”

The history of all the northern nations abounds with facts, which prove that their contempt of death originated from an expectation of immortality. It does not, however, certainly appear, what kind of immortality these nations expected. According to Cæsar (l. ii. c. 6.) and Diodorus Siculus (l. i.), they thought, that the soul at death passes from one body to another. This doctrine of transmigration is also ascribed to them by Lucan (Pharf. l. i. v. 454.)

“ If dying mortals doom they sing aright,
No ghosts descend to dwell in dreadful night;
No parting souls to grisly Pluto go,
Nor seek the dreary silent shades below:
But forth they fly, immortal in their kind,
And other bodies in new worlds they find:
Thus life for ever runs its endless race,
And, like a line, death but divides the space.” Rowe.

On the contrary, Pomponius Mela represents the Celts as expecting to pass, after death, into the invisible world. And this notion best agrees with the accounts, which are given by various writers, of the funeral ceremonies practised in the northern nations, particularly that of committing to the funeral pile, or to the sepulchre, whatever had been dear to the deceased. It is also most consonant to the language of the ancient Edda, which every where represents the future life, as an assembly of good or bad men, in a state of reward or punishment, and only speaks of a return to life for the purpose of reuniting the soul and body, after the soul has passed through a necessary course of purification, previously to its admission into the regions of the happy. From this state of purgation none were to be excused, except those who had voluntarily exposed themselves to death in battle: and hence it was, that they who fell in war were deemed to have made a glorious and happy exit from life, whilst they who died by sickness were thought to have perished shamefully and wretchedly. See CELTS and DRUIDS.

Of the opinion of Socrates concerning the human soul, we have already given an account under the article SOCRATES. For Plato’s opinion, see PLATONISM. For an account of the Aristotelian doctrine on this subject, see ARISTOTLE. Strabo taught that the seat of the soul is in the middle of the brain; and that it only acts by means of the senses. (See STRABO.) Dicaearchus, of whom Cicero speaks as a learned and eloquent writer, maintained, that there is no such thing as mind, or soul, either in man or beast; that the principle, by which animals perceive and act, is equally diffused through the body, is inseparable from it, and expires with it. For the opinion of the Stoics, see STOICS. For the opinion of Pythagoras and his followers, see PYTHAGOREANS. See also EMPEDOCLES, DEMOCRITUS, and HERACLITISM.

The Epicureans took the substance of the soul, we mean of the rational soul, to be a subtle air, composed of their atoms, or primitive corpuscles. See EPICUREANS.

The tenets of the modern Platonists with regard to the soul of man, may be found in the writings of Plotinus, Jamblichus, and Porphyry, who may be reckoned among the principal persons that belonged to the Eclectic sect. Plotinus taught, that the first principle of the universe, which is distinct from the universe, is the cause of intellectual life and the source of essence and being, simple in its own nature, and having no place, and destitute both of motion and rest; infinite and unlimited, essentially good, and fair and beautiful, the author of all that is lovely, the beginning and end of beauty. From this first principle proceeds

proceeds mind, or intellect, and soul, or the active principle. The primary essential good is the centre; mind, the light emerging from it, and remaining fixed; soul, the motion of the emerging light; and body, the opaque substance, which is illumined by the soul. From the emanative energy of mind is produced soul, or the active principle of life. This divine principle is the fountain, whence all life is derived. It subsists, as well as intellect, within the divine essence, and is therefore *ὑπερέσμιον*, supramundane. This is the immediate source of the principle which animates the world, *ἐγκόσμιον*, and which is diffused, in various portions, through animated nature. The souls of men and inferior animals constitute the common limit between the intellectual and sensible world. The human soul is derived from the supramundane soul, or first principle of life, and is in this respect sister to the soul of the world. Souls are not in the body as their place, nor as their receptacle, nor as their subject, nor as a part of a whole, nor as form united to matter, but simply as the animating principle; and it is in this respect only, that we know the soul to be present with the body. The power of the soul is diffused through every part of the body; and though it be said to reside in its chief instrument the brain, it is incorporeal, and exists entirely every where within the sphere of its energy. Partaking of the nature of real being, it is immutable. It is the principle of motion, moving itself, and communicating motion to bodies. The vices and infelicities of the soul, are wholly derived from its union with the body.

Souls, in the periodical revolutions of nature, separate themselves from their fountain, and descend into the lower regions of the world. In their passage, they attract to themselves an ethereal vehicle, and at last sink into animal bodies, as into a cavern or sepulchre. But when, by the power of reminiscence, they again turn themselves to the contemplation of intelligible and divine natures, they regain their freedom. God, on account of his greatness, is not known by intelligence or sense, but by a kind of intuition superior to science, by means of which the soul can see him in his real nature, as the fountain of life, mind, and being, and the cause of good. A soul which has attained to this vision of God will lament its union with the body, and will rejoice to leave its prison, and return to the divine nature from which it proceeded. After death, the souls of men pass into other animals, or ascend into superior regions, and are converted into beings of an higher order, according to their present degree of defilement or of purification.

The human soul, according to Jamblichus, has an innate knowledge of God, prior to all reasoning, having originally derived its essence from, and subsisted in, the divine nature. By the intervention of *dæmons*, it enjoys communications with the superior divinities, and with God himself. Prayers, hymns, lustrations, and sacrifices are the means by which this intercourse is maintained. The mind of man, as we learn from the writings of Porphyry and others, originally a portion of the divine nature, having fallen into a state of darkness and defilement by its union with the body, is to be gradually emancipated from the chain of matter, and by contemplating real entities, to rise to the knowledge and vision of God. The end of philosophy is, therefore, the liberation of the soul from its corporeal imprisonment. For this purpose it must pass through the several stages of the human and divine virtues. The human virtues are physical, economical, and political; or those which respect the care of the body, and the offices of domestic and civil life. The divine virtues are purgative, theoretic, and therapeutic: the first class consists in bodily abstinence, and other

voluntary mortifications; the second comprehends all those exercises of the intellect and imagination, by which the mind contemplates abstract truth, and intelligible natures; the third includes those religious exercises, by which the philosopher is qualified for, and admitted to, an immediate intercourse with superior beings, attains a power over *dæmons*, and ascends so far above the ordinary condition of humanity, as to enjoy the vision of God in this life, and to return, at death, to the divine mind, whence it first proceeded. Thus, we have given a specimen of the visionary subtleties of the Alexandrian philosophy, or that of the Eclectic sect.

According to the popular doctrine of the Jews, in and after the tenth century, the soul of man is a thinking substance, having three faculties, the vegetative, the sensitive, and the rational: it is possessed of liberty, and is immortal. After death it is not immediately admitted to celestial joys, but wanders in this world, chiefly about its body, during which time it is tormented by evil *dæmons*; in this purgatory it is cleansed from its stains; after which it passes into either bodies of men, or inferior animals. There will be a resurrection of the bodies of dead men, and an universal judgment, which will be succeeded by a state of retribution. The soul will enjoy eternal life in paradise, and the wicked will be consigned to the infernal regions; the Jew for a time, but the infidel for ever. The world will be destroyed; but the materials of which it is composed will remain. Thus the modern Jews blended tenets, which they derived from their sacred scriptures, with opinions which they borrowed from their Gentile neighbours. They first suffered their doctrines to be corrupted by the Egyptian philosophy, and afterwards learned from the Saracens to reason, after the Peripatetic manner, upon metaphysical subjects; of which examples may be seen in the writings of Maimonides, and in the book *Cofri*. The human soul, according to the Cabbalistic doctrine, proceeding by emanation from the Deity, is an incorporeal substance, of the same nature with the divine intellect. Being united to the body, one complex nature is produced, endued with reason, and capable of action. The human soul consists of four parts, "nephesh," or the principle of vitality; "ruach," or the principle of motion; "nefchamah," or the power of intelligence; and "jehidah," a divine principle, by means of which it contemplates superior natures, and even ascends to the *Enfophic* world. All souls were produced at once, and pre-existed in Adam. Every human soul has two guardian angels, produced by emanation, at the time of the production of souls. The mind of man is united to the divine mind, as the radius of a circle to its centre. The souls of good men ascend above the mansion of angels, and are delighted with the vision of the first light, which illuminates all the world.

The doctrine of the Arabians, stated by Al-Gazel, is, that the souls of men are immortal, and that their bodies will be raised from the dead. In the interval between death and the resurrection, souls remain in an intermediate state; and after the resurrection the good and faithful shall be rewarded, and the wicked and unbelieving shall be punished; but they who, after having suffered punishment, shall confess one God, will, through his favour, be released from their confinement, and placed among the blessed.

The Cartesians make thinking the essence of the soul; and, from this principle, deduce its immateriality and immortality. But, according to Mr. Locke, &c. the principle is false; nor is there any need to define the soul a substance that thinks, to prove it immortal. It is enough that the soul be capable of thinking, and that it produce its own thoughts,

thoughts, without making thinking its essence. It is no more essential to the soul to think than to will; for a thing I can conceive the soul without, cannot be its essence.

Again, if thought be the essence of the soul, as a thing cannot produce itself, its own being, or essence; the soul does not produce its own thoughts, nor its own will: and thus it is brought to the condition of brutes, or even of inanimate bodies, without any action, any liberty, &c.

If the Cartesians only mean this of the faculty of thinking, they do wrong even to call this the essence of the soul. It is no more its essence than the faculty of willing is. And we conceive something in the soul prior to both those faculties.

The soul is a spiritual substance, proper to inform or animate a human body: and, by its union with this body, to constitute a reasonable animal or man. This is its essence, and this its definition.

It must be owned, the Cartesians prove the spirituality and immortality of the soul, from its thinking, exceedingly well; but they are not to have the honour of this proof as their own invention. All the great philosophers used it before them, and use it still.

For an account of Leibnitz's doctrine concerning the soul, see LEIBNITZ, LEIBNITZIAN *Philosophy*, MONAD, and *Pre-establiſhed HARMONY*.

Spinoza, and his followers, allowing only of one kind of substance, *viz.* matter; maintain the soul to be of the same substance with the body, *viz.* material. See SPINOZISM.

The doctrine of the materiality of the human soul has been adopted and maintained by several modern writers; and even by those who have distinguished themselves as able and zealous advocates in the cause of religion, both natural and revealed. In this number we may reckon Dr. Priestley, who, rejecting the commonly received notion of matter, (see MATTER,) as an absolutely impenetrable, inert substance, and premising, that the powers of sensation or perception, and thought, as belonging to man, have never been found but in conjunction with a certain organized system of matter, maintains, that those powers necessarily exist in, and depend upon, such a system. In proof of this doctrine, it is alleged, that perception and thought are not incompatible with the properties of matter, considered as a substance extended and endued with the powers of attraction and repulsion; and, therefore, if one kind of substance be capable of supporting all the known properties of man, true philosophy, which will not authorize us to multiply causes or kinds of substance, without necessity, will forbid us to admit of any substance in the constitution of human nature, essentially different from matter. The proper seat of the powers of perception and thought, according to this writer, is the brain; because, as far as we can judge, the faculty of thinking, and a certain state of the brain, always accompany and correspond to one another; and there is no instance of any man retaining this faculty, when his brain was destroyed; and whenever that faculty is impeded or injured, there is sufficient reason to believe that the brain is disordered in proportion. Dr. Priestley apprehends, that sensation and thought necessarily result from the organization of the brain, when the powers of mere life are given to the system, and that they follow of course, as much as the circulation of the blood follows respiration; but he professes to have no idea at all of the manner in which the power of perception results from organization and life.

To this reasoning it has been replied, in general, that Dr. Priestley's account of matter does not answer to the common ideas of matter, or that it is not solid extension, or an impenetrable and inert substance, which is the only matter that

is the object of natural philosophy; but something not solid, that exists in space, and so far agreeing with spirit; and consequently, if such matter is, as he asserts, the only matter possible, it will follow, not that we have no souls distinct from our bodies, but that we have no bodies distinct from our souls, and that all in nature is spirit. Besides, it has been farther urged, that a connection and dependence by no means prove sameness.

From the dependence of actual sensations and thought on the brain, we have no more reason to conclude that the brain is the mind, than a savage who had never heard the music of a harpsichord, and did not see the hand that played upon it, would have to conclude, that it played upon itself, and was the musician; because he could trace all the sounds to the instrument, and found that when the strings were out of order, the music was disturbed or destroyed. What experience teaches us is, that the exercise of the mental powers *depends* on the brain and the nerves; not that the mind *is* the brain and the nerves. We are sure the mind cannot be the brain, because the brain is an assemblage of beings; whereas the mind is one being.

It has been further objected by an anonymous writer (Edinb. Rev. N^o XVII.), that it is unphilosophical to class perception among the qualities of matter, when it is obvious, that it is by means of perception alone that we get any notion of matter or its qualities; and that it is possible, with perfect consistency, to maintain the existence of our perceptions, and to deny that of matter altogether. The other qualities of matter are perceived by us; but perception cannot be perceived; all we know about it is, that it is that by which we perceive every thing else. It sounds somewhat absurd and unintelligible, to say that perception is that quality of matter by which it becomes conscious of its own existence, and acquainted with its other qualities. It is plain that this is not a quality, but a knowledge of qualities; and that the percipient must necessarily be distinct from that which is perceived by it. We must always begin with perception; and the followers of Berkeley will tell us, that we must end there also. At all events, it certainly never entered into the head of any plain man to conceive, that the faculty of perception itself was one of the qualities with which that faculty made him acquainted; or that it could possibly belong to a substance, which his earliest intimations and most indelible impressions taught him to regard as something external and separate.

The following lines, if we may be allowed to avail ourselves of poetry in the illustration of a metaphysical question, forcibly express the universal and natural impression of mankind on this subject.

“Am I but what I seem, mere flesh and blood?
A branching channel, and a mazy flood?
The purple stream, that through my vessels glides,
Dull and unconscious flows like common tides.
The pipes, through which the circling juices stray,
Are not that thinking I, no more than they.
This frame, compacted with transcendent skill,
Of moving joints, obedient to my will,
Nursed from the fruitful glebe like yonder tree,
Waxes and waxes: I call it *mine*, not *me*.
New matter still the mouldering mass sustains;
The mansion changed, the tenant still remains,
And, from the fleeting stream repair'd by food,
Distinct, as is the swimmer from the flood.”

But, besides the impropriety of making the faculty of perception a quality of the thing perceived, and of absurdly converting our knowledge of the qualities of matter into another

another quality of the same substance, chargeable upon the doctrine of materialism, it is alleged that to call perception a *quality* at all, is a gross and unwarrantable abuse of language. Perception is an act or an event, a fact or a phenomenon, of which the percipient is conscious; but it cannot be intelligibly conceived as a quality; and, least of all, as a quality of that substance which is known to us as solid and extended. 1st. All the qualities of matter, it has been already stated, are perceived by the senses; but the sensation itself cannot be so perceived: nor is it possible to call it an object of sense, without the grossest perversion of expression. 2dly. All the qualities of matter have a direct reference to space or extension, and are conceived, in some measure, as attributes or qualities of the space within which they exist. When we say that a particular body is solid, we mean merely that a certain portion of space is impenetrable; when we say that it is coloured, we mean that the same portion of space appears of one hue,—and so of the other qualities: but sensation or thought is never conceived to occupy space, or to characterize it; nor can these faculties be at all conceived as definite portions of space, endued with perceptible properties. In the third place, all the primary qualities of matter are inseparable from it, and enter necessarily into its conception and definition. All matter must necessarily be conceived so extended, solid, and figured. It is obvious, however, that thought or sensation is not an inseparable attribute of matter, as by far the greater part of matter is entirely destitute of it; and it is found in connection with those parts which we term organized, only while they are in a certain state, which we call alive. If it be said, however, that thought may resemble those accidental qualities of matter, such as heat or colour, which are not inseparable or permanent; then we reply, that none of these things can properly be termed matter, more than thought or sensation; they are themselves substances, or matter possessed of inseparable and peculiar qualities, as well as those which address themselves to the other senses. Light is a material substance, from which the quality of colour is inseparable; and heat is a material substance, which has universally the quality of exciting the sensation of warmth. If thought be allowed to be a substance in this sense, it will remain to shew that it is material, by being referrible to space, and liable to attraction, repulsion, condensation or reflection, like heat or light.

Thought, as the advocates of materialism allege, is nothing else than motion; but, without attempting to define motion, it is sufficient to observe, that it is not a quality of matter; it is an act, a phenomenon, or a fact; but it makes no part of the description or conception of matter, though it only exists with reference to that substance. Let any man ask himself, however, whether the motion of matter bears any sort of resemblance to thought or sensation; or whether it be even conceivable that these should be one and the same thing? But, it is said, we find sensation always produced by motion; and as we can discover nothing else in conjunction with it, we are justified in ascribing it to motion. This is not the question. It is not necessary to inquire, whether motion may produce sensation or not, but whether sensation be motion, and nothing else. It seems pretty evident that motion can produce nothing but motion or impulse, and that it is at least as inconceivable that it should ever produce sensation in matter, as that it should produce a separate substance, called mind. But this is not the question with the materialists. Their proposition is, not that motion produces sensation, which might be as well in the mind as in the body; but that sensation is motion; and that all the phenomena of thought and perception are

intelligibly accounted for by saying, that they are certain little shakings in the pulpy part of the brain.

That sensation may follow motion in the brain, or may even be produced by it, is conceivable at least, and may be affirmed with perfect precision and consistency; but that the motion is itself sensation, and that the proper and complete definition of thought and feeling is, that they are certain vibrations in the brain, is a doctrine that can only be wondered at, and that must be comprehended before it be answered.

No advocate for the existence of mind, ever thought it necessary to deny that there was a certain bodily apparatus necessary to thought and sensation in man, and that on many occasions the sensation was preceded or introduced by certain impulses and corresponding movements of this material machinery; we cannot see without eyes and light, nor think without living bodies. All that they maintain is, that these impulses and movements are not feelings or thought, but merely the occasions of feeling and thought, and that it is impossible for them to confound the material motions which precede their sensations, with the sensations themselves, which have no conceivable affinity with matter.

Dr. Priestley farther argues, that all our ideas either proceed from the bodily senses, or are consequent upon the perceptions of sense; and hence infers, that the notion of the possibility of thinking in man, without an organized body, is not only destitute of all evidence from actual appearances, but is directly contrary to them. Moreover, if the mind was naturally so independent of the body, as to be capable of subsisting by itself, and even of appearing to more advantage after the death of the body, as some of the advocates for an intermediate state have maintained, it might, he says, discover some signs of its independence before its death, and especially when the organs of the body were obstructed, so as to leave the soul more at liberty to exert itself, as in a state of sleep or swooning, which most resemble the state of death, in which it is pretended that the soul is most of all alive, most active, and vigorous; but, judging by appearances, the reverse of all this is the case. Besides, if the mental principle was, in its own nature, immaterial and immortal, all its particular faculties would be so too; whereas we see that every faculty of the mind, without exception, is liable to be impaired, and even to become wholly extinct before death. Whence he infers, that the substance, or principle, in which these faculties exist, must be pronounced to be mortal too. He adds, if the sentient principle in man be immaterial, it can have no extension, but every thing within it, or properly belonging to it, must be simple and indivisible; and if this were not the case, the soul would be liable to corruption and death. But Dr. Priestley observes, that, whatever ideas are in themselves, they are evidently produced by external objects, and must therefore correspond to them; and since many of the objects or archetypes of ideas are divisible, it necessarily follows, that the ideas themselves are divisible also; and hence he infers, that the sentient principle in man, containing ideas which certainly have parts, and are divisible, and consequently having extension, cannot be that simple, indivisible, and immaterial substance, that some have imagined it to be; but something that has real extension, and therefore may have the other properties of matter. To this reasoning an excellent writer replies, that it would be as proper to assert that ideas are hard or round, as to assert that they are divisible. Perception is a single and indivisible act; and though the object perceived may be divisible, the perception of it by the mind cannot be so. Dr. Priestley farther adds, that

the soul possesses a great variety of mental affections, which necessarily imply alteration, especially melioration and depravation, which is something so similar to corruption, that it has universally obtained the same name, and which is certainly incompatible with natural and perfect simplicity. This writer alleges also, in favour of the system of materialism, that we hereby get rid of many difficulties, which must embarrass the opposite system; such, *e. gr.* as these—what becomes of the soul during sleep, in a swoon, when the body is seemingly dead (as by drowning, or other accidents), and especially after death? also what was the condition of it before it became united to the body, and at what time did that union take place? what are the nature and state of the souls of brutes? what is the use of the human body? &c. The system of materialism, he says, which revelation uniformly supposes, is clogged with no difficulties of this kind. Man, according to this system, is no more than what we now see of him. His being commences at the time of his conception, or perhaps at an earlier period. The corporeal and mental faculties, inhering in the same substance, grow, ripen, and decay together; and, whenever the system is dissolved, it continues in a state of dissolution, till it shall please that Almighty Being, who called it into existence, to restore it to life again. Accordingly the Christian system provides no reward for the righteous till the general resurrection of the just, nor any punishment for the wicked till the end of the world. Hence also the doctrine of the pre-existence of human souls, and that of the pre-existence of Christ, is rejected, as having no other foundation than the notion of there being something in man quite different from his corporeal organized system.

Dr. Priestley argues in many parts of his work on the supposition, that, according to the ideas of modern immaterialists, spirit can have no relation to place, and is incapable of being present any where. But Dr. Clarke, and some others of the best modern writers, did not entertain these ideas of spirit. Time and place are necessary to the existence of all things; and hence Dr. Clarke infers, that infinite space and duration are the essential properties of the Deity. Sir Isaac Newton was also of the same opinion; and Dr. Price observes, that if spirit exists at all, it must exist somewhere, as well as in some time.

Dr. Priestley deduces another argument in favour of the material system, from the consideration, that spirit and body have no common property, and that it must, therefore, be impossible for them to act upon one another: against which it has been objected, that his principles tend to prove, that the Deity is material, as well as all inferior beings: and if matter be a power of attraction and repulsion united to extension, the Deity must be the same. But if this maxim be not universally true, and the Deity be immaterial, as Dr. Priestley himself asserts, it will follow, that spirit may act upon matter, without having any other common property with it than being locally present to it; and one of his chief arguments for the materiality of the soul will be given up. Besides, allowing this maxim, how is it possible to avoid asserting the impossibility of the creation of the world out of nothing? For what common property can the Creator have with *nothing*? Dr. Priestley has laboured to prove, that the scriptures, both of the Old and New Testament, suppose and inculcate the doctrine of the uniform composition of man, or of the materiality of the human soul; and that, in conformity to this doctrine, the state of retribution does not take place till after the general resurrection. Accordingly, his system leads him to deny the natural immortality of the soul, and its conscious existence in the intermediate

state. To those who object, that if the soul be not naturally capable of surviving the body, or if death is unavoidably its destruction, then the resurrection must be the resurrection of a non-entity; he replies, that though the power of thinking cannot exist without its substance, which is an organized system, yet if this property of thinking necessarily attends the property of life, nothing can be requisite to the restoration of all the powers of the man, but the restoration of the body to a state of life. And he apprehends that a resurrection properly so called (because this can be only a resurrection of something that had been dead, *viz.* the body), is manifestly useless, upon the supposition of there being a soul distinct from the body; it being, upon this hypothesis, the soul, and not the body, that is the seat of all perception, and the source of all action. See *SLEEP of the Soul*.

Dr. Priestley conceives, that the three doctrines of materialism, of that which is commonly called Socinianism, and of philosophical necessity, are equal parts of one system, being equally founded on just observations of nature, and fair deductions from the scriptures; and that whosoever shall duly consider their connection and dependence on one another, will find no sufficient consistency in any general scheme of principles that does not comprehend them all. But it has been urged by another able writer, that if man be the matter itself which constitutes the man, and not its form or arrangement, as Dr. Priestley allows, the man will always remain while the matter which constitutes him remains, however different its organization or arrangement may be: that since death does not destroy the matter which constitutes man, it does not destroy the man; and that, consequently, he goes on to exist after death, or is naturally immortal: that, in order to the resurrection of the same man, the same matter must arise; and that it is no less possible for man to have existed *before* his birth, than it is, that he should exist *after* his death; and that, consequently, all the support to the Socinian scheme, which Dr. Priestley derives from his sentiments of materialism, falls to the ground. To this reasoning, however, he replies, that the pre-existence of the materials of the man Jesus is a very different kind of pre-existence from that of those who make Christ, or rather the principal part of him, to have pre-existed in an active state. We shall here subjoin the following argument, urged by the learned Dr. Clarke against Mr. Dodwell, in proof of the immateriality and natural immortality of the soul. That the soul cannot be material, he says, is demonstrable from the single consideration even of bare sense and consciousness itself. For matter being a divisible substance, consisting always of separable, nay, of actual separate and distinct parts; it is plain, unless it were essentially conscious, in which case every particle of matter must consist of innumerable separate and distinct consciousnesses, no system of it in any possible composition or division, can be an individual conscious being: for suppose three, or three hundred particles of matter, at a mile, or any given distance, one from another, is it possible that all those separate parts should, in that state, be one individual conscious being? Suppose, then, all these particles brought together, into one system, so as to touch one another, will they, thereby, or by any motion or composition whatsoever, become any whit less truly distinct beings than they were at the greatest distance? How then can their being disposed in any possible system, make them one individual conscious being? If you suppose God by his infinite power superadding consciousness to the united particles, yet still those particles, being really and necessarily as distinct beings as ever, cannot be themselves the subject in which

which that individual consciousness inheres; but the consciousness can only be superadded by the addition of something, which, in all the particles, must still itself be but one individual being. The soul, therefore, whose power of thinking is undeniably one individual consciousness, cannot possibly be a material substance. See on the subject of this article, Brucker's History of Philosophy, by Enfield. Priestley's Disquisitions relating to Matter and Spirit, 8vo. 1777. Correspondence between Dr. Price and Dr. Priestley, 8vo. 1778. Clarke's Demonstration of the Being and Attributes of God. Answer to Dodwell. Controversies with Collins; and Letters between him and Leibnitz. Butler's Analogy, chap. i. Baxter's Matho, vol. i. Enquiry into the Nature of the human Soul, &c. vol. i.

The notions of the ancients were very various with regard to the seat of the soul, and the mode of its action on the body. Some have maintained, that it is equally diffused through every part of it; and others say, that whilst it influences and acts upon every part of the body, it has its principal residence in some particular part. Since it has been discovered, by the improvements in anatomy, that the nerves are the instruments of perception, and of the sensations accompanying it, and that the nerves ultimately terminate in the brain, it has been the general opinion of philosophers that the brain is the seat of the soul; and that it perceives the images that are brought there, and external things, only by means of them. Des Cartes, observing that the *PINEAL Gland* (which see) is the only part of the brain that is single, all the other parts being double, and thinking that the soul must have one seat, was thus determined to make that gland the soul's habitation; to which, by means of the animal spirits, intelligence is brought of all objects that affect the senses. See *CARTES* and *CARTESIANISM*.

Others have not thought proper to confine the habitation of the soul to the pineal gland, but to the brain in general, or to some part of it, which they call the "sensorium." Even the great Newton favoured this opinion, though he proposes it only as a query, with that modesty which distinguished him no less than his great genius.

"Is not," says he, "the sensorium of animals the place where the sentient substance is present, and to which the sensible species of things are brought through the nerves and brain, that there they may be perceived by the mind present in that place? And is there not an incorporeal, living, intelligent, and omnipresent Being, who, in infinite space, as if it were in his sensorium, intimately perceives things themselves, and comprehends them perfectly, as being present to them; of which things, that principle in us which perceives and thinks, discerns only in its little sensorium, the images brought to it through the organs of the senses?" His great friend Dr. Clarke adopted the same sentiments with more confidence. In his papers to Leibnitz, we find the following passages. "Without being present to the images of the things perceived, the soul could not possibly perceive them. A living substance can only there perceive when it is present, either to the things themselves, (as the omnipresent God is to the whole universe,) or to the images of things, (as the soul of man is in its proper sensory). Nothing can any more act, or be acted upon, where it is not present, than it can be where it is not. We are sure the soul cannot perceive what it is not present to, because nothing can act, or be acted upon, where it is not." See *SENSORIUM*.

Mr. Locke expresses himself in such a manner, that, for the most part, one would imagine, that he thought the ideas, or images, of things, which he believed to be the immediate objects of perception, are impressions upon the mind itself;

yet in some passages he rather places them in the brain, and makes them to be perceived by the mind there present. From such passages, cited by Dr. Reid (*ubi infra*), it may be inferred, that he thought there are images of external objects conveyed to the brain. But whether he thought, with Des Cartes and Newton, that the images in the brain are perceived by the mind there present, or that they are imprinted on the mind itself, is not obvious. This hypothesis is founded on three assumptions; and if any one of them fail, it must fall to the ground. 1. That the soul has its seat, or, as Mr. Locke calls it, its presence-room, in the brain: 2. That images are formed in the brain of all the objects of sense: 3. That the mind or soul perceives those images in the brain; and that it perceives not external objects immediately, but only perceives them by means of those images. The first assumption is not sufficiently established to warrant our founding other principles upon it. Of the second there is no proof or probability, with regard to any of the objects of sense. The brain has been dissected times innumerable, by the nicest anatomists; every part of it has been examined by the naked eye, and with the help of microscopes; but no vestige of any external object was ever found. The brain seems to be the most improper substance that can be imagined for receiving or retaining images, being a soft, moist, medullary substance. The third assumption is as improbable, as that there are images of external objects in the brain to be perceived. If our powers of perception, says Dr. Reid, be not altogether fallacious, the objects we perceive are not in our brain, but without us. Reid's Essay on the Intellectual Powers of Man, Ess. ii. ch. 4. See *PERCEPTION*.

Borri, a Milanese physician, in a letter to Bartholine, "De Ortu Cerebri, et Ulu Medico," asserts, that in the brain is found a very subtle fragrant juice, which is the principal seat or residence of the reasonable soul; and adds, that the subtlety and fineness of the soul depends on the temperature of this liquor rather than on the structure of the brain, to which it is usually ascribed. This liquor, we conceive, must be the same with what is usually called the *nervous juice*, or *animal spirits*: the constitution of which is, doubtless, of great importance, with regard to the faculties of the soul.

Mr. Locke distinguishes two principal faculties or powers of the rational or human soul, *viz. perception* and *willing*. See *POWER*.

To these, other philosophers add others; as *sensation*, *liberty*, *memory*, *imagination*, and *habit*.

The mystic divines distinguish two principal parts of the soul: the *superior part*, which comprehends the understanding and the will, and the *inferior part*, which comprehends imagination and sensation.

As to the soul of brutes, the Cartesians, and some others, deny its existence in the common sense of the word soul; that is, they strip it of all the properties or faculties of the human soul: and the Peripatetics, on the contrary, invest it with the greatest part, if not all of them.

In man, a particular agitation of the fibres of the brain is accompanied with a sensation of heat; and a certain flux of animal spirits towards the heart and viscera is followed by love or hatred.

Now the Peripatetics maintain, that brutes feel the same heat, and the same passions, on the same occasions; that they have the same aversion for what incommodes them; and, in the general, are capable of all the passions, and all the sensations we feel.

The Cartesians deny they have any perceptions or notices at all, that they feel any pain or pleasure, or love or hate any thing.

thing. The ground of their opinion is, that they allow of nothing in brutes but what is material : and that they deny sensations and passions to be any properties of matter.

Some of the Peripatetics, on the other hand, maintain matter, when subtilized, framed, ranged, and moved, in a certain manner, to be capable of sensation and passion ; that beasts may feel and perceive, by means of the animal spirits, which are a matter thus modified ; and that even the human soul itself only becomes capable of sensation and passion by means of it.

The maintainers of the contrary opinion urge that appearance of sense, of fear, caution, love for their young, admirable sagacity, both for their own preservation and that of their species, visible through the whole brute creation. And it is true, that all the actions of beasts plainly express an understanding, for every thing that is regular expresses it, even a machine or watch expresses it, and a plant much more ; the radicle of the seed turning downwards, and the stem upwards, whatever situation the seed is sown in ; the young plant knitting from space to space to strengthen it, its putting forth prickles, &c. to defend it, &c. mark a great understanding. All the motions of plants and brutes plainly discover an intelligence ; but the intelligence does not reside in the matter thereof ; it is as distinct from the beast or plant, as that which ranged the wheels of the watch is distinct from the watch itself.

For, in effect, this intelligence appears infinitely great, infinitely wise, infinitely powerful ; and the same which formed us in our mother's womb, which gave us our growth, &c. Thus, in brutes there is not either understanding or soul, in the sense we generally use the word ; they eat without pleasure, cry without pain, grow without knowing it. They fear nothing, know nothing ; and if they act in such manner as shews understanding, it is because God, having made them, to preserve them, has formed their bodies so as to avoid whatever might hurt them mechanically.

Otherwise it might be said, that there is more understanding in the vilest insect, nay, in the smallest grain, than in the most knowing men ; for it is evident, either of them contains more parts, and produces more regular motions and actions, than we are capable of understanding. Thus does the great F. Malebranche argue against the souls of brutes. (*Recherche de la Verité*, liv. vi.) On this subject, see BRUTES and INSTINCT.

In connection with the interesting subject of this article, we shall here introduce some appropriate observations of an acute and elegant writer. (See Stewart's *Elements of the Philosophy of the Human Mind*.) This writer agrees with Dr. Reid in supposing, that the notions we annex to the words matter and mind, are merely relative. If I am asked, says he, what I mean by matter ? I can only explain myself by saying, it is that which is extended, figured, coloured, moveable, hard or soft, rough or smooth, hot or cold ; that is, I can define it in no other way, than by enumerating its sensible qualities. It is not matter or body which I perceive by my senses ; but only extension, figure, colour, and certain other qualities, which the constitution of my nature leads me to refer to something which is extended, figured, and coloured. The case is precisely similar with respect to mind. We are not immediately conscious of its existence, but we are conscious of sensation, thought, and volition ; operations, which imply the existence of something which feels, thinks, and wills. Every man too is impressed with an irresistible conviction, that all these sensations, thoughts, and volitions, belong to one and the same being ; to that being which he calls *himself* ; a being which he is led,

by the constitution of his nature, to consider as something distinct from his body, and as not liable to be impaired by the loss or mutilation of any of his organs. From these considerations it appears, that we have the same evidences for the existence of mind, that we have for the existence of body ; nay, if there be any difference between the two cases, that we have stronger evidence for it ; inasmuch as the one is suggested to us by the subjects of our consciousness, and the other merely by the objects of our perception. But as from our earliest years the attention is engrossed with the qualities and love of matter, these phenomena occupy our thoughts more than those of the mind, and we are perpetually tempted to explain the latter by the analogy of the former, and even to endeavour to refer them to the same general laws ; and we acquire habits of inattention to the subjects of our consciousness, not easily surmounted. If, therefore, our notions of mind and matter are merely relative ; if we know the one, only by such sensible qualities as extension, figure, and solidity, and the other, by such operations as sensation, thought, and volition, we are warranted in saying, that matter and mind, considered as objects of human study, are essentially different ; the science of the former resting ultimately on the phenomena exhibited to our senses, and that of the latter, on the phenomena of which we are conscious. Instead, therefore, of objecting to the scheme of materialism, that its conclusions are false, it would be more accurate to say, that its aim is unphilosophical. It proceeds on a misapprehension of the proper object of science ; the difficulty which it professes to remove being manifestly placed beyond the reach of our faculties. Surely, when we attempt to explain the nature of that principle which feels, and thinks, and wills, by saying, that it is a material substance, or that it is the result of material organization, we impose on ourselves by words, forgetting that matter as well as mind is known to us by its qualities and attributes alone, and that we are totally ignorant of the essence of either. Should it be said that the unknown substance which has the qualities of extension, figure, and colour, may be the same with the unknown substance which has the attributes of feeling, thinking, and willing ; this is only an hypothesis, which amounts to nothing more than a mere possibility ; and even if it were true, it would no more be proper to say of mind that it is material, than to say of body that it is spiritual.

SOULS, *Cure of*. See CURE.

SOULS, *Migration of*. See MIGRATION and METEMPSYCHOSIS.

SOUL, *Sleep of the*. See SLEEP of the Soul.

SOUL-SCOT, a certain fee paid by our Saxon ancestors to the priest on opening a grave.

SOUL'S CHEAT, a legacy anciently bequeathed at their deaths by our scrupulously pious ancestors, to the parish-priest, to compensate for any tithes that might have been forgot in their lives.

SOULAINES, in *Geography*, a town of France, in the department of the Aube, and chief place of a canton, in the district of Bar-sur-Aube ; 12 miles N. of Bar-sur-Aube. The place contains 763, and the canton 7723 inhabitants, on a territory of 265 kilometres, in 21 communes.

SOULAMEA, in *Botany*, slightly altered from *Soulamoe*, the name given to the plant in the island of Ternate. Lamarck Dict. v. 1. 449. Jull. 429. This is no other than what we have described under the article REX AMARORIS, to which we refer the reader. Commerfon, it seems, gathered this curious plant at Port Praslin, in the Arsacides. Lamarck describes the flowers with a three-cleft calyx, three petals, six stamens, and two stigmas. The germen is superior.

Fruit

Fruit an inverfely heart-shaped *capsule*, compressed, dilated at the margin, of two cells, each containing an oval *seed*; but it often happens that one of thefe feeds is abortive.

SOULANCOURT, in *Geography*, a town of France, in the department of the Upper Marne; 4 miles E. of Bourmont.

SOULE, a small country of France, fo called before the revolution, fituated between Bearn and Navarre, of which Mauleon was the capital, now in the department of the Lower Pyrenées.

SOULLIERES, a town of France, in the department of Mont Blanc; 20 miles E. of St. Jean de Maurienne.

SOULONA, a town of Thibet; 20 miles E.S.E. of Coucour-Hotun.

SOULTZ, a town of France, in the department of the Upper Rhine, and chief place of a canton, in the diftrict of Colmar. The place contains 4298, and the canton 9317 inhabitants, on a territory of $87\frac{1}{2}$ kilometres, in 9 communes.

SOULZ-SOUS-FORETS, a town of France, in the department of the Lower Rhine, and chief place of a canton, in the diftrict of Wissembourg; 2 miles S. of Wissembourg. The place contains 1269, and the canton 13,768 inhabitants, on a territory of 145 kilometres, in 26 communes.

SOUM, in *Agriculture*, a term denoting the palturage of a full-grown cow. It is moftly applied to lands in the moory ftate, and fuch as are under the fheep-walk fyftem. It nearly answers, in fome refpects, to *gaite*. It is much ufed in the northern parts of Scotland. In the county of Perth, a horfe is accounted two founs; in fome places four fheep, but in other places five, are eftimated at one foun; and of young cattle according to their age. The grafs of a foun, in hilly ground, is valued, on an average, from five to feven fhillings, according to its quality. By fome, much cenfure has been beftowed on this mode of afcertaining the value of pallure or grafs-land in the Highlands: but in mountainous diftricts, where the ground has never been meafured, and probably never will, where one mountain is exactly different from another in the quality and quantity of its produce as a pallure, and where there is even a great diverfity in different regions of the fame mountain, it is perhaps not eafy to conceive a better method of afcertaining the value of pallure than by the number of cattle it can maintain. Whoever propofes to explode any old cuftom, ought, it is fuppofed, to fubftitute a better in its place.

Such old cuftoms are now, however, a great deal more neglected and difregarded, even in thefe Highland fituations, than was formerly the cafe; juft in the fame manner as the term *gaite* has partially grown into difufe in different diftricts in the fouthern parts of the kingdom.

SOUMENZAC, in *Geography*, a town of France, in the department of the Lot and Garonne; 7 miles N.W. of Lauzun. N. lat. $44^{\circ} 41'$. E. long. $0^{\circ} 27'$.

SOUND, *SONUS*, a perception of the foul, communicated by means of the ear; or the effect of a collision of bodies, and a tremulous motion confequent upon it, communicated thence to the circumambient fluid, and propagated through it to the organs of hearing.

Sound is not fimply a vibration or undulation of the air, as fome have called it, for there are many founds in which the air is not concerned, as when a tuning-fork or any other founding body is held by the teeth: nor is found always a vibration or alternation of any kind, for every noife is a found, and a noife, as diftinguifhed from a continued found, confifts of a fingle impulfe in one direktion only, fometimes without

any alternation; while a continued found is a fuceffion of fuch impulfes, which, in the organ of hearing at leaft, cannot but be alternate. If thefe fuceffive impulfes form a connected ferief, following each other too rapidly to be feperately diftinguifhed, they conftitute a continued found, like that of the voice in fpeaking; and if they are equal among themfelves in duration, they produce a mufical or equable found, as that of a vibrating chord or ftring, or of the voice in finging. Thus, a quill ftriking againft a piece of wood caufes a noife, but ftriking againft the teeth of a wheel or comb, a continued found; and if the teeth of the wheel are at equal diftances, and the velocity of the motion is conftant, a mufical note.

To illuftrate the caufe of found, we obferve, firft, that a motion is neceffary in the fonorous body for the production of found. Secondly, that this motion exifts, firft, in the fmall and infenfible parts of the fonorous bodies; and is excited in them by their mutual collision and percuffion againft each other, which produces that tremulous motion fo obfervable in bodies that have a clear found, as bells, mufical chords or ftrings, &c. Thirdly, that this motion is communicated to, or produces a like motion, ufually in the air, or fuch parts of any material fubftance as are fit to receive and propagate it, inafmuch as no motion of bodies, at a diftance, can affect our fenfes, without the mediation of other bodies, which receive thofe motions from the fonorous body, and communicate them immediately to the organ. Laftly, that this motion muft be communicated to thofe parts that are the proper and immediate inftruments of hearing. See EAR.

Further, that motion of a fonorous body which is the immediate caufe of found, may be owing to two different caufes: either the percuffion between it and other hard bodies, as in drums, bells, ftrings, &c. or the beating and dafhing of the fonorous body and the air immediately againft each other, as in wind-inftuments, flutes, trumpets, &c.

But, in both cafes, the motion, which is the confequence of the mutual action, and the immediate caufe of the fonorous motion which the air conveys to the ear, is an invifible, tremulous, or undulating motion, in the fmall and infenfible parts of the body.

To explain this, all fenfible bodies are fuppofed to confift of a number of fmall and infenfible parts or corpufcles, which are of the fame nature in all bodies, and are perfectly hard and incompressible.

Of thefe are compofed others, fomewhat greater, but ftill infenfible; and thefe different, according to the different figures and union of their component parts. Thefe, again, conftitute other mafles, bigger and more different than the former; and of the various combinations of thefe laft, are thofe grofs bodies compofed that are vifible, tangible, &c. The firft and fmalleft parts, we have obferved, are abfolutely hard; the others are compressible, and are united in fuch manner, that, being compressed by an external impulfe, they have an elastic or reftitutive power, by which they reftore themfelves to their natural ftate.

A fhock, then, being made by one body upon another, the fmall particles, by their elastic principle, move to and again with a very great velocity, in a tremulous, undulating manner, fomewhat like the vifible motions of groffer fprings; as we eafily obferve in the ftrings of mufical inftruments. And this is what we may call the *fonorous motion*, which is propagated to the ear; but obferve, that it is the infenfible motion of thofe particles next the fmalleft, which is fuppofed to be the immediate caufe of found; and, of thefe,

only those next the surface communicate with the air, the motion of the whole, or of the greater parts, being no farther concerned, than as they contribute to the other.

To apply this theory, strike a bell with any hard body, and you easily perceive a sensible tremor on the surface, spreading itself over the whole, and that more sensibly as the shock is greater. Upon touching it in any other part, the motion and the sound too are stopped. Now this is apparently a motion of the small and insensible parts, changing their situation, with respect to one another; which being to many, and so closely united, we cannot perceive their motions separately and distinctly; but only a trembling, which we reckon to be the effect of the confusion of an infinite number of little particles, closely joined, and only moving in infinitely little lines.

M. Perrault adds, that the visible motion of the parts contributes no otherwise to sound, than as it causes the invisible motion of the smaller parts, which he calls *particles*, to distinguish them from the sensible ones, which he calls *parts*, and from the smallest of all, which we call *corpuscles*.

This he supports from the instance of a chord or string, which being struck, and the sound, and sensible undulations, at rest again, if you approach the chord softly with the finger, you will find a small tremulous motion, which is the remains of the vibrations of the whole string and the parts. Now the parts vibrate without any sound; but no sooner is the vibration felt by the finger, than the sound is heard again; which he ascribes to this, that the motion of the parts being insufficient to move the particles, whose motion is the first that ceases, requires some assistance from dashing against the finger, whereby to become enabled to give the particle the motion necessary for the producing of sound. He finishes his proof by the instance of flutes, which, when made of different matters, as wood, metal, &c. whose parts are very different, but their particles nearly the same, if their lengths and bore be the same, there is very little sensible difference in their sounds.

The sonorous body having made its impression on the contiguous air, that impression is propagated from one particle to another, according to the laws of pneumatics.

A few particles, for instance, driven from the surface of the body, drive their neighbouring particles into a less space; and the medium, as it is thus rarefied in one place, becomes condensed in the other; but the air, thus compressed in the second place, is, by its elasticity, returned back again, both to its former place and its former state; and the air contiguous to that is compressed; and the like obtains, when the air less compressed expanding itself, a new compression is generated. From each agitation of the air, therefore, there arises a motion of the air, analogous to the motion of a wave on the surface of the water; which we call a *wave*, or *undulation* of air.

In each wave the particles go and return back again, through very short, but equal spaces; the motion of each particle is analogous to the motion of a vibrating pendulum, while it performs two oscillations; and most of the laws of the pendulum, with very little alteration, are applicable thereto.

The only condition necessary for the production of a simple sound, is a sufficient degree of velocity in the motion or impulse which occasions it. A very moderate velocity must be sufficient for producing an impression on the ear; and when the sound is continued, it may remain audible with a velocity of no more than one hundredth part of an inch in a second, or perhaps with a velocity much less than this; but at its origin, it is probable that the velocity of the motion

constituting a sound must always be considerably greater. A continued sound may be produced by a repetition of separate impulses, independent of each other, as when a wheel strikes in rapid succession the teeth of a pinion, so as to force out a portion of air from between them; when a pipe, through which air is passing, is alternately opened and shut, either wholly or partially, by the revolution of a stop-cock or valve; or when a number of parallel surfaces is placed at equal distances, in a line nearly perpendicular to them, and a noise of any kind is reflected from each of them in succession:—a circumstance which may often be observed, when we are walking near an iron railing, an acute sound being heard, which is composed of such reflections from the surfaces of the palisades. See SOUND, in *Music, infra*.

Sounds are as various as are the means that concur to their production. The principal varieties result from the figure, constitution, quantity, &c. of the sonorous body; the manner of percussion, with the velocity, &c. of the vibrations consequent thereon; the state and constitution of the medium; the disposition, distance, &c. of the organ; the obstacles between the organ and the sonorous object, and the adjacent bodies. The most notable distinction of sounds, arising from the various degrees and combinations of the conditions mentioned, are into *loud* and *low* (or strong and weak); into *grave* and *acute* (or sharp and flat, or high and low); and into *long* and *short*: the management of which makes the office of music. See the next article.

M. Euler is of opinion, that no sound, making fewer vibrations than 30, or more than 7520 in a second, is distinguishable by the human ear. According to this doctrine, the limit of our hearing, as to acute and grave, is an interval of eight octaves. Tentam. Nov. Theor. Mus. cap. i. sect. 13.

The velocity of sound is the same with that of the aerial waves, and does not differ much, whether it go with the wind or against it. By the wind, indeed, a certain quantity of air is carried from one place to another; and the sound is accelerated, while its waves move through that part of the air, if their direction be the same as that of the wind. But as sound moves much more swiftly than wind, the acceleration it will hereby receive is inconsiderable; and the chief effect we can perceive from the wind is, that it increases and diminishes the space of the waves, so that by help of it the sound may be heard to a greater distance than otherwise it would. See WIND, & *infra*.

That the air is the ordinary medium of sound, and that the presence of this, or of some other material substance for its transmission is necessary, appears from various experiments in rarefied and condensed air. In an unexhausted receiver, a small bell may be heard at some distance; but when exhausted, it can scarcely be heard at the smallest distance. If the air be condensed, the sound will be louder proportionably to the condensation, or quantity of air crowded in, of which we have many instances in Mr. Hauksbee's experiments. From these experiments (Phil. Trans. 1709, xxiv. 1902, 1709, xxvi. 367, 371.) it appears, that a bell was heard at the distance of 30 yards, when the air was in its common state, at 60 with the force of two atmospheres, at 90 with the force of three: beyond this the intensity did not much increase.

Besides, sounding bodies communicate tremors to distant bodies; *e. g.* the vibrating motion of a musical string puts others in motion, whose tension and quantity of matter dispose their vibrations to keep time with the pulses of air, propagated from the string that was struck. Galileo explains this phenomenon by observing, that a heavy pendulum

lum may be put in motion by the least breath of the mouth, provided the blatts be often repeated, and keep time exactly with the vibrations of the pendulum, and also by the like art in raising a large bell.

Dr. Priestley constructed an apparatus in order to ascertain whether the intensity of sound is affected by any other property of the air in which it is made besides its mere density. The result of his experiments with different kinds of air was, that the intensity of sound depends solely upon the density of the air in which it is made, and not at all upon any chemical principle in its constitution. In inflammable air the sound of the bell he used was hardly to be distinguished from the same in a pretty good vacuum; and this air is ten times rarer than common air. In fixed air the sound was much louder than in common air, so as to be heard about half as far again; and this air is in about the same proportion, denser than common air. In dephlogisticated air the sound was also sensibly louder than in common air. Experiments and Observations, &c. vol. v. p. 296, &c.

But it is not the air alone that is capable of the impressions of sound, but water also, as is manifest by striking a bell under water, the sound of which may plainly enough be heard, only not so loud, and also a fourth deeper, according to good judges in musical notes. And Mersenne says, a sound made under water is of the same tone or note as if made in air, and heard under water.

It does not appear that any direct experiments have been made on the velocity with which an impulse is transmitted through a liquid, although it is well known that liquids are capable of conveying sound without difficulty. Professor Robison informs us, that he heard the sound of a bell transmitted by water, at the distance of 1200 feet. It is easy to calculate the velocity with which sound must be propagated in any liquid, of which the compressibility has been measured. Mr. Canton has ascertained, that the elasticity of water is about 22,000 times as great as that of air: it is, therefore, measured by the height of a column, which is in the same proportion to 34 feet, that is 750,000 feet; and the velocity corresponding to half this height is 4900 feet in a second. In mercury also, it appears from Mr. Canton's experiments, that the velocity must be nearly the same as in water; in spirit of wine a little smaller. The experiments were made by filling the bulb of a thermometer with water, and observing the effects of placing it in an exhausted receiver, and in condensed air; taking care to avoid changes of temperature, and other sources of error. The fluid rose in the tube when the pressure was removed, and subsided when it was increased. A slight correction, however, is necessary, on account of the expansion and contraction of the glass, which must have tended to make the elasticity of the fluids appear somewhat greater than it really was. See COMPRESSION.

The least elastic substance that has been examined is perhaps carbonic acid gas, or fixed air, which is considerably denser than atmospherical air, exposed to an equal degree of pressure. The height of the atmosphere, supposed to be homogeneous, is, in ordinary circumstances, and at the sea-side, about 28,000 feet; and in falling through half this height, a heavy body would acquire a velocity of 946 feet in a second. But from a comparison of the accurate experiments of Derham, made in the day-time, with those of the French academicians, made chiefly at night, the true velocity of sound is about 1130 feet in a second; which agrees very nearly with some observations made with great care by professor Pictet. This difference between calculation and experiment, which has long occupied the attention

of natural philosophers, has been in a great measure removed by the suggestion of La Place, who has attributed the effect to the elevation of temperature, which is always found to accompany the action of condensation, and to the depression produced by rarefaction. When the density of the air is changed, while its elasticity remains unaltered, which happens when it is expanded by heat, or condensed by cold, the height of the column, and consequently the velocity, will also be altered; so that for each degree of Fahrenheit's thermometer, the velocity will vary about one part in a thousand. Bianconi has actually observed this difference of velocity according to the different heights of the thermometer, and it may be shewn less directly by means of the sounds of pipes; but it has not been accurately determined whether or not the correction, on account of the effect of compression in causing heat, remains unaltered, although Bianconi's experiments agree very well with the supposition that no material change takes place in this respect. The velocity of sound must also be, in some measure, influenced by the quantity of moisture contained in the atmosphere: it must be a little diminished by cold fogs, which add to the density, without augmenting the elasticity; and increased by warm vapours, which tend to make the air lighter: and these two opposite states are probably often produced in succession, in wind instruments blown by the mouth; the air within them being at first cold and damp, and afterwards warm and moist.

In pure hydrogen gas, the velocity of sound ought, from calculation, to be more than three times as great as in common air; but the difference does not appear to have been so great in any experiment hitherto made on the sounds of pipes, in gases of different kinds. For such experiments, the comparative specific gravity of the gas may be most conveniently ascertained by Mr. Leslie's method of observing the time employed in emptying a vessel through a small orifice, by means of the pressure of an equal column of water; according to the simple theory, the velocities of the gas thus discharged ought to be in the same proportion as the respective velocities with which sounds would be transmitted by them: and if any variation from this proportion were discovered, it must be attributed to the different degrees of heat produced by condensation in the different fluids. Steam, at the temperature of boiling water, is only one-third as heavy as common air; consequently the velocity of sound in steam must be nearly three-fourths greater than in air.

A certain time is always required for the transmission of an impulse through a material substance, even through such substances as appear to be the hardest, and the least compressible. It is demonstrable that all minute impulses are conveyed through any homogeneous elastic medium, whether solid or fluid, with an uniform velocity, which is always equal to that which a heavy body would acquire by falling through half the height of the modulus of elasticity, that is, in the case of the air, half the height of the atmosphere, supposed to be of equal density; so that the velocity of sound, passing through an atmosphere of an uniform elastic fluid, must be the same with that of a wave moving on its surface. In order to form a distinct idea of the manner in which sound is propagated through an elastic substance, we must first consider the motion of a single particle, which, in the case of a noise, is pushed forwards, and then either remains stationary, or returns back to its original situation; but, in the case of a musical sound, is continually moved backwards and forwards, with a velocity always varying, and varying by different degrees, according to the nature or quality of the tone: for instance, differently in the notes of
a bell

a bell and of a trumpet. We may first suppose, for the sake of simplicity, a single series of particles to be placed only in the same line with the direction of the motion. It is obvious, that if these particles were absolutely incompressible, or infinitely elastic, and were also retained in contact with each other by an infinite force of cohesion or of compression, the whole series must move precisely at the same time, as well as in the same manner. But in a substance which is both compressible and extensible or expansible, the motion must occupy a certain time in being propagated to the successive particles on either side, by means of the impulse of the first particle on those which are before it, and by means of the diminution of its pressure on those which are behind; so that when the sound consists of a series of alternations, the motion of some of the particles will be always in a less advanced state than that of others nearer to its source; while at a greater distance forwards, the particles will be in the opposite stage of the undulation; and still further on, they will again be moving in the same manner with the first particle, in consequence of the effect of a former vibration.

It is well known, that solid bodies in general are good conductors of sound: thus, any agitation communicated to one end of a beam is readily conveyed to the ear, applied to the other end of it. The motion of a troop of cavalry is said to be perceived at a greater distance, by listening with the head in contact with the ground, than by attending to the sound conveyed through the air; and we may frequently observe, that some parts of the furniture of a house are a little agitated by the approach of a waggon, before we hear the noise which it immediately occasions. The velocity, with which impulses are transmitted by solids, is in general considerably greater than that with which they are conveyed by the air. Mr. Wunsch has ascertained this by direct observations on a series of deal rods closely united together, which appeared to transmit a sound instantaneously, while a sensible interval was required for its passing through the air. He also found that the blow of a hammer on a wall, at the upper part of a high house, is heard as if double by a person standing near it on the ground; the first sound descending through the wall, the second through the air. It appears from experiments on the flexure of solid bodies of all kinds, that their elasticity, compared with their density, is much greater than that of the air: thus, the height of the modulus of elasticity of fir wood is found, by means of such experiments, to be about 9,500,000 feet; whence the velocity of an impulse conveyed through it must be 17,400 feet, or more than three miles, in a second. It is obvious, therefore, that in all common experiments, such a transmission must appear perfectly instantaneous. There are various methods of ascertaining this velocity from the sounds produced under different circumstances, by the substances to be examined; and professor Chladni has, in this manner, compared the properties of a variety of natural and artificial productions.

Sound may be propagated not only in single right lines, or in parallel lines, but usually the impulse that occasions it, more especially when sound is transmitted through a fluid, spreads in every direction, so as to occupy at any one time nearly the whole of a spherical surface. It is impossible, however, that the whole of this surface should be affected in a similar manner by any sound, originating from a vibration confined to a certain direction, since the particles behind the sounding body must be moving towards the centre, whenever the particles before it are retreating from the centre; so that in one half of the surface, the motions may be called retrograde or negative, while in the other they are direct or positive: consequently at the sides,

where these portions join, the motions can neither be positive nor negative, and the particles must remain at rest: the motions must also become gradually less and less sensible, as they approach to the limit between the two hemispheres. This statement may be confirmed by an experiment on the vibration of a body, of which the motion is limited to a certain direction; the sound being scarcely audible, when the ear is in a direction precisely perpendicular to that of the vibration. The sound, thus diverging, must always be spread through a part of a spherical surface, because its velocity must be equal in every direction; so that the impulse will always move forwards in a straight line passing through the centre of the sphere, or the vibrating body. But when a hemispherical pulse arrives at the surface of a plane solid obstacle, it is reflected, precisely in the same manner that a wave of water is reflected, and assumes the form of a pulse proceeding from a centre at an equal distance on the opposite side of the surface. This reflection, when it returns back perpendicularly, constitutes what is commonly called an *echo* (which see): but in order that the echo may be heard distinctly, it is necessary that the reflecting object be at a distance moderately great, otherwise the returning sound will be confused with the original one; and it must either have a smooth surface, or consist of a number of surfaces arranged in a suitable form: thus there is an echo not only from a distant wall or rock, but frequently from the trees in a wood, and sometimes, as it is said, even from a cloud.

If a sound or a wave be reflected from a curved surface, the new direction which it will assume may be determined, either from the condition that the velocity with which the impulse is transmitted must remain unaltered, or from the law of reflection, which requires that the direction of the reflected pulse or wave be such as to form an angle with the surface, equal to that which the incident pulse before formed with it. Thus, if a sound or wave proceed from one focus of an ellipse, and be reflected at its circumference, it will be directed from every part of the circumference towards the other focus; since the distance which every portion of the pulse has to pass over in the same time, in following this path, is the same, the sum of the lines drawn from the foci to any part of the curve being the same; and it may also be demonstrated that these lines form always equal angles with the curve on each side. (See ELLIPSE.) If an ellipse be prolonged without limit, it will become a *parabola* (which see); hence a parabola is the proper form of the section of a tube, calculated for collecting a sound which proceeds from a great distance into a single point, or for conveying a sound nearly in parallel directions to a very distant place. It appears, therefore, that a parabolic conoid is the best form for a hearing trumpet, and for a speaking trumpet. See TRUMPET.

The decay of sound is the natural consequence of its distribution throughout a larger and larger quantity of matter, as it proceeds to diverge every way from its centre. The actual velocity of the particles of the medium transmitting it appears to diminish simply in the same proportion as the distance from the centre increases; consequently their energy, which is to be considered as the measure of the strength of sound, must vary as the square of the distance; so that, at the distance of ten feet from the sounding body, the velocity of the particles of the medium becomes one-tenth as great as at the distance of one foot; and their energy, or the strength of the sound, only one-hundredth as great. Young's Lect. on Nat. Phil. vol. i. lect. 31.

The space through which sound is propagated, in a given time, has been very differently estimated by authors who have

have written concerning this subject. Roberval gives it at the rate of 560 feet in a second; Gallendus, at 1473; Merfenne, at 1474; Du Hamel, in the History of the Academy of Sciences at Paris, at 1172; the Academy del Cimento, at 1148; Boyle, at 1200; Roberts, at 1300; Walker, at 1338; fir Isaac Newton, at 968; Dr. Derham, in whose measure Mr. Flamsteed and Dr. Halley acquiesced, at 1142.

The reason of which variety Dr. Derham ascribes partly to some of those gentlemen using strings and plummet, instead of regular pendulums; and partly to there not being distance enough between the sonorous body and the place of observation; and partly to there being no regard had to the winds: Derham having found the effects of the wind, though not of any changes of weather.

But by the accounts since published by M. Cassini de Thury, in the Memoirs of the Royal Academy of Sciences at Paris for the year 1738, where cannon were fired at various as well as great distances, under great variety of weather, wind, and other circumstances, and where the measures of the different places had been settled with the utmost exactness, sound was propagated at a medium at the rate only of 1038 French feet in a second. The French foot exceeds the English by nearly seven lines and a half, or is as 107 to 114; and consequently 1038 French feet are equal to 1106 or 1107 English feet. The difference, therefore, of the measures of Dr. Derham and M. Cassini is 34 French, or 36 English feet, in a second. According to this last measure, the velocity of sound, when the wind is still, is settled at the rate of a mile, or 5280 English feet in $4\frac{2}{3}$ seconds.

According to Mayer, the velocity of sound in a second is 1105 feet; according to Müller, 1109; and according to Piçet, about 1180. According to Bianconi (C. Bon. ii. i. 365.), in summer, the thermometer being at 20°, 70 vibrations of the pendulum elapsed while a sound passed over 13 miles; in winter, 79 seconds, the thermometer being at 12°. In a cloud or mist, 155" elapsed while the sound passed and repelled. Hence the air should expand $\frac{1}{100}$ for 21.2°, or $\frac{1}{100}$ for 1° of the thermometer employed, probably Reaumur's, which is $\frac{1}{100}$ for 1° of Fahrenheit. The mean difference of the temperature of the air was probably somewhat less than is supposed, perhaps 17° or 18°.

Chladni infers, from the longitudinal vibrations of different substances, a velocity of 7800 feet in a second in tin, 9300 in silver, 12,500 in copper, 17,500 in glass and iron, 11,000 to 18,000 in wood, and 10,000 to 12,000 in tobacco-pipes. These observations are fully confirmed from different grounds. According to the elasticity of fir, as inferred from an experiment of Mr. Leslie, the velocity of an impulse should be 17,300. The velocity may be easily calculated from the sound of a brass-rod: if the number of vibrations of the gravell found in a second be n , the velocity will be $978 \frac{n l}{d}$, l being the length, and d the depth

in feet. From an experiment of this kind, Dr. Young says (Lect. on Phil. vol. ii. p. 266.) that he found the velocity 17,700 in crown glass, and 11,800 in brass.

Some of the most considerable queries, relating to the laws of sounds, have been proposed by Dr. Derham; and he answered several of them accurately, from experiments made for that purpose by himself, as follows:

How far does a sound move in a second of time? Sound moves 1142 feet, or 380 yards in a second, which is just an English mile in $9\frac{1}{4}$ or 9.25 half seconds; two miles in $18\frac{1}{2}$;

three miles, or a league, in $27\frac{3}{4}$, &c.; and about 13 miles in one minute.

But sea-miles are to land-miles nearly as 7 to 6; and, therefore, sound runs a sea-league in about 12 seconds of time. It is a common observation, that persons in good health have about 75 pulsations, or beats, of the artery at the wrist, in a minute; consequently, in 75 pulsations, sound flies about 13 land-miles, and about $11\frac{1}{2}$ sea-miles, which is about one land-mile in six pulses, and about one sea-mile in near seven pulses, or a league in 20 pulses. And hence the distance of objects may be found, by knowing the time which sound takes to move from those objects to an observer: *E. g.* upon seeing the flash of a gun at sea, if 56 beats of the pulse at the wrist were counted before the report was heard, the distance of that gun may be easily found by dividing 56 by 20, which gives 2.8 leagues, or about eight miles.

Does the report of a gun, discharged with its mouth towards us, come sooner than when the muzzle is from the observer? By repeated experiments it appears, there is no difference in the sound from this different direction.

Do sounds move in the same time, through the same spaces, in all states of the atmosphere, and heights of the barometer, by day and by night, in summer and in winter, in snowy and in clear weather, in this or that climate? By repeated experiments, it does not appear there arises any difference from any of these different circumstances.

Do the winds affect the motion of sounds? By repeated experiments, it appears, there is some, though a very small difference, in the velocity of sounds, with or against the wind; which is also augmented or diminished by the strength or weakness of the wind.

Do a great and intense sound, and a small or languid one, move with the same velocity? It appears that they do.

For by experiments, a cannon fired with a half-pound charge of powder, was heard at about the distance of $17\frac{1}{2}$ miles, in the same time after the flash was seen, as when fired with a charge of six pounds.

Does the sound of a gun move equally swift at all elevations of the gun? It does.

Do different quantities or strengths of gunpowder occasion any difference as to the velocity of the sound? None.

Does sound move in a right line the nearest way, or does it sweep along the earth's surface? And is there any difference in the time, if the piece be discharged in an acclive and a declive position? Sound moves the nearest way; and the velocity appears to be the same in acclivities as in declivities.

Have all kinds of sounds, as those of guns, bells, &c. the same velocity? And are sounds equally swift in the beginning of their motion and in the end? There appears no inequality in either of these respects; and, therefore, the times in which sound is heard are proportional to the distance; that is, at a double distance it is heard in twice the time, &c.

SOUND, for the Reflection, Refraction, &c. of. See ECHO and PHONICS.

SOUNDS, Articulate. See ARTICULATE.

SOUND, in Music, denotes a quality in the several agitations of the air, considered as their disposition, measure, &c. may make music or harmony.

Musical sounds are most frequently produced by the alternate motions of substances naturally capable of isochronous vibrations; which substances may be either solids or fluids, or instruments composed of a combination of fluids with solids. The resonance of a room or passage is one of the

the simplest sources of a musical sound; the walls being parallel, the impulse is reflected backwards and forwards continually, at equal intervals of time, so as to produce the effect of a musical sound. When we blow obliquely and uniformly into a cylindrical pipe closed at one end, the impulse or condensation must probably travel to the bottom and back, before the resistance is increased; the current of our breath will then be diverted from the mouth of the pipe, for an equal time, which will be required for the diminution of the resistance by the discharge of the condensed air, so that the whole time of a vibration will be equal to the time occupied by an impulse of any kind in passing through four times the length of the pipe. An open pipe may be considered nearly as if it consisted of two such pipes, united at their closed ends; the portions of air contained by them being agitated by contrary motions, so as always to afford each other a resistance similar to that which the bottom of the stopped pipe would have furnished. It is probable, says Dr. Young, that when an open pipe is once filled with air a little condensed, the oblique current is diverted, until the effect of the discharge, beginning at the remoter end, has returned to the inflated orifice, and allowed the current to re-enter the pipe. Where the diameter of the pipe is different at different parts of its length, the investigation of the sound becomes much more intricate; but it has been pursued by M. Daniel Bernouilli with considerable success, although upon suppositions, says Young, not strictly consistent with the actual state of the motions concerned.

In the same manner as an open pipe is divided by an imaginary basis, so as to produce the same sound with a stopped pipe of half the length, a pipe of any kind is capable of being subdivided into any number of such pipes, supposed to meet each other's corresponding ends only; and in general the more violently the pipe is inflated, the greater is the number of parts into which it subdivides itself, the frequency of the vibrations being always proportional to that number. Thus, an open pipe may be divided not only into two, but also into four, six, eight, or more portions, producing the same sounds as a pipe of one-half, one-third, one-fourth, or any other aliquot part of the length; but a stopped pipe cannot be divided into any even number of similar parts; its secondary sounds being only those of a pipe of which the proportion is determined by the odd numbers, its length being, for example, one-third, one-fifth, or one-seventh of the original length. These secondary notes are sometimes called harmonics; they are not only produced in succession from the same pipe, but they are also often faintly heard together, while the fundamental note of the pipe continues to sound. When the pipe has a large cavity connected with it, or consists principally of such a cavity, with a small opening, its vibrations are usually much less frequent, and it is generally incapable of producing a regular series of harmonics.

It is obvious, from this statement of the analogy between the velocity of sound and the vibrations of the air in pipes, that they must be affected in a similar manner by all alterations of temperature. Thus, the frequency of the vibrations of a pipe must be increased nearly in the ratio of 33 to 34 by an elevation of 30 degrees of Fahrenheit's thermometer; and if this change be accompanied by a transition from dampness to simple moisture, the sound will be still more altered.

Dr. Chladni has discovered that solids of all kinds, when of a proper form, are capable of longitudinal vibrations, exactly resembling in their nature those of the air in an organ-pipe, having also their secondary or harmonic notes related to them in a similar manner. These vibrations are

always far more frequent than those of a column of air of equal length, the velocity with which an impulse is transmitted by a solid of any kind, being usually from 5 to 16 times as great as the velocity of sound in air; so that the longitudinal sounds are always extremely acute, when they are produced by substances of moderate length. These sounds afford perhaps the most accurate mode of determining the velocity of the transmission of an impulse through any elastic substance, and of obtaining from that velocity the exact measure of its elasticity: they may be easily exhibited by holding a long bar or wire of iron or brass in the middle, and striking it at one end with a small hammer in the direction of its length.

The vibrations by which solid bodies most usually produce sound, are, however, not longitudinal, but lateral, and they are governed either by a tension, derived from the operation of a weight, or of some other external force, or by the natural elasticity of the substance. The vibrations of extended substances resemble most in their properties those of elastic fluids, and they occur the most frequently in practice, although the vibrations produced by the elasticity of the substance may be considered as the most natural. See STRING and VIBRATION.

Sound is the object of music; which is nothing but the art of applying sounds, under such circumstances of tone and time, as to raise agreeable sensations.

The principal affection of sound, by which it becomes fitted to have this end, is that by which it is distinguished into *acute* and *grave*.

This difference depends on the nature of the sonorous body; the particular figure and quantity of it; and even, in some cases, on the part of the body where it is struck; and this is that which constitutes what we call *different tones*.

The cause of this difference appears to be no other than the different velocities of the vibrations of the sounding body. In effect, the tone of a sound is found, by abundance of experiments, to depend on the nature of those vibrations, whose difference we can conceive no otherwise than as having different velocities; and since it is proved, that the small vibrations of the same chord or string are all performed in equal time, and that the tone of a sound, which continues for some time after the stroke, is the same from first to last, it follows, that the tone is necessarily connected with a certain quantity of time in making each vibration or each wave; or that a certain number of vibrations or waves, accomplished in a given time, constitute a certain and determinate tone. From this principle are all the phenomena of tune deduced.

If the vibrations be isochronous, the sound is called musical, and is said to continue at the same pitch; and is said to be acuter, sharper, or higher, than any other sound, whose vibrations are slower and graver, and flatter or lower, than any other whose vibrations are quicker. See UNISON.

From the same principle arise what we call *concord*s, &c. which are nothing but the results of frequent unions and coincidences of the vibrations of two sonorous bodies, and consequently of the waves and undulating motions of the air occasioned by them.

On the contrary, the result of less frequent coincidences of those vibrations is what we call a *discord*.

Another considerable distinction of sound, with regard to music, is that by which they are denominated *long* and *short*; not with regard to the sonorous body's retaining a motion, once received, a longer or a less time, though gradually growing weaker, but to the continuation of the impulse

impulse of the efficient cause on the sonorous body, for a longer or shorter time, as in the notes of a violin, &c. which are made longer or shorter by strokes of different length or quickness.

This continuity is properly a succession of several sounds, or the effect of several distinct strokes, or repeated impulses, on the sonorous body, so quick that we judge it one continued sound, especially if it be continued in the same degree of strength; and hence arises the doctrine of *measure* and *time*.

Sounds, again, are distinguished, with regard to music, into *simple* and *compound*, and that two ways. In the first, a sound is said to be compound, when a number of successive vibrations of the sonorous body, and the air, come so fast upon the ear, that we judge them the same continued sound; as in the phenomenon of the circle of fire, caused by putting the fire-end of a stick in a quick circular motion; where, supposing the end of the stick in any point of the circle, the idea we receive of it there continues till the impression is renewed by a sudden return.

A simple sound then, with regard to this composition, should be the effect of a single vibration, or of so many vibrations as are necessary to raise in us the idea of sound. In the second sense of composition, a simple sound is the product of one voice, or one instrument, &c.

A compound sound consists of the sounds of several distinct voices or instruments, all united in the same individual time and measure of duration, that is, all striking the ear together, whatever their other differences may be. But in this sense, again, there is a two-fold composition; a natural and an artificial one.

The natural composition is that proceeding from the manifold reflections of the first sound from adjacent bodies, where the reflections are not so sudden as to occasion echoes, but are all in the same tune with the first note.

The artificial composition, which alone comes under the musician's province, is that mixture of several sounds, which being made by art, the ingredient sounds are separable and distinguishable from one another. In this sense the distinct sounds of several voices or instruments, or several notes of the same instrument, are called simple sounds, in contradistinction to the compound ones, in which, to answer the end of music, the simples must have such an agreement in all relations, chiefly as to acuteness and gravity, as that the ear may receive the mixture with pleasure.

Another distinction of sounds with regard to music is that, by which they are said to be *smooth* and *even*, or *rough* and *harsh*, also *clear* and *hoarse*: the cause of which differences depends on the disposition and state of the sonorous body, or the circumstances of the place; but the ideas of the differences must be sought from observation.

Smooth and rough sounds depend principally on the sounding body; of these we have a notable instance in strings that are uneven, and not of the same dimension or constitution throughout.

M. Perrault, to account for roughness and smoothness, maintains, there is no such thing as a simple sound; but that the sound of the same chord or bell is a compound of the sounds of the several parts of it; so that where the parts are homogeneous, and the dimensions or figure uniform, there is always such a perfect mixture and union of all the sounds, as makes one uniform and smooth sound: contrary conditions produce harshness. In effect, a likeness of parts and figure make an uniformity of vibrations, by which a great number of similar and coincident motions conspire to fortify and improve each

other, and unite, for the more effectual producing of the same effect.

This account he confirms from the phenomenon of a bell, which differs in tone according to the part it is struck in; and yet strike it any where, there is a motion over all the parts. Hence he considers the bells as composed of an infinite number of rings, which, according to their different dimensions, have different tones, as chords or strings of different lengths have; and when struck, the vibrations of the parts immediately struck specify the tone, being supported by a sufficient number of consonant tones in other parts. This must be allowed, that every note of a stringed instrument is the effect of several simple sounds; for there is not only the sound resulting from the motion of the string, but that from the motion of the parts of the instrument, which has a considerable effect in the total sound, as is evident from hence, that the same string on different violins sounds very differently.

But Perrault affirms the same of every string itself, and without considering the instrument. Every part of the string, he says, has its particular vibrations, different from the gross and sensible vibrations of the whole; and these are the causes of different motions and sounds in the particles, which uniting compose the whole sound of the string, and make an uniform composition, in which the tone of the particular part struck prevails, and all the others mix under a due subordination with it, so as to make the composition smooth and agreeable. If the parts be unevenly or irregularly constituted, the sound is harsh; which is the case in what we call *false* strings, and various other bodies, which, for this reason, have no certain and distinct tone, but a composition of several tones, which do not unite and mix, so as to have one predominant to specify the total tone.

As to clear and hoarse sounds, they depend on circumstances that are accidental to the sonorous body; thus, a voice and instrument will be hollow and hoarse, if raised within an empty hoghead, that yet is clear and bright out of it; the effect is owing to the mixture of other and different sounds, raised by reflections, which corrupt and change the species of the primitive sounds.

For sounds to be fit to obtain the end of music, they ought to be smooth and clear, possessing especially the first quality: since, without this, they cannot have one certain and discernible tone, capable of being compared to others, in a certain relation of acuteness, of which the ear may judge, and of consequence they can be no part of the object of music.

Upon the whole then, with Mr. Malcolm, we call that an *harmonic* or *musical* sound, which, being clear and even, is agreeable to the ear, and gives a certain and discernible tune (hence called *tunable* sound), which is the subject of the whole theory of harmony.

Dr. Burney, in the discussion of the subject of this article, observes, that enquiries concerning the absolute production and modification of sound belong to physics; whereas a musician only examines sounds comparatively one with the other, and considers their proportions and relation as divided into concords and discords. (See CONCORD, DISCORD, and RELATION.) And it is only in this light, he says, that we shall consider sound in the residue of this article. We shall examine sound under three different heads; the tone, the force, and the quality of tone. Under these heads, sound admits of modification: first, from grave to acute; secondly, loud and soft; thirdly, harsh and sweet, or dull and brilliant.

We shall first establish it as a principle, that whatever is the cause of sound, its vehicle is the circumambient air; because

because the air is the only medium of which we are certain, between the sounding body and the organ of hearing: that we must not multiply bodies unnecessarily, as the air is sufficient to explain the formation of sound; and it is found by an exhausted receiver, that sound cannot be produced without air.

The continuance or permanence of sound can only be occasioned by the agitation of the air. As long as this agitation continues, the tremulous motion of the air is communicated to the ear, and likewise prolongs the sensation of sound. And there is no way more simple of accounting for the duration of sound, than in supposing that the succession of vibrations continues to renew the impression. Further, this agitation of the air, of whatever kind it may be, can only be produced by a similar agitation in the several parts of the sounding body; and it is a certain fact, that these several parts of a sounding body are in constant vibration as long as it continues to sound. If we touch the body of a violoncello, or any instrument, while it is sounding, we feel it tremble under the hand, and we may even see the string tremble as long as it sounds. It is the same with a bell caused to sound by a blow of the clapper, we may feel and see it tremble; and grains of sand, if sprinkled on its surface, will be seen to jump and skip. If a string is relaxed, or a bell cracked, there is no longer either sound or vibration. If, therefore, neither the bell nor the string can communicate to the air no motion but such as they have themselves, there can be no doubt but that sound is produced by the vibrations of the sounding body, and is propagated by similar vibrations, which this tremulous body communicates to the air.

This being supposed, let us first examine what constitutes the ratio of sound, with respect to grave and acute.

Rousseau, in his article *Son*, sound, repeats all the experiments for measuring and comparing sound with sound, which we have given, and shall give, under the different heads of tuning glasses by water, see *ARMONICA*; strings by weight; by moveable bridges, see *MONOCHORD*; by the number of vibrations, see *RATIO*; by the relative length, thickness, and tension of a string, which see; by the beats of organ-pipes, see *BEAT*; by the holes in flutes and hautbois, which serve to shorten the tube; by the different columns of air, which form the different tones of horns and trumpets: these are all upon the same principle as the sons harmoniques of the violin and violoncello. See *HARMONICS*.

The second point to be considered in analysing sound, is its force, which depends on the vibrations of the sounding body: the more powerful and strong these vibrations are made, the more vigorous and audible is the sound. A certain limited degree of force can only be given to a pipe or string, beyond which all its proportions are broken, and its tone rendered false and disagreeable to the ear. The velocity of sound has been considered by the most eminent philosophers and mathematicians; but the result of their enquiries and experiments have materially varied. Halley and Flamsteed make sound move, in England, 1070 Fr. feet in a second; and La Condamine 174 toises in Peru; while Merfennus and Gassendi assure us that the wind being favourable or contrary, neither accelerates nor retards the motion of sound. But since the experiments of Derham (Phil. Transf.), and the Academy of Sciences at Paris, former calculations are regarded as erroneous.

Without slackening its pace, sound becomes weaker by extent from the place of its production; but if not checked by any obstacle, nor repressed by the wind, it generally moves in the ratio of the squares of the distance.

Thirdly, as to the difference of sound in the quality of tone, it certainly does not arise from its elevation in the scale, nor from its force. The tone of a flute and a hautbois, though perfectly in tune together, can never resemble each other. There will always be a softness and smoothness in the flute, and a spirit and agreeable vibration of the reed in the hautbois, which must ever prevent similarity; without mentioning the different tones of voices, by which individuals are as well recognized as by their features. See *VOICE*.

Rousseau says, a composer does not consider merely whether the sounds he uses are high or low, but whether they should be loud or soft, rough or smooth, dull or brilliant; and he distributes them to different instruments and voices accordingly; sometimes in solo parts, and sometimes in *tutti*, or full chorus; at the extremities or medium of instruments or voices in piano or forte, as the composition shall require.

For the appreciable extent of the musical scale or compass, it depends on our power of perception, though in nature it is infinite. Lengthen or shorten a musical string to a certain degree, and it produces no sound. We can neither augment nor diminish the compass of the flute at our pleasure, or the length or shortness of an organ-pipe; both have their limits. All appreciable sounds are comprised, according to Euler, within the numbers 30 and 7552. So that by the experiments of this great geometrician, the lowest sound of which we can ascertain the tone, makes 30 vibrations in a second, and the highest 7552 vibrations in the same time; an interval of nearly eight octaves. See *EULER*, and *COMPASS*.

In our present system of music, we have but one octave of twelve sounds, the rest are all replicates, recurrences, or repetitions of these twelve semitones in the octaves above and below; and if we could use all these octaves or recurrences of sound in the first octave, they amount in all to 96, which is the greatest number of practicable sounds in music, generated by one fundamental.

It is impossible to calculate, with similar precision, the number of practicable sounds in the music of the ancients. For the Greeks may be said to have formed as many systems of music, as they had different ways of tuning their tetrachords. It appears, in reading their treatises of music, that these different tunings amounted to an indefinite number, including all the changes of genus and mode which a new found or key would introduce. See *TETRACHORD*, and *SYSTEM of the ancient Greeks*.

With regard to the twelve sounds of the modern system, the tuning never changes, and they are always immoveable. Brossard pretends that they are moveable, founding his opinion of their being often altered by flats and sharps; but the changing the chord or string, or its sound, are different things.

SOUNDS, Harmonical. See *HARMONICS*.

The harmonical sounds, *viz.* the twelfth and seventeenth above the principal (as well as some others), have been long known to accompany every fundamental sound; and may naturally, and in general, be supposed to be produced by the partial or separate vibrations of the string or sonorous body, spontaneously dividing itself, according to a determinate law, into three, five, or other aliquot parts of the whole, considered as unity. The theory of M. Rameau, which has been so excellently illustrated by M. d'Alembert, in his *Elémens de Musique*, is founded on these harmonical sounds. See *FUNDAMENTAL Base*, *HARMONY*, and *SYSTEM*.

SOUNDS, Harmonic, denote also a singular kind of sounds, which are produced in certain instruments, such as the violin and violoncello, by a particular motion of the bow, and by placing

placing the finger lightly in certain divisions of the chord or string. On account of their sweetness, they are called *fluted* sounds. By sliding the finger lightly from sharp to flat, from the middle of a chord which is touched at the same time with the bow, we hear distinctly a succession of harmonic sounds from flat to sharp, which are very astonishing to those who are not acquainted with the theory. See *Sons Harmoniques*.

The principle on which this theory is founded is, that if a chord be divided into two parts which are commensurable with each other, and consequently with the whole chord, and the obstacle placed at the point of division obstructs, in an imperfect manner, the communication of the vibrations from one part to another; when it is sounded, it will not yield the sound of the entire chord, nor that of its greater part, but that of the smaller part, if it exactly measures the other; or if it does not measure it, the sound of the greatest aliquot common to these two parts. Let a chord, as 6, be divided into two parts, as 4 and 2, the harmonic sound will be produced by the small part, 2, which is the aliquot of the other, 4; but if a chord, as 5, be divided into two parts, as 2 and 3, then, as the small part does not measure the greater, the harmonic sound will proceed from the half, 1, of the small part; unit being the greatest common measure of the two parts 3 and 2, and of the whole chord 5. By means of this law, which is conformable to the experiments of M. Sauveur and of Dr. Wallis, it is easy, by a very simple calculation, to assign to each tone the harmonic sound which answers to it. Whilst the finger slides the length of the chord, we obtain a series of harmonic sounds, which succeed each other rapidly according to the order of the divisions of the chord, to which the finger is successively applied.

The first column of the following table exhibits the sounds which the divisions of the instrument would yield when touched full, and the second column shews the *fluted* sounds corresponding to them when the chord is touched harmonically.

TABLE of Harmonic Sounds.

The whole chord	} gives	the unison.
The minor third		the 19th, or double octave of the 5th.
The major third		the 17th, or double octave of the major third.
The fourth		the double octave.
The fifth		the 12th, or octave of the same 5th.
The minor sixth		the triple octave.
The major sixth		the 17th major, or double octave of the 3d.
The octave		the octave.

After the first octave, *i. e.* advancing from the middle of the chord towards the bridge, we shall have again the same harmonic sounds in the same order on the same divisions, *i. e.* the 19th on the minor 10th, the 17th on the major 10th, &c. *Encyclopédie*, art. *Harmoniques Sons*. See *HARMONICS*, and *HARMONY*.

SOUNDS, *Third*, denote those which are produced by sounding two notes at the same time, either on the same or on two different instruments; and which are almost always graver than the lowest of the two tones that generated them, and are their proper fundamental base.

The discovery of these sounds has been generally ascribed to Tartini, who published an account of them in his "Tratto di Musica, secundo la vera Scienza dell'Armonia," printed at Padua, 1754; but the *Encyclopédie*, art. *Harmonie*, attri-

butes the first discovery, though probably unknown to Tartini, to M. Romieu, of the Royal Society of Sciences of Montpellier, who published an account of it in a memoir in 1752.

The experiment may be made by founding the perfect interval of a 3d, 4th, or 5th, &c. either on two strings of the same violin, or on two violins played upon at the distance of about thirty feet, with a strong bow, and holding out the notes; or with two trumpets, hautbois, or German flutes; the hearer, in the last mentioned cases, playing himself in the middle of the interval between the two instruments. Thus, *e. gr.* the interval C *e*, or a major 3d, produces C, the octave below the lower note; C sharp *e*, a minor 3d, produces A, a tenth below the graver tone; B *e*, a 4th, gives E, the octave of the upper note; B *f* sharp, a 5th, produces an unison to B; B *g*, a 6th, generates the double octave below the upper note; and B flat *g*, or the major 6th, produces E flat, the 5th of the lower note, &c.

M. Tartini observes, that the third sound resulting from the 4th, from two 3ds, from two 6ths, whether major or minor, is the most easily distinguished, because this sound is always more grave than either of the two which produce it; that the third sound produced by the 5th is distinguished with greater difficulty, because it is an unison of a graver sound; and that it is more difficult to distinguish it in the tones major and minor, because these tones, differing little from one another, are easily confounded in the intonation; and for the same reason, with greater difficulty, in the semitones major and minor.

The author, in a song composed of two parts, discovers, by means of two corresponding sounds, the third sound resulting from them; and this, he says, is the true base of the song; and every other base will be a paralogism. From his experiments and reasoning he concludes, that if any adjoining two simple intervals in the harmonic series 1, $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, &c. be sounded, the third sound will always be that of half the string; that the smaller the interval is, the farther distant is the third sound: so that, *e. g.* the third sound to the interval of the semitone minor G G sharp, is the 26th below G natural.

M. Serre, of Geneva, in his "Essai sur les Principes de l'Harmonie," printed at Paris in 1753, mentions this discovery of Tartini as a fact sufficiently ascertained; and adds, that he has produced the same effect by means of two fine female voices, as Tartini had done by instruments; but he mentions only the third sound produced by the third major, and that produced by the third minor: and there is this difference between the results of these two gentlemen. According to M. Tartini, the two sounds of a third major, as *ut mi*, produced the octave *ut* below *ut*; and according to M. Serre, a double octave: according to the former, the two sounds of a third minor, *la ut*, produced the tenth major, *fa* below *la*; but according to the latter, the seventeenth major below *la*, or the octave under the tenth *fa*. M. Serre takes no notice of a third sound produced by any other two sounds, and it does not appear that he made any trials of this kind.

As to the physical cause of these third sounds, it is much more difficult to offer any plausible conjectures concerning it, than concerning the harmonical notes mentioned in the preceding article; because all those of the latter kind being more acute than the principal, or generating tone, are, for that reason, capable of being actually and immediately produced by the vibrations of certain portions of the string or other sounding body; whereas, in the third sounds, a tone is heard always (except in the case of the fifth), and often

considerably below the pitch of either of the bodies whose vibrations it accompanies, and which consequently cannot immediately proceed from either of these bodies. To take the first of the above-mentioned intervals, that of the greater third, for an example: a third sound is here heard, such as would be produced by the actual vibration of a string of the same diameter and tension with, but of double the length of, that which produced the lowest note of the interval. As no such string, however, is employed in the experiment, we are obliged to seek for the cause of this new sound in the air, or other medium of sound, or in the organ of hearing, or in some internal modification of the sensitive faculty.

As the immense variety of our sensations of colour is justly supposed to be produced by an equal diversity of coloured particles of light, each highly qualified to excite one particular sensation and no other, so some, with M. Mairan, have supposed, that our numerous and diversified sensations of musical tones are not produced by the undulations of the air, considered in its whole mass, but by aerial particles, specifically different in elasticity, magnitude, figure, &c. each capable of exciting, by its motions or other modifications, the idea of only one determinate tone. Therefore we might say, that the two orders of particles which give the tones C and *e*, either by an harmonical congruity in their spring with that set of particles which give the third sound C below, or by some other peculiar affinity to them, are qualified, by their joint action on these last-mentioned particles, to give them that particular modification, by which they excite in us the sensation of that specific tone to which they are adapted. Or, may we not conceive in general, that a mixture of two given tones may excite the idea of a third and different sound, in some such manner as two given colours, *e. g.* blue and yellow; nay, the past impressions of these colours excite the idea of green, different from both of them.

But if the effect is produced merely by the organ of hearing, we may observe, that, from a consideration of the spiral and conical structure of the cochlea, some physiologists have been tempted to imagine, that the branches or filaments of the auditory nerve, after passing out from the nucleus or axis of the cochlea, are strained upon the spiral plates, like the radii of a circle, and become gradually shorter and shorter toward its apex. It may be supposed likewise, that of these nervous strings, the longest, which are in the basis of the cochlea, are adapted to receive the tremors or other impressions, and convey to the mind the ideas, of grave tones; and the shorter nervous chords, fixed more towards the apex of the cone, those of acute sounds. This being allowed, and taking the former interval C *e* for an example, it may be said that the tone C, besides acting on the nervous chord appropriated to excite the idea of that tone, must act likewise on another nervous chord of double its length, situated towards the basis of the cochlea, &c. and which is naturally adapted to receive and transmit to the mind C, the octave below; but which the upper tone C now divides into two equal parts, each giving tones unison to the said note C. The tone *e*, in like manner, will excite five equal vibrations in each of the halves of this nervous chord; all which, likewise, produce sensations unison with itself. These phenomena at least are invariably observed to be produced in musical strings. Thus we obtain the unisons to C and *e*: and farther, the last-mentioned chord thus vibrating in two and in ten parts, and from one extremity of it to the other, may fairly be supposed to vibrate in its whole length; in which case it must excite in the mind the idea of its own fundamental tone, the third sound C, an octave below the first of these notes, and a tenth below the latter. See, on the sub-

ject of this article, Encyclopédie, art. *Basse FONDAMENTALE*. Principles and Power of Harmony, 4to. 1771, and Monthly Rev. vol. xlv. p. 371, &c.

SOUND, in *Geography*, denotes a strait or inlet of the sea, between two capes or head-lands.

The Sound is used, by way of eminence, for that famous strait which joins the German sea to the Baltic.

It is situate between the island of Zealand and the coast of Schonen. It is about sixteen leagues long, and in general five broad, excepting against the castle of *Cronenburg*, (which see,) where it is but one; so that there is there no passage for vessels but under the cannon of the fortrefs.

This was first erected for the better commanding of the Sound, as was also *Helsingburgh*, on the opposite shore in Schonen, for the protection of ships from pirates, then numerous in that sea.

This has given occasion to the Danes to settle a toll on all vessels, which is said to be one of the best revenues of the crown of Denmark; and to forbid all pilots from pailing through the Great and Little Belt, which are two other inlets into the Baltic, though somewhat less commodious than the former.

All nations who traffic into this part of the North are subject to this toll: the Swedes, indeed, were exempted from it by the treaty of 1644, but by the treaty of 1720, they are excluded the privilege, and put on the same footing with their neighbours.

By the treaty of Spire, made between the Danes and Charles V. in behalf of his Netherland subjects, the toll for this passage was fixed at two rose nobles for a ship of two hundred tons; yet, in the year 1640, the same was raised to upwards of five hundred rix-dollars.

The connivance of our king James I. who had married a daughter of Denmark, and the wars which the Hollanders had been long engaged in for their liberty, furnished the occasion for so grievous an exaction. Of late years, the toll has been again reduced to an easier footing.

Cromwell was bent on extorting this passage from the Danes, and had probably effected it, but that, before the fleet for that purpose arrived there, he died.

However, in 1659, England, Holland, and France, by treaty, obliged Denmark to stipulate, that it shall never be increased upon the said three nations, who are mutual guarantees to this treaty.

The origin and progress of this imposition (which, from an easy contribution, of which we have an account so early as 1348, voluntarily paid by merchants for maintaining lights on certain places of the coast, and for protection of ships from pirates, and of which the king of Denmark was only treasurer or trustee, grew at length to be a heavy burden on trade, as well as a kind of servile acknowledgment of his sovereignty of these seas) is given in lord Molesworth's Account of Denmark, chap. iii. p. 11. seq.

As to the present state of this toll, Dr. Busching, in his New Geography, observes, that it is on an equal footing with all nations, excepting the Hamburgers, who pay more than others: the English, Dutch, Swedish, and French ships, are not searched when provided with proper passes, according to treaties; and pay down only 1 per cent. for such goods as are not specified in the tariff. But all other nations pay 1½ per cent. and must submit to be searched. With regard to the Hanse Towns, on the Baltic, there is a great variety in the toll they pay, for almost every one of those towns is treated with in particular. See DENMARK and ELSINEUR.

On the Sound, accounts are kept in rix-dollars, of 4 orts, which contain 96 skillings Danish, or 48 skillings Hamburg

burgh money. The tolls paid at the passage of the Sound are reckoned in rix-dollars, Swedish specie, which are $12\frac{1}{2}$ per cent. better than crown money, and therefore $19\frac{7}{7}$ per cent. better than Danish currency; but this rix-dollar is $2\frac{2}{5}$ per cent. worse than the effective rix-dollar specie of 7 marks 6 skillings Danish currency. The tolls are also sometimes settled in crown money. In paying duties at the Sound, the shipping is reckoned for 300 lbs.; the stein or stone for 30 lbs.; the Russian berkowitz for 300 lbs.; and the pood for 30 lbs. Here are also certain regulations for foreign measures, an abstract of which is given in Kelly's Cambist.

SOUND, in the *Manege*. A horse is said to be found that does not halt. When a jockey feels a horse he warrants him found hot and cold; that is, that he does not halt either when you mount him or when he is heated, nor yet after alighting, when he stands and cools.

SOUND, an instrument which surgeons introduce through the urethra into the bladder, in order to discover whether there is a stone in this viscus or not. The found is usually made of very highly polished steel, that it may be well calculated for conveying to the surgeon's fingers, a sensation of any thing against which its end may strike. It is also generally less curved than a catheter, so that its end may be more easily inclined to the lower part of the bladder, where the stone is most frequently situated.

SOUND-BOARD, or *Wind-chest*, of an organ, is the principal part of that most noble and comprehensive instrument, and that which feeds all the pipes with wind. See **ORGAN**.

The found-board, or *fommier*, as it is called in France, is a reservoir, into which the wind drawn in by the bellows is conducted by a port-vent, and thence distributed into pipes placed over the holes of its upper part. The wind enters the pipes by valves, which are opened by pressing the keys, after drawing the registers by the stops, which prevent the air from going into any of the pipes, except those required. Organs, whose longest pipe in the diapason is four feet, have their found-board from five to six feet. Organs of sixteen feet have two found-boards, which communicate the wind from one to the other, by means of a pewter port-vent.

SOUND-HOLM, in *Geography*, one of the smaller Shetland islands, near the S.W. coast of Yell.

SOUNDING, in *Navigation*, the act of trying the depth of the water, and the quality of the bottom, by a line and plummet, or other artifice.

There are two plummets used for this purpose; one of which is called the hand-lead, weighing about 8 or 9 lbs. and the other the deep-sea lead, which weighs from 25 to 30 lbs. and both are shaped like the frustum of a cone or pyramid. The former is used in shallow waters, and the latter at a great distance from the shore, particularly on approaching the land after a sea voyage. Accordingly, the lines employed for this purpose are called the deep-sea lead-line and the hand-lead line. The hand-lead line, which is usually 20 fathoms in length, is marked at every 2 or 3 fathoms; so that the depth of the water may be ascertained either in the day or night: at the depth of 2 and 3 fathoms, there are marks of black leather; at 5 fathoms, there is a white rag; at 7, a red rag; at 10, and at 13, black leather; at 15, a white rag; and at 17, a red one.

Sounding with the hand-lead, which the seamen call heaving the lead, is generally performed by a man who stands in the main-chains to windward. Having the line all ready to run out, without interruption, he holds it nearly at the distance of a fathom from the plummet, and having swung the latter backwards and forwards three or four times, in order to acquire the greater velocity, he swings it round his head,

and thence as far forwards as is necessary; so that, by the lead's sinking whilst the ship advances, the line may be almost perpendicular when it reaches the bottom. The person sounding then proclaims the depth of the water in a kind of song, resembling the cries of hawkers in a city; thus, if the mark of 5 is close to the surface of the water, he calls, 'by the mark 5,' and as there is no mark at 4, 6, 8, &c. he estimates those numbers, and calls, 'by the dip 4, &c.' If he judges it to be a quarter or a half more than any particular number, he calls, 'and a quarter 5,' and 'a half 4,' &c. If he conceives the depth to be three-quarters more than a particular number, he calls it a quarter less than the next: thus, at 4 fathoms $\frac{3}{4}$, he calls, 'a quarter less 5,' and so on.

The deep-sea lead-line is marked with two knots at 20 fathoms, 3 at 30, 4 at 40, &c. to the end. It is also marked with a single knot at the middle of each interval, as at 25, 35, 45 fathoms, &c. To use this lead more effectually at sea, or in deep water on the sea-coast, it is usual previously to bring-to the ship, in order to retard her course: the lead is then thrown as far as possible from the ship on the line of her drift, so that as it sinks, the ship drives more perpendicularly over it. The pilot feeling the lead strike the bottom, readily discovers the depth of the water by the mark on the line nearest its surface. The bottom of the lead being also well rubbed over with tallow, retains the distinguishing marks of the bottom, as shells, ooze, gravel, &c. which naturally adhere to it.

The depth of the water, and the nature of the ground, which are called the foundings, are carefully marked in the log-book, as well to determine the distance of the place from the shore, as to correct the observations of former pilots. Falconer.

For a machine to measure unfathomable depths of the sea, see **ALTITUDE**.

SOUNDING the Pump, at Sea, is done by letting fall a small line, with some weight at the end, down into the pump, to know what depth of water there is in it.

SOUNDING, in *Surgery*, the operation of introducing the found. See **SEARCHING for the Stone**.

SOUNDIPOUR, in *Geography*, a town of Hindoostan, in Bahar, 8 miles S. of Rotalgur.

SOUNE, a small island in the Indian sea, near the coast of Africa. S. lat. $10^{\circ} 57'$.

SOUNISA, a town of Asiatic Turkey, in the government of Sivas; 27 miles N. of Tocat.

SOUNMEN HARIO HOTUN, or **SOUMEN Char**, a town of Chinese Tartary, in the province of Hami; 15 miles N.W. of Hami-Hotun.

SOUP, or **SOOP**, a kind of pottage made of bread, and broth, or of the juice of flesh, or other matters, usually served at the beginning of a meal.

The word is French, formed from the Italian, *zuppa*, or *suppa*, of the Latin, *sapa*, wine boiled away to a third part. Others derive it from the Celtic, *fouben*, which signifies the fame.

Soup is esteemed essential to a French dinner. Sometimes they heighten the relish by the addition of onions, or leeks, or cabbage, or turnips, &c.

SOUP, *Portable*, is a kind of cake, formed of concentrated broth, which, being freed from all fat, and having by long boiling evaporated the most putrescent parts of the meat, is reduced to the consistence of a glue, as in reality it is, and will, like other glues, in a dry place, keep found for years together. Sir John Pringle inclines to believe, that the gelatinous parts of animal substances, such as compose these cakes, are not of a nature much disposed to putrefy. But, however that be, captain Cook observes, that, in his voyage
(see

(see SCURVY), this soup was the means of making his people eat a greater quantity of greens than they would have done otherwise, and so far we must allow it to have been virtually antiseptic. For the method of preparing cakes for portable soup, by Chaptal, &c. see JELLY.

SOUP, in *Agriculture*, a term applied to such liquid animal food or provisions, as are formed by cutting various dry materials, such as hay, straw, &c. and blending them with liquid matters; and also to such as are prepared with meals of different sorts, such as that of oats, peas, beans, and others of a similar kind. By this practice, the substances are not only found to go much farther, but to have a much greater effect in promoting the growth or fattening of the animals.

The advantages of preparing the food, and feeding some sorts of animals in this way, are now well known, as such food not only goes much farther, but affords a much greater improvement in the animals. The advantage of feeding young hogs with soups of these kinds are fast becoming well understood; and the animals are found to go on far better with them than in the old methods of proceeding, but there is still much to be done in regard to the modes of preparing of them, and the conditions in which they should be at the time they are given. See SWINE.

SOUPROSSE, in *Geography*, a town of France, in the department of the Landes; 6 miles S.E. of Tartas.

SOUR. See SUR.

SOUR, a river of France, which rises near Bastogne, in the department of the Forests, and runs into the Moselle, 3 miles above Treves.

SOUR Gullan, a town of Algiers, near mount Jurjura.

SOUR-Dock, in *Botany*. See SORREL.

SOUR-Food, in *Agriculture*, such food as has been rendered sour by the acetous fermentation, and which has lately been said to be of superior utility in the fattening of animals. Oxen as well as swine have lately been supposed by some to feed faster, where their food has been brought into this condition before using it, than when used in the natural state. See STALL-feeding.

SOUR-Gourd, in *Botany*. See ADANSONIA.

SOUR-Grass, in *Agriculture*, the coarse tufty herbage usually met with about the dung-heaps in fields, and where there is much stagnant moisture. It is observed by Dr. Darwin, that where a piece of grass is over-run with tussocks of sour-grass, which often happens near towns, he has been informed, that lime or coal-ashes spread on them, would render the grass sweeter, so that horses or cattle would eat it. But he supposes the more certain and advantageous management would consist in mowing it frequently, and giving it to horses or cattle in the stable or stall; as he believes they will eat it greedily after it has been a few hours withered, and thus the land will not only yield more provender at present, but after a few mowings a sweeter grass will rise in the place of that which was of a bad kind, or of too luxuriant growth, for which purpose it should be mowed as near the ground as may be; or if it be frequently mowed during the summer, and left on the ground, some cattle will eat it, when it is withered to a certain degree; by which the disagreeable flavour of it is probably lessened or destroyed. Proper drainage and close feeding such lands, are likewise useful methods of bringing them into a state of better and sweeter grass.

SOUR-Krout. See CROUTE.

SOUR-Land, in *Agriculture*, a term applied to cold clayey soils, and such as have some sort of impervious strata at no great distance from the surface, by which they are kept in a wet and sour state. See CLAY, and Clayey SOIL.

SOUR-Sop, in *Botany*. See ANNONA.

SOURA, in *Geography*, a town of the Arabian Irak, on the Euphrates; 153 miles N.W. of Bassora.

SOURA, a town of Portugal, in Estremadura, situated on the river Soure; 7 miles S.S.E. of Montemor o Velho.

SOURABAYA, a pleasant town on the N.E. coast of the island of Java, situated on the banks of a river, a mile and a half distant from the sea-shore, so that only the flag-staff can be seen from the road. The river is navigable up to the town for vessels of 100 tons burthen, and the bank on one side is made convenient for tacking. The Chinese carry on a considerable trade here, and have a town on the side of the river opposite to Sourabaya. The country near the town is flat, and the soil light, so that they plough with a single bullock, or buffalo. The latitude in Sourabaya road is $7^{\circ} 11'$ S. The Dutch had a resident in this place, with the rank of senior merchant, and the title of the commander of the eastern district. The chief commodity of this government is rice. The interior parts of the country, near the mountains, are infested with a breed of fierce tigers, which render travelling dangerous. Here is also a breed of horses, small, but handsome and strong. The Javanese in the vicinity are numerous. Stavorinus's Voyage, vol. ii.

SOURAH, a town of Hindoostan, in the circar of Aurungabad; 20 miles S.S.E. of Jaffierabad.

SOURAN, a town of Persia, in Khorassan; 255 miles N. of Herat.

SOURAPATA, a kingdom on the S. coast of the island of Java.

SOURATAU HOUTCHIN, a town of Chinese Tartary, in the country of the Monguls. N. lat. $53^{\circ} 54'$. E. long. $114^{\circ} 34'$.

SOURDEVAL, a town of France, in the department of the Channel, and chief place of a canton, in the district of Mortain; 4 miles N. of Mortain. The place contains 3896, and the canton 9580 inhabitants, on a territory of 115 kilometres, in 9 communes.

SOURDON, in *Natural History*, the name of a bivalve shell-fish found on the coast of Poitou, and other places. It is a small fish, its length being little more than an inch, and its breadth about three quarters of an inch; its shells are both considerably convex; the outer surface is deeply furrowed, but the inside is perfectly smooth: the fish buries itself lightly in the sand, and has a pipe of communication, which it raises to the surface; but as this creature never buries itself deep, the pipe is necessarily very short; but they are cut into several segments at the extremity, and appear as it were fringed, and have several hairs growing from these segments. The sourdon is capable of a progressive motion by means of a limb, somewhat resembling that of the other chamæ, but more than any approaching the nature of a leg, as it in some measure represents, in miniature, a human leg with a clumsy boot upon it: by means of this limb the creature can easily bury itself in the sand, or rise up out of it, or move horizontally on the surface, and that as well backwards as forwards, and with more swiftness than could well be supposed. Mem. Acad. Par. 1710.

SOURE, in *Geography*, a river of Portugal, which runs into the Mondego; 4 miles S. of Montemor o Velho.

SOURERAH, a town of Hindoostan, in the circar of Cicacole; 40 miles W.N.W. of Ganjam.

SOURI, a town of Persia, in the province of Laristan, on the Persian gulf; 38 miles S.W. of Ormus.

SOURING Lime for Mortar and Plaster, in *Rural Economy*, the practice of macerating and rendering it proper

per for these uses. It has been stated by the writer of an "Essay on Quicklime as a Cement," that when lime is to be employed for making plaster, it is of great importance that every particle of the limestone be flaked before it is worked up; for, as the smoothness of the surface is the circumstance most wished for in plaster, if any particles of lime should be beaten up in it, and employed in work before they have had sufficient time to fall, the water will continue to act upon them after the materials have been worked up, will infallibly flake such particles, which will then expand themselves in a forcible manner, and be productive of those excrescences upon the surface of the plaster, which are commonly known by the name of blisters. Consequently, if it be intended to have a perfect kind of plaster, which is capable of remaining smooth on the surface and free from blisters, there is an absolute necessity for allowing the lime of which it is composed, to lie for a considerable length of time in maceration with water, before it is wrought up into plaster, which is a process or operation that is here termed *souring*. Where the limestone is of a pure quality, and has been very perfectly calcined or burnt, there will seldom be any danger of the whole of the lime falling at first; but where it has been less perfectly burnt, there will be many particles, which will require to lie a long time before they will be completely reduced into powder. This macerating process or operation is consequently more necessary with impure than pure lime; but still it ought on no occasion to be omitted or neglected, as there is not the smallest probability, but that some blisters would appear on the surface of plasters made with even the purest lime, when worked up and applied immediately after being flaked, without undergoing this *souring* process in some degree.

The practice is also common of *souring* the lime when it is intended for being used in mortar; but although it is not so indispensably necessary in this case, as in that where it is designed for plaster, yet, when properly performed, it is evident, it is said, that it must even in this instance too be of utility; as any dry knots of lime that may fall after the mortar is used, must have a tendency to disunite the parts of it, which have already been united, and to render the mortar or cement much less perfect than if the whole had been properly mixed up with the materials and allowed to *four* before using. More circumspection is, however, requisite, it is said, in *souring* lime for mortar than for plaster; for, as it is not necessary that plaster should be endowed with a stony degree of hardness, there is no loss sustained by allowing a great proportion of the lime which is designed for that purpose to absorb its air before it be used; for a very small quantity of caustic or quicklime will be sufficient to unite the whole into one slightly coherent mass. Consequently, the only circumstance which is necessary to be attended to in *souring* lime for plaster is, that it be allowed to macerate long enough, as there is no danger of ever erring on the opposite extreme. It is indeed necessary, it is said, on some occasions, it should lie a very long time, before any certainty can be had, that all the particles are thoroughly flaked, as pieces of lime-shells have been known to lie upwards of six months exposed to all the changes of the winter weather, and fall after that period. Such slightly burnt limes are indeed, it is said, usually separated in *sifting* the lime for plaster; but as some small chips may escape, it is always the safest way to allow lime to lie in the *four* a very considerable length of time. Another advantage of some consequence likewise, it is said, attends this practice; as, if by such means a large proportion of the lime be allowed to absorb its air, and become

in the mild or effete state, when it is wrought or beaten up for use, the water can have no sensible effect upon this mild lime; it will only separate the particles of the caustic lime more perfectly from each other, so as to permit it to dry without cracks of any kind, and render the surface of the plaster a great deal more smooth and entire, than could have been the case, if the whole had been made use of while in the perfectly caustic state. By this means too, those crystalline exudations, which are so common on walls newly plastered, will be the best and most effectually prevented. On all which accounts, the practice of *souring* lime, which is designed for plaster, to macerate or *four* a long time with water, should never, it is said, except in cases of necessity, be neglected or overlooked.

However, as lime, from the moment of its being fully flaked, begins to absorb air, and continues to take up more and more every minute from that time until it becomes perfectly mild or effete, so as to be rendered gradually less and less proper for forming mortar of any kind, it necessarily follows, that where lime designed for this purpose is permitted to lie long in the *four*, a great part of it will be converted into chalky matter, or uncrystallized mild or effete lime, in which state it will be capable of having so much sand added to it, or of forming so good a mortar as would have been the case, if a larger proportion of the sandy material had been made use of in the first place, and been wrought up as speedily as possible, without so much *souring*, into mortar, and immediately made use of. The evil will also be increased where the lime has been but slightly burnt, consequently the best burned lime should always be preferred for this use, which, when carefully sifted after flaking, will soon fall sufficiently for this purpose; as the main point here is to have the mortar firm and binding; and the falling or bursting of very small unflaked particles of lime in the mortar afterwards, will not be productive of such evident inconvenience as is the case in the making and using of plaster. In the making of good mortar, it will consequently be necessary to get the best burnt lime, and to only suffer it to macerate or *four* with water a very short time before it is wrought and applied. The best burnt lime, however, mostly requires some days to macerate and *four* with water, before the whole becomes fully flaked and fallen for this use.

This doctrine of the nature and utility of the *souring* process in the making of these substances is supposed to receive additional proof and support from the practice which was followed by the ancients, which is very similar to this, if the accounts given of it by Vitruvius and Pliny can be depended on. The former, it is said, expressly recommends that the lime should be macerated or *soured* in water, for exactly the same reasons that have been already seen, as it is only by that means, he asserts, that the plaster can be prevented from blistering. His words are these: "*tunc de albariis operibus est explicandum. Id autem erit recte, si glebæ calcis optime, ante multo tempore quam fuerit, macerabuntur. Numque cum non penitus macerata, sed recens sumitur—habens latentes crudos cuculos, pustulas omittit.—Qui calculi dissolvunt et dissipant tædiorii positiones.*" Vit. lib. vii. c. 2.

The latter points out, it is said, in a still more clear manner, the difference between the quality of the lime, which is necessary for making mortar and plaster:—a certain proof, it is conceived, that the ancients had been very accurate in the observing of facts, as they could have no idea of the reasoning by which those facts might have been corroborated or explained.

"*Ruinarum urbis,*" says he, "*ea maxime causa, quod*

furto, calcis sine ferrumine suo cementa componuntur. *Intrita* quoque quo *vetustior, eo melior*. In antiquarum (antiquis) ædificiis invenitur, ne recentiore trima uteretur redemptor; idio nulla (nullæ) tectoria eorum rimæ fædaverè." Plin. Hist. lib. xxxvi. c. 23.

In this passage, the writer strongly contrasts, it is said, mortar (*cementa*) with plaster (*intrita*). The first, he contends, by implication, ought always to be composed of lime *cum ferrumine suo*; that is, lime which still retains its *gluten*, cementing or adhering principle; lime that still keeps or possesses that quality, by which it is enabled to unite detached matters into a solid body, and *glue* them, as it were, together. In other places of the same work, the author, it is said, describes it as *calcis quam vehementissimæ*; lime in its most acrid state; that is, perfectly *caustic* lime. And this quality he plainly hints, it gradually loses by time, so as to come at length to be *sine ferrumine suo*: in which state, as it is impossible to become a good firm mortar or cement for building with, those who make use of it as such are severely reprehended. But although the practice of using old and inert lime for mortar is condemned, it is immediately added, as has been seen above, that for plaster it is better than new, because it is not so subject to crack in the work.

Thus it would seem, that the importance of the souring operation or process, for these different purposes, was well known at an early period, though the principles on which its utility depended, were probably far from being understood.

SOURIS, LAKE *des*, in *Geography*, a lake of Canada, the direction across which is amongst islands, N.W. by W. six miles. In this traverse is an island remarkable for a very large stone in the form of a bear, on which the natives have painted the head and snout of that animal; and here they were also formerly accustomed to offer sacrifices. This lake is separated only by a narrow strait from the lake du Serpent, which runs N.N.W. seven miles, to a narrow channel, that connects it with another lake, bearing the same name, and running the same course for 11 miles, when the rapid of the same denomination is entered on the W. side of the lake. A singular circumstance is observable here, that for three or four miles on the N.W. side of this lake, there is an high bank of clay and sand, clothed with cypress trees, no such case occurring on any other lake described by Mackenzie; as they are bounded, particularly on the N., by black and grey rocks. Mackenzie's Travels, Introd.

SOURIS, in the *Manege*, is a cartilage in the nostrils of a horse, by means of which he snorts. See SNORT.

The cutting of this cartilage is called in French *effou-riffer*.

SOURMAN, in *Geography*, a town of Thibet; 250 miles N.E. of Lassa.

SOURNAT, a town of France, in the department of the Correze; 9 miles N.N.W. of Uffel.

SOURNIA, a town of France, in the department of the East Pyrenées, and chief place of a canton, in the district of Prades; 7 miles N. of Prades. The town contains 842, and the canton 3718 inhabitants, on a territory of 160 kilometres, in 12 communes.

SOUROUBEA, in *Botany*. See RUYSCHIA.

SOURTOU, in *Geography*, a town of Chinese Tartary. N. lat. 44° 51'. E. long. 94° 24'.

SOURUNGE, a town of Hindoostan, in the circar of Cicacole; 35 miles S.W. of Ganjam.

SOUSEL, a town of Portugal, in Alentejo, containing about 1300 inhabitants; 6 miles N.N.W. of Eûremoz.

SOUSOU, a town of Asiatic Turkey, in Natolia; 24 miles N. of Satalia.

SOUSOUGHRLIK, a town of Asiatic Turkey, in Natolia; 20 miles S.E. of Balikeftri.

SOUSSERAC, a town of France, in the department of the Lot; 6 miles E. of St. Ceré.

SOUSTONS, a town of France, in the department of the Landes, and chief place of a canton, in the district of Dax. The place contains 2578, and the canton 6604 inhabitants, on a territory of 417½ kilometres, in 11 communes.

SOU-TCHEOU, SOO-CHOO, or SOO-CHOO-FOO, a city of China, of the first rank, in the province of Kiang-nan, situated in the vicinity of Nan-lum, on a river which communicates with the lake Tain-hoo. This is reckoned one of the most agreeable cities in China, and compared by Europeans, who have seen it, with Venice, with this difference, that the latter is built in the sea, and Sou-tcheou is intersected by canals of fresh water, branching from the principal canal, over each of which branches is erected an elegant stone-bridge. In the walls of the city are turned several arches, through which the canal passes. Under these walls are drawn up an immense number of vessels; and one ship-building yard contained, when this city was visited by the embassy, sixteen upon the stocks, close to each other, each of the burden of about two hundred tons. The suburbs are very extensive. Sou-tcheou is large and very populous; the houses are neat and well built, and the inhabitants respectably dressed, mostly in silk. The women, says sir John Staunton, were fairer than those in the north; many of whom wore a small cap of black satin, adorned with spangles upon the forehead, brought down to a peak above the eye-brows; and they had ear-pendants of gold or crystal.

There is not perhaps in the universe, according to Grofier's account, a country more delightful, either for pleasantness of situation, or mildness of climate. The air is so temperate, provisions so plentiful and cheap, the soil so fruitful, and the manners of the people so gentle, that this city is considered as the paradise of China. "Above (say the Chinese authors) is the celestial paradise; but the paradise of this world is Sou-tcheou." Upon observing the continual motion of its immense number of inhabitants, and the confusion occasioned every where by their commercial intercourse with strangers, one would be induced to believe that the trade of all the provinces centered in it. The brocades and embroideries manufactured here are in great request through the whole empire. The jurisdiction extends over only eight cities, one of which is of the second class, and the rest of the third; but all these cities are beautiful, and about two or three leagues each in circumference. In the vicinity of this city is found that remarkable tree which furnishes tallow, the "croton sebiferum" of Linnæus. See CROTON. N. lat. 31° 22'. E. long. 120°.

SOUTELLO, a town of Portugal, in the province of Beira; 17 miles W. of St. Joao do Pefqueira.

SOUT-EL-TELL, a mountain of Algiers; 30 miles N.E. of Tremecen.

SOUTERRAINE, LA, a town of France, in the department of the Creufe, and chief place of a canton, in the district of Gueret; 17 miles W. of Gueret. The place contains 2665, and the canton 10,237 inhabitants, on a territory of 275 kilometres, in 11 communes. N. lat. 46° 15'. E. long. 1° 34'.

SOUTH, one of the four cardinal points of the compass. See CARDINAL Points.

SOUTH, ROBERT, in *Biography*, a divine of the church of England, eminent for learning, talents, and wit, was the son of a London merchant, and was born at Hackney in

1633. He was educated at Westminster school by the celebrated Busby, from whence he was elected to Christchurch, Oxford. Here he was soon distinguished for his classical attainments, of which one of his products was an elegant Latin poem addressed to Oliver Cromwell, on the conclusion of the Dutch war. Another poem of his, which was much read and applauded, was entitled "Musica Incantans," which was afterwards printed separately, at Dr. Fell's request. In 1657 he commenced M.A., and in the following year he received holy orders from one of the deprived bishops, and being soon after chosen to preach the assize sermon before the judges, he made a violent attack upon the Independents, which ingratiated him with the Presbyterians. Soon after the Restoration, he was chosen public orator of the university. In this office he acquitted himself so much to the satisfaction of lord Clarendon, when complimenting him at his investiture as chancellor of the university, that he was taken under the protection of that eminent man, and appointed his domestic chaplain. He was promoted to a prebend of Westminster in 1663, and was in the same year admitted to the degree of D.D. He soon succeeded to a canonry of Christchurch, and in 1673 he attended as chaplain to the younger son of the earl of Clarendon, in an embassy to Poland. On his return he was presented to the rectory of Islip, in Oxfordshire, and became greatly distinguished by his turn for humorous sarcasm, in which he indulged even in the pulpit. During the reign of Charles II. Dr. South was, from principle, a strenuous assertor of the royal prerogative, as he was also during the following reign, though he was fully sensible of the dangers to which the established religion was exposed under the bigotted and gloomy James II. He nevertheless refused to join in an invitation to the prince of Orange to come to its rescue; and after the arrival of that prince, he declined subscription to the association for his support, which was signed by the vice-chancellor, and several heads of colleges in Oxford. When William was seated on the throne, he did not scruple taking the oath of allegiance to the new government, but he is said to have rejected the offer of some persons in power to place him in one of the sees vacated by the nonjuring bishops. His political conduct continued the same; he was a violent enemy to toleration, and to any concessions for conciliating the separatists. In 1693 he engaged in the controversy respecting the doctrine of the Trinity with Dr. Sherlock, and is said to have displayed as great a want of Christian charity, as abundance of learning and orthodox zeal. He now began to decline in health; and though his mind was active, yet his bodily powers failed him, and he passed the greater part of queen Anne's reign in a state of inaction; but on Sacheverel's trial, he exerted himself vigorously to procure a lenient sentence from the judges. When his friends came into power, towards the close of that reign, he was solicited to accept the bishopric of Rochester and deanery of Westminster, but he replied, such a chair would be too uneasy for an old infirm man to sit in. The queen's decease was considered by him as a signal of his own approaching dissolution, "since," he said, "that all that was good and gracious, and the very breath of his nostrils, had made its departure to the regions of bliss and eternal happiness." He died in July 1716, at the age of 83, and was interred with much solemnity in Westminster Abbey.

Dr. South cannot be regarded as a proper pattern of a Christian minister, the follower of the meek and holy Jesus; though his sincerity as a true believer of the doctrines of revealed religion has never been doubted. His temper was harsh and unamiable, irascible and unforgiving, and his talents for wit and humour led him too frequently to in-

dulge in ill-natured sarcasm. His talents were considerable, and he is usually reckoned among the good writers of the time, though he frequently manifested a want of taste in not adapting his wit to subjects suited to it. He is author of Sermons, in six volumes, which have passed through many editions. After his decease there appeared his "Opera Posthuma Latina," and his English posthumous works, which consisted of three additional sermons; Travels into Poland, and Memoirs of his Life, in 2 vols. 8vo. Biog. Brit.

SOUTH, in *Geography*, a short river of Anne Arundel county, in Maryland, which runs easterly into Chesapeake bay; its mouth is about six miles S. of Annapolis city, and is navigable for vessels of burden ten or twelve miles.

SOUTH Anna, a branch of North Anna river, in Virginia, which together form Pamunky river.

SOUTH Bay, a bay in Hudson's Straits, on the N. coast of Labrador, W. of Cape Chidley.—Also, an arm of lake Champlain, extending westerly from its south extremity. Where it unites with the lake, it receives Wood creek from the south.

SOUTH Cape, a cape at the southern extremity of New Holland. S. lat. $43^{\circ} 42'$. E. long. $146^{\circ} 56'$.

SOUTH Creek, a river of North Carolina, which runs into Pamlico Sound, N. lat. $34^{\circ} 54'$. W. long. $76^{\circ} 48'$.

SOUTH Downs, downs of England, in the county of Suffex, between Brighthelmstone and Lewes.

SOUTH Downs Sheep. See SHEEP.

SOUTH-East Bay, in *Geography*, a bay of the S.E. extremity of Tavia-Poenammoo. S. lat. $46^{\circ} 45'$. W. long. $191^{\circ} 21'$.

SOUTH Esk. See ESK.

SOUTH Friar's Bay, a bay on the S. coast of the island of St. Christopher; 3 miles E.S.E. of Basseterre.

SOUTH Hams, a tract of land in the county of Devon, England, in the vicinity of Torbay, celebrated for cyder.

SOUTH Haven Point, a long crooked projection of land on the coast of Dorsetshire, in the English Channel, which forms one of the points of entrance into Pool harbour.

SOUTH Head, a cape on the N.E. coast of New Holland. S. lat. $24^{\circ} 2'$. W. long. $108^{\circ} 17'$.

SOUTH Hero. See HERO. North Hero, in 1810, contained 552, and South Hero 826 inhabitants.

SOUTH Island, a small island in the Indian sea, near the E. coast of Madagascar. S. lat. 17° . E. long. $50^{\circ} 20'$.—

Also, a small island in the strait of Saleyer, near the S. coast of the island of Celebes. S. lat. $5^{\circ} 45'$. E. long. $120^{\circ} 51'$.

—Also, a small island in the East Indian sea, near the S.W. coast of the island of Bouton. S. lat. $5^{\circ} 42'$. E. long. $122^{\circ} 50'$.—Also, a small island in the North Pacific ocean.

N. lat. $24^{\circ} 22'$. E. long. $141^{\circ} 20'$.

SOUTH Key, a small island in the Spanish Main. N. lat. $15^{\circ} 40'$. W. long. $82^{\circ} 35'$.—Also, one of the Bahamas, in the West Indies. N. lat. $22^{\circ} 21'$. W. long. $74^{\circ} 6'$.

SOUTH Mountain. See BLUE Ridge.

SOUTH Point, a cape on the S. coast of the island of Anticosti. N. lat. $49^{\circ} 5'$. W. long. $62^{\circ} 35'$.—Also, a cape at the southern extremity of the island of Barbadoes. N. lat. 13° . W. long. $58^{\circ} 23'$.—Also, a cape on the S.W. coast of Sir Henry Martin's island. S. lat. $8^{\circ} 58'$. E. long. $220^{\circ} 15'$.—Also, a cape on the S.W. coast of the island of Fortaventura. N. lat. $28^{\circ} 1'$. W. long. $14^{\circ} 1'$.

SOUTH River, a river of Antigua, which runs into the sea, a little to the north of Young Point.—Also, a river of Canada, which runs into the St. Lawrence, N. lat. $46^{\circ} 56'$.

W. long. $70^{\circ} 26'$.

SOUTH Salem, a post-township of America, in the State

of New York, and county of West Chester; 50 miles from New York; bounded north by North Salem, east by the state of Connecticut, south by Connecticut and the towns of Pounbridge and Bedford, and west by Somers. The whole of this township may be called a good farming country. In 1810, the number of its inhabitants was 1566. This town was formerly called Salem, but its name was altered in 1808. The inhabitants manufacture most of their clothing in their own houses.

SOUTH Sea. See **PACIFIC Ocean.**

SOUTH-Sea Castle, a fortress of England, in the vicinity of *Portsmouth*; which see.

SOUTH-Sea Company. See **COMPANY** and **FUND.**

SOUTH-Sea Tea, in *Botany*, &c. See **LEX.**

SOUTH Thule, in *Geography*, a point of land in the South Atlantic ocean, being the most southern land discovered by navigators. S. lat. $59^{\circ} 54'$. W. long. $27^{\circ} 45'$.

SOUTH-West Bay, a bay on the south-west coast of Tavai-Poenamoo, between Cape South and Cape West.

SOUTH-West Cape, a cape on the south coast of New Holland, north-west of South Cape. S. lat. $43^{\circ} 37'$. E. long. $146^{\circ} 7'$.

SOUTH-West Point, a cape on the south-west coast of the island of Anticosti. N. lat. $49^{\circ} 25'$. W. long. $63^{\circ} 4'$.

SOUTHADLEY, or **SOUTH HADLEY,** a post-town of America, in the state of Massachusetts, and county of Hampshire, on the east bank of Connecticut river; 12 miles N. of Springfield; incorporated in 1753, and containing 902 inhabitants.

SOUTHAKER LEDGE, a reef of rocks, near the south coast of Labrador. N. lat. $50^{\circ} 5'$. W. long. 60° .

SOUTHAM, a small market-town in Southam division of Knighthow hundred, Warwickshire, England, is situated 10 miles from Warwick, 12 from Coventry, and 82 N.W. from London. In *Domesday* book the name is written *Suchan*, and the town is there said to contain four hides, with two mills, and woods of one mile in length and half a mile in breadth; all which belonged to the king. Henry III. granted it a weekly market, and an annual fair. The market is held on Mondays, but little business is transacted. The chief sources of emolument are the two roads which pass through it: that from Coventry to Banbury, and that from Warwick to London. The parish church is a handsome edifice, with a spire rising from a square tower at the west end. The population of the parish, in the year 1811, was returned as 1007; the number of houses 165.

Two miles from Southam is the village of Long Itchington, where the earl of Leicester magnificently entertained queen Elizabeth, July 9, 1575, in her progress to Kenilworth. The village is now small, but appears to have been of considerable consequence at the time of the Conquest, and for some succeeding ages. It was the birth-place of St. Woltan, bishop of Worcester, in the eleventh century, a man of some eminence in the pious chronicles of that period. *Beauties of England and Wales*, vol. xv. part 2. Warwickshire, by J. N. Brewer.

SOUTH AMBOY, a town of America, in Middlesex county, New Jersey, containing, by the census of 1810, 3071 inhabitants. See **PERTH-Amboy**, which contained 815 inhabitants.

SOUTH AMERICA. See **AMERICA.**

SOUTHAMPTON, or **SOUTHTON,** an ancient borough, port, and corporate town of Hampshire, England, is seated on a neck of land, which is bounded on the west and south by a broad lake-like expanse, called the Southampton Water, and by the river Itchin on the east. From this peculiarity of situation, it has only one approach by

land, from the north; and from the same cause, the first buildings of the town appear to have been raised at the extreme point of land, and to have progressively continued in a line northward, on a ridge of ground between the two waters. Hence the town was soon formed by one long street, flanked and guarded by embattled walls, and strongly fortified gates towards the water on the south, and to the inland country on the north. The present Southampton is comparatively a modern town, and originated in the superior eligibility of its site, for commerce, to the station at Bittern, the Claufentum of the Romans, and the Hamton of the Saxons, &c. The ancient history, before the Norman conquest, applies chiefly to Old-Hampton; but it is almost impossible to ascertain when the old town was deserted, and the new one formed and governed by its own laws. It is evident that Hampton must have been a town of consequence under the Anglo-Saxon dynasty, as it imparted its name to the whole county, and is still the county town.

Historical Events.—The origin and name of this town have occasioned much conjecture and dissertation. The most natural supposition is, that it was derived from the river *Ant*, or *Anton*, near the southern extremity of which it stands. This river, after flowing from the upper parts of the county, and giving appellations to several places in its course, here widens into a considerable estuary; and, in conjunction with the Itchin, forms the head of the Southampton Water, the supposed *Antona* of Tacitus. There are indeed those who prefer deducing it from *Ham*, a home or residence, with the adjunct *Ton*. *Domesday* book and other ancient records, however, clearly favour the former opinion; for in these writings it is spelt *Hantun*, and *Hantune*. The prefix of *South* evidently arose from its relative situation to *Northam*. The county itself was also called *Hantunscyre*, though its name has been long altered into *Hampshire*.

It appears from the Saxon Chronicle, that in 873 Hanton was attacked by the Danes, who landed from 33 ships; but, after committing many atrocities, they were repulsed and driven to their ships. About the year 980 another body of Danes landed here, and ravaged the town and its neighbourhood; and it was scarcely 12 years afterwards, that they are recorded to have a third time plundered Southampton, under the command of Sueno of Denmark, and Olaus of Norway.

It does not appear with any certainty, whether the town had been fortified previous to these devastations; though an eminent antiquary, sir Henry Englefield, suggests the opinion, that a *castle* was built here by the Saxons, very soon after they had achieved a permanent establishment in this country. "The peculiar advantages of the narrow and rather high point of land on which Southampton now stands," says the worthy baronet, "commanding at once the Itchin and Test rivers, and very easily fortified on the land side, could not escape their notice; and from the high circular hill, on which the keep of the castle formerly stood, and the curved line of its yet remaining wall, we have probable grounds for supposing it to be among the most ancient of the Saxon castles."

The different assaults made on Hanton by the Danes, render it probable that it had very early risen to some importance; and most likely from its commerce, to which its situation was very favourable. The accession of Canute to the British sceptre, however, put a period to the Danish ravages in this island; and Southampton appears to have become an occasional residence of that sovereign: for it is here that he is recorded, by Henry of Huntingdon, to have repressed the impious flattery of his courtiers by a most impressive

SOUTHAMPTON.

pressive lesson. They had hailed him as one whose royal mandate all nature must obey. To put this supposed omnipotence to the test, and to reprove the flattery, he, descending the beach, commanded, says the historian, a chair to be set for him; in which having seated himself, he said to the flowing tide, "Thou art under my dominion, and the ground on which I sit is mine; nor did ever any disobey my commands with impunity: therefore, I command thee not to wet the clothes or feet of me, thy lord and master." But the rude waves, continues the historian, presently came up to his royal feet, and dashed over him; when, springing back, he exclaimed, "Let all the inhabitants of the world know, that the power of monarchs is a vain and empty thing; and that no one deserves the name of king, but He, whose will, by an eternal decree, the heavens, the earth, and the sea, do obey." Nor would he ever after suffer the crown to be put on his head, but caused it to be placed on the great crucifix at Winchester. And it is worthy of remark, that all the coins of Canute seem to give sanction to this story; as they either represent him as wearing a mitre, or a cap, or a triangular covering, similar to that on the coins of St. Edward. See CANUTE.

Several circumstances prove, that this town had attained considerable importance before the Norman invasion; though it appears to have suffered greatly from the ravages of earl Tolstan. Henry I. is supposed to have made it a borough by charter; as the "burgesses of Southampton" are mentioned in his grants to the canons of the priory of St. Dionysius, which he had founded. Many privileges were granted to the burgesses by king John, who exempted them from toll, passage, and portage, by sea and land, in fairs and in markets, throughout all his dominions; as well on this side the sea as beyond. By the same charter he granted them the port of Portsmouth, in *ferm*; for which, together with the *ferm* of Southampton, they were to pay 200*l.* yearly. The agreement to pay this sum sufficiently indicates the opulence and flourishing state of the town at that period; which appears to have arisen principally from the wine trade: and, so early as 1215, the merchants of Southampton are recorded to have imported more wine than any others in England, those of London excepted. White or sweet wines were then mostly in use, and these were chiefly imported from Genoa and Venice, by aliens; who were restricted to this port by a duty payable to Southampton, even if the wine was landed elsewhere.

In the reign of Henry III. the barons of the Cinque Ports became very troublesome to the merchants of Southampton, by frequently attaching their persons, and seizing their goods, under pretended reference to ancient grants. The king, being appealed to on this subject, issued a writ, dated May 14, 1252, commanding the barons to desist from their outrages; and four years afterwards he invested the burgesses with new privileges, by a very ample charter, dated at Bristol, July 14, 1256. It appears that Southampton first sent members to parliament in the 23d of Edward I. Considerable trade was now carried on between this port and France; and the detention, at St. Valery and Barfleur, of some ships belonging to Southampton, was in great measure the cause of the war between this country and France, toward the conclusion of the 13th century.

The trade of this town continued very flourishing till the rupture with France in 1338, on account of the refusal of the states of that kingdom to acknowledge the claims of Edward III. to its throne. The same year the mayor and bailiff were commanded, by writ, to cause all their ships, of 40 tons burthen and upwards, to be victualled, and furnished with men at arms, ready to defend the land, in case

of invasion. These preparations, however, were made too late. The French, with their allies, the Spaniards and Genoese, landed in October, from a fleet of 50 galleys; and, having slain all who opposed them, entered and plundered the town, and afterwards destroyed the greater part of it by fire. Many of the principal inhabitants were, at the same time, inhumanly put to death. The invaders did not, however, effect this devastation with impunity: several distinguished personages of their own party were slain, and, among them, the son of the king of Sicily. This fatal event interrupted the growing prosperity of Southampton; as many of the merchants were totally ruined, and others afterwards removed to places less exposed to invasion. In the following year an act was passed for rebuilding and strongly fortifying the town; and the king, in a new charter, confirmed all the grants made by his predecessors, and invested the inhabitants with additional immunities.

In the reign of Richard II. a plan was proposed, by a rich Genoese merchant, for rendering Southampton one of the principal ports of Europe; but the jealousy of some London merchants is said to have defeated the design, and to have caused the assassination of the projector.

In July, 1345, the army, which afterwards so memorably distinguished itself on Cressy's plains, was embarked at this port. That gallant army of Britons also, which gained immortal fame at the battle of Agincourt, under Henry V., in 1415, was assembled and embarked at Southampton; and it was here that the foul conspiracy against the life of that monarch was timely discovered and punished. The principal conspirators were Richard, earl of Cambridge, grand-father of king Edward IV., lord Scrope of Masham, and sir Thomas Grey of Northumberland. They were brought to trial, condemned, and executed in this town. Lord Scrope, who had been a particular favourite of the king, was hanged, drawn, and quartered: the others were beheaded; and their bodies were interred in the chapel of the *Domus-Dei*, or God's House; as is recorded by an inscription on a stone, erected by a predecessor of the present earl of Delaware. Historians differ widely respecting the motive to this plot. Some say, that the project was suggested by the court of France; which, terrified at the preparations of Henry, had engaged these three noblemen, for the bribe of a million of livres, to murder the king at Southampton; an account which Shakspeare seems to have credited. See his play of Henry V. act ii. sc. 2.

"See you, my princes and my noble peers," &c.

With greater probability, however, others appear to think that the conspiracy was formed originally by the earl of Cambridge, second son of the duke of York; who, having espoused the sister of the earl of March, had zealously embraced the interests of that family, and engaged lord Scrope and sir Thomas Grey to second his views. See Holingshed's Chronicle.

The trade of Southampton must have been in a very flourishing state in the reign of Henry VI.; or we can hardly suppose that so great a man as the lord mayor of London, and keeper of queen Margaret's wardrobe, sir Thomas Cooke, would have borne the office of customer of this port.

In the reign of Edward IV., when the feuds between the houses of York and Lancaster raged with their utmost violence, scarcely a day elapsed which was not marked with some hostilities of the opposite parties. That division of sentiments, with respect to the two contenders for the crown, which pervaded almost all England, subsisted at Southampton; and at last raged with such fury, that a
fierce

fiere skirmish ensued between the partisans of the white and red roses, in which several of the inhabitants lost their lives. The Yorkists being at length victorious, the leaders of the Lancasterian party were made prisoners. Edward was of a temper too jealous and severe to pardon so great an insult on his government. Hastening immediately to Southampton, he commissioned Tiptot, or Tiptoft, earl of Worcester, to fit in judgment on the prisoners. About twenty of them were tried, condemned, and executed; but the malice of the monarch, not satisfied with that infliction, which ought to have closed the scene of human punishment, permitted their breathless carcases to be impaled, and exposed in this horrid state to the public gaze: a mean gratification of impotent revenge, useless as it was unpopular, which brought a deserved odium on the king, and on Tiptot, as the minister of his vengeance. Leland's Collectanea, i. 502.

Among the number of royal visitors who have occasionally honoured Southampton with their presence, it reckons the emperor Charles V., who, in 1522, embarked here on board the English fleet, which conveyed him to Spain. We have also to mention Edward VI. In the year 1552 this prince, having been attacked by both the measles and small-pox, his constitution was so much weakened, as to render relaxation absolutely necessary. By the advice of his physicians, therefore, he made a tour of amusement through the western and southern parts of his kingdom, attended by 320 soldiers, and courtiers and servants to the amount of 4000 horse. Amongst other places, he visited Southampton, and was received by the inhabitants with much respect, and costly preparations. In 1534, Philip, then prince of Spain, but who afterwards reigned as Philip II., landed here, when he came to marry Mary I. queen of England. Queen Elizabeth kept her court here in 1569; and in 1575 granted to the corporation the arms, which are now used in the town-seal.

Camden, who wrote in the reign of queen Elizabeth, says, that the town was, in his time, famous for the number and beauty of its buildings, its affluent inhabitants, and the resort of numerous merchants. But after this, Southampton appears to have declined in its trade and consequence; being, in the year 1695, (as Gibson, in his edition of Camden, observes,) "not in the same flourishing state as formerly: for, having lost its trade, it has lost also most of its inhabitants; and the great houses of its merchants are now dropping to the ground, and only shew its ancient magnificence." Since that time, however, trade has again brought its advantages to Southampton: numerous opulent families also have been attracted, by the beauty of its neighbourhood, to settle in and around it; and it is at present a town of the first beauty and consideration in the west of England.

Commerce and Trade.—Southampton has many considerable wine, corn, and timber merchants. Hemp, iron, and tallow, from Russia, and tar and pitch from Sweden, are imported. English iron is brought coast-ways from Wales; and coals, lead, and glass, are conveyed by the colliers from Newcastle. The importations from Portugal are chiefly wine and fruit. To Jersey and Guernsey 6000 tons of unwrought wool are allowed to be exported annually; great part of which is again returned, manufactured into coarse knit hose. During the last war, large quantities of Spanish wool were landed here. Contracts for biscuits for the navy, and bread and clothing for the army, were executed to a considerable extent. A silk-manufactory employs a number of children. Ship-building is also carried on at different docks near the town. At Woodmill, in the neigh-

bourhood, the late Mr. Walter Taylor's curious machinery for the manufacture of blocks and pumps for shipping still exists; but the chief business of supplying the navy is now transferred to Portsmouth dock-yard. The latest bye-laws for the regulation of the port and harbour of Southampton were arranged in an act of parliament, passed 43d Geo. III.

The corporation, according to its last charter, granted by Charles I., consists of a mayor, a recorder, nine justices, a sheriff, two bailiffs, twenty-four common-councilmen, and as many burgessees. All who have passed the chair are aldermen. The town, which was made a borough by Henry II., and by king John (or, as others say, by Henry VI.) a county in itself, is independent of the lord lieutenant and sheriff of Hampshire. The mayor is admiral of the liberties, from South-sea castle to Hurst castle, and half sea over from Calshot to the Isle of Wight. There are about 700 voters for the two members in parliament for this place; and not only those who pay scot and lot, but out-burgessees also vote. It may be here observed, that several royal burgessees have been enrolled among this corporation: the late prince of Wales, in 1750, at his particular request; the late dukes of York, Cumberland, and Gloucester; his present majesty; the prince regent; the dukes of York, Kent, Cumberland, Sussex, and Cambridge; the duke of Wirtemberg also, who passed through this town immediately after his arrival from the continent.

There are two annual fairs, the principal of which is Trinity fair, held near Chapel Mill, adjoining to the town. It commences on Saturday noon in Whitfun-week, and continues till Wednesday noon in Trinity-week; but Monday is the chief day of business, when there is a tolerable show of cattle. The senior bailiff presides during the fair, having a tent, in which he entertains the corporation, and his other visitants. During the continuance of the fair, no one can be arrested for debt within its precincts. St. Mark's fair is held above Bar, on the 6th and 7th of May. Three weekly markets, on Tuesday, Thursday, and Saturday, are well supplied with excellent fish, poultry, meat, butter, fruit, and vegetables.

The salmon taken in the Southampton Water is excellent, though much less plentiful than formerly; when it is said to have been necessary to stipulate in indentures, that apprentices should not be obliged to eat of this fish oftener than once a day.

Public Buildings, &c.—Of late years Southampton has been much frequented as a watering-place; for which purpose its peculiarly healthful and pleasant situation is extremely favourable. The assembly-rooms are situated near the west quay, and very elegantly fitted up. A theatre was erected here in 1766; but not being found large enough, a new one, on a much more commodious and extensive scale, has since been built on the site of St. John's hospital.

The population of Southampton, as returned under the act of 1801, was 7913, viz. 3390 males, and 4523 females; the number of houses was 1582. But the return of 1811 stated the population at 9617, viz. males 4130, and females 5487; the number of houses 1669.

As already noticed, the northern extremity of the old High-street is terminated by an ancient fortified gate-house, called the Bar-gate. This is a curious structure, and consists of a central arched passage, about eighteen yards in length, and four in width. On both sides of this are two lateral passages, or postern door-ways. This majestic portal was principally built in the reign of Edward III.; and, according to the architecture of that time, it is both machicolated and embattled. On its north front are portrayed two gigantic figures, one on each side of the gate-
way;

SOUTHAMPTON.

way; which are traditionally said to have been intended to represent, the one, Ascupart, or Ascapard, a terrible giant and mighty warrior; and the other, sir Bevois, or Bevis, of Southampton, who, according to the popular legends, slew him in combat. Over the arches of the gate is the town-hall, which is 52 feet long, and 21 feet wide.

The Castle was situated on the west side of the town, but very little of the ancient building itself is remaining. Its area was of a form approaching to a semicircle, or rather of a horse-shoe; in the southern part of which stood the keep, on a very high artificial mount. This keep was circular, but has given place to a smaller and more modern round tower, erected with the materials of the former one. The view of the town and the adjacent country from this spot is extremely interesting. The castle was purchased by the late marquis of Lansdowne, who made great additions and alterations to it, and fitted it up in a costly, but fantastic style.

There were formerly in Southampton six parish churches: those of Holy-Rood, St. Michael, All-Saints, St. Lawrence, St. John, and St. Mary. But in the reign of Charles II. the parishes of St. John and St. Lawrence were united, and the church of the former was taken down: a burying-ground now occupies the spot on which it stood.

Holy-Rood church has a fine organ, and several handsome monuments; one of which, by Rybrack, to the memory of Miss Stanley, has an inscription from the pen of the author of "The Seasons," Thompson. St. Michael's church is the most ancient in the town, and has a fine slender octangular spire, which greatly adds to the beauty of many prospects: it was erected for a mark or guide to ships entering the port. In the north aisle of the chancel is a handsome monument to the memory of the lord chancellor Wriothesley; and in the opposite aisle, on the south, is a curious antique font. In this church the mayor is always sworn into office. All-Saints church is a modern structure, which does honour to the genius of its architect, the late Mr. Revelly. St. Mary's and St. Lawrence's churches are not particularly remarkable.

A spacious mansion in Porter's-lane, near the site of the Water-gate, displays considerable antiquity. It has been minutely described by sir H. C. Englefield (*Archæologia*, vol. xiv.), in a "Walk through Southampton," who conjectures it to have constituted a part of the palace occasionally inhabited by the Saxon and Danish sovereigns. The length of the building in front is 111 feet.

The *Domus-Dei*, or God's House, is an hospital, founded, according to Leland, in the reign of Henry III., by two merchants, brothers, of the names of Gervasius and Protosius. "These two brethren, as they learned, dwelled in the very place, where the hospital is now, at such time as old Hampton was brent by pyrates; these two brethren, for Goddes sake, caused their house to be turnid into an hospital for poor folkes, and endowed it with some landes." By a charter of 6 Edw. III., however, it seems that Roger Hampton founded it; but at what time is not known. It was given by Edward III. to Queen's college, Oxford, which had been founded by Philippa, his consort; and to that institution it still belongs. The present establishment consists of a warden, four aged men, and as many women, who are allowed two shillings each, weekly, from the college; and have a yearly donation of coals, under the will of the late Mrs. Fifield, of Southampton.

Among other ancient institutions in this town was a house of Grey friars, founded in the year 1240, but of which scarcely any remains are now standing; part of its site being occupied by Gloucester-square; and another

part by a building now used as a warehouse, "for the vast quantities of Spanish wool, which, by *strefs of weather*, are landed here every year." St. John's hospital, for the instruction of six boys in the woollen manufacture, has been lately given to the poor-house by the corporation, with the consent of the heirs of the founder.

A free grammar-school was established in Southampton by Edward VI., in an old building in Winkle-street, now used as a carpet-manufactory; from which, many years afterwards, it was removed to its present situation, an ancient mansion, known by the name of West-Hall. Here are also a charity school, a Sunday school, and a school of industry; and near the entrance of the town, on the right, is a neat range of alms-houses, for eighteen poor widows, who are allowed two shillings each, weekly, from the produce arising from a bequest by Robert Thorner, esq. of Baddesley, who died in July, 1690.

The environs of Southampton are noted for picturesque scenery, handsome villas, and interesting objects of antiquity. About one mile north-east of the town is the site of the ancient *Claufentum*. The situation of this station has been a matter of dispute among antiquaries, nor was it exactly settled till the year 1792, when the Rev. Mr. Warner published an essay to prove it to be at Bittern, and rendered any farther doubt on the subject superfluous: moreover, some late discoveries made there, in the formation of the bridge over the Itchin, and of the road connected with it, have fully confirmed whatever Mr. Warner had previously advanced as conjectural. An account of these discoveries has been published, with an engraved plan of the situation, in the first volume of "The Hampshire Repository." The time when *Claufentum* became a station has also been a subject of dispute; but Mr. Warner pronounces it to have been formed under the direction of Vespasian, during his continuance in the southern parts of Britain.

In 1804 and 1805 other discoveries were made at Bittern, by the late proprietor, Henry Simpson, esq. of which a detailed account has been given by sir H. C. Englefield, bart. in his "Walk through Southampton," 2d edit.

Immediately facing Bittern, on the west side, is Bevis-Hill, so called from a tradition, that sir Bevis, the famous knight of Southampton, lies buried under it. It now makes part of the gardens formed by the late earl of Peterborough, and in which his lordship was used to walk with Arbuthnot and Pope.

About half a mile north of Southampton is Belle-Vue, a handsome building, with highly picturesque pleasure-grounds, belonging to Josiah Jackson, esq. Two miles from this town, towards the north-east, is Portwood House, a mansion of the late Giles Stibbert, esq. who erected it in 1771, from designs by Mr. Crunden, architect. Since then it has been much altered. Seated on an eminence, it commands extensive and diversified views of the Itchin river, Southampton Water and town, and much fine wooded scenery. In the parish of South Stoneham is Wood-Mill, built by the late Walter Taylor, for the manufactory of blocks and pumps for the navy. The improvements made in these articles by Messrs. Taylor and son, have been of great importance in naval tactics. In 1759 these gentlemen exhibited specimens of blocks, shivers, and pins before the Board of Ordnance, who immediately commissioned the inventors to prepare and supply all the gun-tackle blocks for the navy. From this time several improvements were made in the machinery and mechanical formation of blocks, &c. and equal improvements in the construction of ship-pumps. By one of these, called the double bailing machine, four tons of water may be raised in two minutes and a half, and even with or with-

out the atmosphere. (Prints and descriptions of these machines are published in the "Hampshire Repository.") North Stoneham Park, the seat of Mrs. Fleming, is a handsome house, in a fine park, the latter of which was laid out by the late Mr. Brown. In the adjoining church is a superb monument to lord Hawke, who died October 17, 1781. See HAWKE.

The remains of St. Dionysius's priory form a pleasing object from Bittern. They stand at the distance of two miles from Southampton, on the western side of the Itchin, in the grounds which belonged to the late general Stibbert.

At the distance of four miles from Bittern, in a southern direction, are the ruins of Netley, or Letley abbey, on the eastern bank of the Southampton Water. Their situation is very beautiful. The field on which they stand commands several views of the river beneath, equally beautiful, but various according to the spot whence they are seen. The profusion of ivy which covers the mouldering walls; the various shrubs and trees that now occupy the site and walls of the church; the fragments of architecture lying around in disorderly ruin; and the elegance of those few parts which have yet escaped destruction; combine to form a scene which contemplation cannot leave without reluctance. The founder of this abbey, it is believed, was Henry III., who took a certain number of monks from the abbey of Beaulieu, and placed them at Netley, about the year 1229. The monks were of the Cistercian order, and the house itself was dedicated to the Virgin Mary and St. Edward. The site of Netley abbey, with all the buildings, was, at the dissolution, granted by Henry VIII., in the twenty-eighth year of his reign, to sir William Paulet, afterwards marquis of Winchester: they next became the property and residence of the earl of Hertford; and since then were inhabited by the marquis of Huntingdon. The whole is at present the property of lady Holland, widow of the late sir Nathaniel Dance Holland, who has a life-interest in them by virtue of her marriage with her former husband, the late Mr. Dummer, who purchased them of Henry Clift, esq. The principal parts of Netley abbey that remain, are the walls of the church, the kitchen, and the refectory. These are in a state of ruin, but display such elegancies of architecture, as convince us, that the fabric must have been originally of great beauty. On the shore, at a short distance from the abbey, stands a fort, or small castle, called Netley castle, in a dilapidated state, which appears to have been erected by Henry VIII. at the time of his building Cowes and Hurst castles. The passage by water to the Isle of Wight, about fifteen miles distant, is delightfully pleasant.

As natives of Southampton, who have rendered themselves eminent, we cannot omit to mention the names of Nicholas Fuller, a learned divine, born in 1557, who died in 1622-3; Dr. Isaac Watts, born in July 1674, who died in 1748; and Richard Pococke, a distinguished traveller, and bishop of Meath, born in 1704, who died in 1765. See accounts of these under their respective heads.

Southampton lies S.W. from London, at a distance of seventy-four miles, by the way of Basingstoke.

"A Walk through Southampton," by sir Henry Englefield, bart. 8vo. 1805, an interesting and truly rational essay on the antiquities of Southampton and Clausentum. "The Southampton Guide;" "A Companion in a Tour round Southampton," 12mo. 1809; "A Visit to Netley Abbey," 2d edition, all by Mr. John Bullar, a schoolmaster of Southampton, are useful and interesting topographical volumes, and contain much original information. "The Southampton Guide," 18th edition, by T. Skelton, is a well-digested essay on the history, &c. of the town and of

objects in its vicinity. In the Beauties of England, vol. vi. is a copious account of the town and county, by J. Britton and E. W. Brayley.

SOUTHAMPTON, a county of Virginia, between James's river and North Carolina, containing, by the census of 1810, 13,497 inhabitants, of whom 6406 are slaves.

SOUTHAMPTON, a town of Massachusetts, in the county of Hampshire, separated from East Hampton by Pawtucket river; about 9 miles S.W. from Northampton. It was incorporated in 1753, and in 1810 contained 1171 inhabitants.

SOUTHAMPTON, or *South Hampton*, a township of New Hampshire, in Rockingham county, on the south line of the state, which separates it from Massachusetts; 16 miles S.W. of Portsmouth. It was taken from Hampton, incorporated in 1742, and contains 427 inhabitants.

SOUTHAMPTON, a post-township of New York, in Suffolk county, on the S. side of Long island; 100 miles E. of New York; bounded N. by Riverhead and Southold, E. by East Hampton, S. by the Atlantic ocean, and W. by Brookhaven. Its length E. and W. is about 23 miles, and its medial breadth $4\frac{1}{2}$ miles. The soil is light and sandy on the W. and N., but fertile in the S. and E. It is well wooded with pine, oak, walnut, &c. and supplies New York with large quantities of cordwood for fuel. The land requires manure, but with good management yields tolerable crops of grain and grass. Fish is much used for manure. In 1810 this township contained 3899 inhabitants, including 61 slaves, and 475 electors. By means of Sagg-harbour, which is a port of entry in the N.E. corner of this township, it carries on a small trade.

SOUTHAMPTON, a township of Pennsylvania, in Bucks county, containing 739 inhabitants.—Also, a township in Franklin county, containing 1060 inhabitants.—Also, a township in Bedford county, with 932 inhabitants.—Also, a township in Somerset county, having 455 inhabitants.

SOUTHAMPTON, or *South Hampton*, a township in the eastern part of Nova Scotia, in Halifax county, formerly called Tatmagruche; 35 miles from Onslow.

SOUTHAMPTON, or *South Hampton*, a post-town of New York, in Genesee county; 486 miles from Washington.

SOUTHAMPTON Water, or *Triffanton Bay*, a bay of the English Channel, on the coast of Hampshire, extending from about three miles above Southampton to the channel that separates the Isle of Wight from the continent. N. lat. $50^{\circ} 48'$. W. long. $1^{\circ} 7'$. See SOUTHAMPTON.

SOUTH BOSTON, a small town in Virginia, in Halifax county, on the N. side of Dan river.

SOUTH BRANCH HOUSE, a station of the Hudson's Bay Company, in North America, situated on the E. side of Saskatchewan river.

SOUTH BRIMFIELD, a township of the Massachusetts, in Hampshire county; 80 miles W. of Boston; incorporated in 1762, and in 1810 containing 645 inhabitants.

SOUTH BROUGH, a small township in the eastern part of Worcester county, Massachusetts, incorporated in 1727, and in 1810 containing 926 inhabitants; 30 miles W. by S. from Bolton.

SOUTH BRUNSWICK, a township of New Jersey, in Middlesex county, containing 2332 inhabitants.

SOUTHBURY, a town of Connecticut, in New Haven county, containing 1413 inhabitants.

SOUTH CAROLINA. See CAROLINA.

SOUTH EAST, a post-township of New York, in the S.E. corner of Dutchess county; 18 miles E. of West Point; its extent is about six miles square; it is bounded on the S. by West Chester county, E. by Connecticut,

N. by

N. by the town of Patterfon, and W. by the town of Carmel. The face of the country is rocky, mountainous, and hilly, but the foil is in general good, and adapted to grafs. It is well watered, and affords tolerably good crops of grain and fruits. It abounds with iron-ore of good quality. And the river Crotan, which runs through it, affords excellent mill-feats. "Joe's" hill or mountain lies near the centre of this town, and extends to Connecticut. Here are five natural ponds, the largeft, called Peach-pond, being about two miles long and one wide. The population confifts of 1887 perfons, and here is one meeting-houfe. Their domeftic looms produce 21,000 yards of cloth.

SOUTH-END, a hamlet in the parifh of Prittlewell, hundred of Rochford, and county of Effex, England, is fituated on the acclivity of a well-wooded hill, at the mouth of the Thames, nearly oppofite to Sheernefs, forty-two miles eaft from London. Within the laft twenty years this place has obtained fome repute for fea-bathing; and though previously but little known, has been fince advancing to importance. Some refpectable lodging-houfes have been erected for the accommodation of vifitors; and alfo an afsembly-room. At a fmall diftance from the hamlet is a ftone, placed as a boundary mark of the extension of the jurifdiction of the corporation of London over the river Thames, in the eaftern direktion. The village of Prittlewell is built on the declivity of a hill, on the fummit of which is the parifh church, a large and refpectable edifice, the tower of which ferves as a land-mark to veffels failing into the Thames. About a quarter of a mile north of the church was a priory of Cluniac monks, founded in the reign of Henry II. Beauties of England, Effex, vol. iii.

SOUTHERN, THOMAS, in *Biography*, a dramatic writer, is faid to have been born at Stratford-on-Avon, about the year 1662, though others affume that he was a native of Dublin, and educated at the univerfity there till his eighteenth year, when he came to England. He was entered of Pembroke college, Oxford, in 1680, and foon after compofed a tragedy, entitled "The Perfian Prince, or Loyal Brother," which was acted in 1682. He took up his refidence at the Middle Temple in 1683, and in the following year another play compofed by him was acted and published. When James II. came to the crown, he rewarded Southern for his loyalty in defending his caufe, when his exclusion from the throne was warmly, or indeed violently agitated, by giving him a captain's commiffion in the troops intended to oppofe the landing of the prince of Orange. When his military fervices became of no account, he returned to his dramatic career, and wrote feveral pieces, both in tragedy and comedy, from which he drew a liberal fubfiftence. Though Southern does not rank with the higheft of our dramatic geniufes, yet he was capable of deeply interefting the paffions. His belt pieces were "Ifabella," and "Oroonoko;" the latter, formed upon one of Mrs. Benn's novels, was faid to have been taken from a real ftory. Southern was apt to mix fcenes of low and indecent comedy with his tragic fcenes, but they are fo managed that they may be eafily feparated, and leave pieces which are occasionally viewed with applaufe. He lived to a great age, and bore a very refpectable character. He died in 1746, at the age of 84. His plays were published collectively by T. Evans, in 3 vols. 12mo. Biog. Brit.

SOUTHERN Hemisphere. See **HEMISPHERE**.

SOUTHERN Ocean. See **OCEAN**.

SOUTHERN Sign. See **SIGN**.

SOUTHERN States, in *Geography*, a denomination comprehending the following ftates of America; *viz.* Maryland, Virginia, Kentucky, North Carolina, Tenefsee, South Carolina.

rolina, and Georgia, bounded N. by Pennsylvania. The ftates above-mentioned contain, by the cenfus of 1810, 3,246,455 inhabitants, including 1,099,523 flaves. The principal productions of this diftrict of the Union are, tobacco, rice, indigo, wheat, corn, cotton, tar, pitch, turpentine, and lumber; and in this diftrict is fixed the permanent feat of the general government, *viz.* the city of *Washington*, which fee.

SOUTHERNWOOD, in *Botany* and the *Materia Medica*. See **ARTEMISIA**.

SOUTHFIELD, in *Geography*, a township of America, in the ftate of Maffachufetts, and S.E. corner of Berkfhire county; bounded S. by the Connecticut line, containing 147 inhabitants.—Alfo, a township of New York, and the capital of Richmond county, on the S. fide of Staten ifland; 12 miles S. of New York; comprehending an extent along the fea, and at the Narrows, of about eighteen miles in length. The furface is diversified, and the land of various qualities. The fouth part is level, and fit for farming. Here is a tract of natural meadow, around the Great Hills, being a fmall bay, noted for its dams. Here is a very extenfive fhad-fiftery at the Narrows, on the E., within half a mile of which is the plain called "Old Town," which was fortified by the early inhabitants, for defence againft the Indians. The whole population of this town in 1810 was 1007, with 97 electors. The "Narrows, (which fee,) leave an opening for the united waters of the Hudfon and Eaft rivers to communicate with the ocean, 1905 yards wide. On the weft fhore are erected the various military works, defigned for the protection of the trade of New York, and for military defence againft naval foes. Thefe confift of feveral forts and batteries, erected by this ftate fince the year 1807, at a very confiderable expence. Fort Richmond is the principal work, being formed of ftone, and well fupplied with all the apparatus and means of defensive warfare. The telegraph, for speedy communication with New York, ftands on the high grounds in the rear of fort Richmond.

SOUTH GEORGIA. See *NEW GEORGIA*.

SOUTH HEMPSTEAD, a poft-townfhip of New York, in Queen's county, on the S. fide of Long ifland, 22 miles nearly S.E. from New York. It is bounded N. by North Hempstead, E. by Oyster bay, S. by the Atlantic ocean, and W. by Jamaica. This townfhip has the greateft aggregate population of any in the county, and there are feveral fmall villages, the largeft of which is of the fame name with the town. Although it has fome fmall ftreams of water, it principally depends upon tide-mills. The land is generally under good cultivation. The whole population in 1810 was 5804, and at this time it had 445 fenatorial electors. Rockaway beach on the fea-fhore is much frequented in fummer for fea-bathing, and the various pleafures of fifhing, fhooting, &c. Game is very plentiful.

SOUTHILL, a parifh in the hundred of Wixantree and county of Bedford, England, is fituated about four miles diftant from Biggleswade, nine miles from Bedford, and forty-three N. from London. In ancient records it is called South-Yewel. The manor is the property of lord Ongley, who alfo holds the manor of Stamford, or Stamford-bury, in this parifh. The monks of Warden abbey had a manor here in 1369, called Gatelyn's Bury. Sir George Byng, a naval officer of eminance in the reigns of queen Anne and George I., purchafed an eftate and fettled in this parifh. In 1721 he was created a peer, by the title of baron Byng of Southill, and vifcount Torrington. He died in 1733, and lies buried in the parifh church. His unfortunate fon, admiral John Byng, who was fhot by fentence of a court-martial, March 14, 1757, was born and interred

at Southill. He is generally considered to have fallen a victim to the violence of party. There is an inscription in the church to his memory, written, it may be thought, with too much asperity for so sacred a place. There are also several other inscriptions in memory of other branches of the family. The present lord Torrington sold his estate at Southill, in 1795, to Mr. Whitbread, who left it to his son, Samuel Whitbread, esq. M.P. lately deceased. This mansion, which is called Southill-House, ranks among the first in the county. It was built about the year 1795, by Holland the architect. The internal decorations are very elegant. Over the doors of some of the principal rooms are subjects in basso-relievo of animals by Garrard, and paintings of game by Gilpin. In the billiard-room is a collection of Garrard's models of sheep and cattle. Over the book-cases, in the library, are portraits of the principal clerks in Mr. Whitbread's brewery; and over the chimney-piece, that of Mr. Whitbread, sen. placed there by his son, with this modest and appropriate motto, "Nobis hæc otia fecit."

The parish of Southill was inclosed by an act of parliament, passed in 1797, and was then computed to contain 2600 acres. The population return of the year 1811, stated this parish (including the hamlets of Broom and Stamford) to contain 185 houses, and 1024 inhabitants. Lysons's *Magna Britannia*, Bedfordshire, 4to. 1806.

SOUTHOLD, or **SOUTH-HOLD**, a post-township of New York, in Suffolk county, comprising the N.E. part of Long island, bounded N. by Long island Point, southerly by the waters that separate it from the towns of East Hampton and Southampton, and W. by Riverhead. The extent of Southold from W. to E., where it terminates in a point, exclusive of the islands, is twenty-two miles, and its greatest width three miles. In 1810 its population was 2613, including 30 slaves, and it then had 306 electors. Southold town has a street five miles long, in which are the post-office, a meeting-house, and two school-houses, with 160 families; 100 miles E. of New York.

SOUTHOLD, a township of Upper Canada, in Suffolk county, W. of Yarmouth, and bounded on the S. by lake Erie.

SOUTH HUNTINGTON, a township of Pennsylvania, in Westmoreland county, containing, in 1810, 1656 inhabitants.

SOUTHING, in *Navigation*, the difference of latitude a ship makes in sailing to the southward.

SOUTHINGTON, in *Geography*, a township of America, in Connecticut, and county of Hartford; 20 miles S.W. of Hartford, containing 1807 inhabitants.

SOUTH KINGSTON, a township of Rhode island, in Washington county, on the W. side of Narraganset bay, containing 3560 inhabitants.

SOUTH-MOLTON. See **MOLTON**, *South*.

SOUTHWALLS, a town on the S. coast of the island of Pomona. N. lat. 58° 40'. W. long. 3° 3'.

SOUTHWARK, commonly called *The Borough*, a town of Surrey, England, also a suburb of the city of London, and generally regarded as part of that vast metropolis. It is, however, completely separated from London by the river Thames, which at this place is 915 feet across; and over which a bridge was constructed anterior to the Norman conquest. Southwark occupies an area of about one mile and three quarters from east to west, by one mile in an opposite direction. Nearly the whole of this extent is now covered with houses, public edifices, and streets, whilst the bank of the river is occupied by numerous warehouses, manufactories, timber and coal-yards, glass-

houses, &c. The Borough is also noted for its number of hop-warehouses. On the east it is bounded by the parish of Rotherhithe, on the south by that of Newington-Butts, on the west by Lambeth, and on the north by the river Thames. For accounts of each of which, see the respective words.

Ancient History.—Although part of the present district was probably occupied by some Roman villas during the dominion of the Romans in Londinium, yet there is no evidence of its having been a station, or military post. Indeed, it was most probably at that time a marshy tract of land. By the Saxons it was called *Suth*, or "South Work," in reference to some military work or fortification, bearing that aspect from London: it was also called the Borough, or Burg, probably for the same reason. It was anciently a distinct corporation in itself, and was governed by its own bailiffs; but in consideration of the inconveniences arising from the escape of malefactors from the metropolis into this place, it was, in 1327, granted by Edward III. to the corporation of London, on payment of 10*l.* annually. It was then called the *village* of Southwark; it was afterwards styled the *bailiwick* of Southwark, and the mayor and commonalty of London appointed the bailiff. This power, however, not being sufficient to remedy the evil, a more intimate connection was thought necessary; and in the reign of Edward VI. it was united to the city of London, at the earnest and incessant request of the citizens to the lord protector, who was at length prevailed on to grant it; perhaps induced to comply by the consideration of 647*l.* 2*s.* 1*d.* paid for the charter. It was formed into a 26th ward, by the title of "Bridge Ward Without;" and 500 marks more were paid for certain privileges, antecedently enjoyed by the archbishop of Canterbury, the abbot of Bermondsey, the priors of St. Mary Overy's, or Charles Brandon, duke of Suffolk. In consequence of this, it was subjected to the lord mayor of London, who has since appointed the steward and bailiff. Southwark, however, being divided into two parts, this is to be understood only of the division called the *Borough Liberty*, which consists of three of the parishes belonging to the town, with the greater part of a fourth parish. For the city division, the lord mayor, by his steward, holds a court of record every Monday at the sessions-house on St. Margaret's Hill in this borough, for all debts, damages, and trespasses, within the limits of his jurisdiction. To this ward of Bridge Without, which is not represented in the court of common-council, the senior alderman, or father of the city, as he is called, is always removed, as to an honourable sinecure, which exempts him from the fatigues usually incurred in the other twenty-five wards. The other division of Southwark is called *The Clink*, or *The Manor* of Southwark, and is subdivided into the great liberty, the guildhall, and the king's manor; for each of which subdivisions a court-leet is held, where the constables, ale-conners, and flesh-tasters, are chosen, and other business of that kind transacted. This division is in the jurisdiction of the bishop of Winchester, who, besides a court-leet, keeps here a court of record on the bank-side near St. Saviour's church, by his steward, or bailiff, for pleas of debt, for damages, and trespasses. Court-leets are also kept at Lambeth, Bermondsey, and Rotherhithe, three districts adjoining to the Borough.

The first time that Southwark is mentioned in history, is on the occasion of earl Goodwin's sailing up the river to attack the royal navy of fifty ships, lying before the palace of Westminster. This was in 1052; when, we are told, he went *ad Subwecree*, and staid there till the return of the tide.

Although the borough of Southwark has so long been a ward

SOUTHWARK.

ward of the city of London, it still retains the privilege of sending two members to parliament, as it has done ever since the 23d Edward I.; but it is not ascertained when it first sent representatives. The right of election is in the inhabitants paying foot and lot, amounting to about 3200.

The things most worthy of note in the borough-town of Southwark, properly so called, are the churches, the hospitals, and the prisons.

The parishes are St. George the Martyr, St. Olave, (part of this parish is in the city of London,) St. John Horsely-down, St. Saviour, (commonly called St. Mary Overy's,) St. Thomas, and Christchurch: these parishes were found, in 1811, to contain 12,217 houses, and 72,119 inhabitants; viz. 33,611 males, and 38,508 females. The families chiefly employed in agriculture were 116, and those occupied in trades, manufactures, and handicraft, 10,510.

Churches.—The parish church of St. George the Martyr is situated a little to the south of the Marshalsea. The original edifice was of very ancient foundation, and belonged to the abbey of Bermondsey, to which it was given, in 1122, by Thomas Arderne. Being in a very ruinous state, the parishioners obtained an act of parliament for taking down the old church, and erecting another; in consequence of which the present structure was begun in 1734, and finished in 1736. In the old church was interred Edward Coeker, the celebrated arithmetician; and the infamous bishop Bonner, who died miserably in the Marshalsea in 1569, is said to have been buried in the church-yard, under the east window.

St. Olave's church is situated in Tooley-street, near the south end of London-bridge. The original edifice is mentioned as early as 1281, but the date of its erection is unknown. Part of this old church having fallen down in 1736, an act was obtained to rebuild it, and the present structure was finished in 1739.

Eastward of St. Olave's is the parish of St. John Horsely-down, corruptly so called from Horse-down having been originally a grazing-ground for horses. St. John's is one of the fifty new churches ordered by act of parliament to be built in the metropolis, and was finished in 1732, when this district was separated from St. Olave's, and constituted a distinct parish.

St. Saviour's church, commonly called St. Mary Overy, originally belonged to a nunnery founded by a female, prior to the Norman conquest, and endowed by her with the profits of the ferry across the river Thames at this place before the erection of London-bridge. This house was afterwards converted into a college for priests, by whom the first bridge over the Thames was built of wood, and kept in repair, till they were enabled, by the munificence of benefactors, to supply its place by another of stone. In 1106 the college was transformed into a priory of canons regular; but these were scarcely settled, when the bishop of Winchester brought in secular canons in their stead. The revenues of this priory, at its surrender in 1539, were valued at 62*l.* 6*s.* 6*d.* per annum. On its suppression, the inhabitants of Southwark purchased the church belonging to it, which was by charter appropriated to the joint use of the parishioners of St. Mary Magdalen and St. Margaret, by the name of St. Saviour's. This church is built upon the plan of a cathedral, though of smaller dimensions. Part of the original architecture is perceived in the interior, near the west front of the church; as all the rest of the fabric exhibits the styles in use between the 13th and 16th centuries. The tower, standing in the centre, rises in three stories, the walls finishing with battlements, and being adorned at the angles with turrets and pinnacles. It was

from this tower that Hollar took his celebrated views of London, both before and after the great fire in 1666.

This church has three chapels: viz. our Lady's, or the New Chapel, at the east end of which is run out a small monumental chapel, and which, after this edifice became parochial, was let for upwards of 60 years, by the churchwardens, for the purpose of a bake-house; St. John's, now the vestry, on the north side of the choir; and St. Mary Magdalen's, on the south side. In our Lady's chapel is a grave-stone, ten feet in length, on which was formerly a border, and a figure in brass of a bishop in his pontifical habit; it is supposed to cover the remains of the celebrated William of Wykeham, bishop of Lincoln, and afterwards of Winchester, who died in 1395. Eastward of the altar is the monument of Lanelet Andrews, bishop of Winchester, who died in 1626, aged 71. His effigy, in full proportion, habited as a prelate of the order of the Garter, lies on a tomb of black and white marble. At his feet are his arms, within a garter, between two small figures of Justice and Fortitude. Here also is a pleasing mural monument, from a design of Mr. Soane, to the memory of Abraham Newland, esq., late cashier to the bank of England, who was interred here November 28, 1807. In the north aisle is a curious monument, with a statue for Gower, one of the earliest English poets, and a benefactor of this church, to the rebuilding of which he contributed about the year 1400. On the wall are painted three female figures, crowned with dual coronets, representing Pity, Mercy, and Charity. See "The History and Antiquities of the Church and Parish of St. Saviour," by Concanen and Morgan, 1 vol. 8vo. 1795.

St. Thomas's church stands on the south side of St. Thomas's-street. The original church, being old and ruinous, was taken down, and rebuilt in 1702.

The parish of Christchurch was taken out of that of St. Saviour, and was originally part of the district called the liberty of Paris Garden. The first church was erected at the expence of Mr. John Marshall, of Southwark, and finished in 1671; when he endowed it with an estate of 60*l.* per annum, towards the support of the minister. This edifice, however, in consequence of the badness of the foundation, soon became so ruinous, that, in 1737, Mr. Marshall's trustees applied to parliament for power to rebuild it, with the sum of 2500*l.*, which had accumulated in their hands from the trust; and obtained an act for that purpose. The present structure was accordingly erected. It stands on the west side of the road leading from Blackfriars-bridge.

For the hospitals in and near the borough of Southwark, see *St. Thomas's HOSPITAL*, *Guy's HOSPITAL*, and *Magdalen HOSPITAL*.

Here we may mention some other charitable establishments in the vicinity of Southwark. The Asylum is a foundation for preserving friendless and deserted girls under twelve years of age from the danger of seduction and prostitution. This excellent charity was set on foot by the well-known magistrate of Bow-street, sir John Fielding. The first female children were admitted in July, 1758; and they are instructed in such a manner as to render them most useful to society. This building stands at an angle, formed by the meetings of the Westminster-road from the Borough to the Stone's-End, and the direct road to Kensington and Vauxhall.

A little farther on the north side of the Westminster-road is a neat modern edifice, called the Freemasons' Charity-School, appropriated for female children from five to ten years of age; though no child who has not had the small-pox, or who has any defect in her sight or limbs, or is weak

or sickly, can be admitted. Every child applying for admission, must produce a certificate from the master and wardens of the lodge in which her father was made a mason, with a certificate of the marriage of her parents. Sixty girls are maintained and educated in this benevolent institution, which owes its origin to the philanthropic mind of the late chevalier Bartholomew Ruffini, of Pall-Mall.

To the southward of this, and on the site of the Dog and Duck tea-gardens, is a noble edifice, the new Bethlehem hospital, which cost about 150,000*l.* in building. The edifice is large, commodious, and admirably adapted to its destination. It is intended to accommodate 400 patients, and has very recently been completed from the designs of James Lewis, esq., architect. It was commenced in 1812, is about 580 feet in length, and is built chiefly with brick, having stone dressings, a bold portico in the centre, and a dome. About twelve acres of garden ground, &c. attach to this hospital, where some of the patients are allowed to exercise. Among the important improvements and reformations of the present time, is the humane and rational system of managing insane patients, that has been very recently adopted; and in the further improvement of which the English legislature is now engaged. See *Bethlehem HOSPITAL*.

At the point of conflux of the London, Westminster, and Blackfriars-roads, we find an extensive range of buildings for the protection and support of the indigent blind, maintained, like the other institutions that we have mentioned, by voluntary contributions. The unfortunate objects are taught to manufacture baskets, clothes-lines, and fash-cord, which are sold at the school. See *BLINDNESS*.

On the right-hand side of the London-road stands the building belonging to the Philanthropic Society, incorporated in 1806. See *Philanthropic SOCIETY*.

Near Cuper's bridge is established the Refuge for the Destitute. The object of this most benign and excellent charity is to provide a place of refuge for persons discharged from prison, or the hulks, unfortunate and deserted females, and others, who, from loss of character, or extreme indigence, cannot procure an honest maintenance, though willing so to do. They are engaged in useful trades and manufactures suited to their sexes; and as an incitement to good conduct, a certain portion of their earnings is set apart, and allowed them, if discharged with credit to themselves.

Prisons, &c.—At the end of the Borough High-street is St. Margaret's Hill, the site of the ancient church of the same name; which, being forsaken on the union of the parish with St. Saviour's, was converted into a sessions-house and prison, since removed to Mill-lane, and called the Borough compter. The whole has lately been rebuilt, but has nothing worthy of particular notice. In the front, facing Blackman-street, which is a continuation of the High-street, the hutings for the election of representatives for this borough are usually erected. On the opposite side of the street was the Tabard Inn, which was the residence of the abbots of Hyde, in Hampshire, whenever business or their parliamentary duty required their presence in the metropolis. This was the house celebrated by Chaucer as the place of rendezvous for pilgrims repairing to Becket's shrine at Canterbury; and the very building described by him existed till 1676, when it was burnt, with the sessions-house, and other contiguous edifices. When rebuilt, it was ignorantly called The Talbot, under an idea that this was the same with Tabard; and by that appellation it still continues to be known.

On the north side of Tooley-street, next to the Thames, is the Bridge-house, a foundation which seems to be coeval with London-bridge; having been used as a store-house for

stone, timber, and other materials employed in its repairs. It is under the superintendance of two officers, called bridge-masters, who are elected by the livery of London. Below the Bridge-house, on the banks of the Thames, stood the inn of the abbot of Battle. The spot, still called Battle-bridge, was thus named from a bridge over a water-course flowing out of the Thames, built and repaired by this prelate, on whose ground it was situated. In the front of this mansion were the gardens belonging to it; the recollection of whose embellishment is yet perpetuated by the Maze, and the Maze-pond.

On the east side of Blackman-street is the Marshalsea, a court of law and a prison, originally intended for the determination of causes and differences between the king's menial servants, and under the controul of the knight-marshal of the royal household. It had particular cognizance of murders and other offences committed within the king's court. To this place also, persons guilty of piracies and other offences on the high seas are committed, though the offenders are tried at the Old Bailey, in London. The prison, which contains about sixty rooms, is too small, and much out of repair. In 1377 it was broken open by a mob of sailors, and four years afterwards by Wat Tyler's followers. It escaped, however, in the riots of 1780, though the King's Bench, the Borough prison, and the Clink, were all at that time the objects of popular fury. See *COURT of Marshalsea*.

The county-gaol and house of correction is situated in Horsemonger-lane, at the south-east end of Blackman-street. This gaol, which has been recently built, is exclusively for the county of Surrey. It was rendered remarkable in the year 1802, when colonel Edward Marcus Delpard, and six of his associates, were hanged upon a platform on the top of the gaol, being convicted of high treason, upon the evidence of an accomplice. The heads of these wretched persons were severed from their bodies, and held up to the view of the spectators, numbers of whom fainted at the sight.

At the south-west end of Blackman-street is the prison of the King's Bench, a place of confinement for debtors, and for all persons sentenced by that court to suffer imprisonment. It consists of one large pile of brick buildings, comprehending 224 rooms. The south centre has a pediment, under which is a chapel. The place is surrounded by a brick wall about thirty feet high, defended by *chevaux de frise*; without which the marshal, or keeper of the prison, has very handsome apartments. Prisoners in any other gaol may remove here by habeas corpus. The liberties, or *rules*, as they are termed, extend about three miles round the prison; and the right of residing in any part of them may be purchased by debtors at the rate of ten guineas for the first hundred pounds, and about half as much for each succeeding hundred pounds, of the fums for which they are in custody. Day-rules, of which three may be obtained in every term, may be purchased for four shillings and twopence the first day, and three shillings and ten-pence the others. Each person must also give good security to the marshal. The day-rules, however, only authorise the prisoner to go out on the days for which they are bought. The inside of this extensive prison resembles a small town, from the circumstance of its being furnished with butchers' shops, bakers', green-stalls, &c.; while the throng of people constantly at play give it the appearance of a fair. See *COURT of King's Bench*.

The Clink was a gaol at Bankside for the confinement of such as should "brabble, fray, or break the peace on the said bank, or in the brothel-houses." This prison still exists,

SOUTHWARK.

exists, and has been represented as a filthy, noisome dungeon. The bishop of Winchester's steward tries pleas of debt, damages, or trespass within the Clink liberty for any sum.

Palaces, Theatres, &c.—Contiguous to the priory of St. Mary Overy, and nearly at the foot of London-bridge, was situated the bishop of Winchester's palace. The house was built about 1107, by William Gifford, at that time bishop of Winchester, upon a piece of ground belonging to the prior of Bermondsey. Bishop Beaufort, uncle to Henry VI., on being created a cardinal on his return from France, was met by the mayor and aldermen of London, and conducted by them in great pomp to this his palace in Southwark. During the civil wars this place was for some time a prison for the royalists. Sir Francis Doddington and Sir Kenelm Digby were both confined here at once; and here the latter wrote his book on "Bodies, &c." Winchester house was sold by parliament, in 1649, to Thomas Walker of Camberwell, for 43*8*ol. 8*s.* 3*d.* with the park included. The buildings, in the old plans of London, appear to have formed two court-yards, with various offices, &c. The south side was bounded by beautiful gardens, statues, fountains, &c.; the north side by the river; the east by the monastery of St. Saviour; and the west by the Bear-gardens. The greater part of the building, which is still remaining, is occupied by corn-lofts, warehouses, &c.

What is now denominated Bankside, was formerly a range of dwellings, licensed by the bishops of Winchester "for the repair of incontinent men to the like women," and denominated the Bordello, or stew-houses. These brothels were subject to various laws and regulations enacted by parliament; among which we find the following: "that they were to be kept shut on Sundays and holidays; that no married women should be received into them; that no man should be drawn or enticed thither; and that no steward should keep any woman who had on her the venereal disease, then termed the 'perilous infirmity of burnings,' or fell bread, ale, fish, or any victuals." (See BURNING.) In 4 Rich. II. these houses, then belonging to Sir William Walworth, lord mayor of London, were rented of him by froes, or bawds, of Flanders, and were destroyed by the Kentish rebels under Wat Tyler. It seems probable, that resentment for the personal injury sustained on this occasion may have had its share, as well as loyalty, in producing the action for which Walworth is particularly distinguished. The ordinances respecting these houses were, however, again confirmed by Henry VI.; but in 1506 they were for some time uninhabited. It was not long, however, before they were again opened, that is, so many as were permitted; "for whereas," says Fabian, "before were eighteen houses, from thenceforth were appointed to be used but twelve only." These privileged stews had signs painted on the fronts, which looked towards the Thames; as the boar's head, the cross keys, the gun, the cardinal's hat, &c. Stow relates, that the women who frequented them were forbidden the rites of the church, and excluded from Christian burial, unless they were reconciled to it before they died. A plot of ground, called the Single Women's church-yard, at some distance from the parish church, was therefore appointed for their interment. In 1546, these stews were suppressed by Henry VIII.; and it was proclaimed by sound of trumpet, that they should be no longer privileged and used as a common brothel, but that the inhabitants were to keep good and honest rules, as in other places of this realm.

Not far from St. George's church stood the magnificent palace of Charles Brandon, duke of Suffolk, the deserving

favourite of Henry VIII. After his death, in 1545, it devolved to the king, who established here a royal mint. At that time it was called Southwark Place, and in great measure preserved its dignity. Edward VI. once dined in it. His father and successor presented it to Heath, archbishop of York, as an inn or residence for him and his successors whenever they repaired to London. As to the mint, it became a sanctuary for insolvent debtors; and at length, becoming the pest of the neighbourhood, by giving shelter to villains of all sorts, it aroused the attention of parliament; which, by the statutes 8 & 9 Will. III. and 9 & 11 Geo. I. entirely took away its abused privileges.

In the parish of Christchurch, near the water on the Bankside, stood Paris Garden, one of the ancient playhouses of our metropolis. Ben Jonson is reproached by Dekker, an envious critic, with his ill success on the stage; and, in particular, with having performed the part of Zuliman at Paris Garden. It seems to have been much frequented on Sundays. This profanation, however, was at length fully punished by a dire accident which befel the spectators in 1582; when the scaffolding suddenly fell, and multitudes of people were killed or miserably maimed. The omen seems to have been accepted; for in the next century the manor of Paris Garden was erected into a parish, and a church founded under the name of Christ's church.

Near this scene of amusement were the Bear-garden, and a place for baiting of bulls. "Herein (Stow tells us) were kept bears, bulls, and other beasts to be baited, as also mastives in several kennels nourished to bait them. These bears and other beasts are there kept in plots of ground scaffolded about for the beholders to stand safe." This was at that time an amusement for persons of the first rank: our great Elizabeth caused the French ambassadors to be carried to this theatre, to divert them with these bloody spectacles.

Not far from the spot in which the Bear-garden was, near Bankside, is Globe-alley; so called from that theatre which flourished in 1603, with a licence under the privy seal, granted by James I. to Shakspeare, Fletcher, Burbage, Heming, &c. and where the plays of our inimitable Shakspeare were first represented. See PLAYHOUSE.

About ten years after it had been licensed, "by the negligent discharging of a peal of ordnance, close to the south side thereof (says Stow), the thatch took fire, and in a very short space the whole building was quite consumed, and no man hurt, the house being filled with people to behold the play of Henry VIII." In the following spring it was rebuilt; but in the next reign it fell into disrepute. See an interesting account of and disquisition on the Globe theatre and the old playhouses in the Gentleman's Magazine for 1816, and in Malone's and Chalmers's accounts of the English stage, in the third volume of the edition of Shakspeare's Plays, 1813.

St. George's Fields, which have borne their share of celebrity in ancient times, having frequently been the scene of grandeur and cavalcade, and sometimes the rendezvous of rebellion and tumult, and which, less than half a century ago, were mere marshes, and only passable to foot-passengers, are now almost covered with newly-erected buildings, from the ditch at the end of Great Surrey-street, or Burrow's buildings, to the Fishmonger's alms-houses, in one direction; and from the Marshalsea prison to the late Dog and Duck, in the other direction; with several irregular indentations in its circumference. Where the principal roads meet, an Obelisk was erected in 1771, in honour of Brads Cradby, esq. the patriotic lord mayor of London, who had been confined in the Tower, with alderman Oliver, for the conscientious

tious discharge of his magisterial duty. An inscription on one side of it expresses the cause of its erection; and those on the other three sides mark the distances from Fleet-street, London and Westminster bridges. This obelisk is about a mile from the one at the end of Bridge-street, on the city side of Blackfriars-bridge.

One of the new bridges for which acts of parliament have recently been obtained, is designed to cross the Thames from the bottom of Queen-street, Cheapside, to Bankside, and to be called the Southwark bridge: it is also proposed to form a handsome street from the foot of it to St. Margaret's Hill.

In Union-street, northward of the mint, is Union-hall, a handsome structure, appropriated to the purposes of a police office for the Borough.

At the foot of Blackfriars-bridge is a large range of buildings, which were erected by a company of gentlemen some years since, with a view of counteracting the impositions too common in grinding of corn. There was a steam-engine, made by Messrs. Boulton and Watt, of Birmingham, which turned ten pair of stones, each pair grinding nine bushels of corn every hour, without intermission by day or night; besides which, it gave motion to the various apparatus for hoisting and lowering the corn and flour out of and into the barges; for fanning the corn, to keep it free from impurities; and for sifting and dressing the meal from its first state, till perfectly cleared for the use of the baker. The accidental burning of these mills, on the 3d of March 1791, forms a kind of epoch among the remarkable fires that have occurred in and about the metropolis. Such a body of light and heat was scarcely ever known as displayed itself on this occasion. The fire broke out about six in the morning, and burnt with such amazing rapidity, that the house of the superintendent, at one corner of the building, was all that escaped the fury of the flames. Out of 4000 sacks of flour, 36 only were saved. The front, &c. remained some years unrepaired; but the whole range has lately been formed into a row of handsome private houses.

On the opposite side is Albion-place, containing the house belonging to the British plate-glass manufactory. This company, incorporated in 1773, carries on a flourishing concern here, and at their works at Ravenhead, in Lancashire.

On the west side of Blackfriars-road, near the bridge, is the building occupied a few years since by Sir Ashton Lever's museum, removed thither from Leicester-square, when, by lottery, it became the property of Mr. Parkinson. This astonishing collection of subjects of natural history here experienced the most mortifying neglect, till, in 1806, it was finally dispersed by public auction, in a sale which lasted 40 days. The premises are now occupied by the Surrey Institution, one of those useful establishments which are intended to promote the diffusion of science, literature, and the arts, and which was opened March 25, 1808.

Surrey chapel, on the east side of Blackfriars-road, is a large octagonal building, for the use of Protestants of the Methodist persuasion, under the Rev. Mr. Rowland Hill, a rather eccentric preacher, but a most worthy man. It is calculated to hold nearly 5000 persons, and can seldom contain the numbers that flock to it for admittance. The organ, by Elliot, has been much admired for its sweetness of tone, as well as for its extensive powers: it has, in fact, been asserted, that on the performance of one of the hymns descriptive of thunder, many of the congregation have fainted.

The Royal Circus is situated at the end of Blackfriars-road, near the Obelisk, before-mentioned. It originated in

a subscription in favour of Mr. Hughes, a riding-master, who, in conjunction with the late Mr. Dindin, exhibited ballets, pantomimes, and horsemanship, with considerable success. Through some disagreement this house was several years shut up; but was at length opened by Messrs. Jones and Cross. In August 1805, the whole building was consumed by fire, but in the course of the following year it was rebuilt in a manner superior in taste and elegance to the former structure. Under the management of Mr. Elliston, of Drury-lane theatre, the exhibition of horsemanship was abolished; and, with the new appellation of the Surrey theatre, this place has acquired more of the spirit and character of the legitimate drama. Bray's History and Antiquities of Surrey, 3 vols. folio. Description of Surrey in the 14th vol. of the Beauties of England, &c. by F. Schöberl, 1813. Picture of London, 1815. SOUTHWARD, *East*, a township of Pennsylvania, in Philadelphia county; containing 7264 inhabitants.

SOUTHWARD, *West*, a township of Pennsylvania, in Philadelphia; containing 6443 inhabitants.

SOUTH WASHINGTON, a town of North Carolina, on the N.E. branch of Cape Fear river, which is navigable so far for boats; 36 miles from Wilmington.

SOUTHWELL, or SUELL, called *Suthell*, an ancient market-town and parish in the wapentake of Thurgarton, and county of Nottingham, England, is 14 miles N.E. of the county-town, and 138 N.N.W. from London. It is seated on a gentle eminence, on the bank of the river Greet, celebrated for its red trout. Some writers have conjectured it to have been the Ad Pontem of the Romans, but without sufficient grounds of authenticity. There is, however, an ancient trenchment in the vicinity. Its modern appellation is said by Dugdale to owe its origin to a spring or well to the southward of the church. The government of the town is divided between the clergy, called prebends, and laity, or justices: the former exercising authority over one part of the town, called the Prebendage, including the collegiate church and its property; and the latter over the other part, called the Burgage, which comprehends all that part between the market-place and the river. The custodes rotulorum, and the magistrates for this jurisdiction, who are nominated by the archbishop of York, and constituted by a commission under the great seal, hold their sessions both at Southwell and at Scrooby, and perform all other judiciary acts distinct from the county. A collegiate church is said to have been founded here by Paulinus, archbishop of York, about the year 630, and this seems to have been always under the patronage of the prelates of that see, though the first grant we meet with of this is by king Eadwy to archbishop Osefytel, in 958. It appears by Domesday book, that here were several canons at the Conquest, but the number of sixteen was not settled till the next century, and so many continue to this day; for though the then archbishop surrendered this church to king Henry VIII., 1540, yet he established the chapter shortly after, and endowed it with the greatest part of its ancient possessions; and though it suffered again in the time of Edward VI., it was restored by Elizabeth, and confirmed by James I.

The collegiate church is a large, ancient, and very curious edifice. It consists of a nave, with two aisles, two towers at the west end, a transept, a choir with aisles, and a chapter-house. The extreme length from E. to W. is 306 feet, width of transept from N. to S. 121 feet, and breadth of nave

nave 59 feet. The oldest parts, the nave, western towers, and transept, are commonly said to be of Saxon architecture, built during the short reign of Harold; but we should rather refer them to an age after the Norman conquest. The choir, with its splendid stone stalls, as well as the very beautiful chapter-house, are all about the date of Edward III.'s reign. Between the nave and the choir is a stone screen of very elaborate workmanship, with niches, pilasters, pinnacles, crockets, &c. A large alabaster altar-tomb is raised in this church to the memory of archbishop Sandys. In the church-yard was a college for chanting-priests. Here is now a free-school, under the care and government of the chapter, who chooses the master. Two fellowships and two scholarships in St. John's college, Cambridge, are in the presentation of Southwell college. These were founded by Dr. Ketton, canon of Salisbury, in the time of Henry VIII. The archbishops of York formerly had a palace here, situated on the south side of the church-yard, and which was once a large and elegant building: the ruins of it are still extensive, but divested of all its architectural forms. Some windows, and a circular chimney of the age of Henry VIII., yet remain, and being deeply overshadowed with ivy and embosomed in trees, add much to the romantic beauty of the place. The archiepiscopal parks were once four in number; or, according to Leland, three; but they have been divided and enclosed since the destruction of the palace in the civil war of Charles I. During those unhappy times the king was often here; and the town frequently experienced the fate of war. Southwell, according to the population return of 1811, contained 561 houses, occupied by 2674 persons: though not a place of much trade, it has a respectable market on Saturdays, and an annual fair. Dickinson's History and Antiquities of Southwell, 4to. 1787. At the end of Dugdale's History of St. Pauls, is an account of the church of Southwell. Thoroton's History, &c. of Nottinghamshire, by Throsby, in 3 vols. 4to. 1790.

SOUTH WEST POINT, a post-town of Tennessee, at the confluence of the Clinch with Tennessee river, where a block-house is erected; 40 miles from Knoxville.

SOUTHWICK, a township of America, in the state of Massachusetts, and county of Hampshire; 110 miles from Boston: incorporated in 1770, and containing 1229 inhabitants.

SOUTHWIST. See **WIST**.

SOUTHWOLD, a market-town in the hundred of Blything, and county of Suffolk, England, is situated on an eminence overlooking the German ocean, but nearly surrounded by the river Blyth, which here discharges itself into the sea. Its ancient name was Sudwald, or Southwood. It is distant from Ipswich 36 miles N.E., and 105 miles, in the same bearing, from London. The manor was an ancient donation from Alfric, bishop of the East Angles, to the abbey of Bury St. Edmunds, by which it was held for the victualling of the monks. From the dimensions of this manor given in Domesday Survey, Gardner, in his History of Dunwich, calculates that the sea has since gained upon this coast one mile, one furlong, and nineteen perches. In the tenth year of Henry IV. Southwold was exempted from the payment of any customs or tolls, for their small boats, passing in or out of the river or port of Dunwich. Henry VII., in consideration of the industry and good services of the men of Southwold, made the town a free burgh or corporation, to be governed by two bailiffs, a recorder, and twelve aldermen; to whom and the commonalty he gave his lordship, called Queen's demesne revenues, and also the privilege of admiralty, for the annual payment of 14*l*. He further granted them exemption from all dues and customs

payable to Dunwich, and conferred on the town the rights of a haven, which probably caused the denomination of the port of Dunwich to be changed to that of Southwold. Henry VIII. not only confirmed all his father's grants, but added many gifts, franchises, and immunities. These royal favours gave great encouragement to the trade and navigation of the town, of which the fishery constituted a material part, being carried on by merchants, who annually fitted out vessels for taking cod and other fish in the North sea. The herring-fishery off their own coast was highly conducive to the prosperity of the town. Though in some degree affected by the dissolution of religious houses, yet Southwold retained an extensive trade, and surpassed all the neighbouring towns in shipping and commerce. But the greatest calamity that ever befel it was on the 25th of April, 1659, when a fire, heightened by a violent wind, consumed, in the space of a few hours, the town-hall, market-house, prison, granaries, warehouses, and 238 dwelling-houses, and other buildings, with the principal part of the goods and merchandize of the inhabitants; the total loss exceeded 40,000*l*. to the ruin of more than 300 families, so that the town never recovered its former importance. About a century afterwards the commerce was considerably improved: the entrance to the haven being subject to be choaked up, an act of parliament was obtained for repairing and improving it: one pier was erected on the north side of the port in 1749, and another on the south in 1752. The establishment of the Free British Fishery, about the same time, also contributed to the prosperity of the town; two docks were constructed, and various buildings erected for making nets and depositing stores. A chapel appears to have been built here in the reign of king John, by the prior and monks of Thetford, who were patrons of the church of Reydon, to which Southwold was then only a hamlet. This chapel being destroyed by fire about 220 years after its erection, the present edifice was erected about 1460, and was then made parochial, and in 1751 was separated from Reydon, and made a distinct curacy. The length of this fabric is 143 feet; the width 56 feet: it has two aisles, separated from the nave by seven arches, and six pillars of elegant workmanship. The tower, about 100 feet in height, is a fine piece of architecture. Though Southwold has many good houses, it has no other building worthy of particular notice. On the cliffs are two batteries, one of which is a regular fortification, with a parapet and six guns; the other has but two. On a hill called Eye-hill, vestiges are seen of an ancient encampment, which Gardner conjectures to have been a camp of the Danes, when they invaded the country in 1010. The population of Southwold in the year 1811 was returned to parliament as 1369; the houses 326. A respectable market is held on Thursday; and here are two annual fairs.

Southwold-bay, commonly called Sole-bay, is celebrated as the scene of a most obstinate and sanguinary engagement in 1672, between the combined fleets of England and France on one side, and the Dutch on the other. The former, consisting of 101 sail, were lying in this bay on the 28th of May, when the Dutch fleet, composed of 91 men of war, 54 fire-ships, and 23 tenders, commanded by the famous De Ruyter, bore down upon them so unexpectedly, that many of the ships were obliged to cut their cables, that they might get out more expeditiously, and arrange in order of battle. The French bore but a small part in the engagement, which was vehemently contested by the English and Dutch during the whole of the day, till at nine at night, the Dutch vessels being dreadfully shattered, were obliged to retreat, and the English, having equally suffered, were not in a condition to pursue them. In this conflict the Eng-

lish lost six ships, and about 2003 men killed and wounded. The Dutch lost only three ships; their loss in men must have been very great, but the States forbade the publication. *Historical Account of Dunwich, &c.* 4to. 1754. *Beauties of England and Wales*, vol. xiv. Suffolk, by F. Schoberl.

SOUTO MAJOR, a town of Portugal, in the province of Beira; 14 miles N.W. of Pinhel.

SOUTOUX, an Indian village of Louisiana, on the W. side of the Mississippi river, opposite to the Nine-mile Rapids, and 28 above Riviere de la Roche. N. lat. 41° 50'.

SOUTSONE, a town of Little Bucharía; 150 miles W.N.W. of Cashgar.

SOUVERABO, a town of Africa, on the Grain Coast.

SOUVERINHO, a town of Portugal, in the province of Alentejo; 17 miles W.N.W. of O Crato.

SOUVIGNY, a town of France, in the department of the Allier, and chief place of a canton, in the district of Moulins; 6 miles W. of Moulins. The place contains 2659, and the canton 10,022 inhabitants, on a territory of 340 kilometres, in 11 communes.

SOUZA, LOUIS DE, in *Biography*, a Portuguese writer, born at Santarem, was son of a man of rank, governor of the castle of St. George de la Mina. He was educated to the profession of arms, and served first in the order of Malta, when he was taken prisoner by the Turks. After recovering his liberty, he served with the troops in America and the East Indies. After this he married, but the loss of a child and other afflicting circumstances impressed both him and his wife with a spirit of devotion, and they took the religious habit in the Dominican order, De Souza changing his baptismal name of Manuel for that of Louis. He had already acquired a good share of literature, and had written an elegant preface to the Latin poems of Falcone. He was, therefore, chosen to write the history of his order in Portugal in the vernacular tongue, of which he printed the first volume, folio, in 1623. From his papers two other volumes were printed after his death. He was author also of the "Life of Dom. Bartholemew, one of the Martyrs," printed in 1619, and of which a French translation has been given; and "A History of John III. King of Portugal," which has not been published. De Souza is accounted one of the best writers of his country.

SOW, in *Geography*, a river of England, in the county of Stafford, which runs into the Trent, 3 miles E. of Stafford.—Also, a river of England, in the county of Stafford, which runs into the Avon, 4 miles N. of Warwick.

Sow, in *Zoology*. See SUS, HOG, and SWINE.

Sow, in the *Iron-works*, the name of the block or lump of metal they work at once in the iron-furnace. The size of these sows of iron is very different, even from the same workmen and the same furnace. These furnaces having sand-stone for their hearths and sides, up to the height of a yard, and the rest being made of brick, the hearth, by the force of the fire, is continually growing wider; so that if it at first contains as much metal as will make a sow of 6 or 7 cwt., at last it will contain as much as will make a sow of 20 cwt.

Sow, in *Ancient Military Language*, a kind of covered shed, fixed on wheels, under which the besiegers filled up and passed the ditch, sapped or mined the wall, and sometimes worked a kind of ram.

Some say it derived its name from the soldiers lying under it close together, like pigs under a sow; though another reason is given for that appellation, namely, its being applied to digging and rooting up the earth. The former was alluded to by the countess who defended the

cattle of Dunbar against king Edward III., when she threatened, that unless the Englishmen kept their sow better, she would make her cast her pigs. Camden, who mentions this circumstance, says, "the sow is yet used in Ireland." Two machines, the one called the boar and the other the sow, were employed by the parliamentarians in the siege of Corfe-castle, Dorsetshire. The sow was similar in construction to the *Cattus*, (which see), cat-house, or cat, so called because under it soldiers lay in watch, like a cat for its prey; some of these cats had crenelles and chinks, from whence the archers could discharge their arrows; these were called castellated cats.

Sow, or *Hop-sow*, in *Agriculture*, a name applied in some districts, as in the county of Essex, to a tool or contrivance for pulling or forcing up hop-poles out of the earth in which they have been fixed. It is constructed of a stout strong tapering sort of pole or stake, about three inches in diameter, and five feet in length, to which, at the distance of nearly a foot from the lower or larger end, is firmly fixed and clinched a small bar of iron, about half an inch square, and a foot long, which is bent nearly in the middle, so as to form an acute angle with the stake, four inches or rather more being open at the upper end of it, which make a sort of hook with the stake, by which the pole is grasped, and the inside of the iron bar being raised and roughed by the smith, somewhat in the manner of teeth, when fixed upon the lower end of the hop-pole, near the surface of the ground, is enabled to bite and hold it fast; when, by the lower end of the tool being made to rest upon the ground on the opposite side of the hop-pole to that on which the workman stands, and the whole acting as a lever, is readily, and with facility, made to raise or lift the hop-pole out of its socket in the solid ground, though it may be set a foot or more into it.

It is a simple, cheap, and effective invention for accomplishing this necessary purpose in hop-management. In the county of Kent, the implement employed in the same intention is denominated a *hop-dog*; and those in other hop districts have most probably the same name given to them. See HOP.

Sow-Bread, in *Botany*, &c. See CYCLAMEN.

The roots of the round-leaved fow-bread with a purple under-side, have a nauseous, acrid, biting taste: by drying their acrimony is abated; nevertheless, when taken internally, they betray a great degree of irritating power. Dried and powdered they have been given in doses of a drachm, and found to operate as a strong, inflammatory, but slow cathartic. The juice is said to purge when applied externally to the belly in ointment; and the juice or bruised root to be of great efficacy for softening and discussing indolent hard tumours. The flowers are of a different nature, and have not been used medicinally; and the use of the roots is now, among us, in a great measure, laid aside. Lewis.

Sow-Thistle. See SONCHUS.

The common fow-thistle has been much recommended by authors as a refrigerant and attenuant. It was prescribed by many of the old physicians in stranguries, and other disorders of the urinary passages; and ordered externally in cataplasms, in all kinds of inflammations.

Sow-Thistle, Downy. See ANDRYALA.

Sow and Pigs, in *Geography*, rocks in the German sea, near the E. coast of England, and the county of Northumberland; 3 miles E.N.E. of Blythe. N. lat. 55° 9'. W. long. 1° 12'.—Also, rocks on the coast of Massachusetts, in Buzzard's bay, lying off the S.W. end of Catahank island.

SOWAGEPOUR, a town of Hindoostan, in Bahar ; 27 miles N.N.W. of Hajypour.

SOWERBÆA, in *Botany*, was so named, by the writer of the present article, in commemoration of his friend and fellow labourer, Mr. James Sowerby, F.L.S., &c. an excellent botanist and artist, to whose accuracy and acuteness of observation he acknowledges himself to have been often indebted, in the course of his own botanical studies and publications ; and to whom various other authors have been no less obliged.—Sm. Tr. of Linn. Soc. v. 4. 218. Ait. v. 2. 231. Brown Prodr. Nov. Holl. v. 1. 285.—Clafs and order, *Triandria Monogynia*. Nat. Ord. *Spathacea*, Linn. *Asphodeli*, Jull.

Gen. Ch. *Cal.* Common Sheath of several membranous, permanent scales ; the outer ones ovate, concave ; inner in many fine segments. *Cor.* Petals six, ovate, equal, permanent ; three of them interior. *Stam.* Filaments six, short, broad, flattened, obtuse, three of them barren ; anthers three, on the three filaments opposite to the interior petals, oblong, each of two linear spreading lobes, of one cell, slightly connected a little above their base only, divaricated at each end, permanent. *Pist.* German superior, roundish, with three furrows ; style thread-shaped, permanent ; stigma simple. *Peric.* Capsule roundish, three-lobed, of three cells and three valves ; the partitions from the centre of each valve. *Seeds* one or two in each cell, angular, rough.

Eff. Ch. Sheath of many valves. Petals six. Stigma simple. Anthers with divided cells. Three alternate filaments barren. Seeds nearly solitary.

1. *S. juncea*. Rush-leaved Sowerbæa. Sm. Tr. of Linn. Soc. v. 5. 159. t. 6. Ait. n. 1. Br. n. 1. Ker in Curt. Mag. t. 1104. Andr. Repof. t. 81.—Native of Port Jackson, New South Wales. First cultivated by Messrs. Lee and Kennedy, in 1792. It is a hardy greenhouse herbaceous plant, flowering in the early part of summer, and easily increased by parting its fibrous perennial roots in the spring, planting them in peat-earth. The whole herb is smooth, destitute of a stem. *Leaves* numerous, radical, sheathing, erect, linear, acute ; channelled above ; semi-cylindrical beneath ; their sheaths crowned internally with a simple membranous *spicula*, like that of a grass. *Stalk* solitary, erect, simple, above a foot high, taller than the leaves, bearing a rather dense umbel, of copious, elegant, rose-coloured, scentless flowers, much resembling those of several species of *Allium*, on capillary partial stalks, each of which has, as Mr. Brown remarks, a joint under the flower. The capsules become pendulous as they ripen, each enclosed in its shining, scarcely altered, corolla. *Anthers* yellow.

The authority of Mr. Brown, who has examined this plant in its native country, induces us to correct some of our ideas concerning it, which indeed had never been very firmly impressed in our mind. The cells of the anthers prove to be simple, and though they first open at the top, by a seeming pore, they soon split all the way down, by a furrow, which gives them the appearance of being two-celled. Though nearly separate, therefore, through their whole length, these cells together constitute but one anther, as in the *SCITAMINEÆ*, see that article, whose cells are still further disjointed. The genus of *Sowerbæa* is, nevertheless, perfectly distinct, though nearly related to *Allium*. The herb, when bruised, has no peculiar scent.

SOWING, in *Agriculture*, the act of scattering, or putting the seeds of grain, plants, &c. on or into the ground, in order to their producing crops. See *SPREN*.

With regard to the period or season of sowing, or putting crops into the soil, it is remarked, that the most proper and advantageous season for sowing or setting such as possess

the habit, or are capable of perfecting and ripening their seed or produce in the same year, is that of some of the more early spring months, according as they are more forward or late in their kinds, and the climate more mild, or the contrary ; while, on the other hand, such as are, from the peculiarity of their nature or habits, incapable of completing their vegetation in the same year, the most favourable period will be some of the more early autumnal months, according to the differences of their habits, and the variations of climate and season : as by these means, in the former case, the seeds, grains, or roots, become perfectly evolved, and the radicles of the young plants firmly established in the soil, and capable of sustaining themselves against the hot season sets in, which is to bring them to maturity ; and, in the latter, the seeds have attained such a state of growth, and so far fixed their roots in the ground, as to be capable of supporting themselves, without sustaining much injury from the severity of the winter season, and consequently advance with greater rapidity in their vegetation in the spring, in order to perfect their seed by the heat of the summer season.

And it is further stated, on the authority of lord Orford, that the practice is advised of sowing certain sorts of grains and seeds, and also of setting particular kinds of roots, at much earlier periods in the spring than is commonly had recourse to by the farmer. Thus, it is said, by putting barley into the ground in the beginning of February, great advantage has been supposed to have been derived in the forwardness and fineness of the grain. But against this method it has, however, been ingeniously suggested by Dr. Darwin, that as much moisture, with or without subsequent frost, is more liable to destroy the embryo in its very early state in the seed, than after it has shot out roots and a summit, and thus acquired some habits of life, such early sowing must, in some cases, be practised with caution. But that such an objection cannot be brought against the early autumnal sowings.

The crops of autumn-sown wheat should be constantly put into the ground in the latter end of September, or beginning of the following month ; but the former, if possible. And the spring-sown kinds should not be later than the end of March ; as, when later sown, they never ripen well. And with oats and barley crops, February, March, and April, are the seasons usually had recourse to. But from grain seeds and roots requiring such different lengths of time in arriving at maturity, the particular period at which each sort of grain, seed, or root, should be sown, set, or put into the earth, with the greatest chance of success, will be more fully noticed, seen, and pointed out, in speaking of the cultivation and growth of the different sorts of crops.

The last mentioned ingenious writer has likewise remarked, that the difficulty of determining the best season for sowing, or putting in seeds in the spring, owing to the variation of the weather in the same latitude, as well as of laying down or fixing the exact seasons for sowing in different latitudes, occasioned Linnæus to form or construct what he terms a calendar of Flora, which was afterward adapted to this climate by Stillingfleet ; and which consisted in observing the first appearance of the root-scions, or flowers of the uncultivated native vegetables ; with directions to sow the *cerealia*, or harvest-seed, when such plants or flowers became visible. By attention to observations of this kind, on such sorts of uncultivated plants, in many climates, the above writer conceives such tables might be constructed, as would point out the most proper times of sowing the most useful seeds or grains in every latitude and situation.

situation. And he further adds, that another tabular view of the climates where plants grow naturally, and of their native situations, in respect to moisture or dryness, hill or valley, with the kind of soil where they were originally found, might also contribute to their successful cultivation.

The following is the order of leafing of a few trees and shrubs, which Mr. Stillingfleet has put down, as noticed by himself, in the county of Norfolk, in the year 1755.

Plants.	Seasons.
1. Honeyfuckle	January 15
2. Gooseberry	March 11
3. Currant	11
4. Elder	11
5. Birch	April 1
6. Weeping willow	1
7. Raspberry	3
8. Bramble	3
9. Briar	4
10. Plum	6
11. Apricot	6
12. Peach	6
13. Filbert	7
14. Sallow	7
15. Alder	7
16. Sycamore	9
17. Elm	10
18. Quince	10
19. Marsh elder	10
20. Wych elm	12
21. Quicken-tree	13
22. Hornbeam	13
23. Apple-tree	14
24. Abele	16
25. Chestnut	16
26. Willow	17
27. Oak	18
28. Lime	18
29. Maple	19
30. Walnut	21
31. Plane	21
32. Black poplar	21
33. Beech	21
34. Acacia robinia	21
35. Ash	22
36. Caroline poplar	22

Also, the conformity between vegetation and the arrival of certain birds of passage is, he says, extraordinary. Of this he gives an instance, marked down by himself, in the above-mentioned county, in his diary of the same year.

April 16th, young figs appear.

17th, the cuckoo sings.

And he notices, that the word *κοκκυζ* signifies a cuckoo, and likewise a young fig; and that the reason for it is, that in Greece they appeared together. He also states, that the same year he first found the cuckoo-flower to blow the 19th of April. He likewise further adds, that, according to Linnæus, the wood anemone blows from the arrival of the swallow. In his diary for the year 1755, he finds the swallow appeared April the 6th, and the wood anemone was in blow the 10th of the same month. He adds also, that the marsh-marigold blows when the cuckoo sings; and according to his diary, the marsh-marigold was in blow April the 7th, and the same day the cuckoo sung.

It has also been remarked, that a due temperature of the season, with respect to heat or cold, drought or wet, (for all these greatly influence the state of the earth,) is essentially

necessary, and should be carefully attended to by the cultivator, when he sows; but the precise time most proper for this work cannot, by any means, be invariably fixed, because it will always depend on the concurrence of a variety of circumstances. The seasons are more or less forward, and the ground is more or less dry, in some years than in others. A proper series of well-made observations would furnish the best rules in this respect, but certainly would not fix the time of sowing to any particular day or week, for years to come. Linnæus's method, of carefully observing the foliage of trees, &c. would determine the proper time for spring sowing. And Pliny, after mentioning the several constellations by which farmers were guided in his time, instructs the farmer with regard to autumnal sowing, upon a principle similar to that of the great modern naturalist. Why, says he, does the husbandman look up to the stars, of which he is ignorant, whilst every hedge and tree point out the season by the fall of their leaves? This circumstance will indicate the temperature of the air in every climate, and shew whether the season be early or late. This constitutes an universal rule for the whole world; because trees shed their leaves in every country, according to the difference of the seasons. This gives a general signal for sowing; nature declaring that she has then covered the earth against the inclemency of the winter, and enriched it with this manure.

It can, therefore, only be observed in general, that it is better, as has been suggested, to sow early in autumn than too late, provided the season will admit of it; because the plants are better able to resist the severity of the winter, after they have acquired a certain degree of strength; and their roots being then longer, and consequently better fixed in the earth, they will be less liable to be thrown out by the frost. For this reason, in particular, perhaps the colder the climate is, the earlier the wheat should be sown. Some lands are of such a nature, that they swell greatly in hard frosts; and subsiding again upon a thaw, leave the roots of plants quite bare upon their surface. There have indeed been years, in which fields sown very late, for instance in December, have done extremely well; but that ought not, on any account, to be made a rule, experience shewing that such late sowings very seldom answer. On the other hand, the corn is likewise exposed to many dangers, when sown too early; for the stalks, which shoot up before winter, cannot well bear hard frost; though wheat would not be hurt by them, when only in the blade. M. de Chateauxvieux is clearly of opinion, that though the proper time of the year for sowing be come, the corn should not be put into the ground, if the temperature of the season be not favourable; and that, on the contrary, the sowing of it ought to be deferred, in hopes of a change. If, says he, the weather is very hot, and the earth extremely dry, it will be absolutely necessary to wait till some rain has fallen; for otherwise the feed will rise but very imperfectly. This he is sure of, by which he contradicts the common saying of some farmers, that the earth is the best granary to keep the corn in. Full of this notion, whenever the stated times come round, they sow, without distinction, in wet land or in dry. Even heat does not hinder them: they think their feed will certainly sprout well after the first rain; but he has always experienced that the plants have come up thin. But to satisfy himself still farther on this point, he tried an experiment purposely to know whether corn can be sown, with any reasonable expectation of success, when the weather is very hot, and the earth very dry. Upon reading M. Duhamel's Treatise on the Preservation of Corn, he has observed that he had found, by his experiments, that wheat

SOWING.

dried in a stove, heated to 60 degrees of M. de Reaumur's thermometer, had lost its faculty of growing. From thence he conjectured, that wheat which should undergo a heat, for example, of 30 degrees during a longer time, would be equally parched up, and rendered incapable of vegetating. He considered the earth, when hot and dry, as a kind of stove, in which the seed, if it remain too long without receiving any moisture, may become so dry, that the greatest part of it will never be able to sprout. This reasoning is just, and he therefore determined to have recourse to that trusty guide, experience.

He was sure that the wheat which he sowed was perfectly sound, and in every respect capable of growing. It was, therefore, quite clear, that so great a number of grains out of the whole, which did not sprout at all, lost the faculty of growing, by their being parched up by the heat and dryness of the earth. To be still more certain of this, three weeks after he had sowed these grains, he watered half of them several times, but to no purpose; not one of them rose, and he found several of them quite whole in the earth where he had sown them.

Upon the whole he concludes, from his own repeated practice, that the best time for sowing, in such a climate as Geneva, (which differs very little from our's,) is from the 20th of August to the end of September; and thinks that even the first fortnight in October may be taken in, if the land cannot possibly be sowed sooner. But he allows of this only in a case of necessity, and judges that, rather than sow later, it is best to stay till spring. Thus, says he, it is that experience and observation teach us to leave off bad customs, or such as are not founded on principles with which a man of sense may rest satisfied.

In the northern tracts of the island, where the summer season is not of much length, but stormy and extremely variable in the state of the weather, early sowing is said to have been lately found to be attended with many advantages; and that the prejudices in favour of a late performance of this sort of business is fast wearing off; as the good effects of putting seed into the ground as early as the season will admit, are so evident, in such a climate, and the benefit of the practice so great and manifest, that the most prejudiced are beginning to suspect their late sowings to be bad, and that the practice of those who eagerly catch and embrace the very first opportunities which the state of the weather will allow, of sowing their grain crops, bids the fairest for saving them, at the latter end of the season. The hazard to be dreaded from it with some sorts of grain, as oats, is very little, while the benefit to be derived is very great. The advantages of it are very important, in having the best part of the summer season for bringing the crops to full perfection, which increases the value of the grain, and in having long days and a favourable season for cutting, collecting, and securing the produce in perfect condition: while late sowing, on the contrary, occasions the risk of having the crops exposed, after being cut, for weeks together, in the fields, under rotting rains, until the sheaves become each a mass of vegetation. Instead of fixing upon any exact period for commencing the business of sowing, which is extremely absurd, especially in such a climate, the prudent cultivator will regulate his conduct in this respect by the state of the weather, and the appearances which have been suggested above. And as the gardener forms an annual calendar of the weather for himself, by what he sees coming on in his garden; so should the farmer, by the course of experience and information, learn to distinguish the proper times for performing the particular operations of his art; not, however, by having recourse to any precise

or set period of the season, but by reference to certain natural appearances, which may indicate the mildness or clemency of particular seasons, or the contrary. This may be particularly useful in the business of sowing different kinds of crops.

In many districts towards the southern extremity of the kingdom, the utility and benefits of early sowing have been likewise noticed and experienced, as the earliest sown crops, especially of the wheat kind, have been almost invariably found the best. This opinion, which is of some standing, is, in some measure, confirmed by the assurance, that nearly the whole of the famous crops which have been produced and talked of by the farmers in these districts, were raised from early sowings. Now and then a crop may contradict this conclusion, but they are very rare, and mostly arise from some unobserved circumstance in the land which produced them. There can, therefore, be no reason for doubting that more early sowing than is at present practised, in many cases and circumstances of land, may be highly advantageous and beneficial to the farmer, not only in the quantity of produce, but in several other ways.

It is of the greatest consequence to the farmer, that seed in sowing be placed in the earth at a proper depth, and in the best manner; but experience is yet wanting to determine with due exactness, what is the depth which best suits each kind of grain in different soils. In the spring sowings, when there is mostly much moisture in the soil, from the wetness of the previous seasons, less depth may be required than in the summer, where the land is rendered more dry and parched. From half an inch to an inch and a half, may be fully sufficient for the seeds of the grain, turnip, and carrot kinds, so as that they may be fully protected from birds and insects. And for root-seeds, such as potatoes, from two to four inches, in proportion to the state of the soil, may be quite sufficient.

But, in the very early autumnal sowings, as from the excessive drying heats of the summer season, there must in common be a deficiency of moisture in the earth, it may be better to have the seed put in somewhat deeper, as from two inches to three or more, in order that their vegetation may not only proceed more speedily, but their roots be more fully guarded from the effects of the frosty nights, which usually take place soon after such sowings. And in this way they are more effectually protected from the attacks of birds and other vermin, which are generally more eager and destructive in their attacks, from the diminished quantity of food at such periods of the year.

However, in general, as the process of sprouting or early vegetating is found to be greatly promoted by the seed being fully supplied with oxygen air, it may be the most beneficial practice to have them put into the soil, in rather a superficial manner, or but lightly covered, as by such means they may be the most fully supplied with atmospheric air. And for this reason, too, it may be the most advantageous method to have the seeds or roots deposited in the soil as soon as possible after it has been turned up by the plough or spade, as, in such circumstances, it must contain the largest proportion of atmospheric air among its constituent particles; which, it is observed by Dr. Darwin, may be necessary to stimulate into elevation the plume of the embryo plant, as the moisture of the earth is necessary to stimulate the root into its elongation downwards.

The particular state of the season and climate in which the sowings or plantings are performed, may likewise have some influence on the crops. It has been commonly supposed that the best practice is that of sowing in dry seasons, and setting out plants in such as are moist; but it is obvious,

a late writer thinks, that, in so far as the sowing is concerned, this business ought, in some respect, to be conducted according to the differences of the qualities of the lands and the nature of the climate, in regard to its warmth, or the contrary. Thus, in the drier and more mellow and porous descriptions of soils, and the more warm and genial climates, it may, in many cases, be advantageous, not only to sow in the wet, or rather moist seasons, but also at more early periods, than in such as are more retentive of humidity; as from the moisture being commonly, in such sorts of lands, quickly dissipated, a more certain and expeditious vegetation of the seed may in this way be secured. But in the more heavy and wet kinds of soil, where the climate is colder, it will constantly be a more beneficial method to choose, if possible, a dry and warm season for performing the business of sowing or putting in the crops, as by such means the grain will be more certain of vegetating, and in less danger of perishing by the over-abundant wetness, and the want of heat in such lands and climates. And it has been justly remarked by Dr. Darwin, that in some clayey grounds, much softened by rain, if the seed be put into holes and a dry season succeed, an almost impenetrable crust may be produced by the quick exhalation of the moisture, and what is termed by the farmers, the setting of the clay; and in this manner the vegetation and early growth of the crop be much retarded, or in a great measure prevented. And that though it has been ingeniously suggested that useful purposes in the early vegetation of some sorts of plants may be answered by the sowing of the fruits or husks that surround particular kinds of seeds and berries, no experiments have yet been made to shew whether the sowing the chaff, or covering of the grain with it, might not, in particular circumstances of the soil and climate, be of utility in affording it warmth and protection in the first stages of its growth.

With regard to the methods of sowing or putting the seed into the earth, there are different ones in use, not only in districts where the nature and qualities of the soils are different, but in those in which they have much similarity. It is observed, that the most general and common mode, as well as that which is more or less prevalent in almost every part of the kingdom, is that of sowing or casting the seed over the surface of the ground by means of the hand, having it afterwards covered to a proper depth by harrowing. In this method of performing the business, the most usual practice, especially where the ridges are equal in breadth, and not of too great a width, as five or six yards, is that of dispersing the seed regularly over each land or ridge in once walking round; the seedman, by different casts of the hand, sowing one half going and the other in returning. In doing this, it is the custom of some seedsmen to fill the hand from the basket or hopper which they carry along with them, as they make one step forward, and disperse the seed in the time of performing the next; while others scatter the seed, or make their *casts*, as they are termed by farmers, in advancing each step. Mr. Parkinson states, in the account which he has given of Irish farming, that he found a good sower the most difficult thing to be met with; in fact, he did not himself know the true art of sowing seed broad-cast until he went to America, and the man from whom he took the idea there attracted his notice, from the particular manner in which he walked while sowing, which was precisely as if he had been blind, keeping his eyes on the seed as he threw it, by continually looking upwards. It is consequently evident, that in accomplishing this business with regularity and exactness, upon which much of the success of the crop must depend, there is con-

siderable difficulty, and the proper knowledge and habit of which can only be acquired by experience. Wherever this method of putting in the seed is had recourse to, it is consequently of importance for the farmer either to perform the operation himself, or to be careful in selecting such persons as are conversant with the business, as he may otherwise incur much unnecessary expence in the waste of seed, and run considerable risk in respect to his crop. Mr. Marshall, finding a great waste and inconvenience attending the broad-cast sowing, ordered his seedman to walk on the left-hand inner furrow, with his face towards the land to be sown, and to make his cast diagonally, not across the land. This gave him a great scope; and after a few minutes practice he made very good work: before night he walked at the rate of three or four miles an hour, and though a young seedman, made as good work as could be wished. A man walking in the smooth, open, inner furrow, may sow three acres in less time, with more ease, than one walking among the rough clods and loose mould could sow two acres. This method proved superior to the usual way, being cropped as well, and with less seed. The extra expence of sowing is about two-pence an acre, but the saving of the seed was at least two shillings *per acre*. The method observed was for the seedman to walk up one side of the ridge or bed, and down the other side; always keeping his face, and the hand with which he sows, towards the bed he is sowing. He always keeps his eye on the edge of the opposite interfurrow, and delivers his seed principally on the side of the bed next to it: as he returns, the sides of course are reversed, and the beds become evenly seeded. An old seedman, who has been used to throw large handfuls with all his might, in wide casts straight across his walk, will find it awkward at first to make the snug diagonal cast which is necessary in sowing five-bout beds singly.

But it is observed, that the usual way of sowing in broad-cast cannot answer all the intentions of placing the seed properly in the earth, and must be attended with several inconveniencies: such as the seed's becoming the prey of various birds and animals; its being laid so superficially, that the sun often parches it, or a long continued rain, instead of promoting a kindly vegetation, soaks into the grains, and bursts them; the seed is very unequally sown, because of the inequality of the handfuls which different sowers grasp, and a great part of it necessarily falls together into hollows, where the surface of the ground is any way unequal, &c. And that, sensible of these disadvantages, farmers have, especially for their winter grain, sometimes adopted the method of sowing under-furrow, that is, sowing one half of the seed in broad-cast, and then ploughing it in; and afterwards sowing the other half, which is covered by harrowing. But this method is also liable to almost as many objections as the other; for the quantity sown in each particular spot, and the equal distribution which ought to take place throughout the whole, cannot but be even more uncertain than in the broad-cast, where the whole is sown at once; nor dares the farmer, in this sowing under furrow, omit sowing the second quantity, lest a great part of what has been ploughed down be buried so deep that it cannot rise, especially if the soil is at all strong. And another general fault in the common way of sowing is, that too much seed is employed; partly because custom has established a kind of rule in that respect, and partly on account of the allowances which it is necessary to make for what the birds eat, and for what lies too deep ever to rise; the circumstances by which a very great quantity of corn is absolutely lost. See *BROAD-CAST Sowing*.

There are inconveniencies and difficulties in this manner

SOWING.

of sowing, on many other accounts; as where the lands or ridges are liable to vary in their dimensions or breadths at the different ends or parts, the sowing is not performed without great trouble and waste of seed, as the scattering of it, in turning so often on the different parts, is prevented from being effected in so regular and exact a manner, as when the seedman is directed by a particular furrow-slice. The sowing is, therefore, sometimes very imperfect in such cases, even with good seedsmen. In sowing in this way there are probably, too, less economy, less exactness in many points, and less attention provided for the management of the crops, while they are growing afterwards.

Sowing in the broad-cast manner has, however, many advocates, and is probably the most prevailing practice in most districts of the kingdom; and some think that, in common, all sorts of grain produce the largest quantity on the acre, when sown in this method. It should, notwithstanding, perhaps give way to the machine practice of sowing, wherever it can be had recourse to with ease and facility.

In general it is, however, supposed, that these inconveniences may be prevented by the drill method of sowing, which drops the seed at whatever depth and distance experience has shewn to be the fittest for the particular kind which is sown; fills all the furrows with earth, so that none of the grain remains uncovered; and lets fall into each furrow the exact quantity of seed which has been found to be most proper. In this way the seed is of course distributed with greater regularity and exactness, both in regard to depth and the distance of the rows, by which the crops not only succeed better, but are more capable of being assisted in their culture afterwards; while much seed is saved. It is likewise believed to have many other advantages over the common method of sowing. See *DRILLING*.

It evidently admits more air and light for the growth and maturation of the crops, and produces a better and more abundant quantity of them. In sowing wheat and other grain crops in this way, they should probably not have more space between the rows than about seven inches; but in other kinds it should vary, according to the nature and habits of the growth of the plants, and the state of the soil. The sowing in this way in too thin a manner has often been injurious to the cultivator.

Sowing is sometimes performed likewise in methods between those of the broad-cast and the drill, as by means of tools with different numbers of shares. The sowing is, in these cases, executed, when the land becomes firm and rather solid, immediately after the tool, over the whole surface of the land in the broad-cast way, the seed molly falling into the little furrows or openings that are left by the implement. In sowing in this manner, there are the advantages, it is observed, of having the land firm between the small drills, of the seed taking firmer hold of the ground, of its being readily performed and attended with little trouble, of the seed coming up with great regularity, of the crop being less liable to accidents, in consequence of the action of the sun and air being more free, of its affording a greater facility in the after-culture, and of the quantity of grain being increased. On light and dry soils, this mode of sowing is said to be attended with the best effects. Some, however, think that one cast before and another after this tool is the most preferable mode of sowing.

But whatever may be the benefits of sowing in the drill manner, it has hitherto made no very great progress, though it is evidently a most useful method.

There are also other methods of sowing, as by dibbling, dropping, and setting with the hand, which, under different

circumstances, are found very beneficial modes. See *DIBBLING* and *RIDGE*.

These are, however, methods which are only suited to particular situations and circumstances of land.

All these different ways of sowing, or putting the seed into the ground, may perhaps be found useful, and be practised with success, under different circumstances and conditions of land; as where one mode is improper, or not capable of being had recourse to, another may be substituted, in order to supply its place, and accomplish this important business of the farmer, in the most proper and desirable manner.

In sowing small seeds for plants, constant attention is necessary to the times or periods at which the plants will be wanted for setting out as crops, and the different sowings made accordingly. For these sowings, small suitable portions of land, in a fine state of preparation and cultivation, and which are well secured, are always to be chosen. The sowings for cabbage, and other similar sorts of plants, should be made at two or three different times, both for the autumn and spring crops, in order that the plants may be strong and healthy. And for raising spring plants of the several different other kinds, as those of the lettuce, or other similar sorts, the seeds should be sown at two or more separate times, in the early spring season, that good plants may be in readiness for setting out, when wanted. In general, small spaces of ground will be sufficient for these purposes, as they may contain the quantities of plants which are necessary. The sowings, in such cases, are to be made in a regular, but not too thick a manner; the plants being afterwards, when of some growth, properly thinned, that they may become strong plants. In sowing some sorts of small seeds, it is useful to mix a little ashes, or some other similar substance, with them, to make them sow better. The sowing of grass-seeds should always be performed in as regular and exact a manner as possible. See *GRASS* and *GRASS-Land*.

SOWING of Seeds, in *Gardening*, the practice of putting seed into the ground, in the garden manner; in which different methods are made use of, according to the sorts: as broad-cast sowing and raking-in, drill sowing, bedding-in sowing, &c.; in each of which there are some advantages in different ways.

The first is the most common and expeditious method of sowing, both for many of the principal crops to remain, and for transplantation; and is performed by sowing the seed with a spreading call evenly all over the surface of the ground, either in one continued plat, or when divided into beds, which is immediately raked with a large rake, to bury all the seeds a due depth in the earth; some requiring to be raked in as light as possible, others half an inch or an inch or more deep, according to their kinds and sizes, &c.

In preparing for this method of sowing, the ground is previously dug over in the common way, or in such a manner as is necessary; making the surface level with the spade, as the work proceeds; and, according to the nature of the seed, sowing it as soon as possible afterwards. And this sort of sowing should generally be performed in dry weather, particularly the early sowings in winter and spring; but in hot weather, in summer and autumn, it may often be eligible to take advantage of sowing immediately after a shower of moderate rain. And as to the sowing the seed in the broad-cast way, it is effected occasionally both with an open and locked hand. In the former case, it is performed by delivering the seeds with an open hand, and broad-spreading call, as practised in sowing corn in the open fields, previously stepping out the ground in breaks, or certain widths,

SOWING.

as a guide to sow with the greater regularity; proceeding with the sowing along each space with a regular step and cast, giving the hand a proper sweeping cast forward, fully expanded at the delivery of the seeds, making them spread abroad evenly in every part; and thus proceeding up one space, and down another, till finished; which method is practised in large kitchen-grounds, in sowing any considerable space in one continued plat. But the latter is practised occasionally, both in sowing large continued plats of ground, and narrow beds, &c.; but more generally the latter, especially when intended sowing them bed and bed separately; or on narrow borders, and other small plats of ground, commonly sowing or delivering the seeds with a locked or close hand, discharging them from between the fore-finger and thumb; opening or pinching the thumb more or less, according to the size and nature of the seeds, and thickness they require to be sown; giving the hand a sort of jerking turn, or cast forward, at the delivery, to cause the seeds to spread regularly, and in an exact manner.

As soon as the seeds are sown, they should be directly raked in, before the surface of the ground is rendered either too dry by the sun or wind, or made too wet by rain, in a regular and even manner, so as to bury them sufficiently according to their kinds; all large stones, lumpy clods, and rubbish, being cleared off; smaller or larger rakes being used, as they may be necessary. See *Garden-RAKE*.

But previously to the raking in the seeds, sown on the general surface in one continued space, where the ground is loose, light, and dry, and in a dry season, it is sometimes the practice, after sowing, to tread them in evenly by treading the ground all over lightly and regularly with the feet. It is also sometimes proper to pare up the loose earth of the alleys an inch or two deep, and spread it thinly over the surface. The work of treading in the seeds is performed with the feet nearly close together, taking short regular steps, treading the surface all over, once in a place, with but small spaces between the steps.

And in extensive market kitchen-gardens, where large tracts of ground are sown at once, instead of raking in the seed, they, for the sake of expedition and cheapness, have light short-tined harrows to draw with men, with which they harrow in the seeds; and sometimes in light dry ground, and a dry surface, they afterwards roll the ground with a light wooden roller, to close and smooth the surface over the seeds more effectually; performing it when the surface is a little dried, so as not to adhere to the roller.

Also in large garden-farms in fields, where they commonly plough and harrow the ground for the reception of the seeds, they practise only the broad-cast sowing in continued tracts, for almost all their esculent seeds, except pease, beans, and kidney-beans; the ground being prepared by ploughing, and afterwards rough-harrowed, to smooth the surface moderately; the seeds being then sown in the spreading open-handed manner, and harrowed in either with a light short-toothed horse-harrow, or by men for particular crops; when, if very dry weather, they roll the surface afterwards with a wooden roller, drawn by horses, &c. to smooth the surface.

In these sowings, the land may either be formed into small beds of four or five feet in width, sowing each in a separate manner; or the whole may be rendered even, and then sown all over the surface, to be afterwards trodden into beds of suitable breadths, as already suggested. The intervals, in both cases, when the sowing is finished, are to be thinly pared and cast over the beds, which are then raked over in a regular neat manner, the whole length of them. The forming the land into small beds may, in some cases, be the

most desirable and advantageous practice; as where it is wet, and not capable of bearing treading, the intervals can be sown in not only to sow the seed, but perform the raking of it in, without injuring the beds by trampling upon them. Besides, when weeding, watering, or transplanting the crops become necessary, they are capable of being sown in for performing such works, as well as for culling and gathering the produce of them. In kitchen-gardens, however, where there is a scarcity of ground, or where it is of consequence to make the most of every part of such ground, and to use the utmost expedition in sowing or putting in the seed, the whole surface method, in one continued plat, may be the most eligible plan of seeding the land, especially in very large grounds, for the main crops of such kinds, as the carrot, the parsnip, turnip, leeks, onions, spinach, lettuce, radish, and some others.

In the raking or harrowing in the seed, in this mode of sowing, great care is to be taken not to draw the mould and seed into lumps or heaps, but to bury it regularly in the soil, and finish the work in a neat manner. Where the seed has been trodden in, but slight raking is necessary.

This mode of sowing and covering in the seed may be had recourse to for most of the esculent crops, some flower plants, &c.

It may be remarked, that the second method of sowing is necessary for many sorts of seeds, esculent, flower, tree, and shrub kinds in the nursery, both for the plants to remain where sown, and for transplantation; which is performed in drills, from a quarter or half an inch to two or three inches deep, according to the sizes and sorts of seeds; which being sown evenly along the bottom of the drill, the earth is drawn evenly over them with a hoe or rake, the depth as above, and the surface lightly raked smooth. This mode is always proper for large kinds of seeds, such as pease, beans, kidney-beans, and many large kinds of tree and shrub seeds, nuts, and berries; it being not only the most ready method of committing those large seeds to the ground the proper depth, but, by being in rows at a distance, best suits the nature of the growth of these sorts of plants, and their methods of culture. Many kinds of small seeds are also the most conveniently sown and cultivated in drills; such as several of the kitchen-garden plants, as parsley, chervil, coriander, all the sorts of small fallading, and sometimes spinach, beet, &c.; also some of the aromatics, when designed as edgings; and also occasionally in rows in beds, both to remain and for transplanting, such as thyme, savory, hyssop, &c.; likewise many sorts of flower-seeds for transplantation, and sometimes to remain. It is performed by drawing the drills with a common drawing-hoe, larger or smaller, in proportion to the sorts of seeds to be sown; setting a line as a guide to draw the drills straight by, which are drawn of different depths, as the sorts and sizes of the seeds may require, and at proportionable distances, from three or four inches to as many feet, according to the nature of the plants. Sometimes, when very small drills are required for fine or small seeds, to be sown in a bed, border, or hot-bed, it is done with the end of the finger, or with the end of a small flat stick.

The seeds should in general be sown and covered in directly, if the ground be dry and in good order; but if the soil be wet, especially at an early season, it may be proper to suffer the drills to lie or be open and exposed to the sun and air an hour or two, or more, to dry a little, particularly for tender seeds in early sowings, in the full ground. The sowing in the drills is performed for the most part with a locked or closed hand, discharging the seeds from between the fore-finger and thumb, scattering them

them evenly along the bottom of the drill, some forts requiring to be sown thinly just along the middle, such as in the angular drills drawn corner-ways of the hoe, for peas and many other larger feeds; also sometimes for smaller feeds when intended for edgings; but in the shallow flat-bottomed drills, it is generally intended for the feeds to be scattered evenly the whole width of the drill, thicker or thinner, according to the nature of growth of their respective plants.

The work of covering or turning in the earth into the drills over the feeds, may be performed occasionally with the rake, hoe, and feet; but the rake or hoe is the most proper for general practice for all smaller feeds, drawing the earth evenly into the drills a regular depth, fully to the depth of the drill, whether deep or shallow: however, peas, beans, kidney-beans, and such like larger feeds, in large drills at wide distances, are often covered in with the feet, by slipping them lightly along each side of the drill alternately, turning the earth evenly in over the feeds; the surface being then lightly trimmed along with the rake, to smooth it and clear it of large stones, &c.

This is a manner of sowing which has not only the advantage of putting in the feeds to the most equal, regular, and suitable depths, but of placing them in rows at such distances, as may admit the sun, light, and air, in the most effectual manner for promoting the growth of the plants as crops. Besides, the moulding up, and necessary culture afterwards, can be better and more beneficially performed.

In the last method of sowing, the ground being dug and formed into four or five-foot wide beds, with alleys a spade's width or more between bed and bed, and the earth drawn off the top of the bed with a rake or spade half an inch, or an inch, or more deep, into the alley, the seed is sown all over the surface of the bed; which done, the earth in the alley is immediately, either with a rake, drawn spreadingly upon the bed again over the feeds the same depth, or spread over with a spade, and the surface raked smooth and even in a similar manner. It is often practised in the nurseries, especially in sowing some large sorts of feeds, as well as others, but not very frequently in kitchen-gardens. It is not so expeditious as the broad-cast sowing, but is very proper for many sorts of small feeds, and many sorts of the tree and shrub kind, being a very regular method of sowing, so as to cover all the feeds an equal depth, and is performed two or three different ways; such as by the rake, by the spade, and by sifting. It is also sometimes performed with the rake and spade together, particularly when intended to sow any large feeds a good depth, using the rake to shove or rake the earth from off the bed into the alleys; or if it cannot be conveniently performed with the rake a proper depth, it is effected with the spade, trimming or paring the earth evenly off the surface into the alleys; then sowing the feeds all over the surface; and if they are of the larger berry, nut, or stone kind, or any other large feed, previous to covering them, pressing or patting them all evenly down into the earth with the back of the spade; and then, either with the rake or spade, spreading the earth out of the alleys evenly over them; though if it is a deep covering, especially when taken off with the spade, it is most eligible to use the same implement in returning it, being careful to spread it evenly, to cover the feeds all equally a proper depth, smoothing the surface with the rake in finishing the work.

Another method sometimes practised with large feeds is, that when the ground is laid out in beds unraked, the seed is sown on the surface, and with a rake stricken a little into the earth, then with a spade paring the alleys, and casting

the earth evenly over the bed, half an inch, or an inch or more deep, as may be required, raking the surface even. This is also sometimes practised in wetish ground, at an early season, when it does not readily admit of treading or raking. And by deepening the alleys and raking the beds, it drains the moisture from the surface, which is a great advantage in many cases.

The method by sifting is sometimes practised for several small light feeds of a more delicate nature, that require a very light covering of earth when sown; as, in order to cover them as shallow as possible, it is done by sifting fine earth over them out of a wire or chip sieve. Before the seed is sown, the surface of the bed, &c. is raked fine; then the earth thinly shoved off the surface of the bed with the back of the rake into the alley, making the surface as smooth as possible, and then sowing the seed, smoothing it down lightly with the spade, and sifting the earth in the alleys evenly over it to a suitable thickness, as half a quarter or a quarter of an inch deep; or sometimes the surface is only raked as smooth as possible without drawing off the earth, and sometimes only lightly smoothed with the back of the spade, then sowing the seed, and letting some loose fine earth from the alley, or some brought for the purpose, be sifted thinly over it. This, too, is a sort of broad-cast sowing, as the seed is sown over all the surface, but in a somewhat different way to that manner of sowing. But the modes of sowing the different sorts of feed crops are more fully explained under their respective heads.

In the sowing of all kinds of garden feeds, a greater and more exact attention to times and seasons is necessary than in the field, not only for the production of full and good crops of different kinds, but that of having them in due, proper, and regular succession. Small errors, in this respect, are not unfrequently productive of much trouble, inconvenience, and disappointment to the cultivators of such crops, but also to those who make use of them. The neglect of only a few days or a week, in some cases, is even of very material consequence in the raising of crops of this nature.

The larger principal crops are constantly to be sown as near their proper times as possible, and the successional ones in due order after them. Sometimes, however, small crops are sown to come in before the large main ones in particular instances, in which a nice attention to the proper season is requisite.

Small feeds must also be regularly and exactly sown in order to have proper supplies of different sorts of young plants for setting out at proper times and in proper succession.

For flower feeds, exact periods of sowing, according to the nature and habits of the plants, must be likewise chosen in the view of having them in the fullest and best perfection, as well as for proper successions in different cases.

In most cases of garden sowing, it is better to be rather too early than too late, in the different seasons for performing the business.

SOWING-Machine, an agricultural implement, which, as its name imports, is employed for sowing feeds, and distributing them at regular distances upon the land.

The greater number of sowing-machines which are in use, are called *drilling-machines*, because they deposit the feeds in parallel and equidistant rows, or drills extending the whole length of the field. This system of sowing corn, or other feeds, which was invented by Tull, has many advocates, whilst others prefer the ancient mode of broad-cast husbandry, in which the seed is scattered equally over the whole surface of the land. For the comparative advantages

tages of these methods, see the articles DRILL, DRILLING, HOING, HUSBANDRY, and *Drill MACHINE*.

Mr. J. Horn of Dover, Kent, constructed an *universal five-furrow machine* of this nature, which he recommended as suited for either broad-casting or drilling all the different sorts of grain, pulse, and seeds, with equal regularity and ease, as well as in any quantity or proportion, and depth, that may be thought proper. And which also possesses, he says, the peculiar advantage of sowing turnips, so as to ensure the crop against the ravages of the fly. This advantage is obtained by sowing the *usual quantity* of turnip seed *broad-cast* by the machine, and at the same time striking furrows at a proper distance apart in the land; by this means part of the seed is deposited in the drills, and the rest sown in broad-cast between them, so that if it proves a dry season, it is favourable for that deposited in the drills, if a wet season, for that which is sown broad-cast between them: and if that part of the seed which is sown broad-cast is carried away by the fly, that which is deposited in the drills, by coming at another period of time, is saved, and *vice versa*. If the whole grows, the farmer has then the opportunity of selecting the most vigorous plants from both. But notwithstanding these stated advantages, the machine is, we believe, little employed by the cultivators of land.

No machine, as far as we know, has hitherto been invented, which is well contrived for, and adapted to, the purpose of general sowing, though a great number of attempts of this kind have been made at different times, in the view of supplying so great a defect in the agricultural machinery of the country. They have all been found on trial, and when put fully to the test, to be materially defective in some important point or other, which rendered them either wholly useless, or only capable of being employed under particular circumstances. This has been equally the case, whatever may have been the nature or kind of construction, in which they have been formed. In order to construct a machine to be generally useful in this intention, it must be free from every kind of fault or defect in the delivery of all sorts of grain, pulse, and seeds, be capable of very great nicety and variation in sowing all these different articles, be very easy and exact in the movements of the internal parts, have great latitude of motion, giving way, and taking up in the shares or other parts, which are made use of in forming the little furrows or drills in the land, be capable of being guided and directed with ease and facility in a regular, steady, and exact manner, be cheap and reasonable in the expence of its construction, &c. But very few of these materially important points and objects have yet been accomplished in a full, complete, and satisfactory manner, in any of the sowing machines which have been contrived and constructed. Some of them, as already suggested, have a defect in some one of the particulars, some others in another, by which means they become neglected and of no use to the farmer, whose sowing must at least be performed with a certain degree of correctness.

It is evident, therefore, from what has been said, that the constructors of such sorts of machinery, to render it generally useful, should have a full and competent knowledge of the most proper proportions or quantities of the above several kinds of articles which are to be sown, as well as of the most suitable widths, distances, or spaces between the rows, which are necessary to be sown and left, in different cases and circumstances, in sowing with machines of this nature, as where this is not the case, there must frequently, if not generally, be much loss sustained in making such machines to sow too much or too little seed, as the dif-

ferences in the seed, and the spaces which are required in different states and circumstances, and conditions of land and season, are very great. The proportions of seed that are the most beneficial for early and late sowing are by no means the same; nor does different kinds and states of the soil admit of the same. They may differ also on some other accounts. The spaces, which are the most useful, likewise vary greatly in different kinds of soil, crops, and cultivation. It is consequently seen, that a perfect knowledge of this sort is absolutely necessary, and that such sowing machines as are incapable of sowing any kind of grain or seed in any proportion or quantity which may be required, are by no means fit for public or general use. In the internal parts of machines of this sort there should be great simplicity and incapability of being put out of order, the moving cylinders, or other parts supplying their places, being made so as to admit of great variation in the degrees of their motion or velocity. The utility of tin cylinders for this purpose is somewhat doubtful, and the shaking or sifting principle has not been found to succeed well, except in the case of round seeds, such for instance as those of the turnip, cabbage, rape, clover, and some other similar kinds, and even in these cases sometimes, with some of these seeds, a seed will stick in a hole which will permit another sort to pass in a free manner, and in those sorts which most readily pass, there is rarely a deficiency of some small seeds, of which two are capable of entering the same hole at the same time, which, by sticking fast together, impede and prevent the delivery in such machines. On this account, some sowing machines sow too much of one sort of such seeds and scarcely half enough of another. Pierced cylinders of the tin kind might probably be made to sow peas, which are nearly round in their form; but they would not be found to answer the same purpose for wheat or beans, and still less for barley or oats. And the same may perhaps be the case in sowing some other sorts. It is therefore probable, that wooden or metal cylinders, which have grooves on their surfaces, and brushes to promote and regulate the delivery, are the best modes which have yet been discovered for effecting the purpose of sowing in a proper manner in these machines, though they are far from approaching any sort of perfection in the business.

The shares, or other contrivances, which are made for the purpose of forming the little drills or furrows in the ground for the reception of the seed, should have great power and facility of moving and giving way in an upward direction in case of their meeting with any hard impeding substances in the soil, and that they may be used on all sorts and forms of ridges. They should also have the capability of being wholly taken up, when occasion may require, as in turning at the ends of the ridges, and in removing from one place or field to another, in order to prevent the machine from being broken and destroyed.

These machines should likewise have great ease and capability given them of being directed and guided, while in their work, by the exact regulation of the share or sowing parts only, or by these in connection with the other parts, as where there is a want or any material incorrectness in this respect, the after-culture of the crops may be greatly impeded or wholly hindered from taking place.

There is, consequently, a variety of points and circumstances which should engage the attention and consideration of the agricultural artificer and mechanic, who is anxious to succeed in the construction of useful machinery of this sort, and particularly that of a general or universal sowing-machine.

The article *Drill MACHINE* contains an account of sowing

ing-machines that are intended to sow the seeds in drills, and a minute description of one invented by Mr. Salmon, which is very superior to the others, as it is capable of being guided, and thus laying the drills in exact straight lines, a circumstance of the first importance in the operation of drilling, that the horse-hoe, which is to pass in the spaces between the drills, may not cut the young plants.

The term *sowing-machine* is almost exclusively confined to some implements lately introduced for sowing seeds in the broad-cast manner, that is, for distributing them equally over the whole surface; and this operation can be much better performed by the aid of a machine, than by scattering it abroad by hand, as in the ordinary method. The most approved sowing-machine is that of Mr. Bennet's, which is extremely simple: a slight wooden box, or trough, of a triangular figure, about five inches each side, and five or six feet in length, is held horizontally by the sower, who carries it suspended by a belt round his neck, so that the length of the trough is before his breast crosswise. The trough is filled with the seed which is to be sown or distributed; and at the bottom angle of the trough is a slight wooden axle, extending the whole length of it. This axle is turned round by an endless band and a wheel, which is mounted in a frame upon the top of the trough, and furnished with a small handle, conveniently situated for the sower to turn it round, and thus give motion to it. The axle has several notches, or small cups, cut in it at various places, and the bottom angle of the trough is open all the length; but the axle lying immediately beneath, closes the opening, and by hair-brushes is made so close, that no seed can pass, except when the axle is caused to revolve; the cups or notches then become filled with the seed, which is contained in the bottom of the trough, and they carry down their contents of seed through the bottom of the box, and it drops on the ground in a slight shower before the sower. The cups or notches are so arranged at intervals round the axle, that they will distribute the seed in the most equal manner possible, upon the whole breadth of ground over which the trough moves, when it is carried forwards as the sower walks in a straight line from one side of the field to the other; but the regular distribution of the seed, in the direction lengthwise of his walk, will altogether depend upon the precision with which he turns the handle of the wheel with a regular motion. As this is rather difficult to effect, Mr. Bennet has made another machine, which runs upon a wheel, like a wheel-barrow; and the motion of this wheel is communicated by wheel-work to the central axle, so that it turns regularly, and distributes the seed always in a given proportion to the distance of land over which it travels. The trough of this latter machine is the same as the former; and the axle, with the notches, is situated at the bottom of it; but, instead of the belt, the trough is carried, by being fixed transversely across two long rails, which, at the fore-end, have the wheel between them, and the other ends are formed into handles, by which the sower supports the machine, and wheels it before him in the same manner as a wheel-barrow. A pinion is fixed on the axle of the wheel close to the side of it, and turns a wheel and spindle, extending to the wheel on the axis of the trough, to keep the same in constant motion, and deliver the seed regularly upon the ground, in proportion as the machine advances; and means are provided by which the rate at which the axle delivers the seed can be increased or diminished at pleasure, to distribute more or less seed upon the ground.

Another class of sowing-machines are called dibblers, and are intended to make a small round hole to receive the

seeds, and then to drop them into it. We have seen several attempts to perform this operation by machines, but they have not fully succeeded. One of them was by means of a wheel provided with points projecting from its circumference, and placed at such distances from each other as the holes were intended to be. The machine being wheeled along in the same manner as a wheel-barrow, the points of the wheel were intended to dibble or pierce holes in the ground over which it passed, and the machinery in the feed-box, which was fixed upon the handles behind the wheel, followed, and let fall the intended quantity of seed into each hole so made. The objection to this machine was, that the points of the wheel, in lifting up or drawing out of the ground, drew up with them lumps of earth, and soon clogged the whole.

An ingenious dibble or sowing-machine, for acorns, was presented to the Society of Arts by Mr. Waistell in 1811, an account of which is published in their Transactions for that year. The dibble, or piercer, which makes the hole in the earth, is an iron rod, a quarter of an inch in diameter, and about four feet in length, round pointed at the lower end, that it may penetrate the ground. At the upper end of the rod a handle is fixed, to draw it up and force it down by. This rod is contained within the hollow of a wooden tube or staff, of the same length as the iron rod, and about two inches in diameter externally, so that the iron rod can be drawn up and down therein in the same manner as a rammer in the barrel of a musket: the lower end of the staff terminates in an iron tube, to which the iron rod is closely fitted, and the tube is made taper on the outside. The point of the dibble, when put down into the tube, projects a very small quantity beyond the end of the tube, and the whole is formed to a regular conical point, proper to pierce the ground. On one side of the staff a tin tube is united to it, and communicates sideways with the interior passage, or bore of the staff, at about six inches from the point. This tube is continued nearly up to the top of the staff, and is within side of the same bore as the aperture through the staff.

The dibble is forced into the ground, to make the hole, by two handles, which project from it crossways, on each side, at the upper end; and on each side of its point, or rather on each side of the iron tube which contains the iron rod, and forms the point of the dibble, are fixed two wings, or leaves of iron, projecting on each side about three inches. The operation of sowing with this implement, is to force the dibble into the ground by its handles, and thus make the hole; then draw up the iron rod, so that its point rises above the place where the tin tube communicates with the interior passage of the staff, and drop the acorn down the tin tube, and it will pass through that communication, and drop into the hole; the rod being pressed in again, carries the acorn down to its place, in the bottom of the hole made by the point of the dibble. In drawing out the dibble from the ground, it must be gently turned round backwards and forwards, by which means the wings, or leaves, projecting sideways from its point, will loosen the surrounding earth, and cover up the acorn.

A great advantage proposed by the inventor of this implement is, that acorns can be planted by it in the middle of any bush, without first removing it. For this purpose, the dibble is to be pressed down into the ground through the bush; then raising up the rod, so that its point will be raised above the point of communication between the interior of the tin tube and the cavity of the staff, an acorn is to be dropped into the tin tube, which will fall down

through the tube into the hole made by the point of the dibble. In drawing up the dibble out of the ground with the motion above-described, the earth will be covered in upon the acorn. Thorns, bushes, and thickets, says Mr. Waitell, are the natural guardians of young oaks from the depredations of cattle of all kinds, in forests and other grounds where they pasture; and by this means, acorns may be deposited in the interior of bushes, as well as in open grounds, with rapidity and accuracy.

SOWING-Plough, that instrument of this kind which is employed for the purpose of sowing, or of forming the land in a proper manner for the seed being put into it, after it has undergone the necessary ploughing. There are many ploughs of this sort in use in different districts of the kingdom, and they are constructed in several different ways in different places, and with very different numbers of shares, or contrivances for forming the little drills, or small furrow-openings in the land, which are to receive the seed. They are made with three, five, seven, and nine of these shares or parts, according to circumstances, and the intentions of sowing which they are to serve. Low iron wheels, in combination with tines or teeth, are sometimes likewise made to answer the purpose of forming the little openings for the feed in these ploughs. And they have many other variations in their structure in other parts. These kinds of sowing-ploughs are now beginning to make their way, somewhat rapidly, in the mouldering chalky-land districts of the country, particularly where the soils are of a light, dry, friable nature. They constitute, in some measure, a plan between the drill and broad-cast methods of sowing, as the seed is sown or scattered over the land by the hand, after it has been furrowed by the plough in a suitable manner. The Berkshire nine-share sowing-plough is said to be used with the most beneficial effects. After the land is properly prepared and rolled, this plough is passed over it, and the grain or other seed sown broad-cast and harrowed in; by which means it comes up, it is observed, with as much regularity as if it had been drilled. It is indeed suggested, that in many soils and situations this sowing-plough might undoubtedly be found preferable to the best drill-machine. See **SOWING**.

The pressing-plough, and probably some others, are of this kind, though they may possess other highly useful properties, in different intentions. See **Pressing-Plough**.

The utility and preference in favour of these sorts of sowing-ploughs, probably, in a great measure, depend upon their being attended with but little labour, trouble, or difficulty in the performance of the business, and their requiring little knowledge in the persons who conduct and manage them. There may also be something on such light soils, in their rendering the land more solid, in putting in some sorts of crops, as those of the wheat kind, &c. See **TREADING and WHEAT**.

SOWING-Roller, that sort of implement of this kind which is constructed for the purpose of sowing different sorts of grain and feeds. Implements of this nature have been lately contrived, and formed in several different modes and manners, in the view of effecting this intention in a more complete and satisfactory manner than has been commonly the case formerly. They are, however, for the most part, still defective in all or some of the ways which have been noticed in speaking of sowing-machines, and to be remedied, most probably, in the ways, and by the means, which have been there suggested and pointed out. See **ROLLER**.

In a sowing-roller which has been lately invented, the heavy expence commonly attendant upon constructing such implements, and their being mostly applicable only to one particular purpose, has induced the inventor to fix and

attach a complete feed-distributing apparatus to the common field-roller, which is capable of feeding, it is said, any given number of little rows or furrows made in the ground by itself, or of sowing the land broad-cast, if that mode should be preferred. This sowing implement, which is wholly formed on the above principles, from its very great powers, the ease with which it may be constructed, being such as that any tolerable good village wheelwright may put together, and the little liability there is of its being out of order, warrant, it is supposed, the assertion, that it is a more effectual sowing tool than any which has yet been offered to the public. It is in this case calculated and constructed on a narrow scale, that is, with a roller of only four feet two inches in length, and twenty-eight inches in diameter; as such a block of wood is easily to be procured in almost any situation, but it may be formed of much larger dimensions.

This sowing-roller consists of a roller-part, the gudgeons of which pierce the shafts of the tool, and after passing through them about two inches, are bent at right angles, so as to form cranks, which, by means of parallel bars of communication, give a rotatory motion to a tin cylinder, which, for the sowing of small seeds, such as those of turnips, rape, cabbage, clover, and others of the same nature, may be about a foot in diameter, but for different sorts of grain larger, and perhaps somewhat differently modified. This tin cylinder is to be shut at each end, by means of a piece of stout board, turned so as to fit exactly, and to be fastened in with very great nicety and firmness. The whole surface of it is to be pierced with small holes, so that when it is furnished with seeds, the revolutions of it may cause them to pass through into the funnel for their distribution. It is also internally divided and separated by several diaphragms of the tin kind, by which the feed is prevented, when the implement is on a declivity, from being thrown all to one end of the cylinder, by the force of its own weight or gravity. Each compartment is provided with a small slider, which moves in a groove internally, by means of which it is supplied with feed when it is wanted. The axis, or axle-tree, is square, from the end or place of its entrance into the cylinder, to that of its exit at the opposite end. Both ends of this axis, as well as those of the gudgeons in the ends of the roller, are turned for cranks; but in order that there may be no possible check given to the motion of the cylinder, the two cranks, that is those of the roller and of the cylinder, on the right side of the implement, are to be set at right angles with the direction of those on the left side of it, so that when the former are vertical, the latter will be horizontal; as is seen to be the case in many pieces and sorts of machinery, as in those of windlasses for pits and wells, hand-mills, and some others, where two persons are employed, one at each end of the power which gives the motion.

There is a strong plank, about two inches in thickness, and two feet at least in depth, which reaches all across the tool; the whole of it that is above the shafts, resting upon them by means of a shoulder at each end. It is supported by a strong iron stay, as it is a part which must be very firm, on account of the whole stress of the shares bearing upon it. All of it that is above the shafts, which need not be more than eight inches, serves as a foot-board, while that part which is under the shafts forms the front part of the feed-funnel. A strong wooden slip or strap, for a support, should be fastened firmly, at its upper end, to the side of the shaft, taking care that it be out of the way of the crank on the axis of the roller. The other end may be fixed as a buttress, at the back of the projecting elbow of the above plank or board, so as to strengthen and enable it to resist the

the pressure occasioned by the action of the shares. The back part of the funnel is formed by a thin deal board, which is secured at its upper part to the shafts. The sides of the funnel are closed under the shafts with moderately thin deal boarding. The funnel, when ready for directing the feed, reaches within four or five inches of the ground; it has no bottom, so that when the implement is in motion, it will, in this state, sow broad-cast with much regularity and exactness. When thus employed, however, instead of having the chain which hangs in loops, at six inches apart, all along the bottom part of the back-board, for the purpose of covering in the feed, and filling up the little furrows made by the shares in the business of drill-sowing, a broad but short harrow is to be fixed to, and appended from, the bottom part of the back-board, which, passing before the roller, covers the broad-cast work, which is immediately afterwards compressed by the roller coming over it, and finished. It must be noticed, that the loops of the chain used in drill-sowing hang in those parts of the back-board that lie over the intervals between the small furrows. This is managed by having a number of tenters, into which a long chain may be looped, as the occasion may require. The shares have each a standard, the latter being long enough to measure the whole depth of the front board or plank noticed above. The foot part of these spreads a little at the heel, so that it may stand open to about two inches and a half at that part; the length of the sole part may be five inches, and the step about three inches, the point and the upper part being sharp. At the back part of each standard are two slit-springs, which serve to keep them tight, when they are put into the groove in the front board or plank. At the top, in the front part, for about eight inches downwards, the standards are furrowed in an horizontal manner, so as to form teeth or cogs, which fit into the grooved bar that passes all across the tool, whereby the several standards, and

the shares that are fixed to them, are capable of being either raised or lowered. This is effected by means of the small winch handle. There are two rows of staples driven through the front board or plank, and rivetted firmly within the funnel. These staples should admit the standards to pass up them from below, when fitting into their places, and should fit them exactly in breadth; but in depth some allowances should be made for the play of the two back springs. The upper row of staples should be just between the shafts, the lower one within four inches of the bottom of the board. Great care should be taken to place those in the upper row perfectly in a line with those below; and both lines should be in a correct parallel with the grooved bar, otherwise they never will work up and down so freely, or in so proper a manner, as they ought to do. The standards should be about half an inch in breadth and nearly an inch in depth, from front to back, exclusive of the slit-springs, which are not to be rivetted, but welded on, that they may not weaken the standards, which must also be perfectly smooth and straight. The number of the staples in each row is seventeen; but as it is supposed that six inches will be as small an interval as will ever be wanted in this method of sowing by means of drills, no more than nine shares can ever be required for the purpose.

The tabular form and representation which is introduced below will give a clear view of the manner in which the shares should be distributed in the seventeen sets of staples, which are calculated for sowing any number of rows in this implement; considering always that the tool, in returning, must pass more or less distantly from its preceding track, according as the vacancies on the right of the row of shares may indicate: thus, for instance, when sowing at a foot interval, as both ends of the line will bear shares, a foot distance should be allowed, as is exemplified in the third column below.

Sowing-Distance Table.

Staples.	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	In return- ing leave a space of
Intervals of six inches.	+		+		+		+		+		+		+		+		+	Six inches.
Nine inches.	+			+			+			+			+			+		Six inches.
Twelve inches.	+				+				+				+				+	Twelve inches.
Fifteen inches.	+					+					+					+		Nine inches.
Eighteen inches.	+						+						+					Three inches.
Twenty-one inches.	+							+							+			Twelve inches.
Twenty-four inches.	+								+								+	Twenty-four inches.

It is to be noticed, that the crosses in the above table shew in which of the staples the shares should be set, in order to sow at the distances expressed in the first column of it; all

the other shares may be drawn up, or wholly taken out and removed.

The staples are counted from the left of the implement; calling

calling that which is nearest to the winch of the cylinder of it the first. The driver is also considered as beginning on the left of the field, and making up the broken parts, on the right of the numbers, &c. by preserving about the distances specified in the right-hand column of the table, taking the mark of the roller for his guide. In broad-cast work he must return close to his former track.

It remains now to be shewn how, or in what manner, the grain is brought into the little furrows made by the shares; for this purpose, the funnel is divided into sixteen compartments; and for the very same reason, to make the seed fall equally through the bottom, when the implement may be working on a declivity. But all the partitions are made to slide out, they being formed in battened grooves. This is for the purpose of introducing the *drill bottoms*, as they are called; one of which is for nine rows, and another for three. Each of them, it is said, is nothing more than a wedge-like block, which being let down into the bottom of the funnel, fits exactly at the edges; and by means of holes of a conical form, which are scooped out in it, and corresponding small tin spouts below to direct what seed they respectively receive, in a forward manner, shooting it, as it were, under the hollow heel of the share, distribute the seed into the number of furrows which are made for receiving it.

The middle hole or scoop only, however, is of equal extent to the right and left of the tin spout; the other two scoops are necessarily of a something shelving or slanting form; it being indispensable to allot to each spout an equal surface on the block; and to shelve the scooping to the spot where its spout is fixed.

The drill bottoms may thus be changed at pleasure; the partitions will keep them duly in their places. But although there are sixteen compartments in the funnel, no more partitions are to be used than may be necessary to correspond with the number of scoops and spouts in the drill bottom. It is to be remembered, that, as there will be seed falling from the whole length of the cylinder into the funnel, and that as there will be occasionally a portion of the drill bottom parted off, which has no spout, such compartment should when necessary be emptied, and the seed be put into those divisions only of the cylinder which are over the spouts.

The two shafts of the tool are connected firmly together by a strong thwart or tie, and which, when the other parts are united with it, render the whole completely substantial. Under the hinder end or part of the shafts, a scraper is carried quite across, and is bolted in with the cross piece, which has an iron edge, and serves to divert the roller of the adhesive foil that would otherwise accumulate about it. The upper and under edges in the back part of the thwart are completely rounded off, so as to be semicircular. This thwart should be inserted as close as possible to the back of the cylinder; because its purpose is to aid a sheep-skin wrapper in lapping round under it, thus keeping the seed in, when the cylinder should not sow. The wrapper extends the whole way across, and should be about two feet deep; each edge, that is of the top and bottom, but not of the sides, should be affixed to a lath, in order to make it draw backward and forward in a straight line. The place should be cut to about half an inch in length, by which means it will, when passed under the cylinder with the wool side upwards, repel the seeds when they attempt to pass through the perforations. This wrapper should always be passed under, while the implement is turning at the ends of the lands; but at other times it draws over the cylinder, the flesh side uppermost, and serves to keep out wind and rain. There are two little pullies affixed into the shafts, close

under the fore-board, which serve to pass cords over, so that by the aid of the rounded back of the thwart, the wrapper may glide easily, either over or under. When brought round under the cylinder, its front lath hitches to two hooks, under the half foot-board, in order to prevent its receding, and to keep it tight to the cylinder. It may be noticed, that it is of more importance to keep the wrapper tighter to the front than to the back part of the cylinder; because the revolution of the latter being against that of the fun, the same as that of the roller's when viewed from the left side, it is obvious, it is said, the grain will cast forward, and have a tendency to relinquish the hinder part of the cylinder, as it rises in that part. It is likewise suggested, that although the axis of the cylinder in this implement is made to pass through the shafts, it would ride on them to more advantage, and render it far easier to shift the drill bottoms and the partitions in the funnel. Indeed, it is thought, that the former might be made to fit in by a flap, made to open at the bottom of the back-board.

There is a small stiff bolt affixed to a cross-piece, for the purpose of sliding into the grooves of the bar near the cylinder, so as to keep it fixed, and prevent its turning either way, when pressed by the action of the shares. In setting the shares to any desired depth, by turning the winch, the bolt must be drawn back, otherwise the grooved bar cannot turn; but as soon as it is put to the proper depth, the bolt is to be pushed in again to its opposite groove.

The ends of the cranks on the axis of the roller are split like spring keys, and have a catch, over which the hind end of the parallel iron slides, and is kept in its place. This is more clearly evident in the terminations of the same cranks. When the cylinder of the implement is not to turn, as in passing from one place to another, &c. the springs are to be pinched together, and the parallel iron to be drawn off; which is then to be hitched up to a hook at the side of the driver's seat, which seat is supported by the standards which are let into the shafts. The ends of the cranks might, it is supposed, be perforated and keyed, but these modes would not be so good as the plan which is here adopted.

It will be readily remarked, that by far the greater part of the machinery in this sowing-roller relates to the drill practice of putting in the seed; as when it is made only to broad-cast, nothing but the cylinder and two thin boards, forming a directing funnel, will be necessary. It is also suggested, that the great strength of the fore-board, already noticed, would likewise be unnecessary, as there would be no shares, no staples, nor grooved bar; and that there would not be any occasion for a drill bottom, though an immense saving of seed, and great facility of hoeing the young crops, would arise, it is asserted, from adopting such a mode of committing the seed to the soil. The tin spouts, in such case, it is supposed, should rather point backwards than forwards; for, if unprotected by preceding shares, they might be liable to injury from clods, &c.; their diameter ought to be, it is said, about an inch for white corn, but that for small seeds half an inch might answer better and in a more perfect manner. The harrow, prepared with a sufficient number of sharp tines, suited in length to the kind of seed, would cover it sufficiently; and the roller would finish the work in a complete manner. Thus, if corn were sown at nine inches or a foot asunder, it would, it is contended, be so little disturbed by the harrow, as to come up in rather broad lines, but with interval enough for the free action of a six-inch hoe. It is farther also to be well noticed, that, as the roller and the cylinder each revolve in the same period of time, that the larger the cylinder, the more seed will be sown; unless a small one be more pierced, that

that is, have more holes in it, in proportion as it is smaller than the roller. In the proportions which have been made use of in the above instance, the roller being twenty-eight inches in diameter, its circumference will be more than seven feet, whereas the cylinder is but one foot in diameter, therefore little more than a yard in circumference. Consequently, as the roller will pass over full seven feet of ground, while the cylinder presents only three feet of revolving surface, the latter must be so much pierced as to allow the seed to fall *very freely*, otherwise the ground will be but thinly sown, and the business, of course, imperfectly performed.

The one-foot cylinder has been already considered, and suggested as being the most applicable to small seeds, and which the considerations just stated seem more fully to confirm. They likewise seem to strengthen the suggestion, that, for white corn, peas, and other similar sorts of articles, the cylinder would be more suitable, if it were enlarged, according to the number of pecks or other measures required to sow an acre. It is a necessary caution that, in sowing with this implement, the cylinder be never filled too full; it ought indeed, in no case, to be more than three-fifths filled, and, if only filled up to the axis of it, so much the better. While the seed is putting in, which should be done by means of a short, broad, tin funnel, the wrapper should be passed under the cylinder to keep it in, as seen in describing the tool.

It is suggested further too, that, by previously setting the centre shares of the implement rather higher than those towards the sides, which may be easily done by taking out the grooved bar, by unkeying the strap by which it is held down into the box near the winch, it may be made to sow on narrow ridges, which is very necessary and desirable in different situations, but it will then require that a suitable roller should be used; or by setting the middle shares deep, pulling off those towards the sides, the implement might be made to work with a common furrow-roller. In either case the points and tops of the shares should, it is said, form a curve corresponding with the shape of the roller, but more especially where the ridges are very narrow, and much raised in the crown.

It is obvious, the inventor says, that the whole of the above sowing apparatus is capable of being attached to any common well made *field-roller* which is of a good size in the barrel, and fitted into a proper frame, with a seat, and other necessaries; and that every part of the broad-cast machinery may be connected with it at very little expence. These are very important considerations in such sorts of tools; but, besides, the roller will still be a roller, and useful as such; while the sowing part, being only necessary when that operation is to take place, may at other times either be left at rest, or be altogether removed.

It is stated in conclusion, that by means of this sowing-roller, the work of sowing, harrowing, and rolling may go on all at one time, and that, by a change of horses once in the day, a field of ten acres may be easily sown and finished in that time. That in hot dry seasons, when farmers are under the necessity of catching and taking the advantage of smart showers, for the sowing of their turnip seed in particular, a tool that is capable of effecting so much cannot but be highly useful. The land will not only be better and more expeditiously sown, but be left in a more suitable state for preventing the effects of the weather. It will probably too not be much less beneficial for the purposes and intentions of sowing in other cases.

The great power, together with the ready and extensive application of the roller, hold out to the agricultural mechanic, means which ought not to be overlooked in the con-

struction of tools and machinery of this nature, as they afford prodigious facility in forming and giving them motion.

SOWINS, or SOWINGS, in the manufacture of linen-cloth, are used in a rather coarse and pretty thick but not over thick state, by weavers, in dressing and preparing their yarn of this kind for the loom, or being woven into cloth. It takes away, combines, and hardens the loose parts of the threads or *sleepings*, as they are called, and gives a sort of body to the whole divided parts of the yarn before the operation of weaving begins to be performed, and consequently greatly facilitates the work. In this process or practice the best flour is likewise sometimes employed in the same way, as going farther and answering better, especially for fine cloths.

SOWLEE, in *Geography*, a town of Bengal; 17 miles E. of Boglipoor.

SOWNE, a term used in the exchequer; seeming to be a corruption from the French *souvenu*, *remembered*.

Such estreats and casualties as the sheriff by his industry cannot get or levy, are said to be estreats that *sowne* not, that is, are not to be remembered, or are not in demand. On the contrary, estreats that *sowne*, are such as he may gather.

SOWRAY, in *Geography*, a town of Hindoostan, in the circle of Chanderee; 40 miles S.E. of Chanderee.

SOWREE, a town of Hindoostan, in Bengal; 15 miles N.E. of Jellalore.

SOXALÆ, or CAMELOBOSCI, in *Ancient Geography*, a people of Germany, who inhabited the vicinity of the deserts. Ptolemy.

SOXINI, or SOCCINI, MARIANO, in *Biography*, denominated the elder, an eminent canonist, was born at Siena in 1401. He studied first at his native place, and then in Padua, in which last university, after he had taken his degree, he was for some years professor of the canon law. He then returned to Siena, where he taught as a professor during the remainder of his life. He was very intimate with Eneas Sylvius, afterwards pope Pius II., who has written a panegyric upon him in one of his letters in the most magnificent terms, assigning to him almost universal proficiency in science and the arts, with the greatest excellence of moral character. Soxini was sent by the state to compliment Sylvius when he ascended the papal throne, on which occasion he was nominated consistorial advocate. He died in 1467, leaving behind him a considerable reputation for learning and integrity. His works, consisting of "Consultations," "Commentaries on the Books of Canon Law," and tracts upon "Legal Subjects," have been frequently reprinted.

SOXINI, or SOCCINI, BARTOLOMEO, a celebrated civilian, son of the preceding, was born at Siena in 1436. He studied the law under different masters at Siena and Bologna, and after he had been admitted to a doctor's degree he became professor of the civil and canon law in his native city. He was, in 1473, invited to Pisa, where he taught both branches of law, and in this city he resided twenty years, with some occasional absences. He took an active part in the civil dissensions of Siena, and was, at one time, in the list of the banished citizens. He was employed in embassies from the Siense to the Florentines, and it is said he engaged in a military attempt to change the constitution of Siena. At Pisa the famous Jason del Maino was his rival, and they held frequent public disputations, at one of which Lorenzo de Medici was an auditor. Jason being hard pressed by the arguments of his antagonist, quoted, in his own favour, a text which he had invented for the occasion. Soxini, with equal readiness, in-

vented another to oppose it, and being asked by Jason where he had found it, "Next to that which you have just now quoted," he replied. The fame which he had acquired caused him to be invited to Padua in 1489, with the offer of a large salary, which he determined to accept, but his intentions being known he was detained. For some time he was professor at Padua. He died in 1507, having been three years deprived of the use of his speech. His works as an author were "Consultations," "Comments on the Code and Digest," the "Rule of Right," and other pieces of a similar kind. He was not estimable as a practical moralist. He was addicted to gambling, and would sometimes leave his scholars without a lesson, and pass whole nights at the gaming table, the consequence of which most destructive habit was, that he did not leave money enough behind him to pay the expences of his funeral. He was extremely greedy of money, charged very high for his opinion, which he would sometimes give to both parties in a suit. He was free of speech, sarcastic and jocular. His faults were borne with on account of his high professional character. Angelo Politiano, speaking of his intended correction of the Pandects, says, "I must have recourse to the assistance and advice of that singularly excellent doctor of Siena, Bartolomeo Soxini, whom I may boldly denominate the Papinian of our age."

SOXINI, MARIANO, denominated the younger, grandson of the first Mariano, was born at Siena in 1482: he studied the law under his uncle Bartolomeo, and after taking his degree, taught alternately the civil and canon law at his native city, till he removed to Paris in 1517. Returning to Siena in 1524, he was employed as ambassador to the republic of Florence, and also to pope Leo X. He was engaged in the following year by the republic of Venice, to occupy a professorship at Padua. He remained at that university till the year 1542, when the offer of a higher salary drew him to Bologna. Here he continued till his death, though he received the most flattering invitations, with the promise of large salaries, from Cosmo, duke of Florence, the king of Portugal, and other princes and states. He died in 1556, and his German scholars in Bologna shewed their respect for his virtues and talents, by carrying his body on their own shoulders to the tomb. He was author of many works, which were once in considerable estimation, though they are now forgotten.

SOXINI, LELIO, son of the preceding, was born at Siena in the year 1525. He was destined by his father for the legal profession, but having in the course of his studies attended to scriptural truths, he felt reason to question the validity of the doctrines of the Catholic church. For the purpose of farther enquiry, he made himself acquainted with the languages in which the Old and New Testament were written, also with the Arabic and other oriental languages. About the year 1546 he joined himself to a society attached to the principles of reformation in religion, and the members of which speculated very freely on the mysteries contained in the doctrines of the Trinity, and the atonement. Their objects being discovered, some were apprehended, and others gladly fled from the iron arm of persecution. Two of those who fell into the hands of the priests suffered death as heretics, and those who remained concealed themselves, or withdrew into foreign countries. The subject of this article quitted Italy in 1547, and travelled during the four following years into France, England, Germany, and Poland. He then fixed at Zurich, where he maintained a correspondence with the reformers in various parts of Europe, by whom he was held in high esteem, till he shewed a leaning to the doctrines of Arianism. Calvin, who was ever

eager in detecting heresy, wrote him a letter of admonition, which was followed by a still stronger warning, the burning of Servetus, and which was sufficient to deter Lelio from taking a very active part in propagating the doctrines to which he adhered. On the death of his father, in 1556, he obtained letters of legation from the king of Poland to Venice and Florence, which enabled him to settle the affairs of his inheritance. He died in 1562. He was mild and gentle in disposition, averse from all controversy, and was evidently led by conscience to differ from those with whom he lived. Some writings have been attributed to him, but critics are very doubtful as to what he really wrote. Bayle.

SOYDE, in *Geography*, a town of Norway; 36 miles N. of Stavanger.

SOYDPOUR, a town of Bengal; 25 miles S.W. of Silhet.

SOYLAND, a township of the parish of Halifax, Yorkshire. See HALIFAX.

SOYOLLA, the principal island of a cluster in the Red sea. N. lat. 14° 2'. E. long. 59° 38'.

SOYON, a town of France, in the department of the Drôme, on the Rhone; 6 miles S. of Valence.

SOZ, a river of Russia, which runs into the Dnieper, 16 miles S. of Bilitzi, in the government of Mogilev.

SOZO, in *Ancient Geography*, a town of Asia, in the interior of Media. Ptolemy.

SOZOMEN, HERMIAS, in *Biography*, an ecclesiastical historian, contemporary with *Socrates* (see his article), was born of respectable parents, as some say at Salamis, in the isle of Cyprus, but according to others, at Gaza or Bethelia, in Palestine. Having studied the law at Berytus, he practised as an advocate at Constantinople, devoting his leisure hours to the composition of his ecclesiastical history. This work contains, in nine books, an account of the affairs of the church, from the third consulship of Crispus and Constantine, Cæsars, to the 17th consulship of Theodosius the emperor, in whose time he wrote, and to whom he dedicated his performance; that is, from the year 324 to the year 439, or during a period of 115 years. Cave represents him as flourishing about the year 440. In his history, which is written in a more florid and elegant style, but with less judgment, than that of *Socrates*, he has introduced many eulogiums of a monastic life, to which he was attached in consequence of his education among monks, and he has added many narrations of the actions and manners of the recluses, and his testimony to the early practice of public penance in the Roman church, together with a detail of the particular ceremonies of which it consisted. To the orthodox, however, he has given offence by his commendations of Theodore of Mopsuestia, with whom originated the heresy of two persons in Christ. His history is chargeable with several notorious errors in the relation of facts. He is supposed to have died about the year 450. Sozomen's history is printed with that of *Socrates*, and the other Greek ecclesiastical historians. A work of Sozomen, not now extant, containing, in two books, a summary account of the affairs of the church, from the ascension of Christ to the defeat of Licinius, was written before his history. In moderation and candour Sozomen resembled *Socrates*; and it is true of the former, as well as the latter, that he always speaks with great respect of the sacred scriptures. Dupin. Lardner.

SPA, or SPAW, in *Geography*, a town of France, in the department of the Ourte, belonging to the bishopric of Liege, in Germany, and situated in the marquisate of Franchimont, on a small river which runs into the Ourte. It was formerly a small village, but since the discovery of

its mineral waters, about the year 1326, and the celebrity which they have acquired, it has been considerably enlarged; and now consists of two streets, joined by a bridge over the stream that runs through it, together with several smaller streets and rows of houses; those of more ancient date being irregularly arranged, and constructed of wood and plaster, and the more modern built with brick and stone. The soil about the town is rocky, gravelly, or loamy, intermixed more or less with iron ore. The country about it abounds with hills and woods, so that it is not fertile in grain, but it has plenty of sheep, kine, and poultry, and great quantities of game, and the streams furnish an ample supply of various kinds of fish. During the season in which the waters are used, the town resembles a fair in its variety of booths, toys, &c. Its vicinity affords pleasant and salubrious rides, and many agreeable and romantic walks: and its visitors are gratified with evening amusements in public rooms adapted for this purpose. Some have supposed that the medicinal waters of this place are those that are mentioned by Pliny in his "Natural History," but others apprehend that those were the waters of Tongrés. These waters were at first the property of the community of Spa, but they were afterwards taken possession of by a bishop of Liege, until an appeal was made to the imperial chamber, which restored them to the original proprietors, who impose a small duty on every flask exported under their seal. In the year 1794, Spa was taken by the French; 16 miles S.E. of Liege. N. lat. 50° 31'. E. long. 5° 30'. The waters are furnished by various springs. Those of the Pouhon spring have been preferred, by our chief physicians, to any others in or near the country of Liege; particularly to the waters of Bru, which they complain have been imposed on the public, to their and their patients' frequent disappointment.

However, as the Spa waters are impregnated with different proportions of the same ingredients, they may be chosen differently, according to the intentions with a view to which they are used. The Pouhon is the strongest chalybeate. This is in its most perfect and natural state in cold dry weather; but in warm moist weather it loses its transparency, appears turbid or wheyish, contains less fixed air, or carbonic acid gas (see *CARBONIC Acid*), and is partly decomposed. This water, which is colder by many degrees than the heat of the atmosphere, is supposed to contain the greatest quantity of fixed air of almost any acidulous water; and in consequence of this ingredient, it has a remarkable sprightliness and viscosity, and boils by mere warmth; but this soon flies off if the water be left exposed, though it may, in a great measure, be preserved in well-corked bottles. It is capable of dissolving more iron than it naturally contains, and of thus becoming a stronger chalybeate, on account of the great quantity of fixed air which it contains: and for the same reason an ebullition is raised in it on the addition of acids, which disengage its fixed air. This water mixes smoothly with milk, whether it be cold or of a boiling heat.

The Tonnelet and Geronsterre waters are weaker chalybeates, but brisker and more spirituous. The Groesbeck, Sauveniere, and Wartroz, are still weaker chalybeates, but highly impregnated with calcareous and selenitical earths, and contain also a greater proportion of the fossile alkali. The Geromont is likewise a weak chalybeate, but contains a great deal of calcareous and selenitical earths, and about three times as much alkaline salt as any of the others. The four last waters, therefore, will be better in disorders arising from an acid cause, and as diuretics, particularly the Geromont. The Bru, or Churon water, approaches to the nature of

the Tonnelet, and though it has been decried, is said, in consequence of every trial, not to be inferior to any of the Spa waters.

All the waters that are comprehended under this denomination, abound with fixed air; they also contain more or less iron, fossile alkali, and calcareous and selenitical earths, together with a small portion of sea-salt, and an oily matter common to all waters. All these ingredients are kept suspended, and in a neutral state, by means of the fixed air, on which the virtues chiefly depend; though they are probably rendered more active and penetrating, both in the first passages, and also when they enter the circulation, by means of that small portion of iron, earth, salt, &c. with which they are impregnated.

These waters are diuretic and sometimes purgative; and, like other chalybeate waters, they tinge the stools black. They exhilarate the spirits much better than wine or spirituous liquors, and their general operation is by strengthening the fibres. They cool and quench thirst much better than common water.

They are found excellent in cases of universal languor or weakness, proceeding from a relaxation of the stomach, and of the fibres in general, and where the constitution has been weakened by diseases, or by a too sedentary life; in weak, relaxed, gross habits; in nervous disorders; at the close of fits of the gout and rheumatism; in such asthmatic disorders and chronic coughs as proceed from too great a relaxation of the pulmonary vessels; in obstructions of the liver and spleen; in scorbutic and other putrid disorders; in hysterical and hypochondriacal complaints; in paralytic disorders; in gleets; in the fluor albus; in fluxes of the belly; in the gravel and stone; in female obstructions; in barrenness; and in most other cases where a strengthening and brisk stimulating resolving chalybeate remedy is wanted: but they are generally hurtful in hot, bilious, and plethoric constitutions, when used before the body is cooled by proper evacuations; they are also hurtful in cases of fever and heat, in hectic fevers, and ulcerations of the lungs, and of other internal parts, and in most confirmed obstructions attended with fever. The usual season for drinking them is in July and August, or from May to September. The quantity to be drank is such as the stomach can bear without heaviness or uneasiness; but it is advisable to begin with drinking a glass or two several times in a day, and so increase the quantity daily, as the stomach can bear; and during the course to continue that dose, and to diminish the quantity at the close in the same degree as it was augmented at the beginning. Moderate exercise is proper after drinking. Previous to the use of the water, the first passages should be cleaned by gentle purges, and, if necessary, an emetic should be given; and during the course, costiveness should be prevented, by occasionally adding Rochelle salts or rhubarb to the first glasses of water in the morning; and a cooling regimen should be observed.

The Spa water is also used externally, in a variety of cases, with good success. It is used as an injection in the fluor albus, and in ulcers and cancers of the womb, and also in the gonorrhœa; it is serviceable for washing venereal aphthæ, and ulcers in the mouth, phagædenic ulcers, by way of gargle for relaxed tonsils, and for fastening loose teeth, and in other cases of relaxation. It is also said to cure the itch, and similar complaints, by washing and bathing, an internal course being observed at the same time. Elliott's *Mineral Waters*, p. 201, &c.

The town of Spa being resorted to by persons from all parts of Europe, on account of its waters, has always been allowed a neutrality during the hottest wars.

SPAAD, or **SPALT**, *Spatum*, a word used in several different senses; sometimes for a species of English fibrous talc, or of gypsum; and sometimes for spar.

The various kinds of spaad are found pretty frequently in England and Germany, and sometimes brought from the Levant: they are all soft, and easily pulverized.

SPACE, **SPATIUM**, a simple idea, the modes of which are distance, capacity, extension, duration, &c.

Space, considered barely in length between any two bodies, suggests the same idea which we have of distance.

If it be considered in length, breadth, and thickness, it is properly called *capacity*.

When considered between the extremities of matter, which fills the capacity of space with something solid, tangible, and moveable, it is then called *extension*.

So that extension is an idea belonging to body only; but space, it is plain, may be considered without it.

Space, therefore, in the general signification, is the same thing with distance considered every way, whether there be any solid matter in it or not.

Each different distance is a different modification of space; and each idea of any different space is a simple mode of this idea. Such are an inch, foot, yard, &c. which are the ideas of certain stated lengths, which men settle in their minds for the use, and by the custom of measuring. When these ideas are made familiar to men's thoughts, they can in their minds repeat them as often as they will, without joining to them the idea of body, and frame to themselves the ideas of feet, yards, and fathoms, beyond the utmost bounds of all bodies; and by adding these still to one another, they can enlarge their idea of space as much as they please.

From this power of repeating any idea of distance, without being ever able to come to an end, we acquire the idea of immensity.

Another mode, or modification, of space, is taken from the relation of the parts of the termination of extension, or circumscribed space, amongst themselves; and this is what we call *figure*. This the touch discovers in sensible bodies, whose extremities come within our reach; and the eye takes, both from bodies and colours whose boundaries are within its view; where, observing how the extremities terminate, either in straight lines, which meet at discernible angles, or in crooked lines, in which no angles can be perceived; by considering these as they relate to one another, in all parts of the extremities of any body or space, it acquires the idea we call figure, which affords to the mind infinite variety.

Another mode belonging to this head is that of *place*; which see.

Another mode of space is the idea which we get from the fleeting, and perpetually perishing, parts of succession, which we call *duration*.

Space is usually divided into *absolute* and *relative*.

SPACE, *Absolute*, is that considered in its own nature, without regard to any thing external, which always remains the same, and is infinite and immoveable.

SPACE, *Relative*, is that moveable dimension or measure of the former, which our senses define by its positions to bodies within it; and this the vulgar use for immoveable space.

Relative space, in magnitude and figure, is always the same with *absolute*; but it is not necessary it should be so numerically: as if you suppose a ship to be, indeed, in absolute rest, then the places of all things within her will be the same absolutely and relatively, and nothing will change its place; but suppose the ship under sail, or in motion, and

she will continually pass through new parts of absolute space: but all things on board, considered relatively, in respect to the ship, may be, notwithstanding, in the same places, or have the same situation and position, in regard to one another.

The Cartesians, who make extension the essence of matter, assert, that the space any body takes up, is the same thing with the body itself; and that there is no such thing as mere space, void of all matter, in the universe; but this see disproved under **VACUUM**.

The Cartesians, who do not allow of any distinction between space and matter, were naturally enough led to the opinion, that space or extension was a substance. Others, who admit a vacuum, and consequently an essential difference between space and matter, assert also that space is a substance. Among these we find s'Gravesande, *Introd. ad Philos. sect. 19*.

Others put space into the same class of beings as time and number; that is, they make it to be no more than a notion of the mind. Hence, according to these authors, absolute space, of which the Newtonians speak, is a mere chimera. See the writings of the late bishop of Cloyne, *passim*.

Space and time, according to Dr. Clarke, are attributes of the Deity, and the impossibility of annihilating these, even in idea, is the same with the necessary existence of the Deity. See Watt's *Phil. Ess. Ess. i*.

SPACE, in *Geometry*, denotes the area of any figure; or that which fills the interval or distance between the lines that terminate it.

The *parabolic* space is that included in the whole parabola.

The *conchoidal* space, or the *cissoidal* space, are what are included within the cavities of the conchoid and cissoid. By the new methods now introduced, of applying algebra to geometry, it is demonstrated, that the conchoidal and cissoidal spaces, though infinitely extended, are yet finite magnitudes.

SPACE, *Cycloidal*. See **CYCLOIDAL**.

SPACE, *Elliptic*. See **ELLIPTIC**.

SPACE, in *Mechanics*, the line a moveable body, considered as a point, is conceived to describe by its motion.

SPADA, **LIONELLO**, in *Biography*, was born at Bologna in 1576, in a very low condition of life; and when a boy he became the servant of the Caracci, and ground and prepared their colours. The constant opportunity he possessed, whilst with these great men, of seeing pictures, and hearing discussions on the principles of the art, roused a latent disposition to study and design, which his masters saw and encouraged; and at length they admitted him into their academy, where they had the gratification of seeing him become one of their most eminent disciples; though he never arrived at any very great degree of grandeur or purity of invention. His style is a compound of the Caracci and Caravaggio's manners, and is wrought with great boldness. His principal productions are, The Miraculous Draught of Fishes, in the refectory of S. Procolo at Bologna, and St. Dominic burning the forbidden Books, for the church of that saint, in the same city. This last is considered as his very greatest work. The latter part of his life was passed at Parma, in the service of the duke Ranuccio. He died in the 46th year of his age, in 1622.

SPADA, in *Geography*, a cape of the island of Candia; 24 miles N.W. of Canea.

SPADE, in *Agriculture* and *Gardening*, a well-known sort of tool, employed in digging the land. There are several forms and kinds of them in use for different purposes, as those of common digging, draining, and making of earth fences,

fences and embankments of different sorts, as well as many others, in the former of these arts. The most handy and convenient form of them, for common work, is probably that in which they are made strong in the back, and have a slight bend or curve in the handle or shaft, as by means of this the labour is performed with greater ease and facility. Various forms, shapes, and sizes of spades are had recourse to in performing the operations of draining, mound-fencing, and embanking, according to circumstances; as well as in particular works of other kinds. See SPADE, *Draining*.

The spade is also an useful garden implement, which is used for digging and preparing the soil for the reception of all sorts of seeds and plants. There are several sorts and sizes of spades occasionally employed in this art, though the common large digging spade is, in most places, almost commonly used for all kinds of digging and spade-work, which, however, in many instances, cannot be so conveniently used as a middling or small spade; it is, therefore, eligible for every garden to be furnished at least with three different sizes of spades, to suit every department of gardening the more commodiously; such as the common large digging spade, for all common digging and spade-work; a middling and a small spade, for digging particular narrow compartments, and between small plants closely placed in beds and borders, &c.

The first sort is usually from fourteen to fifteen inches long in the plate, and nine broad, narrowing gradually half an inch or an inch less at the bottom. The second sort should be about a foot long in the plate, and seven or eight inches broad. The small spade, which is about eight or nine inches long in the plate, and five wide, is convenient in pointing up or slight digging, and in fresh loosening the surface between close-placed small plants, in beds and borders, &c. where neither of the two former spades can be readily introduced: it is also useful in planting and potting many sorts of small plants, taking up small roots, and other light purposes.

And other sorts are likewise in use for different purposes, as a very small narrow spade, having the plate about seven inches long, by three and a half or four wide, which is very useful in small compartments of beds, borders, &c. containing some particular close-placed, small plants of flowers, and others, both in occasionally slightly digging, or loosening the earth between them with greater ease and effect, than a larger sized spade; also sometimes in similar compartments, in occasionally trimming round the bottom part of some straggling fibrous-rooted plants; and it is also often useful in taking up and transplanting small plants, and taking off root offsets and slips, in particular sorts, in which a larger spade would not be so convenient. And further, a semi-circular or scooped spade is another sort of a smallish size, having the plate made hollow, like a scooped garden-trowel, which is very useful in taking up small plants with balls of earth, to preserve the ball more firmly about the roots.

Proper garden-spades have the plates wholly of iron, not above a quarter of an inch thick upward, growing gradually thinner from the middle downward; the tree, or handle, being generally of ash, about two feet long, and an inch and half thick, with a firm open handle at top, formed out of the solid wood, just big enough to admit of taking ready hold.

SPADE, *Draining*, that sort which is employed for the purpose of cutting out field drains. Spades for this use are made of different breadths, so as to follow each other, and

cut the drains narrow at the bottoms. There are usually a top or upper, middle, and pointed bottom spade made use of in this work.

And there is a sort of spade or shovel, which is turned up on the sides, that is useful in taking out the small pieces of earth from the bottoms of the drains. Likewise a spade or tool of the scoop kind.

Also a wooden spade, employed in soft peaty soils, where the common draining-spades cannot be used. See SPRING and SURFACE-*Draining*.

SPADE, *Paring*, that sort of spade which is made use of in removing the sward from grass-land. See PARING Spade, and SHOVEL.

SPADE, *Turfing*. See TURFING.

SPADE also denotes any gelded beast, or a deer three years old.

SPADE-*Bit*, the quantity of earth raised by the spade in one effort. Hence probably *spit*. It also signifies the broad iron part of the spade.

SPADE-*Bone*, a term provincially applied to the shoulder-bone, probably from its being used formerly as a spade.

SPADE *Land, To*, provincially to pare ground, or break-plough it.

SPADICEOUS, or SPATHACEOUS *Plants*, in *Gardening*, those the flowers of which are protruded or produced from a sort of scabbard, or sheath, which is burst open. There is a great number of flower, as well as other garden-plants, which are of this sort, as of the former, the narcissus or daffodil and jonquil, the lily daffodil, the Guernsey lily, the aphodol lily, the sea daffodil, the different varieties of crocus, the meadow saffron, the common snow-drop, the leucium, or greater snow-drop, and many others; and of the latter, the onion, the leek, the garlick, and some others.

These are, for the most part, useful and valuable plants in either the common or flower-garden.

SPADING, in *Agriculture*, a term applied, in some districts, to the practice of taking off the sward or surface of grass-land by means of the paring-spade, in the view of burning it. It is a method which is by no means unusual in many districts, though the paring-plough mode is by far the most cheap and convenient. In the county of Devon, when the spading of the surface of a field or portion of land is determined upon in this intention, it is pared off, in a clean manner, to the extent of from three-fourths to one inch in thickness; the slices of which are then set up edgeways, and when dry, collected into heaps, or what are provincially termed beat-barrows; and by the assistance of furze, fern, heather, hedge-row, and copse faggots, or some other similar material, the whole pared substance set fire to and reduced to a mass of ashes, which, when cool, are spread, either with or without being mixed with other matters, such as lime, good mould, or the scrapings of roads, as the circumstances of the cases may require, over the land in an equal and exact manner. In this way coarse grass-lands are sometimes brought into a state of cultivation, and wheat, as well perhaps as some other crops, in different instances, well prepared for and got into the ground. See PARING and BURNING, and SOD-*Burning*.

It is, however, a tedious and laborious method of cultivating and preparing land, which can probably be only practised in particular situations and circumstances.

The paring-plough, which is designed to be introduced in the place of the tool employed in this sort of work, and which is much superior in the facility, expedition, and manner in which it performs it, has a wide-winged flat share, that measures about fourteen inches from the land-side to the

the angular point of its right side, or cutting wing. In the beam part of this implement, and preceding a sharp comb, which is welded on to the coulter-margin of the share, is a sliding-foot, fixed in such a manner as to regulate the exact thickness of the slice which is meant to be pared off, with great precision. And the share and comb of the tool being kept very sharp by frequent grinding, enable it to perform the paring of the grassy, or other surface, in a very perfect manner. This implement is held in an horizontal manner when at work, so as to cut a smooth and even furrow at the bottom part; whereas the tool usually made use of is held in an oblique direction, so as to cut the spine or green sward to a feather-edge on the furrow side, the whole of which is to be gradually lifted up, and turned, with its green side, perfectly underneath. The work is performed, in these cases, by what is commonly called splitting or dividing. See SPLITTING.

SPADIX, in *Botany* and *Vegetable Physiology*, a flower-stalk, whether simple or branched, included within a *Spatha*, or Sheath. Such occurs in the natural order of *Palme*, which tribe Linnæus principally had in view in the technical use of this term. Indeed the word, which is Greek, $\sigma\pi\alpha\delta\iota\zeta$, *palme* to the Latins, is almost exclusively applied by the ancients to the very same thing, the branched fruit-stalk of the date-palm. Linnæus, however, extends it to the *Arum* family, by a very fair analogy, though in that tribe it is unbranched; and by a further stretch of analogy, to *Acorus*. In some of the *Liliaceæ*, composing his *Spathaceæ*, though he uses the term *Spatha*, he does not employ that of *Spadix*. Jussieu and his followers have perhaps done well in excluding the *Spatha* itself from making a part of the generic character, in the natural family last-mentioned, though they retain it, as well as *Spadix*, in the *Palme*. The *Spadix*, like other flower-stalks, is solely destined to bear the flowers and fruit, and when the latter is perfected, the part in question withers and falls off. See FRUCTIFICATION, CALYX, PALMÆ, and SPATHA.

SPADO, among the Romans, differed from an eunuch only in this, that the latter was deprived both of the penis and testes, but the spado of the testes only.

SPAFFORD, in *Geography*, a township of America, in New York, situated in the S.W. extremity of Onondaga county, 13 miles S. of Onondaga; bounded N. by Marcellus and Otisco, E. by Tully, S. by Preble in Cortlandt county, W. by the Skeneateles lake, or the county of Cayuga. It was erected in 1811, from the N.W. quarter of the military township of Tully, and its population is included in that of Tully. Its area is about five miles square; the central part has an extensive valley of fine land, extending N. and S., the eastern and western extremes being hilly. The soil is chiefly a strong and productive loam; the timber, maple, beech, bass or tilia, butter-nut, and a variety of other kinds. It is well watered by springs and brooks, and has some small streams for mills, the largest of which is the inlet of Otisco lake. The first settlements were made about the year 1806, and the inhabitants are farmers from the eastern states. Here are two or three mills, and as many school-houses, in which are also held the meetings for worship. Spafford comprises as much of the military township of Sempronius as lies E. of Skeneateles lake.

SPAGIRIC, an epithet given to chemistry; which is called the *spagiric art*, or *medicina spagirica*; and to chemical physicians, who are also called *spagirists*.

It is chiefly restricted to that species of chemistry which works on metals, and is employed in the search of the philosopher's stone.

Vossius derives the word from $\sigma\pi\alpha\zeta$, *to extract*, and $\alpha\gamma\gamma\epsilon\mu\alpha\iota$, *congregate, to collect*; which are the two principal offices of chemists. Paracelsus first introduced the word.

SPAGIRICAL PHYSICIANS. See PHYSICIANS.

SPAGNOLETTO, IL, in *Biography*, the cognomen of a Spanish painter, a native of Xativa, in Valencia, whose real name was Josef Ribera. He studied for a short time under Ribalta; but, before he was sixteen, determined upon visiting Italy, to cultivate his taste, and exercise his talents in the art he had solicited for study, although he had no other means of support than what he could obtain by the exercise of his juvenile powers. It was in the 17th year of his age, in 1606, that he arrived at Naples, where he was captivated by the striking and powerful style of M. A. Caravaggio, whose favour he courted and obtained; and by whom he was encouraged and instructed during his residence in that city. From Naples he went to Parma, to see and study the works of Correggio, and thence to Rome, attracted by the reputation of Raphael and Michael Angelo; and although the influence of the style of Caravaggio still predominated in his productions, yet it was not without considerable refinement in feeling, obtained by contemplation of the works of those great men.

After a short residence at Rome, he returned to Naples, where his prospect of employment was much more favourable, partly from the number of excellent artists then practising in the former city, and probably more from the connection between the court of Naples and that of his own country, and its natural partiality to Spaniards. He was there taken under the protection of the viceroy, and employed in several considerable works, which were sent into Spain. The principal among those detained at Naples are, the Martyrdom of St. Jannarius, in the royal chapel; St. Jerome and St. Bruno, in the church of the Trinita delle Monache; and the taking down from the Cross, at the Carthusians.

The subjects he chose for the employment of his pencil are generally of a severe or gloomy nature, and his colouring and execution correspond with their character; being free and bold in style, and dark and strong in hue and arrangement of light and shade. He died in 1656, at the age of 67. He sometimes indulged himself in engraving, and has left about twenty plates of etchings, executed in very much the character of his pictures.

SPAHIS, from the Persian *esparwhee*, q. d. *horseman*, called also *Spaogians*, horsemen in the Ottoman army; chiefly raised in Asia.

The great strength of the grand seignior's army consists in the janizaries, who are the foot, and the spahis, who are the horse. The aga, or commander of the spahis, is called *spahilar agasi*. See AGA.

The spahis are the flower of the Turkish cavalry, and make a part of the grand seignior's guard. They are composed of young men brought up in the seraglio, of soldiers taken from among the janizaries, and others who have distinguished themselves. The spahis are spread over all the towns, and more particularly in the country places; they are almost all married and settled; they exercise different professions, or sometimes apply themselves to the culture of the land; they receive a daily pay, have their appropriate officers, and assemble at the first order, armed and equipped, under the colours of their district. These are a more ancient corps than the janizaries; their pay is greater; and they are understood to be the sons of Mussulmans in a certain degree of affluence; they fight under the same ensigns as the ziamets and timariots, and ought to succeed them in the possession

possession of their fiefs, if the regulations of the first sultans were more respected, or the national interest a little more consulted. Under the first sultans, the spahis formed the principal strength of the Ottoman armies. Almost always in the field, familiarized to military exercises, hardened to the fatigues of war, stimulated by interest, glory, religious fanaticism, and the example of the sultan, it is not surprising that nothing should withstand their arms, and that the modern Greeks, enervated by luxury and riches, solely occupied by intrigues and idle speculations, should be as soon subjugated as conquered. The "Timari-spahis," who are much more numerous, serve in consequence of their possessing a "timar," or fief, on condition of bringing into the field a certain number of men, in proportion to the strength of it. These possessions descend to their children or heirs, when of an age to serve; otherwise, they are given to others, and sometimes, as a recompence, to old soldiers. See **TIMAR**, and **TIMARIOTS**.

SPAUD, or **SPAYD**, a term used by sportsmen for a red male deer three years old.

SPAIN, in *Geography*, a country of Europe, situated between the 36th and 44th degrees of N. lat., and having its western extremity about 9° W. long. from London. Its greatest length from west to east is about 600 miles, and its breadth from north to south is more than 500; so that it forms, if Portugal be included, almost a compact square, and is surrounded on all sides by the sea, except where the Pyrenean range of mountains presents a grand natural barrier against France. The precise western boundary is formed by the river Bidasoa, and the isle of Pheasants is near its mouth. The last town in Spain is Irum, near the Bidasoa. Excluding *Portugal* (which see), the boundaries betwixt these two kingdoms depend more on artificial conventions than on rivers or mountains. The superficial contents of Spain have been estimated at about 148,000 square miles. It lies between the fifth climate on the south, and half-way between the sixth and seventh on the north; the longest days are, therefore, 14½ hours in the southern part, and 15½ in the northern.

The first known division of Spain, into Hispania Citerior and Ulterior, took place under the Romans; but these were soon denominated Lusitania, Bœtica, and Tarraconensis. (See **HISPANIA**.) Lusitania comprehended the eastern part, and extended as far as the Atlantic ocean: its limits were marked on the north by the Duero, on the south by the Guadiana, and from one to the other by a straight line drawn from Simancas to Puente de PArzobispo, and from thence as far as the country of the people called Oretani, in which the town of Almagro at present stands. It included in its extent the towns of Avila, Salamanca, Coria, the territory of Plasencia, Truxillo, Merida and Portugal, the kingdom of Leon, and part of Estremadura. See **LUSITANIA**.

Bœtica was almost surrounded on two of its sides by the Guadiana, bounded on the south by the Mediterranean and the ocean, and terminated on the east by a line drawn from Murgis or Muxacra, a village near the ancient promontory of Charidemus, now called the Cape de Gatte, to the territory of Castulo, which was nearly in the same situation as the modern Cazlona, and to the country of the Oretani. It formed what is called Andalusia, containing the kingdoms of Seville, Jaen, Cordova, and Granada; it also included a part of modern Estremadura, and extended as far as Badajoz, which was within its boundaries. See **BÆTICA**.

Hispania Tarraconensis comprehended all the other parts

of Spain, and was the same with that called Citerior Spain. See **HISPANIA**.

The division of Spain, now stated, underwent some alterations under the last Roman emperors, and was totally changed after the invasion of the northern nations. It was subjected by the Vandals about the year 415, after the Romans had maintained possession of it for about five centuries; and the Visigoths, under Euric, subdued the whole of Spain, excepting Galicia, which was held by the Suevi, who had entered into the country with the Vandals. With this conquest, which occurred A.D. 472, commence the modern kingdom and history of Spain. The Arabs, or Moors, began their conquest A.D. 709, and soon extended it over the whole of Spain, except the mountains of Asturias, where, as well as in Biscay, king Pelagius maintained a limited dominion. The descendants of Pelagius, who fixed the royal residence at Oviedo, which was built in 761, defended their own small territory, and recovered Galicia, and part of Leon and Castile. In the year 914, the kings, as their territory extended towards the south, began to reside at Leon, from which they took their title; and in the 11th century, *viz.* A.D. 1117, that of Castile was added, the kings of Castile having become kings of Leon and the Asturias A.D. 1037. In 1162 the county of Barcelona was transferred to the king of Aragon, whose royalty commenced A.D. 1035. The small kingdom of Navarre, the capital of which was Pampeluno, commenced, as some say, A.D. 857, or, according to others, under Fortunio I. A.D. 880. The reign of Alphonso the Wise began A.D. 1252, and was distinguished by the protection which it afforded to the arts and sciences. Nevertheless, the Moors must be regarded as the chief possessors of Spain, until the middle of the 13th century. Their government in Spain was conducted by governors deputed by the caliphs, until the year 756, when Abdoulrahman seized the sceptre of Spain, and became the Moorish king of Cordova. This dynasty, under which Spain extended its commerce, and acquired very considerable wealth and power, continued until the year 1098, when the caliphate expired, and the Moorish governors of several provinces usurped the royal style, in Cordova, Seville, Valencia, and Granada, and rivalled the small Christian kingdoms, till the middle of the 13th century, when the latter became predominant, and Spain resumed her situation among the states of Christendom. The last of the Moorish royalties which was subdued, was the kingdom of Granada; and the crowns of Castile and Aragon were united in the persons of Isabella and Ferdinand V. A.D. 1474. Charles V. emperor of Germany, having married the heirs of Aragon and Castile, established the Spanish monarchy on its present basis, A.D. 1516; and in consequence of the accession of American wealth, the power of Spain arrived at its zenith. In 1580 Portugal was added to Spain by Philip II., the son of Charles V.; but it revolted under Philip IV. A.D. 1640, and became a separate kingdom. The Austrian dynasty terminated at the death of Charles II., who died without issue, A.D. 1700; and this event was succeeded by the accession of Philip V. of the house of Bourbon.

From the preceding abstract of the principal epochs of Spain, it appears that this kingdom arose from the union of the provinces of the two crowns of Aragon and Castile; the number being four for that of Aragon, and twenty-two for Castile, without including the lordship of Biscay and Navarre. The provinces of the crown of Aragon consist of the kingdom of that name, the kingdom of Valencia, the principality of Catalonia, and the kingdom of Majorca: those

SPAIN.

those of the crown of Castile consist of the kingdom of Galicia, the provinces of Burgos, Leon, Zamora, Salamanca, Estremadura, Palencia, Valladolid, Segovia, Avila, Toro, La Mancha, Murcia, Guadalaxara, Cuença, Jaen, Granada, and Seville. Although this division of Spain is the most ancient, and serves as the basis for the imposition and levying of the taxes, for the municipal laws, and the nature of privileges, the modern division of Spain, with respect to the administration, is limited to thirteen provinces, kingdoms, or lordships, all of which have a captain-general, except Navarre, the intendant of which has the title of viceroy.

The population of Spain consisted originally of Celts from Gaul, and of Moors from Africa; the latter of whom, being more warlike, expelled the former. Towards the east, it received large colonies of Carthaginians, and afterwards of Romans. In the fifth century it was conquered by the Vandals, and next by the Visigoths, from whom several ancient families pretend even now to deduce their origin. The Mahometan Moors were so totally expelled, that they may be considered as almost extinct; and few families of Arabian extract now remain. We may, therefore, regard the modern Spaniards as descended from the African Iberians, the Celtiberian or German Gauls, the Romans, and the Visigoths. The population of this country has varied much at different periods. In the time of Julius Cæsar it has been said, that it contained at one period 40,000,000 of people, and at another period 52,000,000. This estimate, though apparently exaggerated, derives some degree of probability from the consideration of the numerous armies which Spain furnished for a series of years, during the Punic wars, in the time of the Romans and Carthaginians. The population of the towns seems to give us a very high idea of that part of the country in which they were situated. Merida afforded a garrison of 80,000 infantry and 10,000 cavalry; and at the same period, the population of Tarragona amounted to about 2,500,000 inhabitants. The population of Spain sustained but little diminution under the dominion of the Goths; but it very sensibly decreased during the Moorish dynasty, on account of the multitude of victims that fell a sacrifice to the sanguinary sword of the conquerors, and of those who voluntarily exiled themselves, in order to avoid oppression. Spain, however, was again re-peopled by the Christians, who retook from the Moors the lands which they had rapaciously seized. Navarre, which formed a separate state, contained about 800,000 inhabitants; and near the same period, the states dependent upon the crown of Aragon, which constituted the kingdom of that name, with those of Valencia and Catalonia, furnished a very powerful army; and the town of Tarragona alone contained 80,000 families, or 350,000 inhabitants. The kingdom of Granada, subjugated by the Moors, had, at the same era, a numerous population. The city of Granada comprehended 70,000 houses, occupied by 250,000 persons, and furnished 50,000 soldiers. The kingdom, of which it was the capital, reckoned the number of its inhabitants at 3,000,000, on an extent of territory 70 leagues long by 30 in breadth. After the union of the different parts of the Spanish monarchy, in the reign of Ferdinand V. and Isabella, its population is said to have been 20,000,000; but as this estimate is exaggerated, it should be reduced at least one-third. In the year 1688 it amounted to no more than 12,000,000; and on the death of Charles II. and accession of Philip V., in the year 1700, its numbers were reduced to 8,000,000. During the civil wars, which desolated Spain in the first 13 or 14 years of that mo-

narch's reign, it suffered a still greater diminution, so that the population of the whole kingdom could not then have exceeded 6,000,000. Under the pacific reigns of the princes of the Bourbon family, the number of people in Spain greatly increased. The enumeration made by royal mandates, in the years 1767 and 1768, reported the population at 9,307,804 persons; and by a new census, taken in 1788 and 1789, by order of the king, the returns presented 10,061,478. The latest estimate, formed in the year 1797, contains a much higher number, and is said to have exceeded 12,000,000.

The state of the Spanish population, in the year 1788, is exhibited in the following table.

		According

SPAIN.

According to a statement published at Madrid in 1802, the whole population of Spain appears to be 10,409,879; and those who constitute the different classes as follows:

Men	5,204,187
Women	5,205,692
	10,409,879

Out of this number, the calculation gives

Of single men, religious, and widowers	3,257,022
Of nuns, widows, &c.	3,262,196
	6,519,218
Total	6,519,218
Married persons	3,890,661

As to the proportion between the extent of territory and the number of inhabitants, no estimate sufficiently accurate has ever been made in Spain. For want of a more exact estimate, we shall here subjoin that of Hassel, published at Brunswick, in the "Statistique Européenne," which is supposed to be pretty accurate. According to this, Spain contains 25,145 square leagues, of 25 to a degree, and 10,730,000 inhabitants, which will allow 425 inhabitants for every square league. It will hence be easy to ascertain the other numbers, by calculating after the proportion of 9 to 25. The equatorial degree is 25 French leagues, and 15 German miles; then reckoning their surfaces as the squares of their sides, 9 square German miles are equal to 25 square leagues of France.

	Square German miles.	Inhabitants in general.	Inhabitants by square Miles.
The whole of Spain	9053	10,730,000	1185
Kingdom of Castile	6628	7,278,000	1098

Lordship of Biscay, comprising Alava, Guipuzcoa, and Biscay	280	300,000	1071

Others have stated the population of Spain at 11,000,000, and allow 74 persons to a square mile. Of its ancient po-

pulation, numerous vestiges exist in various parts of the country. And among the causes of its depopulation we may reckon the contagious fevers frequent in the southern provinces, incessant intestine wars, the emigrations to America, the invasion of the country by the Moors, the want of encouragement to agriculture, the multitude of detached farms, the effect of the *mesta*, (which see,) or wandering flocks, the number of unmarried clergy and monks, and, more especially, that fanatic and mistaken zeal, which proscribed, on account of their religious tenets, two classes of wealthy and industrious people, the Jews and the Moors. These were peculiarly valuable, on account of their intimate acquaintance with agriculture, arts, trade, and commerce. An edict issued at Granada, March 30, 1492, against the advice of the ministry, and many members of the supreme council, ordained, that every Jew who did not profess Christianity within six months, should be constrained to quit all countries under the government of the Catholic kings. Another equally impolitic edict was published in the year 1614, by which numbers of Moors, who, after having been subdued, had remained peaceably in Spain, were expelled the country. About 100,000 Jewish families pretended to be converted, and in the issue became victims to the inquisition. More than 800,000 Jews left the kingdom, and migrated to France, Italy, Africa, and the Levant, and carried with them the wealth and other species of property which they had acquired by industry and trade. All the Moors, to the amount of 2,000,000, departed, leaving their towns and villages deserted. We might add, as another collateral cause of the depopulation of Spain, the depredatory cruising of the Barbary pirates, for the space of 300 years, by which they made numerous captives, both at sea and by incursions on the coasts.

Towards the end of the 8th, and commencement of the 9th century, Spain was inhabited by four principal nations; viz. the natives, then known by the name of Romans; the Goths, comprehending the remains of the Suevi, Alani, and Vandals, several of whom were confounded with the natives and Moors, though a considerable part had taken refuge in the Asturias and Navarre; the Moors, with whom the natives of Africa were mingled; and the French, who occupied a great part of Catalonia, Navarre, and the Pyrenees. Each of these nations brought with it its own genius, manners, laws, and customs; and besides, the expulsion of the Moors from Spain was succeeded by the formation of several independent sovereignties, each of which had its own laws and particular form of government. Hence resulted a diversity of genius, temper, manners and customs; which, though in some degree modified by the present uniformity of government, still subsists; so that there are no two provinces exactly resembling each other in manners and character. Some customs, however, and some traits of character, correspond to one another in all the provinces. The national pride is every where the same, and this the Spaniard energetically expresses by his gestures, words, and actions. In many cases this is the pride of virtue, or a natural dignity of sentiment, which soars above vice and folly. With this pride, which is discernible in all ranks of life, and in all classes of society, the Spaniards combine, in a very eminent degree, temperance and valour. Of their valour in more remote ages, Thucydides, Diodorus Siculus, Livy, Strabo, and Lucius Florus, furnish a variety of instances; nor have they altogether lost this distinguishing quality of their ancestors. In this respect, some shades of difference have been observed among the military of different provinces. The Galicians are accounted the best soldiers in Spain. Strabo has said of them, that they were warlike, and that it was difficult to subjugate

SPAIN.

subjugate them. The valour of the Catalonian is said to be the most intrepid; that of the Aragonese the most considerate; that of the Andalusian the most presumptuous; that of the Castilian the coolest; and that of the Biscayan more active amongst rocks than on the plain. The Spaniards are reckoned to be, in general, very grave and reserved; and in their address, cold and repulsive; but blended with their gravity, they manifest a degree of gaiety, particularly since the accession of the house of Bourbon, which is frank and lively. Notwithstanding this occasional vivacity, the Spaniard is very tardy and slow in all his operations, respecting not only business and politics, arts and sciences, but even their amours and pleasures. That indolence and hatred of labour which prevail in their national character, have produced an aversion for agriculture and commerce, the effects of which have been nationally injurious. It has been observed, however, that this kind of apathy and indisposition to labour, solely, or principally, prevail in those parts where industry is without a spur, activity without an object, and commodities without a vent. The provinces near the sea are all industrious; the inland provinces, destitute of canals and navigable rivers, and, till of late, of roads, and possessing no cheap or easy mode of communication, have no means of supporting industry.

The Spaniards were formerly very jealous of their wives and mistresses; the women were shut up in their own houses as in a kind of prison, where thick lattices concealed them from the observation of impertinent curiosity. They received few visits in the apartments to which they were confined, and which no man could enter without great difficulty and many precautions. They were placed under the guardianship of one or more duennas, and could not take a single step, either in their own houses or abroad, which was not subject to their inspection. Whenever they went out, a veil concealed the face from every passenger.

Times are greatly altered; husbands are now much less suspicious—more reasonable, or more easy—and women much more accessible. Lattices and jealousy have disappeared; duennas only exist in romances; veils, under the name of *mantelas*, have become an ornament which gives effect to beauty; all houses are thrown open; the men, gallant and amorous as ever, are become less captious; the women have recovered a liberty by which they are, perhaps, less tempted to go astray than formerly, when their virtue was entrusted to locks and grates, and to a superintendance often faithless, and easy to be corrupted.

Both the men and women have gained by the change; the former have become less morose, more frank and agreeable; the women more attractively disclose the many easy graces with which they were endowed by nature.

Several of the games, diversions, and public spectacles of the Spaniards, are derived from the Moors, and to the same origin we may trace many of their customs, and even that kind of dress and mode of living which were long prevalent in this country. After the expulsion of the Moors, the Goths and native Spaniards, blended together and forming one nation, adopted the same costume and manners. On the accession of Philip V. the Spanish habit was neglected and disused, and the French, which still prevails, substituted for it. The Spaniards are now as luxurious in their dress as they were formerly simple; they make use of the richest stuffs and silks, as well as of embroidery in silk, gold, and silver. The most varied and conspicuous colours have succeeded to black, which was, for several centuries, the national costume. The common people, however, in several of the provinces, retain their ancient mode of clothing, with some diversity in different parts of the country. Different

professions have their peculiar costume in Spain. Uniforms are very numerous, and are not confined to the military. The Spanish nobility have an uniform for the holy week; they wear it at court and in town, and the king and royal family wear the same. The coat is of black velvet, lined with crimson satin, with gold, or gold embroidered buttons, and facings of gold brocade on a crimson ground, or of satin of the same colour embroidered with gold. The waistcoat is the same as the facings, and the breeches are black. This dress is handsome and dignified. Among the amusements of the Spaniards we may reckon the festivals of the church, which in several of the provinces, particularly in Aragon, are attended with very brilliant and magnificent decorations; the fire-works, which are very common in Spain; the masquerades, which were formerly much in fashion in Spain during the carnival, particularly in Aragon; and the bull-fights, which were the true national spectacle; but this amusement was suppressed several years ago. The amusements of people of rank chiefly consist in dancing and cards; and the theatre is much frequented, though the plays and music do not correspond in excellence with the national refinement.

The origin of nobility in Spain cannot be precisely ascertained. Of this order of persons no traces appear, whilst the country continued under the dominion first of the Carthaginians, and afterwards of the Romans. The rudiments of it first manifested themselves under the Gothic kings; but it was almost totally annihilated by the Saracenic invasion. After the expulsion of the Moors, a regular order of nobility began to grow up in the newly established kingdoms of Spain, with peculiar modifications in different states. The only method of acquiring nobility in this country is by a royal grant, as it is not attached to the exercise of any office, civil or military: and the price of a patent of nobility varies in the different provinces. Of late years a distinction has been taking place, between the titled and untitled nobility. The former are so called because they have obtained from the king the title of grandee, of duke, of count, of marquis, or of viscount. These titles of nobility are hereditary in the families of those to whom they have been granted, and descend first to the males, according to seniority, and then to the females, who have a right to transfer them to their husbands and to their children. The titled nobility, unless they have been advanced to the dignity of grandee, enjoy few privileges above those that are entitled. The grandees, of whom there are several classes, are at the head of the Spanish nobility, and at court take precedence of all secular dignities, except those of constable and admiral of Castile. The most valued privilege belonging to the grandees is that of being covered in the royal presence. The number of titled nobility in the year 1787 was as follows; 129 grandees, 535 marquises, counts, and viscounts; of these latter, 142 habitually resided at court, and the rest in the provinces.

The military orders in Spain were formerly eleven, all of which are become extinct. At present there are seven different orders, *viz.* those of the Golden Fleece, of San Jago, or St. James of the Sword, of Calatrava, of Alcantara, of Montesa, of Charles III., and of Maria Louisa. Of these, the first has passed by succession to the Spanish crown, the four next are the military orders properly so called, and the two last are of modern institution. (See *GOLDEN FLEECE*, *St. JAMES of the Sword*, *CALATRAVA*, *ALCANTARA*, *St. GEORGE of Alfama*.) For the four last named military orders the qualifications at present necessary are eight years of active service in the Spanish army, and proofs of nobility of four degrees, on the side of both father and mother. The only

only advantage that accrues of necessity, on admission into any of these four orders, is the honour of wearing the cross, besides a few unimportant privileges: the commanderies are places of pecuniary profit, belonging to those who have taken the vow of combating the infidels, of fidelity towards the sovereign, and, of conjugal charity. The order of Calatrava has 20 of these, valued at 71,250*l.* sterling; that of San Jago has 87, valued at 81,250*l.*; that of Alcantara has 37, worth 39,000*l.*; and that of Montesa 13, at 12,588*l.* To each of the orders belong monks, and several convents of nuns. The order of Charles III. was founded by the king of that name, on the 19th of September, 1771, and placed under the immediate protection of the Holy Virgin, under the title of the Conception. Of this order the sovereign is chief; he alone nominates the grand crosses and knights. The order is composed of sixty grand crosses, two hundred pensioned knights, and an indefinite number of others; of a grand chancellor and minister, who is always the patriarch of the Indies; of a secretary, a master of the ceremonies, and a treasurer.

The cross of this order is of eight points, surmounted by a royal crown, with a figure of the conception in the middle; it is worn hung to a ribband of three equal stripes, the two outer of which are blue, and the inner white. The grand crosses wear this ribband much broader than the knights, faldierwise from the right shoulder to beneath the left arm, with a conception of silver embroidery on the left side of the habit and cloak. On days of ceremony they wear a long cloak, and a collar, the links of which are formed alternately of the king's cypher and the arms of Castile. The knights wear the cross hung from the button-hole by a narrow ribband. The pensions of the knights (of which there are 200) are each fixed at the sum of 4000 reals: they are given to military men, to men of letters, to lawyers, to gentlemen, and to those employed in the ministerial departments. This order has a supreme council, composed of the sovereign, of the grand chancellor of the order, who is also vice-president, of a secretary, a fiscal, an accountant, and ten counsellors.

The order of Maria Louisa is very modern, having been established in 1792, by Charles VI., who named it after the queen his wife. Only ladies are admitted into this order. The grand-mastership is vested in the queen, and the number of ladies is thirty. The cross of the order is a medallion, with a portrait of the queen, hung to a violet ribband, divided in the middle by a white stripe, and worn faldierwise.

In Spain there is a description of persons denominated "Mayorazgos." The term, derived from the word *mayor*, or first-born, implies, strictly speaking, the right possessed by the eldest-born of a family, to inherit certain property, on the condition of transmitting it entire and undiminished to those who may be possessed of the same right on his decease.

The import of this term has, however, been much extended by use; for, though it properly means only the right of succession to a perpetually entailed estate, in virtue of primogeniture, yet it now signifies, in addition, the cause which produces the right, the property which is the object of it, the actual possessor of the property, and the person who stands next in succession.

Of these mayorazgos there are five classes or kinds, distinguished by certain circumstances incident to the descent or transfer of property. Many disadvantages have attended the extensive multiplication of mayorazgos; especially when the succession descends to females. Instead of perpetuating families, for which purpose the institution was intended, it very much contributes to their extinction; it injures the ge-

neral progress of agriculture, and it encourages idleness, to which the Spaniards are very much addicted.

Literature, Sciences, the Arts, and Language.—The state of science in Spain, before the time of the Romans and Carthaginians, is wholly unknown; but when the Romans introduced with their arms the arts of civilization, the Spaniards began to cultivate literature and the sciences, and produced several writers who attracted distinguished notice: such were L. A. Seneca, a native of Cordova; the geographer M. Pomponius Mela, of Andalusia; and J. M. Columella, of Cadiz, whose works on agriculture and rural economy are even now held in high estimation. Under the Goths, when literature was restrained and oppressed, Spain furnished persons no less distinguished by their virtues than by their talents and writings. To this class we may refer Hosius, bishop of Cordova; Gregorius Boeticus, bishop of Elvira; S. Ildefonso, archbishop of his native place, Toledo; S. Isidore, a native, and afterwards archbishop, of Seville; Priscillianus of Galicia; Petrus of Saragossa, a distinguished orator; Aurelius Prudentius, of Calahorra, an esteemed poet; and Aquilius Severus, who wrote an account of his travels in Africa. The invasion of the Moors introduced a period of barbarism; but at this time we find, without mentioning persons of less note, king Alphonso IV. of Castile and X. of Leon, who was celebrated for his acquirements in various departments of literature and science; who was a legislator, orator, historian, poet, mathematician, and astronomer; and who merited the appellation of "El Sabio," the sage, which was conferred upon him by general consent. Although the native Spaniards were plunged in ignorance, the Moors united with the most romantic bravery, a passionate love of science and the arts. Besides their theatres, public shows, and tournaments, they established public schools in every town under their dominion, of which those of Seville, Cordova, and Granada, obtained a high degree of reputation. They established in various places colleges and academies, as well as libraries, for the promotion of science and literature. The sciences cultivated by them with eminent success were, geography, experimental philosophy, optics, botany, chemistry, medicine, natural history, geometry, and other branches of the mathematics. When the Moors were expelled, the fortunate and brilliant reign of the Catholic sovereigns Ferdinand and Isabella was the era in which knowledge revived, and its boundaries were enlarged during the reigns of Charles V. and Philip II. During the inauspicious period that succeeded the reign of Philip II., several persons of distinguished genius and attainments exerted themselves for the protection and encouragement of science; and it would be tedious to mention even the names of those who excelled in various branches of learning. We cannot, however, forbear mentioning Benedict Feyjoo, a Benedictine monk, who died at Oviedo in 1762, and who did honour to his country at a time when literature, science, and the arts, were almost wholly neglected and unknown. To him Spain was indebted for the restoration of literature, good taste, and the love of study. We might also enumerate among its distinguished poets and historians, Quevedo, Cervantes, Saavedra, Lopez de Vega, Guevara, Mariana, Granada, Solis, Herrera, &c.

The number of universities, or rather academies, in Spain, was formerly twenty-four, but the following seventeen are all which now remain, *viz.* that of Pampeluna, in Navarre; of Oviedo, in the Asturias; of San Jago, in Galicia; of Seville, and of Granada, in the provinces of the same name; of Huesca and Saragossa, in Aragon; of Avila, Osma, and Valladolid, in Old Castile; of Toledo, Sigüenza, and Alcalá de Hamarez, in New Castile; of Cervera, in Catalonia;

lonia; of Orihuela and Valencia, in Valencia; and of Salamanca, in the province of Leon. Several of these scarcely deserve notice. Those of Saragossa, Alcala, and Cervera, retain some degree of importance; but the most ancient and most celebrated is that of Salamanca; for an account of which see that article. The most popular university at present is said to be that of Valencia. The conventual schools are numerous; and Spain has four military schools, *viz.* at Barcelona, Zamora, Cadiz, and Segovia. Public libraries are also numerous.

The native tongue of the ancient Spaniards was utterly lost during the domination of the Romans, whose language in the corrupt form of the middle ages became that of Spain. The Goths brought into the country their own Teutonic dialect; and as the natives continued to speak Latin, their language became at length a mixture of Latin and Teutonic. The Arabs, in their turn, introduced the speech of their country, vestiges of which remained after their expulsion. Hence it appears, that the Spanish language was compounded from three different sources: the Latin prevailed over the other two, and the Gothic still preponderates over the Moorish. Within the last two or three centuries the Spanish language has undergone considerable alterations; it still, however, preserves the same roots, the same turn of phrase, and the greater number of its words, but altered in their inflections and terminations. The Spaniards themselves boast, among other excellencies, of the facility with which it is pronounced; it is founded, they say, exactly as it is written, but this assertion is too general. In some respects this language is very rich; it abounds in compound words, in superlatives, derivatives, augmentatives, diminutives, and frequentative verbs; it has many quite synonymous words, and others which well express the different shades of meaning. In the technical terms of arts and sciences, it is, however, extremely poor; a few of these it has borrowed from the Latin, and almost all the rest from the French.

On the whole, the Spanish is one of the finest of the European languages. It is dignified, harmonious, energetic, and expressive; and abounds in grand and sonorous expressions, which unite into measured periods, whose cadence is very agreeable to the ear. It is a language well adapted to poetry, but it also inclines to exaggeration, and its vehemence easily degenerates into bombast. Though naturally grave, it easily admits of pleasantries. In the mouth of well educated men it is noble and expressive; lively and pointed in that of the common people; sweet, seductive, and persuasive when uttered by a female. Amongst the orators it is touching and imposing, though rather diffuse; at the bar and in the schools it is barbarous; and is spoken by those about the court in a concise and agreeable manner.

The Spaniards articulate strongly, and sometimes with a kind of guttural sound, which greatly impairs the grace and dignity of their speech, but the pronunciation differs materially in different provinces. In Catalonia it is harsh and constrained; harsh also and dry in Aragon; quick and lively in Biscay; agreeably modified in the kingdom of Valencia; boastful and mouthy in Andalusia; softer, sweeter, and more natural in Castile.

The Spanish language is not spoken with the same purity in all parts of the kingdom. Besides the old provincial dialects, which still prevail in many parts, the Basque is still spoken in Biscay; and the language is mixed with French in Navarre, with Portuguese in Galicia, and with Arabic in Murcia and Andalusia. It is in New Castile, and especially in the ancient kingdom of Toledo, that it is best spoken; and there that a stranger ought to learn it

who desires to become acquainted with all its delicacies and beauties. The ancient Limoufine or Provençale forms the basis of the dialects of Catalonia and Valencia.

Basque is spoken in the lordship of Biscay, in Guipuscoa, and in the greatest part of Alava. This language is very ancient; it differs entirely from the Spanish, either ancient or modern; it existed before the arrival of the Romans, and was then unlike what was spoken in the other parts of Spain; it is mentioned by Strabo, Seneca, and Pomponius Mela. It has been preserved to our days almost without alteration or corruption, particularly in the more mountainous parts. It is very difficult to strangers, and appears to those who do not understand it a coarse and barbarous tongue, destitute of elegance and expression; but such as are versed in it account it very sweet and expressive.

The Spaniards, abhorring the Moors, disdained to apply themselves to the arts which they exercised; and hence proceeded a general contempt for artificans, which has been perpetuated to the present time, and has greatly retarded their progress in Spain. The arts which are employed in manufactures are much advanced in Spain. The 16th century was the most brilliant period of the arts in Spain, as well as of the sciences, of literature, and of the power and grandeur of the monarchy. Many able architects appeared at once under Charles V. and Philip II., who erected numerous edifices, that will immortalize the reigns of those princes and the names of the artists, such as John de Herrera, Cepedes, Pedro de Uria, and John Baptist Monegro of Toledo, the latter of whom assisted in the building of the Escorial, and of the church of St. Peter at Rome. The structures of this age are the finest in Spain. Architecture, however, very much declined in the 17th century; but about half a century ago it began again to be cultivated with success. Spain justly boasts of a number of sculptors of distinguished merit, among whom we might mention Paul Cepedes of Cordova, and Alonzo Cano of Granada. Of all the liberal arts, painting is that which has been most cultivated in Spain; and though the Spanish school is little known, it deserves notice, as occupying a middle place between the Italian and Flemish schools, being more natural than the first, more noble than the second, and participating the beauties of both. It has particularly excelled in sacred subjects. Most of the painters of Spain are of the 17th or the end of the 16th century. In the 18th century painting was almost totally annihilated in Spain; but the Spanish school was recovered about the middle of the same century by Antonio Raphael Mengs. Spain now possesses an academy of painting at Seville, and two academies of the fine arts, one at Madrid, and the other at Valencia; and public, gratuitous schools for drawing have not long ago been established in various places. The Spaniards have a taste for music, and have cultivated it with success. They prefer the Italian to the French music, the latter being in their opinion too languid and monotonous. The Moors were the first in Spain who cultivated music scientifically, and who established schools for teaching it; and the Spaniards have been led to imitate them. The Moorish music consisted chiefly of soft and tender airs, sung by one or more voices, and accompanied by the lute; and the modern Spaniards have also their national music, resembling that of the Moors, and confined to detached airs, which are sung by one or more voices, and accompanied by the guitar. Spain has also adopted the musical instruments generally used among other nations, and it has some that are peculiarly its own. Different provinces have their appropriate instruments. For the history of Spanish music, see the sequel.

We have already mentioned dancing as one of the amusements

ments to which the Spaniards are much addicted. Besides those dances which are provincial, they have three which are national; *viz.* the fandango, the bolero, and the seguidilla. The fandango is very ancient; it is probably referred to by Martial, and it is defined by Baretto to be a regular and harmonious convulsion of all parts of the body. The bolero, which is quite modern, is an imitation of the former, but shortened and modified, and stripped of all those accessories, which give to the fandango so very free a character. The seguidilla is an imitation of the steps of the two others formed into a ballet. These dances are usually performed to the sound of the guitar, accompanied by the voice of the player. The women very correctly mark the time with the heel, a motion which adds a new grace.

Climate, Soil, and Agriculture.—The climate of Spain is equal, if not superior, to that of any country in Europe; it is in general very dry, and irrigation is rendered difficult by the chains of mountains that intersect it. The climate is various in different provinces, and in those that lie to the south the heat is insalubrious, and sometimes occasions epidemic diseases that are very fatal. These are partly owing to stagnant and undrained marshes, and to the neglect of proper culture. The chains of mountains that intersect the country at various distances from E. to W. serve to temper the climate, and supply cooling breezes. In the south the sea-breeze, commencing about nine in the morning, and continuing till five in the afternoon, moderates the heat of summer: and the severity of winter in the northern provinces is allayed by the gales of the ocean, at no great distance. It has been observed, that the temperature of Spain is influenced by its peculiar configuration, and by the singular height of this country above the level of the sea, inasmuch, that although from the N.E. it gradually becomes lower, yet the high plain, or table land of the Castiles, has an elevation of upwards of 300 fathoms. According to the observations of Humboldt, the interior of Spain is an elevated plain, and the highest of any of the same kind in Europe, which occupies a large extent of country. The mean height of the barometer at Madrid, observed by Don Felipe Bauza, shews that capital to be elevated at 309 $\frac{1}{2}$ fathoms above the level of the ocean, allowing the barometer on the coasts to be at 338 and 24 lines. Hence it appears that the elevation of Madrid is 15 times greater than that of Paris, three times greater than that of mount Valerian, and also three times greater than that of Geneva, which is 188 fathoms above the level of the sea. This height of the plain of the Castiles has an obvious effect upon its temperature. The mean temperature of Madrid appears to be 59° of Fahrenheit, while that of Petersburg is 39° 52' 30"; that of Berlin, 46° 57' 30"; that of Paris, 53° 56' 15"; that of Marseilles, 58° 33'; that of Toulon, 61° 15'; that of Naples, 63° 30'; and that of the countries situated under the equator and on the level of the ocean, from 70° to 81°. Genoa is four degrees more to the north than Madrid, and yet the temperature of Genoa raises the glass almost two degrees higher than that of the capital of Spain. Such is the influence of local causes, of the elevation of scite, the proximity to the sea, a chain of mountains which keeps off the cold northerly winds, and a great number of little circumstances, the combination of which moderates the temperature of places.

If the mean temperature of the elevated plains of Spain is 59° of Fahrenheit, that of the coasts from the 41st degree of latitude to the 36th, is between 63 $\frac{1}{2}$ ° and 68° Fahrenheit. Thus we see banana-trees, heliconias, and fugar-

canes, growing upon these coasts in situations that are sheltered from the cold winds.

Upon the whole, the face of the country is in most seasons delightful, abounding with excellent and fruitful pasturage, vineyards, and groves of orange-trees; and the hills stocked with wild thyme and other odoriferous plants. The rivers and streams are numerous; and the chains of mountains afford a great variety to the prospect. The most northern of these chains is regarded as a continuation of the Pyrenees, passing on the S. of Biscay and the Asturias into Galicia; and it is variously denominated, as the mountains of Biscay, the Sierra of Asturias, and the mountains of Mondonedo in Galicia. It is also known by the names of the mountains of Santillana, of Vindo, and of the mountains of Oea. We here observe that the term "Sierra," peculiar to Spain, denotes a chain of mountains, the successive peaks of which present the resemblance of a *saw*. The gypseous and argillaceous mountains of this country rarely exhibiting any supreme elevation, like those in the granitic chains, naturally suggested this appellation. The second chain of Spanish mountains extends from near Soria on the N.E., and pursues a S.W. direction towards Portugal. This chain is called that of Urbia, or Guadarama, and also the Montes Carpentanos. The third is that of Toledo, or Guadalupe, running nearly parallel with the last. These two central chains seem to contain great quantities of granite. Next towards the S. is the Sierra Morena, or brown mountains, which are followed by the most southern ridge, that of the Sierra Nevada. On the E. there is a considerable chain, which connects the two central ridges, and advances towards the Mediterranean in the N. of Valencia. There are also considerable ranges of hills in this part of the kingdom, generally running from N. to S. Near Barcelona is a remarkable solitary mountain, at a distance appearing like a fugar-loaf, and on a nearer approach jagged like a saw, with pyramidal rocks; composed of facillite or pudding-stone, formed of limestone gravel united by calcareous cement; and so high, that from its summit may be seen the islands of Majorca and Minorca, at the distance of 50 leagues. The circumjacent region consists of argillaceous schistus, with clay and sand. Not far from this mountain, called Montserrat, near the village of Cardona, is a hill three miles in circumference, which is a mass of rock-salt, used in the dry climate of Spain for vases, snuff-boxes, and trinkets, like our Derbyshire spar.

According to the description of the ingenious observer, Mr. Townsend, the northern side of the Pyrenees (which see) is chiefly calcareous, surmounted with argillaceous schistus; but the southern is granite, and of course barren. The hills to the S. of Gerona are also granitic. The highest ridge in Spain, near Daroca, from which originate the Tajo and the Ebro, seems to be composed of argillaceous schistus, and free-stone, probably resting on granite. Near Achnuala the mountains are limestone with shells, and in some places contain beds of red gypsum, with crystals of the same colour. In general, gypsum is as abundant in Spain as chalk is in England; and the gypsum produces crystals of sea-salt and Epsom salt, and abundance of nitre. The mountains on the N. of Madrid, forming part of the central chain, are granite. Those to the N. of Leon are chiefly marble or limestone, on a basis of argillaceous schistus, rising in bold and rugged rocks, which afforded a barrier to the remains of Spanish liberty. In returning towards the S. the soil of La Mancha is sandy, the rock gypsum. The higher regions of the Sierra Morena are granite: the lower, argillaceous schistus with gypsum and limestone. The granite is of two kinds, the red and the white. Near Cordova the highest hills

are covered with rounded masses of granite, grit, and limestone. Near Malaga are branches of the Sierra Nevada, or snowy chain, an appellation which might be extended to the central range between Old and New Castile, which, according to Mr. Townsend, may at some times be visible at the distance of 100 miles: these branches present limestone and marble, surmounted by argillaceous schistus. Near Alhama, S.E. of the city of Granada, are found rocks, which, on a basis of shingle or round gravel, present sand-stone with shells, surmounted with facelite; but in general the rocks are gypseous, with strata of the same substance crystallized. Mr. Townsend supposes that the power of the sun contributes to impregnate chalk with vitriolic acid, thus forming gypsum. The S.E. part of Spain seems to be equally calcareous, and the cathedral of Murcia is built with pisolite, a sort of free-stone, resembling the roe of fish. The aventurine is found in the mountain of Gata, towards the frontiers of Portugal; the Cape de Gata presents also some singularities, and appears to some travellers to have been volcanic.

The forests, or rather chaces of Spain, are numerous. They are little cultivated, and are partly reserved for the pleasures of hunting; such is that of the Pardo, which is barren of trees, and extends about 30 miles. Some of the forests are haunted by smugglers and banditti, who rob travellers, and often commit murders.

Spain, including the whole country S. of the Pyrenees, in relation to botany, and its vegetable productions, has been divided into the sea-shore, the high mountains, the lower ones, the arable lands, the grazing tracts and marshes along the rivers, and the vicinity of Lisbon and Oporto. The sea-shore, with respect to its vegetables, resembles for the most part the northern coasts of the Mediterranean; the flat sandy tracts being occupied by the sea-daffodil, the shrubby glass-wort, and the *salvia fida* and *fativa*; and of the latter there are extensive plantations in the vicinity of Alicante and Barcelona, the ashes of which yield the barilla, of which some thousand tons are annually manufactured: the rocks on the coast are chiefly calcareous, and abound with several vegetables, and particularly with the *stipa tenacissima*, or esparto grass, used in making ropes, mats, chair-bottoms, &c. The high mountains of Spain are covered with snow only for a few weeks in the year, and in these elevated regions are found the finest timber trees, and other vegetable productions of the same kind with those that are met with in the north of Europe. The long ranges of hills that occupy the greatest part of Spain, consist either of extensive arid tracts of sand, arenaceous sand-stone, and ferruginous rubble forming the heaths, of dry calcareous districts forming the sheep-walks, or of moist rough granitic and marble ridges, with a shallow soil, forming the woodlands. The Spanish heaths are gayer and richer with plants than those of any other European country. The sheep-walks are for the most part open downs, with little shelter, excepting occasionally groves of chestnut-trees or evergreen oaks. In the wood-lands the trees are neither so large nor so ample in their foliage as those of the German and English forests. The maritime provinces of Spain abound with wood; but in the interior provinces trees are rare, and plantations are not sufficiently encouraged. Portugal and Spain are deficient in respect of water; the rivers flow through rocky channels, and therefore the marshes and bogs are infrequent. The vicinity of Lisbon and Oporto, and of a few other towns on the coast, afford a number of Indian, African, and American plants.

In zoology, Spain is celebrated for its horses and mules,

the latter however being more regarded than the former, which are said to degenerate, and particularly for its sheep, which are superior to those of other countries with respect to the delicacy of the mutton and the beauty of the fleece.

In mineralogy, Spain was formerly more distinguished than it has been in later times. Pliny, Strabo, and Polybius, speak in high terms of commendation of its precious metals; so that Britain and other maritime regions received their gold and silver from Gaul and Spain, in return for cattle, hides, and other products. At present the silver-mines are almost wholly confined to Guadalecanal in the Sierra Morena, though rich veins of the same metal, in a fuliginous state, exist in many places. The quicksilver mines of Almadan in La Mancha furnish America with mercury for refining its more precious metals. Calamine, cobalt, antimony, copper, tin, and lead, are found in Spain; its iron is valuable; and coals are obtained in the district of Villa Franca, in Catalonia, where also occur gold, silver, copper, and lead. Amber and jet are found in the territory of Betonica, in the Asturias. The other minerals it is needless to enumerate. Murcia produces a fine red earth, called "almagra," which is mingled with the Spanish snuff. The aventurine of Spain is a felspar sprinkled with golden mica.

Few of the mineral waters of Spain are much celebrated. The hot springs near Oviedo resemble those of Bath; and those near Alicante are warm springs of a chalybeate nature, rising like the fumes among calcareous hills.

We shall now advert to the *agriculture* of Spain. The soil in Spain is generally light, and reposes on beds of gypsum; nor is any country in Europe upon the whole so fertile as this, or possessing equal advantages at all seasons of the year. It was, indeed, in this region that the ancients fixed the seats of the Elysian fields, and the gardens of the Hesperides. When the Romans first entered Iberia, they were astonished at the productive and flourishing state in which many parts of it were found; and they encouraged the existing industry, so that Spain became the granary of their empire, and the nursery of their armies. The northern nations, when they took possession of the country, parcelled out the lands, and turned their attention to the improvement of agriculture. They constructed subterraneous buildings, or granaries, in use before their time, for the preservation of corn, and encouraged the formation of canals and sluices, for the irrigation of the land. Under the Moors agriculture was in a still more flourishing state; and the era of their expulsion designates the epoch of the decline of agriculture. The Spaniards, deprived of their assistance, possessed neither talents, activity, nor persevering industry, for the cultivation of their lands; and though they had an excellent soil, and numerous rivers to counteract its aridity, and nothing but industry and labour were wanting, scarcely two-thirds of the country were under cultivation: so that they have been under a necessity of importing a large quantity of corn from foreign countries. Many attempts were made by successive Spanish monarchs to rouse the spirit and invigorate the system of agriculture; but they proved, from various impeding causes, in a great degree ineffectual. A variety of circumstances contribute to diminish the number of persons that are inclined to labour, as well as to contract the portion of time that may be employed for this purpose. Although Spain has a population of 10,143,965 persons, yet of these, the women, children, and old and infirm men, constitute five-eighths of the whole, and reduce the population to about 3,803,981 men. From this number must be subtracted the secular and regular clergy, military and navy, nobility, students, counsellors, scribes, domestics, and tax-

SPAIN.

tax-gatherers, amounting to 1,221,799 persons; so that the number of those who might be actively employed in agriculture, subject to a still further reduction, amounts to considerably less than 2,582,592. The number of working days is much lessened by the multiplicity of feasts and holidays. The want of good roads and of convenient markets, the high price of labour, and the "melta" (which see), very much impede agricultural improvement. Under all these disadvantages, so fertile is the soil and so favourable the climate, Spain produces a very considerable quantity of various sorts of grain; but different provinces are more or less distinguished in this respect. Flax, hemp, sugar-canes, madder, foda, saffron, broom, honey, palms and dates, cork-trees, kermes or gall-insects, and different kinds of fruit, almonds, nuts, figs, carob-beans, olives, vines and dried raisins, may be reckoned amongst its productions. The common course of husbandry about Barcelona, as Mr. Townsend informs us, begins with wheat; which being ripe in June is immediately succeeded by Indian corn, hemp, millet, cabbage, kidney-beans, or lettuce. In the second year these crops succeed one another as before. In the next year they sow barley, beans, or vetches, which being taken off the ground before Midsummer, are followed, as in the former year, by other crops, changing them according to the season, so as to have on the same spot the greatest variety. Wheat produces a ten-fold crop, and in rainy seasons fifteen for one. Near Carthagena, the course is wheat, barley, and fallow. For wheat they plough thrice, and sow from the middle of November to the beginning of December; in July they reap from 10 to 100 for one, as the season happens to be humid. The Huerta, or rich vale of Alicant, yields a perpetual succession of crops. Barley is sown in September, reaped in April; succeeded by maize, reaped in September, and by a mixed crop of esculents which follow. Wheat is sown in November, and reaped in June; flax in September, pulled in May. In the vale of Valencia wheat yields from 20 to 40; barley, from 18 to 24; oats, from 20 to 30; maize, 100; rice, 40. In the more southern provinces, the land is almost equally fertile: and the sugar-cane is successfully cultivated near Granada. The Spanish plough is generally light, and is drawn by oxen with the yoke over the horns. All the provinces of Spain produce wine. The eastern and southern provinces contain a vast number of vines; but the northern and western not so many. But the wines vary in respect of quality in the different provinces, and in the several districts even of the same province. The ordinary wines of the country are red wines; but many districts of Spain produce excellent sweet wines. The old sherry wine, "Xerez seco," is the sherry sack of Shakspeare. The dried grapes or raisins form in the kingdom of Valencia, where they annually produce 88,461½ cwt. and usually export 36,538 cwt., and particularly in that of Granada, the environs of Malaga furnishing annually 288,461½ cwt. and exporting 240,577 cwt., a very considerable article of commerce. In the latter province, they are simply dried in the sun, without any other preparation; in the former the grapes are steeped in boiling water, sharpened with a ley made of vine-stems, and then exposed to the air and suspended in the sun, till they are sufficiently dry. Those of Malaga are of a superior quality, in greater estimation, and obtain a higher price than any other. They are naturally larger, and of a more delicate flavour than any others. The cultivation of sugar-canes prevails on an extensive scale on the side of Granada, where enough is grown to supply a considerable manufacture of sugar. Formerly they had no fewer than twelve sugar-mills between Malaga and Gibraltar, the four principal of which were at Madrid, near which place the

best canes were produced. But the cultivation of cotton has been substituted there in the place of sugar. Olive-trees thrive in almost every part of the country. The olives grown in the districts of Alcala and Guadaira, in the kingdom of Seville, are larger and finer than any in Europe, and the best adapted for pickling. The greatest quantity of oil is produced in the kingdom of Valencia; viz. 88,000 quintals, or 84,615 cwt. annually. Wood is scarce in the two Castiles, Estremadura and Leon. The cables of the Spanish vessels are often made of esparto from Murcia.

In Spain several economical societies have been lately established, particularly at Valencia and Saragossa, with a view to the encouragement of agriculture; and in connection with the society of the latter place is a charitable bank in favour of distressed farmers. Money is advanced sufficient to defray the expences of harvest, and two years are allowed for returning, by instalments, the sums thus advanced. This establishment commenced its operations in June 1805, and it then distributed 458*l.* 2*s.* sterling to 110 husbandmen; and in the month of August following it had furnished sixty-two horses to an equal number of other indigent farmers. The principal economical institution for the promotion of agriculture is that at Madrid.

Manufactures and Commerce.—Spain, celebrated in remote periods for the fertility of its soil, and the variety of its productions, was equally signalized by the industry of its inhabitants. The Greeks and Romans found this country farther advanced in all kinds of useful arts than they could possibly have imagined. It was in the city of Zoela, in the district of Tarragon, that the first linen stuffs were manufactured; and the cloths of Xativa, or San Felippo, the ancient Sætabis, were famous through Greece and Italy. At Carthagena very fine stuffs were fabricated from the bark of trees; and the manufacture of woollen cloth had arrived at a high degree of perfection, and the Spaniards possessed the art of dyeing cloth of a very beautiful purple colour, which they learned of the Phœnicians, so that they supplied all Italy with this article. The Celtiberians knew the method of tempering steel, and nothing could resist the force of their swords. The manufactures of Spain, however, were injured by the invasion of the northern nations; and were again revived by the Moors, who exhibited to the Spaniards an example of genius, activity, and industry. The two nations, viz. the Moors and the Spaniards, divided between them the manufactures of Spain: those of leather, linen, silk, &c. were almost wholly in the hands of the Arabs; and those of arms, and articles fabricated of wool, were in the hands of the Spaniards. When the Moors were expelled in 1614, the manufactures which had flourished under their direction sunk into decay and ruin. The history of Spanish manufactures may be divided into three periods. The first commences with the re-union of all parts of the monarchy, under the reign of Ferdinand and Isabella; in the year 1475; and extends down to the death of Philip II. in the year 1598. The second comprises the reigns of Philip III. Philip IV. and Charles II., that is to say, during the whole of the 17th century. The third includes the 18th century; but strictly speaking, it did not begin till the year 1720.

The first was a brilliant period for Spain; manufactures of every kind were much increased, and for a time they became very famous. The second period witnessed their decline and decay, and their fall was as rapid as their elevation. Spain then no longer employed foreign merchandize. The third period furnishes an interesting index of the efforts which were used for a series of time to reinvigorate the national manufactures. During the first, Spain was in a flourishing state; but it had not then arrived at that high degree

of improvement described by the greater part of modern writers; who have affected to believe that the country then had attained the acmè of its wealth and splendour.

During the whole period that elapsed, from the commencement of the 14th to the close of the 16th century, Spain was perfectly independent of foreign nations; manufacturing the greatest part of its silk and wool, and exporting more manufactured than raw articles. But during the progress of the 17th century, the manufactures of cotton, linen, and hempen cloths, gloves, and swords, entirely vanished, and by the close of this century, scarcely the smallest vestiges remained, so that Spain was absolutely destitute of trade. When Philip V. ascended the throne, the intestine wars during the first fourteen years of that monarch's reign, and the low state of the national finances, prevented the government from paying any attention to the state of the country in this respect. Some measures were adopted for the revival of the manufactures, when tranquillity was restored. Ferdinand VI. did more for this purpose than any of his predecessors, and his successor Charles III. followed his example. The manufactures of Catalonia were the first that revived subsequent to the war waged respecting the right of succession. In a short period manufactures were established, and by a spirit of rivalry quickly multiplied. By degrees new branches of manufacture were adopted in various places, and the different ramifications are numerous at the present day. These are so numerous in the different provinces and towns of the country, that our limits will not allow an enumeration of them in this place. Some account of them occurs under the names of the respective provinces and towns, in the course of this work. The state of Spanish manufactures in the 15th and 16th centuries, will lead us to conclude that commerce was then in a flourishing condition; and its ramifications extended to all parts of Europe. Almeria, Valencia, and Barcelona, no less important, in a mercantile view, than the Hanseatic towns, pushed their commercial concerns into Syria, Egypt, Barbary, and the Archipelago. The trade of the country, however, was at this time very much, if not wholly, in the hands of the Jews; while the Spaniards were either engaged in war, or indulging themselves in a state of peace. The Moors conducted their agricultural and manufacturing concerns, and the Jews became their merchants and bankers. The expulsion of the Jews, in the year 1492, deprived Spain of its most active merchants; this was followed by the expulsion of the Moors, in 1614; so that commerce was deprived of its active and intelligent agents, and ceasing to be nourished by the produce of the soil, manufactures instantaneously disappeared. The Barbary pirates likewise infested the Mediterranean sea, and seized all the Spanish ships which sailed from the southern parts; and Spain being unable to defend commerce on the coast, the whole trade was carried on in foreign bottoms. The government also had adopted a system peculiarly calculated to paralyze commerce: it had restricted the colonial trade to entering by one port only on the continent, Seville first, and Cadiz afterwards. Moreover, during the war about the succession, Philip V. prohibited the exportation of all the produce of the country to the nations with which he was at war. The country at different times made fruitless attempts for reviving its commerce. Philip was scarcely in quiet possession of the throne, before he turned his attention to the revival of commerce; he encouraged manufactures, and conferred honorary rewards on trade; he granted premiums to merchants, and instituted commercial boards. Charles III. permitted a general trade, and moderated the duties imposed upon imported merchandize. In 1764 he established pack-

cts, which sailed regularly every month to the Havanna and Porto Rico, and others every two months for Rio de la Plata; and allowed every packet-boat to take out half a cargo of Spanish produce, and return half freighted with the productions of America. The Spaniards themselves displayed a spirit of activity and enterprise, of which they were thought to be altogether incapable. About the year 1728, the Caraccas company of Guipulcoa was established, and this company produced prompt and extensive advantages. This company was suppressed about the year 1781 or 1782. In the year 1784, a new company was formed, under the firm of "the Philippines;" and the ships belonging to this concern sailed from Cadiz; but though its commencement was promising, many unfavourable circumstances occurred, and it sustained very heavy losses; nevertheless, at the close of the year 1796 it derived a profit of nearly 229,166*l.* 13*s.* 4*d.* sterling. The internal trade of Spain is very inconsiderable, for want of sufficient means of communication; but it carries on a foreign trade with every country in Europe. The principal transactions, however, are with England, Holland, Italy, France, and its American colonies. The principal articles of foreign commerce are wine, brandy, oil, soda, barilla, fine wool, tobacco, dried raisins and figs, nuts, dates, sumac, anchovies, rice, kermes, salt, madder, bar-iron, and anchors. Although Spain exports immense quantities of its agricultural productions, it sends abroad none of its manufactured articles, but all those it receives from foreign countries. The following articles are imported into Spain, viz. from Holland, tapes, linen-drapery, common lace, cutlery goods, and paper;—from Silesia, linen-drapery;—from Germany, particularly Hamburg, quantities of haberdashery;—from England, calicoes, iron and steel goods, fine cloth, cod-fish, and ling;—from France, calicoes, linen-drapery, silk-stockings, silks, camlets, and other kinds of worsted stuffs, fine cloths, gilded articles, jewellery, iron goods, steel goods, haberdashery, and perfumery: and Spain carries on a considerable trade with her American colonies. Biscay is the only province of Spain that is interdicted a free trade with the colonies. The colonies supply Spain with coffee, sugar, some cotton, tobacco, cocoa, leather, and particularly gold and silver, both in ingots and coined into money.

The manufactures and commerce of Spain are considerably checked by the royal monopolies, which comprehend the following articles; viz. broad-cloth, at Guadalajara and Brihuega; china, at the palace of the Buen Retiro; cards, at Madrid and Malaga; glass, at St. Ildefonso; paper, in Segovia; pottery, at Talavera; saltpetre, at Madrid and various other places; stockings, at Valdenoro; swords, at Toledo; tapetry, at Madrid; and tiline, at Talavera. The king has also the monopoly of brandy, gunpowder, lead, quicksilver, sealing-wax, salt, sulphur, and tobacco. Most of the royal manufactures may be regarded as monopolies, as no private capital can vie with the treasury.

Government, Military, and Revenue.—Spain was never governed by a king who was not of foreign origin. Monarchs either of a Gothic or Moorish race, French or Austrian, or of the royal house of France, have occupied the Spanish throne from the year 411 till the present day. The Goths reigned in Spain from the year 411 till 711; the Moors from 711 till 716 in part of the Asturias, till 820 in Catalonia, till 750 in Sobrarba, till 923 in Leon, till 1073 in different parts of the two Castiles, till 1118 in Aragon, till 1236 in Cordova and Jaen, till 1248 in Seville, till 1264 in Valencia, till 1265 in Murcia, and even so late as 1492 in Granada. During the wars against the Moors, the Goths reigned

SPAIN.

reigned in the Asturias, Galicia, and finally in the kingdom of Leon till 1038.

The house of Navarre descended from the French house of Bigorre, which had previously reigned in Castile for ten years, united with it the crown of Leon till the year 1126. This was succeeded by the family of Bourbon, descended from the royal family of France, which reigned over these countries till 1555. The house of Charlemagne, a French family descended from that prince, ruled over Catalonia from the year 802 till 1132. The French family of Bigorre first reigned in Sobrarba, and afterwards in Aragon, from the year 750 to 1162; at that period the French family of Barcelona succeeded to the government, and united to the crown of Aragon that of Catalonia, and afterwards the kingdom of Valencia, over which it reigned till the year 1430. These parts of Spain then came into the possession of the princes of the French branch of Navarre, which reigned in Castile, and continued in their descendants to 1515; at which time the different states of the Spanish monarchy were under the government of Joanna the Foolish, who reigned over them till her death, which happened in 1555. The Austrian family then possessed the throne of Spain till 1700, since which time it was occupied by a branch of the house of Bourbon, till the late revolution, which placed the crown upon the head of Joseph I., brother of Napoleon Buonaparte, emperor of the French; but this revolution has terminated in the restoration of Ferdinand VII., who succeeded on the abdication of his father in 1808.

The Spanish government, which was of a limited nature, during the dynasties of the kings of Castile and Aragon, afterwards became an absolute monarchy.

Philip V. suppressed the states-general, their last meeting having been held at Saragossa in the year 1720; and since that period no further power is left to the Cortes of Castile and Aragon, but the privilege of sending deputies to the states-general, whenever they are summoned by the monarch. The whole authority centres at present in the king and his ministers; and the national affairs are conducted by the different councils appointed by the crown, which deliberate and form their plans in the capital: some of them possess both legislative and executive power, and exercise the double function of advising the king and administering the justice. The council of Castile, in this distribution of power, is paramount; its decrees being decisive in the courts, but its judgments are under the controul of the king. The chief councils in Spain are, 1. That of dispatches, called also the Junto, or cabinet council, being composed of the king and his ministers of state. 2. The council of state, in which the king presides, and of which the archbishop of Toledo is always a member. 3. The royal council of finances, called the Hazienda. 4. The supreme council of war. 5. The supreme council of Castile. 6. The supreme council of Aragon. 7. The supreme council of the inquisition. 8. The royal council of the orders of knighthood. 9. The royal council of the Indies. 10. That of the crusade, composed of a commissary-general, a member of the council of Castile, and another of that of Aragon, who manage the sale of little papal bulls, granting certain indulgences to the purchasers. In Spain there are five ministers of state; corresponding to our foreign secretary, secretary for the home department, secretary at war, first lord of the admiralty, and chancellor of the exchequer, or prime minister.

The laws of Spain are contained in several ancient codes; and recourse is also had to the civil and canon law. The "Escrivanos," or attorneys, are numerous, but instead of explaining the codes, they often impede the administration of justice. Mistaken mercy frequently retains criminals

in long durance, so that when they are executed their offence is forgotten, and the example of punishment has no effect.

With respect to the military of Spain we may observe, that when Philip V. ascended the throne, there were not 15,000 troops in the kingdom, and it had not a single ship of war fit for the sea. This prince directed his attention to military arrangement and discipline; and his successors, by following the same course, have obtained a respectable army; and by the increase and strength of its naval institutions, Spain has also become a maritime power. In the year 1807 the army staff included 5 captains-general, 5 inspectors, 87 lieutenant-generals, 123 field-marshal, and 213 brigadier-generals, besides military intendants, military commissioners, treasurers of the army, military judges, &c. The military establishment of the royal household consists of four companies of life-guards, a company of halbardiers or spearmen, a regiment of infantry called the Walloon guards, and a regiment of cavalry called the royal carabinieri. The life-guards are divided into four companies, the Spanish, the American, the Italian, and the Walloon; and each consists of natives of these respective countries. The militia is distinguished by the appellations of milices provinciales, or provincial militia, divided into 42 battalions, and distributed through the different provinces, and the milices urbanas, or civic militia, which neither receive pay nor are liable to be called away from their homes. The Spanish troops all wear a red cockade, except the Walloon and Swiss guards; that of the former being red and black, and that of the latter red and yellow. The whole military force of Spain, in time of peace, is computed at about 60,000. The naval forces of Spain consist of a marine staff, a corps of marine officers, a corps of naval cadet-guards, and three corps of engineers, artillery, and infantry, appropriated entirely to the service of the navy. The ships of the line can scarcely now be computed at more than 50.

The revenues of the king of Spain, on the continent, consist in monies arising from his own landed estates, customs, all kinds of taxation, &c.; which revenues amount at present, for the whole of Spain, to 8,097,813*l.* 6*s.* 4*d.* sterling, without including various considerable sums from different sources, which cannot be ascertained, for want of accurate information. The king of Spain also derives considerable revenues from the two Indies; but the expence of collecting, &c. is so great as to absorb nearly two-thirds. The total revenues of the Spanish colonies amount to 27,000,000 piastres fortes; and deducting expences, scarcely more than 9,000,000 piastres arrive at the royal treasury. The revenue of Spain has been stated by some writers at 5,500,000*l.* sterling, so that each person pays 10*s.* to government for protection. For the nature of the taxes we may refer to Laborde and Townsend's tables. The gabel is one of the most productive; and the clergy pay about 15,000,000 of rials. The expenditure now equals, or exceeds the income; and the national debt gradually enlarges. The colonies, as some of the best judges have estimated them, do not yield above 1,000,000*l.* sterling, exclusive of the duties. Bourgoing computes the revenues of Spain at 616,295,657 rials, and its money in circulation he states at 80,000,000 of dollars; estimating the rial at 5 sous of France, and the dollar at 20 rials.

Religion and ecclesiastical Government.—The religion of Spain is the Roman Catholic, professed with a degree of fanaticism which exceeds that of any Italian state, or even the Papal territory. The inquisition, established in 1480, by Ferdinand and Isabella, and lately restored with the return of the present sovereign, after its abolition, has produced

duced the most injurious effects; and the number of monks, under the obligation of celibacy, but under the influence of existing passions, has been very detrimental and even destructive to morals. The number of the Spanish clergy has been variously stated by different writers. Mr. Townsend states it at 188,625; others compute the clergy at 400,000. Laborde, in a table drawn up from the enumeration of them in 1788, reckons the secular clergy at 60,238, the ministers of churches at 15,834, the monks of 1925 convents at 49,238, and the nuns of 1081 convents at 22,347; and reckoning the population at 11,000,000, the clergy of Spain form one-sixty-ninth of the whole. Spain is divided into ecclesiastical provinces, over which presides an archbishop, with the rank of metropolitan: these provinces are again subdivided into dioceses, each of which is governed by a bishop. The archbishoprics are eight in number, and the suffragan bishoprics are forty-four. The archiepiscopal seat of Toledo is the first in rank, and the wealthiest in Spain: it confers on its possessor the title of primate, and a revenue of about 125,000*l.* sterling. The Mosarabic ritual, adopted in Spain, on the expulsion of the Arabs, declined after the introduction of the French princes, and was finally superseded by that of the Romish church. It still subsists, however, at Salamanca and Toledo, where are two chapels served by a numerous body of clergy, in which public worship is performed according to this ancient form.

The Spanish nation recognizes no authority or jurisdiction of the pope in the temporal concerns of ecclesiastical benefices. No briefs nor bulls are received, published, or executed in Spain, unless they have been examined by the chamber of Castile, and have received its *exequatur*, or licence.

In consequence of the same concordat, and of various briefs and royal edicts founded upon it, the king at present nominates not only to those benefices, the patronage of which belongs to the crown, but also to all the benefices in the patronage of the church, which become vacant during any of the eight months formerly reserved by the pope, as well as to all those that become vacant, in consequence of the former incumbents having been promoted by the king: the crown also issues licences, to enable those who are nominated to take possession of their preferments. The revenues of consistorial benefices, during their vacancy, go to the crown, on condition of their being applied to charitable uses. The annates, demi-annates, and quindennes, belong to the king, who also has the right of granting pensions on the archbishoprics and bishoprics, to the amount of one-third of their entire revenue.

The pope, however, still preserves in Spain two very important privileges, namely, the supreme administration of the *contentious jurisdiction* over all cases that are brought before the ecclesiastical tribunals, and the free and independent nomination to fifty-two of the best benefices. The imposts of various kinds and denominations, payable by the clergy of Spain, amount annually to about 437,840*l.* 18*s.* 2*d.* sterling, exclusively of some other charges. Burgoing, Townsend, Fischer, Laborde, Pinkerton.

History of the Music of Spain.—It seems as if a late musical historian had placed the Spaniards lower among European musicians, in the 15th and 16th centuries, than in equity they ought to have been, by imagining Morales the first practical musician of eminence in that country, and Salinas the only theorist that was produced there during the 16th century. (See *MORALES*.) Indeed we know but little of the state of music in the interior parts of that kingdom, during this period; but, if we may judge by the

musicians it furnished to the Papal chapel, both composers and singers, we may conclude, that the richest and most powerful nation in Europe, as Spain then was, would not breed musicians as the Africans do slaves, or the Circassians women, merely to transport them for the use or pleasure of others; they could doubtless then have afforded to keep a few for their own amusement.

The Spaniards, so far from neglecting music, seem to have taken it very early into the circle of the sciences, in their universities; for Salinas tells us, that the musical professorship, which was conferred upon him at Salamanca, had been founded and endowed by Alfonso, king of Castile, furnished the Wife. And Bartolomeo Ramis, the opponent of Franchinus, in 1482, was public professor of music at Toledo, and afterwards at Bologna. Of Guillerm de Podio, a priest, we have likewise a work, entitled “*Ars Musicorum, five Commentarium Musicæ Facultatis*,” published 1495; and another written in the Spanish language, by Francesco Trovar, “*Libro di Musica Pratica*,” Barcelona, 1519; “*Arte di Canto Llano*,” del Alfonso de Castillo, Salamanca, 1504; “*El Maestro o Musica de Vieguela de Mano*,” by Don Ludovicus Milan, a nobleman of Valentia, 1534; “*Silva di Sirenas*,” or a treatise on the vitruela, or viol, by Henrico de Valderrabano, Valladolid, 1547; “*Arte de la Musica*,” by Melchior de Torres, alcala de Herrerres, in New Castile, 1554. At the same place likewise was published, in 1557, “*Tratado de Cifra nueva para Tecla, Harpa y Vieguela Canto Llano, de Organ y Contrapunto*,” by Lud. Venegas de Hinestroia. There was likewise published at Alcala, by Cyprian de la Huerga, a Cistercian monk, who died 1560, a treatise “*De Ratione Musicæ et Instrumetorum Usû apud veteres Hebræos*,” and at Granada, 1555, “*Libro de la Declaracion de Instrumetos*,” by Joan Bermudo.

All these writers on the subject of music, and many more, appeared in Spain before Salinas; of whom an account is given under his biographical article.

Many more names of Spanish theorists and practical musicians might be enumerated here; but as we have neither seen nor heard any of their productions, we are unable to estimate their worth. In 1613, however, a work was published in Spanish, by Cerone, in folio, which contains more information concerning every part of the art and science then known, than any other elementary book which we have seen in any language. The title of this treatise is the following: “*El Mellopeo y Maestro. Tractado di Musica teorica y pratica*,” Napoli, 1613. See *CERONE*.

Andres Lorente was author of a treatise, now become very scarce, entitled “*El Porque del la Musica*,” 4to. 1672. For a farther account of this book, see *LORENTE*, and *Dr. WORGAN*.

Pablo de Zaragoza Nassarre was author also of a treatise on music, in Spanish, entitled “*Fragmentos Musicos*,” in four parts, a distinct treatise, 4to. Madrid, 1700. For a further account of this work, see *NASSARRE*.

About the middle of the last century was published at Madrid, in Spanish, “*An Essay on Church Music*,” by Feyjoo. We have never seen the book in the original, but an anonymous translation into English appeared in 1778. The author begins with a heavy complaint against the corruption and degeneracy of music, ancient and modern; joining with Plutarch in asserting, that music was at first only used in the temples of Greece; but passing to the theatre, a new and lighter style was invented, which being adopted in the temple, rendered it unfit for the serious service of religion. It was not till the latter end of the 17th century, that secular music, by additional refinements in singing, and improvements

improvements in instrumental music at the opera, was thought worthy of being introduced, on great festivals, into the church, in Roman Catholic countries: on other days, *canto fermo*, and masses set alla Palestrina, were continued, and are still continued in the cathedrals of Italy; though, even in the 16th century, masses *concertati*, or accompanied with a band of instruments, according to Montaigne, (*Journal d'un Voyage*,) were common throughout Italy and Germany.

We know not what the state of ecclesiastical music may be in Spain at present; but we have always understood that the music, *à capella*, in Spain, was more solemn and learned than elsewhere. The poet Yriarte, whose judgment and taste are correct and elegant, and who has no prejudices, except in favour of good music of every kind and country, speaks highly of the music of the church in Spain.

But Feyjoo's Essay is constant complaint and censure. Yet from the time of Charles V., an excellent musician himself, the Spanish monarchs have patronized music in a more distinguished manner, both in the church and the theatre, than any other sovereigns in Europe, till the late Charles VI., an *amouf*, who succeeded Ferdinand IV., and who turned Farinelli out of the kingdom, whose good conduct merited equal praise with his talents. See FARINELLI.

The author before us asks, whether all the music of the church should not be grave? We answer, no; not invariably. Are there not days and psalms of jubilation and thanksgiving, as well as of penitence, sorrow, and supplication! As the Calvinists confine all music to syllabic psalmody, this pious Spaniard would have no other music tolerated in the church than *canto fermo*.

We own the impropriety, and have censured it, in the admission of secular music in our cathedrals during the reign of Charles II. and his successors; when, in the compositions of Weldon and Dr. Greene, the divisions and ritornels wanted due gravity and dignity, and were manifestly introduced to display an active throat and a lively finger, for want of judgment and decorum in the composer, who forgot the place and occasion of the performance.

The Spanish writer very justly censures the admitting into the church the productions of insipid pretenders to composition, without genius or science; and finds, as is found every where else, that the number of bad composers and bad performers so far exceeds the good, that men of true genius and due cultivation are phenomena that rarely appear. Don Feyjoo has celebrated a Spanish composer, Don Antonio de Lites, whose name has never penetrated into other parts of Europe, in the highest terms of panegyric.

The Essay on Church Music was written about the middle of the last century, when the general style of Italy was frivolous, and that of Germany rude, pedantic, and inelegant; but so many great composers have appeared since in both countries, that Don Feyjoo's strictures have lost their force. There have been bad composers in all ages, but perhaps never more good ones at any period of time, than within the last 30 years.

Duron, the author, we supposed, meant Durante, was not only one of the greatest masters of harmony himself, but formed disciples of the greatest abilities that have ever issued from the Neapolitan school; but we find in Yriarte, that there had been among the masters of former times a Spanish composer of the name of Duron.

The rest of this Essay is exaggeration of invective, either to mortify Farinelli, and the great Italian composers and singers whom he engaged for the court of Spain, or to

flatter the successor of Ferdinand, who hated music, and expelled all the Italian musicians from his court.

The same anonymous gentleman has given us a translation of a letter of the learned Benedictine on the subject of music, entitled "The wonderful Effects of Music, and a Parallel between ancient and modern Music."

Here the author relates all the old stories of the miraculous powers of ancient music. He, however, doubts of the facts; and relates, *per contra*, what we have been told of the power of modern music over disease and the passions.

No new materials appear in this letter, or ingenious conjectures to determine the dispute, whether the ancients or the moderns had cultivated music most successfully; and the author leaves the subject just as he found it, without clearing up his own doubts, or those of his readers. He is always, however, inclined to give the preference to ancient music, without any thing to guide him but his prejudice, his determination to allow nothing that is new in music to be right, and the assertions by writers in favour of ancient counterpoint, that have been long since clearly confuted.

The last writer on music in Spain, that has come to our hands, is the ingenious and agreeable poet, Yriarte, of whose charming poem, "La Musica," we but lately procured the beautiful third edition, printed at the royal press in Madrid, in 1789, with elegant designs well engraved.

As this is a work but little known in our country, and does honour to the author, and to the art of practical music in all its branches, we shall be somewhat diffuse in our account of it.

D. Tomas de Yriarte writes like a man of the world, with an enlarged taste, and extensive knowledge of the subject. He has illustrated his doctrines from the most eminent moderns. Canto I. gives an outline of the general history of the musical art; calls on music itself to inspire and assist him, without applying to Apollo and his nine attendants, or even repeating old fabulous accounts of the miracles performed by Orpheus, Amphion, Linus, Terpander, or Olympus.

He describes the importance of *tone and time*. The first includes the formation of the scale, and its divisions into intervals; the second, the time-table, or musical characters for measuring the duration of sounds.

II. Musical expression; its use in the church, the theatre, the chamber, and to man alone; its powers over the passions.

III. The dignity and use of music, particularly in the temple, the theatre, in society, and in solitude; enumeration of celebrated ancient Spanish composers.

IV. Use of music in the theatre resumed; Jomelli; dancing, architecture, painting, poetry, decorations; modern composers for the lyric theatre celebrated.

V. Use of music in private society; eulogium on silence at concerts, and invective against those who attend not with due respect for the art and for talents; of opera scenes in concerts; of instrumental music proper for a concert-room; sonata, concerto, duo, trio, quartetto, symphony; necessity of variety and foreign music to keep off languor, and excite attention; praise of the German composers of instrumental music, particularly Haydn for invention; of the utility and delight which music affords in solitude, as well to those that are ignorant, as those that are learned in the art; of the study necessary for a good composer in examining the scores of celebrated authors, to detect errors and plagiarism, as well as to discover how good effects are produced; censures the pedantry of dry fugues and canons, that have no other merit than the difficulty of composing them; extraneous modulation; confusion of multiplied parts

parts in different styles and movements, which destroy the effect of each other; recommends the avoiding of all excesses of all kinds, as harmony, literally and figuratively, implies *just proportion*; celebrates the good taste which is manifest in the Royal Academy at Madrid, in the public distribution of premiums to artists in painting, sculpture, architecture, and engraving; to which have been added poetry and eloquence. It is proposed, in addition to all these arts, to establish an academy, or scientific body of music.

In the course of this last canto there is an animated eulogy on Haydn.

“Sólo á ta número, Háydén prodigioso,” &c.

“To thee alone the muses have confin’d
A genius ever fertile and refin’d;
So new thy strains, so copiously inspir’d,
That curiosity is never tir’d;
Thy works a thousand times repeated, still
With rapture new experienc’d ears can fill.

To sooth, to calm, or noble deeds inspire,
Thy fancy still is fed with heaven’s own fire.
In every trait a judge profound can find
Some grace or beauty of a higher kind;
Expression touching, modulation new,
In themes which none but gifted men pursue.

Surrounded by thy countrymen renown’d,
In thee alone the listening world has found
A power to interest, and render dear
Each sweet vibration of th’ enraptur’d ear.
To distant climes the happy means convey,
As light and heat sent forth from solar ray,
And while these inspirations wide expand,
Conferring honours on thy native land.”

SPAITLA, a town of Africa, in the kingdom of Tunis, anciently called “Sufetela,” represented by Dr. Shaw as one of the most remarkable places in Barbary for the extent and magnificence of its ruins. Here are found a triumphal arch of the Corinthian order; a pavement of large black stone, with a breast-high parapet on each side, which leads from the arch to the city; a beautiful portico at the end of the pavement, opening into a spacious court; the ruins of three contiguous temples, of which the columns, pediments, and entablatures are entire, &c. &c. Spaitla is pleasantly situated upon an eminence, shaded all over with juniper-trees; 110 miles S.W. of Tunis. N. lat. 35° 10'. E. long. 9° 10'.

SPALATRO, a sea-port of Dalmatia, situated on a peninsula, with a good harbour; the see of an archbishop. The harbour is large and deep, and well frequented by foreign vessels, which come for merchandize from Bosnia, such as iron, hides, wrought copper, wool, blankets, beeswax, orpiment, silk, cotton. Spalatro is built on the ruins of Dioclesian’s palace, for an account of which see SALONA. Without the walls is a sulphureous spring, of considerable service in chronical diseases. N. lat. 43° 22'. E. long. 16° 45'.

SPALDING, an ancient and respectable market-town in the wapentake of Elloe, parts of Holland, and county of Lincoln, England, is situated 8 miles W. from Holbeach, 41 miles S.E. from Lincoln, and 101 N. from London. Being in the midst of a fenny district, and almost encompassed by the river Welland, and an ancient drain called the Well-lode, and having numerous other drains in its vicinity, Spalding has been, with some degree of propriety, compared to a Dutch town. Though thus situated, and not apparently

congenial to healthfulness, its claim to antiquity is testified by many remains discovered in and about the town. That it certainly existed before the foundation of Croyland abbey, is evinced by king Ethelbald’s charter to that monastery, describing its bounds as extending “*usque ad ædificia Spaldeling.*” Prior to the Conquest the manor was the property of Algar, earl of Mercia; but was granted by the conqueror, with the whole of the division of Holland, to his nephew, Ivo Taillebois, who erected a castle here, of which the moat was to be distinguished in 1746, in that part of the Castle-fields called Coney Garth. In the year 1051, Thorold de Bokenhale founded and endowed a priory here, and made it a cell to Croyland; but the inhabitants were forced to abandon it after the Conquest, through the oppression of Taillebois, who about 1074 gave the church and manor to the abbey of St. Nicholas at Angiers, whence some Benedictine monks were sent over, and it became an alien priory. It was in succeeding times a monastery of great consequence. From this place Egelric, abbot of Croyland, made a firm causeway, named Elrick-road, through the marsh called Arundel forest, to Deeping, being an extent of twelve miles. It was formed by driving in piles of wood, which were covered with gravel. This road is now distinguished by the name of “The Gravel.” The conventual church not being sufficiently large, the prior pulled it down in 1284, and built the present parish church, which is a light structure, with a handsome spire, having crockets at the angles: the porch appears to have been added about the end of the 15th century. A free grammar-school was erected in the reign of Elizabeth, by the will of John Blanch. Another, called the Petty school, was founded in 1682, by Thomas Wellesley; here is also a blue-coat charity-school. An almshouse for twenty-two persons was founded in 1590; and another for eight widows in 1709.

For many centuries Spalding has been the principal seat of jurisdiction for the division of Holland. In the Saxon times the courts of law were held here by the earls; and subsequent to the Norman Conquest, the priors were invested with the judicial authority: even capital offences were cognizable in the conventual court. But at the dissolution of religious houses, the power of deciding on life and death was removed from all such inferior courts. Since that time a court of sessions has been held here; for which purpose a town-hall, or court-house, was erected, at the expence of Mr. John Holstan, at the north-west end of the market-place; the upper rooms are used for the quarter-sessions, the courts-leet and baron, and the courts of request and sewers; the lower part of the building is let out for shops, and the rents appropriated to the use of the poor, conformably to the will of the donor. Spalding, since the river Welland has been made navigable to the town, has had a good carrying and coaling trade. Barges of about 40 tons burthen come up to the centre of the town, where are quays and spacious store-houses: but vessels requiring a larger draught come only to Boston Scalp, nine miles distant. Attempts have been made to introduce manufactures into Spalding, but without success: the town derives its chief support from agriculture, and the extensive grazing carried on in its neighbourhood. Wool consequently forms a very prominent article in its trade; and some of the manufacturing towns of Yorkshire and Norfolk are supplied from hence. A market is held on Tuesdays, and five fairs annually, besides two statutes for hiring servants. In the population return of the year 1811, the number of houses was stated to be 951; the inhabitants 4330.

A literary society was established at Spalding in the beginning of the last century, under the auspices of Mr. Maurice Johnson,

Johnson, an eminent native of this town, on the principle of that of the antiquaries of London; to which transcripts of the minutes and records were regularly sent for upwards of forty years, till the death of Mr. Johnson, which happened in 1755.

In the vicinity of Spalding is Ayfcough Fee-Hall, the residence of Maurice Johnson, D.D., a descendant of Mr. Johnson above-mentioned. The mansion was built about 1420, but having been altered at different times, exhibits scarcely any thing of its original architecture. The present possessor has, however, endeavoured to restore it to its ancient character.

At Pinchbeck, about three miles north of Spalding, are some considerable remains of an ancient mansion, formerly called Pinchbeck-Hall, from a family of that name. Being afterwards possessed by the Otway family, it acquired the appellation of Otway-Hall. It appears to have been an extensive structure, and to have been built about the time of Henry VIII. It was moated round, and some of the windows have pointed lights with square heads. The chimnies are singularly lofty, and the gable ends have at the sides and centres, spire-shaped ornaments, crowned with ornamental balls. Beauties of England and Wales, vol. ix. Lincolnshire, by J. Britton, F.S.A.

SPALES, CROSS-SPALES, in *Ship-Building*, are deals or fir-planks, nailed in a temporary manner to the frames of the ship, at a certain height, and by which the frames are kept to their proper breadths, until some of the deck-knees are fastened. The main and top-timber-breadths are the heights frequently taken for spaling the frames, but that of the gun-deck ports is much better; yet this may be thought too high, if the ship is long in building.

SPALETHRA, or SPALATHRA, in *Ancient Geography*, a town of Greece, in Thessaly. Steph. Byz. Scylax states it to be a maritime town of Magnesia.

SPALMADORI, in *Geography*, a small island in the Grecian Archipelago, between the island of Scio and the continent of Asia. N. lat. $38^{\circ} 36'$. E. long. $26^{\circ} 7'$.

SPALT, a town of Bavaria, in the bishopric of Aichstat; 16 miles E.S.E. of Anspach. N. lat. $49^{\circ} 7'$. E. long. $10^{\circ} 52'$.

SPAN, a measure taken from the space between the thumb's end and the tip of the little finger, when both are stretched out.

The span is estimated at three hands' breadths, or nine inches.

SPAN, in *Rigging*, a short rope, having a block, thimble, or eye, spliced into each end: the middle is hitched round a mast, yard, gaff, cap, or stay, from whence the ends branch out. Spans are sometimes fastened at both ends, and a block, &c. in the bight. They are used to lead ropes through, which pass through blocks or thimbles, to increase power, or to prevent their swinging about. *Spanning of booms*, is confining them by several turns of rope. *Spanning of runners*, is taking several turns with small rope round both runners, abast the mast, and frapping the turns.

SPAN-*Shackle*, a bolt having a large ring in the head of it.

SPANANTHE, in *Botany*, a genus of umbelliferous plants, received by Jacquin from the Caraccas, and so named by him, from *σπανος*, rare, and *ανθος*, a flower, because of the scarcity of this tribe in tropical countries.—Jacq. Coll. v. 3. 248. Sprengel Umbellif. Prodr. 34.—Clafs and order, *Pentandria Digynia*. Nat. Ord. *Umbellifera*.

Gen. Ch. Cal. Umbel simple, of several rays; involucre of several lanceolate leaves; perianth of five ovate, acute, permanent leaves. Cor. *Universal* uniform; all the

flowers perfect and fertile; *partial* of five lanceolate, inflexed petals, channelled at the back. *Stam.* Filaments five, awl-shaped, erect, about as long as the petals; anthers roundish, of two lobes. *Pistl.* Germen inferior, ovate, rather compressed, with two lateral furrows, prominent, blunt and divided at the summit; styles two, awl-shaped, divaricated, shorter than the stamens; stigmas simple. *Peric.* none; fruit ovate, solid, transversely divisible into two parts. *Seeds* two, five-ribbed, contracted at their conjunction, convex at their sides.

Ess. Ch. Umbel simple. Involucrum of many leaves. Perianth of five permanent leaves. Petals undivided. Fruit oblong-ovate, solid. Seeds five-ribbed; contracted at their conjunction; convex at the sides.

1. *S. paniculata*. Panicked Spananthe. Jacq. Coll. v. 3. 247. Ic. Rar. t. 350. (Hydrocotyle Spananthe; Willd Sp. Pl. v. 1. 1363. Ait. Hort. Kew. v. 2. 118.)—Native of the Caraccas, according to Jacquin. It was also found in moist places near Lima, by Dombey, one of whose specimens, under the name of *Pbellandrium ciliatum*, was given to the younger Linnæus. We received a living one from the stove at Kew, in October 1790, an earlier period by five years, than is marked for the introduction of this curious plant by Mr. Aiton. The root is biennial, consisting of many fibres. *Stem* from one to three feet high, erect, branched, leafy, round, striated, smooth, hollow; sometimes partly zigzag. *Leaves* alternate, on long stalks, simple, triangular, or somewhat heart-shaped, from one to three inches broad, pointed, copiously ferrated; entire at the base; reticulated with numerous veins, which, on the upper side especially, bear a greater or less number of bristly hairs; the under side is paler and nearly smooth. The insertion of the footstalk is marked with a tuft of bristly hairs. *Stipulas* oblong, membranous, fringed, united to the base of the footstalk. *Umbels* simple, small, on long stalks, variously collected into branched panicles, or sometimes irregular compound umbels, accompanied by ovate, or lanceolate, ferrated *bracteas*. *Petals* white, inflexed, and partly heart-shaped; by no means so flat and spreading as in Jacquin's figure, from whence his description seems to be taken. We have not seen the ripe fruit, and have therefore been obliged to form our description thereof from Jacquin and Sprengel. The latter, in the *Prodromus* of his new arrangement of the *Umbellifera*, of which we hope to speak hereafter, in its proper place, has widely separated this plant from *Hydrocotyle*; and we have already, see HYDROCOTYLE, n. 13, hinted a doubt on this subject, which was suggested by the very different habit of *Spananthe*. But surely the learned author last named has widely erred, in classing *Hydrocotyle* among the genera with compressed flat fruit, like *Tordylium*, *Heracleum*, &c. Its fruit indeed is compressed, but transversely, not laterally, so as not to differ in that respect from the present genus; which, however, appears to us sufficiently marked by its large and permanent *perianthium*, to say nothing of the more oblong, and not semi-orbicular, shape of its seeds. If we were furnished with these in a perfect state, we should probably find other distinctive characters.

SPANCEL, in *Rural Economy*, a term signifying a rope to tie a cow's hinder legs while milking, &c.

SPANDAU, in *Biography*, a very pleasing and extraordinary performer on the French horn, in the service of the stadtholder at the Hague in 1772, who in 1773 came to England, where he was heard with the greatest pleasure. He contrived in his performance so to correct the natural imperfections of the horn, as to make it a chamber instrument. He played in all keys, with an equality of tone, and

as much accuracy of intonation in the chromatic notes, as could be done on a violin; by which means, and his delicacy, taste, and expression, he rendered an instrument which, from its force and coarseness, could formerly be only supported in the open air, in theatres, or spacious buildings, equally soft and pleasing with the sweetest human voice. In 1783 some exquisite pieces for the horn of his composition were circulated in MS. from the German and Dutch music-shops; but we believe they were never printed.

SPANDAU, in *Geography*, a town of Brandenburg, in the Middle Mark, situated on the Havel, at its union with the Spree. This town, though not large, is both flourishing and populous, with a considerable foundery of arms; 11 miles N.E. of Potsdam. N. lat. $52^{\circ} 33'$. E. long. $13^{\circ} 11'$.

SPANDEN, a town of Prussia, in Oberland; 14 miles E. of Holland.

SPANDONCEA, in *Botany*, a genus so called by professor Desfontaines, in honour of M. van Spaendonck, botanical draughtsman at the Royal Garden of Paris. This genus had previously been named in Italy *Panciatia*, and originally by Forkall *Cadia*; which last appellation, though of Arabian origin, has been retained. See CADIA.

SPANDRIL, in *Architecture*, the open space between the outward moulding of an arch, from its impost to the horizontal member or line which surmounts it.

SPANGENBERG, in *Geography*, a town of the principality of Hesse Cassel; 17 miles S.E. of Cassel. N. lat. $51^{\circ} 8'$. E. long. $9^{\circ} 36'$.

SPANGLES for *Paper-hangings*. See PAPER-hangings.

SPANHEIM, FREDERIC, in *Biography*, an eminent theological professor, was born in 1600, at Amberg, in the Upper Palatinate, where his father held an office in the electoral court. He studied at Heidelberg and Geneva, and in 1621 engaged himself as preceptor in the family of the governor of Ambrun, in Dauphiné, where he remained three years. From thence he passed to Paris, and afterwards paid a visit to England, and returning to Geneva, he obtained a chair of philosophy in the college in 1626. Soon after this he was admitted a minister, and in 1631 he succeeded M. B. Turretin in the professorship of theology at Geneva. The reputation which he acquired in the exercise of this office procured him various invitations, and having accepted one from the university of Leyden, he removed thither in 1642. In this situation he augmented his former reputation, as well by his lectures and sermons, as by the works which he composed. He passed a very laborious life, and died in the 50th year of his age. He was supposed to have shortened his days by the greatness of his labours, which are thus described. "He gave public lectures in theology four times a week, and private lectures of different kinds to his pupils; he examined candidates, and preached in two languages, *viz.* the German and the French: he was accustomed frequently to visit the sick, wrote a vast number of letters, and would compose, at the same time, two or three books on different subjects: he assisted every Wednesday at the prince of Orange's council at the Hague, and was rector of the university. Amidst all these various occupations, he found leisure to keep the accounts of his house, which was always well filled with boarders." Spanheim was a man of great learning and capacity, and he is thus characterized by Saumaïse, who felt no love for him. "He had a strong head, well filled with erudition: he was fitted for business, firm, ardent, and industrious. He was a rigid opponent of all that he regarded as innovation in doctrine; and readily entered into controversy, not only with the enemies, but with the friends of the church, when he suspected that they deviated from orthodoxy." He never, it is said, suffered phi-

losophy to intrude into the mysteries of theology, but exerted all efforts to keep the latter uncontaminated. His works were very numerous, and on divers subjects: some were political, as "Le Soldat Suedois," composed at the request of the Swedish ambassador; "Mercurie Suisse;" "Commentaire historique de la Vie et de la Mort de Christophe, Vicomte de Dhona;" "Memoires sur la Princesse Louise Juliane, Electrice Palatine." These were all published without his name: of his theological works, the principal is one on "Universal Grace;" "Dubia Evangelica;" "Epistola ad Buchananum de controversiis Ecclesiæ Anglicanæ;" "De Autore Epistolæ ad Hebræos."

SPANHEIM, FREDERIC, second son of the preceding, was born at Geneva in 1632, was likewise a professor of theology of high reputation. He studied under his father at Leyden, and began his career as a preacher in 1652, and by his overbearing eloquence, excited the jealousy of Alexander More, then famous in the United Provinces. Receiving an invitation from the elector-palatine to occupy the chair of theology at Heidelberg, he took the degree of D.D. at Leyden in 1655, and then took possession of his post. He acquired the esteem and confidence of the elector; and it is to the honour of both, that he did not forfeit them when he was the only person who strongly and firmly opposed that prince's design of divorcing his wife, and remarrying. He received invitations from several other universities, and accepted that from Leyden in 1670, when he was made professor of theology and sacred history, in performing the duties of which he acquired a very high reputation. His life was disquieted by some controversies in which he engaged, and into which none should enter who have not strong nerves, that will bear to be assailed by the weapons of an enemy. For several years before his death he was allowed to omit his duties as lecturer, in order that he might devote his whole time to learned writings. These were so numerous, that when collected, they filled three volumes in folio, which were printed at Leyden in 1701-3; in the former of these years the learned professor died. Among his works the most esteemed is a summary of ecclesiastical history of the 16th century.

SPANHEIM, EZEKIEL, an eminent scholar and statesman, eldest son of Frederic, was born at Geneva in 1629. He accompanied his father to Leyden in 1642, when he was already far advanced in the knowledge of the learned languages, and he soon acquired the esteem both of Saumaïse and Helvetius, who at this period were residents in that university. In 1651 he was nominated professor of the belles lettres at Geneva, and in the following year was admitted into the great council. His high reputation caused him soon after to be invited by the emperor to superintend the education of his only son, and in this situation he applied himself to gain a thorough knowledge of the public law of Germany. Having obtained leave to travel into Italy, he was charged by his master to watch over the political intrigues of the Catholic electors at Rome; and at the same time he made himself acquainted with the science of medals and classical antiquity. While out on this tour he was introduced to the celebrated CHRISTINA (see her article), then residing at Rome, who favoured him with a gracious reception, and also to the still more illustrious lady Sophia, electress of Hanover, who brought him back with her to Heidelberg in 1665. The elector-palatine, then engaged in various other projects, permitted Spanheim to enter into the service of the elector of Brandenburg, for whom he resided nine years in the quality of envoy-extraordinary. On his return to Berlin he was made one of the ministers of the state, and at the peace of Ryfwick, he was deputed again

to France. The elector, being now acknowledged king of Prussia, conferred upon M. Spanheim the title of baron, and sent him in the character of extraordinary minister to queen Anne of England. He was received at her court with all the respect and honour due to his merit, and was, on account of his talents, elected fellow of the Royal Society. He died in this country, at the age of 81. It is said of this author, that he filled his diplomatic character as if he were entirely detached from letters, and his literary character as if he had no concern with politics. His erudition was solid and extensive, of which he gave various proofs in his writings. The earliest of these were either theological or juridical; but he is best known as an antiquarian and critic. "His work," says his biographer, "entitled 'De Usu et Prestantia Numismatum Antiquorum,' in two volumes folio, is accounted one of the best treatises that ever appeared on the medallic science." His translation into French of the "Cæsars," of the emperor Julian, with illustrations; his edition of the same work, with a preface and notes; and his observations on Callimachus and other authors, with some dissertations on subjects of antiquity in the collection of Grævius, are reckoned extremely valuable contributions to critical literature. The wife of this learned professor, who died the year before him, was worthy to be his partner, from her extraordinary acquisitions, being mistress of various languages, and well acquainted with the philosophy of the ancients.

SPANIARD'S BAY, in *Geography*, a bay on the E. coast of the island of Cape Breton.—Also, a bay on the N. coast of the same island. N. lat. 46° 15'. W. long. 60° 20'.

SPANIEL, HISPANIOLUS, or *Canis Avicularius* of Linnæus, a variety of the *Canis familiaris*, a species of dog used in fowling. See DOG.

From the name, it may be supposed that we were indebted to Spain for this breed. There are two varieties of this kind; the first formerly used in hawking to spring the game, the same with our starters; the others used only for the net, and formerly called *index*, or *fetter*. This kingdom has been remarkable for producing dogs of this sort, particular care having been taken to preserve the breed in the utmost purity. They are distinguished by the name of English spaniels; so that, notwithstanding the derivation of the name, it is more than probable they are natives of Great Britain.

The pointer, which is a dog of foreign extraction, was unknown to our ancestors.

The aquaticus, or finder, in Dr. Caius's systematic arrangement (see DOG), was the same with our water spaniel, and used to find or recover the game that was lost.

The spaniel is of great use, but subject to many distempers; among these the mange is a very frequent one, and is the most pernicious of all others to his quiet and his beauty; and is very apt, when one dog has it, to spread to others that come in its way. As a remedy for this disease, some have recommended a decoction of a large quantity of brimstone, with some common salt and wood-ashes, in water and urine, of each equal quantities: this is to be used three or four times a day, washing the creature well with it before the fire, or in the warm sun. If this is not strong enough, the same ingredients, with the addition of a considerable quantity of wood-foot, are to be boiled in strong vinegar, and the liquor used in the same manner; but this must never be used in cold weather, as it would then endanger the creature's life.

When this disease is not in a violent degree, it may be cured by the herb agrimony internally taken. The method

is to pound the roots, leaves, and seeds of this plant in a mortar, and mix them with a large quantity of wheaten-bran; they are to be then made into dough in the common way, and baked in an oven; the dog is to have no other bread but this for some time, but he is to eat of this as often and as much as he will: this, without any further care, has cured many. See *Diseases of Dogs*, under DOG.

Another very troublesome disorder in this creature, is what is called the *formica*: this infests only the ears, and is caused by flies, and by the dog's scratching for them. The best medicine for the cure of these is this: take a quantity of pure and clean gum tragacanth, infuse it in white-wine vinegar; let as much vinegar be used as will serve to soften it, and when it has lain a week in it, let it be taken out and ground on a marble, as the painters grind their colours, adding to it rock-alum and galls, reduced to powder, of each two ounces; all this is to be well mixed together, and the matter, if it grows too stiff in the grinding, is to be moistened with some of the vinegar in which the gum was soaked: when all is thoroughly mixed, and ground fine, it is to be put in a gallypot, and a small quantity of it applied to the creature's ear every night, till the complaint is removed.

The swelling of the throat is another disease very common to spaniels, but the cure of this is easy; there needs only to bathe it well with oil of chamomile, and afterwards wash it with a mixture of vinegar and salt; this done night and morning, will, in a few days, wholly remove the complaint. Spaniels will sometimes, when they have much rest and good food, lose their sense of smelling, but this is recovered by a brisk purge and repeated airings; a very common dose, on this occasion, is a drachm of jalap, and two drachms of sal gem, mixed up into a bolus with oxymel of squills: this is to be rubbed over with some butter, and will be got down in that manner pretty easily, and will work briskly.

SPANIEL, *Gentle*. See LAP-DOG.

SPANISH *Academy, Bible, Black, Brown, Coinage, Coins, Epocha, Inquisition, Language, Measures, Order, Plough, Silk, Soap, Wax, and White*. See each article, and SPAIN.

SPANISH, or *Lisbon, Bean*, in *Agriculture*, the common name of a particular sort of bean, which is smaller than the long pod kind, but which ripens about the same time, and is very productive. See BEAN.

SPANISH *Broom*, in *Botany*. See SPARTIUM.

SPANISH *Chestnut*, in *Planting*, a tree of the deciduous timber kind. See CHESTNUT-TREE.

This is a most valuable sort of tree, as it affords, in a quick, speedy, and abundant manner, the best sort of hop-pole that has yet been met with, and which far surpasses that of the ash, being considerably more durable.

SPANISH *Elm*, in *Botany*. See CORDIA.

SPANISH *Flies*. See CANTHARIDES.

SPANISH *Juice*. See LIQUORICE.

SPANISH *Potatoes*, in *Gardening*, the common name of a plant producing white, tuberos, eatable roots, somewhat like large kidney potatoes of the same colour, and of a sweetish taste. They are usually brought here from Spain. See CONVOLVULUS.

SPANISH *Sheep*, in *Agriculture*, a breed of very fine short-woolled sheep, originally imported into this country from Spain. See SHEEP.

SPANISH *Windlass*. See WINDLASS.

SPANISH *Wool*. See SHEEP and WOOL.

SPANISH *Cove*, in *Geography*, a creek at the western extremity of the county of Cork, Ireland, between Crookhaven and Mizen Point.

SPANISH Creek, a river of Florida, which runs into the river St. Mary.

SPANISH Main, that part of the Atlantic ocean which washes the N. part of South America, from the Leeward islands to the isthmus of Darien. The term is also applied to the coast.

SPANISH Point, a cape on the N.E. coast of the island of St. Vincent. N. lat. $13^{\circ} 24'$. W. long. $61^{\circ} 12'$.

SPANISH River, a river and settlement on the island of Cape Breton.

SPANISH Town, or *St. Jago de la Vega*, a sea-port town of Middlesex county, and capital of the island of Jamaica, situated on the banks of the river Cobre, about six miles from the sea, and containing between 500 and 600 houses, and about 5000 inhabitants, including free people of colour. It is the residence of the governor, or commander-in-chief, who is accommodated with a superb palace; and here the legislature is convened, and the court of chancery and the supreme court of judicature are held. N. lat. $18^{\circ} 1'$. W. long. $76^{\circ} 44'$. See JAMAICA.

SPANISH Town, or *Virgin Gorda*, one of the Virgin islands in the West Indies, called also Pennilton, belonging to the English, and having two good harbours. N. lat. $18^{\circ} 20'$. W. long. $63^{\circ} 48'$. See VIRGIN ISLANDS.

SPANN, in *Commerce*, a corn-measure of Sweden; two spans being equal to a *Tunna*; which see.

SPANNBERG, in *Geography*, a town of Austria; 5 miles S. of Zisterzdorff.

SPANNER, in *Rural Economy*, the name of a wrench or nut screw-driver, which is often very useful for the farmer.

SPAR, in *Mineralogy*, a name given by working miners in England to all crystallized minerals which have a shining lustre: it is synonymous with *spath*, from the German.

The observation that spar is continually formed at this time in caves and grottoes under ground, has given birth to many different conjectures as to the origin of that substance. We have accounts from Switzerland, and other places, that the snow, by long lying on the earth, and being subject to repeated freezing, is at length hardened into spar: this is much of the nature of that opinion of the ancients concerning crystal, that it was water frozen by severe colds to a sort of ice, much harder than the common kind: both are equally erroneous and absurd. But more rational conjectures, as to its original, are, that it is produced either by effluvia alone, or by the joint force of effluvia issuing up from the depths of the earth, and mixing with water oozing out of rocks into their cracks and cavities, or by the same water or effluvia passing through beds of this sparry matter contained in clay. In the first place, we are to observe, that spar is capable of being dissolved either by water or vapour, and suspended imperceptibly in either; and that though it remains suspended a long time, yet there are occasions of its separating itself from either of these vehicles; such are long standing still, and evaporation. What is called the growth and formation of spar, therefore, is properly perhaps only the change of place in this substance; and all that these agents, waters and vapours do, is only to wash it out of the strata of earth or stone, in which it lay in scattered particles, and bring it together into the cracks and crevices of stones, where it may again separate itself, and become more pure and perfect.

The operation of nature, in this case, is very like that of art in extracting of salts from the various bodies they are mixed with; and spar, in its two states, when blended in the strata of stone, &c. and when pure, and in form of crystals in the cracks, may be compared to alum, for

instance, in its bed, and when purified. The alum, in the common stones from which it is made, is not perceptible to the eye, but lies in scattered particles; water being added to this, takes up the salt, and when it has been managed by evaporation and rest, yields it again purified and alone, and it forms such crystals on the sides of the vessel as the other does on the sides of the fissures of stone, which are the vessels where the water, out of which it was formed, was set to evaporate, and to rest a proper time.

That some spars grow from vapours alone is evident, from the stalactites, or stony icicles, hanging down from the roofs of our caverns, which, though they grow downwards, yet have many times little plants of the same substance growing out at their sides, and standing upwards, contrary to the growth of the other, and evidently formed of the matter separated from the vapours in their ascent, as the stalactites themselves are from such as have ascended to the roof, and there been condensed into water, and sent down again in drops. Nor is the sparry matter alone thus raised in vapour, for even the metals, and other bodies as little likely as those to be thus raised, yet are found to form stalactites.

The mundics, in general, though they never form regular stalactites, yet often are found adhering to the sides of them, and the metals, particularly iron and lead, form regular stalactites; the iron ones very common and very perfect; the lead less perfect and more rare; and Dr. Brown gives us abundant instances of spars growing entirely from vapours in the baths of Buda in Hungary.

Mr. Beaumont is of opinion, that earth by degrees will ripen into spar; but this is an error. He founds his opinion on certain stalactites, and stalagmites, found in caverns, partly earth, and partly spar, and supposes that the whole would in time become spar; but there is nothing in nature to warrant this conjecture. Phil. Trans. N^o 129.

M. de Jussieu has given us, in the Memoirs of the Paris Academy, a very remarkable account of the recrystallization, or reproduction, of the parts of spar, after solution. Mem. Acad. Paris, 1719.

The denomination of spars, says the editor of the Chemical Dictionary, is given to many stones of different properties and appearances, which do not possess constantly any one common character or mark, by which they may be certainly distinguished from other stones. In general, we may observe, that they are most frequently found in mines, and that they generally consist of smooth and shining plates or laminæ; that some are transparent, and others opaque; that some are colourless and others coloured; that they are crystallized in various determinate figures, or possess no determinate shape; and, lastly, that they differ so much in hardness, density, degree of fusibility, and in their most essential chemical properties, that they cannot be considered as forming a distinct class of fossil substances.

The several stones to which the name of spar has been given are, the calcareous, the gypseous, the fluors, and felspar. Calcareous spars are soft heavy stones, which have the common chemical properties of calcareous earth. The texture is laminated, some of them have no determinate figure, and others from their form are called rhomboidal. Some spars, called dog's-tooth spars, have a pyramidal figure; but when these are broken, their fragments shew that they also consist of rhomboidal particles. Some rhomboidal spars are transparent, others are opaque; some are colourless, and others are coloured; and some of them have a property of doubly refracting the rays of light: this spar has been called refracting spar, or island crystal. Its figure

is that of an oblique parallelepiped, contained within six parallelogrammic sides, and eight solid angles. Each of the obtuse angles of the parallelograms is $101^{\circ} 52'$; and each of the acute angles is $78^{\circ} 8'$. These calcareous spars may be distinguished from others by effervescing with acids.

The gypseous, or selenitic spars, are gypseous earth, distinctly crystallized. The form of the crystals is rhomboidal. They are also called selenites and glacies Mariæ. These spars sometimes assume other forms, and are very heavy.

Mr. Margraaf has shewn, that under this class are to be comprehended those white opaque spars, which by calcination with inflammable matters are capable of receiving a phosphoric quality, similar to that of the Bolognian stone, which he also shews is a gypseous spar. For the spars called fluors, see FLUOR.

The felspar, or *spatum scintillans*, differs from all the preceding, in being too hard as to be capable of striking ignited sparks from steel. For which reason it is referred by Cronstedt to the siliceous class of earths, and by him called rhombic quartz, because the particles of which it consist seem to be parallelepipeds, each of which is contained within six rhomboidal sides. Its colours are various, white, grey, and red.

Several other fossil substances consist of large plates, and are, therefore, said to have a sparry texture. Such are some kinds of talcs, of hornblende, of quartz, of amianthus, and some calciform ores of metals.

SPARS, in *Medicine*, have from the earliest times been recommended in nephritic complaints. Some have used one kind, some another, as the lapis judaicus, the sparry incrustations of caverns, petrified oyster-shells, and water in which large quantities of spar are sustained. After all, the nephritic virtues of spar want sufficient proof; some even suspect its use to be more hurtful than beneficial. See CRYSTAL.

SPARADRAP, SPARADRAPUM, in *Pharmacy*, &c. an ancient name for a kind of fear-cloth; or a linen-cloth smeared on both sides with some kind of plaster, or unguent.

The sparadrap is sometimes also called *tela Gualteriana*, or *tela Gualteri*; sometimes *tela emplastica*.

It is prepared by melting a sufficient quantity of some plaster or unguent, and dipping a linen-cloth therein, till such time as it hath imbibed its fill. It is then taken out, cooled, and polished on a marble.

SPARAGUS, or ASPARAGUS, *Sprage*, in *Botany*. See ASPARAGUS.

SPARAXIS, so named by Mr. Gawler, now Ker Belenden, from *σπαρξεν*, a tearing, or plucking, in allusion to the torn appearance of the sheath, which makes a principal part of the generic character.—Ker in Sims and Kon. Ann. of Bot. v. 1. 225. Ait. Hort. Kew. v. 1. 85.—Class and order, *Triandria Monogynia*. Nat. Ord. *Ensatæ*, Linn. *Irides*, Just.

Gen. Ch. *Cal.* Sheath inferior, of two membranous, dry, unequal, clasping valves, torn and shrivelled at the extremity. *Cor.* of one petal, superior; tube funnel-shaped, slender at the base; limb dilated, in six segments, either regular or irregular, spreading or partly erect. *Stam.* Filaments three, inserted into the upper part of the tube, thread-shaped, straight, a little inclining, rarely ascending, much shorter than the limb; anthers oblong, incumbent. *Pist.* Germen triangular; style thread-shaped; stigma three, spreading, recurved, oblong, downy. *Peric.* Capsule roundish-oblong, full of unequal swellings, thin, of three cells and three valves. *Seeds* numerous, globose.

Ess. Ch. Sheath of two valves, membranous, dry, jagged. Corolla tubular. Stigmas three, oblong, recurved. Capsule roundish-oblong, tumid.

Obf. The character of this genus chiefly depends on its sheath, which is large, and exhibits its distinctive marks, as above described, sufficiently clearly. The limb of the corolla is either regular and spreading, or converging downwards, or two-lipped, with an erect hood; in which last case the *stamens* and *style* are upright, otherwise spreading, or inclining. The *bulb* is solid, ovate, pointed, clothed with reticulated scales. The *stem* most frequently bears axillary bulbous buds. *Leaves* from six to ten, sword-shaped, with fine parallel ribs. *Flowers* rather large, and somewhat distant from each other; never crowded or numerous. *Ker.*

1. *S. anemoniflora*. Large White Sparaxis. Ker n. 1. (*Ixia anemoniflora*; Willd. Sp. Pl. v. 1. 200. Jacq. Ic. Rar. t. 273.)—Stem single-flowered, as tall as the leaves. Corolla regular; its segments obovate, four times as long as the tube.—Native of the Cape of Good Hope. Cultivated by Jacquin. The *stem* is about a foot high, simple, oblique, with five or six leaves at the bottom only, which are linear and glaucous, the longest of them nearly equal to the stem. *Flower* two inches in diameter, pure white, with yellow anthers; its tube equal to the sheath, which measures about a quarter of an inch.

2. *S. fragrans*. Sweet Yellow Sparaxis. Ker n. 2. (*Ixia fragrans*; Willd. Sp. Pl. v. 1. 197. Jacq. Ic. Rar. t. 274.)—Stem usually two-flowered, shorter than the recurved leaves. Corolla regular; its segments elliptic-lanceolate, thrice as long as the tube.—Native of the Cape. Cultivated by Jacquin. *Stem* a span high, leafy. *Leaves* linear, narrow, green, about twice the length of the stem, all more or less recurved. *Flowers* about half the size of the foregoing, yellow, with white many-cleft sheaths.

3. *S. tricolor*. Three-coloured Sparaxis. Ker n. 3. Ait. n. 1. (*Ixia tricolor*; Curt. Mag. t. 381. Schneevogt. Ic. t. 39. Redout. Liliac. t. 129.)—Stem two or three-flowered, taller than the erect lanceolate leaves. Corolla regular; its segments obovate, twice the length of the tube. Sheath corrugated, spotted.—Native of the Cape, from whence it was introduced into the Dutch gardens, and thence into ours. It flowers, like the rest of its family, in the frame or greenhouse, about May. The *foliage* is green. *Flowers* peculiarly splendid, as large as the first species; their tube and base of the limb yellow; middle of the limb marked with an angular, or arrow-shaped, dark purple, or chocolate-coloured, spot; all beyond it of an orange scarlet. The sheaths are wrinkled, furrowed, brown, copiously dotted with a darker tint.

4. *S. galeata*. Hooded Flesh-coloured Sparaxis. Ker n. 4. (*Gladiolus galeatus*; Jacq. Coll. v. 4. 167. Ic. Rar. t. 258. Willd. Sp. Pl. v. 1. 212, excluding most of the synonyms.)—Corolla irregular; its upper segment spreading. Leaves elliptic-oblong.—Native of the Cape: cultivated by Jacquin. The *stem* is leafy, a span high. *Leaves* equitant, vertical, broad, many-ribbed, and obtuse. *Flowers* about three, flesh-coloured or pale purplish; the lower lip yellow: the upper segment, or hood, is remarkably divaricated. Perhaps the irregularity of the corolla would rather authorize the referring this and the following, as most authors have done, to *Gladiolus*, near our fourth species of that genus. See GLADIOLUS.

5. *S. bicolor*. Purple and Yellow Sparaxis. Ker n. 5. Ait. n. 2. (*Ixia bicolor*; Ker in Curt. Mag. t. 348. *Gladiolus bicolor*; Thunb. Diss. n. 16. t. 2. f. 1. Willd. Sp. Pl. v. 1. 216. Jacq. Ic. Rar. t. 240.)—Corolla irregular; its segments converging. Leaves lanceolate.—From the same country.

country. Introduced at Kew in 1786, by Mr. Mallon. The *leaves* are narrower, and more acute, than in the last. *Flowers* three or four, with spotted *sheaths*; their tube, and two lateral segments, pale yellow, or whitish; hood purple; lip deep yellow.

6. *S. grandiflora*. Large-flowered Sparaxis. Ker n. 6. Ait. n. 2. (*Ixia grandiflora*; De la Roche Diff. 23. Curt. Mag. t. 541. Redout. Liliac. t. 139. *I. aristata*; Thunb. Diff. n. 15. Ait. ed. 1. v. 1. 57. Willd. Sp. Pl. v. 1. 203. Andr. Repof. t. 87. *I. foliis gladiolatis*, &c.; Mill. Ic. t. 237. f. 3. *I. uniflora*; Jacq. Ic. Rar. t. 283. *I. holosericea*; Jacq. Hort. Schoenbr. v. 1. 9. t. 17.)

β. Curt. Mag. t. 779.

Corolla regular; its segments obovate-oblong, four times the length of the tube. Stamens and style inclining. Sheath with many awl-shaped segments. Leaves erect, lanceolate.—Native of the Cape. Long since cultivated in the gardens of Europe. The *stem* is about a foot high, bearing usually three or four handsome *flowers*; sometimes but one. *Leaves* equitant, scarcely glaucous, usually much shorter than the stem. *Sheaths* striated, ending in many lax taper segments, of their own length. *Corolla* full two inches wide; usually of a rich deep satin-like purple, edged with white, and paler beneath; but in the variety β, it is whitish, or sulphur-coloured, with some central spots, on the upper side; violet beneath. It must be allowed that authors have multiplied figures of this species in a most blameable manner.

7. *S. bulbifera*. Bulb-bearing Sparaxis. Ker n. 7. Ait. n. 4. (*Ixia bulbifera*; Linn. Sp. Pl. 51. Willd. Sp. Pl. v. 1. 204. Andr. Repof. t. 48. Curt. Mag. t. 545. Redout. Liliac. t. 128. *Ixia foliis linearibus glabris*, caule foliolo bulbifero; Mill. Ic. t. 236. f. 2.)—Corolla regular; its segments elliptical, acute, four times the length of the tube. Stamens inclining. Sheath deeply torn. Leaves erect, lanceolate. Stem bulbiferous, somewhat branched.—From the same country as the last, and known as long in our gardens. It is taller than that species, with paler *leaves*. The *stem* is generally branched and leafy, bearing a few bulbs at each joint, by which the plant may be increased. Each branch usually bears two distant *flowers*, rather smaller than the foregoing, but with the same silky aspect, though their colour is a uniform pale yellow, or white; and their segments are more acute.

8. *S. fimbriata*. Fringed Sparaxis. Ker n. 8. (*Ixia fimbriata*; Lamarek Dict. v. 3. 339. *I. foliis gladiolatis nervosis*, &c.; Mill. Ic. t. 237. f. 1, 2.)—Corolla regular; its segments elliptical, obtuse, four times as long as the tube. Stamens erect? Sheath deeply torn. Leaves erect, bluntish, about as tall as the simple, zigzag, three-flowered stem.—Native of the Cape of Good Hope. Cultivated by Miller. We adopt this species, (though omitted by Mr. Dryander in Ait. Hort. Kew.) on the authority of the authors quoted, for we have had no opportunity of investigating it. Its humble growth, and the abruptness of the *leaves*, seem to indicate a specific difference from the two last. The *stem* bears no bulbs, and is quite simple; leafy at the base only. *Flowers* large; white or yellowish above; tinged with violet beneath. Miller represents both *style* and *stamens* erect, but we dare not implicitly rely on this. The *sheaths* are split into numerous very long and slender segments.

Mr. Ker merely mentions an eighth species, under the name of *S. lacera*, seen by him in sir Joseph Banks's herbarium, with which we are unacquainted.

SPARENBERG, in *Geography*, a town and citadel of Westphalia, in the county of Ravensberg; 2 miles S.E. of Bielefeld.

SPARGANIUM, in *Botany*, *σπαργάνιον* of the Greeks,

a very expressive ancient name, derived from *σπαργάνιον*, a *fillet*, or *bandage*, and alluding to the long flat linear form, and pliant texture, of the ribband-like foliage—Linn. Gen. 480. Schreb. 621. Willd. Sp. Pl. v. 4. 199. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 961. Ait. Hort. Kew. v. 5. 235. Brown Prodr. Nov. Holl. v. 1. 338. Pursh v. 1. 33. Juss. 26. Tourn. t. 302. Lamarek Illustr. t. 748. Leers Herborn. t. 13. f. 11. Gærtn. t. 19.—Class and order, *Monocotyledonia*. Nat. Ord. *Calamaria*, or rather *Piperite*, Linn. *Typha*, Juss.

Gen. Ch. Male flowers numerous, collected into a head. *Cal.* Perianth of three linear, coloured, erect, deciduous leaves. *Cor.* none. *Stam.* Filaments three, capillary, longer than the calyx; anthers oblong.

Female, *Cal.* as in the male. *Cor.* none. *Pist.* Germen ovate, tapering into a short awl-shaped style; stigma oblique, undivided, downy, channelled along the upper side, permanent, usually simple, rarely double. *Peric.* Drupa dry, turbinate, pointed; angular at the base. *Seed.* Nut hard, oblong-ovate, angular, usually solitary; occasionally there are two.

Eff. Ch. Male, Calyx of three leaves. Corolla none. Female, Calyx of three leaves. Corolla none. Drupa dry, with a solitary nut.

1. *S. ramosum*. Branched Bur-reed. Hudf. 401. Fl. Brit. n. 1. Willd. n. 1. Pursh n. 1. Curt. Lond. fasc. 5. t. 66. Engl. Bot. t. 744. Bauh. Theatr. 228. Ger. Em. 45. (*S. erectum*; Linn. Sp. Pl. 1378.)—Leaves triangular at the base; concave at the sides. Common flower-stalk branched. Stigma linear.—Common in ditches, and about the banks of ponds and rivers, throughout Europe; more rare, according to Mr. Pursh, in North America. It appears to be the *σπαργάνιον* of Dioscorides, being the only species Dr. Sibthorp observed in Greece. It is perennial, flowering in July and August. *Root* creeping. *Stem* erect, about a yard high, round, leafy, smooth, alternately branched at the top in a paniced manner. *Radical leaves* triangular at the base, with concave sides; their upper part erect, sword-shaped, smooth, much taller than the stem; *stem-leaves* gradually shorter, flat, clasping at their base. *Partial flower-stalks* racemose, many-flowered; zigzag in the lower part. *Heads* alternate, sessile, globose; the lower ones female, brown; upper male, closer and more numerous, with yellow *anthers*. *Calyx-leaves* spatulate, brown. *Germen* of two cells. *Stigma* elongated, linear, usually solitary; when there are two stigmas, there seem to be two seeds also. The *Sparganium* of Morison, sect. 8. t. 13. f. 2, seems an *Alisma* or *Sagittaria*.

2. *S. simplex*. Unbranched Upright Bur-reed. Hudf. 401. Fl. Brit. n. 2. Willd. n. 2. Pursh n. 2. Curt. Lond. fasc. 5. t. 67. Engl. Bot. t. 745. (*S. erectum* β; Linn. Sp. Pl. 1378. S. n. 345.* Linn. Fl. Lapp. ed. 1. 271. ed. 2. 280. *S. non ramosum*; Bauh. Theatr. 231. *S. latifolium*; Ger. Em. 45. *S. alterum*; Bauh. Hist. v. 2. 541. Lob. Ic. 80.)—Leaves triangular at the base; flat at the sides. Common flower-stalk simple. Stigma linear.—Native of ponds throughout Europe, especially on a gravelly soil, flowering in July and August. More frequent in North America, according to Mr. Pursh, than the *ramosum*, from which Hudson and Curtis first well distinguished this species. It is a smaller plant, and never branched or paniced. The lowermost head of *flowers* is generally stalked; the rest being sessile. *Calyx* green, or whitish, not brown. *Stigma* elongated, mostly simple.

3. *S. natans*. Floating Bur-reed. Linn. Sp. Pl. 1378. Willd. n. 3. Fl. Brit. n. 3. Pursh n. 3. Engl. Bot. t. 273. Fl. Dan. t. 260.—Leaves drooping, flat. Com-

mon flower-stalk simple. Stigma ovate, very short. Head of male flowers nearly solitary.—Native of rivers, pools, and lakes, in Europe and North America, chiefly on a muddy or clay soil, flowering in July. The root is long, perennial, creeping widely. Herb floating, with long flat leaves, half the size of the last; the upper ones sheathing. Cluster of few heads of flowers, of which the top one only, with sometimes a portion of the next, is male; the lowermost is stalked. The short, broad, ovate, always solitary, stigma best distinguishes this from *S. simplex*. Willdenow persists in citing the *Fl. Lapp.* for this, though he refers to it properly under the preceding, except that in both cases he omits the asterisk.

4. *S. angustifolium*. Narrow-leaved Bur-reed. Br. n. 1. (*S. angustifolium*; Michaux Boreal-Amer. v. 2. 189? *S. natans* β; Pursh n. 3?)—"Leaves flat, lax, longer than the stem. Heads of male flowers numerous. Stigma oval. Drupa obovate, even; depressed at the summit."—Found by Mr. Brown near Port Jackson, New South Wales. If the synonyms be right, it is also a native of rivulets in Canada.

SPARGANOPHORUS, from *σπαργανον*, a fillet, and *φειω*, to bear, because the seed is crowned with a membranous band, or border.—Vail. Act. Paris. ann. 1719. Gært. v. 2. 395. t. 165. Michaux Boreal-Amer. v. 2. 95. Pursh v. 2. 518.—We have already spoken of the plant of Vaillant and Gærtner under ETHULIA, (see that article,) of which, in our opinion, it constitutes a genuine species. Perhaps that of Michaux and Pursh may belong to the same genus, but we dare not, without examination, assert this. The word *Sparganophorus*, though not exactly compounded of *Sparganium*, may be thought rather too near to that name, and we, on many accounts, prefer *Ethulia*.

SPARGANOSIS, from *σπαργω*, to swell, in Surgery, an abscess of the breast; a milk-abscess.

SPARGUS, in Ichthyology, a name given by Gaza to the common sparus, which he calls also *fluta*.

Artedi calls it the plain yellow sparus, with an annular spot near the tail. See SPARUS.

SPARHAWK POINT, in Geography, a cape on the north coast of the mouth of the river Piscataqua.

SPARKS'S ISLAND, a small island in the bay of Honduras, at the mouth of the river Roman. N. lat. 15° 54'. W. long. 86° 5'.

SPARLING, in Ichthyology. See SMELT.

SPARLING-FOWL, in Ornithology, a name given in some places, by the country people, to the female merganser, called more usually the *dundiver*.

SPARNECK, in Geography, a town of Germany, in the principality of Culmbach; 3 miles S.S.E. of Munchberg.

SPARRE, ERIC, in Biography, chancellor of Sweden, was born in 1550; but from this time we have no account of him till 1578, when he was appointed supreme judge of Westmanland and Dalecarlia; and in 1582 he became a senator, governor of these provinces, and vice-chancellor of the kingdom. In 1583 he was knighted by king James VI. of Scotland; and in 1587 he went as envoy to Poland, respecting the elevation of Sigismund to the Polish throne. Within about two years from this time he fell in disgrace, was deprived of his employments, and thrown into prison. He was likewise accused of high crimes against the sovereign, John III. On this occasion his letter of knighthood was taken from him by the king, and torn to pieces before his face. He was, however, pardoned, on the intercession of king Sigismund; but was again arraigned, in 1592, before a court at which the king himself presided, on a charge

of having promised the cession of Esthonia, in direct contradiction to the instructions which he had received, when envoy of Poland. He defended himself with great boldness against all his accusers; which so incensed the sovereign, that he drew his sword, exclaiming, that it was given him by God to punish traitors and breakers of their oath. Duke Charles brought forth other accusations against him; but the court broke up, after coming to this conclusion, that Sparre, and the other senators who had been accused with him, were neither condemned nor acquitted. Sparre fell again under the duke's displeasure, on account of a celebrated book which he wrote, entitled "Pro Lege, Rege, et Grege;" which seemed to be directed against the authority exercised by that prince. Having, however, taken an oath of fidelity to the duke, and made a solemn promise of obedience in writing, he was restored to his employments; and, as chancellor of the kingdom, subscribed, in 1593, the reconciliation between him and Sigismund. Notwithstanding this, he was afterwards delivered up to the duke, and suffered under the hands of the executioner, during the bloody scenes that took place at Linköping, in 1600; but he maintained his innocence to the last, and read a protest against those who had doomed him to punishment. He was author of many books, besides the one already referred to, "Pro Lege," &c. among which are the following: "Account of the Coronation of king Sigismund at Upsal, February 19, 1594;" "Sententia Ordinum Regni Sueciæ in quosdam de Collegio Senatorum," &c.; "Adversus Infimulationes et Protestationes à Regis Sigismundi legato Polono, Oratione prolata, Defensio." Gen. Biog.

SPARRING, among Cock-fighters, is the fighting a cock with another to breathe him. In sparring, they put hots on their spurs, that they may not hurt one another.

To spar the cock, imports in general to breathe him, in order to embolden him to fight. See HORTS.

SPARRMANNIA, in Botany, so named by the younger Linnæus, in honour of his distinguished countryman, Andrew Sparrmann, or rather Sparman, the friend and pupil of his father, and the companion of the voyage of the Forsters, round the world. This gentleman is well known in England by the account of his travels in southern Africa, which display great candour and love of truth, as well as the true spirit of Linnæan philosophy and accuracy. He is, we believe, still living in Sweden.—Linn. Suppl. 41. Schreb. 355. Willd. Sp. Pl. v. 2. 1160. Thunb. Nov. Gen. 88. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 3. 298. Juss. 290. Lamarek Illustr. t. 468.—Clas and order, *Polyandria Monogynia*. Nat. Ord. *Columnifera*, Linn. *Tiliaceæ*, Juss.

Gen. Ch. Cal. Perianth inferior, of four lanceolate, undivided, spreading, nearly equal, deciduous leaves. Cor. Petals four, equal, wedge-shaped, flat, undivided, twice the length of the calyx. Nectary? of several thread-shaped, tumid, corrugated, or toothed, bodies, more properly to be esteemed imperfect filaments, or stamens, partly changed to petals. Stam. Filaments numerous, thread-shaped, inserted into the receptacle, about half the length of the petals; anthers ovate, incumbent. Pist. Germen superior, roundish, hispid, with five angles; style thread-shaped, longer than the stamens; stigma in many minute segments. Peric. Capsule five-sided, with five cells; its angles armed with long, straight, rigid, spreading thorns, each tipped with a sharp transparent point. Seeds two in each cell, oblong, smooth, keeled at one side.

Ess. Ch. Calyx of four leaves, deciduous. Petals four. Barren filaments numerous, toothed. Capsule of five cells, angular,

angular, armed with straight pungent spines. Seeds two in each cell.

Obf. Ventenat has justly remarked that the supposed nectaries are, as well as the perfect stamens, inserted into the receptacle, and not, as Schreber after Thunberg asserts, into the germen, and that they are properly to be considered as imperfect stamens.

1. *S. africana*. African Sparmannia. Linn. Suppl. 265. Willd. n. 1. Ait. n. 1. Retz. Obf. fasc. 5. 25. t. 3, (but the synonym, habitat, and all that follows, belong to the preceding *Lagerstromia*.) Curt. Mag. t. 516. Venten. Malmaif. t. 78.—Native of woods and thickets, on the sides of hills, at the Cape of Good Hope, flowering from October to January. It was introduced at Kew, in 1790, by Mr. Masson, and makes a most elegant and splendid appearance in the collection of greenhouse shrubs, in the spring, and early part of the summer. The whole plant is clothed with fine, silky, spreading hairs. *Stem* shrubby, erect, two to six feet high, with round, alternate, leafy branches. *Leaves* alternate, stalked, dependent, large, heart-shaped, pointed, crenate, slightly lobed, veiny, resembling those of some Mallow, *Sida*, or *Hibiscus*. *Stipulas* awl-shaped, lateral, in pairs near the base of each *footstalk*. *Flowers* in large, terminal, hairy umbels, like those of a Cape Geranium, with awl-shaped *bractees*. *Calyx* downy, pale brown, not quite an inch long. *Petals* white, wrinkled, often emarginate. *Filaments* yellow, partly crimson. *Anthers* brown. This shrub is propagated, without much difficulty, either by cuttings or seeds; but we know not whether the latter are often perfected in Europe.

SPARROW, PASSER, in *Ornithology*, the name of a large order of birds. See PASSERES.

SPARROW, *Common*, or *Houfe*, the *Fringilla domestica* of Linnæus, is a well-known bird, and needs no description. Sparrows are proverbially falacious; they breed early in the spring, often in the nests of the martin, after expelling the owner; the martin, however, in revenge, is said to assemble its companions, and to assist in plastering up the entrance with dirt, and thus leaves the invader to perish. See FRINGILLA.

SPARROW, *Hedge*, *Curruca*, or *Motacilla modularis* of Linnæus, a bird of the size of the red-breast, or of the titlark. Its beak is longish, slender, and black; its head is of a deep brown, mixed with ash-colour; the cheeks are marked with oblong spots of dirty white; the back and coverts of the wings are dusky, edged with reddish-brown; the quill-feathers and tail dusky; the rump brown, tinged with green; the throat and breast are of a dull ash-colour; the belly of a dirty white; the sides, thighs, and vent-feathers are of a pale tawny brown; and the legs of a dull flesh-colour. This bird frequents low hedges, particularly those of gardens; making its nest in some small bush, where it lays four or five eggs of a fine pale blue colour; and during the breeding-season it has a remarkable flirt with its wings. The male has a short but very sweet plaintive note, which it begins with the first frosty mornings, and continues till a little time in the spring.

The bird which Linnæus supposes to be our hedge-sparrow, which he describes under the title of *motacilla curruca*, and to which he applies the denomination of *cannavarola*, differs in colour of plumage as well as eggs. Pennant.

It is in the nest of this bird that the cuckoo hatches her eggs for the most part, though not always, the nests of turtle and wood-pigeons being sometimes used by her for that purpose. Hence it was that the ancients made the cuckoo an emblem of such men as made bold with the mar-

riage-bed of others, who, on that account, were called *currucæ*. See MOTACILLA.

SPARROW, *Reed*, *Passer arundinaceus*, the *Emberiza seboenicus* of Linnæus, a bird that lives most commonly among reeds in marshy places, and known among authors by the name of *junco*.

Its nest is curiously contrived, being fastened to four reeds, and suspended by them like a hammock, about three feet above the water. It lays four or five eggs of a blueish-white, marked with irregular purplish veins. This bird is much admired for its song, and like the nightingale it sings in the night. In the male, the head, chin, and throat, are black; the tongue livid; at each corner of the mouth commences a white ring, which encircles the head; at approach of winter the head changes to hoary, but on return of spring resumes its jet colour; the whole under side of the body is white; the back, coverts of the wings, and the scapular feathers, are black, deeply bordered with red; the two middle feathers of the tail are of the same colours, the three next black; the exterior web, and part of the interior of the outmost feather, are white: the head of the female is rust-coloured, spotted with black; it wants the white ring round the neck, but in most other respects resembles the male. Pennant. See EMBERIZA.

SPARROW, *Lesser Reed*, *Willow Lark*, or *Sedge-bird*, *Passer arundinaceus minor*, the *Motacilla faliaria* of Linnæus, is a species of a slender elegant form; the head brown, marked with dusky streaks; over each eye a line of pure white, over that another of black; cheeks brown; throat, breast, and belly white, the two last tinged with yellow; hind-part of the neck and back of a reddish-brown; the back spotted with black; coverts of the tail tawny; coverts of the wings dusky, edged with pale brown; quill-feathers dusky; tail brown, and in the form of a wedge, and making a circle when spread, and legs dusky. This bird is common in low wet grounds, sits on the top of some spray with its wings dishevelled; its song consists of but two notes, which are loud, querulous, and harsh. Pennant.

Ray observes, that the lesser reed sparrow sings sweetly, and some have called it *cannavarola*. See MOTACILLA.

SPARROW, *Solitary*. See PASSER Solitarius.

SPARROW, *Tree*, *Passer montanus*, the *Fringilla montana* of Linnæus, is inferior in size to the common sparrow; the bill is thick and black; the crown of the head, hind part of the neck, and lesser coverts of the wings, are of a bright bay, the two first plain, the last spotted with black; the chin black; the cheeks and sides of the head white, marked with a great black spot beneath each ear; the breast and belly of a dirty white; just above the greater coverts is a row of feathers, black edged with white; the greater coverts are black, edged with a rust-colour; the quill-feathers dusky, edged with pale red; lower part of the back of an olive-brown; the tail brown, and legs of a straw-colour.

These birds are common in Lincolnshire, among trees, and collect, like the common kind, in great flocks. Pennant. See FRINGILLA.

SPARROW, *Water*, *Passer aquaticus*, a bird described by Nieremberg, which, he says, the Indians call *acotolequichitl*. It sings all day long without ceasing, but with no very pleasing note. It is, however, a well-tasted bird. It lives among sedge and bushes, and is of the size and shape of a swallow, but has a black bill and yellow legs; its breast and belly are white, and its back is of a brownish-yellow, variegated with spots of black and white. This bird much resembles our reed sparrow. Ray.

SPARROW, in *Agriculture*, a mischievous destructive bird in corn-fields, and which should mostly be destroyed. It

is observed, that were all the farmers in a neighbourhood to agree to their destruction, by offering rewards for their heads, their numbers might be lessened; and that were the practice general, surely the whole race might be extirpated. It is supposed, that sixpence a dozen the first year, nine-pence the second, and a shilling the third year, would nearly reach their complete extirpation. To enforce which, it should be considered how soon twelve sparrows destroy twelve penny-worth of wheat.

In Kent, they use a species of trap, which is very effectual in taking them. It, according to Mr. Marshall, consists of a small wicker basket, resembling the fruit-sieve of the London markets, with a cover of the same material fitted to it, and formed on the principle of the fish-pot, and the vermin trap, into which the entrance is easy, but the return difficult. These traps, which are an ordinary article of sale in the markets of the district, are constituted of brown unpeeled osiers. The diameter about two feet; the depth nine inches; the cover is somewhat dishing, with a tunnel, or inverted cone, in the centre, reaching to within an inch of the bottom of the basket; the aperture or entrance, formed by the points of the twigs, of which the tunnel is constructed, being about an inch and a half in diameter. And the usual bait is wheat scattered in the basket. The number caught at once, is frequently more than theory would suggest; the contentions of a few that have entered, seldom failing to bring others to the combat.

These mischievous birds, however, soon grow too cunning to be taken in any sort of trap to any extent, which has a chance of extirpating and destroying the race; consequently some more effectual and certain plan, such as that suggested above, or some other, which is better and more fully adapted to the purpose, must be had recourse to in order to completely exterminate them, and prevent the injury they do annually to the farmer, in the destruction of his wheat and other crops. Though these are only small birds, they destroy vast quantities of grain, much more than has indeed been commonly supposed. It is stated to have been calculated to have amounted to a hundred facks of wheat, besides the oats and barley, in the course of only one season, in a township of no very great extent in the north-western part of the kingdom. Where rewards or sums of money are paid for the taking or destroying them, no advantages are gained, except where there are sufficiently ample and proper regulations entered into and enforced, the whole district, parish, or township becoming partakers in the business. No languid or half measures will do any thing useful, or to the purpose, in this sort of undertaking.

It is not improbable, but that these destructive birds might be greatly extirpated and thinned down in their numbers, by the use of some tasteless infusion of a strongly poisonous nature, either to the ears of the grain at the time of harvest, or to the naked grain in the winter season, when they are extremely eager for food, as they are constantly found to remain hovering about houses or other buildings, where the effects of such trials might easily be ascertained. If such a method should succeed, the whole race might readily, and with great facility and certainty, be exterminated.

SPARROW-Grass, in *Botany*. See ASPARAGUS.

SPARROW-Hawk. See HAWK.

SPARROW-Wort, in *Botany*. See PASSERINA.

SPARRY, in *Mineralogy*, having a confused crystalline structure, synonymous with spathose.

SPARRY Iron Ore, denominated also *brown spar* and

pearl spar, is a mineral composed of the oxyd of iron combined with about thirty-five *per cent.* of carbonic acid, and a variable portion of manganese, lime, and magnesia. (See IRON ORES.) As *pearl spar*, this mineral may be classed among the earthy minerals. It has a white colour, passing by various gradations into brown, with a pearly lustre; in the pure white specimens the lustre is brilliant. It occurs in small curved rhomboidal crystals, which do not melt before the blow-pipe, but dissolve with effervescence in muriatic acid. This mineral is generally found in veins, accompanying metallic ores, but is never worked as an ore of iron.

SPARS, in *Rural Economy*, a name often applied to thatching rods, or the spels or rods by which thatch is bound on the roofs of buildings.

SPARS, in *Ship-Building*, small fir-trees; called *cant*, which are from 33 to 35 feet long, and five hands circumference; *barling*, from 30 to 28 feet long, and four hands circumference; *boom*, from 24 to 20 feet long, and three hands circumference; *middling*, from 20 to 16 feet long; and *small*, from 16 to 11 feet long.

SPARSE-LEAVES, *Sparfa folia*, among *Botanists*. See LEAF.

SPARTA, in *Ancient Geography*, a celebrated city of Greece, in the Peloponnesus, and the capital of Laconia. It was situated at the foot of mount Thernax, on the banks of the Eurotas, and to the W. of it.

According to Strabo, this city was founded by Patrocles; but the most common opinion attributes its origin to Leles, in the year 1516 B.C. Some maintain that it originated at Lacedæmon in the year 400 B.C. However this may be, it was known also by this name. However, the appellation of Spartans is applied to the inhabitants of Sparta and its territory, and that of Lacedæmonians to the inhabitants of the whole country of Laconia. (See LACONIA, and LACEDÆMONIANS.) This country was not equal in extent to Athens, containing only 48 *stadia*; but it was adorned in a very eminent degree. At first it had no walls, the Spartans confiding in their own valour for its defence. In process of time, however, they constructed walls about it, when the ambition of Cassander, and the violent assaults of some tyrants, had wearied out and almost exhausted their fortitude. Pausanias says, that it was fortified on occasion of the wars of Demetrius and Pyrrhus, and he mentions in terms of high commendation some pieces of sculpture, for which this city was distinguished. Sparta was famous for a variety of public institutions, among which were the senate of the aged, the senate of the conservators of the laws, the senate of the ephori, and that of the magistrates, denominated *Bidæans*. The first of these was the sovereign tribunal of the Lacedæmonians, which regulated the affairs of the state; the other senators were, properly speaking, archons; the ephori were five, and the *Bidæans* of the same number, whose province it was to direct and superintend the exercises of the youth. The public edifices, temples, statues, and monuments of Sparta, were so numerous and various, that we should far exceed our limits in recounting them. It is not certain at what time this celebrated place was destroyed; but it was succeeded by the modern town of Mistra, which is situated about four miles from ancient Sparta.

SPARTA was also the name of a town situated in the environs of the Euxine sea. Steph. Byz.

SPARTA, in *Geography*, a post-town of America, in Sparta county, North Carolina; 541 miles from Washington.—Also, a post-town of New Jersey, in Suflex county; 117 miles from Philadelphia.—Also, a post-town of Han-

cock county, Georgia, with a court-house and gaol, situated in a fertile and populous country, and a place of considerable trade.

SPARTA, a post-township of New York, in the S.W. corner of Ontario county, 25 miles S.W. of Conondaigua; bounded N. by Genesee and Livonia, E. by Livonia and Naples, S. by Steuben and Allegany counties, and W. by Genesee county. It comprises three townships. The alluvial lands are fine, and the territory is in general good and well settled, principally by emigrants from Pennsylvania. Hemp is raised in considerable quantities. In 1810 the whole population was 1397, with 65 senatorial electors; and the household looms, of which there are 56, produced 17,772 yards of cloth. The whole number of families is 232.

SPARTACUS, in *Biography*, one of the scourges of Roman tyranny and cruelty, a native of Thrace, was born of very low parents, entered the army, then became a deserter, and a robber. Being taken, he was confined as a gladiator in a receptacle at Capua for those unfortunate men whose lives were devoted to the pleasure of the Roman people. He escaped the horrid den, and placing himself at the head of a body of gladiators and fugitive slaves, he took a fortified place in the year B.C. 72, whence he made predatory excursions throughout Campania. His force daily increased, and he defeated several commanders who were sent against him. He marched into Cisalpine Gaul, in order to give the slaves in his army, who were mostly Thracians and Gauls, an opportunity of returning home. Part of them, however, greedy of pillage, separated themselves from their commander, and were cut to pieces. The consul Lentulus, upon this success, which was extremely partial, pursued Spartacus, who turned about and gave him a total defeat; and then, in his turn, becoming the aggressor, he marched against the other consul, Gellius, drove him from the field, and obliged him to take shelter in the walled towns. He retaliated the cruelty of the Romans towards the gladiators, by obliging a number of his captives to fight with each other round the funeral pyre of one of his commanders. He was now at the head of 120,000 men, and with these he ravaged most of the provinces of Italia, and struck such a terror at Rome, that Crassus, at that time the man of the greatest consequence in the city, was sent against him. He soon confined Spartacus in Lucania, and cut off some of his detachments, so that he would gladly have crossed over to Sicily, but being prevented, he took post in a peninsula near Rhegium, where Crassus enclosed him by a rampart drawn from sea to sea. Spartacus, however, found means to break through this barrier, and gain the open country, but he was here deserted by a large body of his followers, who became the victims of Crassus. Spartacus now retreated towards the mountains, and repulsed with loss some of his pursuers. This success was, however, his ruin; for his men insisted upon his return to give battle to Crassus in the open field. Before the commencement of the engagement, Spartacus stabbed his horse, exclaiming, "If I am victorious, I can easily get another; if vanquished, I shall not want any." After a long contest, the Roman discipline prevailed. Spartacus, during extraordinary exertions of valour, was surrounded, and fell pierced with a multitude of wounds. He was unquestionably a brave man, and something more than a courageous barbarian. He had, says Plutarch, not only strength and elevation of mind, but a discernment and civility much superior to his fortune. It is said that his wife accompanied him into the field, pretended to the gift of prophecy, and probably inspired him with a fanatical confidence in victory.

SPARTANBURG, in *Geography*, a district of South Carolina, containing 12,122 inhabitants, of whom 147 are slaves.

SPARTEL, CAPE, a cape of Morocco, W. of Tangier, being a headland, which divides the straits from the Western ocean. After doubling this cape, at the distance of 15 miles stands the little town of *Arzilla*; which see.

SPARTIANUS, ÆLIUS, in *Biography*, a Latin historian, flourished in the time of Diocletian, to whom he dedicated the lives of Adrian, Ælius, Verus, Didius Julianus, Severus, and Pescennius Niger, which, as well as his lives of Caracalla and Geta, are come down to our times. He is one of the writers of the "Historiæ Augustæ Scriptores," but his merits are not very great.

SPARTINA, in *Botany*, a name borrowed from *Spartum*, a kind of broom, or of hard grass, both used in ancient as well as modern times, to make baskets, cordage, &c.—Schreb. Gen. 43.—Class and order, *Triandria Monogynia*. Nat. Ord. *Gramina*.

Gen. Ch. *Cal.* Glume single-flowered, compressed, of two boat-like, compressed, keeled, converging valves; the innermost longest; the broader one striated at the back, and pointed. *Cor.* shorter than the inner valve of the calyx, of two nearly equal, linear, compressed, bluntish valves, clasping each other, the inner one rather the longest. Nectary none. *Stam.* Filaments three, capillary, very short; anthers linear, square, sharpish, cloven at the base. *Pist.* Germen superior, linear, acute; style thread-shaped, erect, longer than the stamens; stigmas two, villous. *Peric.* none, except the calyx, which enfolds the seed, and at length drops it. *Seed* oblong, compressed.

This is all the account we have found of the present genus, of which its author has left nothing concerning the species, whether one or more, nor its native country. These points can only be ascertained from his herbarium; and as yet *Spartina* has not been adopted by any writer that has fallen in our way, though it seems to have the sanction of Schrader in his *Flora Germanica*, v. 1. 169. That author, so learned in grasses, strongly objects to Roth's having referred to *Spartina* by the name of *phleoides*, the *Crypsis schœnoides* of Schrader, Lamarek, and others; as being, he says, widely different, both in habit and the structure of its flowers. *Spartina* however does not find a place in his *Flora Germanica*, and is, therefore, perhaps not of European growth.

SPARTIUM, *σπαρτίον* of Dioscorides, so called from *σπαρτήν*, a rope, because of the use of the long, slender, tough branches, or bark, in making cordage.—Linn. Gen. 368. Schreb. 487. Willd. Sp. Pl. v. 3. 926. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 4. 254. Sm. Fl. Brit. 753. Prodr. Fl. Græc. Sibth. v. 2. 53. Gærtn. t. 153. (Genista; Juss. 353. Tourn. t. 411. Lamarek Illustr. t. 619. f. 1.)—Class and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, somewhat heart-shaped; its margin at the upper side very short; at the lower furnished with five little teeth towards the extremity; coloured, small. *Cor.* papilionaceous, of five petals; standard inversely heart-shaped, very large, entirely reflexed; wings ovate-oblong, shorter than the standard, attached to the filaments; keel of two petals, lanceolate-oblong, longer than the wings, inserted into the filaments, the lower edges of its petals connected by fine hairs. *Stam.* Filaments ten, combined all together at the base, adhering to the germen, unequal, gradually longer; the upper one very short, the remaining nine in one set; anthers rather oblong. *Pist.* Germen oblong, or roundish; style awl-shaped,

shaped, ascending; stigma united to the upper side of its summit, oblong, villous. *Peric.* Legume cylindrical, long, obtuse, of one cell and two valves. *Seeds* several, kidney-shaped, somewhat globose.

Eff. Ch. Stigma longitudinal, villous above. Filaments monadelphous, adhering to the germen. Calyx extended downward.

The Linnæan genus of *Spartium* is, by Jussieu, sunk, partly in *Genista*, after Tournefort, and partly in *Cytisus*. The species in the fourteenth edition of *Syst. Veg.* are sixteen; Willdenow has twenty-five; three of the Linnæan ones being referred to Thunberg's *Lebeckia*. They are all shrubby, with yellow, rarely white, still more rarely purplish, flowers, and either simple or ternate leaves. One only is a native of Britain, though all the rest are of European growth; sixteen are enumerated amongst our garden plants by Mr. Aiton; some of them bearing the open air, others requiring the shelter of a greenhouse; but none of them very tender. As some of the others promise to be well worthy the notice of cultivators, and are easily propagated, we shall take a brief view of the whole, introducing one nondescript species, and offering a few corrections respecting some of the rest.

Section 1. *Leaves simple.*

1. *S. junceum*. Spanish Broom. Linn. Sp. Pl. 995. Willd. n. 1. Ait. n. 1. Curt. Mag. t. 85. Sm. Fl. Græc. Sibth. t. 671, unpublished. (*S. macrolobium*; *Renalm. Spec.* 34. t. 35. *Genista hispanica*; *Ger. Em.* 1313. *Genista*; *Matth. Valgr. v. 2.* 574.)—Branches opposite, round, flowering at the extremity. Leaves lanceolate. Legume linear.—Native of the south of Europe. Frequent, according to Dr. Sibthorp, on dry hills throughout Greece and the Archipelago, where it is known by the name of *σπάγιο*, being unquestionably the *σπαγιον* of Dioscorides. This shrub was one of the first exotics introduced into cultivation in England, where it is quite hardy, flowering most part of the summer, and much esteemed for the beauty, and sweet luscious scent, of its large yellow blossoms. Its height is usually six feet or more, and the copious, long, twiggy, tough branches, bearing a few elliptic-oblong leaves, make a singular appearance. The flowers are sometimes double, but are not improved in beauty by that change.

2. *S. aphyllum*. Leafless Siberian Broom. Linn. Suppl. 320. Willd. n. 2. Pallas Voyage, v. 3. append. 742. t. V. f. 2.—Branches round, straight, wand-like, smooth, subtended by very short, linear-lanceolate, close-pressed, withering leaves. Petals all smooth. Legume ovate, with two seeds.—Found by Pallas in blowing sand of the deserts about the river Wolga, flowering in June. The stems, though shrubby and often six feet high, die down every year. They are slender and much branched, with a small, inconspicuous leaf under each branch. Flowers scattered along the ultimate branches, solitary, on short stalks, small, dull violet; yellowish at the base. Legume a quarter of an inch long, gibbous, compressed, silky, as well as the calyx, flower-stalks, and young branches.

3. *S. monospermum*. White single-seeded Broom. Linn. Sp. Pl. 995. Willd. n. 3. Ait. n. 2. Curt. Mag. t. 683. (*Pseudo-spartium album aphyllum*; *Ger. Em.* 1318.)—Branches round, furrowed. Clusters lateral, of a few rather crowded flowers. Seeds solitary. Leaves lanceolate, silky, as well as the wings and keel.—Native of dry barren hills in Spain, Portugal, and Morocco. A hardy greenhouse plant with us, flowering in June and July. The stem is five or six feet high, with numerous slender, pliant, glaucous, furrowed branches, bearing, while young only, a few simple,

linear-lanceolate, obtuse, silky leaves. Flowers in short, lateral, dense clusters, white, with a dark-red smooth calyx. The standard is streaked minutely with crimson, and silky at the back, about half an inch long. Wings and keel partly, but densely, silky. Seed solitary.

4. *S. sphaerocarpum*. Yellow single-seeded Broom. Linn. Mant. 571. Willd. n. 4. Ait. n. 3. (*S. hyposphærolobium*; *Renalm. Spec.* 35. t. 33. *Pseudo-spartium hispanicum aphyllum*; *Ger. Em.* 1318.)—Branches round, furrowed. Clusters lateral, many-flowered, solitary or in pairs. Seeds solitary. Leaves lanceolate, downy beneath. Wings smooth. Keel somewhat silky.—Native of the south of Europe. A greenhouse plant, cultivated in Miller's time, flowering in June and July. Of more humble growth than the preceding, with more erect, straighter branches, and yellow flowers, not half so large, though more numerous in each cluster. Though the two plants are very distinct, their specific definition is not easy. We agree with Mr. Curtis, as to the probability of Clusius's wooden cuts, and consequently those of Gerard above cited, (which are the same blocks as those of Clusius,) being transposed. Yet we cannot say they are so, for though the inflorescence of Gerard's f. 1, applied to this yellow species, is more like the former, and *vice versa*; the size of the flowers in f. 2 is too large for the present.

5. *S. trifpermum*. Yellow Three-seeded Broom.—Branches round, striated, racemose. Leaves very short, spinous-pointed. Wings smooth. Keel silky. Legume half-ovate, with three seeds.—Gathered on mount Ætna, by the baron Bivona, from whom we, last year, received specimens. This is allied to the two last, though essentially distinct in its fruit, which more resembles that of *S. aphyllum*, n. 3, but is nearly smooth, not silky, and contains three roundish seeds. The flowers, moreover, are disposed as in that species, being loosely scattered along the young branches, not composing lateral clusters: but they are thrice as large, yellow, and fragrant, with more oblong petals, and the keel is silky, in which last character this species agrees with *sphaerocarpum*. We have not seen the young leaves, but those under the flowering branches are small, thick, short, furrowed, with a strong sharp point.—The figure of *Spartium*, *Matth. Valgr. v. 2.* 573, answers well to our plant, except that the flowers are represented much too short, and the legumes too hairy, in which latter circumstance it answers better to *S. purgans*, though, in other respects, not like that species; still less does it resemble the following.

6. *S. cinereum*. Grey-branched Broom. "Villars Prospect. 40." Willd. n. 5. (*Genista scoparia*; *Villars Dauph. v. 3.* 420. *Bellardi Append. ad Fl. Pedem.* 34.)—Branches round, with ten furrows. Leaves lanceolate; silky beneath. Flowers axillary, solitary; their stalks not longer than the calyx. Keel silky. Legume hairy.—Native of sunny hills in the south of France and in Piedmont. The branches are much more leafy than in any of the foregoing. Leaves nearly sessile, about three quarters of an inch long; smooth above. Flowers yellow, much longer than the leaves, on short silky stalks. The calyx also is silky, deeply divided. Keel silky, especially toward the lower edge. Legume hairy, with from three to five seeds. Gerard, from whom, as well as from Bellardi, we have specimens, mistook this plant, as many others have done, for *S. purgans*; but Willdenow well remarks, that the more erect and straight branches, and especially the shortness of the flower-stalks, distinguish it from that species. Villars thinks it may have been confounded with *S. scoparium*, which seems hardly possible. He conceives the figure of Matthioli, *Valgrisian edition, v. 2.* 573, badly copied in Bauhin's *Matthioli*, 852.

SPARTIUM.

f. 1, may have been done for this plant; but it more resembles our *trispermum*.

7. *S. virgatum*. Long-twig'd Broom. Ait. n. 4. Willd. n. 6. (Cytifus tener; Jacq. Coll. v. 1. 40. Ic. Rar. t. 147. Linn. Syft. Veg. ed. 14. 667.)—Branches round, furrowed. Leaves obovate, rather filky. Flowers axillary, solitary, somewhat racemose. Petals all filky. Legume densely hairy.—Found by Mr. Maffon in Madeira, whence it came to Kew garden in 1777. It is a greenhouse shrub, flowering in spring. The copious slender branches bear numerous alternate leaves, half an inch long. The flowers are yellow, very filky in every part, and form clusters at the end of each branch, two or three of the lower ones only being axillary. Legumes lanceolate, pointed, clothed with short dense hairs, and containing three or four round seeds, which are seldom all perfected.

8. *S. ramosissimum*. Branching African Broom. Desfont. Atlant. v. 2. 132. t. 178. Willd. n. 7.—Branches round, furrowed, straight. Leaves obovato-lanceolate, villous. Flowers axillary, on short stalks, somewhat whorled. Petals all filky.—Native of mount Atlas, near Tlemsen. A shrub, two or three feet high, leafless when old, flowering early in the spring. The flowers are yellow, erect. Legume not observed, but the germen is villous. Desfont.

9. *S. purgans*. Purging Broom. Willd. n. 8. Ait. n. 5. But not Linn. Syft. Nat. ed. 12. v. 2. 474. (Genista purgans; Bulliard t. 115. G. five Spartium purgans; Bauh. Hist. v. 1. p. 2. 404.)—Branches round, furrowed. Leaves obovato-lanceolate; filky beneath. Flowers axillary, solitary; their stalks thrice the length of the calyx. Petals all smooth. Legume shaggy.—Native of the south of France. We received it from the late Dr. Broussonet. The stem is woody, very much branched, and strongly furrowed, not spinous. Leaves chiefly on the young branches, small, stalked. Flower-stalks filky, as long as the leaves, or longer. Calyx partly filky. Petals yellow, shorter, and more rounded, than in *S. cinereum*, quite smooth, except the villous hairs, which knit those of the keel together. Legume curved, densely clothed with long shaggy hairs. Linnæus was really unacquainted with this species. His *Genista purgans*, Sp. Pl. 999, is a very spinous shrub, totally different from Bauhin's plant, and may be *S. scorpius*. His *S. purgans*, adopted from Gerard in the 12th edition of Syft. Nat. is our *cinereum*, n. 6; yet we do not judge it right to interchange the synonyms, merely to countenance, still less to conceal, a blunder of our great master, or of his learned correspondent, Gerard. The two plants can never again be confounded.

10. *S. umbellatum*. Umbellate Broom. Desfont. Atlant. v. 2. 133. t. 180. Willd. n. 9. Ait. n. 6.—Branches round, striated, leafy. Flowers capitate. Corolla filky, as well as the legume, and lanceolate leaves.—Native of the sea-coast of Barbary. Sent to Kew by the late Dr. Broussonet. It is a greenhouse shrub, flowering from April to June, very much branched, and readily known by its yellow, filky, capitate, rather than umbellate, flowers. Legume oblong, compressed, densely villous, containing from three to five seeds. The leaves are often ternate, so that this species ought rather to stand in the next section, near *linifolium*.

11. *S. Scorpius*. Scorpion Broom. Linn. Sp. Pl. 995. Willd. n. 10. Ait. n. 7. Prodr. Fl. Græc. n. 1644. (Genista purgans; Linn. Sp. Pl. 999? G. spinosa minor; Ger. Em. 1319. Aspalathus alter tertius; Cluf. Hist. v. 1. 106.)—Branches round, striated, spreading, spinous. Flower-stalks axillary, aggregate. Leaves oblong, hairy, with a spinous point.—Native of Spain, the south of France,

Greece, and the Archipelago. Each of the branches ends in a sharp thorn, and the young ones spread horizontally. The leaves are small, oblong or obovate, loosely covered on both sides with filky hairs. Flowers yellow, their stalks about as long as the leaves, and situated, like them, on the young branches only. We know nothing of the legume. Lamarck says it is smooth. The modern Greeks call this plant *Acôiva*.

12. *S. aspalathoides*. Tubercular Thorny Broom. Desfont. Atlant. v. 2. 136. Willd. n. 11. (Genista aspalathoides; Lamarck Dict. v. 2. 620.)—Branches angular, tuberculated, spinous. Flower-stalks axillary, aggregate. Leaves linear-lanceolate, filky, unarmed.—Discovered by Poiret, on the coast of Barbary, near Tunis. The stem is much branched, two or three feet high; the branches beset with scattered tubercles, and ending in sharp thorns. Leaves in small tufts upon the tubercles; alternate on the young shoots; small, narrow, covered with short, depressed, filky hairs. Flowers twice the size of the last, pale yellow, axillary, stalked, two or more together; their stalks, calyx, and corolla filky. Germen covered with white hairs.

Section 2. Leaves mostly ternate.

13. *S. multiflorum*. Portugal White Broom. Ait. n. 8. Willd. n. 12. (S. album; Desfont. Atlant. v. 2. 132. S. dispermum; Willd. in Rom. and Uft. Mag. fasc. 11. 35. t. 2. Genista alba; Tabern. Kreuterb. 1509.)—Leaves ternate or simple, elliptic-lanceolate, filky. Branches straight, striated, covered with flowers. Legume filky, with two seeds.—Native of Portugal and Barbary. A hardy shrub in our gardens, flowering in May. The stem is from four to six feet high, with copious, erect, long, straight, wand-like branches, covered from top to bottom with elegant, snow-white, stalked, axillary flowers. The leaves are but seldom ternate. The legume is ovate-oblong, compressed, dark brown, clothed with whitish hairs.

14. *S. angulatum*. Angular-branched Broom. Linn. Sp. Pl. 996. Willd. n. 13. Ait. n. 9. Sm. Fl. Græc. Sibth. t. 672, unpublished. (S. parviflorum; Venten. Cels. t. 87.)—Leaves mostly ternate, linear-oblong. Branches with six angles. Flowers terminal, racemose. Legume elliptical, acute at each end, with one or two seeds.—Native of the Levant. Hardy with us, flowering in May and June. Its aspect is that of a Melilot, but the stem is shrubby, with numerous straight upright branches, marked with three decurrent angles from the insertion of each leaf. The leaflets are more or less obtuse, nearly equal, slightly hoary, not an inch long. Flowers small, yellow, numerous, composing long, solitary clusters, at the end of each branch. Legumes pendulous, slightly hairy, compressed, thick-edged, three quarters of an inch long, having an annular appearance at each side from the projection of the usually solitary seed.

15. *S. persicum*. Persian Broom. Willd. n. 14. (Cytifus persicus; Burm. Ind. 163. t. 51. f. 1.)—Leaves ternate, linear-lanceolate, stalked; the middle leaflet twice as large as the others. Branches divaricated, roundish. Flowers terminal, racemose.—Native of Persia. A small species, whose genus seems uncertain, and of which neither we nor Willdenow have seen any specimen. There appears, however, some affinity between it and the last. The flowers evidently compose terminal clusters. The branches, stalks, and calyx are downy.

16. *S. patens*. Woolly-podded Broom. Linn. Syft. Veg. ed. 13. 535. Willd. n. 15. Ait. n. 10, excluding the synonym of Cavanilles. (Cytifus patens; Linn. Syft. Veg. ed. 13. 555. C. pendulinus; Linn. Suppl. 328. C. lusitanicus, medicæ folio, floribus in foliorum alis; Tourn.

Inft.

SPARTIUM.

Inft. 648.)—Leaves ternate, stalked, obovate. Branches round, striated. Flowers lateral, drooping. Calyx two-lipped, broad, silky. Germen very woolly.—Native of Portugal and Spain. Hardy in our gardens, flowering in June and July. The *branches* spread widely, and are clothed with numerous, stalked, silky *leaves*, usually shorter than the large, tumid, pendulous, yellow *flowers*, which are mostly solitary, sometimes in pairs, by the side of each tuft of leaves, on simple silky stalks. The *calyx* is deeply divided, shallow, spreading widely, besprinkled with silky hairs. *Petals* very large, smooth, rounded and obtuse. *Germen* clothed with extremely long, woolly hairs, and sheathed in the permanent *stamens*, but at length becoming an oblong, compressed, wavy, very hairy *legume*, containing several *seeds*. Whatever the plant of Cavanilles' *Icones*, t. 176, may be, its unequal *leaflets*, terminal corymbose *inflorescence*, long slender *calyx*, and smooth *germen*, are all so totally unlike the present species, that we wonder how even the most casual perusal of its name could cause it to be quoted by Willdenow for such.

17. *S. nubigena*. Cluster-flowered White Broom. Ait. ed. 1. v. 3. 13. ed. 2. n. 11. Willd. n. 16. (*S. supranubium*; Masson in Linn. Suppl. 319.)—Leaves ternate, stalked, lanceolate, hairy. Branches round, furrowed. Flowers lateral, aggregate. Upper lip of the calyx abrupt. Germen smooth.—Discovered by Mr. Masson, very high on the peak of Teneriffe, above the clouds, as he meant to express in the specific name. It is a greenhouse plant at Kew, flowering most part of the summer. The bushy *stem*, with its copious furrowed *branches*, much resembles *S. junceum*, but the *leaves* are ternate, small, and the *flowers* very much smaller than in that species, white and fragrant, ranged in lateral tufts along the branches, on silky stalks. The *calyx* is hairy or silky, cup-shaped; its lower lip elongated; upper short and abrupt. *Legume* an inch and a half, or two inches long, curved, compressed, wavy, quite smooth.

18. *S. biflorum*. Two-flowered Terminal Broom. Desfont. Atlant. v. 2. 133. t. 179. Willd. n. 17.—Leaves ternate, linear-lanceolate, stalked, somewhat hairy. Flowers terminal, often in pairs. Calyx villous, its lips nearly equal. Legume smooth.—Native of mount Atlas, near Tlemcen. *Stem* bushy, from one to two feet high, with slender, angular, leafy branches. *Leaves* small, stalked, rather silky. *Flowers* yellow, erect, one, two, or three at the summit of each branch, rather smaller than those of the common *S. scoparium*.

19. *S. linifolium*. Flax-leaved Broom. Desfont. Atlant. v. 2. 134. t. 181. Willd. n. 18. Ait. n. 12. (*Genista linifolia*; Linn. Sp. Pl. 997. Curt. Mag. t. 442. *G. tinctoria hispanica*; Clus. Hist. v. 1. 101. *Genistella infectoria*; Ger. Em. 1316.)—Leaves sessile, ternate, linear-lanceolate, revolute; silky beneath. Clusters terminal. Branches angular, furrowed.—Native of Barbary, Spain, and the south of France. A hardy greenhouse plant in England, flowering most plentifully in May and June. The *stem* is shrubby, much branched, and very leafy. *Leaves* about an inch long, rendered very beautiful by the silvery silkiness of their under side, in which they agree with the *calyx* and young *branches*. *Flowers* of a beautiful golden yellow, in dense tufted clusters. *Legume* short and broad, clothed with shaggy hairs. *S. umbellatum*, n. 10, having frequently many ternate *leaves*, and agreeing nearly with the present species in habit, *legume*, and *inflorescence*, would perhaps have been better placed here.

26. *S. scoparium*. Common Broom. Linn. Sp. Pl. 996. Willd. n. 19. Fl. Brit. n. 1. Engl. Bot. t. 1339.

Curt. Lond. fasc. 5. t. 52. Woodv. Med. Bot. t. 89. Fl. Dan. t. 313. Dreves Bilderb. t. 48. Ehrh. Arb. 56. (*Genista*; Ger. Em. 1311.)—Leaves chiefly ternate, stalked, obovate. Branches angular. Flowers lateral, solitary. Calyx two-lipped, broad, smooth. Legume fringed.—Common on sandy or gravelly dry hills, principally in the north or middle of Europe. Abundant in Britain, flowering copiously in May and June, when it makes a highly ornamental appearance. The *stem* is very bushy, from three to eight feet in height, with innumerable, ascending, angular, smooth, evergreen twigs. *Leaves* deciduous, smooth or somewhat hairy; the upper ones generally simple. *Flowers* axillary, loosely pendulous, solitary, on long stalks, large, usually of a golden yellow; sometimes orange at the outside; very rarely of a pale uniform lemon-colour: their *petals* spread widely in hot sunny weather. *Calyx* bell-shaped, smooth, glaucous and purplish, with two widely-spreading lips, whose teeth are minute and downy. *Legume* compressed, two inches long, smooth, fringed at the margin with dense deciduous hairs. *Seeds* numerous.

21. *S. arboreum*. Tree Broom. Desfont. Atlant. v. 2. 131. t. 177. Willd. n. 20. (*Cytisus foliis subrotundis glabris, floribus amplis glomeratis pendulis*; Shaw Phyt. Afr. n. 191.)—Leaves ternate, stalked, obovate. Branches round, furrowed. Flowers lateral, aggregate, drooping. Calyx two-lipped, spreading. Legume silky, with close-pressed hairs.—Found by professor Desfontaines on mount Atlas, and in vallies near Algiers. From eight to twelve feet high, with a *trunk* often as thick as the arm. It seems akin to the last, but more to *S. patens*, n. 16, of which Desfontaines suspected it might be a variety. Their *foliage* indeed appears much the same, but the *flowers* of the present are more aggregate. The *legume* however seems to afford the most certain specific difference, being twice as long as that of the *patens*, and covered with depressed silky hairs, not long and shaggy ones. Nothing is mentioned of the pubescence of the *calyx*, nor have we seen a specimen: but its teeth are represented like those of *patens*, much more conspicuous than in *scoparium*.

22. *S. radiatum*. Starry Broom. Linn. Sp. Pl. 996. Willd. n. 21. Ait. n. 14. (*S. ramis oppositis angulatis, foliis oppositis subulatis*; Mill. Ic. v. 2. 173. t. 259. *S. minimum montanum triphyllum*; Column. Ecphr. 295. t. 294. f. 2. *Genista radiata, sive stellaris*; Bauh. Hist. v. 1. p. 2. 399.)—Leaves ternate, opposite, linear; with short, dilated, permanent footstalks. Branches opposite or aggregate, angular. Clusters capitate, terminal. Legume ovate, hairy.—Native of Italy and Carniola. Hardy with us, in mild winters at least. Flowering in June and July. The great abundance of naked radiating *branches*, crowned with tufts of handsome yellow *flowers*, readily distinguish this species. The broad, short, permanent, concave *footstalks*, hardening into spinous-tipped scales, under the branches, are very remarkable. The linear silky *leaves*, being opposite and ternate, look as if whorled. The *calyx* is tubular, silky as well as the *keel*. *Legume* short, broadly ovate, pointed, covered with long silky hairs, and containing several small *seeds*.

23. *S. ferox*. Sharp-thorned Broom. Desfont. Atlant. v. 2. 136. t. 182. Willd. n. 22. Ait. n. 15. (*Cytisus foliis oblongis sessilibus glabris, siliquis compressis incanis*; Shaw Phyt. Afric. n. 194.)—Leaves partly ternate, elliptic-oblong, pointed. Branches striated, with spinous points. Clusters terminal. Legume linear, hoary.—Native of Barbary. The *stem* is three or four feet high, with numerous straight leafy *branches*, which, after bearing each a terminal *spike*,

SPARTIUM.

spike, or *cluster*, of yellow *flowers*, become very sharp thorns. The *leaves* are most of them simple, on short stalks, nearly smooth; some of the lower ones ternate. *Corolla* smooth, oblong and slender, somewhat like *Genista tinctoria*. *Calyx* elongated. *Germen* silvery. *Legume* about an inch and a half long, linear, slightly curved, clothed with short, compressed, hoary hairs. *Seeds* numerous.

24. *S. spinosum*. Prickly Broom. Linn. Sp. Pl. 997. Willd. n. 23. Ait. n. 16. Desfont. Atlant. v. 2. 135. (*Acacia altera* Dioscoridis; Lob. Ic. v. 2. 95. *A. altera trifolia*; Ger. Em. 1330. *A. altera*; Matth. Valgr. v. 1. 176.)—Leaves ternate, stalked, obovate. Flowers axillary. *Calyx* smooth. Branches striated, with alternate, spreading, angular, furrowed thorns. *Legume* oblong, smooth.—Native of Italy, Spain, and Barbary. Gerard appears to have cultivated it in 1596, and it is marked by Mr. Aiton, as a greenhouse shrub, flowering in June and July; but we have seldom met with it in collections. The whole bush is armed with very strong, long and sharp *thorns*, spreading in every direction. *Leaves* on long stalks, each of three equal, broadish-obovate, sometimes emarginate, leaflets; rather hairy beneath. *Flowers* half the size of *S. scoparium*, solitary or aggregate, stalked. *Calyx* membranous, with obsolete teeth. *Legume* pendulous, compressed, thick-edged, slightly tumid, smooth, an inch and a half long, with from two to four *seeds*.

25. *S. villosum*. Hairy-podded Thorny Broom. Vahl Symb. v. 2. 80. Willd. n. 24. Sm. Fl. Græc. Sibth. t. 673, unpublished. (*S. lanigerum*; Desfont. Atlant. v. 2. 135. *Cytisus spinosus creticus*, siliquâ villis densissimis longissimis et incanis obductâ; Tourn. Cor. 44.)—Leaves ternate, stalked, obovate. Flowers axillary. *Calyx* hairy. Branches furrowed, spinous, downy. *Legume* linear-oblong, very hairy.—Native of Gibraltar, Barbary, and Crete. Dr. Sibthorp found it every where in Greece and the isles of the Archipelago, where it is known by the names of *ασπάλαρος*, or *ασπάλαθεις*, and he judged it to be the *ασπάλαθος* of Dioscorides. This species flowers in its native country in April. We have never met with a garden specimen. The habit of the whole plant is like the last, but the *spines* are all terminations of *branches*, which are finely downy, and neatly striated. In the *flowers* we scarcely observe a difference, except the dense hairiness of the *calyx*; but the *germen* is excessively hairy, and the *legume* differs essentially in its narrower, more linear, form, and its dense clothing, of long shaggy hairs.

26. *S. horridum*. Many-thorned Broom. Vahl Symb. v. 1. 51. Willd. n. 25. Sm. Fl. Græc. Sibth. t. 674, unpublished.—Leaves ternate, linear, folded, silky. Branches opposite, aggregate, furrowed, spinous. Flowers lateral. *Legume* ovate, hairy as well as the *calyx*.—Native of Spain, as well as of hills in Greece and the Archipelago. This is a very densely branched *shrub*, like a furze bush, beset with innumerable, thorny, clustered, somewhat hairy, *branches*, bearing a very few and small *leaves*. The *flowers* are yellow, but half the size of the last, placed two or three on each young branch, near its point. *Calyx* pale, two-lipped, hairy, as well as the *keel*, and little, tawny, ovate or rhomboid, pointed *legume*, which scarcely contains more than one seed.

The *S. complicatum*, Linn. Sp. Pl. 996, is now *Cytisus divaricatus*, Willd. Sp. Pl. v. 3. 1119. Ait. Hort. Kew. v. 4. 319. Curt. Mag. t. 1387. Sm. Fl. Græc. Sibth. t. 704, unpublished.—*Cytisus* differs from *Spartium* in having the *filaments* separated to the very bottom, into two distinct sets, and the *germen* stalked. There is a general resemblance in habit between some of the species to each other. More

difficulty exists in distinguishing *Spartium* and *Genista*; the latter being characterized chiefly by the depression of its organs of impregnation along with the *keel*, while the *standard* is strongly divaricated. The involute *stigma*, and the *stamens* not being attached to the *germen*, are less obvious distinctions. See GENISTA.

Three Linnæan species of *Spartium*, as we have already hinted, named *contaminatum*, *sepium*, and *cytisoides*, with one from the first edition of Aiton, *sericeum*, all natives of the Cape of Good Hope, are removed by Thunberg from hence, and established, with four other shrubs from the same country, as a distinct genus, named LEBECKIA, in Thunberg's *Prodromus*, and in Willd. Sp. Pl. v. 3. 946. Ait. Hort. Kew. v. 4. 261. This ranges next after *Genista*, and is defined as follows.

Ess. Ch. *Calyx* in five deep acute segments, with rounded sinuses. Filaments monadelphous. *Legume* cylindrical, with many seeds.

Section 1. *Leaves simple*.

1. *L. contaminata*. Narrow-leaved Lebeckia. Willd. n. 1. Ait. n. 1. (*Spartium contaminatum*; Linn. Mant. 268.)—Leaves simple, linear-thread shaped, smooth, stained at the base. Flowers racemose.—Native of sandy ground at the Cape. *Stem* shrubby, branched, smooth and round. *Leaves* alternate, an inch and a half or two inches long, acute, glaucous; flattish above; purple at the base. *Flowers* in a long, simple, terminal *cluster*, orange-coloured, with a yellow *keel*. The *stamens* are described as all equally combined. We know not by what accident Thunberg calls the *flowers* umbellate, which Willdenow copies, in direct contradiction to the Linnæan description subjoined.

2. *L. sepium*. Capillary Lebeckia. Willd. n. 2. (*Spartium sepium*; Linn. Sp. Pl. 995. *Lathyroides*, vel *lathyris* congener, *linariæ foliis*, *æthiopicum*; Pluk. Mant. 114. *Amalth.* t. 424. f. 1. Yellow Cape Broom, with fennel leaves; Petiv. Gazoph. t. 83. f. 3.)—Leaves simple, capillary, smooth. Flowers racemose.—Native of the Cape, like all the rest of the species. This has more copious, longer, and much slenderer *leaves* than the foregoing, with larger *flowers*, whose tenth *stamen* is separated, in its upper part at least, from the rest.

3. *L. pungens*. Spinous Downy Lebeckia. Thunb. Prodr. 122. Willd. n. 3.—“Leaves simple, obovate. Branches downy, all becoming spinous at the end. Flowers solitary.”

Section 2. *Leaves ternate*.

4. *L. armata*. Thorny Grey Lebeckia. Thunb. Prodr. 122. Willd. n. 4.—“Leaves ternate. Branches hoary, round, becoming thorny. Flowers racemose.”

5. *L. densa*. Dense-leaved Lebeckia. Thunb. Prodr. 122. Willd. n. 5.—“Leaves ternate, villous; leaflets convolute, oblong. Flowers racemose, distant.”

6. *L. humilis*. Dwarf Lebeckia. Thunb. Prodr. 122. Willd. n. 6.—“Leaves ternate, villous; leaflets linear-oblong. Flowers racemose, reflexed. Branches incurved.”

7. *L. sericea*. Silky Lebeckia. Thunb. Prodr. 122. Willd. n. 7. Ait. n. 2. (*Spartium sericeum*; Ait. ed. 1. v. 3. 12.)—“Leaves ternate, silky; leaflets linear. Flowers racemose. Branches angular.”—Sent by Mr. Masson to Kew, in 1774. It flowers in the greenhouse, in April.

8. *L. cytisoides*. Cytisus-leaved Lebeckia. Willd. n. 8. Ait. n. 3. (*Spartium cytisoides*; Linn. Suppl. 320. *Ebenus capensis*; Linn. Mant. 264. *Trifolium africanum* fruticosum, folio angustiore, flore rubicante; Commel. Hort. v. 2. 213. t. 107.)—Leaves ternate, silky; leaflets linear-lanceolate. Flowers racemose. Branches round.—Communicated by Thunberg to Linnæus. Masson sent it from the Cape to

New garden in 1774, where it flowers in the greenhouse, in April. We presume this to be nearly akin to the last. The leaves in the original specimen are silky, not villous; each leaflet above an inch long. Flowers large, in terminal solitary clusters. Calyx bell-shaped, smooth, coloured. Petals reddish. Legume long, with the rudiments of many seeds, only one of which is said to come to perfection.

SPARTIUM, in Gardening, contains plants of the deciduous and evergreen kinds, among which the species cultivated are the common broom (*S. scoparium*); the Spanish broom (*S. junceum*); the starry broom (*S. radiatum*); the white-flowered single-seeded broom (*S. monospermum*); the yellow-flowered single-seeded broom (*S. sphaerocarpum*); the scorpion broom (*S. scorpius*); the angular-branched broom (*S. angulatum*); and the prickly broom (*S. spinosum*).

In the first species there are several varieties, some of which merit a place among flowering shrubs; as that with a purple calyx, and the flowers strongly tinged with orange, as well as that which is very hoary.

The second species has also a variety with double flowers.

Method of Culture.—The three first sorts are hardy, but the others more tender, especially in their young growth. And they are all capable of being raised from seeds, and the double-blossomed sorts also by layers and cuttings. The seeds should be sown in the early spring, as about April; the hardy sorts in beds of common earth, either in drills, or by bedding in to the depth of an inch: but in the tender sorts, in pots or beds hooped over to protect them in frosty weather. In the following spring they should be removed into nursery-rows or larger pots, according to the kinds, shortening their tap-roots, and setting them out in rows two feet apart, at the distance of one in the rows, to remain two or three years, when they may be planted out in the shrubbery, or other places where they may be wanted: the tender sorts in pots, being removed to the greenhouse or garden for protection in winter, and managed as the hardy sorts of plants of this kind.

But the layers should be laid down in the autumn or spring, and the cuttings may be planted out in the spring or summer, some in the open ground, and others in pots plunged in the hot-bed, to promote their striking root. They may be managed afterwards as the other sorts. This is the only certain mode of preserving the varieties.

All the hardy sorts are very ornamental in the borders, clumps, and other parts, and the tender kinds in greenhouse collections, and among other more hardy potted plants.

It is constantly proper, as a precautionary practice, to have some of the tender sorts of these plants always in pots, under the greenhouse management, with the view of more certainly preserving them, in case those which are planted out in the shrubberies or other parts of the open grounds should suffer much or be wholly destroyed by the too great severity of very severe winter seasons. And as the long roots of the plants which are naked or but thinly set with fibres, are not unfrequently disposed to run downwards with a long tap-root, they should be planted out when young as much as possible where they are to remain and grow, as they do not succeed well, where they are transplanted or removed into a new situation when of a large or old growth.

SPARTIUM *Scoparium*, *Common Broom*, in the *Materia Medica*. The tops and seeds are directed for use: the tops and leaves have a nauseous bitter taste, imparted by infusion both to water and spirit. They are commended for their purgative and diuretic qualities, and have therefore been successfully employed in hydropic cases. Dr. Cullen ordered half an ounce of fresh broom-tops to be boiled in a pound

of water till one half of this is consumed, and gave of this decoction two table-spoonfuls every hour, till it operated by stool, or till the whole was taken. It seldom failed, he says, to operate both by stool and urine; and by repeating this exhibition every day, or every second day, some dropsies have been cured. It is affirmed, that a patient, by taking half a pint of a decoction of green broom-tops, with a spoonful of whole mustard-seed, every morning and evening, was cured, after being tapped three times, and trying the usual remedies given in dropsies. The ashes of broom have also been much used in dropsies, and principally on the authority of Sydenham, whose account of their good effects has been confirmed by the testimony of Dr. Monro, who gave a drachm divided into three doses every day, and by other writers; the efficacy of this medicine depending entirely upon the alkaline salt, and not at all upon the vegetable from which it is obtained. The seeds and flowers of broom are said to be emetic and cathartic; but the evidence upon which this assertion rests is not wholly to be relied upon, as the former, when roasted, have been used as a substitute for coffee, and the latter employed as a pickle. Ray informs us, from the MS. of Dr. Hulse, that the flor. genist. given in the form of electuary, with honey of roses, were found very efficacious in scrophulous affections. Woodv. Med. Bot.

SPARTOPOLIAS LAPIS, in *Natural History*, a name given by some authors to a whitish agate, variegated with long and slender streaks of grey, disposed in a variously undulated order, and resembling grey hairs.

SPARUS, in *Ichthyology*, a genus of fishes of the order Thoracici, of which the generic character is; teeth generally strong; the grinders somewhat obtuse and crowded; the lips are doubled; gill-membrane five-rayed; the cover fealy; the body compressed; the lateral line curved on the hind part; the pectoral fins are rounded.

The name *sparus* is of Greek origin, being derived from the verb *σπαρίζω*, to palpitate or tremble; and was given to this fish from its remarkable quality of trembling or palpitating all over the body, as soon as taken out of the water.

There are, according to Gmelin, about forty species, separated into divisions, and classed according to their colours; but Dr. Shaw has enumerated nearly four times that number. The greater number of species being exotic, little is known of their history; they are evidently allied to the Labri. See LABRUS.

Species.

§ A. *Marked with a black Spot.*

*AURATUS; or Lunate Gilt-head. The specific character of this is, that between the eyes there is a semilunar spot. The general length of this fish is about fifteen inches; but occasionally it is found of a far larger size: the body is broad and thin; the back rising into a carina. Dr. Shaw gives the specific character as silvery-blueish, with gold-coloured brows, and a purple spot beyond each side the head; but sometimes, he says, with the addition of several brownish longitudinal stripes. It is a native of the Mediterranean, Atlantic, and Indian seas, and held in considerable estimation as food. It was much admired by the ancient Greeks and Romans; by the former it was consecrated to Venus. It feeds on shell-fish, which it grinds with its strong teeth before it swallows. It is sometimes found of the weight of eight or even ten pounds.

ANNULARIS. Yellowish, with a black ocellate spot near

SPARUS.

the tail. This is found chiefly in the Adriatic. The colour of this species resembles that of the common perch: at a certain distance from the base of the tail a round black spot is situated at the bottom of the last dusky bar of the body; the pectoral fins and tail are red, the rest blackish. Native of the Mediterranean, and not at all in esteem for the table.

SARGUS. The body of this is marked with black bands, and a black ocellate spot near the tail. It inhabits the southern coasts of Europe. The body is oval, broad; the teeth are equal, obtuse; and the tail forked. It is nearly of the size of the auratus, and the shape very like that, but deeper in proportion. It is much esteemed as food.

MELANURUS. Body with longitudinal lines and a black ocellate spot near the tail. This species is found in the southern European seas. It is described by Shaw as silvery, with a blue back; the sides have a stripe, spotted longitudinally with brown, and a black spot at the base of the tail.

SMARIS. A black ocellate spot on each side; pectoral fins and tail red. It inhabits the Mediterranean.

MENA. Body variegated; a blackish spot on each side. This is also found in the Mediterranean.

SAXATILIS. Body whitish; a black ocellate spot at the base of the tail. This is found on the coasts of Surinam. The snout is depressed; and the tail rounded.

ORPHUS. A black ocellate spot at the tail; the head is reddish; the tail is entire.

PUNCTATA. Mouth cupidate; the tail entire; in colour it is partly black. It inhabits the shores of Sardinia. In size and colour it is nearly allied to the *S. fargus*.

ARGENTATUS. This has a black spot behind the gills. It is found on the coasts of Japan; is six inches long; the body is covered with silvery scales; before the eyes are two nostrils.

NOTATUS. Dorsal fin divided; the gill-covers and tail spotted with black. It is found at Japan. The head is coated with silvery scales, nearly as long as the fingers.

§ B. *Body mostly red.*

ERYTHRINUS. The tail of this fish is nearly entire; the body red. It inhabits the European, American, and Japan seas. It is often eaten, but is not held in any great estimation; and it has sometimes proved poisonous: the iris is silvery.

INSIDIATOR. Body red, yellowish at the sides; tail a little forked. It inhabits the Indian ocean; is about ten inches long; catches aquatic insects, like the *Chætodon rostratus*, with its snout, which it can lengthen out into a tube; the body is rather broad, fat, coated with large scales of a metallic-green colour at the edge; when dead it becomes brown; the flesh is eatable. It is described as having a compressed head, and scaly; the eyes are lateral; jaws divided, each with two large straight conic teeth in the middle; gill-covers very entire; first lateral line nearer the back, beginning at the end of the dorsal fin, the other straight; the vent is nearly in the middle; the fins are yellowish; the dorsal and anal fins are marked with green bands; the last ray but one of the anal is very long.

* **FORMOSUS.** Red; longitudinal marks on the body and tip of the tail blue. This fish is figured in Dr. Shaw's *Naturalist's Miscellany*, and he suspected that it was a British fish; hence it is marked with an asterisk. The fore-part of the dorsal, and edge of the anal fins, are blue.

* **PAGRUS;** the Red Gilt-head. This is reddish; the

skin, at the end of the dorsal and anal fins, gathered up, and hiding the last rays. It is found in the European seas. In shape, teeth, and size, it resembles *S. auratus*. The iris is silvery; infides of the gill-covers, mouth, and tongue, are of a fine red; at the base of the pectoral fins is a ferruginous spot; the scales are large; and the tail is forked.

SPINIFER. Dorsal spines recumbent; the five middle ones filiform and longer. This inhabits the muddy deeps of the Red sea; is about a span and a half long. The body is silvery, but with a reddish hue; the back is marked with darker lines; the scales are broad, very entire, obscurely streaked, and the flesh is reckoned excellent.

PALPEBRATUS. This is of a chestnut-red; the eyes are of a pale yellow, covered with a loose yellowish membrane. This is found on the coasts of Amboina. It resembles a perch; but the head is more obtuse.

§ C. *Body marked with Lines.*

BOOPS. Longitudinal lines dusky; the four lower ones are gold and silvery. It inhabits the sea round Japan.

CANTHARUS. The tail is without spots; the body is marked with longitudinal lines. It inhabits the coast of Tuscany. The iris is silvery.

CHROMIS. The tail is bifid; the second ray of the ventral fin is setaceous. It inhabits southern Europe.

SALPA. Tail bifid; the body is marked with eleven tawny longitudinal lines. It is found in the Mediterranean.

SARBA. This is of an oblong oval shape, silvery, with numerous obsolete stripes; the ventral fins are yellow, with a golden line on each side near them. It inhabits the Mediterranean, and along the coasts of Arabia. The body is broad, and covered with broad entire scales; there are seventeen longitudinal brownish stripes on each side; the flesh is reckoned pleasant.

SYNAGRIS. The tail is bifid, red; the body is purplish, with seven gold lines on each side. It inhabits South America.

RHOMBOIDES. The tail is entire; the back is caniculate; the body with yellow lines. It inhabits America, and is there called the salt-water bream. The teeth are obtuse; between the roots of the pectoral and dorsal fins a black spot; the ventral, anal, and caudal fins are tawny.

LATUS. Yellowish; the head is silvery; the scales longitudinally imbricate. It inhabits about the coasts of Japan; is three inches long, and one and a half broad.

VIRGATUS. The tail is forked; the body is depressed, oblong, striped with scales. This is found on the coast of Japan.

HAFFARA. Silvery, with fourteen obsolete yellowish-brown lines on each side; the tail is bifid. It inhabits the muddy shores of Arabia; is about a span long; and the flesh is reckoned good.

BERDA. Whitish-ash; lateral scales with each a transverse brown band in the middle; the dorsal spines are recumbent. It is found in the Red sea. The body is oval; the back is gibbous, with obsolete bands; beneath it is white; the scales are broad, round, and entire.

CHILENSIS. The tail is bifid; the body is marked with transverse brown lines on each side. It inhabits, as its specific name denotes, Chili, in South America. It grows to full six feet long; in shape it is oval, depressed, coated with large rhomboidal margaritaceous scales, spotted with white; the flesh is good.

§ D. *Various.*

CHRYSOPS. The tail is semi-lunar; the back is grooved; the

the iris is golden. It inhabits Carolina. The body is blueish.

ARGYROPS. Tail semi-lunar; the back is grooved; iris is silvery. It inhabits Jamaica and Carolina. It resembles the last. The three first rays of the dorsal fin end in a long bristle.

DENTEX. The tail is bifid; the body is variegated; four of the teeth are larger. It inhabits many parts of Europe, and the Cape of Good Hope.

SPINUS. Tail bifid; dorsal spine recumbent. It inhabits South America and India. The body is apparently painted with blue recurved blotches.

RADIATUS; Pudding-fish. The tail is entire; lateral line composed of linear scales, divided into three bifid branches. This is found on the coast of Carolina. Above it is a green purple at the sides; beneath rufous; head varied with blue, yellow, and green streaks.

VIRGINICUS. The tail is bifid; the body with two black transverse bands, and numerous longitudinal lines. It inhabits North America.

MORMYRUS. The tail of this species is bifid; body with numerous silvery and black bands. It inhabits Tuscany.

CAPISTRATUS. The tail of this is entire; the body is reticulate with white. It inhabits America. Body oblong; scales loosely imbricate, with a white band bent into a right angle before the edge.

GALILÆUS. The tail entire; body above is greenish, beneath white. It inhabits the lake Genesareth, in Galilee.

FUSCESCENS. Brownish; scales golden; near the pectoral fins a black spot. It inhabits Japan, and is about four inches long.

* **NIGER;** Toothed Gilt-head. The back is black; the sides brighter; belly silvery. This is found on the coasts of Yorkshire. It is described in Pennant's British Zoology. The body is twenty-six inches long, and ten broad; eyes large; teeth in the lower jaw slender, sharp, and on each side a slender canine tooth, in the upper jaw a single row; the first seven rays of the dorsal fin high, the rest low; this fin and the anal covered with imbricate scales.

SPARUS, among the Romans, a kind of rustic weapon, bent backwards like the foot. It was likewise used for a small dart, or missile weapon.

SPASA, in *Geography*, a town of Russia, in the government of Archangel; 40 miles S.W. of Mezen.

SPASK, a town of Russia, in the government of Kazan, on the Volga; 40 miles S. of Kazan. N. lat. 55°. E. long. 49° 14'.—Also, a town of Russia, in the government of Tambov; 92 miles N.N.E. of Tambov. N. lat. 54° 2'. E. long. 42° 58'.—Also, a town of Russia, in the government of Riazan, on the Oka; 32 miles E.S.E. of Riazan. N. lat. 54° 32'. E. long. 39° 50'.

SPASKAIA, a town of Russia, in the country of the Cossacks, on the Don; 52 miles S.S.W. of Arkadinskaia.—Also, a town of Russia, in the government of Upha; 8 miles S. of Verchouralsk.

SPASKOI, a town of Russia, in the government of Kolivan. N. lat. 55° 38'. E. long. 86° 14'.—Also, a town of Russia, in the government of Tobolsk; 36 miles N. of Tomsk.—Also, a town of Russia, in the government of Tobolsk; 20 miles W. of Narim.—Also, a town of Russia, in the government of Olonetz; 60 miles N.E. of Pudoga.

S^PASM, in *Medicine*, *σπασμοί*; from *σπασω*, *I draw*, or *contract*, a *cramp*, in its modern sense, signifies a continued and painful contraction of a muscle, or any portion of muscular fibres; in which signification it stands in opposition to

convulsion. This, however, appears to have been an arbitrary determination of its acceptation, which does not strictly accord with the original use of the word. For Celsus has distinctly defined *spasm*, as meaning convulsive motion, and applies the word *tetanus* to the rigid and fixed contraction, as we have stated in another place. “*Modo nervorum dilationem, modo rigorem; illud σπασμὸς, hoc τετανωσ, Græcè nominatur.*” (De Medicinâ, lib. ii. cap. 1.) See **CONVULSIONS**. Some writers, however, have applied the term, *spasm*, to both these forms of disease; using the epithet of *tonic* to signify the state of rigid contraction, and *clonic* to denote the violent contractions and relaxations of convulsion. Others again have applied the word to every irregular action of the muscular or moving fibres, in any part of the body. (See Cullen, First Lines, par. 1251.) This latitude has led the celebrated author, just quoted, to bring together diseases, which have very little resemblance in the morbid actions which constitute them; as, for instance, hysteria, diabetes, colic, and hydrophobia, which are classed together as *spasmodic* affections of the natural functions, in his system of nosology.

The various functions of the animal body are performed by certain contractions of the moving or muscular fibres, in which alone that power is inherent. These contractions are excited either by the will, in those muscles which obey the faculty of volition; or by certain stimuli or causes of irritation, appointed by nature for that purpose, in those which are not under the influence of the will. The blood, for instance, excites the motions of the heart; the passing aliments produce the peristaltic contractions of the bowels; and so forth. In a state of health, the contractions are regulated in force and velocity by the will, or by these natural irritations; and whether produced by the one or the other, they are always soon succeeded by a state of relaxation, and are not repeated, until the will or these natural excitements operate again. But in a morbid state, the contractions of the moving fibres, ordinarily depending on the will, are excited without the concurrence of the will, or contrary to what it intends; and in the other functions, they are excited by the action of unusual and unnatural causes, or, from too great mobility, are roused to more violent and continued contractions by the ordinary causes. When the contractions are more violent in degree than is usual in health, and are neither succeeded by a spontaneous relaxation, nor even yield readily to an extension, either from the action of antagonist muscles, or from other extending powers applied, this state is called a *tonic spasm*, or simply a *spasm*. For an account of the successive violent contractions and relaxations under this morbid excitement, see **CONVULSIONS**.

The presence of spasm, in any muscular part, is indicated by intense *pain*, (and it must be obvious, from what has just been stated, that those pathologists, who speak of spasmodic affections of nerves, membranes, and such uncontractible parts, use an erroneous language;) a symptom, however, which occurs also in inflammation of the same parts: and as the remedies for inflammation are injurious in spasm, and *vice versa*, it is always important to ascertain the real origin of such pain. The pain arising from spasm commonly attacks very suddenly, or even instantaneously; it generally comes and goes, or is intense for a while, and then subsides at intervals, as the spasm *recurs* and relaxes; it very often shifts its seat, as different portions of the muscular fibres of any part are successively contracted; and, above all, it is not attended with general fever, and the pulse is neither accelerated, nor increased in hardness. The pain connected with inflammation of any organ is commonly more slow and gradual in its attack; it is accompanied or preceded by shivering;

shivering; it is fixed both in respect to the intensity and to the seat of it; and it is attended by symptoms of fever, heat of skin, a quick and hard pulse, thirst, &c. The kind of pain, too, is described as different: that of spasm being accompanied by a sense of constriction; while that of inflammation is combined with a sense of stabbing or cutting, and often of throbbing, burning, &c.

Of these painful spasmodic diseases, the *tetanus* is the most formidable and fatal, in which all the voluntary muscles are rigidly contracted, and the body and limbs stiffly extended; in short, an universal cramp exists, and the pain of such a condition may be conceived, if we consider the suffering produced by a partial cramp. Sometimes the antagonist muscles of the back are most affected, when the body is rigidly bent backwards, like a bow, and rests upon the back of the head and the heels, when it is called *opisthotonos*; and sometimes the anterior muscles are most contracted, and the bend is forwards, which is called *emprosthotonos*. (See TETANUS.) The jaw is firmly locked in this complaint; and when the spasm is confined to that part, it is called TRISMUS, or locked-jaw; which see. Less formidable, though very painful, spasms occur in the muscular coat of the intestines, constituting *colic*; or in that of the stomach, which is usually called *cramp in the stomach*. In hysterical women, various cramps of these parts, and of the voluntary muscles, are liable to occur. The fit of spasmodic *asthma* is principally produced by a spasmodic contraction of the muscular fibres about the larynx, and of the muscles subservient to respiration.

In the pathological doctrines of Dr. Cullen relative to the nature of fever, *spasm* holds a distinguished place, and is considered, indeed, as the essence of fever. This hypothetical spasm was supposed by him to take place in the extremities of the arteries, and especially of those on the surface of the body, and to be demonstrated by the paleness and shrinking of the external parts, and the suppression of the excretions, constituting the cold fit; and the hot fit, which ensues, was believed to be an effort of the constitution, a reaction of the powers of life, and of the heart and arteries in particular, to overcome and to relax this spasmodic constriction of the extreme vessels; and this reaction, or fever, therefore, is seen to continue until the relaxation of the spasm is effected. (See First Lines of Pract. of Physic, par. 40. et seq.) We have confuted this hypothesis at considerable length, in another place, (see FEVER, Dr. Cullen's Theory,) and shall not dwell upon it here. It is altogether gratuitous, and unsupported by facts; but it has had considerable influence in modern practice.

The causes of *spasm* may be reduced to two heads: *debility*, and its concomitant irritability, in the whole system, or in particular organs, which are, therefore, excited to inordinate actions by the ordinary stimuli; and *irritation*, that is, the actual operation of unusual and extraordinary stimuli. If these two causes are combined, it is obvious that any excitement, very little greater than ordinary, may produce violent spasm, or very inordinate actions: whence it happens, that in constitutions of particular irritability, very slight irritations will occasionally produce the most severe spasmodic disorders. Thus the most violent of all, the *tetanus*, is often occasioned by a scratch or slight wound of the skin; and the locked-jaw of new-born infants appears to originate in the irritation of the meconium retained in the bowels. If the irritation of worms, and even morbid secretions, in the intestines are sufficient, in children, to produce actual convulsions, it need not be matter of surprise that colic and cramp of the stomach should be occasioned, in irritable adults, by undigested food, and hot stimulating

drinks. Very slight irritations, both external and internal, excite spasms in such habits; even the puncture of a needle (Mem. of the Med. Society of Lond. vol. ii.); and the pressure of a tumour on a nerve, irritation from distended vessels, or bony excrescences in the cranium, have all given rise to spasm.

The chief remedies for spasm are those which lessen irritability, or which excite increased power of action, or produce a sudden and considerable commotion, and those which remove the irritating cause. The first mentioned are usually called *antispasmodic* medicines. The most effectual of these are anodyne or narcotic substances, especially opium, hyocyamus, and conium, which tend to lessen the sensibility of the whole frame, and, therefore, to render it less liable to be acted upon by irritants. The term *antispasmodic*, however, has been much applied to medicines of a stimulant quality, and especially to some strong-smelling substances, which alone are much less efficacious in relieving spasm than the narcotics. Of the latter class are musk, castor, camphor, and assafoetida; and of the more stimulant class are alcohol, æther, ammonia, the essential oils, &c. Perhaps the most efficacious remedy is composed by uniting the latter with the anodynes; for we know of no relief to violent spasmodic pain more effectual than that produced by a combination of laudanum with æther. Among the stimulants that are often remedial in cases of spasm, heat is not the least important. Fomentations, hot water, a hot brick, a bag of heated bran, &c. applied externally near the seat of spasm, will often afford speedy relief; and a large draught of hot water, taken as warm as the stomach will bear it, has produced a similar good effect.

It is probably chiefly from the stimulant effect of violent emotions that relief is obtained from them in spasmodic pain; but sudden terror, or surprise, or apprehension, have succeeded in removing it. The influence of mental emotions, indeed, both in producing and curing spasm, and even convulsions of the most violent nature, is equally curious and inexplicable. See IMITATION and CONVULSIONS.

Where spasm depends upon irritation, the cause must be investigated, and, if possible, removed by appropriate remedies, if within their reach. Thus clearing the bowels, where there is an obvious irritation from worms, undigested aliment, morbid bile, &c. will sometimes entirely remove the spasms. In order to prevent a recurrence, by invigorating the system, and thus lessening its irritability, after the spasms have been subdued, it is often necessary to resort to the use of tonic remedies. Of these a great variety has been employed, at different periods, with various reputation. Cold bathing, the use of the shower-bath, or tepid bathing, as at Buxton, may be considered as one of the most effectual tonics; after which may be mentioned some of the metallic tonics, such as the various preparations of iron, copper, zinc, and silver, all of which are often efficient remedies. The cinchona, columba, cascarilla, gentian, and other vegetable aromatic bitters, with or without an addition of the mineral acids, have also their value as tonics, and contribute to restore vigour and lessen irritability in debilitated habits.

SPASMODIC, something belonging to a spasm, or convulsion; as spasmodic medicine, spasmodic disease, &c.

Hunger, according to M. Hecquet, is a spasmodic affection of the fibres of the stomach; unless it arise from the fibres being too much moistened by the liquors thereof, so as to incapacitate them for their office. See HUNGER.

SPAT, a term used by the fishermen for the spawn of oysters, which is cast in the month of May.

SPATAGOIDES, in *Natural History*, the name of a genus of the echini marini, the characters of which are, that it has the aperture for the anus on one side of the upper surface, and has a large furrow on the back, which makes it of a cordated form; but has no furrows on the vertex, but only four or five smooth rays, made of a number of slight transverse litz.

SPATALLA, in *Botany*, a name of Mr. Salisbury's.—Brown Tr. of Linn. Soc. v. 10. 143. Ait. Hort. Kew. v. 1. 203.—Clas and order, *Tetrandria Monogynia*. Nat. Ord. *Proteaceæ*, Jull. Brown.

Ess. Ch. Corolla four-cleft. Stamens in the concave tips of the segments. Nectary four scales beneath the germen. Stigma oblique, dilated. Nut superior. Involucrum of from two to four leaves, containing one, or a very few, flowers. Common receptacle naked.

An occasional irregularity in the *corolla*, and the oblique *stigma*, are the only characters which distinguish this genus from *Sorocephalus*; for in habit they strictly accord. We cannot but, therefore, advise their union, under the latter name, whose derivation is the best.

The species of *Spatalla*, defined by Mr. Brown, are 15, one of which only finds a place in Mr. Aiton's work. They are disposed in two sections, of each of which we shall give an example or two.

Section 1. *Involucrum single-flowered. Stigma concave, spoon-shaped. Corolla unequal. Ten species.*

S. mollis. Soft *Spatalla*. Br. n. 1.—“Involucrum of two entire leaves. Leaves straight, villous, as well as the young branches.”—Native of hills at the Cape of Good Hope. Communicated by Mr. John Roxburgh, to Mr. Lambert. An upright *shrub*, with copious reddish branches; the young ones slender, erect. *Leaves* slightly spreading, seven or eight lines long, silky with moderately spreading hairs, and tipped with a very sharp callous point. *Spike* sessile, erect, solitary, dense, racemose, of an oblong cylindrical shape, hardly an inch in length. *Bractæas* leafy, twice as long as the partial flower-stalks. *Involucral leaves* ovate, villous, the outer one broadest. *Corolla* densely bearded, purplish; the marginal hairs of its larger segment inflexed. *Scales* under the germen linear permanent.

S. prolifera. Proliferous *Spatalla*. Br. n. 8. (Protea prolifera; Thunb. Diff. n. 27. t. 4. Linn. Suppl. 118. Willd. Sp. Pl. v. 1. 518.)—Involucrum of four leaves, withered at the points. *Spike* in a conical head. Flowers nearly sessile. Stem proliferous.—Native of hills at the Cape of Good Hope. An upright *shrub*, from a foot and a half to two feet high, much branched in a proliferous and umbellate manner; the young branches somewhat silky. *Leaves* closely imbricated, hardly three-quarters of an inch long, awl-shaped; silky on the younger branches. *Spikes* sessile, solitary, terminal, but surmounted by subsequent branches from their base. *Corolla* very densely silky; its outer segment twice as large as the others. *Stigma* flattish, with a central tubercle.

Section 2. *Involucrum with three or four flowers. Stigma rather convex. Corolla almost equal. Five species.*

S. incurva. Incurved-leaved *Spatalla*. Br. n. 11. Ait. n. 1. (Protea incurva; Thunb. Diff. n. 22. t. 3. Willd. Sp. Pl. v. 1. 516.)—*Spikes* racemose, somewhat stalked. Involucrum downy, longer than the bractæas, with about four flowers. Leaves incurved. *Corolla* unequal.—Native of moist, sandy, rather shady situations at the Cape of Good Hope. Mr. Masson sent it, in 1789, to Kew, where it flowers in May and June. The leaves are numerous, slender, above an inch long, spreading, ascending at the points.

Spikes generally aggregate, oblong, lax. *Bractæas* nearly the length of the partial stalks. Mr. Brown notices a variety, or perhaps distinct species, whose leaves are shorter and more crowded, *spikes* solitary, and *bractæas* longer than the partial stalks. *S. incurva* bears a close resemblance to some species of *CONOSPERMUM*. See that article.

The descriptions of the genera of *SOROCEPHALUS* (see that article), and *Spatalla*, suggest to us a doubt whether the species of these genera may not, in some instances at least, differ sexually only from each other. Not having seen many of them, we cannot examine critically into each species, but, in a general view, the male organs seem most perfect in *Sorocephalus*, the female in *Spatalla*. The regularity or irregularity of the *corolla* does not seem, in this case, to constitute a sufficient generic difference.

SPATANGI, in *Natural History*, the name of a genus of the echini marini, including all those which are marked in the shape of a heart, and have the aperture for the anus in one of the sides of the upper superficies. These have all a remarkable furrow on the back; their base is nearly flat, and they have several furrows on the vertex. By these characters they are distinguished from the briffi, with which they have in common the marks of two lips to their mouth, and want the teeth which the other kinds have.

SPATAREI, in *Geography*, a town of the island of Samos; 5 miles S.S.W. of Cora.

SPATARO, GIOVANNI, of Bologna, in *Biography*, the disciple of Ramis, a Spaniard, the first modern who sustained the necessity of a temperament; which gave birth to a controversy among musicians in Italy, that continued with great warmth during many years, and which has been revived in France during the latter end of the last century, with due polemic heat, by the writings of the abbé Rouffier. (See *PYTHAGORAS*.) Spataro published a work in defence of his master's opinion, in which he treated the venerable Franchinus, and even Guido himself, with great obloquy, for not having discovered the necessity of a temperament. See *RAMIS*.

SPATHA, is a word used by different authors in various senses: some express by it a rib; others the instrument called by surgeons a spatula, and is used for spreading ointments and plasters; and Celsus calls a sort of incision-knife by this name. It is also used for the external covering of the fruit of the palm-tree, and by others for a sword. This last is indeed its proper signification, and all the others are only metaphorical applications of it to different things, which bear some resemblance to a sword.

SPATHA, in *Botany* and *Vegetable Physiology*, a Sheath, is a sort of *CALYX*, according to Linnæus, (see that article,) more or less remote from the flower, of which, therefore, it does not, like the *perianthium*, properly make a part. If of one valve only, it bursts longitudinally, as in the Narcissus and Snow-drop; but it often consists of many membranous valves, leaves, or scales, as in *Sowerbea*, *Pancreatium*, &c. The natural order of *Palmeæ* exhibits various kinds of *Spathæ*, in great perfection, each enclosing a branched many-flowered *SPADIX*. (See that article.) Perhaps, nevertheless, this organ might more correctly be esteemed of the nature of a *Bractea*, or floral leaf, not constituting, in any case, a part of the fructification, nor affording any share of the generic characters. We cannot but confess, that the more closely the definitions of genera are restricted to the real organs of the flower and fruit, without recurring to the inflorescence, or any of its accompaniments, the more correct and philosophical the science of Botany has always appeared in our eyes. Linnæus, led by Artedi, swerves

from this correctness in the *Umbelliferae*; and for want of sufficient information respecting the flowers and fruit of all the *Palmæ*, he was obliged to advert to other parts, to found any thing like plausible genera. Such aberrations from his own laws should rather be reformed, by those who have the means, than serve as examples for laxity of principle in other instances. The greatest artists ever require the fewest tools, and most simple materials; and the human intellect never makes such attainments as when necessarily put to its utmost exertions. Natural history, when studied with all the accuracy and intensity of which it is capable, becomes as instructive and philosophical a school for the mind as any science whatever; nor does any one require more deep judgment, as well as precise observation.

SPATHALIUM, among the Romans, an ornament which the women wore about their hands, not unlike the coral ones of the moderns.

SPATHELIA, in *Botany*, altered from Dr. Patrick Browne's name for the same plant, *Spathe*, and alluding to the simple undivided stem, crowned with a tuft of luxuriant leaves, like the Palm tribe; *σπαθην* being a palm-tree, or palm-branch.—Linn. Gen. 148. Schreb. 198. Willd. Sp. Pl. v. 1. 1496. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 2. 171. Juss. 371. Lamarck Illustr. t. 209. Gært. t. 58. (*Spathe*; Browne Jam. 187.)—Class and order, *Pentandria Trigynia*. Nat. Ord. *Terebinthaceæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of five oblong, coloured leaves. *Cor.* Petals five, oblong, equal. *Stam.* Filaments five, awl-shaped, ascending, furnished with a tooth at the base; anthers ovate. *Pist.* Germen ovate, shorter than the stamens; styles three, very short; stigmas three, roundish. *Peric.* Capsule oblong, triangular, with three wings, of three cells, not bursting; each cell furnished with a lateral channel, full of resin. *Seeds* solitary, oblong, prismatic, or nearly cylindrical, tapering at each end.

Eff. Ch. Calyx of five leaves. Petals five. Capsule with three winged angles, and three cells. Seeds solitary.

Obs. Gærtner remarks, that the capsule is sometimes compressed, with two opposite wings only, and two cells; but this seems to arise merely from a failure of impregnation of one of the stigmas.

1. *S. simplex*. Sumach-leaved *Spathelia*. Linn. Sp. Pl. 386. Willd. n. 1. Ait. n. 1. (*Aceri* aut *paliuro* affinis arbor, caudice non ramoso, foliis forbi sylvetris, floribus pentapetalis racemosis speciosis purpureis, fructu sicco tribus membranulis extantibus alato; Sloane Jam. v. 2. 28. t. 171.)—Plentiful by the sides of rivers, among the rocky hills of Jamaica, according to Sloane and Browne. The latter erroneously calls it the Maiden-plum tree. This very handsome plant is said to have been introduced into the stoves of England, in 1778, by Dr. William Wright. The root is of a spreading nature, not striking deep. *Stem* quite simple and erect, an inch thick, naked, round, rising like a palm-tree, Sloane says, to the height of 40 feet, and crowned at the summit with a large tuft of pinnate, crenate, spreading leaves, surmounted, in the flowering season, with a vast compound panicle, many feet in height, of handsome purple flowers. The capsules are about an inch long.

SPATHESTER, the name of a surgical instrument used to draw the prepuce over the glans.

SPATHINUS, in *Natural History*, a name given by the Greeks to the stag or deer, when in its second year.

In the first, it was called *nebrus*; in the third year, *dicrotus*; and after this *cerastes*, as long as it lived.

SPATHIUM, in *Botany*, so denominated by Loureiro,

from *σπαθιον*, a little sheath, alluding to the form of its calyx.—Loureir. Cochinch. 217.—Class and order, *Hexandria Trigynia*. Nat. Ord. *Inundatæ*, Linn. *Naiades*, Juss.

Gen. Ch. *Cal.* Sheath stalked, of one leaf, roundish, spreading, single-flowered. *Cor.* none. *Stam.* Filaments six, short, inserted into the receptacle; anthers roundish, of two cells. *Pist.* Germen (superior) roundish, with four horns; style none; stigmas four, oblong, reflexed. *Peric.* Berries four, ovate, pointed, single-seeded. *Seeds* roundish.

Eff. Ch. Sheath roundish, stalked, single-flowered. Corolla none. Berries four, with single seeds.

1. *S. chinense*. *Thong pin ngau* of the Chinese.—Native of marshy places, near Canton in China. The stem is erect, three feet high, herbaceous, with spreading, flaccid, furrowed branches. Leaves heart-shaped, lanceolate, five-ribbed, smooth, scattered, with clasping footstalks. Spikes linear, nearly terminal. Such is the description of Loureiro, who conceives the above plant to be somewhat akin to the Linnæan *Aponogeton*, and also to *Potamogeton*. We have no acquaintance with it.

SPATHODEA, a genus founded by Palisot de Beauvois, in his *Flore d'Oware & de Benin*, on some of the Linnæan *Bignoniæ*, and named from the sheath-like form of their calyx. It is adopted by Mr. Brown, in his *Prodr.* Nov. Holl. v. 1. 471, under the following character.

Calyx sheath-like, cloven down one side, either toothed or entire at the end. Corolla somewhat funnel-shaped, with a five-lobed, rather unequal, limb. Stamens two long and two short, with a fifth abortive filament. Capsule pod-like, falcate, imperfectly four-celled. Partition transverse, corky.

The genus is shrubby or arboreous; with opposite, rarely alternate, pinnate leaves, sometimes simple. Flowers mostly panicle.

Bignonia spathacea, see *BIGNONIA*, n. 18, is an example of *Spathodea*, as is also *S. heterophylla*, and perhaps *alternifolia*, of Brown.

SPATHOMELE, a word used by some to express the spatula, used by the apothecaries and surgeons in mixing and spreading ointments and plasters.

SPATHOSE, in *Mineralogy*, having a crystalline structure.

SPATHULARIA, in *Botany*, from the spatulate shape of its head, a genus of *Fungi*, consisting of only one species.—Persoon Syn. Fung. 610.—Class and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi*. Sect. *Gymnocarpi, helvelloidei*.

Eff. Ch. Club-shaped. Head compressed, membranous, decurrent at each side.

1. *S. flavida*. Yellow *Spathularia*. Perf. Disp. Meth. 36. Comment. 34—36. (*Clavaria Spathula*; Dickf. Crypt. fasc. 1. 21. Fl. Dan. t. 658. *C. spatulata* glabra; Schmid. Ic. t. 50. *Elvela secunda*; Schæff. Fung. t. 149. *Helvella spatulata*; Sowerb. Fung. t. 35.)—Found in fir woods, in autumn. Mr. Crowe first discovered it at Cosey, near Norwich, where, in the plantations of fir George Jerningham, it is very abundant, growing erect, in tufts. The stalk is about a finger's length, half an inch in diameter, hollow, rather uneven, whitish. Head vertical, obtuse, hollow, somewhat obovate, or inversely heart-shaped, pale buff, or yellowish, discharging innumerable minute seeds, in the form of smoke, from marginal pores. See *CLAVARIA*, n. 17.

SPATIUM, Lat., space, is applied to the void between the lines of the staff, upon which music is written. Spaces at first were not used, but there was a line for every sound

found (see NOTATION); but when the lines were reduced to four, as in the canto fermo of the Romish ritual, and afterwards increased to five, as in the present secular music, the spaces came into use; and the lowest was called the first, and so on to the fourth, fifth, and sixth, which unites the base with the treble. See RIGA, LINES, and STAFF.

SPATLING-POPPY, a name given to the common field-lychnis, a species of cucubalus, from the white froth found on it in the spring. See FROTH-Spit.

SPATOLA, in *Geography*, a town of Naples, in Calabria Ultra; 14 miles S. of Squillace.

SPATTERDASHES, a kind of covering for the legs, made of leather, &c. Those of soldiers are made of coarse linen, waxed over and buttoned tight.

SPATTS, a small sort of spatterdashes, reaching only a little above the ankle.

SPATULA, or SPATHULA, formed from *spatha*, of the Greek, *σπαθίον*, which signifies the fame; an instrument used by surgeons and apothecaries; made flat at one end, and round at the other; serving to spread their plasters and unguents.

The surgeons have little steel spatulas. And the apothecaries have also large ones of wood, to stir their drugs in diluting, tempering, or boiling them.

The spatula is used by surgeons to depress the tongue, in order to examine the state of the tonsils, uvula, and fauces, when they are affected with any disorders. It is also used to suspend the tongue, when the frænum is to be divided; for which purpose it has a suture at its extremity, and should rather be made of silver than of any other metal. These spatulæ are made of different shapes.

SPAVIN, formed from the French *esparvin*, which signifies the fame; a disease in a horse: being a swelling or stiffness, usually in the ham, which causes him to halt.

There are two kinds of spavins, *viz.* the *ox*, which is a callous tumour, at the bottom of the ham, on the inside, hard as a bone, and very painful. While it is yet young, some horses only halt with it at the first coming out of the stable. The *dry* spavin is more easily perceived, by the horse's raising one of his hind-legs, with a twitch, higher than the other: but sometimes it is found in both legs.

This kind, which some also call *string-halt*, frequently degenerates into the *ox* spavin; for which there is no remedy, but to apply the fire; and even this is not always successful.

There are two other kinds of spavin, which have their seat in the hoof, *viz.* the *blood* spavin, which is a soft tumour, that grows through a horse's hoof, and is usually full of blood; and the *bone* spavin, or crusty substance growing on the inside of the hoof, under the joint.

SPAWDER, in *Rural Economy*, a term provincially signifying an injury, by the legs of animals being forced too far asunder on ice, or slippery roads, &c.

SPAWN, in *Gardening*, the progeny or offspring of plants or other vegetables; but which is mostly applied to such small offsets, suckers, and sprouts, as rise numerously from the roots, &c. of certain plants, serving for the purpose of increase, which, as being parts similar to the whole plant, when separated from the parent vegetable and planted out, readily grow, and commence proper plants, and thereby renew or increase their respective kinds with great facility and abundance. Some plants produce them in large quantities, others scarcely at all. (See SUCKERS.) And in a more general acceptation, it is likewise peculiarly applied to the progeny of mushrooms, being an offspring from the root of those *fungi*, consisting of minute white parts, shooting and running in the earth or dung, like

small white thready fibres, assuming the appearance of slender white strings, which are productive of numerous minute white knobs, appearing at first of the size of small pin-heads, the whole smelling strong of the mushroom; and those little knobs being infant plants, they gradually increase in size to proper mushrooms, which are quick of growth, and of very short duration; but the same spawn running in the earth, &c. furnishes a plentiful supply of mushrooms from the bottom in regular succession for a considerable time, sometimes several months. See AGARICUS.

This sort of mushroom spawn may be procured at all seasons of the year, but more plentifully towards the end of summer and in autumn, from the places of its growth and production; such as old mushroom-beds, old horse-dung hot-beds, and horse-dunghills that are moderately dry, and which have remained undisturbed several months; also sometimes in old compost heaps, consisting chiefly of horse-dung; in all of which the spawnly substance discovers itself in dry lumps of dung and earth, which lumps should be taken up entire: likewise in stable-yards, where any quantity of horse-dung has lain dry and undisturbed any considerable length of time, lumps of spawn are often obtained. It is also found in great perfection in the horse-rides belonging to great inns, livery-stables, and horse-dealers, especially on the sides next the walls; likewise in horse-mill tracts, where horses are constantly employed in working and dropping their dung, which is swept together on the sides, there to remain; also in kitchen-gardens, where any piece of ground has been dunged in the spring with new, or but moderately rotted stable-dung, or old dry hot-bed dung, &c. and only slightly turned in, as already shewn under the head of making these beds. And sometimes it is produced naturally all over the surface of an old cucumber or melon hot-bed, both in the dung and earth, in autumn or winter, where the frame and lights have been continued over the bed; and where the earth of the bed is of a loamy nature, the spawn in which is often remarkably fine and strong; for in this kind of earth, of a moderately light quality, it is generally of a superior quality, and very productive; so as sometimes, in such old beds, where the frames and glasses remain, and the surface of the bed is covered thickly with dry straw, litter, or hay, under the glasses, to produce a full crop of good mushrooms towards the spring. Mushroom spawn is also obtained in meadows and pastures towards the end of summer and in autumn, before the rain and cold commences, as in the months of August and September, when the mushrooms rise naturally, serving as a direction to the place where to find it; but that found in the other places is mostly the best in quality. Some caution is also necessary in collecting spawn from fields to have it of the right sort.

On this subject it is necessary to observe, that there is also a fruitful and barren sort of mushroom spawn; the former is distinguished by the substance of the fibres or stringy white shoots, &c. and mushroom-like smell, as before observed; but in the latter sort, the thready fibres are far more abundant, fine, and downy, often appearing like a fine white down, and, being of no substance, produce only a flash of small white fungi, destitute of the fleshy part, and which, by the mushroom-men, is commonly called *white-cup*.

Methods are sometimes practised to obtain mushroom spawn more abundantly by art, by the effects of horse-dung, both in hot-beds and compost heaps; sometimes, in the former case, by planting small pieces of spawn, or spawnly earth, along the top edge of the later cucumber

hot-beds in summer, or in the sides of any horse-dung heaps, having a little warmth remaining; so that the moderate heat of the dung in the bed or heap may set the spawn a-running, so as sometimes to produce a few mushrooms in autumn, and increase it considerably for future use in spawning proper mushroom-beds: and in the second case, by a compost of dung and loamy earth together; procuring in spring, or early in summer, a quantity of fresh horse-dung, consisting of plenty of short stuff, and a due proportion of long; and casting the whole into a heap to ferment a fortnight or a month, that the rank burning vapour may pass away; then having some loamy earth, or other good substantial mould, or any spawny soil from old beds, form the dung into a long narrow ridge, mixing some of the earth occasionally towards the outside; and in a fortnight or three weeks, when the heat becomes quite moderate, covering the whole with dry long litter to defend it from the wet, permitting the whole to remain a considerable time, when good spawn will often be produced. The heaps for this use are best formed in dry sheds, &c.

In collecting it from any of these places, the lumps of dung and earth in which it appears should be taken up as entire as possible, put into a basket, and carried into some dry shed, or other place, when the heaps are made out of doors, till wanted, or it may be immediately used in making the beds.

The practice of introducing this sort of spawn, in a suitable manner, into beds properly formed and constructed for the reception of it, is the best and most convenient method, which has yet been found, of raising crops of mushrooms in garden cultivation. The beds for this use are, as has been seen, constantly prepared with new fresh horse-dung which has undergone the process of fermentation, by being thrown into a heap, in order to take off the first violent coarse heat, and then formed in the long narrow ridge manner, somewhat in the shape of a roof, for throwing off moisture, and left exposed in that state until it becomes in a proper state of heat, when the portions of spawny matter are inserted all over the surface, but only just within it, the whole moulded over an inch or two in thickness, and then covered closely with dry litter to a proper depth. The parts of the spawn are consequently planted in a sort of hot-bed, by means of which they rapidly advance in growth, and soon furnish supplies of good mushrooms for use. The spawn, being forced into action in this way, is often not longer than six or eight weeks in producing plentifully; the same bed frequently continuing to afford a supply for five or six months, or longer; but new beds are to be made every year, and sometimes two or three times in that space of time, in order to furnish a constant succession of good mushrooms. See *AGARICUS*, and *SPAWNING Mushroom-Beds*.

Where there is plenty of this fresh stable littery dung and the short stuff in mixture, mushrooms are sometimes not only abundantly supplied, but plenty of spawn for future beds.

No proper seed of the mushroom has hitherto been discovered by which crops of it can be raised by the gardener, though it is well known that it produces seed like other plants, and is naturally produced in that way, as well as by spawn. The extremely minute seeds are said, in this case, to be situated and contained in the *lamellæ* or gills, which, when full grown, and the seeds become quite ripe, discharge and disperse them upon the surrounding ground, from which they are conveyed by the wind and other means to other distant situations, where the soils are suited to their growth. In these they fix themselves and grow, their roots increasing rapidly so as to produce proper spawn.

The situations in which proper supplies of good spawn are to be met with, as well as the formation of it, will in some measure be seen from what has been said. That which is produced in the horse-dung methods is, however, constantly to be preferred to such as is procured from the field, for all the purposes of cultivation in the garden, as producing thicker, firmer, more fleshy, and richer flavoured mushrooms. All old worn-out spawn should, of course, be rejected, as improper and unfit for being made use of in this culture, and the new virgin spawn, as it is termed, or such as has not been in production of mushroom crops, be employed, as in some instances, even the young offspring spawn of such as has been long wrought from bed to bed, will degenerate; there being not unfrequently a very material difference in the goodness of that which is fresh and full of heart, and that which has been long in use, the former producing fine and abundant crops, while the latter only sends up a flash of small trifling heads at first, of none or very little substance, and perhaps no more of any consequence afterwards.

New littery and plenty of short horse-dung, especially when mixed with a little loamy earth, are the most remarkably and abundantly productive of good spawn. When they have lain together for a considerable length of time, they are mostly in a peculiarly fit state for producing it in large quantities.

Spawn of this sort keeps well when laid up close in a dry place, or when put up in hampers or baskets, and covered in a close thick manner by dry litter or mats. The drier it is put up and kept within moderate limits the better, as the more it will improve in its productive properties, and take more freely in the beds when planted, retaining its vegetative qualities for many months.

As this sort of spawn is of great importance and value in many places, where large quantities of mushrooms are raised for sale in the markets, certain persons in such situations often employ themselves at particular seasons of the year, but especially in the autumn, in going about to different parts and collecting it, which near large towns mostly pays them well, being of ready sale at a high price, as six or seven shillings the bushel, and more in some cases.

When it is to be provided in the vicinity of the metropolis, it will commonly be met with in the most ready manner at the neat-house gardens on the different side of it, at the different markets in it, where vegetables are exposed for sale, and in the principal nursery garden grounds.

It is capable of being packed up and sent to any distance when necessary.

SPAWN, Fish, in *Rural Economy*, the oviparous or egg-like granulated substance which is deposited by female fishes, in order to its being impregnated by the more liquid femal matter of the males, and be thereby rendered productive of the young progeny or fry of the particular sort or kind.

Each sort of fish has its peculiar habit or economy in the performance and mode of depositing this material, as may be seen in the following article. Some sorts of fish are likewise much more productive of it than others, consequently more prolific. This is the case with the herring and the salmon, the former of which is only a fish that weighs from five to ten ounces, according to Harmer, but in which the spawa weighs 480 grains, and has the amazing number of 36,960 eggs, when examined about the month of October: the latter, though a much larger fish, is productive of spawn in a very high degree, the number of its ova being almost countless. And there are other
forts

forts of fish, which probably equal or out-number either of these, as the mackarel, sprat, and some others. It is necessary that fish should be as little as possible disturbed at the time of their depositing their spawn in the rivers, and on the banks of the sea-shores, or other places, as it may not only be prejudicial to them, but injurious in preventing the male fish from impregnating it in a proper manner.

SPAWNING of *Fish*, the act of depositing the raw, spawning, or oviparous matter of the female, and of its being impregnated by that of the male, for the purpose of breeding or producing their young. Most sorts of river-fish, and many of those of the sea-kind, produce their young progeny in this way. This operation or work of impregnation is accomplished in different manners as to the mode of its deposition, according to the nature and habits of the fish, and the seasons at which the spawning takes place. In those fishes which spawn in the more still and shallow waters during the spring and summer seasons, such, for instance, as those of the pike, bream, carp, perch, and some other kinds, it would seem to be most commonly the habit to deposit their spawn material on the leaves and vegetables which lie just below the surface of the water, which is in all probability the most favourable situation for it in different respects. While in those fishes which cast their spawn in the winter season, such as the salmon, trout, herring, and many other sorts, spots and places very near the sources or beginnings of rivers and streams, or the more rapid fresh-water currents, are mostly sought for and fixed upon in this intention, where there is a constant flow of fresh water, where all stagnation is prevented, and where the water is the most fully aerated, either in its natural situation or during its fall in rain, as being probably the most suitable and favourable for the purpose. A proper and suitable degree of warmth may also be necessary in this business.

In all other cases the fishes probably deposit their spawn material in such situations as are the most suitable to their particular economies, and where there is the necessary heat, as well as where the water is the most fully saturated and impregnated with air, as it is now well ascertained, that their impregnated spawn material do not produce young ones, any more than seeds vegetate, except where they are freely supplied with air. The fish in the egg or spawn, derives its oxygen from the air which is dissolved in the water that surrounds or flows over it, which, in the first of the above cases, is much supplied to the water by the leaves of the plants on which it is deposited, in performing their healthy functions; which also probably afford a better and more suitable situation for the male fishes impregnating it upon than any others: and in the latter case, it is gained from the perpetual flowings of such fresh and fully aerated waters over it, after it has been the most conveniently and effectually impregnated in such shallow parts, currents, and streamlets. It has indeed been suggested, that in this latter case, it is the instinct leading the fishes to provide a proper supply of air for their spawn material, which is to be deposited, that carries or forces them from the seas, lakes, and other similar situations, into mountainous countries; and which impels and induces them to move against the streams, as well as to endeavour and make efforts for overleaping weirs, cataracts, mill-dams, and other similar erections and works. See SEED.

The spawning and generation of fish was however formerly considered as of a very different nature, and as being performed in a very different manner. It is stated, in speaking of the herring, by the writer of a paper in the third

volume of the "Transactions of the Highland Society of Scotland," that a very singular and seemingly unphilosophical notion had been held with regard to the impregnation of the ova or eggs of fish, and which is not by any means the doctrine or hypothesis of yesterday, but which has prevailed in a greater or less degree, for upwards of two thousand years; that is, from the days of Herodotus, who in treating and speaking of the fish in the Nile, makes the following observation. "At the season of spawning they move in vast multitudes towards the sea, the males lead the way, and emit the engendering principle in their passage; this the females *absorb* as they follow, and in consequence conceive, and when their ova are deposited, they are consequently matured into fry." Beloe's Herod.

And strange and absurd as this supposition and process seem to be, it is asserted, it is said, to be the case by Linnæus, the most learned of all others in the science of animal history: he tenaciously affirms, it is maintained, that there can be no impregnation of the eggs of any animal out of the body, and that as fish have no organs of generation, that deficiency is made up for by adopting the system or notion of Herodotus. This absurd and unfounded notion has likewise, it is added, been attempted to be supported by Kalm, the friend and countryman of the above celebrated naturalist, on a story supposed to have been told by Franklin about two rivers in his province (New England in North America,) which fell into the sea nearly together; in one of which no herrings were ever taken, while in the other they were abundantly caught; the fish, when they come to deposit their spawn, always passing up that river without ever entering the other. In order to try to make the fish take to the other river, this person is said to have put out his nets and taken some of them, as they were coming up for spawning in the productive river. He is said to have taken "the *spawn out of them*, and to have carefully carried it across the land into the other river, where it was *hatched*, and the consequence was, that every year afterwards they caught more herrings in that river; and this is, it is said, still the case." But on inquiry in that country, the writer of the above paper remarks, both the river and the story were unknown to all who were inquired of about the matter.

The same story is since supposed to have been trumped up by a French writer of the name of Nouel, with this strong shade of difference; that the former *cuts* the ova out of the belly of the herring, while the latter says, that the spawn was collected from off plants, where it had been deposited. At one of the sittings of the National Institute in France, in the year 1799, a memoir was read by this member of instruction at Rouen, on the means and advantages of naturalizing the herring, a salt-water fish, in the water of the Seine, near its mouth, &c.; in which, after noticing the various means by which this may be accomplished, it is observed, that "herrings having been found ascending from the sea into one river of the American province, (noticed above,) while a single individual was never seen in another, separated from the other by a narrow tongue of land, and which also communicated with the sea, this philosopher (Dr. Franklin) took the *leaves off some plants on which the herrings had deposited their ova*, already fecundated, and conveyed them to the river which was deprived of the annual visit of these fish. The success of the experiment surpassed his expectation, the ova was completely productive, and the following year the river was peopled with a numerous shoal of herrings, which, since that time, continued to frequent it." Phil. Mag. vol. x. p. 163.

This account the writer of the above paper considers as evidently

evidently founded upon the former, and both, he thinks, come in a very questionable shape; however, the theory of the latter is supposed more rational, and not entirely against established facts; though it should be considered, he conceives, that the European herring is not a native of fresh water, and, as he thinks, never will be naturalized in such waters; but that the spawn of fishes, being fecundated in their own waters, may be transported; and when placed in the same homogeneous element upon leaves, sand, or other matters, where the sun and air, as we have seen above, can have free access, or a proper heat, with oxygen air, as has been shewn already, received, such ova, raw, or eggs, will be animated and become fry in the same time they would have done in their parent beds, cannot be doubted. This is a practice, it is said, which is well known in China; the Missionaries to which have noticed two or three things about it which are singular enough; the first of which is, that in the great river Yangtse Kyang, not far from the city Kyus-king-fu, in the province of Kyang-fi, a prodigious number of barks meet every year to buy the spawn of fishes. About May the people of the country dam up the river for nine or ten leagues together, in several places, with mats and hurdles, leaving only room enough for barks to pass, in order to stop the spawn, which they know how to distinguish at first sight, though the water is scarcely altered; with this water mixed with the spawn, they fill several vessels to sell to the merchants, who, at this season, arrive in great numbers to buy and transport it into divers provinces, taking care to have it stirred up from time to time: this water is sold by measure to such as have fish-ponds and pools belonging to their houses. The manner of propagating the gold-fish from spawn is likewise deserving of attentive consideration. Du Halde's Descrip. of China.

It is supposed by the writer of the paper, that herrings which cast their spawn in the winter months, without doubt deposit it on our shores; but whether upon gravel, sand, stones, fuci, or other plants, is not well ascertained; but thus far we know, it is said, that it cannot be in deep water, unless we suppose it to have such a buoyancy as to be within reach of the sun's genial influence, and, as has been since shewn, that of the free action of the air.

It is believed, and the same writer thinks with reason, that it is impregnated by the male after it is emitted by the spawner or spawning-fish. The raw spawn, or eggs, of these fish, become animated, it is said, in the month of April. It is noticed, that the *fucus palmatus*, and indeed all the numerous species of fuci which grow upon our coasts, it is hardly to be doubted, harbour the spawn of fishes; but that the opinion may readily be either confirmed or confuted by the assistance of a glass of moderate magnifying power.

It is suggested, likewise, that the cause or reason of the herring's quitting the deep seas, is unquestionably that of its casting its spawn in its native water, as the banks and mouths of the rivers where it was produced. And the same is the case with the salmon, the shad, the pilchard, and some others; all of which prefer their natal waters for the purpose of spawning in; and though the herring and pilchard sometimes deviate from this course, the salmon and shad do it very seldom, being more sober and steady in their attachment to their parent haunts. The heaviest salmon are met with in the large rivers, and the largest herrings in the deep waters, each coast and river producing fish which are different in taste, size, and appearance, as is remarkably seen in the shads and salmon of different rivers, and the herrings of different situations. The fry of the herring, as well as of the salmon, when

they have attained sufficient size and strength, quit the shallows and make for the deeps: when the shoals of the former enter the bays, and other similar places, the young ones are noticed to take their final departure from them.

The fecundity of different kinds of fishes is very different; but that of the herring and some others is very great. See SPAWN, *Fish*.

SPAWNING or *Laying Oyster-Beds*, the manner of preparing, distributing, and managing them, in the mouths of the breeding-rivers in particular counties and districts, as in Essex, and probably some others. The exact method of performing the business has not been described; but they are spawned or laid somewhat in the bed-manner. The principal rivers in the county of Essex, where this sort of work, or that of breeding oysters, is carried on, according to the Corrected Agricultural Report of that district, are those of the Crouch, the Blackwater, and the Coln; but the first is by far the most certain in produce of any of them. The beds, or layings, are made in the creeks, and other similar places, on the sides or parts which adjoin the mouths, openings, or beginnings of these rivers. It is from these rivers that the oyster-layings, or beds, are usually stocked; though some are constantly supplied from Portsmouth, or places in its neighbourhood, being brought in the largest sort of oyster-vessels, not only into this county, but Kent, where they are laid for the ensuing season. The Colchester oyster-beds are chiefly at Wivenhoe, being partly supplied by the Kentish oyster-smacks. The beds, or layings, in these different situations, are likewise, in all probability, supplied or furnished with oysters from several other places on the southern coast of this country, as well as the northern one of France.

The breeding-rivers in the county of Essex are said to be very uncertain as to the quantity of oysters they produce; as in some seasons they afford a great quantity, while at other times they only produce what is called a good sprinkling, and sometimes there is none at all. But they seldom all produce or fail, it is observed, in the same season. See OYSTER and *Oyster-Fishery*.

The oyster-fisheries, in different places, are of very great importance to the country at large, as well as to particular counties and districts, especially that of Essex; as they employ great numbers of small vessels, require the labour of many men, and afford considerable profit in the produce of food which they supply, as being principally an article of luxury. In the county just mentioned there are several of these oyster-fisheries. In the Blackwater river and neighbouring parts, there is a considerable fishery of this nature; and West-Mersea is one of the principal stations of the dredgers: above thirty boats, it is said, belong to the island, and are almost constantly at work in this business. Vessels come from Kent to purchase the oysters, and they sell some to Wivenhoe, where what are called the Colchester beds are situated. They are sold by the tub of two bushels, and are generally from 4s. to 6s. a tub; but at present (1807) 6s. A dredging-boat is from fourteen to thirty or forty tons burthen: all are decked and built at Wivenhoe, Brightlingsea, and places thereabouts. The price is 10l. a ton for the hull of the vessel only; the fitting out of one of twenty tons requiring the amount of 150l. From two to four men are required for each vessel, who are paid by shares; and the master has a share for the vessel. In the spring season they go to dredge on the coasts of Hants and Dorset. Sometimes one hundred and thirty vessels have been counted at work within sight of Mersea. This oyster-fishery is, it is said, an object of considerable consequence to the country, from the earnings

being great, and some other circumstances: but when the men die, their families, it is said, come to the parish, greatly increased by the number of apprentices which they have taken. Nothing, however, the writer of the report thinks, can be so preposterous as a police of the poor, which permits the benefits of commerce and manufactures to load the land with rates to the amount of 8*s.* in the pound, when a very small contribution by a box-club, or benefit society, would readily prevent the evil. See SOCIETIES, *Friendly*.

The following interesting account of the oyster-busines in the same district, is from Mr. Bennet Hawes of Mersea, given as from his own local knowledge of the places where it is carried on, in the above report. The number of vessels which are employed in it, of from eight to forty or fifty tons, is nearly two hundred, in which are employed from four hundred to five hundred men and boys. A vessel carrying three men has one share and a half of all the earnings, and the men one share each. Large vessels have generally, it is said, two shares; but none, it is believed, more than this.

It is said that the vessels which are built at East Donyland, Wivenhoe, Brightlingsea, Burnham, and Mersea, for this business, will last from thirty to forty years, when proper care is taken of them. The writer was informed by a person then living at Wivenhoe, that he had, within the last twenty years, built one hundred vessels for the oyster business alone.

There has been an increase of boats, and of course of men, of more than one half within the last thirty years.

At Burnham they have seven dredging smacks, belonging to the company that hire the river of Sir Henry Mildmay, besides four other private ones, and some smaller vessels. The smacks are from eighteen to twenty tons. And there are only about one hundred fishermen and sailors about the place, which are much too few, it is thought, for so fine a river.

Most of the vessels of sixteen tons and upwards, go, it is said, to Portsmouth, or places adjacent, in the month of March, to catch and carry oysters; those under twenty-five tons being employed in catching them, and the larger ones in carrying them into this county and Kent, to be used as noticed above; they generally return from thence in the month of June, when the large ones go after mackerel, herrings, and sprats, during the latter part of the summer, and in the ensuing winter, the smaller ones to the catching of oysters in the breeding rivers, as above.

The oysters are sold to London, Hamburgh, Bremen, and, in time of peace, to Holland, France, and Flanders.

The price has varied but little for these last ten years.

The quantity consumed in a season is scarcely to be calculated; but it is supposed that it cannot be less than 12,000 or 15,000 bushels.

This sort of fishery is so much blended with the others, that it is almost impossible to state the capital which is employed in it, but it is supposed to be from 60,000*l.* to 80,000*l.*

SPAWNING Mushroom-Beds, in *Gardening*, the practice of planting or putting the mushroom spawn into the beds or ridges formed for raising crops of this sort. It is performed in several different manners, as by putting it into the dungy matter immediately below the surface of the beds, which is called spawning in the dung; by depositing it upon the surface of the dung, which is termed spawning on the surface; and by placing it in the mould by which the beds have been previously covered, which is denominated spawning in the earth. In all these modes of performing the work of spawning the beds, they are afterwards

Vol. XXXIII.

to be earthed or moulded over in a neat even manner, with finely reduced rich, loamy, mellow, dry, mouldy earth, so as to perfectly cover in the planted spawnly substance, this being done in the two first methods of planting, to a much greater depth than in the last mode, where an earthy coat, or casing, has been before supplied; an inch and a half, or two inches in depth of mould, being necessary in the former cases, while an inch or less may be fully sufficient in the latter case. The spawn is properly divided into pieces, and put into the beds in all these modes in a regular manner, at narrow distances, both in the rows and spaces between them, as about six or seven inches in each, over the whole of the different sides and ends of them. There is little difference in these modes of putting in the spawn, except that in the two first, and especially in the second, it can be laid in rather more closely than in the last, by which means, sometimes, a more forward and plentiful supply of mushrooms is produced.

After the earthing has been properly accomplished in these different cases, the beds are ready for the reception of the straw coverings, as no light is ever requisite in the growth of these crops. These straw coverings should invariably be applied as soon as ever the state of the beds, in regard to the heat they produce and retain, will permit, after the spawning of them is finished. It should be done to a considerable thickness, especially where the beds are not in sheds, but exposed to the effects of the weather, in order to afford the spawn a proper degree of heat and full protection. Such strawy littery materials may be gradually shook upon them, from the thickness of half a foot, to such depths as are sufficient to produce a suitable warmth for promoting the growth of the spawnly material. They are to be lightly and regularly shaken on over the whole, and to remain constantly, having in some cases other sorts of coverings laid over them, as no sort of moisture must come near the spawn in these cases.

As little exposure to the full air as possible, after spawning the beds, should take place in performing any sort of work about them, as there is much injury and check produced by it in the growth of the spawn, and, of course, in the crops to be raised by it.

The proper running and knitting of the spawn, which may be seen by turning up a little of the strawy coverings, shews the spawning of the beds to have been successfully performed; but this should not be judged of too hastily, as this sort of spawn is sometimes slow in coming into an active state of vegetation. There is also a fine full smell of the mushroom in all such cases. See *AGARICUS*.

SPAWS, mineral waters arising out of the earth; impregnated with nitre, sulphur, alum, bitumen, coppers, or other mineral matter, in passing through the strata thereof; and hence endued with some medicinal qualities, cathartic, diuretic, emetic, alterant, or the like. See *MINERAL WATERS* and *SPA*.

SPAX, a name given by some authors to the common tænia, a small fish of the anguilliform kind, frequent on the shores of Italy.

SPAYING, in *Rural Economy*, the operation of cutting, castrating, or removing the female parts of different kinds of animals, as sows, heifers, mares, &c. in order to prevent any future conception, and promote their fattening. It is usually performed by cutting them in the mid-flank, on the left side, with a sharp knife or lancet, in order to extirpate or cut off the parts destined to conception, and then slitting up the wound, anointing the part with tar-salve, and keeping the animal warm for two or three days. The general way is to make the incision in a sloping manner, two inches

SPAYING.

and a half long, that the fore-finger may be put in towards the back, to feel for the ovaries, which are two kernels as big as acorns, one on each side of the uterus, one of which being drawn to the wound, the cord or string is cut, and thus both taken out.

It may be noticed, that in the Annals of Agriculture, Mr. Foot has suggested the practice of spaying old cows and heifers; as it is a method, he apprehends, that might be performed with safety, and prove of general use in grazing; as cows, when they grow old and fail in their milk, are often attended with difficulty, where the bull goes at large, to keep them from him, especially on commons, during the summer, which put him on trying the experiment on a cow of small value, whose profit for the pail was so far over, that she would not milk for about three months before she became dry. After she had calved about a month, he had her cut; the operator was an ingenious person, and performed the business well, that with a little care of keeping her from the cold (being early in the spring) for about a fortnight he thought her out of danger; and continued milking her as usual all the time. She soon began to thrive, gaining flesh, and before the summer was over, by the time she was quite dry, was much improved, though kept no better than the other part of the dairy on very middling pasturage. At Michaelmas, had she been put to turnips, or good rouse, she would have been fat by Christmas, or soon after. When killed, she sold at 3s. 6d. a stone, about half fat at that time, which he laid at one shilling a stone more than she would have done had she not been cut. And afterwards he had two others cut, that continued to be milked, and grazed well; one he had killed, the other he sold alive, which improved and paid beyond expectation. And though little has yet been done in this way, he is persuaded it will be found of general utility, if attended to. But, however, lately he accidentally met the person that performed the operation, who informed him that he had been sent for within twelve months, or thereabouts, to cut near forty in like manner, which having all done well, none failed; that there appears little or no danger in the case; and he believes it may be found of great advantage to the grazier and farmer, if they are inclined to practise it, as well as to the public at large. In confirmation of the above, the persons who have tried the experiment are, he is informed, William Colhoun, esq. Norfolk, who has cut eight; Mr. Martin, Exning, Suffolk, who has cut six; Mr. Cayson, Chippenham, who has had the operation performed on twenty; and Mr. Robinson, Eriswell, who has performed it on four or six.

And he may further add, that most of these were young heifers between two and three years old (some old cows), that had not taken bull; the young stock appears to thrive apace, and grow in size, as well as to be likely to answer for the butcher soon; they may be fattened with turnips in the winter, or kept on another summer, as the grazier pleases. And in Yorkshire it is very common to fatten their heifers at three years old, which answer as great a purpose for grazing, and are more profitable than older steers or heifers, &c. but those are kept from the bull.

Farther, although there is a method generally practised in spaying calves that are intended for heifers of that name, which are usually cut about six weeks or two months old, yet this other method of treatment, he thinks, is preferable and not so dangerous, for the two-years old beasts may be supposed stronger and more fit to undergo the operation; and, in the next place, it is performed quite differently; what is cut away, is only the ends of what is termed the *lusts*, or generative parts, which are not, when separated from the other parts, bigger than the end of a man's thumb to the

first joint, that makes the operation less painful and dangerous when rightly performed. But he would not advise every butcher, or inexperienced artist, to undertake what they do not understand. He thinks this observation is due to the operators, who have cut upwards of forty head of cow-stock in this manner, (as they informed him,) which have all done, and are doing, well, and he recommends them to public encouragement in an art that is likely to be attended with general utility to the public. They are William Bailey and son, Lakenheath, Suffolk. He may further observe, that a heifer at two or three years old may be defective in the bag, in the loss of teats, or those of small size, not larger than an ewe's, which seldom are profitable for the pail, which may be cut after this mode and grazed.

And Mr. Marshall, in his Rural Economy of Yorkshire, remarks, that it is a fact well established in the common practice of that district, that spayed heifers work better, and have, in general, more wind, than oxen; and it is not doubted that spayed mares would have an equal preference to geldings. The reason held out against this practice, though formidable at first sight, proves a mere shadow on examination. The spaying of fillies would undoubtedly spoil them for brood mares. But does not the gelding of a colt spoil him for a stallion? What breeder, when his mares foal, wishes for fillies? and what dealer would not give 2s. 6d. for each, to have his mares changed into geldings, or perhaps into animals superior to geldings? Besides, in the spring of the year, open mares are faint and troublesome. The only requisites appear to be a safe cutter, and a man of spirit to set him to work, to bring the spaying of female foals into common practice; and it does not follow that, because a part of the female foals should be cut, there would not be open mares to breed from; more than it does, that because some heifers are spayed for the yoke, or for fattening, there are not cows sufficient for the purposes of breeding, and the dairy. He does not mean, however, to recommend a practice of which he has had no experience; but if the experiment has not been tried, it strikes him forcibly, that it is worth the trial; and that it is more than time it were set about. Since this, he however states; that it had been tried in the southern districts, as he saw a mare in 1791, then rising five or six years old, which had been spayed at eight days old by a colt-cutter in the neighbourhood of Petworth; and that she was a well-bred mare, and of a size proper for hunting. The farmer to whom she belonged asked seventy guineas for her, a proof that in his estimation, at least, she had not been injured by the operation. And it is probable, that this practice had been attempted long before that period. See CATTLE.

There can be no doubt but that the notion of injury being done by the spaying of female animals is wholly erroneous, and without any foundation in truth or correct observation, as the experience of every day shews it to be so in the most full and satisfactory manner. The chief reason why a practice, which is beneficial in so many points of view to the interests and advantages of the farmer, has been so little attended to, is the difficulty which is constantly experienced from the want of a sufficient number of expert and proper persons for performing the operation. Such persons are far from being common in any, much less in every district, as some knowledge of a nature which is not readily acquired, and much experience in the practice of cutting, are indispensably necessary to the success of the undertaking. Whenever, however, the utility and benefits of the practice become better understood and more fully appreciated by the farmer, and the operators more numerous, much greater attention

and importance will be bestowed upon it, as it is capable of relieving him from much trouble, of greatly promoting his profits, and of benefiting him in a variety of ways. The facts are long since well proved and ascertained, that animals which have undergone this operation, are more disposed to feed or take on flesh, more quiet in their habits, and capable of being managed with much greater ease and facility in any way whatever, than they were before it was performed. It may also have advantages in other ways, in different sorts of animals; it may render the filly, in the horse kind, nearly equal to the gelt colt for several different uses; and the heifer, in the neat cattle kind, nearly equal to the ox, for all sorts of farm-labour. The females of some other sorts of animals may likewise, by this means, be made to nearly equal the castrated males in usefulness for a variety of purposes and intentions; and in all cases be rendered a good deal more valuable, or manageable, than they are in the present custom which prevails with them.

SPAYING of Fish. See *Castration of Fish.*

SPEAKER of the House of Commons, a member of the house, elected by a majority of the votes, to act as chairman, or president, in putting questions, reading briefs or bills, keeping order, reprimanding the refractory, adjourning the house, &c.

The first thing done by the commons upon the first meeting of a parliament is to choose a speaker, who is to be approved of by the king; and who, upon his admission, begs his majesty, that the commons, during their sitting, may have *free access to his majesty, freedom of speech in their own house, and security from arrests.* See **PARLIAMENT.**

The speaker is not allowed to persuade, or dissuade, in passing of a bill, but only to make a short and plain narrative; nor to vote, unless the house be equally divided. The lord chancellor, or keeper, or any other appointed by the king's commission, is usually *speaker of the house of lords*; and if none be thus appointed, the house of lords (it is said) may elect. The speaker of the house of lords, if a lord of parliament, may give his opinion, or argue any question in the house.

The *speaker of the convocation* is called *prolocutor.*

SPEAKER is used by *rhetorical* writers in the same sense with orator. See **ORATORY.** See also **ELOCUTION, PRO-NUNCIATION, and ACTION.**

As to the character and address of an orator, it is necessary that every thing appear easy and natural, and the disposition of the speaker be discovered by his words: thus would he express what Quintilian calls a propriety of manners: accordingly, the ancient rhetoricians made it a necessary qualification in an orator, to be a good man; since he should always be consistent with himself, or, as we say, talk in character. There are four qualifications more especially suited to the character of an orator, which should always appear in his discourses, in order to render what he says acceptable to his hearers; these are wisdom, integrity, benevolence, and modesty. See an illustration and enforcement of them in Ward's *Orat.* vol. i. lect. 10.

SPEAKING, the art, or act, of expressing one's thoughts in articulate sounds or words.

Pliny, Ælian, Plutarch, and other authors, make mention of several bealls that have spoken: and Pliny himself speaks with assurance, in his history, of an ox that spoke. Philostratus, in his life of Apollonius, gives the like quality to an elm, and even to ships. Homer makes Xanthos, one of Achilles's horses, speak; in which he has been followed by Oppian. But these are all fabulous stories; we have much better authority for a serpent and an ass's speaking, un-

less the cases here referred to be allegorical. See **LANGUAGE.**

SPEAKING-Trumpet. See **TRUMPET, and STENTOROPHONIC.**

SPEAN, in *Geography*, a river of Scotland, which forms a communication between loch Laggan and loch Lochly.

SPEAR, in *Armoury.* See **LANCE.**

SPEAR, in the *Manege.* The feather of a horse, called the *stroke of the spear*, is a mark in the neck, or near the shoulder of some Barbs, and some Turkey and Spanish horses, representing the blow or cut of a spear in those places, with some resemblance of a scar. This feather is an infallible sign of a good horse.

SPEAR-Hand, or *sword-hand* of a horseman, is his right hand.

SPEAR-Foot, of a horse, is the far-foot behind. See **FAR.**

SPEAR, King's, in *Botany.* See **ASPHODELUS.**

SPEAR-Thistle, in *Agriculture*, a plant of the weed kind, which is often troublesome in land. It is a biennial, and of course readily destroyed by taking care to have it mown down or cut over before the time of its perfecting its seeds. It is not unfrequently termed the bur-thistle.

SPEARMINT, in *Botany.* See **MENTHA.**

SPEARWORT, the English name of the *ranunculus flammæus.*

This is with us generally esteemed a poison, but the Scots use it as a medicine. They beat it, and squeeze out the juice, which they take as a purge, drinking a little melted butter or oil before and after it, to prevent its taking the skin off from the throat. It operates very violently, but with robust constitutions it does very well.

They use it also externally in cases of pain in the head, or any other part of the body. They bruise the leaves to a sort of paste, and apply them to the part; they soon raise a blister, and a large quantity of water is discharged, after which the pain goes off. This is a short way of blistering, and answers as safely and as well as our's by the cantharides: but it is a wonder that people, who see this quality in the plant, should dare to take it into their mouths and stomachs.

Spearwort is very prejudicial to sheep, as causing the rot. It is also troublesome in lands of the more wet kinds.

SPECIA, in *Geography*, an island in the Grecian Archipelago, about 10 miles in circumference, at the entrance of the gulf of Napoli. N. lat. 37° 15'. E. long. 23° 23'.

SPECIA Poulo, a small island near the south coast of Specia.

SPECIAL, something that is particular, or has a particular designation; from the Latin *species*: in opposition to *general*, of *genus*. See **GENERAL, PARTICULAR, SPECIES, and GENUS.**

The king, in his letters, frequently says, of our special grace, full power, and royal authority.

SPECIAL Assise, Attorney, Bail, Case, Fee-tail, Issue, Jury, Plea, Session, Statute, Verdict, and Warrant. See the articles.

SPECIALTY, in *Law*, is most commonly taken for a bond, bill, or other instrument in writing. Accordingly, debts by specialty, or special contract, are such by which a sum of money becomes, or is acknowledged to be, due by deed or instrument under seal: such as by deed of covenant, by deed of sale, by lease reserving rent, or by bond or obligation. These are looked upon as the next class of debts after those of record, being confirmed by special evidence under seal.

SPECIE, in *Commerce*, gold and silver coin, distinguished

guished from paper-money; but in Germany, the word specie is applied to the rix-dollar, and its divisions, as coined after the rate of the empire.

SPECIES, an idea, which relates to some other more general one, or is comprised under a more universal division of a genus; as in the definition of any thing, we obtain its general nature or genus, by comparing it with other things that are most like to itself, and observing wherein its essence or nature agrees with them; so we obtain the essential or specific difference, by considering the most remarkable and primary attribute, property, or idea, in which this differs from those other things that are most like it: and this attribute, or specific difference, distinguishes each species from one another, while they stand ranked under the same genus.

The word is Latin, formed from the ancient verb *specio*, *I see*; as if a species of things were a collection of all the things seen at one view.

Species is a mere term of relation: and the same idea may be a species, when compared to another more general one; and a genus, with regard to a more particular one. Thus body is a genus, with regard to an animate and inanimate body; and a species, with regard to substance.

The last species is that which can only be divided into individuals.

Animal is a species, with regard to body; and man is a species, with regard to animal. God destroyed mankind by the deluge; but he preserved the species.

SPECIES, in *Logic*, is one of the five words, called by Porphyry, *universals*.

SPECIES, in *Rhetoric*, is that which comprehends under it all the individuals of the same nature. From hence, we may argue; he is a man, therefore he has a rational soul. And orators sometimes take occasion to descend from the thesis or genus, to the hypothesis or species; that is, in treating upon what is more general to introduce some particular contained under it, for the better illustration of the general.

SPECIES, in the *Ancient Music*, denotes a subdivision of one of the genera.

The genera of music were three, the enharmonic, chromatic, and diatonic; the two last of which were variously subdivided into species: nor was the first without species, though those had not particular names, as the species of the other two had. These species were also called the *chroai*, colours of the genera. See GENUS.

SPECIES is also applied, by ancient musicians, to the different dispositions of the tones and semitones in a fourth, fifth, or octave. Hence they say there are three species of fourths, four of fifths, seven of octaves. Wallis's *Append. Ptolem. Harm.* p. 171.

The Grecians expressed this sense of the term species by *ιδος*, or by *σχημα*. The Latin word, *figura*, has also been taken in the same sense. *Aristox.* p. 6, 74. *Ed. Meib.* Wallis, *ibid.* p. 170.

SPECIES, in *Optics*, the image painted on the retina by the rays of light reflected from the several points of the surface of an object, received in at the pupilla, and collected in their passage through the crystalline, &c.

Philosophers have been in great doubt, whether the species of objects, which give the soul an occasion of seeing, are an effusion of the substance of the body; or a mere impression which they make on all ambient bodies, and which these all reflect, when in a proper distance and disposition; or, lastly, whether they are not some other more subtle body, as light, which receives all these impressions from bodies, and is continually sent and returned from one to another, with the

different figures and impressions it has taken. But the moderns have decided this point by their invention of artificial eyes, in which the species of objects are received on a paper or linen cloth, in the same manner as they are received in the natural eye. The ancients have distinguished the species, by which objects become visible, into *impressa* and *expressa*. The former are such as come from without, or are sent from the object to the organ; such are those we have already been speaking of. And the latter are those, on the contrary, which proceed from within; or that are sent from the organ to the object.

Le Clerc, in his system of vision, by one of those revolutions very frequent in philosophical opinions, has called upon the stage again the species *expressa* of the ancient philosophers. For, according to him, it is not by species or images impressed on the optic nerve, that the soul sees objects; but by rays, which she herself directs to them, and which she uses as a blind man does his staff, to grope out objects.

The Peripatetics account for vision, from a kind of *intentional* species, thus: every object, say they, expresses a perfect image of itself on the air next to it. This expresses another less one on the air next to that; and this a third still less. Thus are the images continued from the object to the crystalline, which these philosophers hold the principal organ of seeing. These they call *species intentionales*; and to account the better for their generation, they affirm, that objects exhibit them in the same manner, as mirrors do a man's face. See VISION.

SPECIES, in *Theology*, denote the appearances of the bread and wine in the sacrament after consecration. Or, as the Romanists define them, the accidents remaining in the bread and wine, by which they become sensible to us, after their substance is destroyed.

The species of the bread, &c. are its whiteness, quantity, figure, friableness, &c. Of wine, its flavour, quickness, specific gravity, &c.

The generality of Romish divines hold, that the species are absolute accidents. And the Cartesians, who are bound to deny any such things as absolute accidents, are greatly puzzled to explain the species, without incurring the censure of heresy. F. Magnan is forced to assert, that the species are mere delusions and appearances, which God impresses on our senses.

SPECIES, in *Commerce*, are the several pieces of gold, silver, copper, &c. which, having passed their full preparation and coinage, are current in public.

SPECIES, *Decried*, or *cried down*, are such as the sovereign has forbidden to be received in payment.

SPECIES, *Light*, are those which fall short of the weight prescribed by law.

The weights of the current coins, as coined, are now as follow; the standard of gold being *3l. 17s. 10½d. per oz.* the mint price of gold; and the standard of silver being *5s. 2d. per oz.* mint price of silver.

	dwt. grs.
Gold, guinea - - - - -	5 9½
half-guinea - - - - -	2 16¾
Silver, crown - - - - -	19 8½
half-crown - - - - -	9 16¼
shilling - - - - -	4 20
sixpence - - - - -	2 10

The current weight of gold:

Guinea - - - - -	5 8
Half ditto - - - - -	2 16
	Under

Under this weight no gold was allowed to pass by proclamation.

SPECIES, False, are those of different metal or alloy from what they should be, &c.

SPECIES, in *Algebra*, are the symbols, or characters, by which quantities are represented.

SPECIES Aromaticæ, a new name given in the late London Dispensatory to the composition usually called *species diambra*. The College observed, that the intention of this medicine was best answered, by composing it of such spices as the daily experience of the table shews were most grateful to the stomach, and by avoiding all ingredients which, though of the aromatic kind, are accompanied with any thing nauseous and disgustful in their flavour; and, therefore, have ordered it to be now made in the following manner. Take cinnamon two ounces, cardamom-seeds, ginger, and long pepper, of each an ounce; make all together into a fine powder.

SPECIES e Scordio, the ingredients of the diascordium electuary in a dry form. The recipe is something altered in the late London Pharmacopœia, and stands thus: take bole armenic, four ounces; scordium, two ounces; cinnamon, an ounce and half; storax, roots of tormentil, bistort, gentian, dittany of Crete, galbanum, and gum arabic and red roses, each an ounce; long pepper and ginger, each half an ounce; opium, three drachms; this may be left out at pleasure; and all are to be beat to a fine powder.

SPECIES, in *Gardening*, has some which consist only of one, as the flowering rush, the hop, and some more; while in others they are numerous, as in the sun-flower, the geranium, the honeysuckle, the willow, and a great many more. There is often, too, some degree of similarity in the culinary or domestic and economical uses, as well as the medicinal properties, in the species of cultivated garden and other plants, which belong to the same genus or family, as in the cases of garlic, onion, leek, shallot, and chives; cabbages, favoys, brocoli, and cauliflower; parsley and celery; the bay-tree, benjamin-tree, saffras, and cinnamon; mugwort, wormwood, tarragon, and southernwood: and the same takes place in many other instances.

The species likewise, in some cases, serves to denote the mode of culture and management which are necessary in the raising and growing of different plants, in the garden manner, as well as their habits of growth and production.

SPECIES of Plants, in *Systematic Botany*, appear, as far as can be ascertained from the universal experience of those who are conversant with them, as well as from every thing that can be gathered from the records of remote antiquity, to remain distinct from each other, marked by their appropriate characters and qualities, and renewing themselves periodically by sexual generation. Such being the case with all the plants of which we have any knowledge, we conclude it to be so with the rest, as well as with animals. The White Blackbird of Aristotle still inhabits the Cyprian groves and copses of Arcadia, undisturbed by the revolutions of two thousand years; and we doubt not that the banks of the Alpheus have been fringed with the same violets and primroses, through uncounted ages, as those with which they are now, every spring, adorned.

Various plants indeed, and especially domestic ones, like domestic animals, are found liable to some variations of colour, luxuriance, and sensible qualities, which have led curious inquirers to doubt whether any species are certainly permanent. This doubt could arise only from a slight view of the subject. Whatever casual aberrations there may be in the seminal offspring of cultivated plants; a little observation will prove how transient such varieties are, and how

uniformly their descendants, if they be capable of producing any, resume the natural characters of the species to which they belong. Nothing can better exemplify this fact, than the series of experiments instituted, on a most extensive scale, upon the Apple-tree, by the celebrated president of the Horticultural Society, Mr. Andrew Knight. They prove that every thing but sexual propagation is only the extension of an individual, whose corporeal frame has but a certain limited existence; the period of which is indeed much longer in some varieties than in others; and hence the valuable Golden-pippin and Nonpareil have enriched our orchards for a long course of years, while numerous new varieties of apples are found to endure but for a few seasons. Some, however, promise to be more lasting, and to supply the place to our descendants, of those kinds, of which we can transmit to them only the names. When varieties originate in the cross impregnation of plants of different species, they partake of the inability to procreate which belongs to mule animals, and are moreover seldom capable of being long increased by cuttings, budding, or other methods. For confirmation of this, see the article *PELAGONIUM*.

The technical discrimination of the species of plants, but vaguely and superficially attended to by the ancients, makes an interesting part of the philosophy of modern botany, which considers their differences as indisputably founded in nature, and for the most part extends that opinion, even to those assemblages of species which we term *genera*. On this subject the reader may consult the article *GENUS*.

Although the distinctive characters of genera are wisely limited, by the most philosophical botanists, to the parts of fructification, those of species are allowed to be taken from any part of the plant. Some characters are found more important or constant in one tribe, others in another; none are absolute, or invariably constant, in any. Number, which in the natural orders of *Caryophylleæ* and *Rosicææ* will sometimes afford even a generic distinction, in others, and even in what regards the stamens of the *Caryophylleæ* themselves, will hardly be found to limit a species. The differences between simple or compound leaves, entire or indented, opposite or alternate ones, are usually striking and unchangeable; but exceptions may be found to all these. Colour of flowers is, on the other hand, seldom to be relied on as a specific difference. It appears so in *Mesembryanthemum*, but to prove it the species must be cultivated from seed. Yet the yellow disk of a compound flower has never been known to change hues with its blue or white radius, nor does such a variation seem within the bounds of possibility. Pubescence is found variable both in its structure and quantity; but less, or not at all, so in direction. Hence the specific characters of *Mentha*, and more recently of the genus *Myosotis*, have been determined better than by any other means.

The inflorescence, or mode of connection of the flowers, is pointed out by Linnæus, as yielding the best specific characters; though he, in theory at least, excludes it from all authority in founding genera. In grasses, nevertheless, every body recurs to this mark; though perhaps sounder principles may hereafter be discovered for arranging even these.

The root almost invariably affords good and unchangeable specific characters; but it is not always accessible, nor readily preserved in a herbarium. Some grasses moreover change their fibrous roots into bulbous ones, in consequence of a fluctuation of soil or nutriment; and the bulbs of other plants very much alter their texture or appearance from similar causes.

Great experience and sagacity, with perhaps a peculiar talent, are requisite to form a good judge of specific characters. To convey a precise idea of them to others, requires a clearness of definition, and a command of language, granted to very few. Linnæus, with good reason, limits such characters to a certain number of words, hardly exceeding twelve. However narrow these bounds may appear, we believe them to be in general, if not always, sufficient; and every person will perceive that the consequence of their transgression is usually feebleness, if not confusion, of definition. It must always be remembered that specific characters are *differences*, not *descriptions*. Hence a specific character for a solitary species of any genus, is an absurdity. It cannot contrast such a species with what are unknown, or perhaps do not exist. A short description may be very commodious or satisfactory to give an idea of the plant, especially if the author mistrusts his genus or its definition; but if the genus be good, the very characters which he will select to delineate the habit, or prominent peculiarities, of the only known species, will, most likely, be common to any new ones that may subsequently be discovered.

Linnæus remarks, that the detection of genuine specific distinctions is the summit of botanical skill. To which we may add, that those have most excelled in this department who have caught the greatest share of the genius of this great man, whose definitions come as near to perfection as art can come to nature.

SPECIFIC, in *Philosophy*, that which is proper and peculiar to any thing; or that characterizes it, and distinguishes it from every other thing. See **PROPER**, &c.

Thus, the attracting of iron is specific to the load-stone, or is a specific property of the load-stone. A just definition should contain the specific notion of the thing defined, or that which specifies and distinguishes it from every thing else.

SPECIFIC, in *Medicine*, such articles in the materia medica as have the special power of curing particular diseases, in all persons, and under all circumstances, without demanding any attention to particular indications. In other words, a *specific* is a certain antidote against a given disease. Notwithstanding, however, the multitude of such specifics, which are every day announced by boasting quacks, and testified to by all ranks of people, who are their dupes, it unfortunately happens that no such remedies exist. As sound science has extended, all these vaunted specifics have successively been banished from the confidence of men of sense and information; and almost every remedy has some obvious action upon the animal system, so that the principles of its operation in particular diseases may be pointed out. Peruvian bark was formerly supposed to be a specific for intermittents and agues; but it is now known to fail in many cases, and not to be more efficacious than other medicines of a tonic power, such as arsenic, and some combinations of bitters with aromatics, which are popularly used in agueish countries. The two medicines which approach the nearest in their qualities to the character of *specifics*, are *mercury*, as the antidote to the venereal poison, and *sulphur*, to that of the itch. Indeed it is only in cases of the actual existence of a morbid poison, that any distinct antidote can possibly exist. But even with respect to these two medicines, it is well ascertained that there are cases of disease, so accurately resembling lues venerea, as not to be distinguishable by the most acute and experienced eye, which nevertheless recover without the aid of mercury (see Mr. Abernethy's "Account of Diseases which strikingly resemble the Venereal Disease"); and we know that the powers of sulphur in curing the itch are considerably augmented by the addition

of other substances, such as hellebore, muriate of ammonia, the white oxyd of mercury, &c. All other instances of pretended specifics are impositions.

SPECIFIC Gravity, in *Hydrostatics*. See **SPECIFIC GRAVITY**.

SPECIFIC Gravity of Living Men. Mr. Robertson, in order to determine the specific gravity of men, prepared a cistern, 78 inches long, 30 inches wide, and 30 inches deep; and having procured 10 men for his purpose, the height of each was taken, and his weight; and afterwards they plunged successively into the cistern. A ruler, graduated to inches and decimal parts of an inch, was fixed to one end of the cistern, and the height of the water noted before each man went in, and to what height it rose when he immersed himself under its surface.

The following table contains the several results of his experiments.

No. of Men.	Height.	Weight.	Height of Water before immersed.	Height of Water when immersed.	Water raised.	Solidity.	Weight of Water.
	Ft. In.	Pounds.	In.	In.	In.		Pounds.
1	6 2	161	19.30	21.20	1.90	2.573	160.8
2	5 10 $\frac{3}{8}$	147	19.25	21.16	1.91	2.586	161.6
3	5 0 $\frac{7}{8}$	156	19.21	21.06	1.85	2.505	156.6
4	5 6 $\frac{1}{4}$	140	19.17	21.21	2.04	2.763	172.6
5	5 5 $\frac{2}{8}$	158	19.13	21.21	2.08	2.817	176.0
6	5 5 $\frac{1}{2}$	158	19.09	21.26	2.17	2.939	183.7
7	5 4 $\frac{3}{8}$	140	19.05	21.06	2.01	2.722	170.1
8	5 3 $\frac{3}{8}$	132	19.01	20.86	1.85	2.505	156.6
9	5 4 $\frac{1}{2}$	121	18.97	20.76	1.79	2.424	151.5
10	5 3 $\frac{1}{4}$	146	18.93	20.66	1.73	2.343	146.4

One of the reasons, Mr. Robertson says, that induced him to make these experiments, was a desire of knowing what quantity of fir or oak-timber would be sufficient to keep a man afloat in river or sea-water, thinking that most men were specifically heavier than river or common fresh water; but the contrary appears from the trials above recited: for, excepting the first and last, every man was lighter than his equal bulk of fresh water, and much more so than his equal bulk of sea-water: consequently, if persons who fall into water had presence of mind enough to avoid the fright usual on such accidents, many might be preserved from drowning; and a piece of wood, not larger than an oar, would buoy a man partly above water as long as he had spirits to keep his hold. Phil. Trans. vol. 1. art. 5.

SPECIFIC Gravity of Metals. See the several metals.

SPECIFIC Heat. See **HEAT**.

SPECIFIC Names, in *Natural History*, are those epithets composed each of one or more terms, and placed after the general name, in the denomination of any species of plant, animal, or mineral, expressing those characters by which it differs from all the other species of that genus.

The more accurate of the modern naturalists have, in their several provinces, set about the reformation of the specific names of things. They first observe, that many of the specific names of the ancients no way answered the intent of their formation, but expressed the more trivial distinctions, or accidents, while they omitted the realities, and more essential grounds of distinction. On this foundation the critical writers of our times distinguish the old specific names into the genuine or true, and the spurious or false ones.

The genuine names are those which express those characters,

ters, by means of which the thing becomes a different species; these are invariable, and by these names the thing is, in some sort, described. The false ones are those specific names which do not, and cannot distinguish the species called by them from the others of the same genus, which may as well belong to some other species as to that, and which therefore are of no use to the student. The true formation of these names is on the real characters of the body to be named; but instead of this, these false ones are often formed from accidental or variable distinctions.

SPECIFIC Waters. See WATER.

SPECIFICATION, a term expressing the engineer's statement of the particulars of width, depth, slopes, &c. which a certain length of canal is to have, when the excavation is to be made by contract.

SPECIFICATION is likewise a term used in obtaining patents. See PATENT.

SPECILLUM, a probe, one of the most common instruments of surgery. See *Surgical Plates*.

SPECIOUS ARITHMETIC. See ARITHMETIC.

SPECKHAVEN, in *Geography*, a harbour on the W. coast of West Greenland. N. lat. 64°. W. long. 49° 40'.

SPECKLED BEANS, in *Agriculture*, a term applied to some sorts of the kidney-bean, which are occasionally cultivated in the field, in some districts. The principal varieties which are grown and cultivated in this way in some parts of the county of Kent, are the black speckled and the red speckled; but many others may be employed for the same purpose.

The tillage preparation of the land for field-crops of this sort is the same as that which is made use of for the growth of the common pea and bean; and the manure, which is commonly ploughed in before the seed is put into the ground, is of the more rotten dung kind. See PEAS and BEANS.

The time of planting crops of this nature in the field is in the early part of the spring, as from about the eighth to the twentieth of May, as when it is done earlier, the crops are in danger of being injured, or wholly destroyed, by the occurrence of a frosty morning, which is then liable to take place.

In setting, the seed-beans are dropped by the hand into holes, or small furrows or drills made for the purpose in the land, in the quantity of from five to ten gallons to the acre, in proportion to the size of the sort which is employed; the smaller the sort of bean, the less the quantity which is necessary.

The crops are repeatedly hoed while growing, so as to be kept perfectly clean and free from weeds of all kinds; and in their more early growth the fine mould is a little drawn up to the rows, in order to promote the advancing of the young plants.

The harrowing of the crops is by pulling up the plants by the roots, as the beans become ripe, during the beginning of the autumnal season. The more early sorts are commonly ready and fit to be pulled about the end of August; but the late ones are often not ripe and ready for pulling until the month of October. Those which ripen so late in the season, and are in danger of being injured by wet weather, are frequently tied up in small bunches, and hung upon poles to finish their ripening, and, when thoroughly dry, are threshed out and sent to market, as they seldom keep well.

These sorts of bean-crops are much cultivated and attended to about the town of Sandwich, and in the Isle of Thanet, in the same county, as well, perhaps, as in some other southern parts of the island, for the purpose of sup-

plying the London feedsmen with these kinds of beans. See PHASEOLUS.

This is a profitable sort of culture in some cases and seasons, but liable to much uncertainty.

SPECTABLES, among the Romans, a title of honour given to the second rank, or degree of nobility, under the Roman emperors, being unknown in the time of the republic. There were two other degrees; the first had the title of *illustres*, and the third that of *clarissimi*.

SPECTACLE, **SPECTACULUM**, *Show*; some extraordinary object, which draws the view and attention; and is not beheld without some emotion or passion of the mind.

The term is chiefly used, by the ancients, for theatrical and amphitheatrical performances; for comedies, combats of gladiators, and of beasts; and even for solemn processions, as those of the Circus, &c.

The people of Rome were extremely fond of spectacles; and the Roman historians observe, that there was no surer way of gaining their affections, and making parties to introduce tyranny and oppression, than by the use of spectacles.

SPECTACLES, an optic machine, consisting of two lenses set in a frame, and applied on the nose, to assist in defects of the organ of sight.

It is well known, that parallel rays, or such rays as proceed from a very distant luminous point, will be collected, by the refractions of all the humours through which they must pass in the eye, to a focus on the retina, which is the true place of the image. But at the same time it is evident, that if that be the focal distance for parallel rays, it cannot be the focal distance for diverging rays; or, in other words, when the objects are situated at a few feet distance from the eye, their true images must be formed farther back; consequently their images upon the retina must be imperfect, unless the retina be situated farther back by an elongation of the axis of the eye, or the focal distance be shortened by the alteration of some other part. But since we may perceive either distant or near objects distinctly, it is evident that some such alteration does actually and necessarily take place. This is called the adjustment, or accommodation of the eye for distinct vision; but the difficulty is to determine how this adjustment is effected.

By some persons it has been attributed to a change in the length of the eye, and by others to a change of curvature in the cornea; but some very recent experiments render those alterations unlikely, at least to the full amount of what may be required. Other ingenious persons have attributed the alteration to a change either of the shape of the crystalline lens, or of its situation, or of both; and this opinion seems upon the whole to be nearer the truth.

That the eye cannot see both near and remote objects distinctly at the same time, may be easily proved. Let a tree, a house, or some other object, be upwards of fifty feet from you; shut one eye, and whilst you are looking with a single eye at the tree, &c. hold a pin, a pencil, or some other object, in the same direction, at about a foot distance from the eye; and it will be found, that whilst you see the pin distinctly, the tree will appear indistinct; but if you adjust your eye so as to see the tree distinctly, then the pin will appear indistinct.

The eyes of some persons are more capable of adjustment than those of others. In old persons the humours grow thicker, and the parts less pliable; hence their eyes are less capable of adjustment than those of young persons.

The eyes of some persons can be adjusted for distant objects better than for near objects, and *vice versa*. When the

SPECTACLES.

the eye is defective, and by its size or other conformation, parallel rays form their foci before they arrive at the retina, then the person can see very near objects only. Such persons are said to be near-sighted, or they are called *myopes*. When the eye is flatter than ordinary, then the foci of rays from pretty near objects are formed beyond the retina. Persons with such eyes are called *presbyta*; they can adjust their eyes for objects beyond a certain distance only. The latter is generally the case with old persons; but the eyes of old persons sometimes are incapable of adjustment both for very near and for very distant objects. This comes from a rigidity or want of pliability in the parts. Those defects are frequently brought on or increased by habit, as by the constant custom of viewing objects either from too near or from too great a distance; as also by the use of improper glasses.

Those imperfections may in a great measure be remedied by the use of proper glasses or spectacles; for since, in near-sighted persons, the rays of light converge to a focus too soon, *viz.* before they come to the retina, concave lenses, which diminish the convergency, must remove the imperfection. And for those who can see distant objects only with tolerable distinctness, *viz.* in whose eyes the rays do not converge soon enough, convex lenses, which increase the convergency, must remove the imperfection.

When the defect comes from rigidity, as in some old persons, then those persons require concave glasses for viewing distant objects, and convex glasses for viewing near objects; for their eyes want both adjustments.

The capability of adjustment is greater or less in different eyes, and it is frequently different in the two eyes of the very same person; but in all eyes there is a limit, within which vision is not distinct. This is called the *limit of distinct vision*; and with some persons it is as short as one inch, whilst in others it exceeds twenty inches; but in common it will be found to lie between six and ten inches.

In Spain, and at Venice especially, spectacles have been used with a different view from either of those above stated; all the people of note and fashion there have them continually on their noses: a folly, that has its source in the natural pride of those people, who value themselves on a profound wisdom; and affect to stare very near at every thing; as if their eyes were weakened, and worn out with excess of attention. Vign. de Mary.

F. Cherubin, a Capuchin, describes a kind of spectacle telescopes, for the viewing of remote objects with both eyes; hence called *binoculi*; though F. Rheita had mentioned the same before him, in his "Oculus Enoch et Eliæ." See BINOCLE.

The same author invented a kind of spectacles, with three or four glasses, which performed extraordinarily.

Spectacles were certainly unknown to the ancients. Francisco Redi, in a very learned treatise on spectacles, will have them to have been invented in the 13th century, between the years 1280 and 1311, (probably about the year 1299 or 1300,) and adds, that Alexander de Spina, a monk of the order of Predicants of St. Catharine, at Pisa, first communicated the secret, which was of his own invention; upon learning that another person had it as well as himself. This history is written in the chronicles of that convent.

The same author tells us, that in an old manuscript still preserved in his library, composed in 1299, spectacles are mentioned as a thing invented about that time: and that a famous Jacobin, one Jourdon de Rivalto, in a treatise composed in 1305, says expressly, that it was not yet twenty years since the invention of spectacles. He likewise quotes

Bernard Gordon in his "Lilium Medicinæ," written the same year, where he speaks of a collyrium, good to enable an old man to read without spectacles.

Mulchenbroeck, Introd. vol. ii. p. 786, observes, that it is inscribed on the tomb of Salvinus Armatus, a nobleman of Florence, who died in 1317, that he was the inventor of spectacles.

Du-Cange, however, carries the invention of spectacles farther back; assuring us, that there is a Greek poem in manuscript in the late French king's library, which shews, that spectacles were in use in the year 1150; nevertheless, the Dictionary of the Academy della Crusca, under the word *occhiale*, inclines to Redi's side; and quotes a passage from Jourdon's Sermons, which says that spectacles had not been twenty years in use: and Salvati has observed, that those sermons were composed between the years 1330 and 1336.

It is probable that the first hint of the construction and use of spectacles was derived from the writings either of Alhazen, who lived in the 12th century, or of our own countryman Roger Bacon, who was born in 1214, and died in 1292 or 1294. The following remarkable passage occurs in Bacon's "Opus Majus," by Jebb, p. 352. "Si vero homo aspiciat literas et alias res minutas per medium crystalli vel vitri, vel alterius perspicui suppositi literis, et sit portio minor spheræ, cujus convexitas sit versus oculum et oculus sit in aere, longe melius videbit literas, et apparebunt ei majores.—Et ideo hoc instrumentum est utile senibus et habentibus oculos debiles: nam literam quantumcunque parvam possunt videre in sufficienti magnitudine." Hence, and from other passages in his writings much to the same purpose, Molyneux, Plott, and others, have attributed to him the invention of reading-glasses.

Dr. Smith, indeed, observing that there are some mistakes in his reasoning on this subject, has disputed his claim. See Molyneux's Dioptrics, p. 256. Smith's Optics, Rem. 86—89.

The essential and extensive use of spectacles, which affords comfort to so great a number of individuals, who would otherwise be a burden to themselves and to society, is an instance of the great usefulness of the science of optics.

No pains have been spared to render spectacles as perfect as possible, and a variety of contrivances have been from time to time offered to the public. Spectacles have been made with two lenses for each eye; also the lenses have been made plano-convex, or plano-concave, or of other shapes; but, upon the whole, single lenses, either double concave, or double convex, of clear glass, well polished and regularly formed, are the best.

When the eyes of persons first begin to be affected by age, the opticians furnish them with spectacle lenses, of about forty inches focus, which glasses are therefore called number 1st, or glasses of the first sight; *viz.* for the sight when it first begins to be impaired by age. But there is considerable difference between the focal distances of spectacles. N^o 1, made by different opticians. When the focal length is about sixteen inches, the lenses are called N^o 2. About twelve inches are the focal length of N^o 3. Ten inches are what they call N^o 4. Nine inches are those of N^o 5. Eight inches give the focal length of N^o 6. Seven inches are the focal length of N^o 7. Six inches are the focal length of N^o 8. And sometimes they make spectacles of a focus shorter still. Concave spectacles are also named by similar numbers.

In choosing spectacles, actual trial is the best guide; but care must be had to use spectacles that do not magnify
more

more than is just sufficient either for reading, or for other necessary purposes.

When a variety of spectacles cannot actually be tried, the defect of the sight may be expressed by mentioning the distance from which the person can read, or other peculiarities, from which the necessary glasses may be determined pretty nearly. For an account of the instrument for measuring the exact limits of distinct vision, invented by Dr. Porterfield, and improved by Dr. T. Young, see OPTOMETER.

Huygens conceived, that the glasses of spectacles, instead of being equally curved on both sides, should have the curvatures of their opposite surfaces in the proportion of 6 to 1, and the most convex side turned towards the object, because he had demonstrated that such a form was best suited to the object-glasses of telescopes, as having less aberration than any other form of lens.

Dr. Wollaston observes, that although it may be true that such a form of glass was best calculated for the object-glass of a telescope, previously to the celebrated discovery of the achromatic object-glass by the late Mr. Dollond, yet whatever advantages might at any time be expected from the telescopic object-glass so shaped, these were not to be obtained by a similar construction in spectacles, as may easily be seen by considering the different uses of the respective instruments.

In a telescope, in the first place, our view is necessarily confined to a very small distance on each side of the axis; and, secondly, every part of the object-glass contributes to the distinctness of any object viewed.

It is under these circumstances alone, that the proportion of the curvatures above-mentioned might be proper for a single object-glass, as being capable of collecting into the same focus the rays that fall on every part of it parallel to the axis. But by spectacles, on the contrary, objects are to be viewed, if possible, in every direction in which they might be seen by the naked eye, which is often removed from the centres of the glasses; consequently, a construction that is calculated to represent correctly central objects alone cannot be the most advantageous.

In spectacles also the portion of the glass employed at once is scarcely larger than the pupil of the eye; so that any endeavour to procure the concurrence of all parts of a glass in any one effect is evidently superfluous, and may also be shewn to be prejudicial.

Mr. B. Martin, so well known by his numerous writings upon philosophical and mathematical subjects, made spectacles sixty years ago, which he called visual glasses, and in which the two glasses were not situated in the same plane, or with their axes parallel to each other, but were placed inclined to each other, in the same angle as the pencils of rays must proceed from the objects which are viewed, and come to the two eyes. Respecting the common glasses, this writer observes, in his treatise upon spectacles, that he considered the two glasses of a common pair of spectacles, when placed both in the same plane, and with their axes parallel to each other, as being most adapted to view objects at a very great distance, where we can see no objects with them at all; for, when we use spectacles, the axes of both eyes are always turned to the object which we view, and meet in a point in it, as in reading, writing, working with a needle, &c.; consequently the axes of the eyes, and of the glasses, are so far from coinciding, that they make a considerable angle with each other, by which means the eye is deprived of the principal pencil of rays, *viz.* those rays which belong to the axes of each of the glasses, and which will

make the most perfect part of the image on the retina of the eye, and which rays alone can produce perfect vision. Those rays alone can enter the eye from the object we look at, which come on one side of the glass, or obliquely to its axis, and are therefore regularly refracted to the eye, so as to make the vision in proportion imperfect.

As the action of light upon the eye tends gradually to weaken it, no more of such an active principle should be admitted into so delicate and fine a structure as that of the eye, than what is quite necessary to illuminate the object, and make it sufficiently visible. But the common size of spectacle-glasses pours in upon the eye-balls three times as much as is necessary for this purpose, and, therefore, is very prejudicial to the eyes in that respect, for in time it makes them weak and watery. Further, it is well known that only a particular quantity of light is proper for perfect and distinct vision; and that a greater or less degree of it always impairs and confuses the image, and consequently the vision of the object. For this purpose, in microscopes, telescopes, and other optical instruments, provisions are made to regulate the quantity of light by proper apertures and diaphragms; but in spectacles, where the quantity of light should be in the highest degree regulated and adjusted, no provision at all has been made, but the tender system of the eye has been left defenceless from the superfluous and injurious particles of light.

In common spectacles, only those rays of light which fall near the axis of the glasses, can be regularly refracted to the eye, and consequently only such can make the image, or vision of the object, in any degree perfect: and, therefore, considering the unreasonable area or diameter of the glasses of common spectacles, there must necessarily be a great quantity of light that will not only annoy the image by suffusion, but greatly affect the eye, and render the image imperfect by an irregular refraction from all the extreme parts of the glass.

The lenses of Mr. Martin's spectacles were so fixed in their frame, that the axes of the two glasses were inclined to each other, and met in one point, situated at the same distance from the glasses as the focus of each glass respectively; or, in other words, the foci of the two glasses were brought into one common point: whereas in the common spectacles, the axes of the two glasses being parallel, the two foci are at the same distance apart as the centres of the glasses are. Mr. Martin also recommended opticians to make the glasses smaller; an alteration which was attended with considerable advantages: for, before his time, the lenses were frequently made an inch and a half in diameter.

Dr. Franklin used a pair of double or bisected spectacles, which he thus describes in a letter to one of his friends, "The same convexity of glass, through which a man sees clearest and best at the distance proper for reading, is not the best for greater distances. I, therefore, had formerly two pairs of spectacles, which shifted occasionally; as in travelling I sometimes read, and often want to regard the prospects. Finding this change troublesome, and not always sufficiently ready, I had the glasses cut out, and half of each kind associated in the same circle; the least convex, for viewing distant objects, in the upper half of the circle; and the most convex, proper for reading, in the lower half of the frame. By this means, as I wear my spectacles constantly, I have only to move my eyes up or down, as I want to see distinctly far or near; the proper glasses being always ready. Although I cannot distinguish a letter, even of large print, by the naked eye, with the assistance of this invention, my eyes are as useful to me as ever they were;

SPECTACLES.

and if all the other defects and infirmities of old age could be as easily and cheaply remedied, it would be worth while to live a good deal longer."

Mr. John Richardson, an optician of London, obtained a patent in 1797 for an improvement in spectacles, which consists in applying extra glasses before the common single lenses, and fitted with joints, so that the extra glasses can at pleasure be turned up out of the way, either on one side, or upwards. The advantage of this plan is stated to be, that it precludes the necessity of two pairs of spectacles for different views, but that any two different powers of sight may be instantly obtained: for instance, the spectacles may be fitted with such lenses as are most proper to enable the wearer to see a prospect in walking or riding; but by turning down the extra lenses, the spectacles will magnify in a greater degree, and be proper for reading or writing; and by the same means, coloured glasses may be applied, to be occasionally turned down over the lenses of the spectacles, to walk in the sun-shine.

Mr. John Isaac Hawkins some years ago introduced a new kind of spectacles, provided with extra arms or joints, which pass upwards over the temples, in addition to the usual jointed arms which hold the spectacles, by passing horizontally round the head. By these additional arms the spectacles are borne altogether from the head, without resting upon the nose, which occasions an unpleasant sensation to those who first begin to use spectacles, although it wears off in a few days; but the advantage of Mr. Hawkins's plan is, that the glasses, without occasioning any pressure on the temples, can be placed at any distance from the eye, and inclined in any direction, as is found most convenient for the view.

Dr. Hyde Wollaston's periscopic spectacles are now much in use, and are so called from the facility which they afford the wearer of looking round at various objects. This invention, for which he obtained a patent in 1804, is intended to obviate that defect of the common spectacle-glasses, which we have before mentioned, *viz.* that no objects appear distinct through them, except such as are seen through the centre of the glasses, or nearly so, and that the vision is indistinct, in proportion as the part of the glass through which the rays pass is farther from the centre: this is most particularly observable in glasses of short focal distance, and considerable magnifying power. It is on this account that opticians have lately made and recommended spectacle-glasses of less diameter than those formerly in use, thinking that the extreme parts of the field of vision, which from indistinctness were of little use, might be spared without much inconvenience. But this alteration in the size of the glasses can scarcely be called an improvement, since for one defect it only substituted another scarcely less objectionable.

Dr. Wollaston, having considered that the portion of any glass employed in any one position of the eye is but small, perceived, that by making the substance of a glass curved, in the manner of a hollow globe, each portion of it might be situated nearly at right angles to the direction of the sight, and would thereby render lateral objects distinct, without impairing the distinctness at the centre.

To illustrate this; supposing the eye to be placed in the centre of any hollow globe of glass, it is plain, that objects would then be seen perpendicularly through its surface in every direction: consequently, the more nearly any spectacle-glass can be made to surround the eye, in the manner of a globular surface, the more nearly will every part of it be at right angles to the line of sight, the more uniform will be the power of its different parts, and the more com-

pletely will the indistinctness of lateral objects be avoided. It is evident, that no other rays than those which pass through the centre of a lens can be at right angles to both surfaces; but it is equally clear, that when any small oblique pencil of rays makes equal angles with the two surfaces of a thin lens, its inclination to each surface will be so small, that its focal length will not sensibly differ from that of a central pencil. Upon this principle Dr. Wollaston's spectacle-glasses are made, of a form not heretofore used for that purpose; the outer surface of each glass, or that which is farthest from the eye, being spherically convex, and the inner surface of the same glass, or that which is nearest the eye, spherically concave. A glass of this sort, adapted for a short-sighted person, will have the interior and concave surface of each glass more curved than the exterior and convex surface of the same glass, by which the rays of light passing through the same are diverged, and the degree of curvature of the interior and concave surface is to be increased in proportion as the person who is to use the glasses is more short-sighted. On the contrary, for long-sighted persons, the form of each glass must be such as to have the exterior and convex surface thereof more curved than the interior and concave surface of the same glass, by which means the rays of light passing through the same are converged; and the degree of curvature of the exterior and convex surface of the glass is to be increased in proportion as the person to use the glasses is more long-sighted.

With a view of obtaining the same effects as Dr. Wollaston's periscopic spectacles, a new species of glasses have been lately introduced at Paris, made by Chambiant, optician, Rue Bassé, Porte St. Denis; they are called *conservees*: these glasses are ground to cylindrical surfaces, instead of the spherical surfaces which have hitherto been employed for spectacles and lenses of all kinds: the opposite surfaces of each glass are segments of two different cylinders, inclined to each other at right angles; that is, the axes of the two cylinders are situated in parallel planes, but in direction they lie at right angles to each other, and in consequence, the direction in which one surface of such a glass is curved, is at right angles to the direction in which the other side is curved. On making trial of a pair of these glasses, we found them very perfect in the field of view, presenting a very distinct vision of objects viewed through the outer parts of the glass, as well as those viewed through its central parts: and the magnifying power of the whole field as nearly equal as the eye could judge.

The inventor has obtained a patent in France for this invention, and makes spectacles of all degrees of magnifying power. He proposes to apply similar lenses to telescopes, microscopes, and other optical instruments, but we have not had an opportunity of examining any of them.

Spectacles are made in great varieties of forms, and ornamented according to fashion, or to the fancy of the wearer. The frames are made of all kinds of materials, such as gold, silver, steel, pearl, tortoise-shell, ivory, bone, and wood. The lenses are usually made of glass, but the better sorts are made of natural crystal, and are known by the name of pebble-spectacles, but in reality most of the spectacles sold under that name are made of a hard sort of glass.

It is observed by Mr. Ware (Phil. Trans. for 1813, part 1.) that short-sightedness usually comes on between the ages of ten and eighteen. This defect of sight, as soon as it is accidentally discovered, is little regarded by persons in the inferior stations of society, and no means are used for correcting it; hence by increased exertions that are made for distinguishing distant objects, the imperfection is not unfre-

quently overcome. But when persons in the higher ranks of life discover that their discernment of distant objects is less quick or less correct than that of others, however slight the difference may be, such persons, influenced perhaps by fashion more than by necessity, recur immediately to the use of a concave glass; and thus their eyes become so fixed in the state requiring its assistance, that the recovery of distant vision is rendered afterwards extremely difficult, if not quite impossible. The number of persons who actually need this assistance, is comparatively very inconsiderable; and therefore it should more generally be avoided. The misfortune resulting from the use of concave glasses is this, that the near-sightedness is not only fixed by it, but from a habit of inquiry with regard to the extreme perfection of vision, frequent changes are made for glasses that are more and more concave, until at length the near-sightedness becomes so considerable, as to be rendered seriously inconvenient and afflicting. It ought to be remembered, that, for common purposes, every near-sighted eye can see with nearly equal accuracy through two glasses, one of which is one number deeper than the other; and though the sight be in a slight degree more assisted by the deepest of these than by the other, yet on its being first used, the deepest number always occasions an uneasy sensation, as if the eye were strained. If, therefore, the glass that is most concave be at first employed, the eye, in a little time, will be accommodated to it, and then a glass one number deeper may be used with similar advantage to the sight; and if the wish for enjoying the most perfect vision be indulged, this glass may soon be changed for one that is a number still deeper, and so in succession, until at length it will be difficult to obtain a glass sufficiently concave to afford the assistance which the eye requires. Mr. Ware observes, that most of the near-sighted persons whom he has known, have had the right eye more near-sighted than the left; and he thinks it not improbable, that this difference between the two eyes has been occasioned by the habit of using a single concave hand-glass; which, being commonly applied to the right eye, contributes to render this eye more near-sighted than the other. In some cases children have manifested near-sightedness almost as soon as they begin to take notice of surrounding objects; but this, which is occasioned by some degree of opacity in the transparent parts of the eye, is very different from that state of the eye to which the term myopic, or near-sightedness, is usually applied; and by which is simply meant too great a convexity either in the cornea or in the crystalline, in proportion to the distance of these parts from the retina. So far from discouraging the use of spectacles in such cases, it is necessary to recur to them, as without them children could not prosecute their learning with ease or convenience. Extreme near-sightedness is sometimes occasioned by an evident change in the spherical figure of the cornea, and its assumption of a conical shape. This morbid state of the cornea admits of no amendment by any glass. The cornea, in most cases of this kind, is preternaturally thin; and it is not unfrequently accompanied with symptoms of general debility, under which last circumstance, chalybeate medicines, and bracing applications to the eye, have afforded considerable benefit. Near-sightedness, our author says, is seldom alike in the two eyes, and he has observed a few cases, in which one eye of the same person has had a near, and the other a distant sight. Dr. Porterfield has suggested, that the pupils of near-sighted persons are more dilated than those of others; but this does not accord with Mr. Ware's observations in such cases. This ingenious writer, whose remarks on all circumstances relating to the eye merit peculiar attention, observes, that near-sightedness has no de-

pendence on the greater or smaller degree of convexity possessed by the cornea, when this circumstance is considered alone; since the length of the axis of the eye from the cornea to the retina, and the greater or smaller degree of convexity in the crystalline humour, must be also regarded before the distance of accurate vision can be determined. It is also no less evident, that near-sightedness is not necessarily occasioned by a morbid protrusion of the whole eye; since some persons are born with eyes of this description, and others acquire the peculiarity, when further advanced in life, in consequence of a morbid accumulation of *aque* at the bottom of the orbit, without either of them being more near-sighted than those who are free from this imperfection. It is a fact often noticed, that old persons, who have been long accustomed to use convex glasses of considerable power, have recovered their former sight, even at the advanced age of 80 or 90 years, and have then had no further need of them. This amendment is ascribed by Dr. Porterfield to a decay of *aque* at the bottom of the orbit; but Mr. Ware attributes this remarkable revolution in the sight of old persons to an absorption of part of the vitreous humours; in consequence of which, the sides of the sclerotica are pressed inward, and the axis of the eye, by this lateral pressure, is proportionably lengthened. This kind of alteration is also sufficient to explain the reason, why such aged persons retain the power of distinguishing objects at a distance, at the same time that they recover the faculty of seeing those that are near; since the lengthened axis of the eye leaves the power by which it is adjusted to see at different distances, precisely in the same state in which it was before the lengthening of the axis took place. The faculty, says Dr. T. Young, of seeing at different distances, is produced by a power in the crystalline humours to become more or less convex, according as the object is more or less distant from the eye.

Although old persons lose the power of distinguishing correctly near objects, and require for this purpose the aid of convex glasses, they usually retain the sight of those that are distant as well as when they were young. Instances, however, occur of persons advanced in life, who require the aid of convex glasses to enable them to see near, as well as distant objects. From the case of persons who have had the crystalline humour removed, Mr. Ware infers, that this humour is indispensably necessary to enable the eye to see at different distances. Such persons also have less power to ascertain the distance of an object when they look through a convex glass than when they view it without this assistance; and accordingly such persons seldom make use of glasses when they are walking; and the inconvenience of glasses is particularly experienced when they descend a flight of steps, or pass over uneven ground. Our author observes, that near-sighted persons do not appear to possess the same extent of vision that is enjoyed by those who have a distant sight, and he verifies the observation by a statement of his own case, whose range of distinct vision did not extend further than an inch and a quarter in either eye, and within these distances he always held a book when he read. He recommends the following rule for determining the concavity of a glass that is best adapted for near-sighted persons, to those who are unable, from distance or any other cause, to suit themselves at the shop of an expert optician. The rule is this: multiply the distance at which the person reads with ease, (which in our author's case, with his left or best eye, was five inches,) by that at which he wishes to read, which may be stated at 12 inches; divide the product, 60, by 7, the difference between the two, and it leaves nearly 9 inches for the focus of the concave glass that shall produce the desired effect. This glass answers to that sold under the name of N^o 6; and this

is a double concave glass, ground on a tool of 8 inches radius on one side, and 11 inches on the other, the mean between which is very nearly 9 inches. From the whole statement of our author, he infers, 1. That near-sightedness is rarely observed in infants, or even in children under ten years of age. It affects the higher classes of society more than the lower; and few instances occur, if any, in which, if the use of concave glasses has been adopted, increasing years have either removed or lessened this imperfection. 2. Although the usual effect of time on perfect eyes is that of inducing a necessity to make use of concave glasses, in order to see near objects distinctly, yet sometimes, even after the age of 50, and after convex glasses have been used many years for this purpose, the eyes have not only ceased to derive benefit from them, when looking at near objects, but they have required concave glasses to enable them to distinguish, with precision, objects at a distance. 3. Although the cause of this change be not always known, yet sometimes it has been induced by the use of evacuating remedies, particularly of leeches applied to the temples; and sometimes by looking through a microscope, for a considerable length of time, on several successive days. 4. Instances are not uncommon, in which persons far advanced in life, (*viz.* between 80 and 90,) whose eyes have been accustomed for a long time to the use of deeply convex glasses, when they have read or written, have ceased to derive benefit from these glasses, and they have become able, without any assistance, to see both near and distant objects almost as well as when they were young. This change is probably owing to an absorption of part of the vitreous humour, by which the axis is lengthened; and thus its length, from the cornea to the retina, is brought into the same proportion to the flattened state of the cornea, or crystalline, or both, which it had to these parts before the alteration took place.

SPECTATOR, a person present at a spectacle.

Among the Romans, spectators, *spectatores*, more particularly denoted a kind of gladiators, who had received their discharge; and were frequently hired to be present as spectators at the combats of gladiators, &c. with which the people were entertained. See **RUDIANIUS**.

SPECTER, in *Conchology*, a name given by the French naturalists to a species of *voluta*, on which there are several reddish broad bands, composed of loose and irregular figures; the ground colour is a fine white. They are called by Latin writers *concha spectrorum*.

SPECTRORUM CANDELA, in *Natural History*, a name by which some have called the belemnites.

SPECTRUM, OCULAR, in *Optics*, a name given by Dr. Darwin (*Phil. Trans.* for 1786) to an image, resembling in form the object to which the observer was attending, and which continues for some time to be visible, on closing his eyes or covering them, after having been long and attentively looking at a bright object, such, *e. g.* as the setting sun. These ocular spectra, he says, are of four kinds; *viz.* 1. Such as are owing to a less sensibility of a defined part of the retina, or "spectra from defect of sensibility." 2. Such as are owing to a greater sensibility of a defined part of the retina, or "spectra from excess of sensibility." 3. Such as resemble their object in colour as well as in form, which may be termed "direct ocular spectra." 4. Such as are of a colour contrary to that of their object, which may be termed "reverse ocular spectra." The author, from experiments which he has detailed, concludes, that the retina is in an active, not in a passive state, during the existence of these ocular spectra; and hence he infers, that all vision is owing to the activity of this organ. In the first case, the retina is not so easily excited into action by less irritation,

after having been lately subjected to greater. In the second, the retina is more easily excited into action by greater irritation, after having been lately subjected to less. In the third, a quantity of stimulus greater than natural excites the retina into spasmodic action, which ceases in a few seconds: and a quantity of stimulus somewhat greater than the last excites the retina into spasmodic action, which ceases and recurs alternately. In the fourth case, the retina, after having been excited into action by a stimulus somewhat greater than the last mentioned, falls into opposite spasmodic action. The retina, after having been excited into action by a stimulus greater than the last mentioned, falls into various successive spasmodic actions. With a greater stimulus, the retina falls into a fixed spasmodic action, which continues for some days; and a quantity of stimulus still greater, induces a temporary paralysis of the organ of vision. For the illustration of the cases, with miscellaneous remarks, we must refer to the author's paper, *ubi supra*.

SPECULA, among the Romans, were places whence a good view might be had of what was doing at a distance. The word is particularly used to signify watch-towers and beacons.

SPECULARES, in *Natural History*, the name of a genus of fossils of the class of the talcs.

The word is derived from the Latin *speculum*, a looking-glass; the bodies of this kind being naturally of bright, glossy, and polished surfaces, and in the thicker masses not transparent, but reflecting the images of things.

The speculars are talcs, composed of visibly separate plates of extreme thinness, and each fissile again into a number of others yet finer.

The bodies of this genus are the common Muscovy talc; the *specularis lucida fusca*, or brown talc, a species little inferior to the former in beauty, and found in Germany and England; and the *specularis amethystina*, called *talc rouge*, or *red talc*, by the French. This is found in Muscovy and Persia, and no where else, as far as is yet known, and is often imported into France in masses, which are of a beautiful purple: we have of it brought into England, but only in thin flakes, fit for the covering of miniature pictures. In these flakes it has none of the redness natural to it in the lump, but is the finest and most transparent of all the talcs.

Pliny, and other of the ancient writers, as well as several of the moderns, use the term *specularis lapis* for that species of talc commonly known by the name of *islinglass*, or *Muscovy glass*.

This has been a substance in great use among mechanics, from the earliest times of which we have any account. It is found in broad flat masses of ten or twelve inches in breadth, and from half an inch to three inches in thickness; and is composed in these of an almost infinite number of broad and beautifully even plates, or flakes, laid with a perfect regularity on one another, and seldom parting naturally from each other, though by art they may be divided, almost without end, into broad and extremely thin laminæ. These are very flexible and elastic, and make no effervescence with aqua fortis. By the last of these properties they are distinguished from the plated spars which some have confounded with them, and by their elasticity from all other fossil bodies.

It is found in many parts of the world. The island of Cyprus abounds with it. It is very common also in Russia, and has of late been discovered to abound in the Alps, the Apennines, and many of the mountains of Germany. It is imported in large quantities into England, and is used by the lantern-makers instead of horn, in their nicer works; by the painters to cover miniature pictures; and by the microscope

croscope makers to preserve small objects for viewing by glasses. The ancients used it instead of glass in their windows. Hill's Hist. of Fossils, p. 72.

Some take the lapis specularis to have been a species of gypsum, and composed of the acid of vitriol and calcareous earth. It came into use at Rome in the age of Seneca (Ep. 90.), and soon after its introduction, was applied not only to give light to apartments, but to protect fruit-trees from the severity of the weather; and it is recorded, that the emperor Tiberius was enabled, principally by its means, to have cucumbers at his table during almost every month in the year.

Dr. Watson apprehends it is still used in some countries in the place of glass; however, it is well known that it was so used in the time of Agricola, for he mentions (De Nat. Fof. lib. v. p. 257.) two churches in Saxony which were lighted by it. Agricola esteemed it to have been a species of plaster-stone, and in speaking of it he remarks, that though it could bear, without being injured, the heat of summer and the cold of winter, yet the largest masses of it were wasted by the rain. However, it differs from plaster-stone in this property, that it does not, after being calcined and wetted with water, swell and concrete into a hard stony substance. Watson's Chem. Ess. vol. ii. p. 297, &c.

SPECULARIA, among the Romans, a kind of window casements, which were used before glass was introduced for this purpose. They consisted of transparent stones, called *lapides specularis*.

SPECULARIA, the art of preparing and making specula, or mirrors: or the laws of mirrors, their phenomena, causes, &c. called also *catoptrics*.

SPECULARIS LAPIS, in *Natural History*. See **SPECULARES**.

SPECULATION. — *Certainty of Speculation*. See **CERTITUDE**.

SPECULATION Shell, in *Natural History*, a name given by the French writers to a very beautiful species of the voluta, usually called by us the Guinea-shell, from its being brought from that part of the world.

SPECULATIVE Geometry, Mathematics, and Philosophy. See the substantives.

SPECULATIVE Music. By this expression is usually understood scientific music, harmonics, the ratio or proportions of sound; in opposition to *practical music*, which implies music composed or performed.

SPECULUM, in *Catoptrics*, is a metallic reflector made use of in catadioptric telescopes, instead of the object-glasses used in dioptric telescopes.

Newton. — Mr. Newton, afterwards the celebrated Sir Isaac Newton, had discovered that *light consists of rays differently refrangible*, and that consequently no figure, which could be given to a single piece of glass, would make all the transmitted rays concentrate in the focus of that glass used as an object-glass: he relinquished his glass-works, and immediately turned his mind to the consideration of what could be done in the construction of a telescope, where the rays of light were made to concentrate by reflection; having previously discovered and proved, that the angle of reflection of all sorts of rays was equal to the angle of incidence, without the least perceptible dispersion. Under an impression that an instrument, founded on this basis, might be made more perfect than could be made with glasses alone, when used in the usual way, he tried such metallic substances as promised to produce a hard and bright texture, and to admit of a good polish, and in

February, 1672, laid before the Royal Society an account of a telescope of an entire new construction, that gave a distinct image, and magnified or increased the visual angle thirty-eight times. It is somewhat remarkable, though not so much to be wondered at, when we consider the genius of the inventor, that this first attempt detected not only the best materials, but the best mode of fusing and mixing them, if not in the best proportions; and left succeeding instrument-makers little more to do than to vary the proportions, and to exemplify the theory which he pointed out by a succession of nice and skilful manipulations. Copper, tin, and a portion of arsenic, with sometimes a little silver, were then, as they are at this time, the essential ingredients of the compound metal that constituted the best speculum. The ingenious Huygens was no sooner informed of the occasion and success of this project, than he calculated and candidly acknowledged the advantage that a good concave speculum must have over convex glasses in concentrating all the different rays of heterogeneous light. With this first instrument the satellites of Jupiter, as well as the lunc of Venus's disc, were clearly perceived. The second telescope, however, was more perfect, and a page of the Philosophical Transactions could be distinctly read with it at the distance of 100 feet. In this construction, which has obtained the name of the Newtonian construction, there were two specula: one speculum, which was ground to a given radius of curvature, was placed at the end of the tube, which was remote from the object to be viewed, and the other, which was small, was plane, and was fixed in an angle of 45° in the axis of vision, so as to reflect the converging rays to a focus, at the focus of a small eye-glass placed at the side of the tube, not far from its anterior end or aperture where the eye was situated to view the object, that actually lay to the left hand. Cassegrain in the same year communicated to the Royal Society the figure of a reflecting telescope, where a perforation in the large speculum admitted the eye-piece to be placed as in the dioptric telescope, which he thought had several advantages, but he did not detail any processes he had used towards attaining such a construction; in reply to which Sir Isaac informed him, that Mr. Gregory had described a similar construction in his "Optica Promota," in the year 1663, from which reply it should seem, that *reflection* had been considered by Gregory before Sir Isaac constructed his telescope, so that the *Gregorian* construction must be considered as preceding the *Newtonian*, so far as relates to the arrangement of its parts; but we are not to conclude from thence, that the best composition for the speculum was not Sir Isaac Newton's. During the correspondence that Huygens had with our author, on the subject of a metallic speculum, he took occasion to observe, that no doubt the superiority of a parabolic curve for the face of the reflecting metal over a spherical one must be known to him, and Sir Isaac was of opinion that some mechanical device might be found out, to produce the desired curvature, better than any of the *conic sections*; that is, as we suppose, better than any tool formed agreeably to one of the conic sections: and with this view Mr. Stephen Gray, we find, presented a project of forming a grinding tool of a *concatenary* shape to be substituted for the parabola, which, however, did not answer in practice. The project was this; a piece of clay was formed thin, when soft, into an exact circular cake, and laid on a suspended horizontal rim or ring of a smaller diameter, so as to allow the cake to assume the shape of the required curve, which it appeared to do; but on baking this convex cake, it was found to have altered its figure,

and to have become flat at the vertex, so as to be incapable of becoming a proper bed for the bituminous coat that was intended to receive the emery.

In the telescope which Sir Isaac Newton first made, the focal length of the concave speculum was 6' inches, that of the eye-piece, which was a plano-convex lens, being just $\frac{1}{4}$ th; but as the metal was neither perfect, nor very highly polished, he thought that the power ought not to be so highly charged for opaque objects, particularly as the aperture was only $\frac{1}{4}$ d of an inch. Supposing the performance of any instrument to be known and approved, the author proposes the subjoined table to shew what ought to be the apertures, lengths, and powers or charges of other instruments to perform equally well. In the first column the length of the telescope is expressed in feet; which quantity doubled gives the semi-diameter of the sphere on which the concave metal is to be ground; in the second column are the proportions of the apertures for these several lengths; and in the third column are the proportions of the charges or diameter of the spheres, on which the convex superficies of the eye-glasses are to be ground.

Lengths.	Apertures.	Charges.
$\frac{1}{2}$	100	100
1	168	119
2	283	141
3	383	157
4	476	168
5	562	178
6	645	186
8	800	200
10	946	211
12	1084	221
16	1345	238
20	1591	251
24	1824	263

Suppose, for example, that a half-foot or six-inch telescope will magnify distinctly 30 times with one-inch aperture, and that it be required to find the dimensions of an analogous four-foot telescope; then opposite 4, in column 1, we see 476, in column 2; and if 100 at the top of this column be considered 1.00, then 476 will be 4.76 for the corresponding aperture; also 168, in column 3, will be 1.68 for the charge, producing a magnifying power of 1.45 times; for if the telescope of six inches magnify 30 times, the focus of its eye-glass must be $\frac{1}{3}$ th of an inch, and $\frac{1}{3} \div \frac{1}{30} = \frac{1}{10}$ nearly will be the focal length of the eye-glass for 4 feet or 48 inches, and consequently this number divided by $\frac{1}{3}$ will give 145 nearly for its power. "But what the event will really be," says Newton, "we must wait to see determined by experience." And experience, we may add, has shewn, that a four-foot reflector, as now made, with the small speculum also concave, will do much more.

Hadley.—From this time we do not find that much, if any, improvement took place in the manipulation of the metallic speculum, till about the year 1719, when Mr. Hadley succeeded in making two reflecting telescopes of 5 feet 3 inches long; one of which he presented to the Royal Society of London, and described in the *Philosophical Transactions* of March and April, 1723. But though Mr. Pound and himself made good observations on Saturn, Jupiter, and their respective satellites therewith,

nothing is said about the means used in casting, grinding, and polishing either of the specula in question. Dr. Robert Smith, in his "Complete System of Optics," has, however, supplied the omission we have just noticed, and has stated at considerable length how Hadley's method of proceeding was practised successfully by Dr. Bradley and himself at Kew, where, after many trials, they produced their first specimen, of 26 inches focal length, in May, 1724. The different processes were now made known to Hawksbee, Scarlet, and Hearne, mathematical-instrument makers in London, who, from that period, continued to manufacture this instrument for sale, which before had been made only by and for private individuals.

We will give here only a short detail of the processes used by Hadley, Smith, and Bradley, in casting, polishing, and figuring their specula; because the modern improvements in this curious art claim our more particular notice. Having fixed on the radius of curvature, and proposed diameter, of the large speculum, two arcs were struck with a beam-compass on two slips of brass, large enough to receive the curves of the same radius as that of the speculum; and when the metal was filed away, so that one of the curves was convex, and the other concave, they were ground within one another with fine emery, till they exactly fitted each other, and then became gauges for forming the wooden patterns by, which were next made in a lathe, of somewhat larger dimensions than were required for the speculum, that the rough edges of the cast-metal might be reduced, as the case should require. From this wooden pattern another of pewter, containing about one-tenth of regulus of antimony, was cast in the usual way, and turned in the lathe to fit the convex brass gauge, and to exceed the proposed speculum by one-twentieth of an inch in thickness, and double that quantity in diameter. The flasks for receiving the pewter pattern, for casting the speculum by, were of iron, and two inches wider, and one inch deeper, than the pattern, in order that the sand might be every where an inch thick; and the ingates for receiving the fluid metal were so made as to allow four or five streams over the face of the sand, which was obtained at Highgate. This sand was neither much wetted, nor rendered too adhesive by an admixture of clay; and when the liquid metal was poured in, the flasks were suffered to remain exposed to the sun, so as to cool gradually, before the metal was taken out, in order that it might neither warp nor crack. With respect to the composition of the metal, above 150 different mixtures were tried before one was determined on, which was preferred to some of the rest. One of the metals was three parts of copper and one and a quarter of tin, which was hard and white, but found to be porous, especially if great heat was used. Another was six parts of Hamburgh plate brass, cast and milled, with one part of tin only; but the fumes of the calamy stone left scabrous streaks on the surface. A third metal, therefore, composed of two parts of the former of these compositions, and one of the latter, was adopted, as being superior to either; but it was found necessary that the copper and brass should be melted together separately, before the tin was melted and poured in. And much importance was attached to the immediate pouring out of the whole mixture, as soon as it could be well stirred: for after cooling, less heat was necessary to melt the whole mixture, than was sufficient to fuse one of the ingredients alone; and the less heat was used in bringing the mass into a liquid state, the less porous the speculum was found to be, when polished. After the metal thus cast had become cool, it was first ground on a common grinding-stone a little concave, till

SPECULUM.

all the sand-holes and inequalities were taken off; and then a smaller grinding-stone, or a piece of one, was shaped so convex as to fit the brass concave pattern, on which the metal was again ground, when fixed upon a block, with a little emery and water, till the gauge fitted it. The diameter of the rough stone was to the diameter of the speculum as 6 to 5. When the strokes in grinding were made in a circular direction, they diminished the edges of the stone; but when made across, they made it flatter, so that it might be made a portion of either a smaller or larger sphere, by the mode of working, and consequently might be made to grind the concave speculum accordingly. But care was taken that as little of the external hard crust was ground away as possible, when the figure was once complete, and the surface even. When the rough grinding was finished, various other tools were used, not only with the speculum, but with each other, to insure an uniformity of shape. A brass concave tool, shaped like the speculum, but of larger diameter, was worked on a marble convex tool, on which were bedded by cement a number of small blue hones, like a pavement; so that the working of the brass concave tool on this pavement made a convex curve over the surface of the pavement, which was thus prepared to smooth the speculum still further, as well as to improve its figure, by varying the mode of applying the grinding strokes. Again, a polishing tool made convex, of glass or fine marble, and brought to its figure by the brass concave tool, was covered with a piece of fine even farcenet, and laced tight behind, on which a solution of pitch in spirits of wine was spread evenly with a varnish brush, till its consistence was uniform, and thick enough to receive a portion of fine putty powder, when another tool, made concave of brass, called a *bruiser*, was used to rub down the gritty matter of the putty occasionally, as well as to grind sometimes the bed of hones, when its figure began to alter too much. During the grinding, a wooden handle was cemented on the central part of the speculum, to move it by. It would be tedious to detail all the variety of precautions, with the succession of circular, spiral, and cross strokes, recommended for giving perfection to the figure and polish of the metal; all which the reader may find in Smith's Optics, from page 301 to page 312, together with the author's mode of examining both the exact length of the focus, and the figure of the curve, by the reflected light of a candle.

In reflecting telescopes of various lengths, a given object will appear equally bright and equally distinct, when their linear apertures, and also their linear amplifications, or magnifying powers, are as the square-square roots of the cubes of their lengths, agreeably to both Sir Isaac Newton and Dr. Smith. For example, suppose that a reflecting telescope, with an aperture of 2.448 inches, have a speculum of two feet focal length, and an eye-glass of $\frac{1}{3}$ inch of an inch focus, where the power will be $\frac{2.448}{\frac{1}{3}} = 102$, and that it be required to have another made of three feet focal length, that shall produce the same brightness and distinctness in the object viewed; first we shall have $2 \times 2 \times 2 = 8$ for the cube, and the square root of $8 = 2.83$, and again the square root of $2.83 = 1.68$; then $3 \times 3 \times 3 = 27$ is the cube of the new focal length, and 5.2 its square root; and again, the square root of 5.2 will be 2.28 ; hence, as $1.68 : 2.28 :: 102 : 138$; therefore 138 will be the magnifying power of the enlarged telescope, 0.261 the focus of its eye-piece, and 3.312 inches its corresponding aperture; for as $1.68 : 2.28 :: 2.448 : 3.312$, &c.; and also $\frac{1}{3} : 0.261 = 0.261$.

The following table, constructed on this proposition, was calculated by Dr. Smith, which we insert, as being in

a form more intelligible to a common workman, than the one we have before inserted from the calculation of Sir Isaac Newton.

Focal Distance of Speculum.	Focal Distance of Eye-Glafs.	Magnifying Power.	Aperture.
Feet.	Inches.		Inches.
$\frac{1}{2}$	0.167	36	0.864
1	0.199	60	1.440
2	0.236	102	2.448
3	0.261	138	3.312
4	0.281	171	4.104
5	0.297	202	4.848
6	0.311	232	5.568
7	0.323	260	6.240
8	0.334	287	6.888
9	0.344	314	7.536
10	0.353	340	8.160
11	0.362	365	8.760
12	0.367	390	9.360
13	0.377	414	9.936
14	0.384	437	10.488
15	0.391	460	11.040
16	0.397	483	11.592
17	0.403	506	12.144
<i>Continued by Edwards.</i>			
18	0.409	528	12.67

24	0.439	656	15.73

This table is adapted for telescopes of the Newtonian construction, in which the figure of the great metal is supposed to be truly spherical; but it is presumed, that when this table supposes the construction to be of the Gregorian kind, the focal length is the sum of the focal lengths of both the specula, or the distance that the rays pass after both reflections, before they come to the eye-glass; and that the large speculum is parabolical.

Short.—We do not find that any optician distinguished himself in the art of making specula for reflecting telescopes, after Dr. Smith's time, till we come to Mr. James Short, whose composition was beautiful, and whose polish, as well as parabolic figure, were excellent; nay, have been considered as standards of perfection for even subsequent opticians to imitate. We have, however, to regret that this consummate workman not only kept his process a secret from the other opticians, but, in order to secure to himself the fame he had acquired of being the first in his line of manufactory, some little time before his death, as we are credibly informed, he employed his founder, Mr. Justice Blackburgh, to destroy all his tools, lest they should fall into some person's hands, who might avail himself of their use; and accordingly they were all melted into a liquid mass: and his long and successful experience has no further benefited posterity, than as it left specimens of workmanship to shew what skilful perseverance could effect.

Short left behind him, however, a table of the apertures, powers,

SPECULUM.

powers, and prices, of reflecting telescopes, constructed by him in the Gregorian form; which, not being generally known, we shall subjoin, by way of effacing the blot on his memory.

Numbers.	Focal Length in Inches.	Diameter of Aperture in Inches.	Magnifying Powers.	Price in Guineas.
1	3	1.1	1 power of 18 times.	3
2	4 $\frac{1}{2}$	1.3	1 25.	4
3	7	1.9	1 40.	6
4	9 $\frac{1}{2}$	2.5	2 40, and 60.	8
5 } 6 }	12	3.0	2 55, and 85.	10
	12	3.0	4 35, 55, 85, and 110.	14
7	18	3.8	4 55, 95, 130, and 200.	20
8	24	4.5	4 90, 150, 230, and 300.	35
9	36	6.3	4 100, 200, 300, and 400.	75
10	48	7.6	4 120, 260, 380, and 500.	100
11	72	12.2	4 200, 400, 600, and 800.	300
12	144	18.0	4 300, 600, 900, and 1200.	800

In this table Mr. Short *always* overrated the *highest* power of his telescopes, according to the authority of the Rev. John Edwards, of whom we shall have occasion to speak hereafter; and to this circumstance alone, we are assured by an ingenious and candid optician, it is to be ascribed, that all following opticians have been obliged, by way of satisfying the expectations of their customers, to overrate the highest power of their telescopes, in order to obtain a price adequate to their respective values. Experimental measurements, indeed, soon detect this false representation; and it would be to the credit of opticians, if they would agree to fix a true measure to each power of their telescopes, and to sell them, notwithstanding, at their accustomed prices: for then their purchasers would not experience disappointment.

Short made two or three Gregorian telescopes of 18 inches focus, with 4.5 inches aperture, and power 170; and half a dozen of 24 inches focus, with 6 inches aperture, with the usual magnifying powers; but one of a Cassegrain form, with a convex small speculum, of the same dimensions, intended to have a power of 355, was not distinct, and would bear only a power of 231.

Mudge.—In the year 1777, Mr. John Mudge produced a paper to the Royal Society, which is printed in their 67th volume, entitled “Directions for making the best Composition for the Metals of reflecting Telescopes; together with a Description of the Process of grinding, polishing, and giving the great Speculum the true parabolic Curve.” It will be sufficient for our present purpose, if we shew in what respects Mr. Mudge’s metal differs from that which we have just described, and in what his improvements in casting consist. In the first place, Mr. Mudge attempted to ascertain what metals, and proportions of those, will produce a composition that has the three requisites of extreme hardness, whiteness, and compactness, or exemption from porosity. The first two qualities, after many experiments, he found were united in a mixture of 14 $\frac{1}{2}$ ounces of grain-tin with two pounds of good Swedish copper; but the quality of compactness was not to be acquired from the mixture simply considered: it was produced principally from the manner in which the mixture was made. It had been usual to melt the copper first, and then to add the tin, and to pour the liquid mixture, with the scoria first taken off, into the flasks, to form the speculum in the first melting; but the metal generally turned out to be porous, when polished. Mr. Mudge, on con-

sidering that putty is tin calcined, began to think, that part of the tin melted in a high heat might be converted into putty, and that the pores might arise from this cause; he, therefore, poured out the liquid compound to form an ingot, which would fuse with a lower heat than the copper alone required; and on using this metal a second time, fused with a moderate heat, it was generally, if not always, found compact. Thus melting a second, or even a third time, proved to be a remedy against porosity; and it was afterwards found, that if an ounce of the tin was reserved to be put into the mixture at the final melting, the brilliancy of the metal was thereby increased. If a spoonful of charcoal dust be thrown into the crucible, before the metal be stirred with a wooden spatula, and poured into the moulds, Mr. Mudge says that the metal will be found to have a cleaner surface, than when no such dust is used. For Mr. Mudge’s method of grinding, polishing, and figuring his specula, see our article GRINDING.

Edwards.—In the Nautical Almanac of the year 1787 is printed a memoir, entitled “Directions for making the best Composition for the Metals of reflecting Telescopes, and the Method of casting, grinding, polishing, and giving the great Speculum the true parabolic Figure,” by the Rev. John Edwards, B.A., of Ludlow. These directions having been considered an improvement on Mr. Mudge’s, in several respects, were published first in a pamphlet, which was soon bought up by the trade; but at the request of the composer of the present article, they were reprinted in Nicholson’s Philosophical Journal, vol. iii. 8vo. Series, p. 490, et. seq., in the year 1800; but with the omission of a portion of the appendix.

After what we have already said on this subject under our article GRINDING, as well as in the preceding part of our present article, it will not be necessary to give the whole of Mr. Edwards’s memoir, but to dwell more particularly on those methods of proceeding which are peculiarly his own, and which constitute his acknowledged improvements. The first object that Mr. Edwards had in view was, like that of his predecessors, to ascertain, by a number of trials of various mixtures, made from the metals and semi-metals, what composition is, on the whole, to be preferred: for which purpose he tried silver, platina, iron, copper, brass, lead, and tin, crude antimony, regulus of antimony, martial regulus of antimony, arsenic, bismuth, zinc, and antimony combined with cawk-stone; and in the appendix to his memoir he gave the result of 71 mixtures, which we will here

SPECULUM.

transcribe, in order that the same experiments may not be fruitlessly repeated by future mechanicians.

1. Copper and grain-tin, equal parts; very bad, soft, and of a blue colour.
2. Copper with arsenic $\frac{1}{6}$; but little different from the first.
3. Tin 2, copper 1; much worse than the preceding ones.
4. Copper 32, tin 16, arsenic 4, fixed with nitre; black and brittle.
5. Copper 6, tin $1\frac{3}{4}$, arsenic 1; very indifferent.
6. Copper 32, tin 14, arsenic 2; a very good metal.
7. Copper 32, tin $13\frac{1}{2}$, arsenic 1; not quite so good as the sixth.
8. Copper 32, tin $13\frac{1}{2}$, arsenic $1\frac{1}{2}$; a good metal.
9. Copper 32, tin 15, arsenic 2; much better than any of the above.
10. Copper 6, tin 2, arsenic 1; compact, but very yellow when polished.
11. Copper 3, tin $1\frac{1}{4}$; compact, and whiter than the tenth.
12. Copper 32, tin $14\frac{1}{2}$; a pretty good metal, but polishes too yellow.
13. Copper 32, tin 15, arsenic 2, flint-glass in powder 3; very bright, but rotten.
14. Brass 6, tin 1; compact, but too yellow.
15. Two parts of the eleventh composition, and one part of the fourteenth composition; compact, but much too yellow when polished.
16. Brass 5, tin 1; somewhat whiter than the fourteenth.
17. Brass 4, tin 1; a good metal, but rather yellow.
18. Brass 4, tin 1, with arsenic $\frac{1}{10}$; whiter than the seventeenth.
19. Brass 3, tin 1; will not polish well.
20. Brass 2, tin 1; of a sparry nature.
21. Tin 3, brass 1; too soft, being only a kind of hard pewter.
22. Brass and arsenic, equal parts; a dirty white colour.
23. Brass, copper, and arsenic, equal parts; a dingy white.
24. Brass and platina, equal parts; very difficult to fuse and mix well together, is then malleable, and of a dingy white colour, like the twenty-second composition.
25. Copper 32, tin 14, crude antimony 4; black and rotten.
26. Copper 32, tin 14, crude antimony 1; blueish, and rough-grained.
27. Copper 32, tin 15, arsenic 4, bismuth 2; much too rotten.
28. Copper 32, tin 15, arsenic 3, bismuth 1; much too yellow when polished, and appears also porous.
29. Copper 2, zinc 1; a pale malleable metal.
30. Copper and zinc, equal parts; still malleable and rough-grained.
31. Copper 32, tin 15, arsenic 4, zinc 4; a good metal, but does not take a high lustre.
32. The thirty-first composition, fluxed with corrosive sublimate; a compact and hard metal, but rather yellow when polished.
33. Copper 32, tin 16; a most beautiful brilliant composition, but much too brittle and rotten.
34. Copper 32, tin 17; blueish and rough-grained.
35. Copper 32, tin 18; blueish and rough-grained.
36. Brass 2, zinc 1; nearly of a gold colour.
37. Brass and zinc, equal parts; a pale gold colour, and rough-grained.

38. Spelter 4, tin 1; very rotten.
39. Copper and crude antimony, equal parts; of a sparry nature.
40. Copper 32, tin 15, arsenic $\frac{1}{4}$ th of the whole; a very beautiful and brilliant metal, but tarnishes when exposed for some time to the air.
41. Silver and bismuth, equal parts; a yellowish-white metal, and not much harder than silver itself.
42. Silver and tin, equal parts; a white metal, almost like silver itself, and much too soft for specula.
43. Silver, tin, and bismuth, equal parts; a dingy white colour, but much harder than the two preceding compositions.
44. Copper 32, tin 15, silver 1; a beautiful compact metal, but polishes rather too yellow.
45. Copper 32, tin 15, silver 2; not so white as the preceding.
46. Copper 32, tin 16, brass 4, arsenic 2; rather too much tin, as the composition was of a blueish complexion, and rough-grained.
47. Copper 32, tin 15, brass 1, silver 1, arsenic 1; a most excellent metal, being by much the whitest, hardest, and the most reflective I have ever yet met with.
48. Common bell-metal; polishes very yellow.
49. Common bell-metal 4, regulus of antimony 1; blueish and rough-grained.
50. Common bell-metal 6, regulus of antimony 1; still blueish and rough-grained.
51. Copper 32, tin 14, regulus of antimony $1\frac{1}{6}$, viz. 1 oz. to 1 lb.; too much antimony, it being of a blueish colour, and rough-grained.
52. Copper 32, tin 13, regulus of antimony $\frac{1}{10}$; blueish and rough.
53. Copper 32, tin 13, regulus of antimony $\frac{1}{10}$, viz. 1 oz. to 2 lb.; a very fine metal, in appearance like thirty-three.
54. Copper 32, tin 13, regulus of antimony $\frac{1}{10}$, viz. 1 oz. to $2\frac{1}{2}$ lb.; a beautiful metal, not much unlike forty-seven, but not quite so white.
55. Crude antimony 16, cawk-stone 1 or 2 oz.; a very bright glassy metal, like the common vitrum antimonii, but by no means fit for mirrors.
56. Copper 32, tin 16, vitrum antimonii made from the cawk-stone 1 oz.; a very indifferent composition, as the vitrum antimonii did not differ in its effects from crude antimony.
57. Copper 32, tin 14, lead 2; no art can make this composition mix intimately, as the lead will always separate from the copper and tin.
58. Copper 32, tin 16, regulus of antimony 3; black, and much too rotten.
59. Copper 32, tin 16, iron-filings 8; a blueish-grey colour, and rough-grained, and appeared somewhat like steel when broken through.
60. Fifty-ninth composition 8 oz., tin 1 oz.; a little whiter than the fifty-ninth, but still too blue.
61. Equal parts of fifty-nine and sixty; still of too blue a colour, and not close-grained.
62. Copper 32, tin 16, arsenic 3, iron-filings $\frac{1}{4}$ of an oz.; a pretty brilliant composition, but much inferior to forty-seven.
63. Platina 1 oz., brass 1 oz., cawk-stone red-hot $\frac{1}{2}$ oz.; excessively difficult to fuse, and of a dirty light brown colour, and somewhat malleable.
64. Copper 32, tin 16, iron-filings 4, regulus of antimony 4, and fluxed with corrosive sublimate; an exceeding hard and compact metal, but of too blue a colour.

65. Copper 2 oz., tin 1 oz., iron-filings 1 dr., regulus of antimony 1 dr.; too blue a colour, and rough-grained.
66. Regulus of antimony and tin, equal parts; sparry, and not fit for mirrors.
67. Cast-steel; will not polish upon pitch, either with putty, or colcothar of vitriol.
68. Steel 1, tin $\frac{1}{2}$; very rough-grained and blueish, and not much different from steel itself.
69. Steel 1, tin 1; rough-grained, and of a blueish colour.
70. Steel 1, and forty-seventh composition 20 parts; rough-grained, and not near so good as forty-seven.
71. Steel 1, and forty-seventh composition 30; not much different from the forty-seventh composition, but not so beautiful and close-grained.

"Many other mixtures," says Mr. Edwards, "were tried, by combining the foregoing compositions in more than a hundred varieties of proportions; but none of them were found equal to N^o 47, as that mixture forms a metal that is the whitest, hardest, most reflective, and takes the highest lustre of any thing I have yet seen."

The mixture, therefore, which was at last chosen from these various experiments, was 32 ounces of pure copper, with 15 or 16 of grain-tin, just enough to saturate the copper, 1 of brass, and 1 of arsenic; which composition will be still further improved, it is said in a note, but we believe not correctly, by 1 of silver. The use of the copper was to lessen the extreme brittleness of the mixture; the arsenic rendered the metal close and free from pores; and the silver, it was thought, improved the brightness, without injuring the hardness, when used in a small quantity. This mixture, it will be remarked, very much resembles Mr. Mudge's, who used $14\frac{1}{2}$ of grain-tin to 32 of copper, but without arsenic, or other addition: he found 15 too hard for the blue stone to take hold of; but Mr. Edwards availed himself of another stone, procured at Edgedon, in Shropshire, situated between Ludlow and Bishop's Cattle, which was keen enough to bite a metal with from 15 to 16 of tin to 32 of copper, which composition Mr. Mudge considers to possess a *maximum* of whiteness as well as of hardness. Mr. Mudge, however, says, that one of his belt workmen, called Jackson, found a stone that would cut a metal of one-third tin and two-thirds copper, but the discovery of such stone, which he always kept a secret, cost him the expense of a journey of two hundred miles; which distance exceeds that of Edgedon from London, by about fifty miles; and, therefore, the stones of Jackson and of Mr. Edwards were probably not from the same quarry, if they were similar in kind. Edwards's mode of casting is nearly the same as Mudge's, both as to a first fusing for the ingot, with a second fusing for the speculum at a lower heat; and as to his flasks and sand (procured from Highgate), a small portion of the tin was also reserved to be put into the crucible at the second melting, when also the arsenic, tied up in paper, was put in; and after the fumes of this ingredient had ceased to ascend, the mixture, stirred with a wooden spatula, while no breath was inhaled into the lungs, was poured into the flasks, the moment that about an ounce of powdered resin, or resin and nitre, had been thrown in and melted, to give a good face, as Mudge did with the charcoal dust. The principal difference from Mudge's process is, that in the first melting, after the brass is made as fluid as possible, the brass and silver must be added with the common black flux, of two parts of tartar to one of nitre, or by stirring the melted mixture with a spatula of birch; after which the tin must be added, and the whole poured out into an ingot, as soon as it is found to be in a liquid state; and after the second melting, when the arsenic has been

added, and also the resin, the flasks receive the metal, with the face downwards; the ingate having been made on the back of the metal near its edge, and its breadth increasing to half the diameter of the metal at the place of joining. The upper part of the ingate should contain as much metal in weight as the speculum and the flasks should be opened, and the sand cleared out, while it remains red-hot, with the face still downwards, and then removed by a pair of tongs into an iron pot, containing a large quantity of hot ashes or small coals, sufficient to bury the metal, where it must remain to cool by degrees with the ashes. We must not, however, omit to mention one precaution, on which some artists seems to be laid, *viz.* that when the pattern, with its ingate, or git, is taken out of the sand, ten or a dozen small holes must be made through the sand at the back of the mould, with a small wire, or common knitting-needle, to permit the air to escape while the liquid metal is filling the mould, which are safer than one large hole: also at the second melting, the flasks must be jogged with a slight stroke or shake, as soon as the fluid metal is poured in, to prevent flakes or air-bubbles being formed on the face of the metal. The git may be taken off, when the metal is quite cool, with a common fine half-round file, to make an incision, after which a gentle blow will remove it. If, however, the metal is cast from a mould too thick, it will not take the parabolic figure. For a speculum of $4\frac{1}{2}$ inches diameter, and 18 inches focal length, the thickness should be $\frac{1}{16}$ ths of an inch at the edge, and the back should be convex, so as to allow the whole metal to be of uniform thickness when ground, in order that it may not yield to the pressure, or incumbent weight, during the grinding and polishing. The handle should be made of the same concavity and convexity as the metal, but double its thickness, and only three-fourths of its diameter; it should also have a hole through the centre, to receive a screw going into the chuck of a lathe, in order that the edge of the metal may be formed, first by a file, and then by a stone from Edgedon, while it is revolving.

The speculum being cast by these directions, is next rough-ground on a common grinding-stone, formed by a bar of steel, while revolving, to the radius of convexity suitable for making the desired concavity of the metal; after this rough-grinding, two tools are all that are requisite; a convex tool made of lead and tin, or else of pewter, and a bed of hones, of the sort already mentioned; for the convex tool serves also for a polisher, in conjunction with its coat of pitch and *colcothar of vitriol*, which is preferred to putty: the polish from the latter is indeed of a white silvery hue, but that from the former gives a fine dark lustre, like the complexion of polished steel, which is deemed preferable. The colcothar, to be good for this purpose, must be of a deep red or purple colour, must dissolve in the mouth without gritty lumps, and feel soft and oily to the touch. It may be levigated with a little water between two bars of polished steel, and worked with two or three additions of water, till it acquires a dark and nearly black colour, when it will be fine enough to be put into a bottle with water for use. We will not repeat all the processes to be attended to in the use of the convex tool, and of the bed of hones, which we have sufficiently detailed under our article GRINDING, but remark only on their dimensions and shape, which form essential considerations in Mr. Edwards's mode of grinding, polishing, and particularly of giving the requisite figure without a succession of tentative operations. The bed of hones should be of a circular figure at the circumference, and in every respect the segment of a sphere, with a diameter just $\frac{1}{16}$ ths of an inch wider than that of the metal, when it is

SPECULUM.

four or five inches in diameter; and the reason is, that if it is much larger, it will enlarge the circle of concavity of the metal worked on it. The convex tool must not, however, exceed the speculum in diameter more than $\frac{1}{7}$ th of an inch, otherwise it will enlarge the radius of concavity too much. Much water used with the bed of hones is detrimental to the figure, and therefore must be avoided in bringing out the scratches of the grinding-stone, and in producing a true spherical face. We have said nothing hitherto of the *shape* of the rough grinder, or convex tool, to be used also as a polisher; this must be *elliptical* at its circumference, and the longer diameter must be to the shorter exactly as 10 to 9, the latter being just equal to the diameter of the speculum to be ground and polished by it. This proportion has been found by experience to give the *parabolic* figure in specula of ordinary dimensions, by the common mode of using the tool in all directions; which discovery by Mr. Edwards gives him a claim to originality of method, as well as of simplicity and certainty in the operations, independently of superior skill in the operator. This elliptical tool is used first after the grinding-stone with fine emery and water, before the bed of hones, and again with the colcothar and water as a polisher, and during the latter operation, it is said to give also the parabolic figure. The preparation of this elliptical convex tool, as a polisher, is thus effected. The pitch is made by boiling tar in a ladle or crucible over a very slow fire, till it is very hard when tried cold, and with this an equal quantity of resin is melted, which prevents too much brittleness, and makes a good, hard, unelastic coat for the reception of the colcothar. With regard to the requisite *hardness* of the pitch, Mudge and Edwards seem to differ in opinion; but as the metal of Edwards is harder than that of the other, and as he uses a different powder for the polish, each opinion may be well founded, so far as relates to his own mode of polishing. The pitch, or pitch and resin, being melted in a crucible, is poured on the heated elliptical tool, and spread to the thickness of a half-crown, with an iron spatula; when it is cooled a little, a sheet of writing-paper is laid on it, and is pressed equally with the concave face of the speculum itself, which does the work of Mudge's concave tool in this respect; and when the paper is removed, it will be seen, by the fine furrows of its face made thereby, whether or not the impression of the speculum has, at the first trial, given its counterpart to the pitch all over; if not, a second impression must be taken in like manner, after the pitch has been softened a little before a fire; otherwise the face of the speculum might have been dipped in water, to prevent adhesion, and then the paper might have been diffused with. The superfluous pitch must now be removed from the edge of the elliptical polisher, and a cone of wood inserted into its central ball, to make it perfectly round, like the hole of the metal before the coating was poured on. The pitch is next saturated with the colcothar and water, and then polishing commences, and is continued, without any particular attention to the strokes, more than is necessary for giving the polish, and when that is finished by cross strokes given in all directions, as usual, the parabolic figure is ensured by the variable dimensions of the polisher's diameter. Lastly, the final polish is nearly attained when black mud is generated quickly on the surface of the metal, which must be partially, but not entirely, wiped off at intervals, till the business is finished, when the truth of the figure and goodness of the metal may be put to the proof that we have described in our former article, as recommended by Mr. Mudge; or may be tried by Edwards's more convenient test, which we shall presently describe.

Since we made the preceding abridgment of Edwards's

directions, we have seen an extract from one of his letters to Dr. Maskelyne, containing *an addition* to his former directions, which, as it is short, we will here subjoin. "Make the brilliant composition first of copper and tin. Melt the proportional quantity of silver and brass in a small crucible by itself. When you put the brilliant composition the second time into the crucible, add also the lump of brass and silver melted together before in a separate crucible; and when the whole is now fluid, add the proportional quantity of arsenic, and then pour it off into the flasks, after the scoria is taken off, and a little powdered resin is thrown into it." The reason assigned is, that as copper requires more heat to melt it, than either silver or brass does, if the brass were put into the high heat of melting copper, its lapis calaminaris would calcine, which will not be the case when the ingot is made liquid by the lower heat of the second melting. The best fuel that Edwards found for melting the metal was coal-coke, as prepared by the maltsters, which casts no smoke, and is more lasting than charcoal: he also found, that the blueish hue of crown-glass used for the eye-piece, best corrects the yellowish colour of objects, as shewn by a speculum, and particularly when N^o 47 is the composition chosen. In trying the figure of the great speculum, Mr. Edwards rejects the diaphragms of Mr. Mudge as unnecessary, and adopts a more simple method, thus; when the specula and eye piece are in their places, he fixes a circle (of white paper probably) of half an inch, or an inch in diameter, at the distance of from fifty to one hundred yards, and gives it a broad black annular margin, by way of contrast; then, when the telescope is adjusted nicely to distinct vision thereby, the screw that moves the small mirror must be turned either way, until a *dark haze* surrounds the circle, (or field of view,) which will become broader and broader the further the screw is turned; now, if the haze is more distinct, and the edge of it better defined when the screw turns to the right hand, or brings the small speculum nearer, from the point of distinct vision, than when the motion is in a contrary direction, the figure of the great speculum is *spherical*; but if, on the contrary, the edge of the haze is better defined by the opposite motion, then the figure is *hyperbolic*; and, lastly, if at equal distances on each side of the true focal point the appearance of the haze is the same, the figure is known to be properly *parabolic*, and fit for its office. The small speculum, in the Gregorian construction, being placed to receive converging rays from the large one, is required to be spherical, as we have before said; but in the Newtonian construction it is made plane, and of an oval shape, to reflect the rays to the eye, placed at an angle of 90°. Mr. Edwards says, he received his instruction how to grind and polish one of these from his friend, Mr. (now Dr.) Herschel, when he lived at Bath. To grind one of the *elliptical specula flat*, a small tool of lead with emery is first used, and then two or more considerably larger ones are used; both the tools and bed of hones should not be less than six inches in diameter. The figure of the tools is not considered to be completed, till the speculum can be first highly finished upon one of them, and afterwards be applied to another, without receiving any change: the last half dozen strokes should be in the direction of the longer axis of the ellipsis. When this is perfected, it must be polished upon the pitch-polisher, of a circular form, the diameter of which is greater than the transverse axis of the speculum by *one-tenth*. As Mr. Edwards speaks of Mr. (Dr.) Herschel as his friend; and as the doctor has not, that we know of, yet published the composition of his metal and mode of grinding, polishing, and

figuring it; we may conclude that he practises Mr. Edwards's process, and particularly as Mr. Edwards gives us the following information in the postscript of his pamphlet. "Mr. Herschel chiefly makes use of a Newtonian reflector, the focal distance of whose great mirror is seven feet, its aperture 6.25 inches, and powers 227 and 460 times, though sometimes he uses a power of 6450 for the sixth stars. Note, if the metals of a Newtonian telescope are worked as exquisitely as those in Mr. Herschel's seven-feet reflectors, the highest power that such a telescope should bear, with perfect distinctness, will be given, by multiplying the diameter of the great speculum by 74; and the focal distance of the single eye-glass may be found, by dividing the focal distance of the great mirror by the magnifying power: thus, $6.25 \times 74 = 462$, the magnifying power; and

$$\frac{7 \times 12}{462} = 0.182 \text{ of an inch, will be the focal length of the}$$

single eye-glass required." When we arrive at our article TELESCOPE, we trust that we shall be able to lay before our readers more minute information respecting the specula, as well as other parts of Dr. Herschel's wonderful instruments, than we have room for in our present article.

Supposing now Mr. Edwards's specula to be finished, it remains that we say a few words respecting his mode of fixing them in his tube, to give a distinct image of the object to be viewed, without which they would be useless. When the large speculum is made to rest against the inner end of the tube for which it is adapted, the arm which carries the small speculum must be first adjusted: in order to do this properly, extend first two fine threads, or wires, across the aperture of the tube at right angles, so as to intersect each other exactly in the axis of the tube; before the arm is finally fastened to the slider, place it in the tube, and through the eye-piece, without glasses, let the eye be directed to the screw-hole in the end of the arm, and if the point of intersection of the cross-wires be at its centre, the hole is in the axis, but not otherwise. When this exactness is obtained by mechanical means, the arm may be there made fast to the slider. In the next place, the small speculum must be placed parallel to the large one, thus; cut a piece of card into a circle about one-half or two-thirds of the diameter of the mouth of the tube, and fix it concentrically at the mouth with a piece of stick, that shall bisect the tube, to the middle of which the circular cord may be tied, so as to exclude all the light, except an annular portion at the circumference of the tube; this being done, turn the telescope to the sky, and the annular light that falls on the great speculum will be reflected on the little speculum, on which it will form an annular light also of smaller dimensions. Now, if the breadth of this small ring of light is observed to be equally broad at every side of the small speculum, the position thereof is parallel to that of the large one, but if not, it must be adjusted till this is the case. But it may so happen, that this adjustment may put the centre of the small speculum out of the axis of the tube, which may be detected thus; examine again the annular light, and take notice whether or not the ring is concentric with the circumference of the metal; if not, it must be made so by the screws of adjustment, or otherwise. In order to be certain that these adjustments of the small speculum are accurate, turn the telescope again to the small circle of paper with a black margin, with the tube quite open, and having made its image concentric with the small speculum at the point of distinct vision, alter the focus by moving the small speculum gradually, till the black margin becomes a black spot, or point; and if this spot lie on the

centre of the small speculum apparently, the two adjustments, for the axis of vision, and for parallelism, are both correct. Again, if a star of the first magnitude appear perfectly round and well defined; and also if the small stars, in the double stars, are well seen, these are proofs of the excellence not only of the figure and polish of the metal, but likewise of all the adjustments.

We have only to add further to what we have said of Edwards's metal and process, that on conferring lately with some of the most eminent opticians of the present day, their opinion is, that reflecting telescopes are brought as near to perfection as art and experience can effect, by Watson, Tulley, and others, but that it is not necessary to adhere rigidly to Mr. Edwards's, any more than to Mr. Mudge's directions; the Edgedon stones, for instance, do not answer the description given of them for cutting the hardest metals, which are always the best when the colour is proper; (the density of which, we understand, may be determined by their specific gravity, without the trouble of previous polishing); neither is a bed of hones indispensably necessary; as the finest emery, that washes off in grinding, may be again used to give a smooth surface before polishing, as the Tulleys, father and son, have sometimes done, perhaps more out of curiosity than choice, and have thus begun and finished the process with only *one tool*, unless the speculum itself be called a tool for equalizing the pitch. Lord Stanhope, and his operator, Mr. Varley, who are engaged in making experiments in polishing specula, have used Welsh slate with success for composing a bed of polishing materials; and no doubt there are various stones not tried that may hereafter prove superior to those hitherto used for this purpose. The brass and silver recommended by Edwards are, moreover, now generally omitted by the best opticians, as tending to diminish the hardness of the metal more than is requisite; but the arsenic is still retained. And, lastly, the property of the *elliptic* tool, ascribed to it by Edwards, is disallowed by several of the most skilful opticians; so that, after all, each workman succeeds best when he practises the methods of grinding, polishing, and giving the requisite figure, in which his own skill and experience have rendered him most expert, and consequently most confident.

SPECULUM, *Horizontal*. See HORIZONTAL.

SPECULUM. This name is given to several instruments employed in *Surgery*, for gaining a view of tumours, or ulcers, situated within cavities. Thus, there are specula ani, specula auris, &c. The speculum oculi is an instrument for opening the eye-lids, and keeping them apart, so that the surgeon may have a good view of the eye.

SPECULUM *Musica*, the title of a musical treatise, written in Latin by John de Muris, (see MURIS), and only to be found among the MSS. in the late king of France's library, at Paris. It is a treatise so ample, and so scarce, that, having procured large extracts from it, and a complete table of its contents, we shall be the more minute in our account of it, as it seems to have been the ground-work of all the musical treatises that were produced by other writers, till the time of Franchinus Gaforius, in the latter end of the 15th century.

This work, which is written on vellum, in folio, contains six hundred pages. The first sentence of the original is, "Libro tertio de Philosophica Confolatione Boetius volens reddere Causam," &c. It is divided into seven books: the first of which treats of the invention of music, and of its divisions, and contains 76 chapters; the second, of musical intervals, 123; the third, of harmonics, or musical proportion, 56; the fourth, of concords and discords, 51; fifth, of the ancient tetrachords, division of the monochord, and doctrines

doctrines of Boethius, 52 chapters; sixth, of the modes and notation of the ancients, of the changes made in their system by Guido, and of the ecclesiastical tones, 113. Book the 7th, of measured music; of discant, in treating of which he has the chapter "de ineptis Discantoribus," part of which has been given in the preceding chapter; of the time-table, moods or divisions of time; of the folly of placing a tail to the semibreve, by which he seems to mean the minim, without naming it; of perfect and imperfect measures; and lastly, a parallel between ancient and modern music, which occupies the last five of the 45 chapters into which this book is divided, the concluding sentence of which is, "Exempli causa describere tibi volo quorum figuræ sunt in hoc ordine consequentes."

Explicit Tractatus Musicæ, Magistri
Johannis de Muris."

Notwithstanding all the nice and subtle divisions and subdivisions of his seven books into 917 chapters, the practical musician would at present profit but little from the study of them, as almost all the doctrines contained in the first five books are speculative, and such as may be found in Ptolemy, Boethius, and other ancient authors, whom almost all the musical writers of later times have copied in pure pedantry, without understanding themselves what they read, and consequently without conveying any useful science to their readers by what they have written. It is only in the two last books that De Muris condescends to speak of the practical music of his own times: in the sixth book he treats of the ecclesiastical tones, notation, and chants, which John Cotton and Walter Odington had done before; and in the seventh he defines cantus mensurabilis, discant, moods, characters of the different duration of sounds, as the long, breve, semi-breve, and their perfection and imperfection. Here he employs several chapters in refuting such as have disputed his doctrines; and lastly, he draws a parallel between the music of the ancients and that of the moderns, in order to ascertain their several degrees of perfection.

It is in mere charity to the curious in musical antiquities that we have bestowed so much pains in examining and describing this book; which, though of difficult access, and more difficult perusal, might tempt them, from the celebrity of the author, to explore its dark regions, and impair their eyes and patience in search of scientific treasures which it does not contain.

SPECULUM *Veneris*, in *Botany*, a name borrowed from the Flemings, given by Gerarde to an annual species of *Campanula*, common in gardens, and remarkable for the brilliancy of its deep-blue flowers with a white centre. Linnæus has retained this as a specific name, and the plant is commonly called Venus's Looking-glass. See *CAMPANULA* and *PENTAGONIA*.

SPEEAN, in *Rural Economy*, provincially used to signify to wean from the dams, as calves, hogs, lambs, and other animals.

SPEEAVE, provincially to say or cut young animals.

SPEECH, the act, or art of expressing a man's thoughts, by certain signs invented for that purpose.

These signs are principally sounds made by the voice, and letters. See *LANGUAGE*.

SPEECH, in *Grammar*, denotes an assemblage of several words ranged in order.

The grammarians generally make eight parts of speech, *i. e.* eight kinds of words used in discourse; *viz.* noun, pronoun, verb, participle, adverb, conjunction, preposition, and interjection; each of which see under its proper article.

F. Bussler, one of the last writers on grammar, only admits of three parts of speech, *viz.* noun, verb, and

modificative; which last includes the *adverb, conjunction, and preposition*.

The ingenious Mr. Harris, after Aristotle, distributes all words into four species, *viz.* substantives, or nouns; attributives, or verbs; definitives, or articles; and connectives, or conjunctions; the two former are principals, or significant by themselves; and the two latter are accessories, or significant by relation. Under these four species are included pronouns, adverbs, prepositions, and interjections. *Hermes*, p. 31.

SPEED, JOHN, in *Biography*, a considerable elucidator of the geography and history of Great Britain, was born in 1552, at Farrington, in Cheshire. He was brought up to the trade of a tailor, and was, by apprenticeship, a freeman of the company of Merchant Tailors in London, when that patron of learning, sir Fulk Greville, discovering his attachment to the antiquities of his country, gave him an allowance to enable him to quit his employment, and devote himself to study. His first publication was entitled "The Theatre of the Empire of Great Britain, presenting an exact Geography of the Kingdoms of England, Scotland, and Ireland, and the adjacent Isles." This work consisted of a set of maps of all the counties, with the ichnography of the principal towns, and brief descriptions, mostly copied from Camden's *Britannia*. His greatest work, the labour of fourteen years, entitled "The History of Great Britain," appeared in the year 1614. It is chiefly a compilation from preceding authors and manuscript records, comprising all the events in British history, from the invasion of Julius Cæsar to the reign of king James I.; and though rude in style, yet it contained more valuable matter, and is better arranged, than the preceding chronicles. Speed, it is said, was the first English writer who, slighting Geoffrey's tales, fell upon more solid matter. He was assisted by sir Robert Cotton, who revised and corrected the whole. Mr. Speed was author of a work entitled "A Cloud of Witnesses, or Genealogies of Scripture," prefixed to the new translation of the Bible in 1611, and to several subsequent editions of it. This useful and industrious man passed 57 years in the marriage state, with a wife, by whom he had twelve sons and six daughters. He died at London in 1629, and was buried in the church of St. Giles, Cripplegate.

SPEEDWELL, in *Botany*. See *VERONICA*.

SPEEDWELL, *Female*. See *ELATINE*.

SPEEDY-CUT, a term used to signify a kind of cut which happens to a horse when put to his speed. See *SHOEING of Horses*.

SPEEN, or *Spaenham Land*, in *Geography*. See *NEW-BURY*.

PEGEL, HAQUIN, in *Biography*, a Swedish archbishop, distinguished for great learning, was born in 1645. After acquiring the rudiments of a good education, he was sent to the academy of Greifswald; made a tour to Germany, Holland, England, Denmark; and on his return took his degree of master of arts at Lund, in 1671. The same year he was appointed chaplain to Charles XI., whom he accompanied in his campaigns during the whole Dutch war. In 1685 he was made bishop of Skara, was translated thence to Linköping in 1691, and in 1711 was raised to the archiepiscopal chair. After the fire which took place at Linköping in 1700, he contributed by his active exertions towards rebuilding the Gymnasium, a service of so much importance, that the remembrance of it is still preserved by an inscription on the front of the building. He augmented the library with a great number of excellent books, and on the death of his son, presented to it a collection of medals and coins. He died at Upsal, in 1714. Among his works, which

which were numerous, are the following: "A History of the Swedish Church; or a Chronicle of the Bishops, in two Parts;" "Sermons on Christ's Sufferings;" "Glossarium Linguae Gothicae;" besides a great number of hymns, and various sermons.

SPEIGHT'S TOWN, in *Geography*, a sea-port of the island of Barbadoes, situated on the west coast, near the northern part of the island, formerly much frequented by the Bristol traders, and thence called Little Bristol. It is a handsome town, containing about 350 well-built houses, disposed into four regular and spacious streets, of which the longest is called Jews'-street, and, with the other three, leads down to the water side. The planters in that part of Barbadoes called Scotland, used to ship off their goods here for England, which occasioned the building of store-houses, and a concourse of people, to the great advantage of the town; but most of the trade is now removed to Bridge-town. It has a spacious church, dedicated to St. Peter, which gave name to its precinct, and is the place where the monthly sessions are held. The town is defended by two forts, besides another in Heathcote's bay, some distance south of the town. One of the above forts stands in the middle of the town, and is mounted with 14 guns; the other, which hath 32, stands at the north end of it: but there are, besides these, several platforms on the sea-shore. N. lat. $13^{\circ} 15'$. E. long. $58^{\circ} 31'$. Edwards's West Indies.

SPEISSE, in *Mineralogy*, a name given by the Germans, and other workers on cobalt, to a sort of impure regulus of bismuth, sometimes occurring in their processes.

It is not uncommon for ores of bismuth to be mixed with the cobalt in the smalt-works. Both this ore and the cobalt yield the blue vitrifiable earth of which smalt is made; but in one of them it is blended with arsenic, and in the other with the bismuth. The separation of it from these two minerals requires different processes, and the workmen, therefore, separate the two minerals, and work each by itself; but it sometimes happens that the ore of bismuth is so like to the true cobalt, that it cannot be distinguished by the eye, and so intimately mixed with it, that it cannot be separated from it; in this case the whole is exposed to the fire together, and after the arsenic is sublimed in form of meal, there remains a coarse and impure regulus of bismuth, which having mixed itself with the earth of the cobalt, and other extraneous substances, is of a reddish-white colour, and very impure and friable. This gives them the trouble of a second operation, by which they separate the pure regulus of bismuth, and the remainder being a mixture of its earth and that of the cobalt, is run together into the blue glass called *smalt*, the earth of bismuth ore being of the same nature with that of cobalt. Phil. Trans. N^o 396, p. 199.

SPEL, in *Rural Economy*, a term provincially used to signify a bar. It also signifies the thin straight or bent ribs in the work of basket or sieve-making in some places.

SPELE, in *Geography*, a town of the island of Candy; 15 miles S.E. of Candy.

SPELK, in *Rural Economy*, a small thin rod, or piece of wood used in thatching. Small hazel rods are mostly employed in this way.

SPELL, a kind of charm, to drive away a disease, by hanging a word or sentence written on a paper about the neck. See **CHARM**.

SPELL, in *Sea Language*, the period in which a sailer, or gang of sailers, is employed in a particular exercise, from which they are relieved as soon as the limited time expires. Such are the spells to the hand-lead in sounding, to the pump, to look out on the mast-head, &c. and to steer the ship, which last is generally called the *trick*.

Spell also implies the relief or return of duty to those services: thus it is said, spell the pump, spell the lead, &c.

SPELLING, that part of grammar properly called orthography.

Dr. Jones gives the following rules, or maxims, of spelling.

1. That all words were originally pronounced as spelt.

2. That in all words whose sounds have been since altered (the origin of the difficulty of spelling), the alteration was made for the sake of ease and pleasure.

And hence, 3. All words that can be written several ways, must be spelt according to the hardest, harshest, and most unusual sound.

SPELLO, in *Geography*, a town of the Popedom, in the duchy of Spoleto. This was anciently Hispellum, and being made a Roman colony by Julius Cæsar, was by him named Colonia Julia Hispella. In the year 1529, it was sacked by Philibert de Châlons, prince of Orange, general of Charles V.; and three years afterwards the walls were ordered to be pulled down by pope Paul III.; 10 miles S.W. of Nocera.

SPELMAN, Sir HENRY, in *Biography*, an eminent antiquary, was descended from an ancient family settled in Norfolk. He was born in 1562, at Congham, near Lynn, and having received a common education, he was sent at an early age to Trinity college, Cambridge. Owing to his father's death, he was called from the university before he had completed his 17th year, and he was afterwards entered of Lincoln's-Inn, in order that he might study the common law, but his inclination was not favourable to legal pursuits: he seems to have given a decided preference to polite literature and antiquities, but these pursuits were cut short by an early marriage, which induced him to settle upon his estate, and take the management of it in his own hands. He did not, however, abandon his antiquarian pursuits, and while he was yet a very young man, he drew up a treatise in the Latin language, entitled "Aspilogia," relative to armorial bearings, and made transcripts of several charters of monasteries in Norfolk and Suffolk. He was also associated to the original society of antiquarians, and became the intimate friend of Cotton, Camden, and other favourers of that class of studies. In 1604 he was elected high sheriff of the country, and about the same time communicated to Speed a description of Norfolk, for his work entitled "The Theatre of Great Britain." In 1607 he was nominated by the king one of the commissioners for settling the titles to lands and manors in certain counties of Ireland, and on this occasion he went thrice to that country. Farming now became irksome, because he probably found it unprofitable: he sold off his stock, let his estates, and came with his family to London, and he chose as the particular object of his studies, the antiquities of English law, as deducible from English records; but he was diverted from his object by an incidental subject. During his residence on his estate, he had purchased the lands of two suppressed monasteries, and being involved in a troublesome law-suit in order to defend his title, he began to entertain scruples concerning the secularization of property once belonging to the church. When, therefore, an uncle of his complained to him of difficulties which he had met with in building upon the glebe of an impropriate parsonage, he plainly gave his opinion, that it was a token of divine displeasure for keeping the parsonage in lay hands, and he drew up a work in 1613, with the title "De non tementandis Ecclesiis; Churches not to be violated; a Tract of the Rights and Respects due to Churches, &c." He practised what he had pleaded for in theory, and being possessed

ferred of an impropriation in Norfolk, he devoted the profits of it to the augmentation of the vicarage.

By king James he was knighted, and on the revival of the society of antiquarians in 1614, he attended as one of the old members; on which occasion he wrote "A Discourse concerning the Original of the four Law Terms of the Year." His zeal for the honour of the church and the authority of the canons, induced him to write a tract in answer to an apology for archbishop Abbot, who had accidentally killed his game-keeper, in which he maintained that the prelate by that act had ceased from his office, and could not be reinstated without a new consecration. Having in the mean time continued his enquiries into legal antiquities, he found that the knowledge of the Saxon language was absolutely necessary to his purpose, which he accordingly set about obtaining, and in 1621 he printed a specimen of his proposed work, which was so much approved, that several eminent scholars urged him to its completion. In 1626 he published the first part, under the title of "Archeologus, in modum Glossarii ad rem antiquam posteriorem." Notwithstanding the applause of the learned, the author was not encouraged by the sale of his work to publish the second part during his life, which he had fully prepared for the press. It was, however, given to the world after his decease, and the whole was entitled "Glossarium Archaologicorum." The object of this work is the explanation of obsolete words occurring in our laws; and it is not a mere glossary, but contains various entire dissertations. He next employed himself in a collection of English laws and statutes, from the Conquest to the ninth year of Henry III., which was printed in 1617. Having been appointed, on the recommendation of archbishop Laud, one of the commissioners for enquiring into the exaction of fees in the courts and offices throughout England, he published, in 1628, a tract "De Sepultura," or concerning "Burial Fees." Before our author had finished his glossary, he engaged in another considerable work, which was "A History of the English Councils." Of this he published in 1639 the first part, which included the period from the first introduction of the Christian religion into England to the Norman Conquest. A second part, only a small portion of which was of his own composition, was printed several years after his death. In the same year he instituted a Saxon lecture in the university of Cambridge, which he intended to have rendered perpetual, but his design was defeated. In 1639 also he published a treatise on "The original Growth, Propagation, and Condition of Tenures by Knights' Service in England," in which he displayed an extent of learning that proved his faculties to be perfect, notwithstanding his advanced age. He lived to complete his 80th year, and died at London in 1641. By the king's order, he was interred in Westminster Abbey. After his decease, two posthumous works of his were published, *viz.* "A Treatise concerning Tythes," printed in 1647; and "A History of Sacrilege," which was destroyed at the printer's by the great fire of London, and a plan of it only preserved. In 1698 bishop Gibson published a folio volume, entitled "Reliquiæ Spelmanniæ," containing a number of his posthumous tracts relative to the English laws and antiquities. He was, says his biographer, a very respectable promoter of antiquarian learning, and a man of great private worth.

SPELMAN, EDWARD, great-grandson of the preceding, resided at High-House, near Rougham, Norfolk, where he died in 1767. He had devoted himself to literature, and made himself known by several publications of considerable worth. The first of these was a translation of Xenophon's "Cyropædia," in two volumes, 8vo. A more elaborate

work was entitled "The Roman Antiquities of Dionysius Halicarnassensis," translated into English, with notes and dissertations, in four volumes, quarto, a work which stands high among our translations from the Greek language. One of these dissertations was a version of a fragment of Polybius on government, particularly that of Rome, to which the translator prefixed a preface, applying the system of Polybius to the English government. This was printed without his name in 1743. He also printed for the use of his friends, and for private distribution only, "A Dissertation on the Presence of the Patricians in the Tributa Comitia:" and after his death the Rev. Mr. Lemon published in 1775, a posthumous work of this writer, entitled "Additional Observations on the Greek Accents." Gen. Biog.

SPELT, in *Agriculture*, a term applied sometimes to wheat-grass, a species of *tritium*, or wheat. It is sometimes written *spelta*.

SPELTA, in the *Materia Medica*, a name used for the grain of the *zea dicoccos*, commonly called *spelt-corn*.

SPELTER, or SPELTRE, a name sometimes given to zinc.

SPELUNCATO, in *Geography*, a town of the island of Corfica; 12 miles E. of Corte.

SPENAZZOLA, a town of Naples, in Basilicata; 13 miles E. of Venosa.

SPENCE, JOSEPH, in *Biography*, was educated at New college, Oxford, of which he afterwards became a fellow. He took the degree of M.A. in 1727, and in that same year made himself known by "An Essay on Pope's Translation of the *Odyssey*." This work displayed a cultivated taste, as well as a sensibility to the beauties of poetry, and was so favourable to the translator, that he sought his acquaintance, and admitted him to a familiar intimacy. In the following year he was elected professor of poetry of the university of Oxford, an office which he held for ten years. After this he travelled with the young duke of Newcastle, and in 1742, having quitted his fellowship, he was presented by his college to a rectory in Buckinghamshire. He resided, however, at Byfleet, in Surrey, at a mansion lent him by the duke his pupil, and thus performed the duties of rector merely by an annual visit, attended with liberal charities. In the same year he was elected king's professor of modern history, at Oxford: this was a duty as easy to be performed as the other, but he did not devote that leisure which his preferments offered him to indolence, for in 1747, he brought to the press his principal work, entitled "Polymetis, or an Enquiry concerning the Agreement between the Works of the Roman Poets and the Remains of ancient Artists, being an Attempt to illustrate them mutually by each other." This was a folio work, with plates. The performance was extremely well received by the public, and still stands very high in the literary world, though it has been slighted by some few, who perhaps hastily condemned, before they had given proper attention to it. In 1754 he was presented with a prebendary of Durham, and he continued to amuse himself with a variety of miscellaneous compositions that appeared in different forms. His last publication was an edition of "Holdsworth's Remarks on Virgil," with notes, and additional observations of his own. In the month of August, 1758, he was found drowned in a piece of water in his own garden at Byfleet, into which it is supposed he had fallen in a fit, the water being 100 fathoms to cover him. He is characterised as being of a social benevolent disposition, and being very much beloved by his friends. He was studious to draw obscure merit into notice, of which he gave evident proofs by his printed account of Stephen Duck; Robert Hill, the learned tailor; and

and Mr. Blacklock, the blind poet. Several of his detached and miscellaneous compositions were inserted in the "Mufæum," and in Doddsley's "Fugitive Pieces." He had collected some MS. volumes of anecdotes of eminent writers, communicated by Pope and others, which are still in the possession of the duke of Newcastle's family, and from which Dr. Johnson was permitted to make extracts for his lives of the poets. Gen. Biog.

SPENCER, JOHN, a learned divine of the church of England, was born in 1630, at Bocton-under-Bleane, in Kent. His father dying while he was an infant, the care of educating him was undertaken by an uncle, who sent him to the free-school of Canterbury. His proficiency in learning procured for him a recommendation to a scholarship in Caius college, Cambridge, where he was admitted in 1645. Passing through the usual gradations in that university, he was chosen fellow of his college in 1655, and took orders: of course he must have complied with the requisitions of the ruling powers at that time. He became distinguished for his pulpit compositions, and was appointed university preacher, in which capacity he took an opportunity of hailing the event of the Restoration by a thanksgiving sermon, which was printed under the title of the "Righteous Ruler," which, in reference to the profligate character of the restored sovereign, must have been regarded as extremely appropriate! Some enthusiasts having, in a periodical paper entitled "Annus Mirabilis," brought to notice a number of pretended prodigies, as portending future changes in the state, Spencer conceiving it to be of dangerous consequence thus to unsettle the minds of the people, published in 1663, "A Discourse concerning Prodigies," wherein a variety of presages by them is reprehended, and their true and proper use is asserted and vindicated. A short extract from the preface will shew the nature of the work: "We have," says he, "of late been persuaded by three or four several impressions of books, that England is grown Africa, and presents us every year, since the return of his majesty, with a new scene of monstrous and strange sights; and all held forth to the people, like black clouds behind a storm, the harbingers of some strange and unusual plagues approaching to the state; and this by persons pretending an intimacy with scripture, and the fathers, Greek and Latin, ancient and modern writers." The work displayed a freedom from credulity and superstition very laudable at that time. To a second edition, in 1665, was added "A Discourse concerning vulgar Prophecies;" in which the vanity of receiving them as the certain indications of any future event is discovered, and some characters of distinction between true and pretended prophets are laid down. This attempt to bring down the public to reason and sobriety was not less timely than the former, and might have been usefully renewed in many other instances and at much later periods. The author in the same year proceeded doctor in divinity. He was, in 1667, presented to a living by his college, and in a very short time after was elected to the mastership of that society, an office which he held with high reputation during twenty-six years. Several preferments were bestowed upon him, of which the last and most considerable was the deanery of Ely in 1667. He had previously been chosen vice-chancellor of the university of Cambridge, and in that quality he made a speech to the duke of Monmouth, when he was installed chancellor, which was printed by Hearne, in his work entitled "Vindiciæ Thom. Caii." It was particularly as a master of Hebrew literature and antiquities he is known in the learned world. His first work was written in the Latin language, a dissertation "De Urim et Thummim,"

which was published in the year 1678. This was a forerunner of his great work, "De Legibus Hebræorum Ritualibus, et earum Rationibus, Libri Tres," 2 vols. fol. 1685; a performance considered so valuable and important, that it was reprinted at the Hague in 1686, and at Leipsic in 1705. The grand object of this work is to prove, in detail, that the rites and ceremonies of the Jewish religion were instituted in direct opposition to the practices of the surrounding idolatrous nations, and in order to establish the strongest distinction between the Jews and them. The same hypothesis has been maintained by several learned men, and has been opposed by others, without affecting on either side the authority of that religion. Spencer's work is still considered as the most complete and judicious treatise in that view of the question. The author died at the age of sixty-three, and he was interred with great solemnity in the chapel of his college, to which society he was a liberal benefactor. He left behind him many MS. additions to his great work; which were entrusted to the care of bishop Tennison, by whom they were bequeathed to the university of Cambridge, and were eventually published in four books, under the care of professor Capellow, in two vols. folio. Biog. Brit.

SPENCER, in *Geography*, a township of America, in Worcester county, Massachusetts, taken from Leicester, and incorporated in 1733, containing 1453 inhabitants; 11 miles S.W. of Worcester.

SPENCER, a large post-township of New York, the capital of Tioga county, is situated near the centre of that county, 50 miles S.E. of Bath; bounded N. by Cayuta and Danby, E. by Candor, S. by Otwego, and W. by Chemung. Spencer was divided in 1811; and Cayuta, Danby, Caroline, and Candor, erected into separate towns from the N. and E. parts. The population of Spencer in 1810 was 3128. It is well supplied with small creeks and mill-streams. The Catetant winds across the northern part with numerous branches; the Cayuta forms the western boundary; and some smaller streams spread over the central part. The soil is of various qualities, and the surface has a considerable hilly aspect, covered with a great variety of forest-trees. The seat of justice for the county has been lately removed from Elmira to this township, and the county buildings are within Drake's settlement, as it is called, situated on the Catetant creek; where is a small village, denominated Spencer; and as its situation is pleasant and healthy, and it is the centre of county business, it promises to become a flourishing county village.

SPENSER, EDMUND, in *Biography*, one of the most distinguished English poets, was born in London about the year 1553. His parents were in humble life, though in his works he claims kindred with the noble family of the Spensers of Northamptonshire. Of his early education nothing is known, but it appears that he was, in 1569, a sizer in Pembroke college, Cambridge. He, in proper time, took his degrees, and in 1576 he was candidate for a fellowship, but was not successful. This disappointment was probably the cause of his quitting the university, which he left for a residence among his relations in the north of England. Here, it appears, he fell in love, and the object of his affection, whom he has commemorated under the name of Rosalindo, after leading him through the usual vicissitudes of a love adventure, finally deserted him. This circumstance is said to have given him a turn to pastoral poetry, since his "Shepherd's Complaint," which is devoted to amorous complaining, was his first publication. It was published in 1579, and dedicated, under the signature of Immerito, to Mr. afterwards sir Philip Sidney. He was introduced to the acquaintance

of this celebrated person by his friend, Mr. Gabriel Harvey, previously to his publishing his "Shepherd's Calendar," which sufficiently refutes a tale concerning his being first made known to sir Philip Sidney by a passage in the Faery Queen, and the munificent reward which he received on the occasion. He was, however, patronized by sir Philip, who introduced him to his uncle, the favourite Leicester, who engaged him as an agent for his service in foreign countries, but it is uncertain whether he ever actually travelled abroad; at any rate he could not have been long in that employ, since, in 1580, he was attending lord Grey of Wilton, appointed lord-deputy of Ireland, as his secretary. In this situation he displayed those talents for business, which are usually, though often very unjustly, represented as incompatible with a poetic genius. He returned with lord Grey in 1582, and was probably some years an attendant at court, and in 1586 he had a grant from the crown of upwards of 3000 acres of land in the county of Cork, out of the vast forfeited property of the earl of Desmond. In 1587 Spenser went over to take possession of this estate; his residence was the castle of Kilcolman, near Doneraile, where, in the style of pastoral poetry, he describes himself as keeping his sheep "under the Mole, that mountain here," and frequenting the coolly shade of the green alders by the Mulla's shore. Here it appears he received a visit in 1589 from sir Walter Raleigh, who had been a commander in Ireland under lord Grey, and had obtained a large grant of land from the crown. Spenser celebrates him in a poem under the title of the "Shepherd of the Ocean," and highly extols his courtesy and elegant accomplishments. At this period Spenser was engaged in the composition of his "Faery Queen," of which he had written the three first books; and accompanying Raleigh the next year to England they were published, with a dedication to queen Elizabeth, and an introductory letter addressed to Raleigh, explaining the plan of the whole projected work. Elizabeth rewarded his poetry and dedication by a pension of 50*l. per annum*, granted in 1591, and he has been termed her laureat, though the title was not formally conferred upon him. Spenser returned to Ireland in 1591, and married a country lass of low degree, but the disturbances in that country forced him to return to England in 1595. Here he printed some poems, and drew up a plan for the entire reduction of that island in the space of two winters, which work he completed in the next year, giving it the title of "A View of the State of Ireland." This piece remained in MS. till it was printed in 1633 by sir James Ware, who bestows much applause on the information and judgment displayed in it, though he intimates, that it was deficient in moderation: and it is generally admitted, that in what he says concerning the history and antiquities of the country there are many errors, and the fanciful turn of a poet is more conspicuous than the sobriety of a judicious enquirer. In 1596 he published a new edition of his "Faery Queen," with additional books, which only completed half his original design. It was currently reported, that the remaining six books were lost by a servant, who was entrusted to carry them to England, which certainly would be one of the greatest disasters that a poet could possibly suffer, and might greatly contribute to break his spirits: the fact, however, is very questionable, and certainly does not stand on good authority: it is most probable that they were never finished. He returned to Kilcolman in 1597, but Tyrone having in the next year broken out in rebellion, and overrun the county of Cork, Spenser was obliged to take refuge with his wife in England, leaving all his property to the spoil and ravages of the insurgents.

His house was burnt, and with it, it is said, an infant who had not been removed. Reduced to a state of indigence, he sunk under his misfortunes in the same year, or in the beginning of the next. He was interred in Westminster Abbey, at the expence of the earl of Essex, several of his brother poets attending, and throwing into his grave copies of panegyric verses. A monument was afterwards erected to his memory by Anne, the celebrated countess of Dorset. Of his family and posterity nothing is known, except that one of his descendants was restored in the reign of Charles II. to so much of the estate in Ireland, as he could prove had belonged to his ancestor; and that another, or perhaps the same, came to England in the reign of William with a similar claim, which was allowed. The works of Spenser are animated with a fervent spirit of piety, and a pure and exalted morality; and though he certainly paid an assiduous court to the great, he was not guilty of that meanness of adulation, which was too much practised even by some eminent persons of that age. The homage paid to the queen was great, but it was deemed impossible to carry this too far.

The poetical reputation of Spenser is chiefly supported by his great work the "Faery Queen," for his pastorals will scarcely please a correct taste; and though critics admit that there is much occasional beauty of sentiment and harmony of versification in his sonnets, hymns, and other miscellaneous pieces, yet on the whole they are scarcely distinguished from the effusions of tedious pedantry common in that age. But the "Faery Queen" is justly regarded as one of the great compositions in English poetry, and has lost none of its value by antiquity. "If its plan is singularly involved, its allegories often defective and obscure, and its adventures extravagant, it is, however, absolutely unrivalled for the fertility of its conceptions, and the vividness of its painting. Its great length, and want of interest as a fable, deter readers, in general, from a complete perusal, but it will always be resorted to by the lovers of poetry as a rich storehouse of invention, especially of that kind which consists in the personification of moral ideas." Biog. Brit.

SPENT, at *Sea*. The seamen say a ship hath spent any malt or yard, when it is broken down by foul weather, or any such accident; but if it be done by an enemy's shot in a fight, they say, *such a yard, or mast, was shot by the board*.

SPERA, in *Geography*, a town of European Turkey, in Dobruzzi Tartary; 40 miles S. of Ismail.

SPERAGE, ASPARAGUS, in *Botany*. See ASPARAGUS.

SPERDILLEN, in *Geography*, a lake of Norway, in Aggerhuus, 32 miles long and 12 wide; 4 miles N. of Christiania.

SPERGULA, in *Botany*, a word which Dodonæus, who is cited as its author, expressly says was latinized from the name of this herb in Brabant, *Spuerie*, whence its English appellation, *Spurrey*. Whether σπερῆ, a modern Greek name for *Verbascum Blattaria*, has any common origin with this Flanders word, or whether both may allude to the copious dispersion of seeds in both cases, and have been derived from the ancient Greek σπερῆν, *to sow, or scatter*, we can only propose as a conjecture. Linnæus, however, seems to have had some such etymology in contemplation, when he, in Phil. Bot. p. 167, explains *Spergula* by "*a scattering of seed*;" though probably he looked no further than the Latin, *spargo*.—Linn. Gen. 232. Schreb. 312. Willd. Sp. Pl. v. 2. 818. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 502. Prodr. Fl. Græc. Sibth. v. 1. 317. Ait. Hort. Kew. v. 3. 137. Fusch v. 1. 320. Will. Gen. 131. t. 7. f. 3. Juss

SPERGULA.

Juss. 301. Lamarck Illustr. t. 392. Gærta. t. 130.—
Class and order, *Decandria Pentagynia*. Nat. Ord. *Caryophylleæ*, Linn. *Caryophylleæ*, Juss.

Gen. Ch. Cal. Perianth inferior, of five ovate, obtuse, concave, spreading, permanent leaves. Cor. Petals five, ovate, concave, spreading, undivided, larger than the calyx. Stam. Filaments ten, rarely but five, awl-shaped, shorter than the corolla; anthers roundish. Pist. Germen superior, ovate; styles five, somewhat reflexed, thread-shaped; stigmas thickish. Peric. Capsule ovate, covered partly by the calyx, of one cell, and five valves. Seeds numerous, globose, but depressed, furrowed with more or less of a notched or dilated border.

Eff. Ch. Calyx of five leaves. Petals five, undivided. Capsule superior, ovate, of one cell, with five valves.

Obf. Linnæus remarks, that this genus differs from *Cerastium* in having undivided petals. Their general habit also differs more than is the case with most genera of this natural order, that of *Spergula* nearly according with various *Arenaria*, from which the five styles only distinguish it. *S. pentandra* has but five stamens.

1. *S. arvensis*. Rough-seeded Corn Spurrey. Linn. Sp. Pl. 630. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 1535. Curt. Lond. fasc. 5. t. 31. (Sagina spergula; Ger. Em. 1125.)—Leaves whorled. Stalks of the fruit reflexed. Seeds kidney-shaped, angular, rough.—Native of corn-fields and waste ground, on a sandy soil, throughout Europe, flowering from July to September. Root annual, small. Herb more or less downy and viscid, very various in luxuriance, somewhat succulent and brittle, with a branched, round, loosely spreading stem, whose joints are beset with copious, whorled, linear, obtuse leaves. Panicles terminal, forked, divaricated, level-topped. Flower-stalks downy; strongly reflexed, from the base, as the fruit ripens. Calyx membranous at the edge, nearly as long as the white petals. Stamens generally ten; sometimes five, or some intermediate number. Capsule almost twice as long as the calyx. Seeds numerous, kidney-shaped or roundish, swelling, angular, with an obsolete, not dilated nor membranous, border; when ripe they are black, and rough all over with minute tubercles or bristles. In Flanders, Germany, and the north of Europe, this herb serves as fodder, and poultry are fed with its seeds. With us it is a troublesome weed, on a light soil.

2. *S. pentandra*. Smooth-seeded Corn Spurrey. Linn. Sp. Pl. 630. Willd. n. 2. Engl. Bot. t. 1536. (*S. annua*, femine foliaco nigro, circulo membranaceo albo cineto; Dill. Giff. 46.)—Leaves whorled. Stalks of the fruit reflexed. Stamens five. Seeds lenticular, smooth, with a membranous border.—Native of Germany, England, and probably other parts of Europe, in sandy ground, flowering in July and August. Mr. Shepherd, curator of the botanic garden at Liverpool, first observed this plant about that neighbourhood, growing along with the preceding species, with which it altogether agrees in general appearance, but the flowers are perhaps rather smaller, and their stamens are rarely more than five in number. The most remarkable difference is found in the seeds, which are compressed and lenticular, always smooth, and bordered by a very conspicuous whitish membrane. Such is the difference likewise between *Arenaria marina* and *rubra*. We cannot but feel a mistrust of this character, however striking, considering the close resemblance between these two *Spergulae*, at least, in other respects. The plant found about Liverpool is certainly what Linnæus and Dillenius intended, and therefore the uncertainty expressed in *Fl. Brit.* respecting *S. pentandra*, is now removed.

3. *S. nodosa*. Knotted Spurrey. Linn. Sp. Pl. 630. Willd. n. 3. Fl. Brit. n. 3. Engl. Bot. t. 694. Curt. Lond. fasc. 4. t. 34. Fl. Dan. t. 96. (*Saxifraga palustris alpinefolia*; Ger. Em. 567.)—Leaves opposite, awl-shaped, smooth; the upper ones clustered. Calyx without ribs.—Native of wet sandy heaths and commons, in the colder countries of Europe, flowering in July and August, but not very common with us. Mr. Goodyer, an accurate and ingenious contributor to the second edition of Gerarde's Herbal, first detected this species in England. Its habit is that of an *Arenaria*, especially the pure white flowers. The fibrous perennial root produces several spreading or prostrate stems, three or four inches long, slightly branched, beset with many pairs of awl-shaped, short, smooth, dark-green leaves, accompanied by axillary tufts of smaller ones, giving the herb a knotty or jointed aspect. Flowers large, stalked, about the extremities of the stems. Styles five, as well as the valves of the capsule, by which alone this plant is separated from *Arenaria*.

4. *S. laricina*. Larch-leaved Spurrey. Linn. Sp. Pl. 631. Willd. n. 4. Sm. Plant. Ic. t. 18. (Alfina n. 61; Gmel. Sib. v. 4. 155.)—Leaves opposite, awl-shaped, fringed, clustered.—A rare species, found by Steller in Siberia. It differs from the last in being somewhat larger, with longer, acute leaves, fringed at the base. English botanists had been accustomed to consider the following as the true *S. laricina*, till the Linnæan herbarium taught them to correct this error.

5. *S. faginoides*. Smooth Awl-shaped Spurrey. Linn. Sp. Pl. 631. Willd. n. 5. Fl. Brit. n. 4. Engl. Bot. t. 2105. (Alfina n. 64; Gmel. Sib. v. 4. 157.)—Leaves opposite, awl-shaped, pointless, naked. Flower-stalks solitary, very long, smooth.—A rare inhabitant of the Scottish highland mountains, flowering in June. Gmelin found it in Siberia. The perennial fibrous root resembles that of *S. nodosa*, but the herb is smaller, more branched and erect, without any axillary clusters of leaves, and having more resemblance to a *Sagina* than an *Arenaria*. Every part is quite smooth, by which, and the want of a bristly point to the leaves, this *Spergula* essentially and constantly differs from the more common one next described. The flowers are terminal, rather drooping, on long, solitary stalks. Petals white, roundish, hardly so long as the calyx. Stamens ten. Professor Swartz describes but five, which makes us doubtful of his plant. Seeds kidney-shaped, without any edge or border.

6. *S. subulata*. Ciliated Awl-shaped Spurrey. Swartz in Stockh. Transf. for 1789, 45. t. 1. f. 3. Willd. n. 6. Fl. Brit. n. 5. Engl. Bot. t. 1082. (*S. laricina*; Hudf. 203. Fl. Dan. t. 858. *S. faginoides*; Curt. Lond. fasc. 4. t. 35. *Sagina procumbens* β ; Linn. Sp. Pl. 185.)—Leaves opposite, awl-shaped, fringed, tipped with a bristly point. Flower-stalks solitary, very long, somewhat hairy.—Native of sandy barren heaths in the north of Europe, flowering with us from June to August. It is perennial, and resembles the last in general habit, but the leaves are constantly fringed with glandular hairs, and tipped with a bristly point. The flowers too are smaller, with generally hairy glutinous stalks, and usually but five stamens. Seeds small, compressed, pale brown, encircled with a black line, but no dilated border.

7. *S. glabra*. Smooth Capillary Spurrey. Willd. n. 7. (*S. faginoides*; Allion. Pedem. v. 2. 118. t. 64. f. 1, excluding the synonyms.)—Leaves opposite, thread-shaped, smooth, clustered. Flower-stalks solitary, very long, smooth.—Common in the grassy alpine pastures of Savoy, according to Allioni, by whose work alone we have any knowledge

of this plant. It vies in magnitude with *S. laricina*, but is much more slender in the *foliage*, as well as quite smooth. *Petals* white, twice as long as the *calyx*. *Stamens* ten.

SPERGULASTRUM, (so called from its resemblance to *Spergula*), a genus of Michaux, *Flora Boreali-Americana*, v. 1. 275. The author speaks of it as a doubtful genus, differing from *Spergula* chiefly in having but four *stigmas*, or rather *styles*, which in one species vary to three. Perfoon and Pursh have published this genus under the appellation of *Micropetalum*, the original name being equally contrary to sense and usage, because it is formed of another established one, merely varied in termination.

SPERJLEN, in *Geography*, a lake of Norway, in Aggerhus; 35 miles N. of Christiania.

SPERLING, OTTO, in *Biography*, son of a person of the same name, was born at Christiania, in Norway, in 1634. He received the early part of his education at Copenhagen; he afterwards studied at the gymnasium of Bordeholm, and then at the academy of Helmstadt. In 1655 he became private tutor to the son of M. Wrangel, governor of Swedish Pomerania, and in 1658 made a tour to Holland, France, and England. In 1662 he went to Hamburg, as tutor to the youngest son of Corfits Ulfeld, and in 1674 took the degree of doctor of laws at Kiel. In 1681 he travelled with the sons of J. A. Von Bachwald, and spent some time at Paris, where he was employed in arranging the library of the celebrated Colbert, for which service he received a pension of 200 rix-dollars as long as that noble-minded man lived. On his return he proceeded to Hamburg, where he practised the law: he was afterwards assessor in the court of Gluckstadt, and in 1690 he was invited to Copenhagen, where he was employed in various important affairs. In 1692 he was elected professor of jurisprudence and history, and afterwards of oratory and history, in the new knights' academy at Copenhagen. In 1698 he obtained leave to resign, on account of his age, but in 1701 he resumed his former station as professor of history and oratory, in which he continued till the suppression of the academy in 1710. He became a member of the Royal Society of London in 1700, and died in 1715. He was author of a great many works, among which were the following: "Monumentum Hamburgense Benedictinum;" "De Danicæ Linguæ ac Nominis antiqua Gloria et Prærogativa inter Septentrionales," &c. Gen. Biog.

SPERLING, in *Geography*, a town of Prussia, in the province of Natangen; 15 miles E. of Angerburg.

SPERLINGA, a town of Sicily, in the valley of Demona; 10 miles S. of Mistretta.

SPERLONGA, a town of Naples, in Lavora; 7 miles S. of Fundi.

SPERM, *СПЕРМА*, *σπερμα*, the seed of which an animal is formed.

SPERMACETI, or **PARMASITTY**, in *Pharmacy*, is a whitish, flaky, unctuous substance, prepared from oil; principally from that of a cetaceous fish, called by some the *male whale*, by others *cachalot*, and by the Latins *orga*; distinguished from the common whale by its having teeth in lieu of whale-bone, and by a bunch on its back. See **PHYSETER**.

The ancients were strangers to the nature of this preparation; and even Schroder seems in doubt, whether to reckon it an animal or mineral substance.

It had its name *spermaceti*, seed or sperm of whale, given it, no doubt, to raise its value, by a notion of its scarcity. The spongy oily mass from which it is made, is found in a large triangular trunk, four or five feet deep, and ten or twelve long, filling almost the whole cavity of the head, and seeming to be entirely different from the proper brain of the

animal. The oil is separated from it by dripping. In this state it has a yellow unctuous appearance, and is brought to England in barrels. An ordinary sized whale, it is said, will yield upwards of twelve large barrels of crude spermaceti. The mode of purifying it in the large way is as follows: the mass is put into hair or woollen bags, and pressed between plates of iron in a screw-press, until it becomes hard and brittle. It is then broken in pieces, and thrown into boiling water, where it melts, and the impurities, which rise to the surface or sink to the bottom, are skimmed off or separated from it. After being cooled, and separated from the water, it is put into fresh water in a large boiler, and a weak ley of the potash of commerce added to it by degrees. This part of the process is thrice repeated, after which the whole is poured into coolers, when the spermaceti concretes into a white semitransparent mass, which, on being cut into small pieces, assumes the flaky appearance which it has in the shops. Some of our druggists, it is said, possess the art of making it from the sediment or fæces of any kind of oil.

Some sophisticate it with wax; but the deceit is discovered, either by the smell of the wax, or by the dulness of the colour. Some also sell a preparation of oil gained from the tail of the whale, instead of that from the brain; which last kind turns yellow, as soon as opened to the air. In the general, there is no merchandize that should be kept closer from the air than spermaceti.

Purified spermaceti is an almost silvery white, friable, semitransparent, unctuous substance, inodorous and insipid, or having very little flavour, and only a slight tallowy odour. It is softer and more brittle than white wax; and it is distinguished from every other species of concrete oil, by its superior transparency, high lustre, and crystalline texture. Its specific gravity is 9.433, and it melts at 112° Fahr.; and at a higher temperature evaporates, with little alteration. By the assistance of a wick, it burns with a clear white flame, superior to that of tallow, and without any disagreeable odour; and this constitutes its excellence as a material for candles. By repeated distillation, the spermaceti becomes permanently fluid at the common temperature. According to the experiments of Crell, its distillation requires a greater heat than fat; and the coagulated oil, thus procured, partly white and partly brownish. By repeated distillation it affords a yellowish acid, and becomes more fluid, but coagulates in the cold. The acid, rectified by distillation, is entirely colourless, and affords the same salts with earths and alkalies as Crell's subacetic acid. The oil unites with ammonia into a saponaceous emulsion. It may be diffused in water by means of the yolk of egg or mucilage. It is sparingly soluble in boiling alcohol, 150 parts of the menstruum being necessary for this purpose; and as the solution cools, the spermaceti is again precipitated. Pure ether very copiously dissolves it, but seems to retain none of it when cold. Oil of turpentine has the same effect. With caustic potash it combines into a soap, soluble in warm water. Fluid ammonia, when cold, has no action upon it; but when warm, very easily dissolves it, forming an emulsion, which is not decomposed either by simple cooling, or by mixture with water; but the addition of an acid instantly precipitates the spermaceti. With concentrated sulphuric acid it forms a brownish solution, which, dropped into water, gives up its spermaceti, apparently unaltered. Like the other fat oils, it dissolves sulphur. By long exposure to the air, it acquires a yellow tinge, and becomes rancid; but it may be again purified, by being washed in a warm ley of potash. The great use of spermaceti is for making candles; and it is also employed in medicine.

Spermaceti candles are of modern manufacture: they are

made smooth, with a fine gloss, free from rings and scars, superior to the finest wax candles in colour and lustre; and, when genuine, leave no spot or stain on the finest silk, cloth, or linen.

In medicine, spermaceti is demulcent and emollient; but for internal use it possesses no advantages superior to those of the bland oils. It is used in dysentery and irritations of the alimentary canal, and also in catarrh and phtisis; but in the latter cases it is less beneficial than the bland oils. Some imaginary virtues have been ascribed to spermaceti, which have occasioned the use of it by women in child-bed. In its combination with water by means of the yolk of egg, it is a pleasant vehicle for opium, when the after-pains are troublesome. It forms a part of the composition of several ointments. The dose is from ʒss to ʒjss, rubbed with sugar, or in the form of emulsion. It possesses a property, which is that of softening the skin, which has occasioned its being used by the ladies in pastes, washes, &c. Its official preparations are the "ceratum simplex" of the Edinb. Ph., formed of six parts of olive oil, three parts of white wax, and one part of spermaceti; the "ceratum cetacei" of the Lond. Ph. (see CERATUM); the "unguentum cetacei," or spermaceti ointment, of the Lond. Ph., formed by melting together, over a slow fire, six drachms of spermaceti and two drachms of white wax, and stirring them constantly till they be cold; and the "unguentum spermatis ceti," or ointment of spermaceti, of the Dubl. Ph., formed by making half a pound of white wax, one pound of spermaceti, and three pounds of prepared lard, into an ointment. These ointments constitute the ordinary dressings for blistered surfaces and excoriations.

SPERMACOCE, in *Botany*, so named by Dillenius, in his *Hortus Elthamensis* 369, from *σπίγμα*, seed, and *ακων*, a sharp point, in allusion to the little erect beaks of the capsules.—Linn. Gen. 50. Schreb. 66. Willd. Sp. Pl. v. 1. 568. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 1. 232. Pursh 105. Juss. 197. Lamarek Illustr. t. 62. Gærtn. t. 25.—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Stellatae*, Linn. *Rubiaceae*, Juss.

Gen. Ch. *Cal.* Perianth small, superior, with four teeth, permanent. *Cor.* of one petal, funnel-shaped; tube cylindrical, slender, longer than the calyx; limb in four deep, obtuse, widely spreading, somewhat reflexed segments. *Stam.* Filaments four, awl-shaped, shorter than the corolla; anthers simple. *Pistl.* Germen inferior, roundish, compressed; style simple, divided in the upper part; stigmas obtuse. *Peric.* Capsules two, combined, oblong, gibbous externally, flat on the inner side, obtuse, each with two beaks. *Seeds* solitary, roundish, rolled in at the edges.

Ess. Ch. Corolla of one petal, funnel-shaped. Capsules two, combined, each crowned with two teeth.

A genus of extra-European weeds, not recommended by any beauty of aspect, or known utility, chiefly the produce of the West Indies, or the warmer parts of North America, a few species only being found in the East Indies. The plants are generally herbaceous, in many instances annual, often rough, with opposite, simple, entire leaves; sheathing, membranous, jagged or bristly, stipulas, like many of the same natural order; and numerous, small, white, reddish, or blueish, whorled or capitate, flowers.

Eight species are enumerated in Linn. *Syst. Veg.* ed. 14, of which the seventh, *S. procumbens*, is the same as *Hedyotis fruticosa* of Linnæus. Willdenow has twenty species, to which three new ones are added by Pursh. Five find a place in the *Hortus Kewensis*. We shall select a few examples, sufficient to give a general idea of the whole.

S. tenuior. Slender Button-weed. Linn. Sp. Pl. 147. Willd. n. 1. Ait. n. 1. (*S. verticillis tenuioribus*; Dill. Elth. 370. t. 277. f. 359.)—Stem smooth, erect. Leaves lanceolate; rough on the upper side. Flowers whorled. Stamens shorter than the corolla. Fruit hairy.—Native of the West Indies. Found also, according to Pursh, in dry gravelly situations, from Virginia to Carolina, flowering from June to August. Root annual. Stem square. Leaves an inch and a half long, lanceolate, acute. Flowers very small, white.

S. glabra. Smooth Button-weed. Michaux Boreal-Amer. v. 1. 82. Pursh n. 2.—Stem smooth, procumbent. Leaves ovato-lanceolate, smooth on both sides. Flowers whorled. Fruit smooth.—On the banks of rivers in most of the western territories of North America, flowering in July and August. The plant is annual. Flowers white, longer than in the former.

S. verticillata. Dense-whorled Button-weed. Linn. Sp. Pl. 148. Willd. n. 9. Ait. n. 4. (*S. verticillis globosis*; Dill. Elth. 369. t. 277. f. 358.)—Hairy. Leaves lanceolate. Whorls globose, many-flowered.—Native of Africa. Cultivated by Sherard. The stem is shrubby, erect, branched, with numerous, narrow, somewhat clustered leaves, and dense whorls of small, white, very copious flowers. Such is the Senegal plant, described by Dillenius. The Jamaica specimen from Brown, which is smooth, and which led Linnæus to admit that circumstance into his specific definition, may possibly be a different species, but we have not sufficient materials to decide this point. Swartz speaks of this last as having, when in flower, the smell of Melilot.

S. hirta. Rough Hairy Button-weed. Linn. Sp. Pl. 148. Willd. n. 12. Swartz Obf. 45. (*S. n. 3*; Browne Jam. 141.)—Stem branched, hairy. Leaves ovato-lanceolate, rough with callous points. Flowers axillary, crowded, sessile. Stamens prominent.—Native of dry grassy places in the West Indies. Root annual. Angles of the stems rough with recurved bristly hairs. Leaves stalked, an inch and a half or two inches long, rough like a file, especially on the upper side. Stipulas fringed with long taper bristles. Flowers small, whitish, with blue anthers. Fruit hairy.

S. villosa. Shaggy Button-weed. Swartz Prodr. 29. Ind. Occ. 1943. Willd. n. 13. (*Pulegium fruticosum erectum, verticillis densissimis*; Sloane Jam. v. 1. 170.)—"Stem shaggy, slightly branched. Leaves ovato-lanceolate, downy; the uppermost four together. Flowers whorled. Stamens shorter than the corolla."—Native of fields and meadows, in the southern part of Jamaica, flowering all the year round. The stem is herbaceous, a foot high, but little branched, square, clothed with soft hairs. Leaves obtuse, with bristly ribs. Flowers white, with whitish, nearly sessile, anthers. Swartz.

S. procumbens. Procumbent Corymbose Button-weed. Linn. *Syst. Nat.* ed. 12. v. 2. 115. Willd. n. 19. (*S. corymbosa*; Linn. Sp. Pl. 149.)—Stem procumbent. Leaves linear-lanceolate, entire, smooth-edged. Corymbs lateral, stalked, many-flowered.—Native of the East or West Indies. Of this we have seen only an imperfect specimen, in the Linnæan herbarium, which we should rather guess to belong to *Hedyotis*, but the fruit is not in a state to decide that question. The leaves are an inch long. Flowers in roundish corymbose heads, composed of crowded leafy whorls, on axillary compressed stalks. Calyx recurved, downy. Corolla hairy within. Stamens prominent.

S. hypsipifolia. Hyssop-leaved Button-weed. Sm. Inf. of Georgia, v. 1. 75. t. 38.—Stem decumbent. Leaves linear-

linear-lanceolate, fringed with bristly teeth. Whorls of few flowers.—Native of Surinam and Georgia. A specimen was sent by Rolander to Linnæus, who marked it *S. strigosa*, but afterwards effaced that name, nor does this species seem to have been any where described, till it appeared in the Natural History of the Insects of Georgia, with the plants on which they feed, published by the writer of this article, from the drawings and papers of Mr. John Abbot. This work is never cited by Willdenow, nor perhaps had it fallen in his way. The species before us has woody, wavy, decumbent, slightly branched, smoothish stems. The leaves are an inch long, remarkable for being bordered with fine cartilaginous teeth, pointing forward, like those of many species of *Galium*. Bristles of the *stipulas* numerous, long, and stout. *Flowers* reddish, three or four in each whorl. *Calyx* fringed. *Fruit* obovate, roughish, red even in an early state, though the *calyx* is green. We should suspect this to be the *S. diodina* of Michaux and Pursh, found in dry barren soils, on iron ore hills, from Virginia to Carolina, but the *flowers* of that species are described as white, and very small, solitary and alternate, the *stem* and *seeds* hairy, which characters do not answer to our plant, though the edges of the *leaves* appear to be similarly rough in both.

S. involucreta. Long-flowered Button-weed. Pursh n. 4.—“Stem alternately branched, very hispid. Leaves ovato-lanceolate, pointed, hairy on both sides. Stipulas with many bristles. Heads terminal, bracteate. Stamens prominent.”—Found in Carolina by Mr. Frazer. About a foot high. *Leaves* broad, rather oblique. *Flowers* white, with a very long tube.

SPERMACEOE, in *Gardening*, contains plants of the herbaceous, annual, and shrubby kinds; among which the species cultivated are, the slender button-weed (*S. tenuior*); and the whorl-flowered button-weed (*S. verticillata*).

Method of Culture.—These plants are increased by sowing the seeds on a moderate hot-bed, early in the spring, or in pots to be plunged in it. When the plants have attained some growth, they should be removed into separate pots, filled with good friable mould, replunging them in the bed. They should afterwards be managed as other plants of the exotic stove kind.

They afford variety in hot-house and stove collections.

SPERMATIC, in *Anatomy*, an epithet applied to various parts belonging to the testicle, as the artery, veins, nerves, cord, &c. See the description of the testis in the article GENERATION.

SPERMATIC Chord, *Disease of*, in *Surgery*. See HYDROCELE.

SPERMATOCELE, a kind of rupture, occasioned by a distension of the femal vessels, by which they are let fall into the scrotum.

SPERMATOPŒA, a name given to such medicines as are supposed to increase the semen.

SPERMATOSIS is a term sometimes used for the formation of seed.

SPERONE, LA, in *Geography*, a cape at the south-east extremity of Corsica; 4 miles E. of Bonifacio.

SPERONI, SPERONE, in *Biography*, a distinguished Italian writer of the 16th century, was the son of Bernardino Speroni, a noble of Padua, in which city he was born in the year 1500. He studied under the famous Pomponazzo, in Bologna. He took his degrees in medicine and philosophy, and was appointed at an early age reader in logic, and professor of philosophy, in the university; but being greatly attached to his former preceptor Pomponazzo, he returned to Bologna, which he did not

quit till the death of that eminent man. He then resumed the professor's chair at Padua, which he held till the death of his father in 1528, and his own marriage. After this he was employed by his fellow-citizens in public business, and was entrusted with several honourable commissions. But he was not less intent upon literature than diligent in active business, and became one of the most learned men of his time. When residing as an envoy at Venice, his speeches before the senate were so much admired, that it has been affirmed, that the judges and advocates belonging to other courts would leave their own places, to hear his pleadings. Nevertheless he was not a lawyer by profession, but only took up, occasionally, the causes of his friends. In 1560 Speroni went to Rome, as agent to the duke of Urbino at the Papal court. He obtained the friendship of the principal men of letters at that capital, and was on terms of particular intimacy with Charles Borromeo; and on that account he was induced to add theology to his other studies. Pius IV. conferred on him the honour of knighthood; and the dukes of Urbino and Ferrara sent for him to their different courts, where he was treated with the greatest respect. Almost all the princes of Italy followed the example of those sovereigns, intreating him to take up his abode with them; but he preferred the tranquillity of private life to the honours that might have been showered upon him. He died at the great age of 88, and was interred with every kind of funeral honour. As a writer, his style is spoken of with singular approbation: it is said to be entirely free from the affected elegance and the prolixity which characterize many authors of that country and period. It rather seems purposely to shun the most ornamented expressions, and yet it is inferior to none in true polish, and unites gravity and precision to harmony and eloquence. One of the most celebrated compositions of Speroni was a tragedy, entitled “*Canace and Macareus*,” which was much applauded by the Paduan academy degli Inflammati. Some copies of it having got abroad without the knowledge of the author, an incorrect edition was printed at Venice in 1546, but with the imprint Florence. Before, however, this surreptitious publication, there appeared in MS. a criticism upon it, in which it was treated with singular severity. This being afterwards printed, Speroni thought it necessary to defend his composition, and a long controversy ensued. The author, no doubt, improved his work before he gave it to the public, sanctioned by his own authority; and when it thus appeared, it was regarded as one of the best productions of that class which the age exhibited. Of the other writings of that author, many are moral treatises in the form of dialogue, in which he was one of the first composers in Italian, and in which he is said to have had few equals. The rest related to polite literature, eloquence, poetry, history, &c.; all displaying an extensive knowledge of books, and a correct judgment. His works have been collected and published at Venice, in 5 vols. 4to.

SPERVERIUS, in *Ornithology*, a name by which Belonius, and some other authors, have called the sparrow-hawk, more commonly known by the names of *nifus*, and *accipiter fringillarius*.

SPESSART, in *Geography*, a large forest of Germany, to the right of the Mayne, extending from Wurzburg to Aschaffenburg.

SPETKER, a river of Switzerland, belonging to the abbey of St. Gal; 4 miles E. of St. Gal.

SPEUSIPPUS, in *Biography*, an Athenian philosopher, son of Eurymedon, by a sister of Plato, succeeded his uncle in his school, over which he presided during eight years, commencing from the death of that illustrious philosopher,

in the year B. C. 348. He placed the statues of the Graces in the school built by Plato in the academy, and closely adhered to the doctrines of his master. His manners, however, were not conformable to his philosophy: he was vindictive, and a lover of pleasure. He was likewise avaricious, and, contrary to the practice of Plato, exacted a gratuity from his disciples. He was admitted to the friendship of Dion while he resided at Athens; and it was by his instigation that Dion, invited by the malecontents of Syracuse, undertook his expedition against Dionysius. (See Dion. in Vit. Corn. Nep.) Becoming paralytic in his limbs, he was conveyed to and from the academy in a carriage of some kind. Upon one of these occasions he met Diogenes, and saluted him; but the cynic, instead of returning the civility, upbraided him for enduring to live under such an infirmity. To which Speusippus replied, "that he did not live in his limbs, but in his mind." At length, overcome by his maladies, and wearied of life, he put an end to his existence, having first constituted Xenocrates his successor in the academy. He was author of several philosophical treatises, which have perished; though it is said that they were held in such estimation by Aristotle, that he gave three talents for them.

SPEY, in *Geography*, a river of Scotland, which rises in the loch of that name, about eight miles S.W. from Fort Augustus, in the county of Inverness, and runs into the North sea, in the frith of Murray; 3 miles N.W. of Fochabers. N. lat. 57° 40'. W. long. 2° 59'.

SPEYERSBERG, a town of Bavaria, in the bishopric of Bamberg; 11 miles N. of Bamberg.

SPEYMOUTH, a parish of the shire of Elgin, Scotland, 1½ mile N.W. from Fochabers.

SPEZZA, or SPETIA, a sea-port town of the Ligurian republic, situated on a gulf of the Adriatic, to which it gives name, and anciently called "Portus Lunæ." At the entrance of the gulf is a small island, called "Palmaria," which makes the harbour safe and large; 35 miles S.E. of Genoa. N. lat. 44° 9'. E. long. 9° 40'.

SPEZZANO, a town of Italy, in the department of the Panaro; 5 miles S. of Modena.—Also, a town of Naples, in Calabria Citra; 4 miles E.N.E. of Cosenza.

SPHACELUS, from σφάζω, *to destroy*, implies, in *Surgery*, the complete mortification of a part of the body. See GANGRENE.

SPHACHIA, in *Geography*, a district or province of the island of Crete, lying towards the south, and extending to the east much more than Cidonia, or Kidonia, which is situated to the north; it is considered as making part of the pachalic of Candia; though the interior police and administration belong to the inhabitants themselves, called "Sphachiots." The first chain of the high mountains of Sphachia, comprised in the province of Kidonia, is covered with snow for four or five months. It is, in general, stony and destitute of earth; but it has a few narrow vallies which are susceptible of culture. Barley is sown here in May, and gathered in September. As soon as the snow is melted, the flocks are brought to these mountains; and though the ground appears almost naked, cattle find a food, which, if not abundant, is very relishing, and very fit for giving to their milk and flesh a quality, unattainable by those that are bred in the most fertile places. The Sphachiots inhabit the high mountains, which extend from E. to W., from the province of Selino, as far as that of Amari. Independently of a great number of villages, which are situated on these mountains, some are found towards the south coast, and among others "Sphachia," their chief place, which is a small harbour that contains

seven or eight large boats, which the Sphachiots use for their trade, and sometimes also for the piracies which they practise in imitation of their ancestors. The Maltese formerly frequented this harbour, and were furnished by the inhabitants with provisions, and all the assistance which they wanted. Sphachia produces scarcely any oil; but it affords a small quantity of wheat, and barley in greater abundance: it also furnishes honey and wax. The principal production consists in little cheeses made with ewes' milk, which are exported to Constantinople. In winter the Sphachiots drive their flocks to the sea-side, in order to obtain plenty of grass; but in summer they remove them back to feed on the rich pastures, which the milder temperature and gradual melting of the snow always maintain in a state of verdure. With the wine which these Greeks make on the first link of the chain of their mountains, they indulge themselves so freely, that they consume their whole stock during the three or four months that succeed the vintage, and in the remainder of the year they are obliged to drink pure water. The inhabitants of the Sphachian mountains are distinguished by their industry and activity; they are shepherds, agriculturists, and artisans; they occupy their land to advantage, and breed a great number of cattle; and manufacture with tolerable skill the cloths which they use, as well as the utensils and implements which they employ. Upon the whole, the Sphachiots have preserved the energy of the independent man, and the activity of a person who enjoys, without molestation, the fruit of his labour.

The Sphachiots, who are considered as the real descendants of those famous Cretans who were so long masters of the country, are distinguished from the other Greeks by their tall stature, their comely appearance, their love of liberty, their courage, their skill, and, above all, the hatred which they have vowed against the usurpers of this island. Under the Romans, the Saracens, the Venetians, and the Turks, the Sphachiots found means to preserve their laws and their customs. They annually appointed their magistrates in the general assemblies of the people. Obligated by the Turks to transport, in summer, from the top of their mountains, the ice necessary for the consumption of the inhabitants of Canea and Retimo, they paid no tax, no impost; they had no agas; they never saw among them the agents of the Turkish government; they formed, in a word, a republic in some measure independent. When, in 1769, some Russian emissaries came to disturb the peace, and impair the happiness, which these privileged Greeks enjoyed on their mountains, the Sphachiots recurred to arms; and some hundreds of the bravest of them went and joined the Mainots, their friends, and proceeded together to offer their services to count Orloff, at a time when they apprehended the Russians were preparing to deliver the Greeks from the Ottoman yoke. The pasha of Candia, informed of the conduct of the Sphachiots, resolved, in the same year 1770, to march against them with all the forces of the island. He wished to exterminate them, and thus to afford a terrible example of severity to all the Greeks who might be tempted to imitate them. The Turks soon united under their colours. The Sphachiots, taking advantage of their rocks and mountains, defended themselves against the attacks of the Turks, and sheltered themselves amidst their crags and precipices. Notwithstanding their resistance, the Turks persevered, though tired of a painful and disagreeable war, and loudly demanding to return home, reduced the Sphachiots to the last extremity. Almost all their villages were set on fire; many of their women and children were carried off, as well as their flocks,

flocks, and their provisions were exhausted. In these circumstances they received with pleasure the first proposals that were made to them, consented to pay their annual tribute, and obtained permission to return to their habitations, and continue their barter with the maritime towns. The Turks treated them in the most insulting and cruel manner, loading 3000 or 4000 Greeks with their baggage, and in their different battles placing them in front, so as to make a rampart of their bodies. This cowardly and barbarous treatment greatly distressed these brave mountaineers; and frequently prevented their firing on their enemies, for fear of injuring those whom they considered as their brethren, still more unfortunate than themselves. Although the Sphachiots pay their karatch with the greatest repugnance, and are disposed to avail themselves of the first favourable moment for shaking off the yoke, which hangs heavy on their necks, they took care, during the last war of the Russians against the Turks, to resist the solicitations addressed to them for taking a part in any hostile armaments. By this wary conduct, they have preserved the few privileges which they have remaining. Olivier's Travels.

SPHÆCULÆ, among the Romans, were tickets of wood, *tefferæ ligneæ*, by which the emperors scattered their presents to people of both sexes in the theatre, or circus.

SPHÆRANTHUS, in Botany, derived from *σφαῖρα*, a sphere, or globe, and *ανθος*, a flower, from the aggregation of its florets into globular heads.—Linn. Gen. 452. Schreb. 591. Willd. Sp. Pl. v. 3. 2394. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 184. Juss. 176. Lamarck Dict. v. 7. 321. Illustr. t. 718. Gært. t. 164. Loureir. Cochinch. 509. Vaill. Mem. de l'Acad. des Sc. 1719. t. 20. f. 12.—Class and order, *Syngenesia Polygamia Segregata*. Nat. Ord. *Compositæ Capitata*, Linn. *Cinacrocephala*, Juss.

Gen. Ch. Common Calyx globular, imbricated with pointed, permanent scales, clothing the general receptacle on all sides; partial one to each scale of the common calyx, many-flowered, of five linear, equal, erect leaves. Cor. partial comprising about three perfect florets in the disk, and mostly five female ones in the radius. Perfect florets of one petal, funnel-shaped, with a five-cleft, spreading limb; female awl-shaped, tubular, with a trifid, very small, closed mouth. Stam. (in the perfect florets) Filaments five, capillary, very short; anthers cylindrical, tubular, longer than the corolla. Pist. (in the perfect florets) Germen shrivelled; style long and rather thick; stigma quite simple: (in the female florets) Germen oblong; style setaceous, the length of the stamens; stigma cloven. Peric. none, except the unchanged calyx. Seeds (in the perfect florets) none; (in the female) solitary, oblong, naked. Recept. common scaly; partial naked.

Ess. Ch. Partial calyx eight-flowered. Florets tubular, perfect; some imperfectly female. Receptacle scaly. Down none.

1. *S. indicus*. Indian Sphæranthus. Linn. Sp. Pl. 1314. Fl. Zeylan. 312. Willd. n. 1. (*S. purpurea alata ferrata*; Burman. Zeylan. 220. t. 94. f. 3.)—Leaves lanceolate, serrated, decurrent, smooth. Peduncles winged. Wings of the stem and stalks serrated.—Native of the East Indies. It flowers at Kew, in the stove, from August to December. Root perennial. Stems herbaceous, branched above and below, smooth. Leaves alternate, sessile, lanceolate, naked, serrated, remarkably decurrent, involute, having the fragrance of oil of lavender. Flowers solitary, terminal, globular, of a blue or purplish colour.

2. *S. microcephalus*. Small-headed Sphæranthus. Willd. n. 2.—Leaves obovato-lanceolate, slightly pointed, serrated,

decurrent, smooth. Peduncles winged. Wings of the stem and stalks entire.—Native of Java.—Willdenow, upon whose authority this and the following species are adopted, says, that this is very like the preceding, but that its wings are entire, not serrated. Leaves obovato-lanceolate, obtuse, with minute, very distant, pointed serratures. Flowers in oblong, not spherical, heads, about half as big as those of the last species.

3. *S. hirtus*. Hairy Sphæranthus. Willd. n. 3. Lamarck Illustr. t. 718. f. 1.—Leaves obovate, serrated, hairy, decurrent. Peduncles winged.—Allied to the first species, but distinct in having obovate leaves, and smaller heads of flowers, as well as in the hairiness of all its parts.

4. *S. africanus*. African Sphæranthus. Linn. Sp. Pl. 1314. Thunb. Prodr. 169. (*Scabiosa minor, alata caule, maderaspatensis*; Pluk. Alm. 335. t. 108. f. 7.)—Leaves decurrent, ovate, serrated. Peduncles round.—Native of the Cape of Good Hope and Madras, flowering at Kew in July and August. Stem herbaceous, about ten inches high. Leaves alternate, ovate-lanceolate. Peduncles sustaining three or four globular heads of flowers of a pale yellow colour.

5. *S. chinensis*. Linn. Mant. 119. Willd. n. 5.—Leaves sessile, pinnatifid.—Native of India. Why then (says professor Martyn) is it named *chinensis*?—It is extremely like *S. indicus*, but a much smaller plant, with pinnate, sinuated leaves, and, if we mistake not, is the very same as the Linnean *Artemisia maderaspatana*.

6. *S. cochinchinensis*. Loureir. Cochinch. 510.—Leaves decurrent, oblong, undivided. Flowers in heart-shaped, ovate, nearly sessile, terminal heads.—Native of China and Cochinchina, among corn, and in gardens.—Stem herbaceous, a foot and half high, erect, round, smooth, whitish, with a few ascending branches. Leaves alternate, sessile, undulated, rugose, woolly. Flowers white, tinged with a little purple. Loureiro observes, that the last species (*S. chinensis*) differs from this only in having pinnatifid leaves.

SPHÆRIA, a genus of the fungus tribe, defined by Micheli, but properly named by Haller, in allusion to the spherical shape of the seed-vessels.—Hall. Hist. v. 2. 120. Schreb. Gen. 770. Perf. Syn. 1. Lamarck t. 879. (*Lichen-agaricus*; Mich. Gen. 103. t. 54, 55.)—Class and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi, angiocarpi*.

Ess. Ch. Capsules roundish, immersed, filled with jelly, which becomes a mass of minute, volatile, seeds.

Perfoon reckons up 184 species, distributed in eight sections, of each of which we shall exhibit examples.

Sect. 1. *Caulescent, elongated or club-shaped; their substance either fleshy or corky*. Ten species.

S. militaris. Scarlet Club-shaped Sphæria. Perf. n. 1. Obs. Mycolog. fasc. 2. 66. t. 6. f. 3. Sowerb. Fung. t. 60. (*Clavaria militaris*; Linn. Sp. Pl. 1652. Hudf. 638. With. v. 4. 361? *C. militaris crocea*; Vaill. Paris. 39. t. 7. f. 4. *C. granulosa*; Bulliard t. 496. f. 1.)—Tawny red, or scarlet, fleshy, club-shaped. Head granulated with the prominent seed-vessels. Perfoon mentions this as found in autumn, after great rains, in wet grassy places, always growing out of some dead caterpillar or chrysalis. The only specimen we ever saw was gathered on a dry gravelly bank above Thorpe, near Norwich, and measured about an inch in height, the head being ovate, of a beautiful scarlet, granulated like orange-peel; the stalk paler and smooth. The figures above cited are rather taller, and generally more yellowish. Withering appears to confound various distinct species under the above name.

S. cutomorphiza. Slender-stalked Sphæria. Dickf. Crypt. fasc.

fasc. 1. 22. t. 3. f. 3. Perf. n. 4. With. v. 4. 389.—Stalk elongated, slender, simple or divided, somewhat compressed. Head roundish, brown.—Found by the late Rev. Mr. Lightfoot, in the woods of the duchess dowager of Portland at Bulltrode, in autumn, but rarely, growing out of some dead insect. The *stalk* was usually two or three inches high, wavy, slender, blackish; sometimes deeply cloven. *Heads* solitary, globular, granulated, brownish, the size of a small pea.

S. ophioglossoides. Fibrous-rooted Club Sphæria. Perf. n. 5. (*Clavaria radicata*; Bulliard t. 440. f. 2. C. *parafitica*; Willden. Berolin. 405. t. 7. f. 17. With. v. 4. 361.)—Stalk simple, yellowish, with a branched fibrous root. Head oval, turgid, black.—Native of sandy heaths, or fir woods, in autumn. Mr. Pitchford found it near Norwich, many years since, nor can there be any doubt respecting the above synonymy. His specimens, like those of Willdenow, grew parasitically, on the *Tuber cervinum*, one or two on each individual, to which they were attached by their long and much-branched fibrous roots. The *stalk*, about two inches high, is wavy or curved, roundish, of a dirty yellow, as well as the *root*. *Head* an inch long, when full grown, granulated, of a glaucous black, solid; pale yellow within.

S. Hypoxylon. Horned Black Sphæria. Perf. n. 7. Obf. Mycolog. fasc. 1. 20. t. 2. f. 1, a, f. Sowerb. Fung. t. 55. (*Clavaria Hypoxylon*; Linn. Sp. Pl. 1652. Hudf. 639. With. v. 4. 369. C. *cornuta*; Bulliard t. 180.)—Clustered, branched, compressed; black and hairy below; whitish and dilated at the summits.—Common on rotten stumps or posts, in woods and gardens, making a conspicuous appearance. Its usual height is three or four inches. The hairiness is most copious and coarse on young plants. In winter the summits of the branches are plentifully covered with white powder, but destitute of the spherical seed-vessels. The latter, according to Perfoon, are perfected in summer. His observations contradict the opinion reported by Withering after Dr. Waller, that the present species is the male of the following. Indeed that opinion is much invalidated by the assertion that *Clavaria ophioglossoides* of Linnæus, (see GEOGLOSSUM,) is only a variety of the *digitata*. Such a mistake is no otherwise accountable, than by supposing the person who made it took the species last described for the *Geoglossum*, and even then his accuracy of judgment could not rank high.

S. digitata. Finger-shaped Black Sphæria. Sowerb. Fung. t. 69. (*S. polymorpha*; Perf. n. 10. *Clavaria digitata*; Linn. Sp. Pl. 1652. Hudf. 639. With. v. 4. 368. Bulliard t. 220. Lichen-agaricus terrestris *digitatus niger*, &c.; Mich. Gen. 104. t. 54. ord. 2. f. 4.)—Clustered, club-shaped, obtuse, tumid, coal-black. Frequent on old rotten stumps in beech woods, as well as on old posts of different kinds, into which its long perennial roots deeply insinuate themselves, the fungus springing up every autumn, in the shape of numerous, simple or divided, hard, black, rough, finger-like bodies, whitish at the summit while young, and tapering below into very slender stalks. Perhaps *S. digitata*, Perf. n. 9, may be a variety only; but the Linnæan synonym belongs to what we have described.

SECT. 2. *Roundish or diffuse, without a stem*. Thirteen species.

S. concentrica. Concentric Black Sphæria. Perf. n. 11. Bolt. Fung. t. 180. (*S. fraxinea*; With. v. 4. 393. Sowerb. Fung. t. 160. *Lycoperdon fraxineum*; Hudf. 641; excluding the synonym of Micheli.)—Roundish, tumid, firm, smooth, with numerous concentric internal layers. Frequent on the decayed stumps of Ash, Willow,

and other trees. Usually coal-black, somewhat shining, in globular masses, the size of a chestnut, or larger, and of the substance and lightness of charcoal.

S. fragiformis. Orange Sphæria. Perf. n. 13. (*Lycoperdon variolofum*; Linn. Syst. Nat. ed. 12. v. 3. 234. Hudf. 645. Sowerb. Fung. t. 271.)—Clustered, somewhat confluent, of a rusty red; black and shining within. Seed-vessels minutely papillary, in the deciduous coat.—Frequent on rotten branches and stumps in damp woods. Each plant is the size of a pea, more or less, bright red when young. In an advanced state they become confluent, of a brick colour, and the coat, in which the minute seed-vessels are lodged, scales off, leaving a black central mass, mistaken by Mr. Sowerby for the seed.

SECT. 3. *Shape roundish, but various and indeterminate*. *Capsules scattered horizontally, with prominent orifices, often spinous*. Twenty-three species.

S. poronia. Dotted Cup Sphæria. Perf. n. 24. (*S. punctata*; Sowerb. Fung. t. 54. *Peziza punctata*; Linn. Sp. Pl. 1650. Bulliard t. 252.)—Stalked; cup-shaped, shallow, white in the disk, with black scattered sunk capsules.—Found in sandy countries, chiefly on horse-dung, rarely on that of cows. It looks like a stalked *Peziza*, scarcely half an inch broad, conspicuous for its white disk, dotted with the black seed-vessels. The substance is firm, or leathery.

S. deusta. Large Spreading Sphæria. Perf. n. 25. (*S. maxima*; Web. Goett. 286. Dickf. Crypt. fasc. 1. 23. *S. versipellis*; Tode Mecklenb. v. 2. 55. t. 17. f. 129. *Hypoxylon ustulatum*; Bulliard t. 487. f. 1. Lichen-agaricus crustaceus *crassius*, *bovinum renem veluti representans*, *niger et quasi deustus*; Mich. Gen. 104. t. 54. f. 1.)—Broad, indeterminate, thick, wavy and tumid; at first grey and powdery; finally black and rigid. Capsules sunk.—Not uncommon on old rotten stumps, over which it spreads, to the extent of two or three inches, in thick, diffuse, unequal masses, finally coal-black, and of the texture of *S. concentrica*, (see the preceding section,) with which Hudson and some other botanists have confounded it. The shape, however, is not globose, nor is the internal substance formed of concentric layers. The *capsules* moreover are larger, and very conspicuous in a vertical section of the plant, being closely ranged, in a simple series, under the external coat, through which their *seeds* are discharged by a slender tube belonging to each capsule.—Perfoon remarks, that this species sometimes acquires a kind of stalk, when growing on very rotten wood, or on the ground near an old stump.

S. ceratosperma. Horn-seeded Sphæria. Perf. n. 38. (*S. Ceratospermum*; Tode Mecklenb. v. 2. 53. t. 17. f. 131. *Ceratospermum nigrum minimum discoides, e diversarum arborum ramorum emortuarum corticibus, et præcipuè corylo erumpens*; Mich. Gen. 125. t. 56. f. 1.)—Roundish, convex, scattered, black. Capsules with long prominent beaks.—Found by Micheli in woods near Florence, chiefly on dead branches of hazel, in the winter. Tode observed it in July, on the dead bark of *Rosa canina*. Each plant is less than a split pea, seated on the dead wood or bark, under the cuticle, and soon becomes distinguished by the protrusion of numerous little black horn-like excrescences, which appear to be the prominent beaks of the sunk *capsules*. Tode's figures, however, do not precisely accord with those of Micheli. We once examined the original specimens of the latter writer, but the horn-like processes had disappeared; nor have we met with any thing in England answerable to this species, though many which belong to Perfoon's eighth, or last, section are sufficiently similar

similar in their mode of growth to explain the nature of that before us.

SECT. 4. *Shape indeterminate. Capsules horizontal; at first marginal, and separate; afterwards confluent.* Twenty-four species.

Perfoon himself doubts the certainty of this section, some of the species seeming rather to belong to that immediately preceding, others perhaps to the eighth.

S. graminis. Grass Sphæria. Perf. n. 50. Obf. Mycol. fasc. 1. 18. t. 1. f. 1 and 2.—Linear-oblong, forming shining black spots upon leaves. Capsules globose, without prominent beaks.—Observed by Perfoon on the leaves of *Elymus europæus* and *Lolium perenne*, in the shape of oblong, black, slightly prominent spots, various in length, which, when cut vertically, display a series of sunk globular capsules, not projecting above the surface.

The rest of this section are similarly parasitical on the leaves or stalks of various plants.

SECT. 5. *Capsules crowded into an elevated tuft, on a common crustaceous receptacle; their beaks converging.* Fifteen species.

S. ferruginea. Rusty-crust Sphæria. Perf. n. 62. Obf. Mycol. fasc. 1. 66. t. 5. f. 1, 2.—Capsules black, with taper straight beaks; their bases surrounded with rusty powder.—Gathered by Perfoon, on dry branches of hazel. It bursts from under the cuticle in little oblong transverse prominent masses, of which nothing appears but the taper spine-like beaks of the little black capsules. When laid bare, a powdery rusty mass, like a crust, is found to accompany the capsules, but Perfoon suspects this may possibly originate from the wood. His figure is admirable, as usual with all that he has published.

SECT. 6. *Capsules ranged circularly, mostly decumbent, without a crust, lodged under the cuticle of plants, their orifices generally crowded together.* Fourteen species, which might perhaps have been comprehended in the last section.

S. convergens. Converging Sphæria. Perf. n. 86. Tode Mecklenb. v. 2. 39. t. 14. f. 111.—Aggregate, slightly prominent. Capsules black, ovate, with straight beaks, all meeting in a point.—On the branches of trees, especially between the bark and cuticle of beech when dry. It consists of little black tubercular spots, each formed of a few minute capsules, ranged circularly, whose beaks, about their own length, meet in a conical point. There are no traces of any crust, or common basis.

S. salicina. Aggregate Willow Sphæria. Perf. n. 88. Obf. Mycol. fasc. 1. 64. (*S. cancellata*; Tode Mecklenb. v. 2. 34. t. 13. f. 107.)—Aggregate, circular. Mouth of the capsules conerected into a rugged perforated disk.—Not rare on dead dry branches of Willows, according to Tode and Perfoon, giving them the roughness of a file when handled. The minute black capsules are so combined at their orifices, eight or ten in each circular assemblage, as to form one body, united by a rugged or reticulated, woody or fungous, substance, of a grey or dirty white.

SECT. 7. *Capsules distinct, forming a roundish tuft, on a common receptacle, and bursting through the cuticle of plants.* Eleven species.

S. coccinea. Scarlet Sphæria. Perf. n. 92. (*S. decidua*; Tode Mecklenb. v. 2. 31. t. 13. f. 104.)—Tufted, pale red. Capsules ovate, smooth.—Said to be not unfrequent on dead branches of beech; consisting of scattered oval tufts, half the size of a pea, bordered by the reflexed torn cuticle of the branch. The capsules are minute, half sunk in the tumid receptacle, each with a short beak. There is a larger and brighter-coloured variety, found by Dr. Roth on the elder.

S. populina. Poplar Sphæria. Perf. n. 94. Obf. Mycol. fasc. 2. 67. t. 5. f. 10, 11.—Tufted, black. Capsules numerous, ovate, smooth, somewhat spreading, seated on a dense receptacle.—On the branches of poplars, but not common. It forms little black scattered tufts, each composed of 25 or 30 ovate, pointed, sessile capsules, divaricated at the points, and, though crowded, quite unconnected at the base.

S. aueuparia. Mountain-ash Sphæria. Perf. n. 96. (*S. cæspitosa*; Tode Mecklenb. v. 2. 41. t. 14. f. 113.)—Tufted, black, powdered with white. Receptacles aggregate, palmate, each bearing several cylindrical capsules.—On dead branches of the mountain-ash in May. This bursts in round, black, hard masses, from under the cuticle of the tree, each the size of a vetch-seed. When magnified, each tuft appears to consist of many hand-shaped erect portions, whose finger-like points are supposed to be the capsules; but the whole seems a very obscure production, nor has it ever fallen under our observation.

SECT. 8. *Capsules solitary, distinct, destitute of a receptacle.* Eighty-three species, subdivided according to the shape or proportion of the mouths, or beaks, of the capsules.

S. pileata. Cap Sphæria. Perf. n. 102. (*S. macrostoma*, var. ϵ , *pileata*; Tode Mecklenb. v. 2. 13. t. 9. f. 78.)—Simple, globose; its mouth inversely conical, flat at the top, with a linear orifice.—Found sunk in the bark of dead branches of trees, in the early spring. Tode. The size of poppy-seed, black and smooth, crowned with a discoid dilatation, in which the mouth is seated.

S. debilens. Wide-mouthed Sphæria. Perf. n. 106. (*S. macrostoma*, var. α , β , γ ; Tode Mecklenb. v. 2. 12. t. 9. f. 76.)—Simple, globose, immersed; its mouth compressed, with tumid lips.—Found sunk in the wood itself of rotten branches of trees, in the month of April. Very near the last, from which Tode considered it as not specifically distinct. The only difference consists in the lips prominent, and not conical, form of the lips of the capsule.

S. rostrata. Needle-beaked Sphæria. Perf. n. 112. Tode Mecklenb. v. 2. 14. t. 9. f. 79.—Simple, naked, globose, granulated, with a very long taper-pointed beak.—Found more or less immersed in rotten beech wood. Each plant consists of a globular, rugged, black, thickly coated capsule, the size of coarse sand, with a curved, sharp, slender beak, four or five times its own length.

S. acuta. Sharp-mouthed Sphæria. Perf. n. 122. Obf. Mycol. fasc. 2. 70. Sowerb. Fung. t. 119.—Scattered, naked, black, shining, depressed, with a cylindrical sharp beak.—Found on the dead stalks of nettles more especially, in the spring. First observed in England by the Rev. Mr. Relhan. It grows in a rather scattered manner; each plant like a minute bottle, vertically flattened.

S. Peziza. Scarlet-cup Sphæria. Perf. n. 129. Tode Mecklenb. v. 2. 46. t. 15. f. 122. (*S. miniata*; Hoffm. Germ. v. 2. t. 12. f. 1. *Peziza hydrophora*; Bulliard t. 410. f. 2. *Lycoperdon hydrophorum*; Sowerb. Fung. t. 23.)—Crowded, dull red, globose, somewhat hairy; at length depressed and concave.—Frequent in the hollows of rotten trees in autumn, composing broad patches, of a dull fearful hue. Each plant is smaller than a mustard-seed, externally roughish or hairy. If Mr. Sowerby be right, the seeds appear to form a white ball, which is protruded out of the capsule, after which the latter becomes depressed and hollow, as all authors describe it when advanced. See somewhat similar in the character of *SPHÆROBOLUS* in its proper place.

S. hispida. Brittly Sphæria. Perf. n. 144. Tode Mecklenb. v. 2. 17. t. 10. f. 84.—Simple, scattered, pear-

shaped, black, clothed with scattered spreading bristles.—Found by Tode on oak branches, stripped of their bark, in September. Each individual is about half a line long, erect, ovate, tapering into a short thick mouth; the outside beset with spreading bristles, which well mark the species.

S. herbarum. Flat Common Sphæria. Perf. n. 153. (*S. complanata*; Tode Mecklenb. v. 2. 21. t. 11. f. 88.)—Simple, scattered, orbicular, more or less depressed, smooth, brown, with a nipple-shaped mouth.—Copious on the dried stalks of various herbaceous plants. Each specimen is about the size of the smallest pin's head. See *S. Saturnus*, Sowerb. Fung. t. 218.

S. moriformis. Mulberry-shaped Sphæria. Perf. n. 168. Tode Mecklenb. v. 2. 22. t. 11. f. 90, 91.—Simple, feathered, elliptical or roundish, closed, tuberculated, black.—Said to be not unfrequent on dead branches, especially of firs. This, like all the following, belongs to a tribe of species destitute of a beak, or any perceptible orifice. Its size is about equal to mustard-feed. The whole surface is tuberculated. The shape elliptical, or globular. Perhaps this may be *S. claviformis*, Sowerb. Fung. t. 337.

S. comata. Tufted Sphæria. Perf. n. 170. Tode Mecklenb. v. 2. 15. t. 10. f. 81.—Simple, crowded, globose, crowned with a converging tuft of capillary fibres, twice its own length.—Observed by Tode on the dead stems and stalks of plants after rain. This is a very remarkable species, on account of the dense tuft of fibres, invariably found to crown the summit of each specimen, and which, therefore, has no appearance of being of an extraneous or parasitical nature. Indeed there are instances of bristles or hairs, either generally or partially clothing some other species. The general colour is black, but a brown variety has been noticed, though rarely, on rotten wood of willows.

S. cylindrica. Cylindrical Ball-bearing Sphæria. Perf. n. 180. Tode Mecklenb. v. 2. 42. t. 15. f. 114.—Simple, scattered, cylindrical, black, bearing a globe of white feeds.—Found by Tode on rotten willows, protruding from the wood in the form of minute, scattered, black points, hardly visible to a casual observer, each crowned by a little white ball of feeds, which betrays some analogy to that of *S. Peziza*; inasmuch that one might almost think such a character, if well ascertained in some other species, might form a generic distinction. We know, however, too little of the different changes, which the fructification of many of the rest undergo, to draw a line between them, and these powdery balls, being doubtless liquid in an early state, come under the essential definition of *Sphæria*. The character of *Nemaspora* of authors, consisting in the permanently gelatinous nature of what its capsules discharge, seems to keep that genus sufficiently distinct from the present.

SPHÆRISTERIUM, σφαιριστήριον, in *Antiquity*, the seventh part of the ancient gymnasium; being that in which the youth practised tennis-playing.

The sphæristerium, or tennis-court, was between the place named *palaestra*, and that where they ran races, which was between the porticoes and the outer wall, though Vitruvius does not make mention of it in the description he gives of the ancient gymnasium.

The exercise here performed was called σφαιριστική, *sphæristica*, and σφαιρομαχία, *sphæromachia*, which some will have to have differed from the modern tennis; but it is not known in what the difference consisted.

The Milesians were particularly averse from this exercise; and the Athenians were as remarkably fond of it. These latter frequently gave the freedom of their city to the sphæristæ, or masters in this art, by way of compliment.

SPHÆROBOLUS, in *Botany*, so named by Tode,

from σφαῖρα, a globe, and βολος, a cast, or throw; because the feeds are forcibly ejected, in the form of a little round ball.—Tode Mecklenb. v. 1. 43. Perf. Syn. 115. (Carpobolus; Mich. Gen. 221. t. 101. Willd. Berol. 414.)—Class and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi, angiocarpi*.

Ess. Ch. Receptacle nearly globose, at length splitting into rays, and discharging elastically the globose seed-vessel.

1. *S. bellatus*. Starry Projectile Puff-ball. Perf. n. 1. (Lycoperdon Carpopolus; Linn. Sp. Pl. 1654. Hudf. 644. Sowerb. Fung. t. 22.)—Found in various parts of Europe, in autumn, upon rotten wood or branches of trees, heaps of saw-dust, or in the tan-pits of hot-houses. In an early state each plant consists of a pale yellow globe, larger than a mustard-feed. Several such grow crowded together in patches, bound down, as it were, with a fine cottony web. After a while, each plant bursts into several starry rays, and, by a momentary explosion, projects, to the distance of six or eight inches, a whitish globular mass of powdery feeds from its internal cavity. Sometimes this ball of feeds remains sticking to the points of the rays. When fallen to a distance, the skin of the ball is found empty, the feeds having flown out in its passage through a hole at the base, which is usually bordered by an inner layer of the outer starry case, or *wolva*, torn away by the ball.

We do not perceive the necessity of changing the original generic name, given by Micheli, whose figures and description of this curious little fungus long excited the curiosity of botanists, before the plant was known to be so frequent as it is. Mr. Sowerby gives the best representation of it. Tode describes a second species, which can scarcely belong to the same genus, and which is figured under the name of *Peziza marginata*, in Sowerby's *Fungi*, t. 16, and under that of *Patellaria excavata*, in Hoffmann's *Plantæ Lichenosæ*, t. 23. t. 3. Albertini and Schweiniz mention this production with doubt, in their learned work on the Niskian Fungi, p. 346. n. 1034; but it seems not as yet well understood.

SPHÆROCARPUS, so named by Micheli, from σφαῖρα, a globe, and καρπος, fruit, in allusion to its spherical seed-vessel.—Mich. Gen. 4. Sm. Engl. Bot. v. 5. 299. Relh. 441. Mart. Mill. Dict. v. 4.—Class and order, *Cryptogamia Algæ?* or perhaps *Hepaticæ?* Nat. Ord. *Hepaticæ?*

Ess. Ch. Calyx inferior, of one leaf, inflated, entire. Seeds very numerous, collected into a globe, at the bottom of the calyx.

1. *S. terrestris*. Reticulated Sphærocarpus. Engl. Bot. t. 299. (*S. terrestris, minima*; Mich. Gen. 4. t. 3. Dill. Mulc. 536. t. 78. f. 17. Targionia Sphærocarpus; Dickf. Crypt. fasc. 1. 8. With. v. 3. 814.)—Micheli first observed this singular little plant in gardens about Florence, in the winter and spring, growing in patches on the ground. The Rev. H. Bryant, Mr. Crowe, and Mr. Woodward, found it, since the publication of Hudson's 2d edition, chiefly in the clover and turnip fields of Norfolk, especially on strong land, covering the earth copiously in the winter months, in patches of a pale glaucous green. The whole habit is delicate and membranous. Fronds simple, roundish or ovate, crowded, wavy, each attached by a fibrous, probably annual, root. The disk of each frond is nearly covered by an assemblage of pear-shaped, reticulated, pellucid, bottle-like calyces, each a line long, contracted at the mouth, and lodging a little ball of green feeds at the bottom of its cavity, clothed with a fine skin. This plant seems to us essentially distinct in genus from TARGIONIA, (see that article,) and more allied to *Blasia* and *Jungermannia*.

SPHÆROCARPUS is also applied by some authors to designate a genus of *Fungi*, the *TRICHIA* of others. See that article.

SPHÆROCARPUS of Gmelin, in his faulty edition of Linn. Syst. Nat., is a scitamineous genus, the *Hura* of Koenig, now considered as a *Globba*.

SPHÆROLOBIUM, was so named by the writer of this article, from σφαῖρα, a globe, and λοβιον, the diminutive of λοβος, a pod, to express the roundish form of its very small legume.—Sm. in Sims and König's Ann. of Bot. v. 1. 509. Brown in Ait. Hort. Kew. v. 3. 13.—Class and order, *Decandria Monogynia*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Jull.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, permanent, bell-shaped, two-lipped; tube angular; upper lip in two abrupt oblique segments, united about half way up; lower in three deep, lanceolate, equal ones; without any lateral appendages. *Cor.* Papilionaceous, of five petals, with claws which are shorter than the calyx; standard kidney-shaped, emarginate, ascending; wings two, half obovate, rather shorter than the standard, converging at the upper margin; keel equal to the wings, of two oblong cohering petals. *Stam.* Filaments ten, linear-awl-shaped, separate, declining, shorter than the keel, the two uppermost with a space between them; anthers roundish, two-lobed. *Pist.* Germen stalked, roundish; style linear, keeled, rigid, obliquely rolled inward, about equal to the keel; stigma smooth, with a membranous dilatation at each side. *Peric.* on a stalk half its own length, obliquely orbicular, turgid, pointed, of one cell and two coriaceous valves. *Seeds* one or two, kidney-shaped.

Ess. Ch. Calyx five-cleft, two-lipped. Corolla papilionaceous. Stigma keeled, with a membranous border. Legume stalked, spherical, turgid, oblique. Two upper flaments distant.

1. *S. vimineum*. Yellow-flowered Sphærolobium. Sm. Tr. of Linn. Soc. v. 9. 261. Sims in Curt. Mag. t. 969. Ait. n. 1.—“Tube of the calyx rather shorter than the lips. Style curved from the very base, included in the keel.” *Brown*.—Native of New Holland and Van Diemen's island. Our specimens were originally sent, in 1793, from Port Jackson by Dr. White. Sir Joseph Banks is said to have introduced the plant at Kew in 1802. It flowers during summer, requiring the shelter of a greenhouse in winter. The stem is erect, shrubby, branched, round, smooth, mostly naked, the youngest branches only bearing a few scattered, small, lanceolate leaves. Flowers numerous, in long straight clusters, rather small. Calyx smooth, a little glaucous. Corolla yellow, the disk of the standard marked with a transverse row of red dots. Legume the size of a vetch-seed.

2. *S. medium*. Small Red-flowered Sphærolobium. Ait. n. 2.—“Tube of the calyx half the length of the lips. Corolla red.” *Brown*.—Observed by Mr. Brown, on the south-west coast of New Holland, from whence it was sent to Kew, by Mr. Peter Good, in 1803. We know nothing of this plant, except the above particulars, borrowed from the *Hortus Kewensis*. The name seems to imply the existence of a third species, of which we have no account.

SPHÆROMACHIA, σφαιρομαχία, in *Antiquity*, a particular kind of boxing, in which the combatants had balls of stone or lead in their hands, which were called σφαίραι.

SPHÆROPHORON, in *Botany*, from σφαῖρα, a globe, and φέρω, to bear, because of the globular fructification.—Ach. Meth. 134. Lichenogr. 116. t. 12. f. 5, 6. Syn. 286. (Sphærophorus; Perl. in Uit. Annal. fasc. 7. 23.)

—Class and order, *Cryptogamia Algæ*. Nat. Ord. *Algæ*, *Lichenes*.

Ess. Ch. *Receptacle* nearly globular, without a border, cartilaginous, with a torn orifice. *Seeds* composing a black powdery ball.

This most elegant genus of the natural family of Lichens, is at once known by its branched, bushy, smooth habit, like that of a coral or coralline. Three species are known.

1. *S. coralloides*. Coral-branched Globe-Lichen. Ach. Syn. n. 1. (Lichen globiferus; Linn. Mant. 133. Engl. Bot. t. 115. L. fruticosus coralloides, non tubulosus, cinereus ramosissimus, receptaculis florum sphæricis concoloribus; Mich. Gen. 103. t. 39. f. 6. Coralloides cupressiforme, capitulis globosis; Dill. Musc. 117. t. 17. f. 35. C. globiferum; Hoffm. Pl. Lich. v. 2. 25. t. 31. f. 2.)—Stem pale brown, cylindrical; its lateral branches elongated, divaricated, forked, with slender white tips. Receptacles globose, smooth.—Native of mountainous rocky heaths, and fir woods, in the cooler parts of Europe. Abundant in Scotland, Wales, Derbyshire, &c. The smooth polished brownish stems compose lax tufts, an inch or two high, soft and pliant when wet, very brittle when dry, resembling little groves of coral. The flowering stems are stouter, more simple, and rather taller than the rest, their strongest branches each terminating in a smooth ball of their own substance and colour, smaller than a pea, opening by a torn mouth at the summit, and containing a dense ball of very black powdery seeds.

2. *S. fragile*. Brittle Globe-Lichen. Ach. Syn. n. 2. Meth. 135. t. 3. f. 5. Engl. Bot. t. 2474. (Lichen fragilis; Linn. Pl. Suec. ed. 2. 425. Fl. Lap. ed. 2. 351. t. 11. f. 4. Ehrh. Crypt. 128. Coralloides fragile; Hoffm. Pl. Lich. v. 2. 34. t. 33. f. 3.)—Stem greyish; its branches crowded, forked, round. Receptacles obovate, rugose. Native of mossy rocks and mountains in the north of Europe. We have found it on the Pentland hills, near Edinburgh, but without fructification. In this state it forms broad patches of dense, pale grey, branching stems, whose branches are round, somewhat annular, obtuse, level-topped. In some German and Swedish specimens, larger and stouter branches bear obovate or pear-shaped receptacles, or seed-vessels, of a dark brown, whose surface is cracked or corrugated, their size about equal to the preceding.

3. *S. compressum*. Compressed Globe-Lichen. Ach. n. 3. (Lichen fragilis; Linn. Sp. Pl. 1621. Jacq. Misc. v. 2. 92. t. 9. f. 6, c. Engl. Bot. t. 114. L. melanocarpus; Swartz Prodr. 147. Coralloides alpinum, corallinæ minoris facie; Dill. Musc. 116. t. 17. f. 34.)—Stem white; its branches compressed. Receptacles somewhat lateral, depressed, smooth.—Found in moist places, under the shade of rocks, on the mountains of Germany, Switzerland, and England, as well as in the West Indies, and at the Cape of Good Hope. This beautiful species, in the polished white of its surface, and its flat palmate ramifications, exceeds the elegance of the foregoing, and still more resembles a coralline. The height of the branching fan-like stem is two or three inches, and the fructification, when present, is copious, usually turned to one side, flattened, often bordered with granulations or shoots; the powder intensely black, mixed with fibres of the same colour.—In the account given in English Botany, the idea of the last species, in a barren state, was comprehended under this.

SPHAGNITES, a name given by some authors to the jugular veins.

SPHAGNUM, in *Botany*, a name used by Pliny for some sort of moss that grows upon trees, adopted by Dil-

lenius and Linnæus, for the genus now called Bog-mofs.—Dill. Musc. 240. Linn. Gen. 562. Schreb. 758. Mart. Mill. Dict. v. 4. Hedw. Fund. v. 2. 85. Theor. t. 12. Sp. Musc. 27. Sm. Fl. Brit. 1145. Juss. 12. Lamarck Illustr. t. 872.—Class and order, *Cryptogamia Musci*. Nat. Ord. *Musci*.

Eff. Ch. Capsule sessile, without a fringe. Veil cut round, its base remaining on the base of the capsule. Anthers each surrounded with a ring.

Obf. Weber and Mohr have justly remarked, that this is the only known genus of mosses in which the germs and capsule are truly sessile, not at any stage of growth elevated on a *pedicellus*, or partial stalk, above the base of the flower. The whole flower indeed, and consequently the ripe capsule, is stalked, which being rarely the case with other mosses, whose *pedicelli* are very long, the two different kinds of stalk have been confounded together.

1. *S. latifolium*. Broad-leaved Bog-mofs. Hedw. Sp. Musc. 27. Fl. Brit. n. 1. Engl. Bot. t. 1405. Turn. Musc. Hib. 5. (*S. palustre* α ; Linn. Sp. Pl. 1569. Fl. Dan. t. 474. *S. palustre molle deflexum*, squamis cymbiformibus; Dill. Musc. 240. t. 32. f. 1.)—Branches tumid, deflexed. Leaves ovate, obtuse, concave. This moss occupies the surface of watery turfy bogs throughout Europe, bearing capsules in summer. Its pale whitish-green hue, often tinged with red, makes the plant conspicuous. The large masses it composes are mostly filled with water, like a sponge, and are not firm enough to be walked upon. *Drosera*, *Erica tetralix*, and the Cranberry, are the chief plants that grow amongst it, often without being rooted in the ground. The stems are various in height, soft and flexible, beset with numerous, short, tumid, tapering branches, slightly bent downward; the uppermost crowded. Leaves imbricated, pellucid, broad, obtuse, entire, incurved, reticulated, without rib or veins. Capsules about the tops of the stems, erect, brown, smooth, on flower-stalks not an inch long. Lid almost flat. Veil thin, more or less of its circular base remaining round the capsule. The softness and elasticity of this moss render it very fit for packing.

2. *S. squarrosolum*. Prominent-leaved Bog-mofs. Mohr Ind. 2. Sm. Compend. ed. 2. 159. Engl. Bot. t. 1498.—Branches deflexed, tapering. Leaves ovate, acute, with recurved, prominent, keeled points.—Native of Germany, Sweden, and England. Mr. Turner gathered this species, which the late Mr. Mohr only had previously mentioned, not described, on bogs at Belton, near Yarmouth, bearing fruit in June and July. It differs from the foregoing in the more taper terminations of the branches, and especially in the spreading recurved points of its leaves, which have a central fold like a keel, and give the squarrose character of the plant. The capsules have a prominent beaked lid.

3. *S. capillifolium*. Slender Bog-mofs. Hedw. Sp. Musc. 28. Fl. Brit. n. 2. Engl. Bot. t. 1406. Turn. Musc. Hib. 6. (*S. palustre* β ; Linn. Sp. Pl. 1569. *S. palustre molle deflexum*, squamis capillaceis; Dill. Musc. 243. t. 32. f. 2, A.)—Branches slender, deflexed. Leaves ovato-lanceolate, pointed, flattish, close-pressed, with straight points.—Abundant on bogs, especially in rather mountainous situations, bearing capsules in summer, and often tinged with red. Its much smaller size, and narrower flatter leaves, distinguish this from both the preceding. The reticulations of the foliage are observed by Mr. I. D. Sowerby to be peculiar, the little transverse veins running in pairs. Sometimes a fold, or keel, resembling a mid-rib, is discernible.

4. *S. cuspidatum*. Long-leaved Floating Bog-mofs. Hoffm. Germ. v. 2. 22. Fl. Brit. n. 3. Engl. Bot. t. 2092. Ehrh. Crypt. 251. Turn. Musc. Hib. 6. (*S. palustris mollis deflexi*, squamis capillaceis, varietas fluitans; Dill. Musc. 244. t. 32. f. 2, B.)—Branches spreading, rather downwards. Leaves lanceolate, long-pointed, wavy, lax.—Most frequent, in pools or rivulets, among bogs in mountainous countries, but Mr. Turner found it near Yarmouth, bearing fruit in summer. This resembles the common *latifolium* in colour, but the more elongated floating stems, distinguish the species before us. The branches are loosely directed downward, pointed, often very slender. The reticulations of the leaves most accord with those of our last species; but their points are more elongated, and edges wavy. Capsule short, and rather bell-shaped when fully ripe.

We have thus brought together four species of the present genus. Hedwig has but two, besides the *S. alpinum* of Linnæus, figured in Dillenius, t. 32. f. 3, which is founded in an error of the last-mentioned author. What he described and delineated, prove to be nothing more than luxuriant bog specimens of *Dicranum flexuosum* of Hedwig and Fl. Brit., Engl. Bot. t. 1491, among which some extraneous bodies had fallen, and these were mistaken for capsules.

SPHENE, in *Mineralogy*, a mineral composed of nearly equal parts of oxyd of titanium, silica, and lime. Its colours are generally a dark brown, inclining to red or yellow. It occurs crystallized in various forms, and also sometimes in masses. The crystals are more frequently four-sided prisms, either oblique or rectangular, or six-sided prisms, with two opposite sides broader than the rest, or elongated octohedrons. The edges of the crystals are frequently bevelled, and the apices of the octohedrons are sometimes flattened as to present a lenticular form.

The fracture of sphene is imperfectly conchoidal; it scratches glass, and is brittle. The internal lustre is shining, inclining to resinous. The specific gravity is from 3.480 to 3.510. It is fusible by the blowpipe into a blackish-brown enamel. This mineral is found imbedded in sienite and granite in various parts of Scotland, and also in Sweden, Norway, France, Switzerland, and in North America. The name sphene was given to this mineral by Häüy, from the wedge-like shape of some of the crystals.

Foliated sphene differs from the above in colour, which is various shades of yellow, inclining to a straw or cream colour, and in the structure, which is foliated, with a double cleavage parallel to the side of an oblique four-sided prism. The cross fracture is foliated. Both these varieties of sphene pass from different degrees of translucency to opacity.

SPHENOCLEA, in *Botany*, so denominated by Gærtner, from $\sigma\phi\eta\nu$, a wedge, and $\kappa\lambda\iota\nu$, to shut up, because of the wedge-shaped seed-vessel.—Gærtner, v. 1. 113. t. 24. f. 5. Willd. Sp. Pl. v. 1. 927. (Gærtnera; Retz. Obs. fasc. 6. 24. Rapinia; Loureir. Cochinch. 127. Pongatium; Juss. 423.)—Class and order, *Pentandria Monogynia*. Nat. Ord. *Lysimachiaz*, Juss. ?

Gen. Ch. Cal. Perianth superior, of five roundish, permanent leaves, broad at the base. Cor. of one petal, shorter than the calyx; tube very short; limb in five lanceolate, equal, erect segments. Stam. Filaments five, capillary, very short, inserted into the tube of the corolla; anthers roundish, two-lobed. Pist. Germen inferior, compressed at the base; style very short; stigma capitate, permanent.

manent. *Peric.* Capsule compressed, wedge-shaped, quadrangular, obtuse, of two cells, bursting all round near the top. *Seeds* very numerous, minute, oblong, affixed to a pendulous receptacle in each cell.

Ess. Ch. Corolla five-cleft, smaller than the calyx. Capsule compressed, of two cells, bursting all round. Seeds numerous. Receptacles curved downwards. Stigma capitate, permanent.

1. *S. zeylanica*. Willd. n. 1. (Pongati; Rheede Hort. Malab. v. 11. 47. t. 24.)—Native of moist situations in the East Indies, Cochinchina, Ceylon and Guinea. The root is fibrous and annual. *Stem* erect, one or two feet high, simple or branched, leafy. *Leaves* scattered, stalked, lanceolate, entire, smooth, somewhat fleshy, about two inches long, of a pale rather glaucous green. *Flowers* greenish-white, in dense, terminal, erect, cylindrical spikes, of no beauty, nor do we know that the plant has any valuable properties. Its general aspect is that of some kind of *Reseda*, particularly the *R. Luteola*. It was originally chosen by sir Joseph Banks to commemorate the eminent botanical merits of Gærtner, for which the striking peculiarities of its seed-vessel made it very eligible; but there is now another GÆRTNERA, of equal singularity and more beauty. See that article.

SPHENOGYNE, apparently from σφην, a wedge, and γυν, a female, in allusion to the wedge-shaped stigmas.—Brown in Ait. Hort. Kew. v. 5. 142.—Class and order, *Syngenesia Polygamia-frustranca*. Nat. Ord. *Compositæ discoideæ*, Linn. *Corymbifera*, Juss.

Gen. Ch. Common Calyx roundish, imbricated; its scales rounded or awl-shaped, concave, with a membranous dilated border, most conspicuous on the inner ones. *Cor.* compound, radiated; florets of the disk numerous, funnel-shaped, five-cleft, equal, all perfect; those of the radius about twenty, ligulate, longer than the diameter of the disk, toothed at the end imperfectly, female. *Stam.* in the florets of the disk, filaments five, capillary, short; anthers united into a tube, nearly as long as the corolla. *Pist.* Germen scarcely discernible in the florets of the radius; in those of the disk oblong, quadrangular; style thread-shaped in both; stigmas in the florets of the radius obsolete; in those of the disk dilated upwards, rather abrupt at the summit. *Peric.* none, except the permanent dry calyx. *Seeds* in the disk only, angular. Down of five rounded, membranous, horizontal scales. *Recept.* chaffy, flattish.

Ess. Ch. Scales of the receptacle distinct. Seed-down of five simple membranous leaves. Stigma dilated upwards, abrupt. Calyx imbricated; its inner scales with a membranous border.

1. *S. anthemoides*. White-crowned Sphenogyne. Ait. n. 1. (Arctotis anthemoides; Linn. Sp. Pl. 1307. Willd. Sp. Pl. v. 3. 2361. Curt. Mag. t. 544. Chamæmelum pumilum, foliis angustis pinnatis; Burm. Afr. 174. t. 63. f. 2.)—Herbaceous, smooth. Leaves simply or doubly pinnatifid, linear-thread-shaped. Seed-down white, with brown awl-shaped ribs.—A native of the Cape of Good Hope, which proves a hardy annual in our gardens, flowering from July to September. Mr. Masson introduced it in 1774. The root is fibrous. *Stem* branched. *Leaves* somewhat like chamomile. *Flowers* terminal, solitary, stalked, an inch and half or more in diameter; yellow above; their rays purple underneath. The pure white chaffy seed-crown, radiated with brown, forms the most striking part of the plant, and may be preserved with everlasting flowers through winter.

2. *S. crithmifolia*. Samphire-leaved Sphenogyne. Ait. n. 2. (Arctotis paleacea; Linn. Sp. Pl. 1307. Willd.

Sp. Pl. v. 3. 2359. After foliis integris angustis, flore magno luteo; Burm. Afr. 176. t. 65. f. 1.)—Shrubby, smooth. Leaves pinnatifid, linear-thread-shaped. Outer scales of the calyx awl-shaped.—Native of the Cape of Good Hope. A greenhouse shrub, cultivated by Miller, flowering throughout the summer. The stem is bushy. *Flowers* large, yellow. Inner scales of the calyx very broad and rounded, while the outer are awl-shaped, and scarcely membranous.

3. *S. scariofa*. Scaly-cupped Sphenogyne. Ait. n. 3. (Arctotis scariofa; Ait. ed. 1. v. 3. 274. Willd. Sp. Pl. v. 3. 2360.)—"Leaves simply or doubly pinnatifid, linear-thread-shaped, smooth. All the scales of the calyx membranous, obtuse, shining; the outermost sessile."—Sent by Mr. Masson from the Cape in 1774. A greenhouse shrub, flowering from April to August. Differs from the last in having all its calyx-scales dilated and membranous.

4. *S. abrotanifolia*. Southernwood-leaved Sphenogyne. Brown MSS. Ait. n. 4.—"Shrubby. Leaves twice or thrice pinnatifid, downy as well as the calyx."—A greenhouse shrub, sent by Mr. Masson from the Cape in 1789, and flowering all summer long.

5. *S. dentata*. Small-leaved Sphenogyne. Ait. n. 5. (Arctotis dentata; Linn. Sp. Pl. 1307. Willd. Sp. Pl. v. 5. 2359. Chrysanthemum foliorum pinnis brevissimis, dentatis; Burm. Afr. 175. t. 64.)—Shrubby. Leaves pinnatifid, nearly smooth; each segment with two or three divaricated hair-pointed teeth. Outer scales of the calyx ovato-lanceolate.—From the same country. A greenhouse shrub, flowering in June and July, introduced in 1787, by Mr. John Hunnemann. The leaves are copious, short, and crisp. *Flowers* hardly an inch broad, yellow. Points of the calyx-scales downy; the inner ones bearing a very thin, pellucid, orbicular appendage.

6. *S. odorata*. Smooth-leaved Sphenogyne. Ait. n. 6. (Anthemis odorata; Ait. ed. 1. v. 3. 238. Willd. Sp. Pl. v. 3. 2186.)—"Shrubby. Leaves flat, smooth; cut or pinnatifid at the extremity. Outer calyx-scales membranous at the point. Seeds smooth, with a slight crown."—Sent by Mr. Masson from the Cape in 1774. A greenhouse shrub, flowering from April to June. The branches are downy. *Leaves* small, half an inch long. *Flowers* on very long, almost naked, stalks.

SPHENOID, in *Anatomy*, one of the bones of the head. See CRANIUM.

SPHENO-MAXILLARY FISSURE, a large interval, in the lower and outer part of the orbit, between the sphenoid and upper jaw-bones. See CRANIUM.

SPHENO-PALATINE FORAMEN, an opening between the sphenoid and palate bones, leading into the nose. The same epithet is also given to certain nerves which go through that opening, and to the levator palati muscle.

SPHENO-PHARYNGEUS, a name applied to a part of the constrictor pharyngis superior muscle. See DEGLUTITION.

SPHENO-PTERYGO-PALATINUS, a name given by Cowper to the circumflexus palati muscle. See DEGLUTITION.

SPHENO-SALPINGO-PHARYNGEUS, a small portion of the superior constrictor of the pharynx, described under this name by Winslow.

SPHENO-SALPINGO-STAPHYLINUS, a name given by Winslow to a portion of the circumflexus palati.

SPHENO-STAPHYLINUS, the levator palati mollis, according to Drake and Cowper.

SPHERE, SPHÆRA, σφαῖρα, in *Geometry*, a solid body contained under one single surface, and having a point in the

SPHERE.

the middle, called the *centre*, whence all lines, drawn to the surface, are equal.

The sphere is supposed to be generated by the revolution of a semicircle ABC (*Plate XIV. Geometry, fig. 2.*) about its diameter AC, which is also called the *axis of the sphere*; and the extreme points of the axis, A and C, are called the *poles of the sphere*.

SPHERE, Properties of the. 1. A sphere is equal to a pyramid, whose base is equal to the surface, and its height to the radius of the sphere.

Hence, a sphere being esteemed such a pyramid, its cube, or solid content, is found like that of a pyramid.

2. A sphere is to a cylinder, standing on an equal basis, and of the same height, as 2 to 3. Hence, also, may the cube, or content of the sphere, be found.

3. A sphere is equal to four times the cone, the base of which is equal to the generating circle, and the height of which is equal to the radius. Or, a hemisphere is equal to twice the cone of the same base and height. And a cylinder, of the same height and base, being a triple of the cone, it follows, that the hemisphere is two-thirds of the cylinder, and consequently the whole sphere two-thirds of the circumscribing cylinder. Archim. de Sph. et Cycl. Apud Opera per Rivaltum, p. 67.

4. The cube of the diameter of a sphere is to the solid content of the sphere, nearly as 300 to 157: and thus, also, may the content of the sphere be measured.

5. The surface of a sphere is quadruple the area of a circle described with the radius of the sphere. For since a sphere is equal to a pyramid, whose base is the surface, and its altitude the radius of the sphere; the surface of the sphere is had, by dividing its solidity by a third part of its semi-diameter, or one-sixth of the whole diameter.

But the solidity of the sphere is the product of $\frac{2}{3}$ ds of the greatest circle by the diameter; and if this product be divided by $\frac{1}{6}$ th of the diameter, the quotient, or $\frac{1}{3}$ of the greatest circle, *i. e.* four times the greatest circle, will be the surface of the sphere.

Otherwise: the surface of a sphere is equal to the product of its diameter, and the periphery of its generating circle; but the area of this circle is equal to the product of the semi-diameter and half the periphery, or one-fourth of the product of the diameter and periphery; and, therefore, the surface of the sphere is equal to four times the area of its generating circle.

Hence, 6. The surfaces of spheres are to one another as the squares of their diameters; because these surfaces, being four times their generating circles, are as these circles, *i. e.* as the squares of their diameters.

7. Spheres being $\frac{2}{3}$ d parts of cylinders of equal base and altitude, and cylinders being as the cubes of their altitudes, are as the cubes, or in the triplicate ratio of their diameters.

8. The surface of any portion of a sphere, greater or less than the hemisphere, is equal to the area of a circle, whose radius is a line drawn from the vertex of that portion to the circumference of the circle which is its base. Archimedes, *ubi supra*, pp. 84, 85.

SPHERE, the diameter of a, being given, to find its surface and solidity. Find the periphery of the circle described by the radius of the sphere, or of the generating circle.

Multiply this, found, into the diameter, or the square of the diameter, by 3.1416, the product is the surface of the sphere. Multiply the surface by a sixth part of the diameter, or the area of the generating circle by $\frac{2}{3}$ ds of its diameter; or, again (because the area of such circle is to the square of the diameter as .7854 to 1), the cube of the

diameter by .5236 (= $\frac{1}{6}$ of .7854); and the product is the solidity of the sphere.

Thus, supposing the diameter of the sphere 56, the periphery will be found 175.9, which multiplied by the diameter, the product 9852 is the surface of the sphere; which multiplied by $\frac{1}{6}$ th part of the diameter, gives the solidity 91623.6. Or thus:

Find the cube of the diameter 175616; then to 300,157, and the cube found, find a fourth proportional. This is the solidity of the sphere required.

For finding the surface and solidity of the sphere by the method of fluxions, see SUPERFICIES and SOLIDITY. For segments and sectors of spheres, see FRUSTUM, SEGMENT, and SECTOR.

SPHERE, Doctrine of the. See SPHERICS.

SPHERE, Projection of the. See PROJECTION.

SPHERE of Activity. See ACTIVITY.

SPHERE, in Astronomy, that concave orb or expanse which invests our globe, and in which the heavenly bodies, *viz.* sun, stars, planets, and comets, appear to be fixed at an equal distance from the eye.

This is also called the *sphere of the world*; and is the subject of the spherical astronomy.

This sphere, as it includes the fixed stars, whence we also occasionally call it the *sphere of the fixed stars*, is immensely great. The diameter of the earth's orbit is so small, in respect to the diameter of this, that the centre of the sphere is not sensibly changed by any alteration of the spectator's place in the several parts of the orbit; but still, in all the points of the earth's surface, and at all times, the inhabitants have the same appearance of the sphere; that is, the fixed stars seem to possess the same points in the surface of the sphere. For our way of judging of the places, &c. of the stars, is to conceive right lines drawn from the eye, or the centre of the earth, through the centre of the stars, and continued thence till they cut the foresaid sphere; the points where these lines terminate in it are the apparent places of those stars.

The better to determine the places of the heavenly bodies in the sphere, several circles are imagined to be described in the surface thereof, hence called *circles of the sphere*.

SPHERE, in Geography, &c. denotes a certain disposition of the circles on the surface of the earth, with regard to one another, which varies in various parts of it.

The circles originally conceived on the surface of the sphere of the world, are almost all transferred, by analogy, to the surface of the earth, where they are conceived to be drawn directly underneath those of the sphere, or in the same planes with them; so that, if the planes of those of the earth were continued to the sphere, they would coincide with the respective circles upon it. Thus we have an horizon, meridian, equator, &c. on the earth.

As the equator in the heavens divides the sphere into two equal parts, the one north, and the other south, so does the equator on the surface of the earth divide the globe in the same manner.

And as the meridians in the heavens pass through the poles of the horizon, so do those of the earth, &c.

With regard, then, to the position of some of the circles in respect of others, we have a right, a parallel, and an oblique sphere.

SPHERE, Armillary, or Artificial, is an astronomical instrument, representing the several circles of the sphere in their natural order; serving to give an idea of the office and position of each of them, and to solve various problems relating to them.

It is thus called, as consisting of a number of fasciæ or rings

SPHERE.

rings of brass, or other matter, called by the Latins *armillæ*, from their resemblance to bracelets, or rings for the arm.

By this it is distinguished from the globe, which, though it hath all the circles of the sphere on its surface; yet is not cut into armillæ or rings, to represent the circles simply and alone; but exhibits also the intermediate spaces between the circles.

SPHERE, *The Armillary*, of Mr. Ferguson, constructed after the model of the glass sphere of Dr. Long, is represented *Plate XX. Astronomy, fig. 5.*

The exterior parts of this machine are a compages of brass rings, which represent the principal circles of the heavens, *viz.* 1. The equinoctial A A, which is divided into 360 degrees (beginning at its intersection with the ecliptic in Aries), for shewing the sun's right ascension in degrees; and also into twenty-four hours, for shewing his right ascension in time. 2. The ecliptic B B, which is divided into 12 signs, and each sign into 30 degrees, and also into the months and days of the year, in such a manner, that the degree or point of the ecliptic in which the sun is, on any given day, stands over that day in the circle of months. 3. The tropic of Cancer C C, touching the ecliptic at the beginning of Cancer in *e*; and the tropic of Capricorn D D, touching the ecliptic at the beginning of Capricorn in *f*; each $23\frac{1}{2}$ degrees from the equinoctial circle. 4. The arctic circle E, and the antarctic circle F, each $23\frac{1}{2}$ degrees from its respective pole at N and S. 5. The equinoctial colure G G, passing through the north and south poles of the heaven at N and S, and through the equinoctial points Aries and Libra, in the ecliptic. 6. The solstitial colure H H, passing through the poles of the heaven, and through the solstitial points Cancer and Capricorn, in the ecliptic. Each quarter of the former of these colures is divided into 90 degrees, from the equinoctial to the poles of the world, for shewing the declination of the sun, moon, and stars: and each quarter of the latter, from the ecliptic at *e* and *f*, to its poles *b* and *d*, for shewing the latitudes of the stars.

In the north pole of the ecliptic is a nut *b*, to which is fixed one end of a quadrantal wire, and to the other end a small sun Y, which is carried round the ecliptic B B, by turning the nut: and in the south pole of the ecliptic is a pin at *d*, on which is another quadrantal wire, with a small moon, Z, upon it, which may be moved round by hand: but there is a particular contrivance for causing the moon to move in an orbit which crosses the ecliptic at an angle of $5\frac{1}{2}$ degrees, in two opposite points, called the *moon's nodes*; and also for shifting those points backward in the ecliptic, as the moon's nodes shift in the heaven.

Within these circular rings is a small terrestrial globe I, fixt on an axis K K, which extends from the north and south poles of the globe at *n* and *s*, to those of the celestial sphere at N and S. On this axis is fixt the flat celestial meridian L L, which may be set directly over the meridian of any place on the globe, and then turned round with the globe, so as to keep over the same meridian upon it. This flat meridian is graduated the same way as the brass meridian of the common globe, and its use is much the same. To this globe is fitted the moveable horizon M M, so as to turn upon two strong wires proceeding from its east and west points to the globe, and entering the globe at opposite points of its equator, which is a moveable brass ring let into the globe in a groove all round its equator. The globe may be turned by hand within this ring, so as to place any given meridian upon it, directly under the celestial meridian L L. The horizon is divided into 360 degrees all round its outermost edge, within which are the points of the compass, for shewing the amplitude of the sun and

moon, both in degrees and points. The celestial meridian L L passes through two notches in the north and south points of the horizon, as in a common globe: but here, if the globe be turned round, the horizon and meridian turn with it. At the south pole of the sphere is a circle of 24 hours, fixt to the rings, and on the axis is an index which goes round that circle, if the globe be turned round its axis.

The whole fabric is supported on a pedestal N, and may be elevated or depressed upon the joint O, to any number of degrees from 0 to 90, by means of the arc P, which is fixed into the strong brass arm Q, and slides into the upright piece R, in which is a screw at *r*, to fix it at any proper elevation.

In the box T are two wheels (as in Dr. Long's sphere), and two pinions, whose axes come out at V and U; either of which may be turned by the small winch W. When the winch is put upon the axis V, and turned backward, the terrestrial globe, with its horizon and celestial meridian, keep at rest; and the whole sphere of circles turns round from east, by south, to west, carrying the sun Y, and the moon Z, round the same way, and causing them to rise above and set below the horizon. But when the winch is put upon the axis U, and turned forward, the sphere with the sun and moon keep at rest; and the earth, with its horizon and meridian, turn round from west, by south, to east; and bring the same points of the horizon to the sun and moon, to which these bodies came when the earth kept at rest, and they were carried round it; shewing that they rise and set in the same points of the horizon, and at the same times in the hour-circle, whether the motion be in the earth or in the heaven. If the earthly globe be turned, the hour-index goes round its hour-circle; but if the sphere be turned, the hour-circle goes round below the index.

And so, by this construction, the machine is equally fitted to shew either the real motion of the earth, or the apparent motion of the heaven.

To rectify the sphere for use, first slacken the screw *r* in the upright stem R, and taking hold of the arm Q, move it up or down until the given degree of latitude for any place be at the side of the stem R; and then the axis of the sphere will be properly elevated, so as to stand parallel to the axis of the world, if the machine be set north and south by a small compass: this done, count the latitude from the north pole, upon the celestial meridian L L, down towards the north notch of the horizon, and set the horizon to that latitude; then turn the nut *b* until the sun Y comes to the given day of the year in the ecliptic, and the sun will be at its proper place for that day: find the place of the moon's ascending node, and also the place of the moon, by an Ephemeris, and set them right accordingly: lastly, turn the winch W, until either the sun comes to the meridian L L, or until the meridian comes to the sun (according as you want the sphere or earth to move), and set the hour-index to the XII, marked noon, and the whole machine will be rectified. Then turn the winch, and observe when the sun or moon rise and set in the horizon, and the hour-index will shew the times of them for the given day. See Ferguson's *Lectures*, p. 194, &c.

Armillary spheres are of different kinds with regard to the position of the earth in them; whence they become distinguished into *Ptolemaic* and *Copernican* spheres: in the first of which the earth is in the centre, and in the latter near the circumference, according to the position which that planet obtains in those systems.

SPHERE, *The Ptolemaic*, is that commonly in use, and is represented (*Plate XX. Astronomy, fig. 6.*) with the names of

of the several circles, lines, &c. of the sphere, inscribed on them. In the middle, upon the axis of the sphere, is a ball, T, representing the earth, on whose surface are the circles, &c. of the earth. The sphere is made to revolve about the said axis, which remains at rest; by which means the sun's diurnal and annual course about the earth are represented according to the Ptolemaic hypothesis; and even by means of it, all problems relating to the phenomena of the sun and earth are solved, as upon the celestial globe, and after the same manner, which see described under GLOBE.

SPHERE, *The Copernican*, (represented *Plate XX. Astronomy, fig. 7.*) is very different from the Ptolemaic, both in its constitution and use; and is more intricate in both. Indeed, the instrument is in the hands of so few people, and its use so incon siderable, except what we have in the other more common instruments, particularly the globe and Ptolemaic sphere, that we shall be easily excused the not taking up room with any description of it.

SPHERES, *Harmony of the*. See HARMONY.

SPHERES, *Obliquity of the*. See OBLIQUITY.

SPHERE, *Rectifying of the*. See RECTIFYING.

SPHERE, *Dialling*. See DIALLING.

SPHERES, polished spherical masses of a mixed metalline composition, used in optics. The manner of making them is as follows.

Take of pure tin, three pounds; copper, one pound; melt these two metals together, and when in fusion cast upon the mass six ounces of burnt tartar, and an ounce and half of saltpetre; and lastly, a quarter of an ounce of alum, and two ounces of arsenic: let all these matters evaporate and burn away, and then cast the pure metal into the figure of a sphere, and it will be capable of a high and elegant polish. *Neri's Art of Glass*, p. 166. See *STEEL-Glasses*.

SPHERICAL ANGLE, is the mutual inclination of two planes, by which a sphere is cut.

Thus, the inclination of the two planes C A F and C E F, (*Plate II. Trigonometry, fig. 1.*) forms the spherical angle A C E.

The measure of a spherical angle, A C E, is an arc of a great circle A E, described from the vertex C, as from a pole, and intercepted between the legs C A and C E.

Hence, 1. Since the inclination of the plane C E F to the plane C A F is every where the same, the angles in the opposite intersections, C and F, are equal.

2. Hence the measure of a spherical angle A C E is described by the interval of a quadrant A C or E C from the vertex C, between the legs C A, C E.

If a circle of the sphere A E B F (*fig. 2.*) cut another, C E D F, the adjacent angles, A E C and A E D, are equal to two right ones; and the vertical angles, A E C and D E B, are equal to one another. The former likewise holds of several angles formed on the same arc C E D, at the same point E. Hence, any number of spherical angles, as A E C, A E D, D E B, B E C, &c. made on the same point E, are equal to four right angles. See *SPHERICAL Triangle*.

SPHERICAL Triangle, a triangle comprehended between three arcs of great circles of a sphere, intersecting each other in its surface.

SPHERICAL Triangles, Properties of. 1. If in two spherical triangles (*Plate II. Trigonometry, fig. 3.*) A B C and a b c, A = a, B A = b a, and C A = c a; then will B, b, and the sides including the angles, be respectively equal; the whole triangles are equal: that is, B C = b c, B = b, and C = c.

Again, if in two spherical triangles A = a, C = c, and A C = a c; then will B = b, A B = a b, and B C = b c.

Lastly, if in two spherical triangles A B = a b, A C =

a c, and B C = b c; then will A = a, B = b, and C = c: the demonstrations of which coincide with those of the like properties in plain triangles; the theorems of the congruency of rectilinear triangles extending to all other curvilinear, circular, parabolical, &c. provided their sides be similar. See **TRIANGLE**.

2. In an equicrural triangle A B C (*fig. 4.*) the angles at the base, B and C, are equal; and if in any triangle, the angles B and C, at the base B C, are equal, the triangle is equicrural.

3. In every spherical triangle, each side is less than a semicircle: any two sides taken together are greater than the third; and all the three sides together are less than the periphery of a great circle; and a greater side is always opposed to a greater angle, and a less side to a less angle.

4. If in a spherical triangle B A C (*fig. 5.*) two legs, A B and B C, taken together, be equal to a semicircle; the base A C being continued to D; the external angle B C D will be equal to the internal opposite one B A C. If the two legs together be less than a semicircle, the external angle B C D will be greater than the internal opposite one A; and if the legs be greater than a semicircle, the external angle B C D will be less than the internal opposite one A; and the reverse of all these holds, viz. if the angle B C D be equal to, greater, or less, than A, the sides A B and B C are equal to, greater, or less, than a semicircle.

5. If in a spherical triangle A B C, two sides, A B and B C, be equal to a semicircle, the angles at the base, A and C, are equal to two right ones: if the sides be greater than a semicircle, the angles are greater than two right ones; and if less, less; and conversely.

6. In every spherical triangle, each angle is less than two right ones; and the three together are less than six right angles, and greater than two.

7. If in a spherical triangle B A C (*fig. 5.*) the sides A B and A C be quadrants, the angles at the base, B and C, will be right angles. And if the intercepted angle A be a right angle, B C will be a quadrant: if A be obtuse, B C will be greater than a quadrant; and if acute, less; and conversely.

8. If in a spherical rectangular triangle, the side B C (*fig. 6.*) adjacent to the right angle B, be a quadrant, the angle A will be a right angle; if B E be greater than a quadrant, the angle A will be obtuse; and if B D be less than a quadrant, the angle A will be acute; and conversely.

9. If in a spherical rectangular triangle, each leg be either greater or less than a quadrant, the hypotenuse will be less than a quadrant; and conversely.

10. If in a spherical triangle A B C (*fig. 7.*) rectangular only at B, one side, C B, be greater than a quadrant, and the other side, A B, less, the hypotenuse, A C, will be greater than a quadrant; and conversely.

11. If in a spherical oblique-angular triangle A C B (*fig. 8.*) both angles at the base, A and B, be either obtuse or acute; the perpendicular C D, let fall from the third angle C, to the opposite side A B, falls within the triangle: if one of them, A, be obtuse, and the other, B, acute, the perpendicular falls without the triangle.

12. If in a spherical triangle A C, all the angles, A, B, and C, be acute, the sides are each less than a quadrant. Hence, if in an oblique-angular spherical triangle, one side be greater than a quadrant, one angle is obtuse, viz. that opposite to this side.

13. If in a spherical triangle A C B, two angles, A and B, be obtuse, and the third, C, acute; the sides, A C and C B, opposite to the obtuse angles are greater than a quadrant; and that opposite to the acute angle, A B, is less than

a quadrant. Hence, if the two sides be less than a quadrant, the two angles are acute.

14. If in a spherical triangle the several sides be each greater than a quadrant; or only two of them greater, and the third be equal to a quadrant, the several angles are obtuse.

15. If in an oblique-angular spherical triangle two sides be less than a quadrant, and the third greater; the angle opposite to the greatest will be obtuse, and the rest acute.

Spherical Triangles, Resolution of. See TRIANGLE.

Spherical Astronomy, that part of astronomy which considers the universe such as it appears to the eye. See ASTRONOMY.

Under spherical astronomy, then, are comprehended all the phenomena and appearances of the heavens and heavenly bodies, such as we perceive them, without any enquiry into the reason, the theory, or the truth of them. By which it is distinguished from *theoretical astronomy*, which considers the real structure of the universe, and the causes of those phenomena.

In the spherical astronomy, the world is conceived to be a concave spherical surface, in whose centre is the earth, or rather the eye, about which the visible frame revolves, with stars and planets fixed in its circumference. And on this supposition all the other phenomena are determined.

The theoretical astronomy teaches us, from the laws of optics, &c. to correct this scheme, and reduce the whole to a juster system.

Spherical Compasses. See COMPASSES.

Spherical Excess, in *Trigonometry*, is the excess of the sum of the three angles of any spherical triangle above three right angles; which excess in seconds, multiplied by the radius of the sphere, is equal to the area of the triangle, as was first shewn by Albert Girard.

It is extremely desirable, in geodetic operations, to be able to ascertain the spherical excess from other principles than those of the observed angles; these being very subject to small inaccuracies, from the effect of refraction near the horizon: and nothing seems better calculated for this purpose, than the foregoing property of the area of the triangle; for this being, as we have stated above, equal to the excess multiplied by the radius of the sphere, therefore, conversely, the area being known or computed on other principles, the excess may thence be determined, and the accuracy of the observed angles submitted to the test thence obtained. Now as such triangles as occur, even in the most extensive surveys, differ but little from rectilinear ones, their areas may be computed as if they really were such, with scarcely any perceptible error; and hence this important object is at once obtained.

The application of Albert Girard's theorem was first made by general Roy, or rather by Mr. Dalby, his assistant, and published in the Philosophical Transactions for 1790, p. 171, where we have the following rule: "From the area of the logarithms of the triangle, computed as a plane one, in feet, subtract the constant logarithm 9.3267737, and the remainder is the logarithm of the excess above 180° in seconds nearly." This rule is very general, and, being the first application of this principle to geodetic computations, is highly creditable to its inventor; but it is not always the most concise; and other rules have since been given by different authors, which are applicable to every variety of data. We can, however, in this place only enumerate some of the principal ones, and must refer the reader for their investigations to the works from which they have been selected.

1. The spherical excess may be found in seconds by the

expression $E = \frac{R''S}{r}$; where E is the excess; S is the surface of the triangle $= \frac{1}{2} bc \cdot \sin. A = \frac{1}{2} ab \cdot \sin. C = \frac{1}{2} ac \cdot \sin. B = \frac{1}{2} a^2 \frac{\sin. B \cdot \sin. C}{\sin. (B + C)}$; r is the radius of the

earth, in the same measure as a, b, c, the sides of the triangle; and $R'' = 206264''\cdot8$, the seconds in an arc equal in length to the radius.

If this rule be applied logarithmically, then $\log. R'' = \log. \frac{r}{\text{arc } r''} = 5\cdot3144251$.

2. Hence is readily deduced general Roy's rule, as above given, viz.

$$\log. E'' = \log. (\text{area in feet}) - 9\cdot3267737.$$

3. Since $S = \frac{1}{2} bc \cdot \sin. A$, we shall manifestly have $E = \frac{R''}{2r^2} bc \cdot \sin. A$. Hence, if from the vertical angle

B, of a spherical triangle ABC, we demit the perpendicular BD, upon the base AC, dividing it into two segments α and β , we shall have $b = \alpha + \beta$; and hence,

$$E = \frac{R''}{2r^2} c (\alpha + \beta) \sin. A \\ = \frac{R''}{2r^2} \alpha c \sin. A + \beta c \sin. A.$$

But the two right-angled triangles being in all practical cases nearly rectilinear, gives $\alpha = a \text{ cof. } C$, and $\beta = c \text{ cof. } A$; whence we have

$$E = \frac{R''}{2r^2} ac \sin. A \cdot \text{cof. } C + \frac{R''}{2r^2} c^2 \sin. A \text{ cof. } A.$$

In like manner, the triangle ABC, which is itself so small as to differ but a little from a plane triangle, gives $c \sin. A = a \sin. C$, also $\sin. A \cdot \text{cof. } A = \frac{1}{2} \sin. 2A$, and $\sin. C \cdot \text{cof. } C = \frac{1}{2} \sin. 2C$; therefore, finally,

$$E = \frac{R''}{4r^2} a^2 \cdot \sin. 2C + \frac{R''}{4r^2} c^2 \sin. 2A.$$

From which theorem a table may be formed, whence the spherical excess may be found; entering the table with each of the sides above the base and its adjacent angle as arguments.

4. If the base b, and height h, of the triangle be given, then we have evidently $E = \frac{1}{2} bh \frac{R''}{r^2}$. Hence results

the following simple logarithmic rule: Add the logarithm of the base of the triangle, taken in feet, to the logarithm of the perpendicular, taken in the same measure, and deduct from the sum the constant log. 9.6278037; and the remainder will be the common logarithm of the spherical excess in seconds and decimals.

5. Again, when the three sides of the triangle are given, then

$$\log. E = \frac{1}{2} (\log. s + \log. (s - a) + \log. (s - b) + \log. (s - c)) - 9\cdot3267737;$$

where $s = \frac{1}{2}$ sum of the sides, or $s = (a + b + c) \div 2$.

The two latter formulae are in fact only particular cases of Roy's general theorem.

6. When any two sides, *a*, *b*, and their contained angle *C*, are given, then we have

$$\cot. \frac{1}{2} E = \frac{\cot. \frac{1}{2} a \cdot \cot. \frac{1}{2} b + \cot. C}{\sin. C}$$

7. When the three sides are given, we may also, instead of the formula in art. 5, make use of the following elegant theorem, discovered by Simon L'Hullier, viz.

$$\tan. \frac{1}{4} E = \sqrt{\left(\tan. \frac{a+b+c}{4} \cdot \tan. \frac{a+b-c}{4} \cdot \tan. \frac{a-b+c}{4} \cdot \tan. \frac{-a+b+c}{4} \right)}$$

One or other of these rules will apply to all cases in which the spherical excess will be required.

We shall conclude this short article with one or two examples of its application, as given by general Roy, Phil. Transf. 1790, p. 172.

Names of Stations.	Observed Angles.
Hanger-hill Tower (a)	42° 2' 32"
Hampton Poor-house (b)	67 55 39
King's Arbour (c)	70 1 48
	<hr/>
	179 59 59

Distance in Feet.

$$\begin{aligned} (a) \text{ from } (b) &= 38461.12 \\ (a) \text{ from } (c) &= 27404.7 \end{aligned}$$

Hence, making the distance from (a) to (c) the base of the triangle, the perpendicular on that base will be equal to $38461.12 \times \sin. 42^\circ 2' 32''$; and, therefore, the area of the triangle =

$$\frac{\text{base} \times \text{perp.}}{2} = 24704.7 \times 19230.56 \times \sin. 42^\circ 2' 32''.$$

Computation.

Log. sin. 42° 2' 32"	=	9.8258661
Log. 24704.7	=	4.3927761
Log. 19230.56	=	4.2839906
		<hr/>
		18.5026328

Taking away 10 for radius, we have 8.5026328 for the log. of the area in feet.

Whence from	-	-	8.5026328
Take const. log.	-	-	9.3267737
			<hr/>
Corresp. numb. .14992	-	-	1.7158591

Whence the spherical excess in seconds is .14992", or 6".15 nearly.

Again, as a second example.

Names of Stations.	Observed Angles.
Hundred Acres (d)	53° 58' 35".75
Hanger-hill Tower (e)	68 24 44
St. Anne's Hill (f)	57 36 39.5
	<hr/>
	179 59 59.25

Distance in Feet.

$$\begin{aligned} (d) \text{ from } (e) &= 71934.2 \\ (d) \text{ from } (f) &= 79211.22 \end{aligned}$$

Log. sin. 53° 58' 35".75	=	9.9078237
Log. 35967.1	=	4.5559054
Log. 79211.22	=	4.8987866

Sum minus radius	=	9.3625207
Subtract const. log.	=	9.3267737

$$\text{Corresp. numb. 1.0858} = 0.0357470$$

Whence the spherical excess is 1".0858.

In this manner the computed spherical excess will enable the observer to examine the accuracy of his observations, and in some degree to correct them; after which he may proceed to calculate the sides of the triangles by the rules of spherical trigonometry, or by Legendre's theorem, viz. "a spherical triangle being proposed, of which the sides are very small, relatively to the radius of the sphere; if, from each of the angles, one-third of the excess of the sum above two right angles be subtracted, the angles so diminished may be taken for the angles of a rectilinear triangle, the sides of which are equal in length to those of the proposed spherical triangle."

SPHERICAL Geometry, the doctrine of the sphere; particularly of the circles described on the surface thereof, with the method of projecting the same on a plane; and measuring their arcs and angles when projected.

SPHERICAL Numbers. See CIRCULAR Numbers.

SPHERICAL Trigonometry. See SPHERICAL TRIGONOMETRY.

SPHERICITY, the quality of a sphere; or that by which a thing becomes spherical or round.

The sphericity of pebbles, fruits, berries, &c. as also of drops of water, quicksilver, &c. and of bubbles of air under water, &c. Dr. Hook takes to arise from the incongruity of their particles with those of the ambient fluid, which prevents their coalescing; and by pressing on them, and encompassing them all round equally, turns them into a round form.

This, he thinks, appears evidently from the manner of making small round shot of several sizes, without casting the lead into any moulds; from drops of rain being formed, in their fall, into round hail-stones; and from drops of water falling on small dust, sand, &c. which soon produce an artificial round mass; and from the small, round, red-hot balls, formed by the collision or fusion of flint and steel, in striking fire.

But all these cases of sphericity seem better accounted for from the great principle of attraction; by which the parts of the same fluid drop, &c. are all naturally ranged as near the centre as possible, which necessarily induces a spherical figure; and, perhaps, a repelling force between the particles of the drop, and of the medium, contributes also not a little thereto. See ATTRACTION and COHESION.

SPHERICS, the doctrine of the sphere, particularly of the several circles described on its surface; with the method of projecting the same in plano.

The principal matters shewn here are as follow:

1. If a sphere be cut in any manner, the plane of the section will be a circle, whose centre is in the diameter of the sphere.

Hence, 1. The diameter HI (Plate II. Trigonometry, fig. 9.) of a circle, passing through the centre C, is equal

to the diameter A B of the generating circle; and the diameter of a circle, as F E, that does not pass through the centre, is equal to some chord of the generating circle.

Hence, 2. As the diameter is the greatest of all chords, a circle passing through the centre is the greatest circle of the sphere; and all the rest are less than the same.

Hence also, 3. All great circles of the sphere are equal to one another.

Hence also, 4. If a great circle of the sphere passes through any given point of the sphere, as A, it must also pass through the point diametrically opposite to it, as B.

Hence also, 5. If two great circles mutually intersect each other, the line of section is the diameter of the sphere; and therefore two great circles intersect each other in points diametrically opposite.

Hence also, 6. A great circle of the sphere divides it into two equal parts or hemispheres.

2. All great circles of the sphere cut each other into two equal parts; and, conversely, all circles that thus cut each other are great circles of the sphere.

3. An arc of a great circle of the sphere, intercepted between another arc H I L (*fig. 10.*), and its poles A and B, is a quadrant. That intercepted between a less circle D E F, and one of its poles A, is greater than a quadrant; and that between the same, and the other pole B, less than a quadrant; and conversely.

4. If a great circle of the sphere passes through the poles of another, that other passes through the poles of this. And if a great circle passes through the poles of another, the two cut each other at right angles; and conversely.

5. If a great circle, as A F B D, passes through the poles A and B of a lesser circle D E F, it cuts it into equal parts, and at right angles.

6. If two great circles, A E B F and C E D F, (*fig. 11.*) intersect each other in the poles E and F of another great circle A C B D; that other will pass through the poles I and i, H and h, of the circles A E B F and C E D F.

7. If two great circles, A E B F and C E D F, cut each other mutually; the angle of obliquity, A E C, will be equal to the distance of the poles H, I.

8. All circles of the sphere, as G F and L K (*fig. 12.*) equally distant from its centre C, are equal; and the farther they are removed from the centre, the less they are. Hence, since of all parallel chords, only two, G F and L K, are equally distant from the centre; of all the circles parallel to the same great circle, only two are equal.

9. If the arcs F H and K H, and G I and I L, intercepted between a great circle I M H, and the lesser circles G N F and L O K, be equal, the circles are equal.

10. If the arcs F H and G I, of the same great circle A I B H, intercepted between two circles G N F and I M H, be equal, the circles are parallel.

11. An arc of a parallel circle, I G, (*fig. 1.*) is similar to an arc of a great circle, A E; if each be intercepted between the same great circles C A F and C E F.

Hence, the arcs A E and I G have the same ratio to their peripheries; and, consequently, contain the same number of degrees. And hence the arc I G is less than the arc A E.

12. The arc of a great circle is the shortest line which can be drawn from one point of the surface of the sphere to another; and the lines between any two points on the same surface are the greater, as the circles of which they are arcs are the less.

Hence, the proper measure, or distance, of two places on the surface of the sphere, is an arc of a great circle inter-

cepted between the same. See more on this subject in Theodosii Elem. Sphær. apud Dechales Curfus Mathematicæ, tom. i. p. 145, &c.

SPHEROID, ΣΦαιροειδης, formed from σφαιρα, *sphæra*, and εἶδος, *shape*, in *Geometry*, a solid approaching to the figure of a sphere, though not exactly round, but oblong; as having one of its diameters bigger than the other; and generated by the revolution of a semi-ellipsis about its axis.

When it is generated by the revolution of the semi-ellipsis about its greater or transverse axis, it is called an *oblong* or *prolate spheroid*: and when generated by the revolution of an ellipsis about its less or conjugate axis, an *oblate spheroid*.

The contour of a dome, Daviler observes, should be half a spheroid. Half a sphere, he says, is too low to have a good effect below.

For the solid dimension of a spheroid, multiply continually together the fixed axis, the square of the revolving axis, and the number .52359877, or $\frac{1}{2}$ of 3.14159, and the last product will be the solidity: *i. e.* $\frac{1}{2} p t t c$ = the oblate, and $\frac{1}{2} p t c c$ = the oblong spheroid, where $p = 3.14159$, t = the transverse, and c = the conjugate axis of the generating ellipsis. Or, multiply the area of the generating ellipsis by $\frac{2}{3}$ of the revolving axis, and the product will be the content of the spheroid: *i. e.* $\frac{2}{3} t A$ = the oblate, and $\frac{2}{3} c A$ = the oblong spheroid; where A is the area of the ellipsis. *E. g.* Required the content of an oblate, and of an oblong spheroid, the axes being 50 and 30. Thus, $50 \times 30 \times .78539816 = 1178.09724$ = the area of the ellipsis. And $1178.09724 \times \frac{2}{3} \times 30 = 23561.9448$ = the oblong spheroid: and $1178.09724 \times \frac{2}{3} \times 50 = 39269.908$ = the oblate one.

Dr. Hutton has demonstrated the rule above given in the following manner. Put $f = B I$ the fixed semi-axis, (*Plate XIV. Geometry, fig. 3.*) $r = I M$ the revolving semi-axis of the spheroid, $a = S I$ any semi-diameter of the section N B M, $b = I K$ its semi-conjugate, $y = A E$ an ordinate to the diameter S I, or a semi-axis of the elliptic section A F C parallel to K L, and $z = E F$ its other semi-axis, also $x = E I$, s = the sine of the angle A E S, or of the angle K I S, to the radius 1, and $p = 3.14159$.

Then, by the property of the ellipse K S L, $aa : bb$

$$:: aa - xx : bb \times \frac{aa - xx}{aa} = yy; \text{ and } b : r :: y : \frac{ry}{b}$$

= z. But the fluxion of the solid K A C L is $psyz \dot{x}$

$$= \frac{psryy \dot{x}}{b}, \text{ by writing for } z \text{ its value } \frac{ry}{b}, = pbsr \dot{x} \times$$

$$\frac{aa - xx}{aa}, \text{ by substituting for } yy \text{ its value } bb \times \frac{aa - xx}{aa},$$

$$= pfr r \dot{x} \times \frac{aa - xx}{aaa}, \text{ by putting for } abs \text{ its value } rf;$$

$$\text{and hence the fluent } pfr r x \times \frac{aa - \frac{1}{2}xx}{aaa}, \text{ or } \frac{1}{2} pfr r x$$

$$\frac{3aa - xx}{aaa}, \text{ will be the value of the frustum K A C L;}$$

which, when E I or x becomes S I or a, gives $\frac{1}{2} pfr r$ for the value of the semi-spheroid K S L; or the whole spheroid = $\frac{1}{2} p F R R$, putting F and R for the whole fixed and revolving axes. Q.E.D.

Corol. 1.—From the foregoing demonstration it appears that

SPHEROID.

that the value of the general frustum K A E C L is expressed by $\frac{1}{2} p f r r x \times \frac{3 a a - x x}{a a a}$.

And if for $f r$ be substituted its value $a b s$, the same frustum will also be expressed by $\frac{1}{2} p b r s x \times \frac{3 a a - x x}{a a}$.

Also, if for $a a$ be put its value $\frac{b b x x}{b b - y y}$, the last expression will become $\frac{1}{2} p r s x \times \frac{2 b b + y y}{b}$, or $\frac{1}{2} p s x \times$

$(2 b r + \frac{r y y}{b})$; which, by writing z instead of its value

$\frac{r y}{b}$, gives $\frac{1}{2} p s x \times (2 b r + y z)$ for the value of the frustum, viz. the sum of the area of the less end, and twice that of the greater, drawn into one-third of the altitude or distance of the ends.

And out of this last expression may be expunged any one of the four quantities b, r, y, z , by means of the proportion $b : r :: y : z$.

When the ends of the frustum are perpendicular to the fixed axis, then a is $= f$, and the value of the frustum becomes $\frac{1}{2} p r r x \times \frac{3 f f - x x}{f f}$ for the value of the frustum whose ends are perpendicular to the fixed axis, its altitude being x .

And when the ends of the frustum are parallel to the fixed axis, a is $= r$, and the expression for such a frustum becomes $\frac{1}{2} p f x \times \frac{3 r r - x x}{r}$.

Corol. 2.—If to or from $\frac{1}{2} p f r r$, the value of the semi-spheroid, be added or subtracted $\frac{1}{2} p f r r x \times \frac{3 a a - x x}{a a a}$, the value of the general frustum K A C L, there will result

$\frac{1}{2} p f r r b b \times \frac{3 a - b}{a a a}$ for the value of a general segment,

either greater or less than the semi-spheroid, whose height, taken upon the diameter passing through its vertex and centre of its base, is $b = a \pm x$.

When a coincides with f , the above expression becomes

$\frac{1}{2} p r r b b \times \frac{3 f - b}{f f}$ for the value of a segment whose base

is perpendicular to the fixed axis.—And here, if we put R for the radius of the segment's base, and for $r r$ its

value $\frac{R R f f}{2 f b - b b}$, the said segment will become $\frac{1}{2} p R R b \times$

$\frac{3 f - b}{2 f - b}$.

And when a coincides with r , the general expression will become $\frac{1}{2} p f b b \times \frac{3 r - b}{r}$ for the value of the segment

whose base is parallel to the fixed axis. And if we put F, R , for the two semi-axes of the elliptic base of this

segment, respectively corresponding or parallel to f, r , the semi-axes of the generating ellipse, when parallel to the

base of the segment, and for $\frac{f}{r}$ and r substitute their

values $\frac{F}{R}$ and $\frac{R R + b b}{2 b}$, the said frustum will be ex-

pressed by $\frac{1}{2} p F b \times \frac{3 R R + b b}{2 R}$, in which the dimensions

of itself only are concerned.

Corol. 3.—A semi-spheroid is equal to $\frac{2}{3}$ ds of a cylinder, or to double a cone of the same base and height; or they are in proportion as the numbers 3, 2, 1. For the cylinder is $= 4 n f r r = \frac{1}{2} n f r r$, the semi-spheroid $= \frac{2}{3} n f r r$, and the cone $= \frac{1}{3} n f r r$.

Corol. 4.—When $f = r$, the spheroid becomes a sphere, and the expression $\frac{2}{3} f n r r$ for the semi-spheroid becomes $\frac{2}{3} n r^3$ for the semi-sphere. And in like manner, f and r being supposed equal to each other in the values of the frustums and segments of a spheroid, in the preceding corollaries, will give the values of the like parts of a sphere.

Corol. 5.—All spheres and spheroids are to each other as the fixed axes drawn into the squares of the revolving axes.

Corol. 6.—Any spheroids and spheres, of the same revolving axis, as also their like or corresponding parts cut off by planes perpendicular to the said common axis, are to one another as their other or fixed axes. This follows from the foregoing corollaries.

Corol. 7.—But if their fixed axes be equal, and their revolving axes unequal, the spheroids and spheres, with their like parts terminated by planes perpendicular to the common fixed axis, will be to each other as the squares of their revolving axes.

Corol. 8.—An oblate spheroid is to an oblong spheroid, generated from the same ellipse, as the longer axis of the ellipse is to the shorter. For, if T be the transverse axis, and C the conjugate; the oblate spheroid will be $= \frac{2}{3} n T^2 C$, and the oblong $= \frac{2}{3} n C^2 T$; and these quantities are in the ratio of T to C .

Corol. 9.—And if about the two axes of an ellipse, be generated two spheres and two spheroids, the four solids will be continual proportionals, and the common ratio will be that of the two axes of the ellipse; that is, as the greater sphere, or the sphere upon the greater axis, is to the oblate spheroid, so is the oblate spheroid to the oblong spheroid, so is the oblong spheroid to the less sphere, and so is the transverse axis to the conjugate. For these four bodies will be as $T^3, T^2 C, T C, C^3$, where each term is to the consequent one as T to C .

To find the content of an universal spheroid, or a solid conceived to be generated by the revolution of a semi-ellipse about its diameter, whether that diameter be one of the axes of the ellipse or not. 1. Divide the square of the product of the axes of the ellipse by the axis of the solid, or the diameter about which the semi-ellipse is conceived to revolve: multiply the quotient by .5236, and

the product will be the content required. That is, $\frac{T^2 C^2}{d}$

$\times .5236 =$ the content; T and C being the transverse and conjugate axes of the ellipse, and d the axis of the solid.

Or, 2. The continual product of .5236, the diameter about which the revolution is made, the square of its conjugate diameter, and the square of the sine of the angle made

made by those diameters, the radius being 1, will be the content. That is, $d e s s \times .5236 =$ the content; c being the conjugate diameter to d , and s the sine of the angle made by the diameters. For the demonstration of this rule, see Hutton, ubi infra.

Hence, if $d = T$, the rule becomes $\frac{1}{2} p T C^2$ for the oblong spheroid: and if $d = C$, it will be $\frac{1}{2} p C T^2$ for the oblate spheroid: and if T , C , and d , be all equal, the rule will be $\frac{1}{2} p d^3$ for the sphere. See MENSURATION. Hutton's Mensuration.

For the method of finding the superficies of a spheroid, see SUPERFICIES; and for the solidity, see SOLIDITY, and the preceding article.

Dr. Halley has demonstrated, that in a sphere, Mercator's nautical meridian line is a scale of logarithmic tangents of the half complements of the latitudes. But as the earth has been found to be a spheroid, this figure will make some alteration in the numbers resulting from Dr. Halley's theorem. Mr. Maclaurin has therefore given us a rule, by which the meridional parts to any spheroid may be found with the same exactness as in a sphere. We have also an ingenious treatise of Mr. Murdoch's on the same subject. See Phil. Trans. N° 219.

Mr. Cotes has also demonstrated the same proposition, Harm. Mens. p. 20, 21. See MERIDIONAL Parts.

SPHEX, in Entomology, a genus of insects of the order Hymenoptera, of which the generic character is as follows. The mouth is formed with an entire jaw; the mandibles are horny, incurved, and toothed; the lip is horny and membranaceous at the tip; it has four feelers; the antennæ have about ten articulations; the wings in each sex are plane, incumbent, and not folded; the sting is pungent, and concealed within the abdomen. The insects of this genus are said to be the most savage and rapacious of this class of beings: they attack whatever comes in their way, and by means of a poisonous sting, overcome and devour others far beyond their own size. Those of division B, hereafter to be described, are found chiefly on umbellate plants; the larvæ are without feet, soft, and inhabit the body of some insect, on whose juices they exult; the pupa has rudiments of wings.

"As the insects," says Dr. Shaw, "of the genus Ichneumon deposit their eggs in the bodies of other living insects, so those of the genus SpheX deposit their's in dead ones, in order that the young larvæ, when hatched, may find their proper food." There are more than a hundred species of the genus SpheX, which are separated into divisions.

Species.

A. Antennæ setaceous; Lip entire; and no Tongue.

APPENDIGASTER. This species is black; the abdomen is petiole, very short, and placed on the back of the thorax; the hind-legs are very long. This is found in divers parts of Europe, Africa, and New Holland.

*MACULATA. Thorax spotted; first segment of the abdomen with a white dot on each side; the second is edged with white. It is, as the asterisk denotes, an English insect. There is a specimen of it in sir Joseph Banks's museum.

FASCIATA. Black; abdomen with two white bands, the first interrupted; and the tail is white. It is found in different parts of Italy. The thorax is black, covered with silvery down on the fore-part; the fore-margin is marked with a white line; the wings are white, but tipped with brown.

SESSILIS, so named on account of its short, cylindrical, sessile abdomen. The insect is black. It inhabits France; is very like the *S. appendigaster*.

PUNCTUM. This is black; but the tail is marked with a white dot. It is an Italian insect.

NIGRITIA. This also is black; the upper wings are marked with a brown band.

B. *Antennæ filiform; Lip emarginate; with a Bristle on each side; the Tongue is inflexed and trifid.*

Of this section there are two subdivisions; the one has a petiolate abdomen, that of the other is sessile.

a. Abdomen petiolate.

LUTARIA. Black; second and third segments of the abdomen rufous; the lip is silvery. It inhabits Kiel.

THOMÆ. Black; abdomen rufous; the petiole, and spot on the back, black. It inhabits St. Thomas's island.

FERVENS. This is likewise black; the abdomen is ferruginous; the wings are brown. It inhabits India.

CYANIPENNIS. Villous, blue; fore-part of the thorax and abdomen grey; the wings are blue. It inhabits Cayenne, and is large. This is a very beautiful insect; the head is blue; the mandibles and antennæ are black; the abdomen blueish-grey; the petiole black; legs black; the joints yellowish.

HÆMORRHOIDALIS. Black; lip, tail, and legs, ferruginous. Inhabits Africa. A specimen is preserved in the museum of sir Joseph Banks.

ARGENTEA. Glossy-black; front villous, silvery; the wings are white, but tipped with brown. It inhabits Comandel, and is a large insect.

RUFIPENNIS. Black; wings ferruginous, tipped with brown. It inhabits Tranquebar, and is large.

FLAVIPENNIS. Black; front golden; abdomen rufous; the petiole and tips are black. It inhabits Italy.

PENNSYLVANICA. This is of a blackish hue; the abdomen is of a full black; but the wings are inclining to a violet. It inhabits America and New Holland.

VIOLACEA. Blue; wings white, tipped with brown; the antennæ are black. It is found at the Cape of Good Hope.

CYANEA. Blue; wings azure, tipped with brown; the antennæ are black. It inhabits North America.

AURULEATA. Head and thorax covered with gold down; the abdomen is black; the base and legs rufous. It is an inhabitant of Tranquebar.

TOMENTOSA. The head and thorax of the insects of this species are covered with a gold down; the abdomen is black; the base and legs are rufous. It inhabits Sierra Leone.

FEMORATA. This is blue; the abdomen is black; the hind-thighs are rufous. It inhabits Italy.

TIBIALIS. Hairy, black-blue; hind-thighs ferruginous; wings black. It inhabits the Cape of Good Hope. A specimen is preserved in the museum of sir Joseph Banks.

FLAVIPES. Villous, black, with a yellow dot before the wings; the legs are yellow; the thighs black. It inhabits America.

ATRA. This is quite black, excepting the lip, which is silvery villous; wings as long as the abdomen. It inhabits Italy.

FIGULUS. Smooth, black; segments of the abdomen at the edges and lip lucid. It inhabits Upsal, in the holes and crevices of wooden partitions, abandoned by all other insects. According to Dr. Shaw, this insect, when it has found a convenient cavity for the purpose, seizes on a spider,

spider, which it kills, and deposits it at the bottom; then laying her egg in it, she closes up the orifice of the cavity with clay; the larva, which resembles the maggot of a bee, having devoured the spider, spins itself up a dusky silken web, and changes into a chrysalis, out of which, within a certain number of days, proceeds a complete insect, which is black, with a slightly foot-stalked abdomen, the edges of the several segments being of a brighter appearance than the rest of the body. The female of this species prepares several separate holes, or nets, in each of which she places a dead insect and an egg; each cell costing her the labour of about two days.

LUNATA. The abdomen of this insect is black; the first segment is marked with a yellow lunule. It inhabits America, as does the next.

AFFINIS. Villous, black; the first joint of the antennæ, scutell, and shanks, are yellow.

JAMAICENSIS. This, as its name implies, is found in Jamaica. The abdomen is black; the first segment, and edge of the others, are yellow.

ERYTHROCEPHALA. Black; head, base of the petiole, and legs, ferruginous. It inhabits Malabar. A specimen is kept in the museum of Sir Joseph Banks.

* **SPIRIFEX.** Black; thorax hairy, and immaculate; petiole of one joint, yellow; as long as the abdomen. There is a variety, of which the petiole and joints of the legs are half yellow. It is found in this country, in divers parts of Europe, and also in Africa, particularly in Egypt, in cylindrical cavities wrought within like a honey-comb, on the sides of cliffs, and in the mud walls of cottages.

MADRASPATANA. Black; thorax hairy, and spotted with yellow; the petiole is yellow, and as long as the abdomen. It inhabits Malabar.

CLAVUS. Black; thorax spotted; abdomen blueish; the petiole long, rufous, with a black band. This is an inhabitant of New Holland.

HOLOSERICEA. Black, with a silvery down; abdomen ferruginous; the petiole is black, and the tail blue. It is found in Barbary.

PUBESCENS. Black, with silvery down; the abdomen is ferruginous, with a black petiole. It inhabits Guinea, and is found among the grass.

CINCTA. Black, with silvery down; the segments of the abdomen are edged with white. This, like the last, is found in Guinea.

LOBATA. Green-blue; thorax with a distinct fore-lobe; the wings are sub-ferruginous. It is an inhabitant of Africa.

CILIATA. Testaceous; abdomen blue; mandibles elongated and ciliate. This is an Indian insect.

COMPRESSA. Shining green; the hind-thighs are compressed, ferruginous. It inhabits Malabar.

SIBIRICA. Polished brassy-green; the abdomen is blue. An inhabitant of Siberia.

ICHNEUMONEA. Fulvous; abdomen black, with a ferruginous base. It is found in divers parts of America.

HIRTIPES. Hairy, dusky; abdomen shining black; wings testaceous. It inhabits Guinea.

ALBIFRONS. Glabrous, black; front covered with a silvery brown; wings white, with a black base. This also is found in Guinea.

MAXILLOSA. Black, with silvery down; abdomen ferruginous at the base; the mandibles are projected, curved, and toothed. It is a large insect, and is found in Barbary.

UNICOLOR. Dusky-brown, with cinereous down. It is found in Spain, on umbellate flowers.

INDOSTANEE. Black; wings blueish-black, with a hyaline thinner margin. Found in Europe and India.

CLAVIPES. Black; petiole ferruginous, clavate, of one joint; legs clavate. This is a small insect, and is found in several parts of Europe.

AUSTRIACA. Black; base of the abdomen with a sulphur-coloured band and two dots; the legs are varied with sulphur; the hind-thighs are thickened. It inhabits, as its name denotes, Austria.

BIDENS. Black; head and antennæ ferruginous; the abdomen is marked with four yellow spots; the thorax is two-spined. It inhabits Mauritania, and is a large insect.

INSUBRICA. Black; front, mouth, scutell, and two bands on the abdomen, of a pale yellow. It inhabits Padua; breeds in chimneys and windows, in the same nest with the Ichneumon seductor.

b. *Abdomen sessile.*

MORIO. Black, immaculate; wings dark brown. It inhabits New Holland.

COLLARIS. Black-blue; fore-lobe of the thorax fulvous. It inhabits New Holland.

FRONTALIS. Black; front and fore-lobe of the thorax yellow. It inhabits New Holland.

ANALIS. Glabrous, black; abdomen ferruginous at the tip; wings white. It inhabits India.

SIMILIS. This insect is glabrous, black, abdomen ferruginous at the tip; the wings are white.

ASSIMILIS. Black; antennæ, tail, and legs, rufous; wings blue; the base and tip white. This is found at Tranquebar.

DIMIDIATA. Black; the head and fore-part of the thorax dull ferruginous; the wings are black. This is an inhabitant of Barbary.

* **FUSCA.** Black, glabrous; base of the abdomen ferruginous. This inhabits gravelly places in Europe; after having destroyed the larva of a moth, it deposits its eggs in its carcase, and then digs a hole and buries it.

VIATICA. Black, downy; fore-part of the abdomen ferruginous, with black belts; wings brown.

URSUS. Black, hairy; second segment of the abdomen ferruginous; wings black.

AMETHYSTINA. Blue; antennæ and legs black. It inhabits Santa Cruz.

CINGULATA. Black; front streak on the fore-part of the thorax, and edges of the abdominal segments, cinereous. It inhabits New Holland.

NIGRA. Black; segments of the abdomen with lucid margins.

LABIATA. Black; segments of the abdomen edged with cinereous; the wings are testaceous, tipped with brown. It inhabits the South American islands.

VARIEGATA. Black, spotted with white; thorax rufous under the scutell; the wings are tipped with brown. This is found in Saxony.

SANGUIOLENTA. Black; thorax rufous before and behind; segments of the abdomen lucid at the margin. This is a very small insect, and is found in several parts of Germany.

MIXTA. Black, varied with yellow; abdomen yellow, with three black bands. This is an American insect.

MAURA. Black; hind-thighs rufous; inhabits Tranquebar.

HYALINATA. Black; four hind-thighs rufous; wings hyaline. Found in Saxony.

FUSCATA. Black; abdomen with a white transverse dot

SPHEX.

on each side; hind-thighs rufous; wings tipped with brown. It inhabits Saxony.

SEX-PUNCTATA. Black, with two white dots under the scutellum, and four on the abdomen; wings tipped with brown.

BI-FASCIATA. Black, immaculate; wings with two black bands. This is an inhabitant of Paris.

GIBBA. Black; abdomen ferruginous, tipped with brown; upper wings brown at the tip. This is found in divers parts of Europe.

FASCIATA. Black; antennæ rufous; wings white, with two brown bands. This is found in New Holland, as is the next.

CINEREA. Cinereous; segments of the abdomen black at the base, and brown at the tip.

TROPICA. Black; second segment of the abdomen ferruginous. This is found in different parts of America.

FUGAX. Thorax covered with gold down; abdomen ferruginous; wings yellowish, with a brown band.

AURATA. Head and thorax with gold down; abdomen black, the edges of the segments cinereous. This is found in the East Indies.

NITIDA. Ferruginous; thorax golden behind; wings yellowish. It inhabits New Holland.

* **RUFIPES.** Black; the segments of the abdomen are marked with a white dot on each side; the wings are tipped with brown. Found in England, and on divers parts of the European continent.

BI-PUNCTATA. Black, glabrous; abdomen marked with two white dots and a band behind; the wings are tipped with brown. This is an European insect.

NIGRICORNIS. Black; head and thorax rufous. It is found in New Holland.

EXALTATA. Black; abdomen rufous, tipped with black; wings brown at the tip, with a white dot.

MACULATA. Black; thorax spotted with white; first segment of the abdomen rufous, the rest with a transverse white line on each side. It inhabits Kiel.

TRICOLORATA. Black; abdomen with silver lunules on each side, the base is rufous, the tip black. This is a Barbary insect.

GUTTATA. Black, glabrous; thorax spotted with white; abdomen rufous, with transverse dots, and black before the tip. This is very like the *S. maculata*, and is found in Italy.

ABDOMINALIS. Black; thorax with a cinereous band before; abdomen rufous; wings tipped with brown. It inhabits Brazil.

CAPENSIS. Black; antennæ, shanks, and wings testaceous, the latter tipped with brown. It inhabits the Cape of Good Hope.

NIGRITA. Black; wings blue. Inhabits Malabar.

TURCICA. Black; thorax with a cinereous band before; abdomen rufous; wings black. It is an inhabitant of Brazil.

NIGRIPES. Black; abdomen ferruginous; wings dusky; legs black. It inhabits Africa.

VILLOSA. Black; abdomen villous, testaceous; wings deep black; legs rufous. It is found at Malabar, and is very small.

DISCOLOR. Black, glabrous; wings yellow, tipped with black. It is found in Barbary.

FLAVA. Black; head, thorax, and tail, ferruginous; wings yellow, tipped with brown. It is found in the East Indies.

BICOLORATA. Black; head, tip of the abdomen, and wings, yellow, the latter tipped with brown. This is a New Holland insect.

SPECIOSA. Deep black; wings rufous, tipped with white.

FULVIPENNIS. Black; head, fore-part of the thorax, tail and legs, rufous; wings fulvous, tipped with blue. This is an inhabitant of India.

NOBILIS. This species is varied with silver and black; wings white, with two black bands. It inhabits Cayenne.

BREVICORNIS. Black; thorax ferruginous; abdomen with six white spots. It is found in Barbary: in a variety the abdomen is immaculate.

OCCELLATA. Black; legs testaceous; wings black, with an ocellar ferruginous spot on the upper pair. Found in Africa.

RUFICORNIS. Blue; antennæ rufous; legs black.

QUADRI-PUNCTATA. Black; antennæ, streaks on the fore-part of the thorax and scutellum; there are four dots on the abdomen, and the wings are ferruginous. It is found in Spain.

CÆRULEA. Blue; wings ferruginous, upper pair whitish at the tip. It inhabits South America, as does the next.

STELLATA. Blue; wings black, upper pair with a rufous spot in the middle, and whitish at the tip.

PLUMBEA. Lead-colour; antennæ black; upper wings tipped with brown. It is found in Spain, and is very small.

PECTINIPES. Black, glabrous; fore-part of the abdomen ferruginous; fore-legs ciliate.

VARIEGATA. Entirely black; wings spotted with white. Seen in divers parts of Europe.

ANTARCTICA. Black; antennæ and legs ferruginous; is about the size of a wasp, and is found at the Cape of Good Hope.

PALMIPES. Black; thorax with two yellow dots at the tip, and one at the base; the fore-legs are palmate. It inhabits Sweden.

EPHIPPICA. Black; front blueish; abdomen with a double ferruginous band. It is the size of a gnat, and inhabits Sweden.

STIGMA. Wings angular, grey-brown and reddish beneath, with white spots. It is an inhabitant of the Cape.

INDICA. Black; antennæ and legs ferruginous; wings blueish-black. It is found in South America.

COLON. Black; antennæ and legs rufous; thorax green; wings with two black spots. It inhabits Sweden.

MAURITANICA. Black; head, antennæ, and legs, ferruginous, with a black border. It inhabits Mauritania, and is reckoned among the large insects of this genus.

COLLARIS. Black; wings brown, with a white band in the middle and at the end; antennæ and legs testaceous. Inhabits Spain, and is the size of a common ant. Its neck is yellow.

CORONATA. Abdomen black, with two yellow belts and dots; head and thorax spotted with yellow. It inhabits Switzerland.

* **XANTHOCEPHALUS.** Black; front yellow; abdomen and legs spotted with yellow. It inhabits England.

* **SPINOSA.** Black; thorax with a spine on each side behind; the lip and breast are silvery. It inhabits England.

ALBOMACULATA. Black; abdomen ferruginous at the base; wings brown, with a white spot at the tip.

TRICOLOR. Black; segments of the abdomen very varied in number, some of them are testaceous, and others dotted with white.

BOOPS. Black; three segments of the abdomen and tarsi testaceous. It is an Austrian insect.

TOMENTOSA. Black, downy; antennæ thick at the base;

base; the three first segments of the abdomen are ferruginous; the base and tip are black.

COCCINEA. Black; antennæ, jaws, tip of the abdomen, and flanks, scarlet; thorax with a tooth on each side behind; wings yellow, the hind margin brown.

SPINIPES. Black, hairy; wings yellow; the hind margin brown, with a black spot at the base of the upper pair; segments of the abdomen vary from two to four, which are yellow on the hind margin of each side. Its abode is not known.

GUTTATA. Black; with white lines and dots; wings pale yellow; legs rufous.

LEUCOMELLIS. Black; wings white towards the hind margin; first segment of the abdomen white on each side; the third with an ovate white spot on the back; the four hind-legs are rufous.

MELANOCHLORA. Black; abdomen ferruginous at the base. This is an European insect.

TESTACEA. Black; legs and abdomen testaceous, the latter brown at the tip.

CASPA. The abdomen of this is black, with four yellow elevated bands; the three upper ones intersected by a triangular black spot. It inhabits near the Caspian sea.

SPHINCTER, in *Anatomy*, a name given to muscles which surround, and have the office of closing, certain openings.

SPHINCTER Ani, the muscle surrounding the extremity of the large intestine. See **INTESTINE**.

SPHINCTER Laborum, the same as the orbicularis oris. See **DEGLUTITION**.

SPHINCTER Iridis. See **EYE**.

SPHINCTER Oesophagi. See **DEGLUTITION**.

SPHINCTER Vagine. See the description of that canal under **GENERATION**.

SPHINCTER Vesicae. See the description of the urinary bladder under **KIDNEY**.

SPHINX, σφιγξ, in *Sculpture*, &c. a figure or representation of a monster of that name, famed among the ancients, now mostly used as an ornament in gardens, terraces, &c.

It is represented with the head and breasts of a woman, the wings of a bird, the claws of a lion, and the rest of the body like a dog or lion.

It is supposed to have been engendered by Typhon, and sent by Juno to be revenged on the Thebans. Its office, they say, was to propose dark enigmatical questions to all passers by; and, if they did not give the explication of them, to devour them.

It made horrible ravages, as the story goes, on a mountain near Thebes, and could not by any means be destroyed, till after Ædipus had solved the following riddle: What animal is it that in the morning walks on four legs, at noon on two, and at night on three? The answer was, Man.

Among the Egyptians, the sphinx was the symbol of religion, by reason of the obscurity of its mysteries. And, on the same account, the Romans placed a sphinx in the pronaos or porch of their temples.

Sphinxes were used by the Egyptians to shew the beginning of the water's rising in the Nile: with this view, as it had the head of a woman and body of a lion, it signified that the Nile began to swell in the months of July and August, when the sun passes through the signs of Leo and Virgo. Accordingly it was a hieroglyphic, which taught the people the period of the most important event in the year, as the swelling and overflowing of the Nile gave fertility to Egypt. Accordingly they were multiplied without end, so that they were to be seen before all their temples, and before all their remarkable monuments,

There are several of these still to be seen; one in particular, near the pyramids, facing the second pyramid on the eastern side, much spoken of by the ancients, being of a prodigious size, and cut out of the rock; the head and neck only appear at present, the rest of the body being hid in the sand. The top of its back only is visible, which is more than 100 feet long. It is of one single stone, making part of the rock on which the pyramids are placed. Its head rises about twenty-nine feet above the sand. This, according to Thevenot, is twenty-six feet high, and fifteen feet from the ear to the chin; but Pliny assures us, the head was no less than one hundred and two feet in circumference, and sixty-two feet high from the belly, and that the body was one hundred and forty-three feet long, and was thought to be the sepulchre of king Amasis.

Some have suggested, that the well of the great pyramid led to this monster, and that the priests resorted thither at certain times to pronounce their oracles; alleging, that a hole placed at the top of the sphinx's head answered their purpose; but this hole is only five feet deep, and communicates neither with the mouth nor with the inside of the monster. The Arabs, inspired by Mahomet with a horror for all representations of men and animals, have disfigured its face with arrows and lances. Some have urged, without sufficient reason, that the sphinx countenances the opinion that the Egyptians were black, the face of that statue having been said to resemble the negro. The statues of the Nile, it is said, were made of black marble, in allusion to his coming from Ethiopia. If the sphinx was a symbol that had any relation to this subject, might not the negro face be given to it for a similar reason? It would hardly have been thought necessary to explain why the figure of the Nile was black, if the complexion of the natives had been generally acknowledged of the same tinge.

The small statues of Isis, &c. frequently found among the ruins of Egypt, are far from resembling those of the negro: the same observation is applicable to the figures in alto relievo and basso relievo, on the walls of Thebes, in the caverns of Gebel-el-Sillili, &c. Of the colossal statues at Thebes, the features are too much damaged to be adduced in proof of the pretended fact.

The learned Mr. Bryant (*Anc. Mythol.* vol. iii. p. 532.) observes, that the sphinx seems to have been originally a vast rock of different strata; which, from a shapeless mass, the Egyptians fashioned into an object of beauty and veneration.

The Egyptians used this figure in their building; from them the Greeks derived it, and afterwards improved it into an elegant ornament.

SPHINX, the *Hawk-moth*, in *Entomology*, a genus of insects of the order Lepidoptera, of which the generic character is as follows: Antennæ somewhat prismatic, tapering at each end; the tongue is exerted; feelers two, reflected; the wings are deflected.

The insects of this genus, of which there are nearly two hundred species, fly abroad only in the morning and evening; they are very slow on the wing, and often make a humming kind of noise: they extract the nectar of flowers with the tongue. The generic name, sphinx, is applied on account of the posture assumed by the larvæ of several of the larger species, which are often seen in an attitude much resembling that of the Egyptian sphinx, viz. with the fore-parts elevated, and the rest of the body applied flat to the surface.

The larva has sixteen feet, and is pretty active; that of the *Zygana*, a division of this genus, is thick and flat, and covered with short hairs; that of the *Sesia* is generally naked, unarmed, and thinner towards the head; the others have a sharp,

sharp, erect, stiff horn behind; the pupa is quiescent: that of the *zygæna* folliculate, and a little tapering forwards, the rest naked and smooth; that of the *sesia* pointed at each end, of the others very obtuse behind.

There are three divisions of this genus; *viz.* A, of which the antennæ are scaly; feelers hairy; tongue spiral; B, in which the antennæ are cylindrical; the tongue is exerted, truncate, and the wings entire; and C, in which the antennæ are thicker in the middle; tongue exerted, setaceous. Of the principal species of these divisions we shall proceed to give a brief account.

Species.

A. *Antennæ scaly; Feelers hairy; Tongue spiral.*

* *OCELLATA.* Wings angular, lower ones rufous, with a blue eye. This is reckoned a very beautiful insect; its upper wings and body are brown, the former finely clouded with different shades, while the lower wings are of a bright rose-colour, each marked with a large ocellated black spot, with a blue interior circle and a black centre. This insect proceeds from a green caterpillar of a rough or shagreen-like surface, marked on each side by seven oblique yellowish-white streaks, and furnished, like the preceding, with a horn at the tail. It is chiefly found on the willow; retires under ground, in order to undergo its change into the chrysalis state, in the month of August or September, and in the following June appears the complete insect.

MYOPS. Wings angular; upper pair with a yellow spot at the tip and posterior angle; lower ones yellow, with a blue eye.

QUERCUS. Wings angular, indented, cinereous, with dark streaks; lower ones ferruginous, white at the angle of the tail. This inhabits Germany. The larva is solitary and of a green colour, with oblique lateral stripes and rufous stigmata; pupa chestnut, with rufous margin.

LUSCA. Wings angular, dusky, with a black dot; lower ones black, with a fulvous band. It inhabits the South American islands. The upper wings are cinereous, with brown flexuous bands; lower wings cinereous at the angle of the tail, with a fulvous blotch; beneath it is a dull grey, and immaculate.

* *POPULI.* Wings indented, reversed, grey; upper pair with a white central spot; lower ones ferruginous at the base. This is found in England and many parts of Europe. It is figured by Donovan, and other writers on natural history. The larva is solitary, rough, green, with oblique white stripes on the sides; the pupa is of a dull brown, but ferruginous behind.

* *TILLE.* Wings angular, with greenish clouds and darker bands; lower ones beneath yellow, testaceous. The larva is solitary, rough, green, with oblique red and yellow stripes on the sides; the pupa is brown.

PYLAS. Wings scalloped, indented, variegated; lower ones fulvous, yellow at the base, and black at the tip. It inhabits Surinam. Lower wings with a marginal black band, and contiguous smaller one; the edge itself is yellowish.

CACUS. Wings indented, black, with three approximate pale streaks; lower ones are yellow, striate with black. The abdomen is marked with cinereous and black belts.

DENTATA. Wings indented; lower ones brown, with a white streak; the abdomen is annulate with white. It is an Indian insect. The head and thorax are blueish, speckled with brown; the upper wings are blueish, with brown specks and bands.

ALOPE. Wings indented, brown; lower ones yellow, tipped with black; abdomen black, with interrupted pale belts.

This is found in divers parts of America. The larva of this species is tailed and glabrous, cinereous on the back, with a broad brown streak before; ocellate in the middle, and ending in a black spot; pupa brown, with rufous rings and streaks.

JATROPHÆ. Wings slightly indented; lower one black, with a rufous base and hyaline band; the head is two-horned. The larva is green, with a moniliform tail; the pupa is brown, with an inflected cylindrical tail.

* *ATROPOS.* The wings of the insects of this species are entire; the lower ones are yellow, with two brown bands; the abdomen is yellow, with belts. This is said to be the largest and most remarkable, if not the most beautiful, European insect of this genus. It is thus described by Dr. Shaw: the upper wings are of a fine dark grey colour, with a few slight variations of dull orange and white; the under wings are of a bright orange colour, marked by a pair of transverse black bands; the body is also orange-coloured, with the sides marked by black bars, while along the top of the back, from the thorax to the tail, runs a broad blue-grey stripe; on the top of the thorax is a very large patch of a most singular appearance, exactly representing the usual figure of a skull, or death's head, and is of a pale grey, varied with dull ochre and black. When in the least disturbed or irritated, this insect emits a stridulous sound, something like the squeaking of a mouse; and from this circumstance, as well as from the mark above-mentioned on the thorax, it is held in much dread by the vulgar in several parts of Europe, its appearance being regarded as a kind of ill omen or harbinger of approaching fate. Reaumur mentions, that the members of a female convent in France were thrown into great consternation at the appearance of one of these insects, which happened to fly in during the evening at one of the windows of the dormitory. The caterpillar from which this curious sphinx proceeds, is in the highest degree beautiful, and far surpasses in size every other European insect of the kind, measuring sometimes nearly five inches in length, and being of a proportional thickness; its colour is a bright yellow; the sides are marked with a row of seven most elegant broad stripes or bands, of a mixed violet and sky-blue colour; the tops of these bands meet on the back in so many angles, and are varied on that part with jet black specks; on the last joint of the body is a horn or process, not in an erect position, but hanging or curving over the joint in the manner of a tail, having a rough surface and a yellow colour. This caterpillar is principally found on the potatoe and the jessamine, which are its favourite food. It changes into a chrysalis in the month of September, retiring for that purpose deep in the earth; the perfect insect emerging in the following June or July. Individuals have been observed to change into the chrysalis in July or August, and then produce the complete insect in November, so that there appear to be two broods or races in a year.

The *S. atropos* is generally considered as a rare insect, and as the caterpillar feeds chiefly by night, concealing itself during the day under leaves, &c. it is not often detected; yet from some singular circumstances favourable to its breed, there are seasons in which it is even plentiful, as was the case in the autumn of 1804, in which the caterpillar was so common in some counties, as to be prejudicial to the potatoe-plants, particularly in some parts of Cornwall and Surry.

“The alteration of form which the whole of the papilionaceous tribe undergo, and in a particular manner the changes of the sphinx genus, afford a subject of the most pleasing contemplation to the mind of the naturalist, and though a deeply philosophical survey demonstrates that there is no

real change produced in the identity of the creature itself, or that it is in reality no other than the gradual and progressive evolution of parts before concealed, and which lay masked under the form of an insect of a widely different appearance, yet it is justly viewed with the highest admiration, and even generally acknowledged as in the most lively manner typical of the last eventful changes."

CHIONANTHI. Wings variegated, with a white dot in the middle; abdomen with three pair of fulvous eyes. This is an American insect. The antennæ are hooked, ferruginous, with a white shaft; lower wings blackish, spotted with white. Larva tailed, with yellow and black bands; the head and tail are red; the pupa is brown.

* **PINASTRI.** Wings entire, grey, with three short black lines in the middle of the upper pair; the abdomen is white, with black bands. The larva is tailed, and greenish, with a ferruginous dorsal line, a lateral yellow one, and ferruginous subocellar stigmata: the pupa is reddish-brown, with white eyes.

* **EUPHORBÆ.** Wings entire, with two dark olive bands; lower ones with a black base, and marginal streak; the antennæ are snowy. It is found in this country, and divers parts of Europe. Donovan has given a figure of it. The larva is black, dotted with white; it has a red line down the back, and lateral yellow spots; the pupa is brown, with black stigmata.

* **LINEATA.** Wings greenish-olive, with a white band, crossed with white streaks; the lower ones are black, with a red band. It is generally described as having a greenish head, with a lateral white line; the thorax is marked with three double white streaks; abdomen with a white line down the middle, and lateral black and white dots; the hind margin of the upper wings is of a purple colour. Beneath it is cinereous, speckled with green.

* **CELARIO.** Wings entire, grey, with silvery-white streaks; the lower ones are brown, with six red spots. The larva is tailed, brown, with two lateral pale lines, and two eyes on the neck, on each side; the pupa is brown before and reddish behind.

* **ELPENOR.** Wings entire, with transverse greenish-brown and red bands; the lower ones are red, with a black base. The larva is tailed, with brown spots and two blue eyes on each side of the neck; the pupa is grey before, behind brown, with darker stigmata.

* **PORCELLUS.** Wings entire, varied with yellow and purple; the abdomen is beneath sanguineous, dotted with white. The larva is without a tail, brown, with three blue eyes on each side of the neck; the pupa is blackish.

* **CONVOLVULI.** Wings entire, clouded; lower ones slightly barred; abdomen with red, black, and white belts. This is found in our own country, and other parts of Europe. The larva is tailed, with oblique white lines on the sides; the pupa is brown, with a reflected involute horn. The eyes of this insect are said to be slightly phosphorescent.

* **LIGUSTRI,** or Privet Hawk-moth. Wings entire; lower ones rufous, with three black bands; the abdomen is red, with black belts. The larva is tailed; in colour it is green, with oblique lateral streaks, which are of a flesh-colour before, and white behind; the pupa is brown; the tail is four-toothed.

CRANTOR. Wings entire, brown, spotted with black; lower ones red, edged with black. It inhabits India. The upper wings are marked with a pale spot at the base; the lower wings are spotted with black at the angle of the tail.

LABRUSCÆ. Wings greenish, with a white dot on the

lower surface of the upper pair; the abdomen is marked with five white dots at the sides. This is an American insect. The lower wings are marked with a black disk, barred with a blue rufous spot at the angle of the tail. The larva is tailed, varied with brown and black; on the tail is a white polished moveable dot.

B. *Antennæ cylindrical; tongue exerted, truncate; wings entire. This division is named*

SESIA.

TANTALUS. Abdomen bearded, the third segment snowy. It inhabits Europe and India. The abdomen is marked with a white and rufous streak; upper wings variegated with three white dots.

HYLAS. Wings semi-transparent; abdomen bearded, green, with a purple belt. It inhabits China. The tail is marked with a white dot at the base; the sides of the base are black.

* **STELLATARUM.** Abdomen bearded, the sides are varied with black and white; the lower wings are ferruginous. The larva is pale rosy, dotted with white; the tail blue, ferruginous at the tip; the pupa is pale, with a brown tip.

PANDORA. Abdomen bearded, with fulvous spots on the sides; the lower wings are ferruginous at the base, and tip with black.

FUCIFORMIS. Abdomen bearded, blackish, with a yellow band near the tail; wings diaphanous, with a darker brown border; beard of the abdomen black on each side. The larva is green, with a yellow lateral line; the horn is erect; pupa folliculate, black, with yellow streaks before.

* **BOMBYLIFORMIS.** Abdomen bearded, greenish, fulvous, with a black band; the wings are transparent, with a fine black edge.

* **APIFORMIS.** This species is of an aspect at first sight more resembling that of a wasp, or hornet, than of a sphinx, the wings being transparent, with merely a slight edging of brown, and the thorax and abdomen varied with black and yellow. The caterpillar inhabits the hollows of poplar, fallow, willow, and lime-trees, feeding on the substance of the bark; changing to a chrysalis in April, and the fly appearing in the month of June.

* **CRABRONIFORMIS.** Wings transparent; abdomen yellow, with black belts; thorax black, with obsolete yellow spots; the head is black, with a yellow ring at the base. The larva is yellow; the pupa is reddish-brown. The male has two black bands near the base of the abdomen; the female is marked with irregular black lines.

* **CULICIFORMIS.** Wings hyaline, with a black band and margin; the abdomen is bearded, with a fulvous belt; the antennæ are white before the tip.

* **TIPULIFORMIS.** Wings transparent, with a black band and margin; the abdomen is bearded, black; the alternate incisions are edged with yellow. This is figured by Donovan. The thorax has a yellow line on each side; tip of the upper wings marked with a brown spot. The larva is solitary, a little hairy, whitish, with yellow head and legs, and a darker dorsal line; the pupa is brown.

* **ZONATA.** Wings transparent, with a black band and margin; the abdomen is bearded, black, with a single belt. It is found in divers parts of Europe, as well as in this country. The head is marked with a thin red margin, on the thorax are two oblique lateral red lines.

ICHNEUMONIFORMIS. Wings transparent, with a black margin and band, in which is a fulvous dot; the abdomen is

marked

marked with alternate black and white belts. It inhabits Auftria.

* **VESPIFORMIS.** Wings transparent, with a black margin and band; abdomen bearded, black, the second and last segments edged with yellow. It is found in this country, and many parts of Europe.

* **CHRYSORRILÆA.** Wings transparent, with a black margin and band; abdomen black, with four yellow belts; the beard is yellow, with a black line in the middle. This is an English insect, and is figured by Donovan.

C. *Antenna thicker in the middle; tongue exerted, setaceous.*

ZYGÆNA.

* **FILIPENDULÆ.** Upper wings blue-green, with six red spots in pairs; the lower ones are red, with a greenish border. It is found in England, and other parts of Europe. The larva is flat, tailed, sulphur-coloured, with four lines of black dots; the pupa is brown, but in the middle it is of a sulphur-colour.

SEDI. Blue; upper wings with three connected red spots; the lower ones are entirely red. It inhabits southern Russia. The spots on the wings are furrounded with a yellow ring, and the lower wings with a fine black edge.

PHEGEA. Green-black; the upper wings are marked with six transparent dots, the lower ones with two; the abdomen with a yellow belt. It is found in many parts of Germany. The larva is brown; the head and legs are reddish; the back is marked with fasciculate white plumes.

CAFFRA. Black; wings brown, with five red dots; the lower ones are red, edged with brown. It is found in many parts of Africa. The head is black; feelers and orbits red; thorax black, with two red dots on each side; dots on the wings furrounded with a black ring.

CASSANDRA. Brown; abdomen with five blue spots on each side; tail, mouth, base of the thighs, and abdomen, scarlet.

ANDROMACHA. Black; wings hyaline, with a black margin and band; the tail is red. It inhabits America.

LETHÆ. Wings black, with two yellow spots; abdomen with red, black, and blue belts, and a white one. This is an African insect.

PECTICORNIS. Brownish; wings violet, with two white bands a little interrupted; the collar is red. It is found in South America.

SYPIUS. Wings black; upper pair with an interrupted testaceous band; lower ones testaceous at the base; the abdomen is dotted with blue. It inhabits different parts of America. The abdomen is black, with testaceous belts at the base; the tip is dotted with blue.

CAPISTRATA. Wings black, with two transparent bands on the upper pair; the lower ones have a transparent disk; the abdomen is red and black on the back. It inhabits America.

COLUMBINA. Wings transparent, with a black spot, and border marked with red. It inhabits South America. The antennæ are pectinate; the head is black, with two red dots; the thorax is marked with white lines; the abdomen is black, the first segment is red, the others are marked with white and red belts.

CAUDATA. Wings yellow, hyaline, tipped with brown; body spotted with gold. This inhabits South America.

DIPTERA. Wings brown; upper pair with five transparent spots; lower ones very short, with a yellow spot. This inhabits the East Indies.

TIBIALIS. Upper wings brown, lower ones hyaline; hind-legs long and very hairy. It inhabits Africa.

CAPYS. Black; upper wings tipped with white. Inhabits Surinam.

* **STATICES.** Upper wings green-blue; lower ones brown. Inhabits divers parts of Europe, as well as this country.

ACIARON. Blue; wings brown; tail rufous. It inhabits New Holland.

STYX. Body and wings blue; thorax rufous. It is found in Africa.

THOAS. Upper wings brown; lower ones black, with semitransparent disk; collar red.

SPHINX, a name given by Reaumur to a very singular species of caterpillar, described in the second volume of his History of Insects.

The reason of the author's having given it that name is, that when it is not eating it erects its head, and with it more than a third part of its body, into a perpendicular situation upon the leaf on which it was before laid all along; it keeps itself a long time in this situation, looking around it with a seeming air of fierceness. There is also a series of broad belts upon the body, which contribute something towards its resemblance to the figure of that imaginary monster.

This caterpillar has a horn on the hinder part of its body, which seems to be of no sort of use, but merely a trouble to the creature. It is hollow, and incloses, in the manner of a sheath, the new horn which is to appear when the creature changes its skin. This the author found to be the case, by cutting it several times, and always finding within it the new horn cut off also at the same place, and had often observed the great difficulty the animal had in changing its skin, when it came to the horn.

SPHINX, Simia. See SIMIA.

SPHONDYLIIUM, in *Botany*, σφονδύλιον of Dioscorides, the Cow-parfnip. See HERACLEUM.

SPHONDYLOCOCCLUS, so called, by Mitchell, from the whorled appearance of the berries, is the Linnæan CAL-LICARPA. See that article.

SPHONDYLUS, in *Ichthyology*, a name given by Pliny, and others of the old authors, to a peculiar species of the syngnathus, or *acus Aristotelis*. It is the species, called by Artedi *syngnathus corpore medio hexagono cauda pinnata*; and by other authors the *acus secunde species*; and by Bellonius and Gefner *typhle marina*.

SPHONDYLUS is also used by some authors, for the stones or bones found in the head of a mullet.

SPHRAGIDE, or *Lemnian Earth*, in *Mineralogy*, a name given by Werner to a substance nearly resembling fullers'-earth, found in the island of Lemnos, in the Mediterranean. It is of a greyish or yellowish-white colour; it has a dull aspect and a meagre feel, in which respect it differs from fullers'-earth; it adheres slightly to the tongue, and falls to pieces when immersed in water. The constituent parts of this mineral, as given by Klaproth, are,

Silex	-	-	-	-	66
Alumine	-	-	-	-	14.50
Magnesia	-	-	-	-	0.25
Lime	-	-	-	-	0.25
Soda	-	-	-	-	3.50
Oxyd of iron	-	-	-	-	6
Water	-	-	-	-	8

This earth is dug but once a year, on the 15th of August, in the presence of the clergy and magistrates of the island, after the reading of prayers. The clay is cut into long pieces of an ounce weight, and each of them is afterwards stamped with a seal, having on it the Turkish name of the mineral. It is in great repute in the East, as an anti-

dote against poison and the plague; and even in the time of Homer was valued on the same account. It was then stamped as at present, and none but priests were allowed to handle it. Severe punishments were also inflicted on those who presumed to dig for it at any other but the stated period. The geological position of this mineral is unknown. See FULLERS'-*Earth*, and LEMNIAN *Earth*.

SPHRAGIS, the seal-stone, a name given by some authors to the single joints of the asterix, when found loose, not joined into a column. See STAR-*Stone*.

SPHRAGIS is also used by some of the old Greek naturalists, to express the spots on the back and sides of a panther.

The skin of this creature is of a pale colour, and these spots are all dark and round, and look like so many regular impressions of a seal, whence the name sphragis.

The Romans called any thing that was variegated in this manner *pantherina*; and we meet with the phrase *mensa pantherina*, used to express tables found of some wood, which was variegated with round spots, in the manner of those sphrages on the back of the panther.

SPHYGMICA, in *Medicine*, a term used by some for that part of the judgment of a physician, which regards the differences of the σφυγμοί, or *pulse*.

SPHYRÆNA, in *Ichthyology*, a name by which some authors have called the *Judis*, or *Lucius marinus*, the sea-pike.

SPHYRÆNA *Altera*, a name given by Appian, and some other of the old Greek writers, to the *fox*, or common pike.

SPICA, in *Botany* and *Vegetable Physiology*, a spike, is a mode of inflorescence, very general in the natural order of *Orchidea*, and frequent among many other tribes of plants. It is composed of several flowers, ranged along a common flower-stalk, without any partial ones, each individual flower being sessile. The spike is generally erect at the time the flowers expand, and the latter are less crowded than in a RACEMUS. See that article, and INFLORESCENCE.

SPICA *Bandage*, in *Surgery*, is a kind of bandage thus called from its interfections, which are supposed to resemble an ear of corn. It is either simple or double. The simple spica, applied to the clavicle, when fractured near the shoulder, consists of a simple band, about five ells long, and three fingers breadth, rolled up either with one or with two heads. The double spica, which is used when the ossa humeri of each arm are dislocated, is a band about seven or eight ells long, and three or four fingers breadth, rolled up with two heads: the middle is fixed under the axilla, and the two heads cross each other upon the shoulder, and go over the breast and back to the opposite axilla; here they cross again, and then rise up over the other shoulder as before, from whence they go across the breast, and back again to the left axilla, where they began, forming an X, by traversing each other upon the sternum and back. See BANDAGE.

SPICA *Virginis*, a star of the first magnitude in the constellation Virgo.

SPICCATO, Ital., distinct, detached, separated, in *Musæ*, as if half the note were cut off by a rest. This term is nearly of the same signification as *sciolto* and *staccato*; except that, on the violin, when spiccato is written over or under a group of notes, they are to be touched lightly with the vibration of one bow; and sciolto and staccato passages and movements require a strong bow to every note.

SPICE, any kind of aromatic drug, that has hot and pungent qualities: such are pepper, nutmeg, ginger, cinnamon, and cloves. Some also apply the word to divers

other medicinal drugs brought from the East; as fenna, cassia, frankincense, &c. See each under its proper article.

SPICE, *All.* See PIMENTO.

SPICE-Wood, in *Botany*, a species of *Laurus*; which see.

SPICES, *Garbler of.* See GARBLER.

SPICHEROEG, in *Geography*, a small island in the German sea, near the coast of Friesland. S. lat. 53° 43'. E. long. 7° 32'.

SPICULUM, in *Roman Antiquity*, a kind of weapon which some will have to be the same with the hasta, or spear.

SPIDER, in *Entomology*, is the trivial name by which the large genus ARANEA is generally known: under that term we promised to give an account of the species in their alphabetical order; this, from a change in the plan, having been neglected, we shall take the opportunity which the word *spider* affords, of enumerating those species in as brief a manner as the subject will allow. We shall, however, be under the necessity of giving in this place the generic character, which is as follows: Mouth with short horny jaws, the lip rounded at the tip; two feelers, incurved, jointed and very sharp at the end; those of the male are clavate; they have no antennæ, generally eight eyes, but sometimes only six. Eight legs; the abdomen is ovate, villous, furnished at the tip with textorial papillæ.

Much interesting matter on the subject of spiders will be found in the article ARANEA; here it may be observed, that in every stage of their existence, these animals prey with the utmost ferocity upon all other insects that they can overcome, and even upon one another: from the papillæ at the end of the abdomen, they throw out at pleasure a number of fine threads, which they unite in various ways, for the purpose of entangling their prey. They every year cast off their old skin, which is performed by suspending themselves in some solitary corner, and creeping out of it. The younger ones have the power of flight, and in the autumn mount in the air to a great height; to perform which, they probably ascend some lofty eminence, and are wafted about by the winds, filling the atmosphere with their fine threads. The spider is infested by the *sphæx* and *ichneumon*; which see respectively.

Gmelin has enumerated more than a hundred and twenty species of this genus, which are separated into distinct sections, according to the number and position of their eyes.

Species.

A. Eyes placed

* EXTENSA. Abdomen long, silvery-greenish; legs longitudinally extended. This species is found chiefly in the woods of this country, and other parts of Europe. The head, thorax, and legs, are reddish; the abdomen is greenish down the back; the first pair of legs very long; the third very short.

PALLENS. Pale testaceous; mandibles ferruginous, with black claws. It inhabits the American islands.

LOBATA. Abdomen ovate, lobed, white, with double brown lines at the tip. It inhabits the Cape of Good Hope.

LONGIMANA. Ferruginous; abdomen long, cylindrical, brown. It inhabits Jamaica. The fore-legs very long, hence its specific name; third pair very short.

REGIA. Villous, cinereous, with a yellow band on the front; the legs are spinous. It inhabits Tranquebar, and is large.

VIRESCENS. Green, with a black cylindrical abdomen; the fore-legs very long. It inhabits Zealand.

SPIDER.

CANCRIFORMIS. Abdomen globular, gibbous, with six spines round the margin. This is found in Jamaica.

VENATORIA. Glossy-black, with a blackish hairy abdomen. This is an American insect, which spins a large cylindrical web under ground, which is covered with a lid; its bite is very painful, and frequently occasions fever, and even delirium, which are however quickly removed by sudorifics.

13-GUTTATA. Black; abdomen rounded, and spotted with red. This is an Italian insect. Its bite is said to be very pernicious; it preys on crickets, which it encompasses and entangles in a web.

* **LATENS.** Black; abdomen greyish, with a black interrupted dorsal line. It inhabits England, and secretes itself under a small web on the under surface of the leaves of plants, and is a small insect.

SIGNATA. Greenish; sides of the thorax black; abdomen with two black lines. It inhabits Kiel, in Germany.

MACTANS. Abdomen ovate, black, with a scarlet dorsal line. This is an American insect. There is a variety whose abdomen is distinguished with two pair of scarlet dots, and a tail.

CICUREA. Pale red, with a cinereous ovate abdomen. This inhabits Germany, and is found in houses.

BICORNIS. The insects of this species are yellowish; the abdomen is depressed, with six impressed dots; the head is two-horned. It inhabits Tranquebar.

NIGRITA. Black; abdomen with two testaceous dots beneath. It inhabits Saxony, and is middle-sized.

CORNUTA. Brown; abdomen oval, cylindrical, above yellowish-white, with four pair of impressed dots and four parallel grey lines behind. This is found in America. It is about the size of a man's finger; the legs are long; the thorax truncate on each side, and ending in two small horns behind.

B. Eyes placed

* **GLOBOSA.** Black; abdomen globular, with crimson sides. It is found in the woods of England and other European countries. The body is very small: the abdomen with an interrupted white band in the middle; the legs are black; the hind ones are the longer.

C. Eyes placed

HORRIDA. Abdomen nearly triangular, the tip truncate and obtuse, the four front legs are the longer. It inhabits Germany, under the leaves of plants, and has a retrograde motion; it is of a singular formation.

MAXILLOSA. Ferruginous, with a greenish abdomen; the legs are pale; the mandibles large and projecting. It inhabits the island of Santa Cruz.

SMARAGDULA. Green; abdomen paler, with a green dorsal line at the base. It inhabits France.

LATRO. Thorax villous, cinereous; abdomen acute, black, with ferruginous spots. It inhabits America.

* **VIATICA.** Brown, with a roundish flat obtuse abdomen; four hind-legs very short. It inhabits Europe, in gardens and meadows, and is small.

* **DOMESTICA.** Abdomen ovate, brown, with five black and nearly contiguous spots, the anterior ones larger. It inhabits Europe, is very common in houses and about windows; it preys chiefly on flies.

DORSATA. Green; abdomen brown on the back. It inhabits Kiel.

TESTACEA. This is testaceous; the abdomen is sub-

globular, dull greenish. It is found in divers of the South American islands.

* **TRILINEATA.** Abdomen ovate, whitish, with three longitudinal lines of blackish dots.

IMPRESSA. Black; abdomen ovate, with six impressed dots, and two yellow dots beneath. It inhabits Norway, on rocks.

* **LEVIPES.** Abdomen rhomboid, depressed, and spotted with black; the legs are extended and variegated. It is found on walls in this country, and other parts of Europe.

TRICUSPIDATA. Greenish; abdomen white, with a reddish tail. It inhabits Saxony. Head, thorax, and legs greenish; eyes, especially the latter ones, elevated.

D. Eyes placed

ARGENTATA. Abdomen white, and brown behind; the margin six-toothed. It inhabits America and the East Indies. Thorax silvery, the margin of the abdomen is armed with three strong spines on each side.

E. Eyes placed

FASCIATA. Silvery; abdomen with a yellowish band; legs annulate with brown. It inhabits Madeira.

* **ANGULATA.** Abdomen ovate, the sides angular and acute on the fore-part; the thorax has an excavated centre. It inhabits our own country, and divers other parts of Europe, in trees, and spins a web, which is perpendicular in its position, and which varies very much in colour.

* **DIADEMA.** Reddish-brown; abdomen gibbous, and marked with white drop-shaped spots in the form of a cross. This is found in our own country in trees, and is reckoned a very beautiful insect. The body varies much in colour from a darker to a lighter reddish-brown; the legs are annulate with brown.

MARMOREA. Brown; abdomen ovate, varied with white and brown; found chiefly on the European continent. Spins its web on the ground; the legs are yellow, annulate with brown.

RETICULATA. Abdomen globular, reticulate, above purplish, clouded with brown, found chiefly in the gardens in Europe.

* **CUCUREBITINA.** Abdomen subglobular, yellow, with a few black dots. It belongs to this and other European countries, is found in trees, and spins a lax web.

CALYCINA. Abdomen globular, pale yellowish. This is an European insect, and is found in the calyces of flowers from which the coral has fallen, and fastens on bees and flies that come to extract the nectar.

8-PUNCTATA. Abdomen roundish, yellow, with four black raised dots on each side; tail rufous. It inhabits Sweden, and is thought by some writers not to belong to this division.

BI-PUNCTATA. Abdomen globular, black, with two hollow dots. It is found chiefly in windows in European countries.

RIPARIA. Abdomen ovate, black-bronze; tail pale yellow, and two-horned. It inhabits Sweden, on gravelly shores.

* **QUADRATA.** Abdomen subglobular, yellowish-rufous, with a white line at the base and four spots. It inhabits the woods of Europe. It is somewhat less than the diadema, and perhaps only a variety of it.

LITURATA. Testaceous; abdomen pale black, with a white margin and marks. Inhabits France.

QUADRI-PUNCTATA. Abdomen oblong; the back black and

SPIDER.

and flat, with four excavated dots. It inhabits Europe, in houses.

MILITARIS. Black; with four spines, the hind ones longer and spreading. This is an American insect, as are the three following.

SPINOSA. Back with eight spines, the two hind ones spreading; abdomen beneath conic. The body is brown, and of a triangular shape.

ACULEATA. Back with six spines, the hind ones spreading.

TETRACANTHA. Abdomen globular, with four spines round the margin. The head and thorax are ferruginous; abdomen with impressed dots at the base.

HEXACANTHA. Abdomen transverse, with six spines round the abdomen. This inhabits Jamaica, and is supposed to be the same, or at most a variety of the cancriformis.

FORNICATA. Sides of the abdomen a little vaulted, with two spines, the posterior one longer. It is found in New Holland. A specimen exists in the museum of Sir Joseph Banks.

* **LABARIUTHICA.** Abdomen ovate, brown, with a whitish pinnate line. It spins an horizontal web on the ground, with a cylindrical cavity.

QUADRI-LINEATA. Abdomen roundish, yellow, with a purplish line on each side, and four dots. It inhabits Sweden. It is hyaline, with a yellow front.

* **REDIUSITA.** Abdomen oval, pale yellow, with a crimson oval crown or ring on the back. It is found in gardens. The legs are long, white, and transparent.

COROLLATA. Abdomen oval, black, with a white oval ring on the back. It inhabits Europe, on plants.

* **MONTANA.** Abdomen oval, white, with grey spots. It inhabits Europe, on trees. The thorax and legs are pale; the fore-legs are long and extended.

SANGUIOLENTA. Abdomen ovate and scarlet, with a longitudinal black line. It inhabits Spain.

NIGRA. Abdomen ovate, and scarlet above. This is an inhabitant of Calabria.

NOTATA. Abdomen ovate, brown, with white transverse curved lines. Found in divers parts of Europe, as are the three following.

RUFIPES. Abdomen brown; legs rufous. Found chiefly on nettles.

NOCTURNA. Abdomen black, with two white dots, and a white lunule at the base.

SEX-PUNCTATA. Abdomen oblong, with three pair of excavated dots.

PALUSTRIS. Thorax and abdomen with a snowy line on each side. Found in the reedy marshes of Germany. The tip of the thorax before the eyes ends in a white line.

* **AQUATICA.** Brown; abdomen ovate, cinereous; the back brown, with two impressed dots. This is found in our own and other European countries, in fresh-water lakes, where it dives to the bottom in search of food, within a globule of air formed by itself. It takes up its winter quarters in a forsaken shell, the aperture of which it closes up with a web. Its jaws are large, strong, black, with scarlet nails.

OBSCURA. Abdomen subconic, dusky, with a whitish dorsal line. It inhabits France, in woods, as does the next.

SCALARIS. Thorax testaceous; abdomen snowy on the back, with an oblong indented snowy spot at the tip.

TRIGUTTA. Yellowish; abdomen black, with three white spots. Found in Alsace.

SCORPIFORMIS. Black; abdomen whitish, with two

black lines; fore-legs very long. Found in gardens at Leipsic. It is small and retrograde.

* **CARNIFEX.** Ferruginous; abdomen grey, with a dorsal line. It inhabits England.

FLAVISSIMA. Abdomen oblong, of a fine rich yellow colour, and smooth. Found in Egypt.

BIMACULATA. Abdomen roundish, chestnut-brown colour, with two white dots. It inhabits Europe, and is less than a flea.

TRUNCORUM. Black, with white dots on the back. It springs to a great distance on its prey. It is an European insect, and found on walls and the trunks of trees.

RUPESTRIS. Abdomen with a black spot, edged with red, and white in the middle. It springs on its prey, and is found chiefly on old walls.

VIRESCENS. Abdomen oblong, yellow-green, with lateral white lines.

SPINIPES. Pale, with spinous legs. A variety has spinous legs, with ferruginous joints. Found in divers parts of Europe.

OPILIONOIDES. Grey, with very long and extremely slender legs. It inhabits Germany and France; spins a very lax irregular web, the threads crossing each other; and is gregarious.

OSBECKII. Pale yellow; abdomen with impressed dots in pairs, with an odd one; the fore-legs are longer. It inhabits Austria, as does the next.

WILKII. Varied with black and grey; legs cinereous, annulate with black; the hinder ones are shorter.

SPECIOSA. Thorax grey, with two brown spots; the abdomen is oval-oblong, with transverse black curves; beneath it is reticulate with black, with two yellow bands. It inhabits Calabria and Siberia, and is domesticated in the houses of the Cossacks. It is a very beautiful species.

F. *Eyes placed*

CLAVIPES. Abdomen oblong, yellow, dotted with white; all the shanks, except the third pair, clavate and hairy. It inhabits South America, in trees and out-houses; spins a strong spreading web, and is a beautiful species.

* **SACCATA.** Abdomen ovate, rusty-brown. This is found in gardens, and it carries its bag of eggs behind it.

FUMIGATA. Abdomen ovate, brown, with two white dots at the base. This is found in Sweden. It lives in meadows, and watches before the nests of larvae, which it catches as they come out, one after another, and sucks out their vitals.

G. *Eyes placed*

FIMBRIATA. Black; abdomen oblong, with a white line on each side. It is found in many parts of the continent of Europe, in reedy marshes.

* **DORSALIS.** Black; thorax compressed, with a white dorsal line. It is common in England. The abdomen is ovate, whitish at the base; the legs are livid.

SANGUIOLENTA. Black; abdomen red, with a black dorsal line. It is found in divers parts of Europe, and springs on its prey.

PUPILLATA. Testaceous; abdomen brown on the back, with subocellar fulvous spots. It inhabits China.

* **SCENICA.** Black; abdomen subcylindrical, with three femicircular white lines on each side. It springs on its prey. It inhabits this and other countries of Europe, on old walls and windows. The body is covered with silvery hair; the legs are short, hairy, black and white.

FULVATA.

SPIDER.

FULVATA. Black; hind margin of the thorax fulvous; abdomen with three fulvous bands. It inhabits Cayenne.

PUBESCENS. Abdomen ovate, brown, with four cinereous spots, the hind ones larger. It inhabits Leipzig.

CINEREA. Cinereous; abdomen brown on the back, with eight cinereous dots. It is found on the shores of the Baltic.

TRILIENATA. Brown; thorax with a paler margin, and lateral dorsal line; abdomen ovate, cinereous; beneath brown. It inhabits Naples.

TARANTULA. Abdomen with triangular black spots on the back; the legs are spotted with black. This is found in the southern parts of Europe, but chiefly in Italy, and likewise in Barbary, in cool caverns, and is the insect whose bite was long supposed to be curable by music only. It is generally admitted to be partially poisonous, but never fatal. See **TARANTULA.**

H. *Eyes placed* : : :

AVICULARIA. Thorax orbicular, convex, with a transverse central excavation. Found among trees in South America, where it preys upon larger insects, and even upon small birds, dropping into their nests, and sucking their blood and eggs. It is said to be of so enormous a size, that its fangs are equal to the talons of a hawk; and its eyes are capable of being set in the manner of glasses, and used as microscopes.

I. *Eyes placed*

PULCHRA. Oval-oblong; thorax villous, white; abdomen and legs black, with yellow bands. It inhabits Helvetia.

K. *Eyes placed* : :

GOEZII. Black; abdomen ovate; front white. It springs on its prey, and is usually found in the woods of Vienna. The abdomen is marked with two impressed dots.

L. *Eyes placed* : : . . .

TRUNCATA. Grey, ferruginous, slightly clouded; thorax globular, and slightly heart-shaped; the abdomen is something triangular, and marked with an obsolete longitudinal cross. It is found in Germany, on oak and other trees.

M. *Eyes placed* : : : :

CONICA. Abdomen ovate, obscurely conic behind, varied with brown and whitish, and black beneath. This, like the last, is found in the woods of Germany, and spins a labyrinthical web.

N. *Eyes placed* :

ALBIFRONS. Hairy; body ovate, and variegated with black and chestnut-brown. It inhabits Luface.

O. *Eyes placed* : : : :

TAURUS. Abdomen flat, with two very long curved spines. Found chiefly at St. Domingo.

ARCUATA. Brown; abdomen with six spines, the middle ones curved, and six times as long as the body. This is found in the East Indies, and is a small insect.

MAGULATA. Thorax silvery; abdomen cylindrical; legs very long and black. It inhabits China.

PILIPES. Brown; abdomen cylindrical, with silvery lines; legs very long and hairy. It inhabits the East Indies, and is a large insect.

MYOPA. Greenish; abdomen red on the back, with a few black dots; the sides are yellowish. It inhabits Kiel. This is a beautiful insect; the mandibles are tipped with black; the thorax with two darker lines; abdomen ovate, pubescent; textorial papillæ tipped with black; legs long, pale greenish; the fore-shanks tipped with black.

LONGIPES. Black; abdomen cylindrical, brown, with six impressed dots; the legs are very long. It inhabits Australasia.

RUFIPES. Ferruginous; abdomen ovate, pale cinereous; legs rufous. It inhabits Morocco.

***SENOCLATA.** Abdomen greenish, with black dots, and a yellow line on the sides. It is found in gardens and on walls.

SCOPULORUM. Abdomen brown, with a pinnate white dorsal line. It inhabits Norway, and is found on rocks.

LUSEA. Pale; abdomen silvery, with black branched lines. It inhabits Traquebar.

PARALLELA. Brown; sides of the thorax and abdomen white; mandibles projecting and parallel. It inhabits the American islands.

SCROFA. Hairy, brown; abdomen semi-orbicular; mandibles black, exerted, and hooked at the tips. It inhabits under ground at Chili, and is about the size of a pigeon's egg.

BICORNIS. Abdomen two-horned. It inhabits Siberia.

CASPIA. Thorax subglobular; abdomen oblong, varied with yellow and black bands. This species inhabits the deserts of Ural, and is regarded by the Calmucks as venomous.

ARGENTEA. Thorax orbicular, depressed, white, with two black fillets; abdomen is ovate, lobed, silvery, with two pair of dots in the middle, and four rows behind. It inhabits the deserts of Ural, and is accounted poisonous by the Calmucks. It spins a perpendicular web.

P. *Number and Position of the Eyes unknown.*

NOBILIS. Thorax orange, with six black spots; abdomen yellow, with seven black spots. It inhabits Sumatra.

CALCEATA. Hairy, grey; legs with two black spots at the tip above; beneath silky, with a green gloss. It inhabits Guinea, and is a very large insect.

***HOLOSERICEA.** Abdomen ovate-oblong, silky, livid brown, with two yellow tubercles beneath.

SPINIMOBILIS. Abdomen roundish, yellowish-brown, with four rows of blackish dots; thighs with black movable spines. This is found at Surinam.

CRUENTATA. Black, with a yellow band at the base of the abdomen; the breast is of a deep red. It inhabits Brazil.

SEX-CUSPIDATA. Brown; back of the thorax six-toothed, with a lateral fulvous spot. It inhabits the Cape of Good Hope.

HIRTIPES. Black; feelers and legs hairy, and pale testaceous. It inhabits Cayenne.

TRIBULUS. Head three-toothed on the fore-part, abdomen covered with numerous spines. It inhabits the Cape of Good Hope.

ELEGANS. Black, with two white curves on the fore-part of the thorax, and a white dorsal line on the abdomen. This is an American insect.

OCELLATA. Pale; abdomen clouded, with a black ring; the thighs are marked with three doubled ocellate spots.

SPIDER.

spots. It inhabits China, and is the size of the tarantula.

ALBA. White; abdomen with five impressed dots; two-horned and depressed at the base, and globular at the tip. It inhabits Siberia, under the bark of trees.

The eggs of some spiders are a very pleasing microscopic object; they are round at one end, and flattish at the other, with a depression in the centre of the flattish end, and a yellowish circle round it. The colour of these eggs is a pearly or blueish-white, and when the young spiders hatch, they come out in their perfect form, and run about very nimbly.

The female spider deposits her eggs, to the number of five or six hundred, in a bag composed of her own web, which she either carries under her belly, or hides in some very safe recess. *Philos. Transf. N^o 272.*

The young spiders are always very beautiful objects for the microscope. The current of the blood may be easily discovered in their legs, and part of their bodies; and many other curious particulars occur in their dissection. There are two or three species of this animal particularly worthy the attention of the curious in microscopic discoveries. 1. A little white field spider with short legs. This is found plentifully among new hay, and its body appears like white amber with black knobs, out of which grow short but sharp prickles. The eyes of these may be very distinctly seen, being very brisk and lively, and some have six, some eight of them; each eye has a pupil of a violet blue, which is beautifully clear and transparent, and is surrounded by a circle of pale yellow. 2. The wandering, or hunting spider, that spins no webs, but runs and leaps by fits. This has two tufts of feathers fixed to its fore-paws, which make a very beautiful appearance before the microscope. The variety and beauty of colouring also, all over this little creature, afford a very pleasing sight. 3. The *long-legs*, or shepherd spider. This is a most wonderful creature: it has two fore-claws at a great distance from the head, tipped with black, like those of a crab, and opening and shutting like the scorpions; these are serrated or indented on their inside. When all the legs are cut from this spider, and it is examined by the microscope, it will be seen that the protuberance on the top of its back is furnished with two fine black eyes. *Power's Microf. Obs. p. 13. Hook's Microgr. p. 200.*

The venom of many kinds of spiders is greater than usually supposed: we have, in the *Philosophical Transactions*, an account of a person in New England who was bitten by a small spider a little above his ankle; he perceived the creature biting, and crushed it to death upon the wound, between his stocking and his leg; in half an hour he felt a pain in that leg, which in another half hour extended itself to the groin, and at the same time he had a creeping pain in the calf of his other leg; and in a quarter of an hour after this it affected his stomach, his back, and his head. The pains were not constant and fixed, but erratic, and very acute, and his pulse was extremely low and heavy. He was relieved, by taking internally spirit and salt of hartshorn in viper-wine, and applying a cataplasm of garlic to the part, and in three or four days wholly recovered.

Boccone mentions a species of large spider, common in the island of Sardinia, whose bite proves mortal within the space of a few hours; the whole body usually swells almost immediately, in consequence of this bite. The cure is performed by oil of olives, in which the creature is infused over the heat of a stove. This is a medicine they always keep ready in the house, and while they use this externally, they give large doses of Venice treacle inwardly, dissolved in strong wine: but many die of this bite, either from the

want of power in the remedies, or from their being used too late.

There is hardly any subject on which there has been a greater difference of opinion than the supposed poison of spiders. To the observations that occur in this article and also under *ARANEÆ*, we shall here add some further remarks, with which we are furnished by Dr. Amoureux, jun. a late French writer. Our spiders in France, says this author, (in his "Notice des Insectes de la France réputés venimeux,") are in general rather ugly than formidable. If any are suspected of being poisonous, it ought not to be the domestic spider with long claws, *aranea phalangiodes*, Linn., nor the mower of the fields, *phalangium opilio*, Linn., the only kinds of the phalangia mentioned by Geoffroy; nor the mason spider, nor the orange-coloured spider, and that entirely white *aranea viatica*, and the *aranea citrina*, Linn., found commonly among vegetables or fruit, and chiefly grapes, nor many others, which we see daily, and of which we have no cause to complain. Swammerdam did not believe that the spider emitted through the stings or darts with which it pierces the animals whose blood it sucks, a venomous liquor. Lister, on the other hand, who says that he had certain proofs of spiders being venomous, expressed the poison from these instruments. *Leuwenhoeck* also advances, that the venom of the spiders is contained in the cavity of the sharp pincers which proceed from the mouth of the insect. Others have said that these forceps are not hollow, but that the venom proceeds from a small trunk which issues from the mouth at the moment when the insect seizes its prey. (See *ARANEÆ*.) Although it be a certain fact, that many spiders, and perhaps all of them, throw out from their mouth a certain liquor, with which they moisten their prey, we may rest assured, says Amoureux, that our spiders have nothing in them of a venomous nature; and this is proved by their being often touched without danger, and by their being eaten without injury. Redi saw people who ate spiders, and from the experiments which he made, he does not believe them to be poisonous. Clark and Roefel maintain, that spiders are not so venomous as is supposed, since many persons swallowed them. A person is mentioned, who ate all he could find, and who found them to be purgative. He spread them on a slice of bread, as if they had been excellent marmalade. Moreover, it is maintained, in opposition to the popular error, that the spider is not able, by its pricking, to kill the toad. It is also well known, that chickens, nightingales, and other birds, eat spiders without injury; and they have been prescribed as a remedy chiefly in the tympanis. Lister, whose observations on these insects have been numerous, says positively, that several spiders have a venomous liquor: but the honorable Mr. R. Boyle assures us, that he never saw any venomous spiders in Ireland. Upon the whole, it is observed, the different effects of spiders are owing partly to a difference in the spiders on which experiments have been made, and the different constitution of the subjects. In ordinary cases of being bitten or punctured by spiders, it will be sufficient to wash the wounded part with brine, to apply theriaca, and to prescribe one or two doses internally. The fresh leaves of sage, or those of plantain, have been recommended as topics, and washing with vinegar. Recourse may also be had to volatile alkali.

Some think the white matter we often find floating in the air towards the end of summer, is produced by spiders. See *Air-THREADS*.

SPIDER, Red. See *ACARUS*.

The red spider is very injurious and destructive to different sorts of plants and fruit-trees, especially in forcing-houses

houses. It is found particularly so to those of the forced French bean, melon, peach, vine, cherry, currant, and some other kinds. The generation and production of this insect are greatly caused and promoted by the dry warm heat that is constantly kept up in the houses which contain these sorts of plants and trees, and there are many other circumstances which combine in bringing it forth. It is an insect which has no wings, and the female is oviparous.

Several different methods have been attempted in order to the removal and destruction of it. Constant daily watering, or washing the trees, are said to have the power of subduing it, but in the execution of the work, care is always to be taken that every part of the leaves be wetted, otherwise the insects shelter and save themselves in the dry parts, and are preserved from the effects of the water.

Moisture conveyed in some way or other is certainly found to be the most destructive, of any thing yet discovered, of these pernicious insects, as well as many others that infest hot-houses. Throwing weak lime-water in a plentiful manner on the under sides of the leaves, where these insects are commonly found, will, for the most part, soon destroy them.

The following directions have been given for the destruction of this sort of spider, when it becomes injurious to melon plants; and the same may probably be found useful for those of the forced French bean, and some other similar kinds.

In cases of dry weather, and with a dry heat, melon plants are very subject to be infested with the red spider; and the appearances of it may constantly be long noticed before the insects can be seen with the naked eye, by the leaves beginning to curl and crack in their middle parts. Whenever they are discovered to be in this state or condition, and there is fine warm sunny weather, the watering of them all over the leaves, both on the under and upper sides, is advised; a watering-pot, with a rose finely perforated with holes, or a garden-engine, which disperses the water in a fine dew-like manner, being employed for the purpose. The work should be performed about six o'clock in the morning, and the plants be shaded with mats about eight, if the sun shine with much power, shutting the frames down closely until about eleven; and then admitting a small quantity of fresh air, letting the mats remain until about three in the afternoon, when they should be wholly taken away. The shade which is thus afforded by the mats prevents the leaves of the plants from being scorched or otherwise injured by the action of the heat of the sun while they are in a wet cooled down state. Where a southerly breeze prevails, watering them again about three in the afternoon is recommended, shutting them up close as before, to keep the heat in, which causes a strong exhalation of the moisture, and is greatly destructive of the spiders.

In all these waterings, the water is to be thrown as much and as finely as possible on the under sides of the leaves, where the insects mostly lodge; the vines or stems of the plants being gently turned in that intention, taking great care not to injure them, by which means the water is capable of being easily thrown over the whole of the under sides of the leaves, it being done in a gentle manner, in the modes already suggested, so as not to wash up the mouldy matters on to the plants: the lights and sides of the frames which contain the plants, should also, at the same time, have water plentifully thrown on and against them. When these waterings are finished, the vines or stems of the plants are to be carefully laid down again in their former positions. And if the day be sunny, the mats may be let remain, as already directed, until the leaves of the plants become perfectly dry, air being admitted according to the heat that may be present

at the time. It is likewise further advised as a precautionary measure, that, before the frames and lights, which are to contain plants of this sort, are employed, they should be well washed, both inside and out, first with clean water, and then with a mixture of soap-suds and urine; a brush or woollen rag being made use of in the operation; as by this method the ova or eggs of the spiders or other insects that may have been deposited and lodged in or on them, in the preceding season, may be cleared away and destroyed. The exhalations of the water which has been thrown upon the plants, and the frames or boxes that contain them, may also be useful in killing these insects, in other cases by keeping them in a close state.

These washings should never, however, be performed in cold frosty periods or seasons; and the water made use of in such cases should always be of the rain or soft kind.

The mould which has formerly been employed in raising these plants, where infested with the spider, should not, on any account, be again had recourse to for the same use, as it may contain the ova of these insects. See CUCUMIS.

The waterings, washings, and other modes and means of removing and destroying this insect, when it infests the fruit-trees and shrubs noticed above, are explained under the different proper heads. See AMYGDALUS, PRUNUS, RIBES, and VITIS.

The species of this genus of insects are extremely numerous, being more than eighty. This sort is very common on trees, especially those of the currant kind, being frequently seen running on the fruit of it. See ACARUS.

This insect is injurious and destructive to plants and trees, and the production of their fruits, by feeding on their juices; as the stems and leaves of them are not unfrequently completely robbed and exhausted of their moisture in this way.

SPIDER'S Silk. See SILK, and ARANEA.

SPIDER'S Web. See WEB.

SPIDER-Shell, a name given to some species of the murex.

SPIDER-Wort, in Botany. See ANTHEMICUM.

SPIEGELBERG, in Geography, a town and citadel of Westphalia, giving name to a small county in the principality of Calenberg; 21 miles S.W. of Hanover.

SPIEI, in the Glass Trade, an iron instrument, hooked at the end, and pointed, with which the workmen take the metal up out of the melting-pots for proofs or assays, to see whether it be fit to work.

SPIELBERG, in Geography, a town of Germany, in the principality of Oettingen, insulated in the margravate of Anspach; 8 miles N.E. of Oettingen. N. lat. 49° 3'. E. long. 10° 13'.—Also, a town of Germany, in the principality of Culmbach; 3 miles E.S.E. of Kirch Lamitz.

SPIELMANNIA, in Botany, named in honour of Dr. John Reinhold Spielmann, professor of medicine and botany at Strasburg, author of a *Prodromus Floræ Argentoratensis*, and other tracts on botany and pharmacy.—“*Medicus Act. Palat. v. 3. 196. t. 10.*” Schreb. 414. Willd. Sp. Pl. v. 3. 321. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 4. 45. Juss. 109. Lamarck Illust. t. 85.—Class and order, *Didynamia Angiospermia*. Nat. Ord. *Personate*, Linn. *Vitices*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, erect, short, permanent, divided into five, linear-awl-shaped, acute, nearly equal segments. Cor. of one petal, salver-shaped: tube cylindrical, incurved, globular at the base, hairy within-side, its mouth closed with hairs; limb nearly equal, cloven into five oblong, truncated, flat, widely spreading segments. Stam. Filaments four, very short, in the tube of the corolla, two of them shorter; anthers oval. Pist. Germen superior, roundish; style short, permanent; stigma hooked.

Peric. a globular, one-celled, succulent drupa. *Seed.* Nut globularly depressed, wrinkled, striated and tuberculated longitudinally, two-celled. Kernels solitary, oblong, more gibbous outwardly, tuberculated and striated longitudinally, each affixed to a fleshy tunic, gibbous on one side, hollow on the other, adhering to the partition.

Eff. Ch. Calyx five-cleft. Limb five-cleft, its mouth closed with hairs. Stigma hooked. Drupa containing a two-celled, tuberculated nut.

1. *S. africana.* Ilex-leaved Spielmannia. Willd. n. 1. Ait. n. 1. (*Lantana africana*; Linn. Sp. Pl. 875. *Jafminum africanum*, *ilicis folio*, flore solitario ex alis foliorum proveniente; Commel. Rar. 6.)—Native of the Cape of Good Hope.—It flowers from February to November.—*Stem* shrubby, five or six feet high, sending out numerous irregular branches. *Leaves* oval, thin, embracing the stem, serrated, pointed, viscid, fragrant; upper ones alternate. *Flowers* solitary, one from the bosom of each leaf, white, somewhat resembling those of *Jessamine*. *Fruit* globular, inspid.

Adanson long ago formed a new genus of this plant, which he called *Ostia*.

SPIERINGS, N., in *Biography*, born at Antwerp in 1633, was a painter of landscape, who formed his style on the study of the works of Salvator Rosa, and particularly remarkable as one of those who produced a portion of the numberless pictures sold as his all over Europe.

SPIETZ, in *Geography*, a town of Switzerland, in the canton of Bern, situated on the W. coast of the lake of Thun; 25 miles S.S.E. of Bern. N. lat. 46° 41'. E. long. 7° 33'.

SPIGELIA, in *Botany*, so called by Linnæus in commemoration of an old botanist, of considerable note, Adrian Spigelius, who was born at Brussels in 1578, and who died at Padua, where he was professor of anatomy and surgery, in 1625. His work, entitled *Isagoge in rem herbariam*, appeared at Padua in 1606, and another edition at Leyden in 1633. (See SPIGELIUS.)—Linn. Gen. 84. Schreb. 110. Willd. Sp. Pl. v. 1. 824. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 1. 317. Juss. 143. Pursh N. Amer. 123. Lamarck Illustr. t. 107.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Stellatae* β, Linn. *Gentiana*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, deeply five-cleft, pointed, small, permanent. Cor. of one petal, funnel-shaped; tube much longer than the calyx, narrowed towards the base; limb spreading, cloven into five broad, pointed segments. Stam. Filaments five, simple; anthers simple. Pist. Germen superior, composed of two globes; style solitary, awl-shaped, the length of the tube; stigma simple. *Peric.* Capsule two-lobed, of two cells and four valves. *Seeds* numerous, very minute.

Eff. Ch. Corolla funnel-shaped. Capsule of two globular cells, with many seeds.

1. *S. Anthelmia.* Annual Worm-grafs. Linn. Sp. Pl. 213. (*Anthelmenthia quadriphylla*; Brown Jam. 156. t. 37. f. 3.)—*Stem* herbaceous. Upper leaves in fours.—Native of the West Indies and South America. It flowers in July.—*Root* annual, fibrous. *Stem* herbaceous, a foot and half high, channelled, branched. *Leaves* opposite, in pairs, those which terminate the branches four together in the form of a cross, ovate, pointed. *Flowers* in short, herbaceous, clustered spikes, ranged on one side of the footstalk.

2. *S. marilandica.* Perennial Worm-grafs. Willd. n. 2. "Hope Act. Edin. 1771, v. 3. 151. t. 1." Curt. Mag. t. 80. Woodv. Med. Bot. 288. t. 105.—*Stem* square.

Leaves all opposite.—Native of North America, on the edges of woods, in rich moist situations, flowering in July and August.—*Root* perennial, fibrous. *Stems* herbaceous, erect, six or eight inches high. *Leaves* opposite, sessile, entire, smooth, spreading. *Flowers* large, and extremely handsome, in a terminal spike, all on one side of the footstalk, of a bright red or rich scarlet on the outside, yellow or orange-coloured within.

The English name of this genus, Worm-grafs, is derived from the peculiar efficacy of both the species as a medicine for persons afflicted with worms. Dr. Brown, in his History of Jamaica, says that no other simple is equally efficacious with *S. Anthelmia* for this purpose, and Mr. Pursh informs us that the roots of *S. marilandica* are in great estimation, and sold under the name of *Pink-root*.

SPIGELIA, in *Gardening*, comprises plants of the annual and perennial kind, the cultivated species of which are, the American worm-grafs (*S. anthelmia*), and the Maryland worm-grafs (*S. marilandica*).

Method of Culture.—The first sort, which is annual, and not hardy in its nature, is increased by sowing the seeds of it upon a hot-bed, or in small pots plunged into one, in the early spring season, treating the young plants afterwards in the manner of those of the tender annual sort.

In the second species, which is perennial, and somewhat hardy, as it does not ripen its seeds well in this climate, it must be propagated by parting the roots in the autumnal or spring months, and putting them in separate pots, or placing them out in warm situations.

The latter kind of these plants, which have the outsidings of their flowers of a bright red colour, and the insides of a deep orange cast, produce a fine ornamental effect, as they make an elegant and beautiful appearance during the summer months, when placed in collections with others.

SPIGELIA, in the *Materia Medica*, the root of the spigelia marilandica, or worm-grafs root, imparts its bitter taste to boiling water. It is purgative and anthelmintic; the latter property having been discovered by the Cherokee Indians, who call it "Unstretta," and many opportunities having occurred in this country, as well as America, for evincing its efficacy in worm cases. In the recent state, and administered in small doses, it occasionally produces giddiness, dimness of sight, and even convulsions; and these effects are ascribed to its narcotic principle, the action of which its powerful cathartic property prevents, when the dose is large. It is usual to administer an emetic previous to the use of it; and to assist its purgative operation by adding two or three grains of calomel, or eight or ten of rhubarb. Its power in expelling lumbrici has been most perceptible; and in vinous infusions of it, it is said to have been beneficial in intermittents. Dr. Barton also recommends it in the protracted remitting fever of infants, which often lays the foundation of hydrocephalus. This root may be administered either in substance, or in the form of aqueous infusion. The dose of the pulverized root may be from grs. x to 3j, given every night and morning till the worms are expelled. Woodville. Thomson.

SPIGELIUS, (or VANDEN SPIEGHIEL,) ADRIAN, in *Biography*, an eminent physician, was born at Brussels in 1578. He studied philosophy and medicine first at Louvain, and afterwards at Padua, where he received the degree of M.D. He became thoroughly skilled in every branch of his profession, and particularly in anatomy and surgery; and after travelling for some time to the different schools of Germany, he settled in Moravia, where he was soon appointed physician to the states of the province. He had there attained to the highest reputation, when he was invited,

in 1616, by the senate of Venice, to occupy the principal professorship of anatomy and surgery in the university of Padua, which had become vacant by the death of Caserius. He accepted the appointment, and acquitted himself with so much success, that he contributed to render the schools of Padua more flourishing than they had ever been; and the senate recompensed his services by creating him a knight of St. Mark, and presenting him with a collar of gold. The apparent vigour of his constitution, his vivacity of disposition, and his years, promised a continuance of life, and an increasing reputation; but he was cut off at the age of 47, in April 1625; according to one account, in consequence of a puncture of his finger by a piece of glass, at the marriage-feast of his daughter, which was followed by a suppurating tumour in the axilla; but according to another, in consequence of an attack of slow fever, brought on by his indefatigable exertions in the performance of his duties. His writings evince that he was a man possessed of very extensive medical knowledge. The first work which he published was entitled "Ifagoges in Rem Herbariam Libri duo," printed at Padua in 1606. This work, though not very systematic, contains some interesting matter. It treats copiously on the virtues of plants, respecting which he is said to have learned much from the Italian peasantry, in a tour which he made in the dress of a rustic. He published also "De Lumbrico lato Liber, cum notis et ejusdem Lumbrici icone," to which was subjoined a letter "De incerto tempore Partus," 1618. "De Semitertianâ Libri quatuor," Francf. 1624. But the most valuable of his writings are those which he composed on anatomical subjects, and which were published after his death by his son-in-law, Crema. These were entitled "De Humani Corporis Fabricâ Libri X, cum Tabulis 98 ære incisif," 1625, folio; and "De formato Foetu Liber singularis, æneis figuris ornatus;" to which was annexed "Tractatus de Arthritide," 1626, folio. The first of these, relating to the structure of the human body, is one of the best anatomical works of the time, written with purity, and arranged with great perspicuity and precision, and containing useful physiological and practical observations. There is an edition of this work published by Bucetius, 1627, who has been censured for intermixing his own observations with the text of the author. The whole works of Spigelius were collected by Vander Linden, and published in three volumes folio, at Amsterdam, in 1645. See Eloy Dict. Hist. de la Med. Gen. Biog.

SPIGNET, in *Botany*. See ATHAMANTA.

SPIGNET, *Meu*. See ÆTHUSA.

SPIGNET, *Wild*. See SERMOUNTAIN and SESELI *Seed*.

SPIGNO, or SPINA, in *Geography*, a town of France, in the department of the Stura, late a marquissate belonging to Piedmont, on the Belbo; 9 miles S.S.W. of Acqui.

SPIGOLA, in *Ichthyology*, a name given by Paulus Jovius, and some others, to that species of perch which is generally called the *lupus marinus*.

It is a genuine perch, and is distinguished from the others by Artedi, by the name of the perch with thirteen rays in the second back fin, and fourteen in the pinna ani.

Authors have called two different fish by this name *lupus marinus*, which, conveying no distinct idea of the characters of the fish, was applicable to one as much as the other: but this name of Artedi admits of no equivocation, and must always distinguish the fish.

SPIKE, in *Geography*, an island in the harbour of Cork, Ireland, which commands the entrance in such a manner, that it has been regularly fortified at a great expence, and is one of the most complete and unassailable fortresses in his

majesty's dominions. The works, now (1815) nearly completed, have given employment to a great number of men for several years. Spike island is immediately opposite to the town of Cove, and about ten miles from Cork.

SPIKE, or *Oil of Spike*, a name given by our druggists to an essential oil, much used by the varnish-makers and the painters in enamel; and of some use in medicine.

This oil, when genuine, is brought from Provence, and some other parts of France, and is there made of lavender. This plant is called in Provence *aspic*, and thence came the name *oil of aspic*, which afterwards degenerated into *oil of spike*. See LAVANDULA, and OIL.

The manner of making the oil upon the spot is this: when the flowers are perfectly ripe, they put them into an alembic with a great quantity of water, and this they distil: after several days' maceration, there arises with the water a large quantity of an oil of a fine pale amber colour, and this, separated from the water, is the true and genuine oil of spike.

The flower of this plant is the part which yields the largest quantity of oil; as is the case with all the plants with galeated flowers, of which the husk, or flower-cup, usually contains almost all the oil of the plant. The aromatic plants, in general, yield indeed but a small quantity of oil, but the vast abundance of this plant, in these places, makes the expence of gathering it so small, that the oil is very cheap. The quantity required on several occasions, is, however, much greater than what all the lavender of the country can yield; and the price it is expected to be sold at is so small, that it is not to be wondered that there are several common adulterations of it.

The most useful ways of sophisticating it, however, are two; the one with the spirit of wine, which is esteemed the least hurtful, and the oil thus sophisticated is often called the very best of the country. The method Mr. Geoffroy took to discover the cheat was this: he procured a long and narrow phial, of an equal diameter all the way up; into this he first put an ounce of fair water, and to this he added an ounce of the oil; he marked the height of the water in the phial, then shook the two liquors together, and they became milky, and heated on the mixture, which alone would have been a sufficient proof that there was spirit of wine in the oil. After some standing the liquor became clear, and the oil floated at the top, but in a much smaller quantity than might have been expected, there being not more than a quarter of an ounce of it, the rest having been spirit of wine, which mixed with the water, and thus left all the true oil, which was only one-fourth of the quantity, to float alone on the water, which was greatly increased in height in the phial. A pint of this oil of spike, therefore, contains only four ounces of the genuine oil, and twelve ounces of plain spirit of wine.

The second method of adulterating this oil, which the same gentleman had suspected, was easily discovered next; for on mixing this quarter of an ounce of pure oil of spike with three quarters of an ounce of oil of turpentine, there was produced an ounce of liquor, which appeared wholly the same with the oil of spike commonly sold in the druggists' shops. And indeed, much of what is usually sold is worse than this, being no other than oil of turpentine scented with a small quantity of true oil of spike.

The ready way of discovering the oil counterfeited with oil of turpentine, is to wet a paper in it, and set it on fire; the turpentine will here be discovered by the thick smoke it yields, it being, of all vegetable oils, that which yields much the thickest cloud in burning; and, on the contrary, that which has been adulterated with spirit of wine, will

be distinguished by the same trial, by its yielding a much finer and thinner smoke, and burning with a bright blue flame. If they be tried by firing them in a spoon, that which is adulterated with spirit of wine will burn very bright, and yield no fume at first; but as it grows near the bottom it will smoke a little, and finally will leave no residuum, except that it varnishes over the inside of the spoon: that adulterated with the oil of turpentine will burn more vehemently, smoke more, and leave a coarser varnish upon the spoon; and if it be of the coarsest kind, that is, if it hath been adulterated with badly rectified oil of turpentine, the fume will be the more abundant, and there will be left in the spoon a fetid matter, resembling melted pitch.

Mr. Geoffroy tried whether, in the business of varnishing, the oil of turpentine alone might not do as well as the oil of spike; he found that it dried perfectly well, but that it left a stinking smell upon the work, which never went off; whereas the mixture of this oil with that of spike, makes a smell like neither, and which soon goes off.

An ounce of oil of turpentine, with only twenty drops, either of our common oil of lavender, or the pure oil of spike, makes a liquor tolerably well scented, and which serves for the purposes of oil of spike. If two drachms of our oil of lavender be added to six drachms of spirit of wine, they immediately mix; and this, afterwards mixed in a small proportion with oil of turpentine, makes a sort of oil of spike.

The most regular method, however, that the artificer can use, if he can get the genuine oil of spike, is to mix one ounce of it with three ounces of oil of turpentine, which perfectly fits it for this purpose, and makes it the same with that in common use. The method of making this perfectly pure, is to redistil it in a *balneum Mariæ*; there will thus be procured an oil highly rectified, and pellucid as water, which will dry away as soon as touched on any thing. The great disadvantage attending the oil of spike adulterated with spirit of wine is, that it will not readily mix with all the sorts of varnish.

Having gone through the properties of oil of spike, in regard to varnish, it remains to inquire into them in regard to its other great use in enamel, and to consider the effects of the two usual methods of adulterating it in this work.

The oil of spike which wants body, is not at all fit for enamelling, because it dries too suddenly, and does not at all assist the natural dryness of the enamel, which is only a sort of powder of glass; and the particles of this powder, with a fluid of too little body, are not manageable by the artists, so that the colour never is brought to a due consistence; and when the oil has too much body, the mixture becomes too tenacious, and is as unmanageable in that extreme as in the other; and this fault is attended with another very great mischief, which is, that the fume raised by this oil, when heated, is often so gross, as to destroy the beauty of the colours. In short, thick oil of turpentine is always destructive of enamels by its smoke.

The true composition for enamelling is oil of spike mixed with spirit of wine, but the proportions must be nicely regulated from repeated trials: for if the quantity of the spirit be too large, it is apt to separate itself from the oil and colour in the drying, and this always spoils the gloss and beauty of the work. Artificers observe, that oil of spike does best for their purposes, after it has been kept two or three years. But this is only owing to the oil's being adulterated with spirit of wine, and usually containing too large a proportion of the spirit when first sent over: it becomes better for use when a part of that spirit has had time to evaporate in the keeping. It would be a better

way for these curious works, to procure the oil pure, and then occasionally mix it with such a proportion of spirit of wine, as experience shews to be the most proper. *Mem. Acad. Par. 1716.*

SPIKE, Lavender. See LAVENDER.

SPIKE, Winged, Grass, in Botany. See STIPA.

SPIKE, Hand, in Mechanics. See HAND-SPIKE.

SPIKE a Gun, in Military Language, &c., signifies to choak up the touch-hole of a piece of ordnance, so as to render it useless. See NAIL.

SPIKE-Roller, in Agriculture, a very useful implement of the roller kind, first introduced by Mr. Randall of York to the notice of the farmer. It has been found of much advantage in bringing stiff cloddy lands into a state of suitable pulverization and fineness of mould for being sown. It is likewise employed, in a beneficial manner, on sward-land that is worn out and mossy, by preparing it for the application of earthy composts and grass-seeds. But it is remarked by the inventor, that in this business the roller must go up and down, till the sward and ground are perfectly well broken up: this being done, the seeds of clover, trefoil, and rye-grass, or any other mixed with them, must be sown in the usual way and quantity; then the compost must be spread over the seeds, so as to cover them; and a common barley-roller, with a thorn-bush fastened to it, must follow, and the ground be shut up, lest the cattle should do harm by treading.

In respect to this sort of roller, the dimensions in length were seven feet, the diameters at the ends eighteen inches, and the whole cylinder made of the heart of oak; and when the irons were burnt in, and the man seated on the box designed for that purpose, the weight of the whole was about a ton. But the blunt ends of the irons were opposed to the clods, and run more taper, till they came to the surface of the cylinder, into which the irons were burnt, and inserted about three inches, which was their length above the surface of the roller, and which he always found very sufficient to crush the hardest clod that ever came in their way. Had he, indeed, attempted to go on the ground, when the soil was not perfectly dry, this position of the irons would have carried the clods round with the roller; for it is not its province to squeeze, but crush. Nor indeed can a man do more harm to his ground than going upon it, when it is not quite dry, with a roller constructed in this way. He had the irons fixed in four inches asunder, in the first row, from end to end. The second row began just between the first and second irons of the first row. The third row was like the first; and the fourth like the second. Then alternately for the whole surface of the cylinder, as near as possible, the irons were four inches asunder in each individual row; and four inches from row to row, as nearly as the superficialities of the cylinder would permit. He does not know how to convey a juster idea of the shape of the irons than to call them ox-harrow teeth, or those of a very large harrow; for when he sent for the workman, he desired him to make so many of this denomination, six inches in length, and burn the small end three inches into the wood. This is a roller that requires a strong team in performing its work.

But in addition to these uses, it has been suggested that it may likewise be very useful in preparing clay for the making of canals, or pieces of water: for where, as sometimes happens, the clay grows dry, and will not admit of being duly tempered for use, without great pains in breaking it, a very large quantity may very soon be reduced to the requisite fineness, by spreading it on hard ground in a due thickness, and passing this roller a few times over it. In extensive works, much trouble and labour may sometimes be

saved by this means, where such a roller is at hand, and the clay prepared in a manner that will answer the purpose much more effectually.

It may also be noticed, that this is a sort of tool which no farm, where the land is a stiff clay, or in the least liable to clot, should want: for besides the constant advantage of saving labour, and bringing land to a better condition for any kind of sowing than the plough and harrow, with any assistance of the work of hands, can make it; in favourable seasons, and under certain circumstances, the loss of the whole crop, by an otherwise unavoidable delay beyond the seed-time, may be with certainty prevented.

It has been stated as an improvement in this implement, in order to prevent its tearing up the ground, and the great stress that is upon the frame in turning, to have it divided into two parts. Let the ends of each part be bound with narrow, but strong, bands of iron, and let the spikes at the ends be placed close to them; let each part have a separate frame; but let the cheeks, in which the inward gudgeons turn, be made of iron plates, about two inches wide above, and four where the gudgeons enter; the thickness, a common flat bar of iron: and these fixed in any firm manner to two cheeks of wood, reaching down just to the bands, and of such a thickness at bottom as not to interrupt the spikes. Let the inward gudgeons be made with quite flat heads, to prevent their slipping out in working, and bring the two ends of the roller nearer together, which is of consequence, as the fewer clots will be milled in working.

Let the frames be joined together by four eyes, like those of a small gate, two at one end, about five or six inches apart; the two at the end of the other, to take place just within them; an iron pin being put through all four, and keyed. Let the thills be placed just on the middle of each frame, and a bar of wood just behind the horse to strengthen them; the bar sawed through in the middle, and joined by a strong flat hinge; one side made to hasp upon a staple, kept down with a wooden clet. This gives the whole proper play in working.

The spikes are about four inches without, and three within the wood: the thickness of the roller and number of spikes may be determined, in some measure, by the nature of the soil it is to work upon. Thus formed, it will be found, it is said, next to the plough, the most useful instrument in tillage, not only in reducing a stiff soil, but, with a bush at its tail, to cover the seed, when sown, much more effectually, and in a better manner, than a harrow, as it turns up the earth light and fine behind it; and, though seemingly unwieldy, will turn with ease, and may be worked with one, two, or three horses at most, upon any land that is of a proper dryness to work upon.

This implement may likewise be employed to assist in reducing the half-burnt turf of burn-baked land, which requires much labour, as commonly done by hand; but by going over the land several times with the spike-roller, and harrowing it with heavy harrows alternately, to pull up the turfs, or ploughing them up, they may be reduced fine in a much shorter time, and at a much less expence, than by beating or breaking them by hand. The mode of constructing the tool, in the common manner, has been already shewn. See ROLLER.

Still more lately, a clod or improved roller of this kind has been constructed by Mr. Blithe Harries of Benthall-house, near Shiffnall, in which the danger of the horses being injured in turning, by the spikes, is obviated. It is found very effectual on strong soils, and well adapted for breaking and reducing clods, pulverizing old turf fallows, and preparing land previous to sowing barley, and many

other purposes. He describes it in the Agricultural Magazine as consisting of twenty-one cast-iron wheels, twenty-one inches and a half in diameter, the edges three inches asunder; or a smaller pattern, consisting of fourteen wheels, twenty-three inches in diameter, the edges four inches and a half asunder, fastened upon an iron axle-tree, with a large wheel at each end to carry it to the field. It is further stated, that the invention is Mr. Gittin's, of the Isle, Shropshire, an ingenious farmer, who had one made at Mr. Onion's foundery, Broseley; and Mr. Harris now makes them at his iron works, the price of which, in either of the patterns, is 10*l.*, exclusive of the row of spikes to clear dirt or stones, and the shafts.

In this state it forms a sort of cutting or bruising implement of the kind, and may be of very great utility in different cases of stiff, cloddy, arable land, as well as in those of the tough, unproductive, overrun sward kind. It is capable of performing a good deal of work, in both these cases, in a short space of time, and in the most effectual manner.

All implements of these kinds having great power and dispatch, are consequently capable of very general application in the business of tillage, as well as grass husbandry. They may be constructed in different cheap methods, and be made use of with much advantage in a variety of situations, where they are at present perhaps wholly, or in a great measure, unknown.

This implement is sometimes called spiky-roller.

SPIKELET, in *Botany*, *Spicula*, is technically used for the assemblage of the florets of grasses, within the calyx; and which consists of two florets only in *Aira* and *Holcus*; of many in *Poa*, *Bromus*, &c.

SPIKENARD, *Bastard French*. See NARDUS.

SPIKENARD, *Celtic*, a species of *Valerian*; which see.

SPIKENARD, *Falſe*. See LAVANDULA.

SPIKENARD, *Ploughman's*. See BACCHARIS.

SPIKENARD, *Ploughman's*, is also the name of a species of flea-bane, or *conyza*; which see.

SPIKENARD, *Nardus*, or *Spica Nardi*, in the *Materia Medica*, a kind of vegetable shoot growing even with the ground, and sometimes, in part, within the ground, belonging to an Indian grassy-leaved plant, of which we have no particular description. The nard, as it is brought to us, is a congeries of small, tough, reddish-brown fibres, forming a bunch, or spike, about the size of a finger.

The *spica nardi* is usually reckoned in the number of roots. It is also called *nardus Indica*; because brought from the East Indies.

It is now kept in the shops chiefly as an ingredient in the mithridate and theriaca, but was formerly employed in the same intention as the Celtic, and is said to be used among the Orientals as a spice. It is moderately warm and pungent, accompanied with a flavour not disagreeable. Lewis.

There is also another kind, called *spica Celtica*, a species of valerian, growing in the Alps, from whence the shops have been generally supplied with the dried roots, consisting of a number of blackish fibres. This root has been recommended as a stomachic, carminative, and diuretic: at present it is scarcely otherwise made use of, in this country, than as an ingredient in mithridate and theriaca, though its sensible qualities promise some considerable medicinal powers. It has a moderately strong smell, of which it is very retentive, and a warm, bitterish, subacid taste, resembling those of common wild valerian. Lewis.

SPIKENARD, *Ointment of*. See NARDINUM Unguentum.

SPIKES, or, as the seamen call them, *specks*, in a *Ship*,
are

are large long iron nails with flat heads. They are of divers lengths, some a foot or two long, and some are jagged, so that they cannot be drawn out again. They are used to fasten the planks and timber. See *MARLING-Spike*.

SPIKING up the Ordnance, a sea-phraze, used for fastening a quoin with spikes to the deck, close to the breech of the carriages of great guns, that they may keep close and firm to the ship's sides, and not get loose when the ship rolls, and by that means endanger the breaking out of the butt-head of a plank. See *QUOIN*.

SPILAMBERTO, in *Geography*, a town of Italy, in the department of the Panaro; 8 miles S.E. of Modena.

SPILANTHUS, in *Botany*, originally called *SPILANTHES* by Jacquin, is derived from *σπίλος*, a spot, and *ανθος*, a flower, because of its dotted or speckled flowers.—Jacq. Amer. 214. Schreb. 543. Willd. Sp. Pl. v. 3. 1712. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 4. 493. Juss. 187. Lamarek Dict. v. 7. 345. Illustr. t. 668. Gært. t. 167.—Class and order, *Syngenesia Polygamia Æqualis*. Nat. Ord. *Compositæ Oppositifoliæ*, Linn. *Corymbiferae*, Juss.

Gen. Ch. *Common calyx* nearly hemispherical, imbricated, with lanceolate, linear, compact scales, in a double row. *Cor.* compound, uniform, tubular, conically convex, the florets numerous, equal, all perfect, funnel-shaped, with a four or five-cleft, reflexed limb. *Stam.* Filaments four or five, capillary, very short; anthers cylindrical, tubular. *Pist.* Germen oblong, compressed; style thread-shaped, the length of the stamens; stigmas two, recurved. *Peric.* none, except the unchanged calyx. *Seeds* solitary, oblong; compressed, flattish. *Down* with a membranous margin, and two unequally-sized awns at the tip. *Recept.* brittle, conical, its scales compressed, deciduous.

Obf. In *S. atriplicifolius* the seeds have no awns; and in *S. Acmella* and *uliginosa* the radius is very small, and composed of only three or five flowers.

Eil. Ch. Receptacle chaffy, conical. Down with two awns, one larger than the other. Calyx nearly equal.

1. *S. urens*. Biting Spilanthus. Willd. n. 1. Jacq. Amer. t. 126. f. 1.—Leaves lanceolate, entire. Stem prostrate.—Native of sandy fields in America, about Carthage, flowering from May to October. *Root* perennial, fibrous. *Stems* herbaceous, round, smooth, procumbent, branched, fibrous at the joints. *Leaves* opposite, sessile, smooth, ribbed. *Flowers* solitary, capitate, terminal, scentless, white, dotted with black.

The leaves of this species possess a hot, pungent flavour, resembling the root of *Pyrethrum*, or Pellitory of Spain, for which they are occasionally substituted.

2. *S. Pseudo-Acmella*. Bastard Acmella or Spear-leaved Spilanthus. Willd. n. 2. (*Verbena Pseudo-Acmella*; Linn. Sp. Pl. 1270. *Chrysanthemum mederaspatanum latifolium, scabiofæ capitulis parvis*; Pluk. Alm. 99. t. 159. f. 4.)—Leaves lanceolate, serrated. Stem erect.—Native of Ceylon, flowering in July. *Root* annual. *Stem* two feet high, round, branched, rather hairy. *Leaves* opposite, stalked, ovate, veined, the stalks channelled and slightly downy. *Flowers* solitary, yellow, on long, upright, naked stalks.

3. *S. Acmella*. Balm-leaved Spilanthus. Willd. n. 3. (*Verbena Acmella*; Linn. Sp. Pl. 1271. *Abcdaria*; Rumph. Amboin. v. 6. 145. t. 65.)—Leaves ovate, serrated. Stem erect. Flowers radiated.—Native of Ceylon, flowering from July to the end of summer. *Stems* about two feet high, much branched. *Leaves* like those of the last species. *Flowers* solitary, radiated, yellow, on very long

stalks. This plant is reputed to be a specific for the stone in the East Indies. It differs chiefly from *Pseudo-Acmella*, in being more branched, and in having radiated flowers.

4. *S. uliginosa*. Boggy Spilanthus. Willd. n. 4. Swartz Prodr. 110. Ind. Occ. 1291.—Leaves ovato-lanceolate, notched. Stem erect, forked. Flowers radiated, terminal, stalked.—Native of the south of Jamaica, in clayey, swampy ground, flowering in the spring. *Root* annual, long, simple, thread-shaped. *Stem* herbaceous, half a foot high, round, smooth, reddish. *Leaves* opposite, stalked, smooth. *Flowers* roundish at first, afterwards conical, yellow.

5. *S. exasperata*. Rough or Warty Spilanthus. Willd. n. 5. Jacq. Ic. Rar. v. 3. t. 584. (*S. radicans*; Jacq. Collect. v. 3. 229.)—Leaves ovate, wavy. Stem forked, ascending, rough with warts at the base. Calyx of five leaves.—Native of Venezuela, and flowering in flowers from July to January. *Root* branched, whitish. *Stem* nearly three feet in height, erect, somewhat hairy, rough towards the base, with sharp, fleshy warts. *Leaves* opposite, stalked, acute, slightly serrated, roughish. *Flowers* solitary, white, on downy stalks. *Seeds* black, fringed with white hairs.

6. *S. alba*. White-flowered Spilanthus. Willd. n. 6. L'Herit. Stirp. Nov. t. 4.—Leaves ovate, wavy; lower ones alternate. Stem branched, ascending. Calyx of many leaves.—Native of Peru. It flowers in June and July. *Root* annual, fibrous, pungent, exciting saliva, whence Murray called this species *salivaria*. *Stem* herbaceous, wavy, upright, rugged, panicled. *Leaves* stalked, spreading, bluntish, hairy, fringed. *Flowers* terminal, solitary, conical, obtuse, white.

7. *S. atriplicifolia*. Orache-leaved Spilanthus. Willd. n. 7. (*Bidens atriplicifolius*; Linn. Sp. Pl. 1168.)—Leaves alternate, deltoid, toothed, stalked, furnished with stipulas. Stem panicled.—Native of South America. *Stem* herbaceous, smooth. *Leaves* alternate, on slender stalks. *Stipulas* equal, kidney-shaped, like little ears. *Flowers* solitary, terminal. *Seeds* without awns, oblong.

8. *S. infipida*. Tasteless or Mild Spilanthus. Willd. n. 8. Jacq. Amer. 215. t. 126. f. 2.—Leaves obovate, toothed, sessile.—Native of America, and found by Jacquin at the Havanna, where it flowers in the winter. *Stems* shrubby, round, branched, procumbent. *Leaves* opposite, nearly sessile, smooth, attenuated at the base. *Flowers* like those of *urens*, and like that species the leaves of this have a salt or biting flavour, but in a milder degree, so that the specific name is not extremely appropriate.

9. *S. oleracea*. Esculent Spilanthus. Willd. n. 9. Jacq. Hort. Vind. v. 2. 63. t. 135.—Leaves ovate, heart-shaped, serrated. Stem branched, diffuse.—Native of the East Indies, flowering at Kew from July to November. *Stems* a foot long, prostrate, round, somewhat rugged. *Leaves* opposite, dark green above, yellowish or glaucous beneath. *Flowers* solitary, terminal, forming a sort of cylinder, yellow. *Seeds* brown, fringed with white hairs.

10. *S. tinctoria*. Dyers' Spilanthus. Mart. Mill. Dict. n. 5. Loureir. Cochinch. 484.—Leaves lanceolate, serrated, smooth. Stem diffuse. Flowers numerous, terminal.—Found on cultivated ground, in China and Cochinchina. *Stem* herbaceous, three feet high, rather procumbent, round. *Leaves* opposite, smooth, rather succulent, bright green. *Flowers* of a blueish-white hue. The leaves when bruised yield a fine blue colour, whence it is cultivated by the natives for dyeing. This is very closely allied to *S. Acmella*.

SPILBACH, in *Geography*, a town of Bavaria, in the territory of Rothenburg; 4 miles W.N.W. of Rothenburg.

SPILE, in *Ship-Building*, a plug made of fir to fill up holes, where nails have been driven, to prevent leaking, &c.

SPILE, in *Rural Economy*, a piece of wood sharpened at the point, and drove down into the ground, on the sides of rivers, or other places, for the purpose of protecting their banks, or other parts, against the destructive violence of the waters. They should be well proportioned for the purpose, and be very firmly driven down by proper machinery.

But in whatever way, or however firmly, spiles may be driven down into the ground, they never form a good or secure defence against the force of river-currents. The only method of completely effecting this is now well understood to be that of making the banks to shelve, or slope well backward from the rivers, and throwing the force of such streams in new, contrary, or other directions than those to which they have been accustomed. In these ways much is not unfrequently accomplished, without any great deal of labour, trouble, or expence in any manner.

SPILE is also a term provincially used to signify the vent-peg of a cask.

SPILEMBERGO, in *Geography*, a town of Italy, in Friuli, on the Tajamento; 14 miles W. of Udina.

SPIILINGS, in *Ship-Building*, the dimensions taken from a rule-staff, a mould's edge, or straight line, to trim or fay one piece to another.

SPIILKEVY, in *Geography*, a town of Norway, in the province of Drontheim; 88 miles S.W. of Romsdal.

SPIILL, *To*, in *Sea-Language*, is to discharge the wind out of the cavity or belly of a sail, when it is drawn up in the brails, in order to furl or reef it. This is performed either by collecting the sail together, or by bracing its edge to the wind, so as to shiver or be laid aback. Falconer.

SPIILLING-LINES, in a *Ship*, certain ropes fixed occasionally to the main-sail, and fore-sail, in tempestuous weather, for raising or furling them more conveniently. They are passed through blocks above the yard, and thence leading down before the sail, come under its bottom, and return upwards behind it to the yard, where they are fastened; so that the sail by this effort is closely and immovably confined to the yard. Falconer.

SPILOMA, in *Botany*, so called by Acharius, from *σπίλωμα*, a stain, or spot, in allusion to the appearance of the fructification.—Ach. Meth. 9. Lichenogr. 23. t. 1. f. 1. Syn. 1. Sm. Engl. Bot. v. 29. 2075.—Class and order, *Cryptogamia Algæ*. Nat. Ord. *Algæ, Lichenes*.

Ess. Ch. Receptacles shapeless, without a border, hairy and powdery, in an uninterrupted crust.

This minute and obscure genus of the Lichen tribe has long been overlooked, or confounded with other things. The species, which are sixteen in Acharius's recently published *Synopsis*, are found either on old wood, the bark of trees, or on rocks and walls. Thirteen are figured and described in Engl. Bot. v. 29—36. Some of these, as *S. Vitiligo*, t. 2075, looks to the naked eye like a little grey dull, scattered over the pales on which it grows, and staining the finger when touched. Others resemble crustaceous Lichens, particularly *Lecidææ*; but are distinguished by their black powder, which comes off with a touch; as *S. versicolor*, t. 2076, and *variolosum*, t. 2077, both found on old trees. *S. auratum*, t. 2078, is still more remarkable for the internal orange-colour of its receptacles, which becomes visible whenever they are rubbed or broken.

SPIILSBY, in *Geography*, a market-town in the east division of the foke of Bolingbroke, parts of Lindsey, in the county of Lincoln, England, is situated on an eminence, overlooking to the south a large tract of marsh and fen land, which is bounded by Boston Deepes and the German ocean.

Spilsby is the chief town in the southern part of Lindsey division, and is 31 miles E. from Lincoln, and 134 miles N. from London. It consists principally of four streets, uniting at the market-place, which forms a spacious square, intersected in the centre by a row of houses, with the market-cross at the east end, and the town-hall at the west. The market-cross consists of a plain octagonal shaft, with a quadrangular base; the whole elevated on five steps. The town-hall, a plain brick building, standing on arches, was built in 1764, on the site of the old hall, which, being in a ruinous state, had been taken down. The general quarter-sessions of the peace, for the southern division of the parts of Lindsey, have been holden here for upwards of a hundred years. The parish-church, situated on the west side of the town, is an irregular building, consisting of north and south aisles, the latter of much larger extent than the rest of the edifice. A chapel occupies the extremity of the body of the church, in which are some ancient monuments, belonging to the families of Beke, Willoughby, and Bertie. At the west end of the church is an embattled tower, of a more modern date than the other parts of the structure, and probably erected about the time of Henry VII. Here is a small free-school, supported by the rents of certain tenements bequeathed for that purpose; and a Sunday school, recently established, promises to be of great advantage to the lower classes of the people. A weekly market is held on Mondays, and three fairs annually. The population return of the year 1811 states the number of houses to be 230, occupied by 963 persons.

At Erefby, two miles from Spilsby, was formerly a mansion, noticed by Leland, belonging to the Bekes and to the Willoughbys. It was taken down, and another built on the site, which was destroyed by fire: a stately avenue of trees leads to the site. The place is now abandoned for the more splendid domain of Grimthorpe. Erefby was a grant from William the Conqueror to Walter Beke. It was possessed successively by the Bekes, Willoughbys, and Berties, till the year 1778, when, with the manor of Spilsby, it became the property of sir Peter Burrell, now lord Gwydir, by his marriage with lady Willoughby, daughter and coheirefs of the duke of Ancaster. Beauties of England and Wales, vol. ix. Lincolnshire, by J. Britton, F.S.A.

SPIN HAY, *To*, in *Military Language*, is to twist it up in very hard ropes, for an expedition: so that it may be the less bulky for the cavalry to carry behind them.

SPINA, in *Botany and Vegetable Physiology*, a thorn originating from the substance of the wood itself. (See **FULCRA**.) Linnæus remarks that a thorn is liable to disappear by culture, or richness of soil, as in the pear-tree. Hence he speaks of such plants as becoming tame by the influence of good treatment; whereas prickles, *aculei*, seated in the bark, are not affected by similar causes. The reason is well explained by Willdenow, who justly considers thorns as of the nature of abortive branches, stunted in their growth for want of nourishment.

SPINA, in *Geography*, a town of France, in the department of the Tanaro; 9 miles S.W. of Acqui.

SPINA Bifida, *Cloven Spine*, in *Surgery*, frequently named also *Hydrorachitis*, is a tumour for the most part situated on the spines of young children, commonly on the lumbar vertebra; occasionally on the dorsal or cervical ones; and sometimes, though less frequently, on the os sacrum.

A tumour of a similar nature is now and then observed upon the head. Richter's Chirurg. Bibliothek, 9 band, p. 186.

In cases of spina bifida, the swelling is soft, and may be gradually

gradually diminished, or even made to disappear entirely by pressure; but it always returns again immediately when the pressure is removed. The fluctuation of a fluid is distinctly perceptible to the touch. The integuments retain their natural colour and appearance. However, the children seem to experience pain when the tumour is compressed, or when they are placed upon their backs. The size of the swelling is extremely various, it does not often exceed that of an orange; but, in a few instances, it is much more considerable.

The generality of children affected with spina bifida are deficient in strength and vigour, and are subject to frequent diarrhoea. Some cannot retain their urine and feces. A weakness and emaciation are often particularly observable in the lower extremities, which, indeed, are sometimes almost paralytic. Though most children agree with this account, it deserves notice, that many others are, in every respect except the tumour, perfectly healthy and well formed.

When a spina bifida is dissected, the swelling is found to consist of a sac, filled with an aqueous fluid, and composed of the integuments, and of the membranous sheath which lines the canal of the spinal marrow. The lining of the spinal canal protrudes through a fissure in the vertebræ. This fissure is owing to an imperfect formation of these bones, and is commonly found at their posterior part, where the spinous processes would otherwise be. The preternatural opening is sometimes confined to one bone, and then the swelling frequently has a small base. In many instances, the ossification of several of the vertebræ is not completed behind, so that the canal for the spinal marrow resembles an open furrow. Even the whole spine, from one end to the other, has been found thus imperfect. (Maret, Mem. de Dijon, vol. ii. p. 105.) The aperture has been known to extend through the body of the affected vertebra, so that the finger could be passed quite through into the abdomen. (Saltzmann, De Tumouribus quibusdam Serosis externis.) In one example, there was not only a furrow in the vertebræ, all the processes of these bones were wanting. Richter's Chir. Bibliothek, 4 b. 2 ft. p. 350.

In general, the sac is filled with a clear, transparent fluid; but occasionally, the contents are turbid, yellowish, and bloody. The portion of the spinal marrow surrounded by the fluid is generally softened, and almost like mucus, or thin matter. Mem. de l'Acad. de Dijon, vol. ii.; and Richter's Anfangsgr. der Wundarzneykunst, band 2. p. 236, Dritte Auflage.

Children afflicted with this disease sometimes suffer at the same time from hydrocephalus. They seldom live longer than a year after birth. The tumour generally continues to enlarge. Occasionally it inflames and ulcerates, and then death very soon follows. Children are observed to live longest when the swelling is remote from the head. The instances of persons attaining a middle age with this disorder are rare, and these subjects have mostly had their lower extremities in a paralytic useless state. Examples, however, are recorded, in which patients labouring under this affliction, have lived to the ages of eight, seventeen, twenty, and fifty. Acrell K. Vetenskaps, Ac. Haedligar, 1748, p. 91. Warner's Cases in Surgery, p. 136, ed. 4. Hochstaetter, Diff. de Spina Bifida, Altorf, 1703.

Experience has proved, that puncturing the tumour with a lancet, and thus discharging the fluid, either at once or gradually, cannot be practised without inducing fatal consequences. Also, when the swelling ulcerates and bursts of itself, the child perishes; nor has tying the pedicles of such spina bifida as have narrow bases proved more successful. Some years ago, Mr. Abernethy suggested the method of letting out the fluid, healing the puncture directly after-

wards, and repeating the same proceedings as often as necessary. (See Abernethy's Surgical and Physiological Essays, parts i. and iii.) This gentleman tried the plan in one instance, and though it was not attended with ultimate success, it did not seem to bring on the sudden fatal symptoms, which are the usual effects of letting out the fluid in the common way.

This last proposal, which originated with Mr. Abernethy, is important, inasmuch as recent observations have proved, that a practice founded on the foregoing principles may actually effect a cure of a disease that, until very lately, always baffled the art of surgery. It is to Mr. A. Cooper that we are indebted for the mode of puncturing spina bifida with a fine needle, thus letting out the fluid from time to time, and promoting a closure of the opening in the spine, by applying a compress and bandage. The adhesive inflammation, in fact, obliterates the cavity in which the fluid collects, and the disease ultimately does not return. In one case, Mr. A. Cooper seems to have accomplished in this manner a perfect cure. See Medico-Chirurgical Transf. vol. ii. case 2, p. 326.

This eminent surgeon, however, pursues two modes of treatment for the relief of children afflicted with spina bifida; one palliative, the other radical.

The first consists in treating the case as a hernia, and applying a truss to prevent its descent; the second, in pricking the tumour with a fine needle, and in producing an adhesion of the sides of the sac, so as to close the opening in the spine, and stop the disease altogether. The first is attended with no risk; the second exposes the patient to much constitutional irritation; but, if successful, hinders the future recurrence of the disease. Even when the adhesive process cannot be effectually accomplished by the second plan, the palliative method may yet be tried. See case 4, lib. supra cit.

Unfortunately, there are numerous cases of spina bifida which leave no hope of cure. The following examples of this description are pointed out by Mr. A. Cooper.

If the tumour is connected with an unnatural enlargement of the head, hydrocephalus internus is conjoined with spina bifida, and the water will accumulate in the ventricles of the brain, whether the radical or palliative treatment of the tumour on the back be tried.

If the lower extremities are paralytic, or the feces and urine are discharged involuntarily, there is no hope of relief.

If the tumour has burst at the time of birth, or soon afterwards, little expectation of a cure can be indulged; for although the opening in the skin may be closed with lint and adhesive plaster, and union be produced, so that no more of the fluid can escape, yet hydrocephalus internus will follow.

The deficiency of the spine is sometimes so great, that the tumour, at the time of the child's birth, is very considerable; the nerves are protruded out of the spinal canal; the spinal marrow is injured; and all attempts at a cure must be unavailing. Medico-Chirurgical Transf. vol. ii.

In this disease, purgatives and diuretics have been tried in vain; and no outward applications, excepting pressure, have been found to do the least good. Richter has suggested making two issues near the tumour; but the proposal hardly frings with it a promise of utility. In short, in the present state of our knowledge, the practice tried by Mr. A. Cooper is the only one in favour of which facts and actual experience can be adduced; and, if we except the cases published by this gentleman, we have no instance on record of a spina bifida being cured or benefited.

When

When the disease does not admit of the radical or palliative cure, the surgeon should instruct the friends of the patient to keep the tumour out of the way of every thing that has a tendency to make it inflame and ulcerate; and, if any thing at all is done, the swelling should be tenderly bathed every now and then with spirituous and mildly astringent lotions, with a view of averting inflammation and ulceration of the skin. First Lines of the Practice of Surgery, by S. Cooper, edit. 3.

SPINA Burgi, in *Botany*, a name used by some authors for the *alaternus*, or ever-green privet, a garden shrub, the fruit of which is a mild astringent.

SPINA Ventosa, in *Surgery*, a caries or abscess of the internal part of a bone. *Spina* was a term applied by the Arabian writers, because the disease occasioned a pricking in the flesh; and the epithet *ventosa* was added, because the part affected communicates a feel as if it contained air. *Spina ventosa* is often employed synonymously with white-swelling. See WHITE-SWELLING.

SPINACH, or *SPINAGE*, in *Botany*. See *SPINACIA*.

Spinach is sometimes cultivated in the field for the advantage of the seed. The different sorts of it are raised in this manner, in order to supply the demand for the different kinds of feed.

The land for these crops is finely prepared by different ploughings and harrowings in the early spring, and a little well rotted dung intimately blended with the soil, where the land is not of a good quality.

The different sorts of seed are then sown in small furrows made for the purpose, in the ground, either by the hand-hoe, or by means of a drill for this use, at the distance of from about twelve to fourteen inches from each other; the prickly sort of seed being used in the proportion of six gallons to the acre, and the round sort in that of four to the same quantity of land.

Some time in the early part of March, when the plants have advanced so as to have leaves of about one or two inches in length, they are thinned out by the hoe to the distance of four or five inches. The rows of plants are always kept well moulded up both before and after the period of thinning, and the whole crop preserved in a perfectly clean state from weeds. As soon as the crop has reached the time of being in full bloom, the greater part of the male plants are drawn out, by the hand, from among the others, by which means the female plants are allowed more room, light, and air to grow in, and thereby to perfect their seed in a better and more full manner. The plants which are thus drawn out answer in a very profitable manner in the feeding of young pigs, and they may probably be given to some other sorts of animals with advantage.

When the crop becomes quite ripe, it is pulled up, and the seed either threshed out on a cloth in the field, or the whole carried to the barn, to be afterwards threshed out. See *SPINACIA*.

The produce is usually from about two to five quarters on the acre, according as the season and other circumstances are less or more favourable.

The cultivation of spinach for seed in the field often turns out very advantageously, but it is attended with some degree of uncertainty, as is the case with most crops of this nature.

It is a crop which is much grown in the Isle of Thanet, and in East Kent, in order to supply seed for the London seedsmen.

SPINACH, *Strawberry*. See *BLITUM*.

SPINACH, *Wild*, in *Agriculture*, the name of a weed, as

the goose-foot. It is very troublesome in some sorts of land.

SPINACHIA, in *Icthyology*, a name given by some authors to our common stickleback, or banstickle, more usually known among writers by the names *pungitius*, or *aculeatus pisciculus*. See *STICKLE-Back*.

SPINACIA, in *Botany*, a name of dubious origin, but the most general and probable etymology deduces it from *spina*, a thorn, on account of the prickly or spinous integument of the fruit.—Linn. Gen. 520. Schreb. 688. Willd. Sp. Pl. v. 4. 766. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 385. Tournef. t. 308. Juss. 85. Lamarck Illustr. t. 815. Gærtn. t. 126.—Class and order, *Dioecia Pentandria*. Nat. Ord. *Holeraceae*, Linn. *Atriplices*, Juss.

Gen. Ch. Male, *Cal.* Perianth inferior, deeply cloven into five concave, oblong, obtuse segments. *Cor.* none. *Stam.* Filaments five, capillary, longer than the calyx; anthers oblong, twin.

Female, *Cal.* Perianth inferior, of one leaf, permanent, cloven into four, alternately smaller segments. *Cor.* none. *Pist.* Germen inferior, roundish, compressed; styles four, capillary; stigmas simple. *Peric.* none, except the surrounding, hardened calyx, which encloses a solitary, roundish seed.

Obf. The fruit is occasionally round, but generally beset with two or four horns or spines.

Eff. Ch. Male, Calyx deeply five-cleft. Corolla none.

Female, Calyx four-cleft. Corolla none. Styles four. Seed solitary, within the hardened calyx.

1. *S. oleracea*. Garden Spinach. Linn. Sp. Pl. 1456. "Schkuhr. Handb. v. 3. 469. t. 324." (*Spinachia*; Ger. Em. 330.)—Fruit sessile.—Native place of growth unknown. It was cultivated in Great Britain so long back as the year 1568, and flowers throughout the summer. *Root* annual. *Stem* one or two feet high, herbaceous, branched, hollow. *Leaves* arrow-shaped. *Male flowers* herbaceous, in long spikes, abounding with pollen. *Female flowers* on a separate plant, in clusters on the stalks at every joint, herbaceous, small. *Seeds* roundish, unarmed, subject to vary with regard to spines.

There are two or three varieties of the garden spinach, one called *prickly*, another *smooth*; differing in the size and shape of the leaves, and in their seeds being more or less prickly.

This plant does not appear to have been known to the ancients. It is called *Hispnac* by Arabian physicians, and has been so long and generally cultivated in Spain, as to have obtained the name of *Hispnanumolus*. A conjecture is proposed by professor Martyn respecting the introduction of this plant into Spain by the Saracens.

2. *S. fera*. Wild Spinach. Linn. Sp. Pl. 1456. (*S. foliis ex deltoideo-ovatis, subsinuatis, capsulis in orbem dispositis*; Gmel. Sib. v. 3. 86. t. 16.)—Fruit stalked.—Native of Siberia, in damp, unfrequented places.—*Root* annual, whitish. *Stem* nearly two feet high, branched, erect. *Leaves* stalked, triangular or ovate, occasionally sinuated, obtuse. *Male flowers* in close heads, near the females, or in solitary, interrupted spikes. *Fruits* axillary, three or more, on stalks of their own length, ovate or obovate, obtuse, slightly keeled on each side, smooth, very obtuse.

SPINACIA, in *Gardening*, contains a plant of the annual culinary kind, of which the species cultivated is the garden spinach (*S. oleracea*.)

There are varieties of this which differ in the size and shape of the leaves, and the greater or less prickliness of the seeds; as the triangular with prickly seeds, in which the

SPINACIA.

leaves are triangular and sharp arrow-pointed, the seeds somewhat armed with short spines; the round with smooth seeds, which has ovate thick leaves, not angular at their base; both the stalks and leaves are much more fleshy and succulent than in the other sort; and the seeds are smooth, without any spines. Of this also there are two or three sub-varieties, differing in the shape, thickness, and size of their leaves.

In each of the principal sorts there are variations in the leaves, as to their form and magnitude, but the broadest and thickest-leaved sorts are far the best in quality. Those with the most thick and stocky leaves, of a strong dark green colour and luxuriant growth, are commonly supposed the most valuable sort of the round kind.

Method of general Culture.—In these plants it is effected only by seed, by sowing it every year in spring and autumn; the former furnishing the main spring and summer crops; and the latter the winter, and those for early spring use. The prickly sort is the best for winter crops, and the round for the summer ones.

The seed should be sown at several intervals of time from January till August, as every month, three weeks, or fortnight, according to the earliness or advanced period of the season, so as to obtain a regular succession most part of the year. The general spring crop should be sown in March, and the general winter crop about the beginning of August.

But in the spring sowings, as the crops in the very early sowings in January run soon to seed, a moderate quantity should only be sown. However, in the autumn sowings, as the plants do not run the same year, good full crops, to stand for winter and early spring use, may be put in.

These plants succeed in any common soil of the kitchen-garden; but the richer in dung the better; always choosing an open situation, not too near low spreading trees, &c. as they never succeed in close or shady places, in which they are always drawn up weak, and soon run to seed without attaining perfection: a warm border may be proper for the early crops; but for the main crops in general, the open quarters are the most suitable, though a broad warm-lying border may also be proper for some part of the later sown winter crops occasionally, for the purpose of having the advantage of a little shelter of the fence, and benefit of the sun during the winter season; and fresh seed should be procured for each sowing, as this will be found of great importance in the free growth of the plants: for the autumn sowings of the winter crops, it is of advantage to procure new seed of the same year.

And after the ground has been properly dug, the seed may either be sown broad-cast, and raked in, or in shallow drills a foot asunder; though broad-cast is the most expeditious, and probably the most proper method for the growth of the crops in the product of large full leaves; sowing it all over the surface moderately thin, either in one continued plat, and trodden down evenly, if light ground, and raked in with a large rake or light harrow; or the ground may be divided into four or five-foot wide beds, with foot-wide alleys between each, especially for the early and winter crops in moist ground; the seeds being sown as above, raking them in evenly: drill-sowing may also be occasionally practised with convenience and advantage, in which the drawing of the drills should be performed with a hoe flatways, near an inch deep, and ten or twelve inches asunder, then scattering the seeds thinly along them, raking the earth over full half an inch deep; which mode is often very proper in sowing between other crops, as between wide rows of beans, peas,

cabbages, &c. as it admits of hoeing up the weeds between the rows with facility; and if sown thin, and the plants be thinned out properly, they grow large and fine, and the produce is very conveniently gathered. It may likewise be sown in wide drills alone, about a foot distance, for a distinct full crop: or in rows two feet asunder, to admit of intercropping in the intervals, with rows of cabbages, beans, and other things occasionally. In these sowings the seeds should be scattered moderately thin, and the plants be afterwards thinned out to three inches distance at least, the seeds being directly raked regularly in: and when sown broad-cast all over the surface, if in light loose land, and a dry warm season in the advanced part of spring, or in the summer and autumn, it may be proper first to tread the seed evenly down, then raking it in effectually with a large rake. The seeds mostly come up in a fortnight; or perhaps, if sown very early in spring, it may be three weeks or a month before they appear.

In respect to the after-culture of the crops, when the plants have three or four leaves an inch broad, they should be thinned out and cleared from weeds, either by hoe or hand; but the former is the most eligible, especially for the broad-cast sown crops; choosing dry weather, and cutting out the plants to three or four inches distance, together with all the weeds in every part; but the above distance is scarcely sufficient, unless it is intended to begin thinning out the plants for use while young: in other cases it is advisable to hoe them out six or eight inches asunder, especially the spring and summer crops of the round spinach, which, having proper room, will grow very large, and spread its broad leaves widely, and does not run to seed so soon as if left close. When the spring and summer-sown crops are left too close, they are apt to draw up weak, and soon go to seed. The winter crops of triangular or prickly spinach, it will be sufficient in most cases to thin out finally to three or four inches distance.

These crops are often sown in spring with other crops, for the sake of cropping the ground to the best advantage; but it is best when performed alone in most instances.

They may, however, in some cases, be put in between the rows of particular plants with some utility in the way of saving ground, where that is material, as between young cabbage and cauliflower plants, which have been finally set out at wide distances for main crops, as well as in the large intervals of pea and bean crops, especially when of the low or dwarf kind, and between some other sorts of general rowed crops with wide spaces. The spinach seed, in these circumstances, is mostly best put into the ground in single or double drills in the middle parts, according to the distances of the rows of the other plants; but it is sometimes sown in the broad-cast manner over the whole surfaces of the intervals, and raked in. And it is occasionally sown over all the piece of ground in mixture with short-top radish seed, and raked in; after which, either immediately or in a short suitable space of time, the plants or other crops are planted out or sown in their regular modes. The sowing of spinach seed in this way, commonly takes place in the early parts of February and the following month, and is practised upon the borders, as well as the large quarters where such main spring crops are to be grown and cultivated. The plants or other crops in this mode growing quickly, have soon the advantage of the mixed crops between their rows, though the small plants of these kinds are not injured or retarded in their growth thereby, as they are ready to be gathered and removed for use long before the main crops have any hurtful tendency.

Immediately

SPINACIA.

Immediately on the removal of such small crops, the intervals of the rows are hoed over to loosen the earth, which is then drawn up to the stems of the plants or other crops. These methods of cropping are, however, only to be used in such cases as the above.

When the plants have leaves two or three inches broad, they may be gathered. The method of which is, either by cutting them up with a knife wholly to the bottom, or drawing and cleaning them out by the root, if the crops want thinning; or only cropping the large outer leaves, the root and heart remaining to shoot out again. With the spring crops, when the plants want thinning, they may be cut up wholly to the root, thinning them out where thickest in a gradual manner, so as to leave the standing plants at least six or eight inches distant to grow to perfection, which, when beginning to shoot for seed, may also be cut up wholly to the bottom: and in the winter crops, if the plants stand too close at first, some may be thinned out quite to the bottom, afterwards the larger outer leaves only must be cropped in the winter and early part of the spring; but when the spring is more advanced, and the plants grown large and require thinning, or when they begin to run to seed, cutting them up to the bottom in a thinning order is the best method.

Some of the best of the different sorts of plants should be left in the spring to stand for seed, which should be collected, when well ripened, in the manner directed below.

Culture in the early and succession Crops.—In raising early crops of this sort, as well as those which are to come in regular succession, during the beginning of the spring and the first part of the summer season, it will be necessary to commence and continue the sowing of the seed at two or three different times in the month of January, when the weather is mild and open, choosing the most dry and warm situations that can be found for the purpose, and only putting in small quantities in each of such sowings, as the crops are extremely liable to be destroyed or to run to seed. In the succeeding month it will likewise be proper to continue the sowings in a more full manner as to the quantities, at two or three additional different periods, in almost any open places of the garden, by which means full successions may be provided, for some length of time, to follow the crops of the first winter sowings, which will now soon run up to seed, these sowings coming in much about the same time. In the two months which follow the last, it will still be proper to proceed or go on with the sowing of this sort of seed every ten days, or fortnight, making use of open but rather cooler situations. By this means regular supplies will be provided for the concluding spring and beginning summer months.

And in cases where constant successions of crops of this kind are wanted the whole of the summer season, it will be requisite and proper to continue the repetition of the sowings every fortnight during the months of May, June, and July, as the plants in these sowings very quickly run up for seed. The most moist spots which the garden affords should now be selected for such crops, they being free and open. It is also advantageous in the summer sowings to have showery weather for performing the work in, when it can be had. The seed should be sown rather thin, when in the broad-cast method; and in the drill mode to only the depth of about an inch. The plants are to be kept pretty well thinned, in order to prevent their drawing up to seed. The sowings which are made in the last of these months, will continue the crops in succession, until they are succeeded by those of the winter sowings.

In these cases the spinach is sometimes not suffered to

grow large, but cut in its young growth, allowing the bottom parts to grow again.

In the after-culture there is nothing material in these crops, besides that which is necessary in the general ones.

Culture in the late or winter Crops.—In these cases the seed is sown to the most advantage for the succeeding crops towards the end of the first week in August, the beginning of the second, and the middle of the third, according to the nature, situation, and state of the ground, as they are the most prevented in common from running up too early to seed, while they get a little growth, and become somewhat forwarded and strong before the winter weather sets in. It is best when the sowings can be performed in rather moist showery times, as when it is done at dry hot periods, the seed is apt to sprout and come up in an irregular manner, the plants appearing in a straggling sparing state. These crops should constantly have, as much as possible, open situations, which lie dry at this season of the year, and which have funny exposures.

The seed is to be immediately sown on the fresh newly turned up soil, either over the whole surface, or in the bed manner, which is more convenient for the cultivation and collecting of the produce. In some places, a slight sprinkling of the brown Dutch and common cabbage lettuce seed, or other similar sorts, are sown along with this kind of seed in these crops, in order to stand for culling out during the winter and early spring months. The seed is to be covered and trod in directly after being sown.

These late crops are also occasionally, though rarely, sown in the drill manner, but the former methods are more suitable in these cases, where gradual thinning is to be practised with the crops, which is by much the best sort of cultivation for having such crops in fine perfection.

Where large crops of the winter kind are raised, as in market gardens, early cabbages are sometimes planted out with these crops in wide rows, as three or four feet apart. The setting out of these plants takes place in October or the following month. At these distances no injury is done to the spinach crops by the growth of the cabbage plants, and in the early spring, the spinach being wholly cleared away for use, a full forward cabbage crop is left, and the most is made of the land and time.

The plants in these late crops want thinning and clearing from weeds early in their growth, as when less than an inch in the breadth of the leaves, which may be done by the use of the hoe in a dry time, leaving the plants not more than three or four inches apart, as some may be gradually afterwards thinned out for use, so as to let them ultimately stand about five inches from each other; the leaves are after this only to be gathered for use, during the whole winter season, the larger outer ones being alone taken, the smaller inner ones being always left to expand themselves by degrees, in their turn, and afford regular successional supplies until the end of the spring, at which time, when the plants begin to grow large and crowd each other, or to shoot up for seed, they may be wholly cleared away.

In these crops much attention is necessary to keep them clear from weeds, by frequent hoeing and hand-weeding, being careful to remove chick-weed, which is always liable to infect these crops much in winter. All the large weeds should be wholly removed from the ground, as if left they do great injury, and not unfrequently take root again.

As the spring advances, the surface of the ground should be lightly hoed among and about the plants, taking a fine mild dry day for the purpose; which will greatly promote the growth of them, and by which they will soon shoot out strongly, becoming further in a fine state of perfection

for use. The large outer leaves are still only to be gathered, except where the plants stand too thick in the crops.

Saving Seed.—The seed being perfectly ripe in the plants which are left for this purpose, which should always be those of the most stocky growth, and which have the largest, the most expanded, and the thickest leaves, is easily known by its turning of a brown colour, and hardening in the tops of the seed-stalks. The plants of the winter crops mostly run up first to form seed-stalks, being soon, however, followed by those of the spring-sowings, and they are commonly loaded with plenty of well-ripened fertile seeds about the close of July or beginning of the following month. In this state the stalks are to be pulled up and spread out to dry for a few days, turning them as it may be necessary, in order to fully dry and harden the whole of the seed in a proper manner. They are then to be beat or threshed out from the seed-stalks upon a cloth, and put up in bags to be kept in a dry situation for use.

The seed which is newly saved is excellent for sowing the winter crops with, provided it be ripe in due time. It will, however, remain perfectly good until the following year's sowing, but should not be trusted to when more than one year old, as new seed is always of material importance in this culture.

It is proper and necessary, in raising the seed of the different varieties, to have the plants of the different sorts, in different situations, at some considerable distance from each other, in order to prevent injury and degeneracy, by the farina of one sort being dispersed over the other.

The plants of the different kinds are readily distinguishable when they are in flower, and the male plants, after they have dispersed their farina, are in some districts, where the providing of this sort of seed is an object, drawn out, so as to leave more room for the feed-plants. See SPINACH.

SPINADESCO, in *Geography*, a town of Italy, in the department of the Upper Po; 4 miles W. of Cremona.

SPINÆ, in *Ancient Geography*, a station in the 13th and 14th Iter of Antonine's Itinerary of Britain, between Durocornovium or Cirencester and Calleva or Silchester in the former, and Cunellio or Marlborough and Calleva in the latter, and corresponding to Speen, near Newbury, (which see.) The number of miles between Cirencester and Speen being only 15, which gives too small a distance, Dr. Stukeley supposes that a station is omitted between these two places; but Mr. Horsley conjectures, that the numerals opposite to Spinis should have been 35.

SPINAL ARTERIES, in *Anatomy*, are two arteries, one anterior and one posterior, both produced by the vertebrales; each of which, as soon as it enters the cranium, sends out a small branch, by the union of which the posterior spinalis is formed. Afterwards the vertebrales advancing on the apophysis basilaris, or production of the occipital bone, detach backward two other small branches, which likewise meet, and by their union form the spinalis anterior. These spinal arteries run down on the fore and back sides of the medulla spinalis, and by small transverse ramifications, communicate with those which the intercostal and lumbar arteries send to the same part. See ARTERY, BRAIN, and SPINE.

SPINAL Marrow. See MEDULLA Spinalis, MEDULLARY System, and BRAIN.

SPINAL Muscles, are those vertebral muscles which are wholly fixed in the spinal apophysis. See MUSCLE and SPINE.

SPINAL Nerves. See NERVE and SPINE.

SPINAL Apparatus, a machine for affording support to

the spine, and imagined by certain practitioners to be useful in cases of disease and distortion of the vertebræ.

SPINALIS, in *Anatomy*, a muscle on the side of the neck, arising from the five superior processes of the vertebræ of the thorax, and the inferior of the neck; and which in its ascent, becoming more fleshy, is inserted into the inferior part of the vertebræ of the neck laterally. It serves to draw the neck backwards. See SPINE.

SPINALIS cervicis, a name given by Albinus to a muscle of the neck, called by Fallopius the *tertium par musculorum dorfi*, and by Cowper and Morgagni, *spinalis colli*.

This is the muscle, which the French anatomists call *les vertebraux externes du demi-épineux, ou le transversaire épineux dorsal*.

SPINALES colli minores, muscles lying between the six spinal apophyses of the neck, and between the last of the neck and first of the back; being inserted in these apophyses by both extremities on one side of the posterior cervical ligament, which parts them from those of the other side. They are likewise termed *interspinales*.

SPINALIS dorfi, a name given by Albinus to a muscle of the back, figured by Eustachius, *Tab. 37*, and called by Fallopius *quinti paris dorfi musculorum pars implantata in spinas vertebrarum thoracis*.

Others, as Spigelius, have called it a part of the semi-spinatus, and others a part of the longissimus dorfi. The French have named it *le grand épineux de dos*.

SPINALIS dorfi major, a pretty long and slender muscle, lying upon the lateral part of the extremities of the spinal apophyses of the back. It is composed of several muscular fasciculi of different lengths, which crossing each other, are inserted laterally by small tendons in the spinal apophyses from the second, third, or fourth vertebræ of the back; and sometimes, though seldom, from the last of the neck, or first of the back, all the way to the first or second vertebræ of the loins, with several irregular decussations, which vary in different subjects. The longest fasciculi are all a little incurvated, and the whole muscle terminates in points at its ends, but is considerably broad in the middle. It communicates by some fibres with the longissimus dorfi and semi-spinalis, and sends off fasciculi to several transverse apophyses of the back, from the fourth to the eleventh. It is called by some semi-spinalis, but very improperly. See MUSCLE and SPINE.

SPINALIS, *femii, colli, and dorfi*. See SEMI-SPINALIS.

SPINALES dorfi minores. These muscles are of two kinds; some go laterally from the extremity of one spinal apophysis to another, being often mixed with the short fasciculi of the spinalis major; the rest lie directly between the extremities of two neighbouring spinal apophyses, being separated from those on the other side by the spinal ligament. These are smaller and thinner than those of the neck, and are properly enough termed *interspinales*. See MUSCLE and SPINE.

SPINALES et transversales lumborum. There are some fasciculi which run up from the superior false spines of the os sacrum to the lower spinal apophyses of the loins, which may be looked upon as so many *spinales lumborum majores*; and there are also some *spinales lumborum minores* between the spinal apophyses of the loins, and *transversales minores* between the transverse apophyses, which are sometimes of a considerable breadth. See SPINE.

SPINALIS Medulla. See MEDULLA, &c.

SPINA-LONGA, in *Geography*, a sea-port town and citadel, situated near a cape of the same name, on the island of Candia, with a good harbour, formerly the see of a bishop; 30 miles E. of Candia. The harbour is formed by a peninsula,

fula, which secures it from the easterly winds. Its entrance faces the N.N.E., but it is sheltered and protected by an islet, on which the Venetians had built a fortress, similar to that of Suda. For a long time the Turks made fruitless attempts to render themselves masters of this fortress; and it was not till the beginning of the last century that the Venetians permitted them to take possession of it. N. lat. $35^{\circ} 13'$. E. long. $25^{\circ} 42'$.

SPINARELLA, in *Ichthyology*, a name given by Belonius, and some other authors, to the little fish called by us the *lesser stickleback*. In the Linnæan system, this is a distinct species of the gasterosteus.

SPINATUS, in *Anatomy*, a name given by Riolanus, and others, to a muscle of the neck, called by Albinus *spinalis colli*, and by Winslow, and the other French writers, *les vertebraux externes du demi-épineux, ou transversaire épineux du col*. See SPINALIS and TRANSVERSALIS.

SPINCOURT, in *Geography*, a town of France, in the department of the Meuse, and chief place of a canton, in the district of Montmedy. The place contains 466, and the canton 9948 inhabitants, on a territory of $287\frac{1}{2}$ kilometres, in 27 communes.

SPINDLE, in *Mechanics*. See Double CONE, and MENSURATION.

The axis of the wheel of a watch or clock is called the spindle, and its ends the pivot.

SPINDLE, *Parabolic*. See PYRAMOID.

For the method of finding its solidity, see SOLIDITY.

SPINDLE, in *Sea Language*, a sort of iron-pin, tapering at the upper end to a point. It is used to stick into the upper end of the top-gallant mast, so as to carry a vane, which, turning thereon horizontally, will shew the direction of the wind. It is usually crowned with a globular or conical piece of wood, called the *acorn*, which prevents the vane from being blown off.

SPINDLE also denotes the lower end or foot of the capstan, which is shod with iron, and becomes the pivot or axis, upon which it turns in the saucer. See CAPSTAN.

SPINDLE, in *Mining*, a piece of wood fastened into either stow-blade. See STOWS.

These stows give a miner, or any other person that owns them, as good a right to a meer or meers of ground, (so that every meer have a pair of stows set on them,) as a deed of conveyance doth to any purchaser.

SPINDLE-Shell. See TRUMPET-Shell.

SPINDLE-Tree, in *Botany*. See EUONYMUS.

It is generally supposed that the euonymus of the ancients is the same plant that we at this time call by this name. The words of Theophrastus have probably given occasion to this opinion; as they found at first reading like words expressing the characters of the fruit of this tree; but on a closer inspection, they will be found to express a fruit of a very different kind. This author says, that the fruit of the euonymus is like the pod of the sesamum, marked with four protuberant ribs, and hard within, and divided into places for four orders of seeds. It is plain by this, that as their sesamum bore an oblong pod marked with four ribs, so as to seem of a quadrangular figure, so did their euonymus, and that in this long pod there were four orders of seeds, each of these orders containing a great many seeds. Now the fruit of our euonymus is short and not at all like a pod, and contains only four seeds, and not four orders of seeds; there is also this farther proof of our euonymus not being that of the ancients, that ours is a wholesome food to cattle, and they are very fond of cropping it whenever they can reach it, and never get any hurt by it; whereas the euonymus of

the Greeks was poisonous to cattle, according to Theophrastus. See FUSANUS and TETRASTOECHON.

SPINDLE-Tree, *African, or Climbing*. See STAFF-Tree.

SPINDLE-Tree, *Baylard*. See KIGGELARIA.

SPINDLING, in *Agriculture*, the act of running to seed in plants of the grain and other kinds. A great deal, in this business, depends upon the manner in which the plants are cultivated.

SPINE, in *Anatomy*, (the vertebral or spinal column; the back-bone, in common language; spina dorsii,) is the articulated bony pillar at the back of the trunk, forming the foundation or basis of support and connection to all the other parts of the frame. It is placed perpendicularly in the body, sustaining the head by its upper extremity, while its lower end rests on the pelvis. The bones of the chest, to which the upper extremities are connected, are fixed to its sides; while the ossa innominata, or the great bones, to which the lower limbs are articulated, are immovably united to it below. It is the point of attachment and support, in front, for the viscera of the thorax and abdomen, and for the great trunks of the blood-vessels. We may thus regard it as the central and most essential piece of the skeleton; as the centre of motion for the head and limbs; and the basis of support for all the great internal organs. Again; the bones which compose it give attachment to the principal muscles moving the head, the shoulders, and the arms, to those which act upon the trunk, and to some part of the abdominal muscles, and of those which move the lower limbs. Further, it constitutes a canal, which receives and protects the medulla spinalis, and gives issue to the various nerves proceeding from that organ to the trunk and limbs. The importance of the spine, on all the accounts just enumerated, is so great, that it constitutes a leading character, modifying all the other details of organization in the animals which possess it. Hence the primary division of the animal kingdom into vertebral and invertebral animals, adopted by the great modern naturalists, with Lamarck and Cuvier at their head, is founded on the presence or absence of the vertebral column.

The spine is formed of twenty-nine pieces of bone, strongly articulated to each other, and placed in succession from above downwards. The twenty-four upper ones are called vertebrae, and are farther named cervical, dorsal, and lumbar, according as they occupy the neck, back, or loins: there are seven of the first kind, twelve of the second, and five of the last. The five other pieces of the column are the sacrum, and the four ossa coccygis, which form the back of the pelvis; the first being articulated to the twenty-fourth vertebra, and the latter to the end of the sacrum and to each other.

The form of the spine is symmetrical; but the two halves do not always correspond accurately in the healthy state, and the deviations are still more remarkable in disease. As the weight to be sustained by this bony column increases constantly from above downwards, the bulk of the vertebrae, and, consequently, the strength of the pillar, increase also in the same direction, with a trivial exception or two, which will be noticed afterwards. In the attitude of standing, the vertebrae are all situated horizontally; their processes, however, deviate in various ways from this direction. They are distinguished numerically in the different regions, excepting the first and second cervical, which are commonly called atlas and vertebra dentata or axis. The general configuration of these bones is the same throughout; they are formed on a common plan, but this plan is modified in each division by circumstances peculiar to the different regions. The distribution of them into three classes is principally founded on these modifications: the classes are indeed named from their position,

position, but the diversities of their external forms characterize them. We shall first describe the general form, and then notice the particular modifications of the vertebræ.

General Form of the Vertebræ.—They consist of various irregular and prominent portions, separated by different intervals, and united by different plates. The principal part of the bone in size is the anterior prominence, called the body; it is cylindrical or oval, and represents the section of a cylinder, being terminated above and below by two flat surfaces, which give attachment to the fibro-cartilages occupying the intervertebral spaces. This body of the vertebræ forms in front a greater or less convexity, in which we observe a kind of transverse depression, bounded by two prominent edges; it is plane, or a little concave, behind, where it corresponds to the vertebral canal: in both situations there are several apertures for the passage of blood-vessels into the substance of the bone. At each side the body is continuous with the rest of the bone by a kind of pedicle.

A large oval or triangular opening, called the ring or foramen, and contributing to the formation of the vertebral canal, which holds the medulla spinalis, is placed immediately behind the body. Directly behind this opening is the spinous process, varying in form and direction in the different regions, projecting backwards beyond the level of the bone, and separated from the corresponding processes immediately above and below it, by a space filled either with muscles or ligaments.

Such are the parts of each vertebræ as come into notice on the middle line of the bone, from before backwards. When we view it laterally, we observe, 1st, two notches, a superficial one above and a much deeper below, excavated on the pedicle, which connects the body to the articular and transverse processes, and forming, when the bones are joined, those lateral foramina of the vertebral canal, through which the nerves are transmitted; 2dly, two articular or oblique processes, a superior and an inferior, furnished with cartilaginous surfaces, by which they are articulated to the corresponding processes of the bones above and below, and having this surface turned backwards or inwards in the superior, forwards or outwards in the inferior; so that each vertebræ is mechanically locked in its situation by the two vertebræ immediately above and below it; its superior articular processes being overlapped by the inferior ones of the bone above, while its inferior processes overlap those of the bone next below: 3dly, a transverse process, directed horizontally, as its name indicates, longer or shorter in the different regions, and giving attachment to muscles; and 4thly, a flattened plate, united to that of the opposite side to form the spinous process.

Particular Forms of the Vertebræ.—The various common circumstances just enumerated are greatly modified in the different regions; it is principally in the middle of each region that we must examine these modifications, which, at either end, gradually approach to the characters of the neighbouring regions.

The Cervical Vertebræ.—Their number is very constantly seven; but instances are mentioned, in which there have been eight or only six. (See Eustachius, *Ossium Examen*, p. 210; and Columbus de Re Anatomica, p. 263.) The peculiarities of form are strongly marked and distinct in this region. The first and second too, in consequence of their articulation to the head, differ widely from the others, and must therefore be described separately.

The *atlas*, or first vertebræ of the neck, deviates more than any other from the general type. It is very much expanded laterally, and its ring or foramen is very capacious. When we look at it in front, it seems to want the body, in-

stead of which we find a small bony arc, flattened in an opposite direction to that of the bodies of the other vertebræ, convex and rising into a tubercle in front, concave behind, where it bears a smooth cartilaginous surface, articulated to the odontoid process, thin above and below, where it is connected, by means of ligaments, to the occiput and second vertebræ. Immediately behind this bony arc is the large ring, larger in this than in any bone of the column, and consisting of an anterior smaller, and a posterior larger division, of which the distinction is marked by two protuberances, between which a transverse ligament is extended. The front of the ring is filled by the odontoid process; its back part is the beginning of the vertebral canal. Instead of the spinous process, and of the laminae which unite to form it, there is a posterior bony arc, about twice as large as the anterior, rising into a small tubercle at the middle, where the spinous process should be, and bounding the vertebral canal behind. The edges of this arc have ligamentous connections above and below. Instead of articular processes, the atlas possesses on each side, above, a large oval cavity, directed obliquely from behind forwards and inwards, covered by cartilage, crossed by a notch, in which a synovial gland is placed, more elevated at its outer than at its inner edge, and corresponding to the occipital condyle, with which it is articulated; below, a large, circular, and nearly horizontal plane, covered by cartilage, and articulated to a corresponding plane of the second vertebræ. A very deep channel, sometimes formed by a bony plate into a complete foramen, is placed immediately behind the superior articular concavity; it is occupied by the vertebral artery, and the first cervical or sub-occipital nerve. The inferior notch, contributing to the opening for transmitting the second cervical nerve, is behind the inferior articular plane: thus the nerves, which in all the rest of the spine go out in front of the articular processes, pass behind them in the atlas. The transverse process is very remarkable for its length, much exceeding that of any other cervical vertebræ. It is formed by a slender anterior and posterior root, between which the foramen for the vertebral artery is placed, uniting into a considerable obtuse prominence. Thus the atlas, with the exception of the thick lateral parts, to which the occipital condyles are articulated, forms nearly a bony ring.

To the tubercle of its anterior arch the longus colli and the rectus capitis internus minor are fixed: to the transverse process, the rectus lateralis, the obliquus superior and inferior, the levator scapulae, the intertransversi, and the scalenus anterior. The rectus posticus minor is fixed to the tubercle of the posterior arch.

The *vertebra dentata*, axis, epistropheus, or second vertebræ of the neck, is distinguished from all others by its odontoid or tooth-like process, and by its large, superior, articular planes. Its body exhibits above, instead of the usual superior surface, a large bony process, called the densiform, odontoid, or tooth-like, having a slightly convex cartilaginous surface in front, articulated to the back of the anterior bony arc of the atlas, a small, concave, articular face behind, on which the transverse ligament plays, and terminating above in a rather unequal obtuse extremity, from which ligaments arise, connecting it to the lateral anterior portions of the foramen magnum. The anterior surface of the body of the axis has a middle line, on each side of which it is slightly hollowed for the longi colli: the posterior, rough, and perforated by small openings for blood-vessels, forms part of the vertebral canal. The inferior surface gives attachment to the first intervertebral fibro-cartilage. The ring is as large in this as in the atlas. The plates of the spinous process

SPINE.

processes are broad and thick, and the process itself is strong and prominent, projecting considerably beyond those of the succeeding bones. It is rough below, and ends behind either in an expanded knob, or in a bifurcated extremity. On each side of the tooth-like process there is a large circular and nearly horizontal plane, for articulation with the atlas. The inferior articular processes are similar to those of the other cervical vertebrae: they are oblique, placed behind the transverse processes, and have their articular faces turned forwards. The superior notches for the nerves are behind the superior planes; while the inferior are in front of the corresponding articular processes. The transverse process is small, and perforated for the vertebral artery by a foramen, which is directed obliquely upwards and outwards.

The axis is united to the head, the atlas, and the third vertebra of the neck.

To its transverse process, the splenius capitis, levator scapulæ, scalenus, transversus cervicis, longus colli, and intertransversi anterior and posterior, are affixed: to the spinous process, the rectus capitis posterior major, the obliquus inferior, the semi-spinalis cervicis, the interspinalis, and multifidus spinæ.

The five lower cervical Vertebrae.—The body is very small, in comparison to the processes and the ring; it is flattened in front, and elongated transversely, so that it is on a level nearly with the transverse processes, instead of projecting into a bony column in front of them, as it does in the other regions of the spine. It is rather thicker before than behind: its superior surface is concave from side to side, rising up laterally into two thin ridges, and rather sloping off in front: the inferior presents just the opposite conformation, so as to fit it to be received into the hollow of the vertebra below. We may notice, in front, a middle surface, corresponding to the anterior vertebral ligament, and two lateral ones, adapted to the longi colli. A small articular surface is observable on each side of the lower edge of the body of the seventh, contributing to the cavity in which the head of the first rib is lodged. The ring for the spinal marrow is large and triangular, with the angles rounded. The spinous processes are prismatic, horizontal, and either bifurcated at the end, or flattened and marked with a groove. They vary considerably in their direction, degree of bifurcation, &c. Three of the four vertebrae immediately succeeding the axis appear very small in comparison to its spinous process; but the spine of the seventh is large and prominent. The notches for the lateral foramina are placed in front of the articular processes; and the superior and inferior ones differ very little in depth. The articular processes are oval in their figure, and directed obliquely: the superior backwards and upwards, the inferior forwards and downwards. The transverse processes increase in size from the axis; there is a deep channel in the superior surface of each, lodging the anterior branch of the corresponding cervical nerve; hence the extremities are bifurcated. Each is perforated at its base by a round hole for the vertebral artery; which has been observed sometimes to be absent in the seventh.

The seventh cervical approaches in all respects very nearly to the characters of the dorsal vertebrae.

The muscles attached to the cervical vertebrae are the interspinales; the intertransversi anteriores and posteriores; the rectus anticus major; longus colli; scaleni, anterior medius and posterior; cervicalis descendens; transversalis colli; sacrolumbalis; serratus posticus superior; rhomboidens minor; trapezius; splenius capitis; and part of the rhomboideus major.

The Dorsal Vertebrae.—Their number depends on that of the ribs: they are very seldom eleven; more frequently thirteen; in which latter case there are generally only four lumbar vertebrae. Their chief characteristics arise from the articulation of the ribs to this part of the column.

The body projects in front, when compared to the vertebrae of the neck: it is thick behind, and narrower in front. The upper and under surfaces are plane. It is convex in front, a little concave behind. It is longer, thicker, larger in all respects, and more cylindrical, in proportion as we descend. The body of the first, or even of the second also, is flattened in front, like those of the cervical; but the third, fourth, fifth, and sixth, have the cordiform shape, being broad behind, and narrow in front; the seventh, eighth, and the rest, are more and more cylindrical. Generally, the third and fourth are the smallest of all. At its lateral and posterior part there is a small articular surface above and below, of which the upper is the largest. These cartilaginous surfaces form, with the corresponding ones of the neighbouring vertebrae, and the intermediate fibro-cartilages, the articular concavities, which lodge the heads of the ribs. Sometimes the first dorsal vertebra has an entire articular concavity at its upper edge, and a half cavity below: or the upper may be a half cavity also, the articulation being completed by the lower margin of the seventh cervical. In the eleventh and twelfth there is a single cavity only, placed either at the upper edge or towards the middle of the bone, and receiving by itself the head of the corresponding rib. The ring is small and circular. The plates are broad, thicker, and more perpendicular than in the neck; and they give origin to a very long spinous process, which is prismatic, pyramidal, broad at the basis, and growing narrower at the opposite extremity, which is pointed, and directed obliquely backwards and downwards. The spinous process of the first dorsal vertebra is thick, extended nearly horizontally, and ends in a flattened tubercle. The second, and particularly the third, is more slanting; the upper margin more acute; and the extremity longer and more pointed. These characters become more strongly marked in the fourth to the seventh or eighth: they are very long, and pointed, the superior edge is very acute, and the inferior surface is nearly flat; they slope so much, that they lie one over the other, in close contact, while those of the three upper and four lower stand quite apart. The effect which this arrangement must have in limiting the posterior inflexion of the column is very obvious. In the four lowest dorsal vertebrae, the depth of the spinous processes, from above downwards, is increased; they are extended more horizontally, and the length of their points is diminished. The spinous processes of the dorsal vertebrae are seldom all arranged in the same perpendicular line: one may deviate to the right, another to the left, &c. The articular processes are perpendicular, the superior being directed backwards, the inferior forwards, excepting the inferior ones of the twelfth, which are turned outwards, to be adapted to the superior processes of the first lumbar vertebra.

The transverse processes are very thick, and considerably inclined backwards: this, together with the concavity of the column in the back, enlarges the space for the reception of the lungs. When the spine is viewed laterally, the transverse processes of the dorsal are considerably behind the line of those of the cervical or lumbar regions. Each of them has a small plane, or very gently concave, surface, on the anterior part of its extremity, by which it is articulated to the tubercle of the corresponding rib. These surfaces are directed upwards in the superior vertebrae, downwards in the inferior. The transverse processes decrease considerably from

from the tenth to the twelfth; and the two last have no surface for articulation with the ribs.

The configuration of the twelfth dorsal vertebra differs very little from that of the lumbar.

To the vertebrae of this region the following muscles are affixed: *viz.* splenius capitis and colli, trachelomastoideus, biventer cervicis, complexus, longus colli, transversalis colli, semispinalis colli, semispinalis dorsi, multifidus spinæ, sacrolumbalis, levatores costarum, intertransversales and interspinales dorsi, latissimus dorsi, rhomboideus major, trapezius, ferratus posticus superior and inferior.

The lumbar vertebrae are seldom six in number, and more rarely four. Their great size, which increases down to the last, distinguishes them from those of the back and neck; while the thick fibro-cartilages, by which they are joined together, and the free space between their spinous processes, give them considerable power of motion. The bodies are large and cylindrical, with flat surfaces above and below, excepting the inferior, which is cut off obliquely, to accommodate it to the sacrum, with which it is united to form the promontory: the ring is triangular, and larger than in the neck. The laminae are thick and strong, and form a large spinous process, which is flattened laterally, terminating above and below in a thin edge, and forming a rounded end behind. That of the last is very short, and sometimes entirely wanting. The transverse processes are flattened, and rather turned backwards: it is short in the first, increases in the second and third, then again diminishes. The articular processes are perpendicular; the superior slightly concave, and the inferior proportionally convex. The former have their articular faces turned inwards and backwards; the latter outwards and forwards: the space between the superior is, therefore, necessarily more considerable than that between the inferior.

The following are the muscles attached to the lumbar vertebrae; *viz.* interspinales and intertransversales lumborum, spinalis dorsi, multifidus spinæ, quadratus lumborum, obliquus internus and transversus abdominis, sacrolumbalis and longissimus dorsi, ferratus posticus inferior, the diaphragm, the plex major and minor.

The bodies of the vertebrae consist almost entirely of spongy texture; it is covered by a very thin layer of compact bone: hence a vertebra, when thoroughly cleaned, is very light in comparison to its bulk. In the recent state it appears bloody and medullary. The circumference of the two surfaces is smooth, the centre rougher. At the same time that the cellular structure of the vertebral bodies increases the strength of the column, without adding to its weight, it makes these bones liable to those affections which belong more particularly to such structure. The compact tissue is tolerably abundant in the atlas and axis; and it predominates considerably in the processes, which, however, are cellular in their middle, and in parts where they are swelled, as at the ends of the spinous processes in the loins, &c. The ossification of the vertebrae goes on in three pieces; one for the body, and the two others for the lateral and posterior parts: yet separate points may be sometimes seen at the bases of the spinous processes. The lateral portions are united to each other behind, at the basis of the spinous process; and they are united in front to the body, at the situation of the articular processes. The atlas usually has five primitive bony pieces; one for the anterior arch, two for the posterior, and one for each side.

We have included the sacrum and the os coccygis in the enumeration of pieces composing the spine, although they are generally denominated bones of the pelvis. Their description may in truth be connected, without impropriety,

either with that of the last mentioned cavity, or of the vertebral column. They belong, however, more naturally to the latter. The sacrum is formed on the same model as the vertebrae, and consists originally of five distinct pieces, just like vertebrae, united by fibro-cartilages; differing from vertebrae only in some insignificant points of size, figure, &c. These pieces are indeed soon consolidated into one bone, which then has much less resemblance to the vertebrae than it had before. One great office of the spinal column, that of continuing and protecting the medulla spinalis, belongs equally to the sacrum. The modification which the spine exhibits in this part, arises from the attachment of the lower limbs: a large surface is necessary for this purpose, and a strong bone; and these conditions are answered in the sacrum, which in every other respect has the configuration belonging to the spine.

The sacrum (os latum, clunium) is the largest bony piece of the vertebral column, placed immediately below the last lumbar vertebra, and at the back of the pelvis; supporting, above, the head, upper limbs, spine, and superior part of the trunk, and transmitting the weight thus received from the last lumbar vertebra to the pelvis, where its broad sides are strongly tied to the ossa innominata, between which it is received like a wedge; and containing the lower extremity of the medulla spinalis. Its basis is joined to the last lumbar vertebra, in the same way as the individual vertebrae are connected to each other; its apex is united to the first bone of the coccyx. When viewed in its situation, it is not placed perpendicularly, but turned backwards, making an angle with the lumbar vertebrae, called the promontory.

The figure of the bone is wedge-shaped or triangular, with the basis turned upwards, the apex downwards, and the two sides placed laterally. It is symmetrical. It is not only broadest above, but also thickest from before backwards, and gradually diminishes downwards in both these directions. It is concave in front, and tolerably smooth, convex, and rugged behind. We shall describe its spinal, pelvic, vertebral, and coccygeal surfaces, and the two lateral sides.

The spinal surface is convex, very irregular, and covered by the origins of the muscles, which fill the lateral hollows of the spinal column. We observe in it, first, on the middle line, four eminences, diminishing in size from above downwards, analogous to the spinous processes of the vertebrae, of which they continue the series, sometimes running into a continuous bony ridge. These are the spinous processes of the sacrum, affording points of attachment to muscles. They are terminated below by a triangular opening, the end of the sacral canal, which is closed by the posterior sacro-coccygeal ligament, and bounded laterally by two prominent knobs, which are usually articulated to two corresponding ones of the coccyx. Under these, sometimes called the descending processes of the sacrum, the last sacral nerve passes. The inferior opening of the sacral canal is sometimes much more extensive, reaching nearly to the upper part of the bone, so that the canal is slit in its whole length: the opening in such instances is still occupied by ligament. 2dly. On each side, a rough depression above, for the insertion of powerful ligaments, which tie the sacrum to the os innominatum; and, lower, four posterior sacral foramina, situated in a channel continuous with that of the vertebrae, but shallower, and filled by the lumbar muscles. These holes, diminishing in diameter from above downwards, are traversed by the posterior branches of the sacral nerves, and communicate with the canal of the bone: they are bounded externally by more or less distinct prominences, which may be considered as representing the transverse processes of the vertebrae.

The pelvic surface is concave, and corresponds more particularly to the rectum. It presents, 1st, on the middle line, four slight transverse ridges, indicating the points of union between the original pieces of the bone, and separated by quadrilateral surfaces, a little concave, which answer to the anterior part of the bodies of the vertebræ; 2dly, on each side, the four anterior sacral foramina, much larger than the posterior, opposite to which they are placed, and with which they communicate by the sacral canal, diminishing in size from above downwards, giving passage to the anterior branches of the sacral nerves, and separated by bony intervals, uniting in a surface, to which the pyramidalis is attached.

The vertebral surface, representing the base of the triangle, exhibits a configuration very similar to that of the surface of a vertebra, and is adapted for union with the last lumbar vertebra. On the middle and anterior part there is an oval smooth surface, cut rather obliquely, to correspond to the oblique inferior surface of the last-mentioned bone, with which it is joined by means of a fibro-cartilage, at an angle, which forms the promontory of the pelvis. Immediately behind this is seen the orifice of the sacral canal, which has a flattened triangular figure, with the basis turned forwards, and the apex towards the spinous processes; diminishes in size from above downwards; is continuous with the vertebral canal, from which it receives the lower end of the medulla spinalis, surrounded by its membranes; communicates externally by the anterior and posterior holes just described, and terminates below at the triangular fissure already noticed. On each side of this round articulating portion the sacrum forms, in front, a smooth, convex, transverse surface, continuous with the iliac fossa, and covered by ligaments. Behind, there are two concave articular processes, facing backwards and inwards, and joined to the inferior articular processes of the last lumbar vertebra. This process is bounded in front by a slight notch, contributing to the opening for the passage of the last lumbar nerve; and behind by a thin edge, forming the lateral boundary of the sacral canal, corresponding to the margin of the vertebral laminae, and having the last of the yellow ligaments attached to it.

The coccygeal surface, representing the base of the triangle, is very small, and forms an oval face articulated to the coccyx.

The edges of the sacrum are formed into broad surfaces, for articulation with the ossa innominata. In these parts, which represent the transverse processes of the vertebræ, the resemblance between them and the former bone is the least. Each edge exhibits, above, a surface above two inches long, and an inch and a half broad, united with the os innominatum by the sacro-iliac symphysis, oblique in its direction, in consequence of the wedge-like figure of the bone, and gradually decreasing in breadth from above downwards, as the whole sacrum diminishes in thickness in the same direction. This articular surface is divided by a waving line from above downwards, into the anterior and posterior part: the former is comparatively smooth, and united by the intervention of a crust of cartilage to the os innominatum; the posterior is scabrous and irregularly excavated, to afford attachment to powerful ligaments passing between the two bones.

The coccygeal extremity, or the apex of the triangle, is an oval surface for articulation with the first bone of the coccyx.

The bony substance of the sacrum is like that of the vertebræ, cellular internally, and covered on the outside with a compact layer. It is more dense in the spinous processes.

The multifidus spinæ, the longissimus dorsi and sacrolumbalis, glutæus maximus, pyriformis, serratus posticus inferior, latissimus dorsi, and obliquus internus abdominis, are connected to the sacrum.

This bone is composed originally of five pieces, exactly resembling vertebræ, joined together by fibro-cartilages, which remain till the fourteenth year, or longer, after which the separate portions are consolidated into one bone. Hence the sacrum and os coccygis have been called the column of false vertebræ. Each of the sacral vertebræ possesses in the fœtus certain distinct bony nuclei, like those of the true vertebræ. There are five in each of the three upper ones, and three in each of the two lower. The lateral portions are consolidated first; the anterior and posterior parts later. The cartilages of the front divisions do not entirely disappear till the time of puberty, or even afterwards.

The sacrum sometimes consists of six portions; very seldom of four.

The *coccyx* (os, or more properly ossa, coccygis) is a triangular symmetrical bone, consisting of four pieces, which are united by cartilaginous ligaments in such a way as to form a continuation of the curvature of the sacrum, placed at the posterior and inferior part of the pelvis, where it supports the termination of the rectum. The first piece is the largest, and they decrease successively, but not always so: their breadth exceeds their length: they are joined by articular surfaces. The first face of the bone is convex, uneven, and marked by prominences, which indicate the original divisions. The great sacro-sciatic ligament, and the glutæus maximus, are attached to it. To the pelvic surface, which is gently concave, marked by transverse ridges, and covered by a thick ligamentous stratum, the rectum corresponds. The sacral surface is the broadest and thickest part of the bone: it has an oval concavity articulated to the sacrum, and behind that two ascending tubercles, which join the two descending ones of the sacrum, and form together the openings through which the last sacral nerves pass out. The edges are uneven, and occupied by the attachment of the less sacro-sciatic ligament: they unite below in a rounded angle, to which the levator ani is connected.

While the bones are separate, the first is the largest: it is triangular, convex behind, and concave in front; the second, third, and fourth, are circular and flattened.

The glutæus maximus, the curvator coccygis, the coccygeus, the levator ani, and sphincter ani, are inserted in this bone.

The bony substance of the coccyx is spongy, and remarkably loose and soft in its texture. In the fœtus the four pieces are completely cartilaginous, and the ossification takes place later than in the sacrum. Late in life the different portions frequently ankylose; and sometimes the bone itself is ankylosed to the sacrum: the latter event is less frequent in the female.

Articulations of the Vertebral Column.—From the great number of pieces which enter into its composition, the joints of the spine must necessarily be numerous. Moveable articulations are required, on account of the motions executed by various parts of the spine; but solidity and strength are also necessary, because the spine is the point of support of the limbs and head, the centre from which their motions proceed, and because it contains the spinal marrow, to which any injury, pressure, or shock, would be so very dangerous. Hence we find the vertebræ joined by very broad surfaces, and otherwise very strongly tied together, so that luxation is impossible, and the spine possesses as

much strength, as if it were composed of a single piece, although a power of motion is combined with that capacity for resistance. The numerous joints, and the great quantity of soft elastic matter in the spine, give a spring to all the motions of the trunk, and stop the effect of all shocks, so as to prevent their propagation, and to obviate concussion of important organs, particularly of the brain. But, besides the articulations which join the component pieces of the spine, there are several others, by which various parts are joined to the spine. Such are the joints of the head with the first and second vertebræ of the neck, and of these vertebræ with each other: these, and the motions they execute, are considered under the article HEAD. The connection of the ribs with the dorsal vertebræ is described under LUNGS. The articulation of the sacrum with the ossa innominata, and with the coccyx, and of the different pieces of the coccyx with each other, are described under PELVIS.

Articulations of the Vertebræ.—These bones are joined, 1st, by their bodies; 2dly, by their articular processes; 3dly, by their laminae; and 4thly, by the spinous processes. The mode of connection is the same throughout the spine, excepting in the case of the atlas and the axis. Of the uniting media, however, some form separate and insulated organs at each intervertebral interval; such are the fibro-cartilages, and the yellow ligaments: others constitute common organs, embracing at the same time the whole vertebral column, or its greatest part, as the anterior and posterior vertebral and the supraspinal ligaments. Yet the fibres of the latter do not run through the whole length.

The bodies of the vertebræ are united by an anterior and a posterior vertebral ligament, and by a fibro-cartilage between every two bones.

The anterior vertebral ligament, or fascia longitudinalis anterior, occupies the anterior surface of the column, extending from the axis to the upper part of the sacrum. It is not equally strong nor broad throughout: it is narrow in the neck, broader in the back, and still wider in the loins. In the first situation it is thin, stronger in the second, and again rather thin in the loins, where the tendons of the crura diaphragmatis are intermixed with it. The fibres of this ligament do not run through the whole length of the column; some end and others begin in each bone. This ligament consists of a thin stratum closely adhering to the bone, and covered, in the neck, by the pharynx and œsophagus, in the back, by the latter, by the aorta, vena azygos, and thoracic duct, and in the loins by the aorta and the inferior vena cava. At the sides it corresponds, in the neck, to the recti majores antici and longi colli; in the loins to the psoæ. It adheres to the fibro-cartilages, and to the projecting edges of the vertebral bodies, more closely than to the concavities of the latter. The more superficial fibres go from one vertebral body or fibro-cartilage to the fourth or fifth below; others belong to three bones or fibro-cartilages; and the deepest only to two. The fibres are interwoven with those on the front of the fibro-cartilages; and they leave small intervals for the passage of vessels. At the sides of this ligament in the neck, under the longi colli, are two small fibrous fasciculi for each vertebra, passing obliquely downwards and outwards from the vertebra above to that next below it.

The posterior ligament (fascia longitudinalis postica) occupies the posterior aspect of the vertebral bodies, where they form the front of the canal, extending from the axis and the occipito-axoid ligament, or apparatus colli ligamentosus, to the sacrum. It is more dense in its structure than the anterior, and appears more distinct, smooth, and shining.

The narrowest part of it is in the back: it enlarges at the fibro-cartilages, and is contracted at the bodies of the vertebræ; thus, when viewed in its whole length, it is alternately contracted and expanded at each vertebra and its neighbouring cartilage. The dura mater covers it behind, separated from it by a loose cellular tissue, never containing fat, but often much serous fluid. It corresponds in front to the fibro-cartilages and the bodies of the vertebræ, adhering less closely to the latter than to the former. Like the anterior ligament, it consists of superficial and deep-seated fibres, of which the former are the longest, and pass over three or four vertebræ, while the latter go from one bone or fibro-cartilage to the next.

The fibro-cartilages (ligamenta intervertebralia) are organs, of which the nature is little understood, holding the middle place, in point of structure, between ligament and cartilage, and occupying the intervals of the vertebral bodies throughout the column, excepting between the atlas and axis. Their form varies according to that of the bodies which they unite; and consequently is different in the neck, back, and loins. Their thickness increases successively from above downwards; so that the lumbar are separated by larger intervals than the cervical and dorsal vertebræ. Moreover, they are thicker in front than behind, in the neck: on the contrary, they are thickest behind in the back; and the arrangement in the loins is the same as in the neck: these differences are obviously connected with the natural bendings of the column. The fibro-cartilages adhere very intimately above and below to the corresponding flat surfaces of the vertebræ. In the fœtus they adhere to the cartilages of ossification; when they are removed nothing remains attached to the vertebræ; but, in the adult, the bony fibres and those of the fibro-cartilages are so completely identified, that we find no instances in the animal economy of stronger union. The circumference of these substances corresponds to the anterior and posterior vertebral ligaments: on each side, they form part of the holes through which the spinal nerves pass; and in the back they contribute to the articular cavities for the heads of the ribs.

The fibro-cartilages are formed externally of concentric fibrous laminae, numerous in front and at the sides, fewer behind, with decussating fibres, separated by more considerable intervals as we approach the centre. In the latter we find a soft pulpy tissue, increasing in quantity as the intervals increase in breadth. The fibrous laminae degenerate gradually into the pulpy structure, which occupies alone the middle of each fibro-cartilage. This tissue is most abundant in the child, where it is also soft, whitish, and even nearly transparent, while it is yellowish and thick in the adult. It becomes dense and compact in the old subject, and is constantly diminishing. To it the fibro-cartilages owe their pliancy and elasticity; while their strength resides in the laminae, which inclose this soft structure. Hence the spine is distinguished by the first property in infancy; while the other predominates afterwards. The laminae soon become red when immersed in water: the middle part swells and rises into a conical projection. If the spine be sawn through longitudinally, the fibro-cartilage swells out, on the cut surface, beyond the bone. The effect of these substances in restoring the column, when it has been bent in any direction, is very obvious. The inflexion compresses the fibro-cartilages at the bent part; and they restore themselves as soon as the compressing cause ceases to act. When the body has been long erect, the fibro-cartilages yield to the weight which presses them from above, and thus the length of the spine, and consequently of the body, is diminished: the cessation of this pressure, when the body is in the horizontal position, allows

SPINE.

allows them to recover their original dimensions. See *CARTILAGE*.

The corresponding faces of the articular processes are covered by thin cartilaginous layers, and furnished with a small synovial membrane, which is very closely drawn between the opposed surfaces, and contains very little synovia. Several short and irregular, but strong ligamentous fibres, lie on this membrane.

The yellow ligaments (*lig. subflava*), so called from their colour, tie together the laminae of the vertebrae, which do not touch each other, and complete the canal of the spine, which would be otherwise open at the intervals of their laminae. The first of these ligaments is placed between the second and third cervical vertebrae; the last between the fifth lumbar and the sacrum. Each consists of two portions, a right and left, united at an angle towards the basis of the spinous process, and having at this union a small interval containing a little cellular tissue. Each portion is attached, above, to the inner surface of the superior lamina; and below to the upper edge of the inferior: hence they are hidden behind, and can only be seen to advantage from the vertebral canal; they may be best exposed by sawing out the spinous processes, and their laminae, from the vertebral column, in one continuous piece. They correspond, in front, to the dura mater, to which they are connected by a loose cellular tissue; behind, to the inner surface of the upper laminae of each interval, and to the multifidus spinæ. The angle formed by the union of the two lateral pieces is continuous in the back and loins with the interspinous ligaments: on the outside each is contiguous to the synovial membrane of the articular processes. Their fibres are numerous and closely set; longer towards the canal, where they appear smooth and polished, than towards the vertebral channel, where they are rough and uneven. There is very little cellular tissue in their composition, so that they are dissolved under ebullition with great difficulty, and resist it longer than any analogous organs. They are elastic, very strong, so that vast force is required to break them: stronger indeed than the fibro-cartilages, in which the fibres are separated by much of the pulpy texture. It is very clear that these ligaments will powerfully tend to restore the spine, after it has been inclined forwards.

The spinous processes, separated by intervals more or less considerable in different situations, are united by two kinds of ligaments; one of which connects the processes themselves, while the other envelops their points.

The interspinous ligaments (*membrana interspinalis*) occupy the intervals of the processes, but do not exist in the neck, where the corresponding spaces are filled by the interspinous muscles. Their breadth and strength increase from above downwards; in the back they are narrow, elongated, and thin, and can scarcely be said to exist in the upper part of the region. They are quadrilateral, broader and thicker in the loins, where they may offer considerable resistance to the separation of the processes. Their points of attachment are the lower edge of one spinous process, and the upper edge of the next: they correspond, in front, to the angle of union of the two portions of the yellow ligaments; behind, to the supraspinous ligaments; and on the sides, to the multifidus spinæ and longissimus dorsi. They are composed of decussating fibres.

The supraspinous ligament (*lig. quo apices vertebrarum connectuntur*) extends along the points of the spinous processes of the back and loins, from the seventh cervical vertebra to the spinous processes of the sacrum. It is very thick in the loins, where it is so interwoven with the tendinous attachments of the muscles, that they can hardly be

distinguished. In the back it is thinner and more distinct from the aponeurosis. The longitudinal direction of its fibres serves to distinguish it from the tendons, of which the fibres are oblique. Its fibres are of different lengths; the deepest go from bone to bone; the more superficial are longer, passing over one, two, or more vertebrae, and giving origin to the aponeurotic fibres of the neighbouring muscles. The skin covers this ligament behind; adhering to it by a close cellular tissue.

The ligamentum nuchæ, which arises from the cervical spinous processes, belongs more to the head than to the spine. It is described under *HEAD*.

The last vertebra of the loins is articulated to the sacrum, just in the same way as the individual vertebrae are joined together; viz. by a fibro-cartilage, by yellow ligaments, by an interspinous ligament, and by articular processes.

The Spine considered as a Whole.—The twenty-nine bones just described, viz. the twenty-four vertebrae, the sacrum, and the four ossa coccygis, are joined by the articulations which have been now explained, (all being connected by the intervention of fibro-cartilages, except the atlas,) so as to form, by their assemblage, the strong but flexible bony column which sustains the head, forms the basis of the trunk, affords a point of attachment to the upper limbs, and below is received between and supported by the haunch bones. We distinguish in it an anterior, a posterior, and two lateral regions, and two extremities. We may observe, in general, that the whole column increases in size from above downwards, as it has to support an increasing weight; but to this there are some exceptions, that will be noticed.

The anterior region, composed of the bodies of the vertebrae and the intermediate fibro-cartilages, presents in some degree the appearance of a bony pillar, which term is little applicable to the rows of bony processes, which form the lateral and posterior aspects of the spine. This region is broad in the neck, narrow in the back, and again spreads out in the loins. Its breadth in the first situation arises from the smallness and inconsiderable prominence of the vertebral bodies; in consequence of which the transverse processes in this region form part of the anterior aspect of the spine; while in the back and loins, the bodies form, by their bold convex projection, the whole front of the column. The front of the spine presents a series of superficial transverse excavations, and of prominent edges which bound them: the number of the latter is double that of the former, as each transverse channel is bounded above and below by a ridge. These excavations are confined to the front in the neck; but they reach to the sides in the middle of the column. The anterior vertebral ligament, the *recti capitis majores*, the *longi colli*, the *vena azygos*, thoracic duct, aorta, and inferior vena cava, cover the spine in front.

We observe, on the posterior aspect, in the middle line, the series of spinous processes, projecting horizontally at the upper and lower parts, and very slanting in the middle. They are separated by intervals, which are large in the neck and still more so in the loins; but very much narrowed in the back, in the middle of which the processes actually overlap. In the neck and loins there are openings between the laminae, leading into the vertebral canal, in the skeleton; but the slanting of the spinous processes covers these in the back. The points of the spinous processes are generally all in the same line; but there may be deviations, arising either from a lateral inclination of the process, or from an unnatural position of the vertebra. On each side of the spinous processes there is a longitudinal hollow, beginning at the upper extremity of the column, and ending below upon the sacrum. These lateral hollows are broad above, contracted

contracted towards the middle, and narrow below. They are formed by the series of vertebral laminæ, separated by larger or smaller spaces, which are occupied by the yellow ligaments. They are filled by the vertebral muscles, particularly by the multifidus spinæ.

The series of transverse processes occupies each lateral region; but they have not all the same direction: they are more anterior in the neck and loins, and thrown backwards in the back. Between them in the neck, and in front of them in the back and loins, there is a succession of large holes, increasing in size from above downwards, and giving passage to the vertebral nerves. In front of these, in the back, are the surfaces for articulation of the heads of the ribs.

The superior extremity, articulated to the occiput, forms a right angle with it on each side; and an anterior and posterior angle, which vary according to the flexion or extension of the head. This extremity presents, from before backwards, the anterior arc of the atlas, the tooth-like process, the commencement of the canal, and the posterior arc of the atlas. On each side of the canal, towards the front, there is the concavity for the occipital condyle, and the large transverse process. The inferior extremity presents merely the small rounded point formed by the last bone of the coccyx.

The length of the spine does not vary greatly in different individuals; the differences of stature depending more on the limbs than on this column. In malformations, however, where it is curved in various directions, the stature is much affected; and the limbs, although not exceeding their ordinary size, appear disproportionately long. We have already observed, that the compression of the fibro-cartilages by the weight which they naturally support, diminishes the length of the spine after long standing; and that the column recovers its former length by repose in the horizontal posture. This effect is less strongly marked in the old subject, where the fibro-cartilages are very dense, and consequently do not easily yield to pressure.

The size of the column increasing from above downwards, in proportion to the greater weight and more powerful effects it has to support, it may be regarded as a pyramid, of which the basis is below, and the apex above. Yet this augmentation is not gradual throughout; and the column may be considered as the assemblage of four pyramids. The upper end, including the atlas and axis, destined for articulation with the head, which it supports, is larger than the immediately succeeding part of the neck. From the third to the seventh cervical vertebra the spine is gradually expanded: thence, to the third or fourth dorsal vertebra, it contracts again; and is gradually augmented from the latter to the basis of the sacrum: it contracts again from the basis of the sacrum to the apex of the os coccygis. Measured transversely, the spine increases from the third cervical to the fifth dorsal vertebra, while the remaining dorsal and the lumbar vertebrae are nearly of the same breadth, or increase very slightly downwards. The depth of the vertebrae is also increased; but the inferior cervical are all nearly of one depth.

The intervertebral intervals are nearly of uniform size, down to the third dorsal; from which they increase downwards. The flat surfaces of a vertebra are always parallel to each other, and the intervals are consequently of the same depth before and behind. There is an exception, however, of the parts in which the column is bent; the intervals of the third, fourth, fifth, and sixth dorsal vertebrae being narrowest in front, while those between the fourth and fifth lumbar, and the sacrum, are broadest in front.

The spinal column is straight, when viewed before or be-

hind; and might be divided by a perpendicular line into a right and left corresponding half: but, when we view it laterally, we find that it is bent in several parts, so as to describe a waving line, in which each anterior prominence is accompanied by a corresponding posterior convexity. The cervical portion projects slightly in front; the dorsal is decidedly convex behind. The concavity of the dorsal part of the spine combines with the inclination backwards of the transverse processes to increase the capacity of the thorax. The greatest depth of this concavity is opposite to the lower bone of the sternum. In the loins, the spine is again convex in front, while the sacrum and coccyx slant backwards remarkably, so as to present a deep concavity. The middle of the first convexity corresponds to the fourth cervical vertebra; that of the succeeding concavity to the seventh or eighth dorsal; the middle of the lumbar projection to the junction of the fifth lumbar vertebra with the sacrum; and that of the sacral concavity to the middle of the bone. About the third, fourth, and fifth dorsal vertebrae, the spine is sometimes a little convex towards the right. This has been ascribed to the presence of the aorta; but that cause is manifestly inadequate. The explanation, which is grounded on the greater use of the right arm, and a consequent inclination of the trunk to the left side, in order to afford a firmer point of support, appears rather more probable. Any habitual attitude, particularly when persisted in from childhood, will affect the direction of the vertebral column. Under various diseased states, remarkable curvatures are produced; in which we find that the vertebrae and their fibro-cartilages become accommodated to the unnatural position, being greatly diminished in depth on the concavity of the curve, so that the two surfaces are no longer parallel. It is also constant, that a bend in one part renders curvature necessary in another, in order to preserve the centre of gravity in a straight line. The position of the head and upper limbs is also calculated to maintain the equilibrium of the body; and thus nearly the whole frame is influenced by a cause originally affecting only a part of the spine.

The canal of the spine extends throughout the column, excepting a small portion of the lower end of the sacrum and the os coccygis: it is continuous, above, with the cavity of the cranium, and ends below on the back of the sacrum. It does not occupy the centre of the column, being placed much nearer to the posterior part. In the neck it is large; more ample in the upper than in the lower part of the back, the narrowest part being from the sixth to the ninth: it expands a little in the eleventh and twelfth dorsal vertebrae, is very large in the lumbar, and again suddenly contracted in the sacrum. Its figure is triangular, with the angles rounded; so that it has an anterior, and a right and left surface; it is more nearly round in the middle, and quite triangular in the sacrum. It partakes of all the curvatures of the spine. It is formed in front of the backs of the vertebral bodies and fibro-cartilages, covered by the posterior ligaments. Behind, the laminæ and the yellow ligaments compose it. On each side it presents a series of twenty-nine large foramina for the passage of the nerves; or there are thirty, if we include the exit of the first cervical pair, between the occiput and the atlas.

This canal is lined by a prolongation of the dura mater, including the medulla spinalis, covered by its arachnoid coat and pia mater. (See BRAIN and NERVOUS System.) The dura mater is surrounded by a loose cellular tissue, containing serous fluid.

Development of the Spine.—Few parts of the skeleton undergo more remarkable changes in the progress of ossification than the vertebral column. It differs much in the child and

SPINE.

and the adult; and in old age is again very different from both.

It is one of the first parts formed in the embryo, where it seems to be a kind of foundation, on which the structure of the body is erected. Its form is discernible at the end of the third week after conception, when we can just see the head and a curved line connected to it. Long before the extremities can be seen, the spine continues visible. The commencement of its ossification by numerous points may be dated about the end of the second month. The gelatinous spine, or carina, as it has been called from its incurvated keel-like shape, is the first trace of development in the incubated egg.

The formation of the spine is more advanced, and its size more considerable, in comparison with other parts, particularly with the pelvis and lower limbs, at the time of birth. Hence the trunk is proportionably longer. The general stature too, at this time, depends on the spine, while in the adult it is influenced more by the lower limbs. This great length of the spine corresponds to the depth of the cranium, which is much more considerable proportionally in the fœtus and young subjects than in the adult. The vertebral canal being also large, the breadth of the column, which depends much on the size of the canal, is considerable. All parts which relate to this excavation are much advanced. On the contrary, whatever has reference to support or locomotion, is little developed at this time. The spinous processes do not exist; consequently the points of attachment for the muscles are weaker. The bodies are still in great measure cartilaginous: behind, where they contribute to the canal, they are the most formed; but there is much soft substance in front, where, when the spine is dried, we see merely a series of rounded bony tubercles. Such a state is very unfavourable to the solid support which is necessary for preserving the erect attitude. At this age, the transverse processes are small in the loins, where they relate to the muscles only; they are much more considerable in the back and neck, on account of their connection with the ribs and the vertebral artery.

The column, at this time, does not form a pyramid, of which the basis is downwards and the apex upwards. The cervical portion is larger than the lumbar, on account of the development of the transverse processes, which, being placed nearly on the same line with the bodies, give to the former region a considerable volume; and of the comparatively imperfect state of the lumbar vertebræ. The dorsal and lumbar regions are nearly equal in size; but in some instances the former vertebræ are largest. As the principal effort, in standing, is supported by the loins, the imperfect state of the lumbar vertebræ is very unfavourable to the maintenance of that attitude in the newly born child. The imperfectly developed state of the bones coincides with the inconsiderable volume of the pelvis.

The direction of the column is remarkable in the fœtus: it is straight, or at least exhibits the hardly sensible commencement of those curves, which it will present in the sequel. In consequence of this straightness, the vacillations which occur in the erect posture of the body, and in all the motions executed in that posture, are much more sensible, and the centre of gravity is more easily carried beyond the basis of support. Hence another reason why newly born children cannot keep themselves upright, or move in that attitude.

The vertebral column, in early age, is small and narrow in front, particularly at the back and loins. In consequence of the want of spinous processes, there is great flexibility, particularly backwards. The latter property is favoured by

the large quantity of soft substance in the column; the cartilaginous portion of the vertebral bodies being added to the fibro-cartilages. The vertebral channels are very shallow, in consequence of the state of the spinous processes. The lateral holes are very large: the last lumbar vertebræ does not form so marked an angle with the sacrum. The upper end of the column does not differ materially from its state in the adult.

As ossification proceeds, all the peculiarities just enumerated gradually disappear. The erect attitude is more secure, and progression is performed with greater facility. Hence the support of the trunk by all the limbs, is a result of the organization of the fœtus. The child, having crawled about for some time, gradually experiences those developments of its bony and muscular fabric, which enable it to appear in the erect posture as a biped. The vertebral column, however, arrives at the state which we have described as existing in the adult, by a very slow progression. At the time of puberty, in both sexes, the atlas and the coccyx are complete. In the six lower cervical vertebræ, the processes are not yet consolidated to the body; and the vertebræ of the back and loins are still less complete, having a bony plate at each surface of the body, and a bony nucleus in the spinous process. Slight marks of the original separation are still visible in the sacrum. In a few years these imperfections disappear; the apices of the spinous processes of the back and loins being among the last parts that are consolidated.

In the old subject, the intervertebral fibro-cartilages shrink and become harder: sometimes, but very rarely, they ossify. The spine, at this age, generally bends forwards, apparently from debility of the posterior muscles: thus, the force which should counterbalance that tendency to fall forwards, arising from the position of the viscera in front of the spine, is gradually lost. To counteract this inclination of the spine forwards, and support the centre of gravity, the pelvis recedes, and the knees and legs project in front. The latter circumstance is more strongly marked in proportion as the inclination of the spine forwards is more considerable. The weight of the trunk being carried towards the front, the base of support must move forwards also. There is always an exact proportion between the bending of the spine, the receding of the pelvis, and the advance of the knees. In this case, the trunk and lower limbs together exhibit the same phenomenon as the spine itself in its particular curves, which balance each other in the neck, back, and loins.

Mechanism of the Spine.—This must be considered in three points of view: 1st, with reference to the canal; 2dly, as the point of support of the trunk; and 3dly, as the centre of the motions performed by the latter.

1. *Of the Canal.*—All the arrangements about the vertebral column are calculated to ensure the safety of this part. The breadth of the vertebral bodies; the multiplicity and strength of the uniting ligaments; the parts lying in front of the spine in the neck, chest, and abdomen; and the thick muscular masses that fill the vertebral hollows behind; all concur in protecting the contents of the canal from external injury. Hence the resistance which the spine opposes to all efforts directed against it; a resistance which renders luxation impossible. The individual vertebræ are capable of so very slight a motion, that the medulla spinalis cannot be compressed in any inflexions of the spine.

2. *Mechanism of the Spine in Standing.*—Here the spine is the point of support of the trunk, of which it transmits all the weight, together with that of the head, to the pelvis.

The mode in which the head is supported on the spine, is considered under the article **HEAD**. The part in front of the articulation certainly preponderates over that behind; but

but the difference is less considerable, than it would appear from noticing merely the relation of the occipital condyles to the front and back of the head, in consequence of the anterior portion containing the face, of which the weight does not correspond to the bulk, while all the posterior part is solid and heavy.

If the position of the head tends to incline the spine forwards, the same effect is much more strongly produced by the situation of the pectoral and abdominal viscera wholly in front, without any thing to counterbalance them behind. The muscles of the vertebral channels, inserted either in the ribs or the vertebræ, exert a constant effort in opposition to that of the anterior viscera, maintaining by their exertion the vertebral column, and, consequently, the trunk, in the erect attitude. The greatest effort is below, where the spine supports the most considerable weight. Here the muscles are thicker, the bones large, and their processes more prominent. Here, too, the sense of fatigue is felt after long standing; whence arises the practice of tying a firm band round the loins, to support the muscles and favour their action.

Thus, in standing, the spine is placed between two forces acting in opposite directions; an anterior passive one, which is the trunk; a posterior active one, the action of the extensor muscles. The habitual tendency of the spine to bend forwards, produced by the weight of the viscera, is further obviated by the hip-joints, at which the trunk is sustained on the lower limbs, being placed in front of the sacro-iliac symphyses. The basis of the trunk occupies the space between the latter symphyses and the cotyloid cavities. It will be readily understood that falls must have been much more frequent, if the thighs had been articulated on the same line with the sacrum. The waving line described by the vertebral column, and allowing extensive motion in the upper parts, without the line of gravity, which passes through all the curves, abandoning the base of support, is another disposition very favourable to the solidity of the trunk in its erect attitude. The gradual increase in size of the column, from above downwards, contributes to the same end. Thus, standing cannot be regarded, by any means, as an attitude of repose; it requires great efforts, which naturally cause considerable lassitude, if the posture be long maintained.

3. *Motions of the Spine.*—The general motions are, forwards, backwards, to either side, or in the intermediate directions. Inclination forwards, or flexion, as it is commonly termed, is the most extensive, as all our principal efforts have this direction. In this motion, the anterior vertebral ligament is relaxed; the fibro-cartilages are loosened in front, and stretched behind; the posterior vertebral ligament, the yellow ligaments, and those of the spinous processes, are stretched. The laminae of the fibro-cartilages, being much more numerous in front than behind, yield more readily to motion in the former than in the latter direction. In extension, we observe phenomena exactly contrary to these. The muscles, however, which produce extension, being fixed to the vertebral processes, are very near the centre of motion, and, consequently, act less powerfully than the flexors, which operate through the medium of the ribs, and, consequently, at a distance from the centre of motion. The spinous processes, too, particularly of the back, limit extension very much.

In inclination to either side, the fibro-cartilages are principally affected; being stretched on one side and relaxed on the other. The ribs principally limit this motion, by coming in contact with each other.

All these motions are much more sensible at the junction of the dorsal and lumbar regions than elsewhere. When they are all performed in succession, the trunk is carried round in

a circular direction, describing a cone, of which the basis is upwards, the apex downwards.

Besides the motions just enumerated, a power of rotation has been ascribed to the spine, in which the vertebræ are supposed to be twisted on their axes. Winflow admits this, and Bichat does the same; adding, however, that it can only be accomplished with considerable difficulty. He calls it a species of general twisting, in which all the ligaments are stretched, resulting from the partial twisting of each fibro-cartilage. When we consider how the vertebræ are joined together; when we reflect on the nature of the fibro-cartilages, on the yellow ligaments, on the mechanical locking of the articular processes, and more particularly on the attachments of the ribs, and the overlapping spines in the back, we shall begin to doubt whether this rotation be possible. Dr. Barclay decidedly denies it. (*Muscular Motions*, p. 337, et seq.) If the head and shoulders be prevented from moving on the trunk, and the pelvis be also kept motionless, no rotation of the spine can be effected. An appearance takes place, which might be ascribed to such a rotation, from a motion of the pelvis on the hips. This may easily be detected, by placing a rod of some feet in length across the pelvis, when any motion of the latter will be immediately visible at its extremity.

The motions vary in each region: on account of the smallness of the vertebræ, the obliquity of the articular processes, the shortness and horizontal projection of the spinous processes, which are not tied together by interspinal ligaments, the quantity of motion in all the directions already enumerated is considerable. The cervical region either represents a simple lever, or it may be considered, in connection with the head, as an angular lever, and will follow all the motions of that part. In one part of this region there is a true rotatory motion; it is at the articulation of the atlas with the axis. Whenever the head is twisted to one side or the other, there is a revolution of the former bone on the latter, and not any general twisting of the spine.

Every thing concurs to limit motion in the back: for example, the articulations of the ribs to the bodies and transverse processes, and their connection to the sternum in front; the length and overlapping of the spinous processes.

In the loins, again, there is free motion; particularly above, at the junction of this region with the back.

The motions of the individual vertebræ are extremely obscure; but they take place in the same direction as the general motion which we have just described. The visible movement of any part of the spine results, therefore, from the combined effect of several hardly sensible motions: one vertebra could not move sufficiently on another to produce a perceptible motion of the trunk. This circumstance concurs with several others relating to the mode of union of the vertebræ, and the mechanical confinement of the articular processes, to render luxation impossible: meaning by that term, a displacement of the bone without any fracture. The effort is distributed over a considerable region, and cannot therefore act sufficiently on a single bone. Neither can any force be easily applied before or behind, sufficient to drive out one vertebra from its place. Moreover, were such a force actually applied, the vertebra could not be displaced forwards without a fracture of its inferior, nor backwards, without that of its superior articulating processes.

Of the muscles which are concerned in these motions, some act directly on the trunk, while others affect it through the medium of the ribs, the scapulae, &c. All of them, being placed on the right or left side of the body, must have the power of moving the trunk laterally, more or less, according to their degree of obliquity, or their distance from the

SPINE.

mesial plane. The following is a list of the muscles which carry it forwards; including both those which act directly and the indirect ones.

Pectorales majores and minores; ferrati magni; obliqui externi abdominis; obliqui interni abdominis; transversi abdominis; recti abdominis; pyramidales; psoæ magni and parvi.

The muscles moving it backwards are, trapezii; rhomboidei; latissimi dorsi; ferrati postici superiores and inferiores; sacrolumbales; longissimi dorsi; spinales dorsi; semi-spinales dorsi; multifidi spinæ; interspinales; intertransversarii dorsi and lumborum; quadrati lumborum.

The muscles of the neck may be arranged in like manner into the two classes of (1) those which incline it forwards; and (2) those which incline it backwards. In both classes, those which are to the right or left of the mesial plane, will inspect the cervical column to their respective sides. These lists include, besides the muscles which act immediately on the neck, those which influence it through the head.

1. Muscles bending the neck forwards: latissimi colli; biventre maxillæ; mylo-hyoidei; genio-hyoidei; genio-hyoglossi; omo-hyoidei; iterio-hyoidei; thyro-hyoidei; iterio-mastoidei; recti capitis interni majores and minores; recti capitis laterales; longi colli; scaleni antici.

2. Muscles bending it backwards: trapezii; rhomboidei minores; ferrati postici superiores; splenii capitis and colli; complexi; trachelo-mastoidei; cervicales descendentes; transversales cervicis; spinales cervicis; semi-spinales cervicis; multifidi spinæ; recti capitis postici majores and minores; obliqui capitis superiores and inferiores; scaleni postici; and levatores scapularum.

The scaleni medii and intertransversales can only inspect laterally.

SPINE, Disease and Curvature of, in Surgery. In the present article we intend to consider a particular disease of the spine, attended with a total or partial abolition of the power of using, and sometimes even of moving, the lower extremities.

It was that eminent surgeon Mr. Pott, who gave the first accurate description of this serious affliction. To this distemper, he observes, children are the most subject; adults are by no means exempt from it; but it hardly ever affects persons after the age of forty. In infants, the true cause of the paralytic disorders of the lower limbs is seldom discovered by parents or nurses, who never imagine that it is situated in the back-bone. When the disease affects a child who has been able to walk, the loss of the use of his legs is gradual, though not very slow. He at first complains of being very soon tired, and is unwilling to move about much; and very shortly afterwards he frequently trips and stumbles, although there be no impediment in his way. Whenever he attempts to move briskly, he finds that his legs involuntarily cross each other, by which he is frequently thrown down. Upon endeavouring to stand erect, even for a few minutes, his knees give way and bend forward.

When the distemper is a little farther advanced, it will be found that the patient cannot, without much difficulty and deliberation, direct either of his feet precisely to any exact point; and very soon after this, both thighs and legs lose a great deal of their natural sensibility, and become perfectly useless for all the purposes of locomotion. In adults, Mr. Pott observed, that the progress of the disease was rather quicker than in children.

The affection of the lower limbs is somewhat different from a common nervous palsy. The legs and thighs are rendered unfit for all the purposes of locomotion, and do also lose much of their natural sensibility; but they have neither

the flabby feel which a truly paralytic limb has, nor that seeming looseness at the joints, nor that total incapacity of resistance, which allows the latter to be twisted in almost all directions. On the contrary, the joints are often very stiff, and the feet frequently cannot be placed flatly on the ground, in consequence of the toes pointing downward.

The disease of the spine varies in situation, extent, and degree; being either in the neck, back, and sometimes, though very seldom, in the upper part of the loins; sometimes comprehending only two vertebræ, sometimes three, or more.

Some patients are rendered totally incapable of walking at a very early period of the distemper; others can manage to move about with the help of crutches, or by grasping their own thighs with their hands.

When a weak infant is the subject, and the curvature resulting from the morbid state of the spine is in the vertebræ of the back, it is not unfrequently productive of deformity, by rendering the back humped, and by alterations which the position of the ribs and sternum undergoes, in consequence of the flexure and morbid state of the spine.

The general health does not seem at first to be materially affected; but when the distemper of the spine has made much progress, many complaints come on, such as difficulty in respiration, indigestion, pain, a sense of tightness in the stomach, obstinate constipations, purgings, involuntary discharge of the urine and feces, &c.

The paralytic affection of the legs is certainly owing to the particular state in which the spinal marrow, surrounded by the diseased vertebræ, is placed. When the distemper has existed only a short time, the ligaments connecting those vertebræ which form the curve are somewhat thickened and relaxed, and the bodies of the bones affected with a change, similar to what takes place in the heads of the bones in cases of white-swelling. (See WHITE-SWELLING.) When the complaint has been of longer existence, the ligaments are now manifestly thickened, and the bones more obviously altered, and even becoming carious. The quantity of elastic substance between the bodies of the vertebræ is much diminished; and, after death, in advanced cases, the bones are always found carious, while a quantity of sanious fluid is lodged between them and the membrane investing the spinal marrow. The corpora vertebrarum, howsoever softened, diseased, or rendered carious they may be, are never found spread and enlarged in their texture. Mr. Pott was well convinced that the bones were not expanded. The disease seems to be very analogous to the affection of the heads of the bones in the scrofulous white-swelling, and as we know that this latter disorder is commonly unattended with any real increase in the dimensions of the diseased parts of the bones, we ought indeed to expect that no such change would prevail in the distemper now under consideration.

The convexity of the curvature is always from within outwards, and is invariably preceded, as well as the paralytic affection of the legs, by a distempered state of the ligaments and bones.

The only thing from which relief is ever obtained in the present distressing affliction, is an issue, made on each side of the spinous processes of the affected vertebræ. The best mode of forming the issue is to rub the potassa cum calcé upon the skin until the part turns brown. To accomplish this object in a neat manner, it is as well to cover and defend the integuments with adhesive plaster, excepting the two longitudinal portions, about half an inch broad, which are to be converted into eschars by the application of the caustic. The end of this substance is to be dipped in water, and freely rubbed on the situation of the intended issues. As

soon as the skin has become quite brown, the caustic may be washed off with some wet tow, the adhesive plaster may be removed, and the part covered with a linseed poultice.

Immediately the eschars are loose, and can be taken away without pain, the issues are to be filled with peas, or kidney-beans. These are to be covered with adhesive plaster, which will confine them in their situation. However, as the hollows soon become filled up with granulations, unless considerable pressure be made, it is generally deemed necessary to bind a piece of pasteboard, or a compress containing a bit of sheet-lead, firmly on the situation of the issues. The pressure thus maintained, though creative of uneasiness at first, will, in the end, save the patient an immense deal of pain; for, in consequence of its operation, the peas or beans will soon form as many little hollows in the cavity of the issue as their own number, and into these the future peas may afterwards be put and retained, without the least uneasiness, provided the surgeon gives particular injunctions not to allow the bandage to be ever slack. The pressure saves the patient, in the end, a great deal of pain, which would otherwise be unavoidable, on account of the surgeon being necessitated to repress the rising granulations in the cavity of the issue, by sprinkling them with powder of cantharides, or the pulv. ex ærug. æris et fabinæ, or even rubbing them with the caustic. In most instances, however, it is now and then requisite to apply one of the above powders underneath the beans or peas. In order to apply peas advantageously, they should be previously softened in warm water, and connected together like beads, by passing a thread through their centre. Then they should be allowed to become completely dry, when they are fit for immediate use. There should always be a greater length of thread than of peas, by which means, two little portions at the ends of the peas may extend beyond each extremity of the issue, and be fixed there by two small bits of adhesive plaster. This little contrivance will have great effect in keeping the whole row of peas in its right situation. When the issue is more than half an inch in breadth, two rows of peas should be placed in it.

It is said that a string of beads answers quite as well as one of peas or beans, and certainly it is more convenient, as, when regularly washed every day, it may be used as long as the surgeon thinks proper; and thus the trouble and expence of getting fresh peas or beans may be avoided.

The issues are to be kept open until the cure is complete; that is, until the patient perfectly recovers the use of his legs, or even for some time afterwards. Mr. Pott judiciously recommends the practitioner to heal at first only one of them.

In conjunction with the issues, bark, sea-air, and sea-bathing, are frequently proper.

There have been various contrivances proposed for the purpose of affording mechanical support to the spine. This method does not, however, promise to be useful. When the morbid affection of the corpora vertebrarum has advanced to a certain state, the adjoining sound bones, both above and below the seat of the disease, become approximated to each other, and at length ankylosed. This salutary process, if influenced at all by mechanically supporting the spine, must obviously be retarded. From this account we also see the reason why the projection of the spinous processes, at least in adult subjects, must always remain. In children, however, a great diminution, and even an entire removal of a certain degree of deformity, may take place during the growth of the body. Pott's *Chirurgical Works*, vol. iii. Cooper's *First Lines of the Practice of Surgery*, edit. 3, part 2.

SPINE, in *Agriculture*, a term signifying provincially the surface turf, sod, or sward of land.

SPINE, a sharp, firm, hard point which is sent off from the woody parts of some sorts of plants. It consequently differs from a prickle, which only rises from the bark of the plant. The spines in plants of this nature are produced either singly, as is the case in most of them; doubly, or by pairs, as in some particular sorts; or in a triple manner, as in the three-thorned acacia.

SPINES of *Echini*, in *Natural History*. These in their fossil state make a great appearance in the cabinets of the curious, and in the works of the learned, and are of an almost infinite variety of kinds; and many of them are of the same figures and dimensions with those of the echini now living in our own and other seas, and well known to us. But beside these, there is an almost infinite variety of others, which, though allowed on all hands to be truly spines of some echini or other, yet evidently differ from those of all the known recent fish of that name, and have certainly belonged to a species of it, of which we have not now the least knowledge. These, however different in shape from one another, yet all agree in their texture and constituent matter.

SPINEDA, in *Geography*, a town of Italy, in the department of the Upper Po; 4 miles N.N.E. of Sabionetta.

SPINELL, or *True Ruby*, *Spinelle* of Haüy and Broch, in *Mineralogy*. (See GEMS.) The colour of this gem is red, blended with tints of blue or yellow; and it occurs in grains, in small rounded fragments, and crystallized. The primitive form of its crystals is the regular octohedron, exhibiting also the varieties of the cuneiform octohedron, the primitive octohedron with the edges of the common base truncated, the same with all the edges truncated, and the primitive octohedron divided obliquely into two segments, which are turned on each other $\frac{1}{4}$ th of a circle, thus forming a solid with alternate salient and re-entering angles. The crystals are small and very small, rarely middle-sized. The faces of the octohedron are smooth, and the planes of the truncatures are longitudinally striated. Its lustre, externally and internally, is brightly shining, vitreous. Its cross fracture is conchoidal, its longitudinal fracture is lamellar in three directions. It varies from translucent to transparent. It is considerably hard, though in this respect inferior to sapphire. Sp. gr. 3.57—3.64. Before the blowpipe it is infusible without addition, but melts with borax, acquiring a green colour. When ground to a very fine powder, it is soluble by long digestion in boiling sulphuric acid. It was first analysed by Klaproth, and afterwards by Vauquelin, with the following results:

	Klaproth.	Vauquelin.
Alumine	- 74.5	82.47
Silex	- 15.5	0.
Magnesia	- 8.25	8.78
Oxyd of iron	1.5	0.
Lime	- 0.75	0.
Chromic acid	- 0.	6.18
	100.50	97.43

Although its geological situation is not known, it occurs imbedded in calcareous spar and adularia, accompanied by mica and magnetic pyrites. See GEMS. See also CORUNDUM. Aikin's *Dict.*

Mineralogists formerly classed all varieties of ruby with spinell, and also the oriental ruby or sapphire. The cochineal-variety of spinell is the Balais ruby of the jewellers, so called from Balachan, the Indian name of Pegu, where it is found. The violet-blue spinell is the almandine of Pliny; it is named from Alabanda, a town in Lesser Asia. The orange-yellow variety is the rubicelle ruby of jewellers. A newly discovered

discovered variety of spinell is called by Werner Salam stone, the name by which it is known in India; its colours are red and blue. It is crystallized in six-sided prisms, variously truncated. It is in general only translucent, and exhibits a pearly light on the surface. It is somewhat heavier than true spinell, but in other characters agrees with it. It is found in the peninsula of India.

SPINET, *Spinetto*, Ital. *Esfinette*, Fr. from *spina*, a thorn, or quill, the tone being produced by a crow's quill inserted in the tongue of a little machine called a jack. (See JACK, and TONGUE.) The instrument consists of a chest or belly, made of the most porous and resinous wood to be found, and a table of fir fastened on rods, called the found-board, which bears on the sides: on the table are raised two little prominences or bridges, in which are fixed as many pins as there are strings on the instrument. See BRIDGE.

It is played with keys, like the virginal, or small piano-forte; the long keys are for the diatonic or natural notes, and the short for the flats and sharps. See KEYS, and SCALE.

The keys, when pressed down at the end by the finger, on the principle of the lever, make the other end throw up jacks, which strike the strings, and cause the sound by means of the quills with which they are armed.

The thirty thickest strings are of brass; the others, for the more delicate tones, are of steel or iron-wire, fastened at one end by hooks, and at the other on pins, by which they receive their tension over the bridges already mentioned.

The figure of the spinet is like that of the harpsichord, a horizontal harp, and the harp an inverted spinet. It is tuned in the same manner as other keyed instruments, by 5ths and 8ths, with or without bearings, as the tuner or the owner of the instrument shall please.

There have been spinets and harpsichords made for curious people with some or all the short keys split or cut in two for harmonics, or at least to perfect some of the extraneous keys, furnishing a different tone for F \sharp and G \flat , D \sharp and E \flat , &c. to perfect some of the most offensive keys in common tuning. Zarlino had an instrument of this kind made at Venice, which we saw at the house of Percezzi, the composer's widow, and it was afterwards sent to England; but the mechanism and tone were so bad, that no tuning could render its sounds agreeable. There are quarter-notes, as they are called, in the Temple organ, to three of the five short keys; but except in psalmody, or very slow movements, Stanley never ventured to touch them.

We have seen spinets made by Haywood, in the time of James and Charles I., with box keys for the natural notes; by Keen and Slade, in queen Anne's time, with the long keys of ebony and the short of ivory; and excellent spinets by the two Hitchcocks, father and son, with ivory natural keys, and ebony or dried pear-tree for the sharps and flats.

The spinet had but a single string to each note. As the spinet rivalled the virginal, the small piano-forte has supplanted the spinet in the public favour; and we believe that very few have been made since the middle of the last century.

SPINIAGOR, in *Geography*, a town of Russia, in the government of Viatka; 40 miles S.W. of Elabuga.

SPINIFEX, in *Botany*, from *spina*, a thorn, and *facio*, to make, because of the thorny nature of its involucreal leaves.—Linn. Mant. 2. 163. Nov. Gram. Gen. 29. t. 1. Schreb. Gen. 744. Willd. Sp. VOL. XXXIII.

gamia Dioecia; rather *Triandria Digynia*. Nat. Ord. *Gramina*.

Gen. Ch. *Cal.* Common Involucrum of two lanceolate, channelled, unequal, spinous-pointed leaves; partial of about four similar ones. Flowers on awl-shaped clustered receptacles, naked above. Perianth of two equal valves, containing one or two florets. *Cor.* of two lanceolate convoluted valves, the innermost enfolding the organs of fructification. *Stam.* Filaments three, capillary; anthers long, linear, cloven at each end. *Pist.* Germen oblong; styles two, thread-shaped, longer than the glumes; stigmas villous, prominent. *Peric.* none, except the hardened corolla, united to the oblong, smooth, solitary seed.

On one plant the flowers are situated at the base of each receptacle, each calyx containing two florets, and the anthers are most perfect in one, the stigmas in the other. On a separate plant the florets are solitary, all male, and numerous along the lower part of each receptacle.

Ess. Ch. Involucrum of two spinous leaves. Calyx of two valves, two-flowered. Corolla of two valves. Seed united to the hardened corolla.

Some flowers male, on a separate plant.

1. *S. squarrosus*. Linn. Mant. 2. 300. Willd. n. 1. (*Stipa spinifex*; Linn. Mant. 1. 34. *Cyperus littoreus*; Rumph. Amboin. v. 6. t. 2. f. 2.)—Smooth. Leaves channelled, rigid, spinous-pointed, rough at the edges.—Native of the sandy sea-shores of the East Indies. A large, rigid, tough, shrubby grass, whose surface is smooth and glaucous. Leaves three or four inches long, with broad sheathing bases, rough-edged. Flowers in large, terminal, aggregate and compound heads, the spinous points of their receptacles and involucreal leaves projecting in every direction. These heads are blown to a great distance by the wind, and roll along the sands with great velocity.

2. *S. longifolius*. Brown n. 1. (*Cyperus*; Peron, Voy. aux Terres Austr. v. 1. 113.)—"Smooth. Leaves flaccid, semi-cylindrical, unarmed, smooth-edged, thrice as long as the seed-bearing receptacle. Glumes of the male flowers rough."—Gathered by M. Baudin, in the tropical part of New Holland. Brown.

3. *S. fragilis*. Br. n. 2.—"Smooth. Leaves flaccid, semi-cylindrical, unarmed, rough-edged, longer than the seed-bearing receptacle."—Observed by Mr. Brown, in the tropical part of New Holland.

4. *S. sericeus*. Br. n. 3.—"Silky. Leaves unarmed, smooth, like their sheaths, at the inside. Point of the male receptacle several times shorter than the spike."—Found by Mr. Brown in the last-mentioned country, as well as in New South Wales.

5. *S. hirsutus*. Br. n. 4. Labill. Nov. Holl. v. 2. 81. t. 230, 231.—Silky. Leaves unarmed, villous as well as their sheaths. Point of the male receptacle nearly equal to the spike.—Native of the south coast of New Holland.

SPINIS. *Attachamenta de Spinis & Bosco*. See ATTACHAMENTA.

SPINNEY, in *Rural Economy*, a term signifying provincially a clump of trees, or small grove or plantation.

SPINNING, the art of combining animal or vegetable fibres into threads or cords, by twisting them together. Wool, silk, cotton, flax, and hemp, are the matters most commonly employed for spinning into threads; and of these, most of the vegetable fibres, except cotton, require to be wetted during the operation of spinning, to render them more supple; but cotton, wool, and silk, are spun in a dry state.

The machines employed for spinning are of very different kinds,

SPINNING.

kinds, and adapted to the materials to be operated upon ; but they have all a spindle, revolving with a rapid motion, to twist the fibres which are attached to the end of it, and are supplied in a regular quantity, as fast as the twisting motion of the spindle will form them into a thread ; and there is also some provision of a bobbin upon the spindle, to take up and retain the thread when made.

The most ancient mode of spinning is by the spindle and distaff, and this method is the simplest of all others. The spindle is nothing more than a piece of hard wood, made round, and sharp-pointed at one end, so that it can be made to spin upon its point, in the same manner as a child's top : the upper part is reduced to a pin or peg, and it is this part which has the fibres united to it, the lower or enlarged part being only to give sufficient weight to make it spin. The spinner must be seated upon the ground, and after having put the distaff in motion upon its point, by twirling it between the hands, get it up to a rapid motion, by striking it occasionally with the hand, with a motion very similar to that by which a child keeps up the motion of his whipping-top, when he draws the lash of a whip round it.

The flax, or material which is to be spun, after being properly prepared, is lapped round the end of the distaff, which is nothing more than a stick that the spinner holds in the left hand, so as to be conveniently situated to draw off from it a few fibres at a time, with the finger and thumb of the right hand, to form the thread. The upper part of the spindle, which is made smaller, like a pin, has the ends of the fibres which are to form the thread attached to it before it is put in motion. These fibres are drawn out of the bunch which is wound upon the distaff, and held between the finger and thumb, so as to be in the direction of the length of the spindle ; therefore, when the spindle is once made to revolve, it twists these fibres together, to form a thread, and as fast as the thread forms, the spinner draws off more flax from the distaff, and guides the fibres between the finger and thumb, so that they shall be regularly delivered out, and make an even thread. The motion of the spindle is constantly kept up, by striking it as often as the hand can be spared from the operation of guiding the thread. When by these means as great a length of thread is formed as is convenient to reach from the end of it to the spindle, the thread is wound upon the outside of the small part or pin of the spindle, for which purpose the spinner applies the fore-finger against the thread, close to the end of the spindle, and bends the thread at that part, so that it will be at right angles with the direction of the spindle, instead of being nearly in the direction of its length ; and also, that it will be guided opposite to the middle of the pin, or small part of the spindle, instead of being at the extreme end thereof. In this situation the motion of the spindle, which is continually kept up, occasions the thread to wind up, or lap upon the pin of the spindle, instead of twisting round upon itself, as in the former case ; but when nearly all the length of thread is thus disposed of, the finger is removed from the thread, and it immediately assumes its original direction, by slipping to the extreme end of the spindle, so as to be twisted round itself by the motion of the spindle, and more fibres are now supplied to it from the bunch upon the distaff, to form a fresh length of thread. In this manner the spinning proceeds, until as much thread is spun and wound upon the pin of the spindle as will make a moderate sized ball.

This simple and inconvenient method of spinning becomes very efficient, when the spindle, instead of being spun upon the ground, is mounted in a proper frame, and turned by a wheel

and band ; this forms a machine which is called the one-thread wheel, and is still used in the country for spinning wool : the spindle is made of iron, and placed horizontally, so that it can revolve freely ; and the extremity of the spindle, to which the thread is applied, projects beyond the support.

The wheel which turns it is placed at one side, the pivots of both being supported in upright pieces, rising up from a sort of stool. The spinner puts the wheel in rapid motion by its handle, and its weight is sufficient to continue the motion for some seconds ; then walking backwards from the spindle, in the direction of its length, she supplies the fibres regularly, and the motion twists them into a thread ; but when a convenient length is spun, the spinner steps on one side, and reaches out that arm which holds the end of the thread, so as to alter the direction of the thread, and bring it nearly perpendicular to the length of the spindle, which motion gathers or winds up the thread upon the middle of the projecting part of the spindle. This being done, she holds the thread in the direction of the spindle, so that it will receive twist, and retreats again to spin a fresh length of thread. For spinning wool, it is not wound round the distaff the same as flax, but the spinner holds a lock of it, doubled over the fore-finger, and draws away the fibres from the middle part of the lock, to do which with regularity is the great art of spinning by hand.

A spinning-machine more perfect than this is the one-thread flax-wheel, with spindle and flyer ; it has the property of constantly drawing up the thread as fast as it is spun, instead of spinning a length, and then winding it upon the spindle. For this purpose the spindle is made longer than the other, and is turned by a band and wheel ; but the wheel receives motion from the foot by a small treadle, because the spinner sits before the wheel to work the spindle, which is supported upon its two extreme ends, and near one end the flyer is fixed ; this is a piece of wood curved to an arc, the vertex of which is fixed on the spindle, and from the extremities of the arc two arms proceed, so as to be parallel to the spindle, and at such a distance from it as to admit a wooden bobbin to be fitted loosely upon the spindle ; and at the same time the arms of the flyer can revolve round the bobbin without touching it. The end of the thread is fastened to the bobbin, and conducted through a hook fixed in the flyer, so that it proceeds from the circumference of the bobbin to this hook, in a direction perpendicular to the bobbin, but turns round the hook so as to come into the direction of the spindle. The thread is then conducted through a perforation made in the centre of the end of the spindle or pivot, upon which it revolves, and to this end of the thread the fibres are supplied. The twisting motion given by the revolution of the spindle forms them into a continuation of the thread, which is gathered up upon the bobbin as fast as the spinner lets it go through her fingers, by a tendency which the bobbin has to turn slowly, at the same time that the flyer to which the thread is hooked is revolving rapidly round the bobbin. For this purpose a string is passed round a small neck upon the bobbin, and one end of the string being fastened to the frame, the other has a small weight to draw it tight round the neck of the bobbin, and occasion friction. In other spinning-wheels, a second band from the great wheel is made to turn the bobbin more slowly than the spindle. The thread which passes over the hook of the flyer is rapidly carried round the circumference of the bobbin ; but as the bobbin follows the motion of the flyer, it only winds up as much thread upon the bobbin as the difference of the two motions ;

and

SPINNING.

and this tendency to wind up can be increased or diminished at pleasure, by the friction which is occasioned by the string or band which passes round the neck of the bobbin. When the winding-up of the thread upon the bobbin has accumulated a ridge of thread upon it opposite to the hook in the flyer, the thread must be shifted to another hook opposite to a different part of the bobbin, for which purpose the arms of the flyer are furnished with different hooks, and this must be repeated several times, until the whole length of the bobbin is filled; it is then taken off to be reeled, and replaced by another empty bobbin.

An improvement was made in the spinning-wheel by Mr. Antis some years ago, which was an application of what Sir Richard Arkwright had before invented. The object is to obviate the necessity of stopping the wheel to remove the thread from one hook to another, in the manner just described. For this purpose, the bobbin is made to move regularly backwards and forwards upon the spindle a space equal to its length, so that every part will, in succession, be presented opposite the hook over which the thread passes, and thus receive the thread regularly upon the whole length of the bobbin. The additional parts necessary for producing this movement are as follow: a pinion of only a single leaf is made to project from the extremity of the pivot of the great wheel, or a worm or endless screw formed on the end pivot, will answer the same purpose, which is to actuate a wheel of seven inches diameter, and ninety-seven teeth; therefore ninety-seven revolutions of the great wheel will produce one revolution of this smaller wheel; upon the face of which a circular ring of wire is fixed, and supported from the wheel by six legs, so as to be oblique to the plane of the wheel, as it touches it at one part, and at the opposite side of the ring projects nearly three-fourths of an inch. This ring of wire gives motion to an upright lever, about fifteen inches long, and moving on a centre at three inches from its lower extremity, where it has a pin fixed in it, and resting against the oblique ring of wire; therefore, when the wheel turns round, it communicates a small motion to the lever, in consequence of its obliquity to the plane in which it revolves. The upper end of the lever is connected to an horizontal sliding-bar, situated beneath the spindle, and having an upright piece of brass, which works in the notch of a pulley, formed on the end of the bobbin, and drives the bobbin backwards and forwards upon the spindle, according as the oblique ring of wire forces the pin at the lower end of the lever in or out, when the wheel moves round. To regulate and return this alternate motion, a small weight hangs by a line to the sliding-bar, and, passing over a pulley, rises and falls as the bobbin recedes and advances, and tends constantly to keep the pin at the lower end of the lever in contact with the wire. It is evident, from this description, that one staple only is wanted to the arms of the flyer, which being placed near the extremity, the thread passes through it, and by the motion of the bobbin, is laid regularly upon it from one end to the other.

The invention has also another advantage over the old method, which always winds the thread in ridges upon the bobbin; and if the thread breaks in reeling the yarn, the whole bobbin may as well be thrown away, because the thread cannot easily be found again; but this improved wheel always winds the threads across upon one another, by which means the end can never be lost.

In order to regulate the friction on the bobbin, and retard its motion in a greater or less degree at pleasure, there is a neck of brass or steel fastened to one end of it, and embraced by a kind of small vice, or pincers, fixed to the

sliding-bar. This vice must be made either with two elastic springs with wooden tops, or of wood wholly, and faced with leather; but if made of wood only, then a spring must be made beneath the shoulder of the screw, to answer the same purpose. By tightening this screw more or less, the friction on the bobbin may be regulated to the greatest nicety, provided the springs are of a strength rightly proportioned to their functions. It will readily appear, that all this may be done without the least effect on the velocity of the whole machine, as thereby nothing is added to the general friction so as to obstruct it.

It was not until the latter end of the last century, that spinning-machines of greater powers were constructed; but all threads were spun by one of the machines which we have described; the first being used for cotton and wool, and the other, with the bobbin and flyer, for flax; but for very coarse threads, two spindles were applied to the latter machine, and the spinner having the wool wound round a band, tied it round her waist, instead of winding it upon a distaff, and was thus able to draw out fibres with each hand, and supply two spindles. And of the other simple spindles, several were made to turn together by the movement of one large horizontal wheel, around which the spindles were arranged in directions radiating from the centre, and each spindle received a rapid motion by the contact of the edge of the large wheel, which was turned round by one person. The spinners each stood opposite to his respective spindle, so as altogether to occupy a large apartment, and by this means they could do much more work than formerly, having none of the interruptions of turning the wheel.

The first improvement of any importance in spinning, was that of the spinning-jenny, invented by Hargraves, as related in our article COTTON; and the machine itself will be described under the article WOOLLEN *Manufacture*. This machine consists of a number of spindles, similar to those of the one-thread wheel, which are all mounted, in a perpendicular direction in the same frame, and turned round by one large wheel, situated in an horizontal direction, and put in motion by a crank at the upper end of its spindle. The threads from each spindle are conducted nearly in an horizontal direction, but being quite at the point or upper extremity of the spindles, do not wind upon the spindles, but will receive twist, because the threads slip over the top of the spindles as they revolve. The threads are guided between two rulers of wood, called the *claps*, instead of the finger and thumb of the spinner. These rulers are made to fit together, so as to hold the fibres between them, and are fitted up with wheels at the end to run upon the frame, and thus advance or retreat at pleasure from the spindles. It was not attempted with this machine to spin a finished thread immediately from the lock of wool or cotton, but coarse and loose threads are previously prepared on the hand-wheel, which can be done with great rapidity, and the coppins or balls of these loose threads are placed in the jenny, and conducted, first between the claps or rulers before mentioned, and then to the spindles. By this means, when the carriage of the claps is drawn backwards from the spindles, the claps being separate, the threads draw between them from off the coppins, and at the same time that portion of each thread which is between the claps and the ends of the spindles, receives its twist; but having drawn out a certain length of each thread in this manner, the claps are shut together; and the motion of the spindles, as also the retreat of the claps, is continued, by which means the threads are stretched out to their intended fineness, and being thus finished, the threads are wound upon the spindles, by being brought opposite to the middle part

SPINNING.

of the spindles by a rail of wood, called the *faller*, which moves upon centres, so as to descend horizontally before all the spindles, and depresses all the threads together, so that they will wind up by the motion of the spindles, and as they wind, the clasps return towards the spindles. The operations are then again repeated, and thus continued, until the coppins or balls of thread, wound upon the spindles, acquire their proper size.

The next improvement in spinning-machines was the introduction of the *slubbing-machine*, or *billy*, for preparing the rovings for the jenny; an operation which was at first performed by the hand-wheel. This machine has similar parts to the jenny, but they are differently arranged, to adapt it to spin the wool as it comes from the carding-machine, in the state of cardings, which are locks of wool drawn out to about the size of caudles, and from two to three feet in length. For this purpose the spindles are made to travel on the carriage, and the clasps stand still, being the reverse of the jenny. The cardings are laid upon an endless cloth, which revolves over two rollers, and lies in an inclined position at the end of the machine; and one carding is laid upon the cloth opposite to each spindle, the ends being pieced with fresh cardings by children, as fast as the spindle works them up. A roller presses down upon the cardings, to hold them fast upon the feeding-cloth, and to make them move with it; and just beyond this roller the clasps are fixed to hold the rovings, when the proper lengths are drawn out by the retreating of the spindles, which, as before stated, are situated in the carriage. The operation of the billy is the same as that of the jenny, *viz.* that the carriage is drawn out, and the feeding-cloth revolves over its roller to give out the cardings until a certain length: the clasp is then shut down, and the further extension of the threads is produced by stretching; which being done, the threads are wound upon the spindles.

The inventions of Sir Richard Arkwright soon superseded these machines. His principal invention in the spinning was the introduction of the rollers, to draw out or extend the fibres to their full length, which is by this means much more perfectly performed than by the fingers of the spinner. For the immediate twisting of the thread, he adopted the spindle, bobbin, and flyer of the old flax-wheel, placed in a vertical position, but added to it the important improvement of raising and lowering the bobbin, to distribute the thread regularly and equally upon all the length of it, the same which we have before described as being applied by Mr. Antis to the common spinning-wheel. A full description of this machine, which is called the *water spinning-frame*, will be found in the article *COTTON MANUFACTURE*, *Plate IX. Cotton Manufacture*.

The spinning-jenny was again introduced, and rendered equal, and for some purposes superior, to the water-frame, by Mr. Crompton, who combined with it the system of rollers of Sir Richard Arkwright, and called it the *mule*. It is also fully described under *Plate XI. Cotton Manufacture*. See *COTTON MANUFACTURE*.

The great success which attended the spinning of cotton by these machines, induced many persons to attempt the spinning of flax and wool by similar means. Short wool, for the manufacture of cloth, is spun by the billy and jenny; but flax and long wool for worsted require very different treatment from cotton and short wool, particularly the flax, owing to the great length of the fibres, and to their being of such irregular lengths: in consequence, when they are extended by the rollers, on Arkwright's principle, some fibres will be broken, if the distances between the rollers is too small; and on the other hand, if the distance is too

great, the fibres will not be properly extended. The latter, however, is the least evil of the two; and, in consequence, the spinning-frames for flax have the rollers, between which the extension or drawing out is effected, placed at a distance of from 14 to 18 inches between the first two pair of rollers, through which the flax passes; the next two pair six or eight inches; after which it is passed between the third pair of rollers at a distance of five or six inches, and then delivered to the spindles, which are similar to those of the water-frame, but placed in an inclined position. The rollers are made in a very different manner from those for cotton, being only narrow wheels just wide enough to receive the fibres of flax between them; and the fibres are prevented from getting out sideways by small tin spouts, through which the flax passes, as the rollers draw it forwards. The reason of this is, that the flinty surface of the flax would soon wear a hollow part round a plain roller, which would then let the flax slip through; but the narrow wheel wears down equally over the whole breadth of its edge. The lower pair of these rollers, or wheels, revolves in a small trough of water: in the same manner as a grind-stone, and thus keeps the flax constantly wet, which is necessary, in order to soften the fibres, and make them spin into a firm and smooth thread.

Worsted is also spun in a frame resembling the water-frame of Arkwright, from which it only differs in the relative distances of the rollers, by which the drawing out or extending of the fibres is effected.

Mellis Clarke and Bugby obtained a patent in 1806, for improvements in a machine for spinning hemp and flax, which is intended to be worked by hand labour, and to be at such a small expence, as to bring it within the reach of small manufacturers. The inventors state it to be constructed upon such safe and easy principles, that no length of experience is necessary to enable children to work it; and that it occupies so little space, that the machines may be placed in small rooms, out-buildings, or other cheap places. To effect the above purposes, it was necessary to get rid of the flyer fixed upon the spindle used in the old machinery for spinning hemp or flax, which additions require a power in proportion of five to one; and also to surmount the difficulty which arises from the want of elasticity in these substances, and which prevents them from being spun, by stretching out at the same time that the thread is twisted, in the manner of the mule or jenny.

These patentees recommend a machine, which is in fact a mule with certain modifications; and to give the effect of elasticity in the fibres, they have two methods. The most simple, and that which they particularly recommend, is to provide a holder of large wire for every spindle, which holders are several inches in length, fixed in an arbor or shaft, that extends from one end of the carriage to the other.

This arbor or shaft, with the holders, may be considered as an enlarged and improved substitute for what is called the *faller* in the mules or jennies for spinning cotton, and the wire-holders fixed therein have elliptical eyes at their extremities, through each of which a thread is conducted in its passage from the rollers which draw out the thread to its spindle. The wire of which the holder is made, after forming the elliptical eye, is left or extended beyond the uppermost part, something in the manner of a cork-screw, so that the yarn may be conveniently slipped in when occasion may require it. These holders for each thread are for the purpose of keeping the yarn in a state nearly vertical over the tops of the spindle, when the carriage which contains them is coming out; and as they will readily yield or spring from the vertical position, they have the same effect as elasticity

in the fibres of the substance which is to be stretched out; but the wires being removed from the vertical situation at the beginning of the return of the carriage, and thrown into nearly a horizontal position, by inclining the shaft into which they are all fixed, they bring the yarn below the tops of the bobbins or quills which are fixed upon the spindles, which will then wind up the threads upon them when the spindles are turned round, and then the wire-eyes being regularly curved, and raised up again by the motion of an elliptic wheel, which is turned round by the machine, they distribute the yarn regularly upon the bobbins or quills, and prevent it from hinkling, and improperly doubling or twisting together. Another method of compensating for the want of elasticity in hemp and flax, is to fix a round bar of wood, about an inch and a half in diameter, the whole length of the carriage, about three or four inches above the tops of the spindles, so that the outer surface, or that next the person who works the machine, may be perpendicular, or nearly so, over the tops of the spindles, the inner side having pieces of wood or metal fixed or nailed thereto, leaving only small spaces or notches between each, for the yarn to pass through. The use of these pieces is to prevent the threads from getting together and entangling. Every thing relating to the wire-holders before mentioned, and the arbor to which they are affixed, must be applied in concert with these pieces of metal, which form a separation between the threads.

The art of spinning, which nature has given to many animals of different kinds for their preservation, and other purposes, is not confined to the inhabitants of the earth or air alone, but is even extended to those of the sea. M. Reaumur has shewn, by a series of curious experiments, that the common muscle, and some other shell-fish of the sea, possess it in a great degree of perfection. See *MUSCLE*.

But he observes, that though the workmanship is the same, the manner of producing it is very different. Spiders, caterpillars, and the like, make threads of any length that they please, by making the viscous liquor, of which they are formed, pass through a fine perforation in the organ appointed for this spinning: but the way in which the muscles form their threads is very different, as the former resembles the work of the wire-drawer, so does this that of the founder, who casts metals in a mould. The canal of the organ destined for the muscle's spinning, which, from its shape, is commonly called its tongue, is the mould in which its thread is cast, and gives it its determinate length. *Mem. Acad. Par. 1711.*

SPINNING-Wheel, in *Rope-making*, for twelve spinners to spin yarn at the same time, is about five feet in diameter, and is hung between two posts fixed in the ground: on its top is fixed a semi-circular frame, called the head, which contains twelve whirls, that turn on iron spindles, with hooks to their front ends to hang the hemp on, and are worked by means of a leather band encircling the wheel and whirls. The whirls are made to run with a truer motion when the head on the rising side of the hand has a larger segment of a circle than the falling side; or in other words, let the base part of the head be longer from the middle than the opposite or falling side, by which means the band will be kept equally tight over the whirls, and consequently the motion be alike to all. N.B. Heads made in this manner have the wheel turned always the same way.

SPINO, in *Geography*, a town of Italy, in the department of the Upper Po; 8 miles W.N.W. of Crema.

SPINOLA, *AMBROSE*, in *Biography*, one of the most celebrated generals of his time, was born in 1569. His family was noble, and originally from Genoa. His brother

Frederic, general of the galleys stationed in the Low Countries, in the service of Spain, engaged him to bring a body of 9000 Italian and Spanish veterans into Flanders, where he soon distinguished himself by his valour and good conduct. He marched against the famous prince Maurice, and it was agreed between him and king Philip that he himself should pay his own soldiers, to be reimbursed afterwards; by which regulation, while the other Spanish troops were extremely disorderly and mutinous for want of their pay, those under his command were patterns of obedience and strict discipline. He was commissioned to raise some additional regiments, in order that he might undertake, in concert with his brother, some important expedition, but the death of the brother, in a sea-fight with the Dutch, put an end to the project. The town of Ostend had been in a state of siege nearly three years, and small progress had been made towards its reduction; for which reason the archduke Albert, governor of the Netherlands, resolved to commit the whole management of it to Spinola. Before he took upon himself the management of this business, he sent some officers to examine the works, and though they differed in opinion as to probability of success, the love of glory induced him to accept the charge. His plans succeeded, and the place surrendered after the end of the third year, having, it is said, cost the lives of 100,000 men. Spinola was rewarded with honours of every kind, and at the conclusion of the campaign, he went to Madrid, and obtained the rank and office of camp-marshal-general, and commander-in-chief of the Spanish and Italian troops. He passed through Paris, and had an interview with Henry IV., by whom he was interrogated as to the plan of the ensuing campaign, of which he gave a faithful account. The king, taking for granted that his intention was to deceive, wrote to prince Maurice just the contrary of what he had heard from Spinola, and afterwards, when he found his mistake, he said, "Others deceive by telling falsehoods, but this man by telling the truth." Spinola now put into execution his design of carrying on the war into the enemy's country, and crossing the Rhine, he penetrated into Overijssel, where he took several places, in which he left considerable garrisons. His progress was at length stopped by prince Maurice, and these two great commanders exhaulted the whole art of war during that and the following campaign, in keeping each other in check. Both parties at length becoming weary with war, a congress was appointed in 1608 to treat of peace at the Hague, and Spinola was at the head of the deputies on the part of the archduke. Wherever he came the people flocked to gain a sight of so celebrated a commander, and they were met at Dordrecht by prince Maurice, who treated his antagonist with the greatest respect. The difficulties arising in the progress of the negotiation were so great, that a truce only could be concluded. In 1621 the war was renewed, on account of a disputed succession to the countries of Cleves and Juliers, and Spinola being placed at the head of an army, penetrated into the latter country and reduced its capital. Prince Maurice was again his opponent, who was not able to prevent the fall of Cleves, or the investment of the strong town of Breda. While this siege was going on, prince Maurice died, and Spinola was brought into a dangerous state of health. The siege was, however, carried on with great vigour, and the town was defended with equal resolution. At length, it becoming evident that the garrison could not hold out any longer, Spinola, in admiration of their valour and perseverance, offered them the most honourable terms of capitulation. These were accepted, and the garrison, greatly reduced, marched out. Spinola drew up his army to salute them, and as they passed, he paid particular compli-

compliments to the governor and principal officers. He distributed money among the soldiers, provided with the utmost attention for the cure of the sick and wounded, and conveyed the rest in the most commodious manner possible to the next fortrefs. Having fulfilled the duties of a hero, he resigned his command, as having no longer an equal foe in the field with whom he could contend. In 1627, passing from Antwerp to Madrid, he took Rochelle in his way, in order to witness the memorable siege of that place. Richelieu consulted him on the best means of bringing it to a conclusion. "Shut the port," he said, "and open the hand;" meaning thereby, that the besiegers should be liberally treated.

The court of Spain recalled Spinola from the Low Countries in 1629, and sent him into Italy, where he in the following year took Casal. The citadel, however, remained in the hands of the French, owing to the impediments thrown in his way by orders from Madrid. The anxiety and vexation which this circumstance occasioned, co-operating with disease, put an end to his life in the same year, at a moment when he was at the summit of his military reputation. It is said that his great antagonist, prince Maurice, gave this testimony to his character, when being asked who was the first captain of the age, replied, "Spinola is the second."

SPINOLETTA, in *Ornithology*, the name of a small bird of the lark kind, the *alauda spinoletta* of Linnæus, called *tordino* by the Venetians, and seeming to be the *stopparola*, as also the *grifola* and *spipola*, of Aldrovandus. It is smaller than the common lark; its head, neck, shoulders, and back, are of a greyish colour, with an admixture of green; its breast and belly white, and its throat spotted; the female differs from the male, in that her belly is yellow; the wing-feathers are of a dusky brown, with whitish or yellowish edges; its tail is moderately long, and part of the feathers are snow-white, the rest brown or blackish; the length of the heel distinguishes this bird from all others, except the lark kind, and it differs from all the species of larks in the colour of its beak and legs, which are black. It is common in the markets of Venice and other places. Ray.

SPINOSA, in *Zoology*, the name by which the Italians call the porcupine.

SPINOSE LEAF, among *Botanists*. See **LEAF**.

SPINOSI PISCES, in *Ichthyology*, such fishes as have some of the rays of their back fins running out into thorns and prickles, as the perch, &c. See **FISH**.

SPINOZA, in *Biography*. See the next article.

SPINOZISM, or **SPINOSISM**, the doctrine of Spinoza; or, atheism and pantheism proposed after the manner of Spinoza.

The great principle of Spinozism is, that there is nothing properly and absolutely existing, but matter and the modifications of matter; among which are even comprehended thoughts, abstract and general ideas, comparisons, relations, combinations of relations, &c.

Benedict de Spinoza, or Espinoza, was a man well known in Holland. He was born at Amsterdam, in the year 1632, being a Jew both by descent and education; but at an early period of his life he manifested such dissatisfaction with the religion of his fathers, and advanced opinions so contrary to their established tenets, that a sentence of anathema was pronounced against him by his brethren. Having been excommunicated from the synagogue, some Christians, who were attached to him, afforded him an asylum, and gave him an opportunity of acquiring a knowledge of the Latin and Greek languages, and of studying the Cartesian philosophy. But as he still continued with great

vehemence to attack the religion of his countrymen, they attempted first to silence him by bribe, offering him an annual pension of 1000 florins, and afterwards to take him off by assassination. Both these measures proving ineffectual, they accused him, before the magistrate, of apostasy and blasphemy; and he was banished from the city. In his exile, he studied mathematics and natural philosophy, and procured a subsistence by polishing optical glasses. He resided chiefly at Rhenburg, where he was often visited by the followers of Descartes, who consulted him on difficult questions. At their request he published, in 1664, "The Principles of the Cartesian Philosophy demonstrated geometrically," with an appendix, containing metaphysical opinions altogether inconsistent with the doctrine of Descartes. In order to escape the odium which was occasioned by this publication, he retired to a village not far from the Hague, whither he was followed by many of his countrymen and foreigners, who were inclined to adopt his doctrines. The elector palatine invited him to occupy the chair of philosophy at Heidelberg; but apprehending that his liberty would be abridged, he declined the proposal, and continued to live in retirement, with great sobriety and decency of manners, until a consumption brought him to an early end, in the year 1667.

Spinoza composed several books in Latin; the most celebrated of which is his "Tractatus Theologico-Politicus," printed at Amsterdam in 1670, in which he attempts to overturn the foundation of all religion: the book, accordingly, was condemned by a public decree of the States; though it has since been sold publicly, and even reprinted, both in Latin and French, in that country, and in English at London.

In this work Spinoza insinuates, that all religions are only political engines, calculated for the public good, to render the people obedient to magistrates, and to make them practise virtue and morality.

He does not here lay down his notion of the Deity openly, but contents himself with suggesting it. In his "Ethics demonstrated geometrically," published among his posthumous works, he is more open and express; maintaining, that God is not, as we imagine him, an infinite, intelligent, happy, and perfect Being; nor any thing but that natural virtue, or faculty, which is diffused throughout all creatures.

His other posthumous treatises are entitled "Politics," "On the Improvement of the Understanding," "Epistles and Answers," and a "Hebrew Grammar." The various impieties contained in these treatises excited general indignation; and refutations were issued by writers of all religious persuasions, who concurred in amply exposing the empty sophisms, the equivocal definitions, the false reasonings, and all the absurdities with which his writings abounded.

The life of Spinoza has been accurately written by Colerus, whose performance was published at the Hague in 8vo. in 1706. But a more ample and circumstantial account of this singular man has been given by Lenglet du Fresnoy, and is prefixed to Boulainvilliers's Exposition of the Doctrine of Spinoza, which was published at Amsterdam, in 12mo., in 1731. Fresnoy republished the work of Colerus, and added to it several anecdotes, borrowed from a Life of Spinoza, written by Lucas, a physician at the Hague.

The learned Fabricius, in his *Bibliotheca Græca*, lib. v. part iii. p. 119, and Jenichen, in his *Historia Spinozismi Lehnhofiani*, p. 38—72, have given an ample list of those writers who have refuted the system of Spinoza. Witsius in

SPINOZISM.

in Holland, Majus in Germany, and De la Mothe in England, wrote against his *Tractatus*; but Bredenburg, according to Mr. Bayle, succeeded best on this subject; who, however, is said to have been afterwards a convert to Spinozism, and to have written a demonstration of the truth of it: a refutation of his defence by Isaac Orobio, a learned Jewish physician at Amsterdam, was published in 8vo. 1703. See also Buddeus's *Theses de Atheismo et Superstitione*, c. i. sect. 26; and Fabricius's *Syllab. Script. de Verit. Relig. Christ.* p. 357, &c. Mr. Bayle, and above all Dr. Clarke and Dr. Cudworth, have distinguished themselves by their refutation of the system of Spinoza. See Bayle's *Dict. art. Spinoza*, and Clarke's *Demonstration of the Being and Attributes of God*, p. 25—45, &c. ed. 1725. Cudworth's *Intellectual System*.

Spinoza, in his *Tractatus* above-mentioned, is very full on the subject of the authors of the scriptures; and endeavours to shew, that the Pentateuch is not the work of Moses; contrary to the common opinion, both of the Jews and Christians. He has also his particular sentiments as to the authors of the other books. This part of the work has been answered by Mr. Huet, in his *Demonstratio Evangelica*; and by M. Simon, in his *Hist. Crit. du Vieux Test.* See **PENTATEUCH**.

Spinozism is a species of naturalism, or pantheism, or hylotheism, as it is sometimes called, *i. e.* of the dogma which allows of no other God but nature, or the universe; and, therefore, makes matter to be God. Accordingly, Buddeus, in a dissertation "*De Spinozismo ante Spinozam*," proves at large, that Spinoza's doctrine of God and the world, is far from being his own invention, but that it had been held by many philosophers of different sects, both among the Chaldeans and Greeks. It is certain, the opinion of the Stoics, and of those who held an *anima mundi*, was not far from it. Lucan introduces Cato discoursing thus:

"Estne Dei sedes nisi terra, et pontus, et aer,
Et cælum, et virtus? superos quid quærimus ultra?
Jupiter est quodcumq; vides, quocumq; moveris."

Luc. Phars. l. 9. v. 578.

Strato likewise, and others among the Peripatetics, maintained something very like it; and, what is more, though no ancient sect seems farther removed from Spinozism than the Platonic, as they attributed the greatest freedom to God, and carefully distinguished him from matter; yet Gundlingius has proved at large, that Plato gave matter much the same origin with Spinoza. But the sect that approached nearest to Spinozism was that which taught, that all things were one, as Xenophanes the Colophonian, Parmenides, Melissus, and especially Zeno Eleates; whence it obtained the name of the "*Eleatic System of Atheism*." To the same may also be reduced the opinion of those, who held the first matter for God, as Amalricus and David of Dinantum. Add, that the sect of Foe in China and Japan, and that of the Soufi in Persia, and that of the Zindikites in Turkey, are found to philosophize much after the manner of Spinoza.

The impious system of Spinoza was so ingeniously maintained, that it found many patrons in the United Provinces, among whom were Lewis Meyer, who republished Spinoza's works, and who himself wrote a work entitled "*Philosophy the Interpreter of Scripture*," and Van Leenhof, an ecclesiastic of Zwoll, who wrote a piece entitled "*Heaven in Earth*," of the doctrine of which he was obliged to make a public recantation. Others, under the pretence of refuting Spinoza, secretly favoured his system.

The chief articles in Spinoza's system are reducible to these: that there is but one substance in nature; and that this only substance is endued with an infinite number of attributes, among which are extension and cogitation: that all the bodies in the universe are modifications of this substance, considered as it is extended; and that all the souls of men are modifications of the same substance, considered as cogitative: that God is a necessary and infinitely perfect Being, and is the cause of all things that exist, but is not a different being from them: that there is but one being, and one nature; and that this nature produces within itself, by an immanent act, all those which we call creatures: and that this being is at the same time both agent and patient, efficient cause and subject; but that he produces nothing but modifications of himself.

As Spinoza taught, that there is no difference of substances, he maintained, that the whole and every part of the material world is a necessary existing being, and that there is no other God, but the universe: and, moreover, since it is absolutely impossible for any thing to be created or produced by another, and also absolutely impossible for God to have caused any thing to be in any respect different from what it now is; every thing that exists must needs be so a part of the divine substance, not as a modification caused in it by any will or good pleasure or wisdom in the whole, but as of absolute necessity in itself, with respect to the manner of the existence of each part, no less than with respect to the self-existence of the whole; consequently the material world, and every part of it, with the order and manner of being of each part, is, upon this scheme, the only self-existent, or necessarily existing being.

And he also maintains, that motion, as a dependent being, has been eternally communicated from one piece of matter to another; and, therefore, without having at all any original cause of its being, either within itself or from without: this, Dr. Clarke has proved to be a plain contradiction, and consequently, motion must of necessity be originally caused by something that is intelligent, or else there never could have been any such thing as motion in the world; and, therefore, the self-existent being, the original cause of all things, must of necessity be an intelligent being. Hence it follows, that the material world cannot possibly be the original self-existent being. For since the self-existent being is intelligent, and the material world plainly is not so, it follows, that the material world cannot possibly be self-existent.

Agreeably to Spinoza's system, he is led to maintain that the supreme cause is a necessary agent, and, therefore, that no thing, or mode of existence of any thing, could possibly have been in any respect different from what it now actually is; because, he says, from an infinitely perfect nature, infinite things in infinite manners must needs proceed: if any thing could possibly be otherwise than it is, the will and nature of God must be supposed capable of change; and if all possible things in all possible manners do not always and necessarily exist, they never can all exist, but some things that do not exist, will still always be possible only, and never can actually exist; and so the actual omnipotence of God is taken away. To this reasoning Dr. Clarke replies, that the first argument is a plain begging of the question; for, that an infinitely perfect nature is able indeed to produce infinite things in infinite manners, is certainly true; but that it must always actually do so, by an absolute necessity of nature, without any power of choice, either as to time, or manner, or circumstances, does by no means follow from the perfection of its nature, unless it be first supposed to be

be a necessary agent, which is the very question begged that was to be proved.

The second argument, he says, is, if possible, still weaker; for, how does it follow, if God, according to his eternal unerring purpose and infinite wisdom, produces different things at different times, and in different manners, that, therefore, the will and nature of God are changeable? It might exactly as well be argued, that if God (according to Spinoza's supposition) does always necessarily produce all possible differences and varieties of things; therefore his will and nature are always necessarily infinitely various, unequal, and dissimilar to themselves.

And as to the third argument, it is just such reasoning as if a man should argue, that if all possible eternal duration be not always actually exhausted, it can never be all exhausted; and that, therefore, so the eternity of God is taken away: a mode of arguing, the weakness of which must be discerned by every one at first sight. Besides, the assertion itself, that no thing, or mode of existence of any thing, could possibly have been made in any respect different from what it is, is so palpably absurd and false, so contradictory to experience and the nature of things, and to the most obvious and common reason of mankind, that of itself it immediately, and upon the first hearing, sufficiently confutes any principle of which it is a consequence. For all things in the world appear plainly to be the most arbitrary that can be imagined, and to be wholly the effects not of an absolute necessity of nature, but merely of a necessity of fitness, or of wisdom and choice. Moreover, Spinoza maintaining that the supreme cause is a necessary agent, is constrained to expose all final causes as the fictions of ignorant and superstitious men; and so laugh at those who are so foolish and childish as to fancy, that eyes were designed and fitted to see with, teeth to chew with, food to be eaten for nourishment, the sun to give light, &c. a mode of arguing to which reply is needless. See the article *God*.

Against Spinoza's system it is alleged by Mr. Bayle, 1. That it is impossible the universe should be but one substance, since every thing that is extended must necessarily have parts, and what has parts must be compounded. And as the parts of extension do not subsist in each other, it follows either that extension in the general is not substance, or that every part of extension is a different substance. Now, according to Spinoza, extension in general is an attribute of substance. And he allows, with other philosophers, that the attributes of substance do not differ really from the substance itself. He must, therefore, allow, that extension in general is substance; whence it will follow, that every part of extension is a particular substance; which overturns the whole system.

2. If it be absurd to make God extended, as this robs him of his simplicity, and makes him be composed of parts, it is still worse to reduce him to the condition of matter, the lowest of all beings, and that which most of the ancient philosophers ranked immediately above nothing; matter, the theatre of all sorts of changes, the field of battle of contrary causes, the subject of all corruptions and generations; in a word, the being, of all others, most incompatible with the immutability of the Deity.

The Spinozists, indeed, maintain, that it is not susceptible of any division; but the argument they allege in proof of it we have elsewhere shewn to be false: it is, that for matter to be divided, it is necessary that one of the parts be separated from the other by a void space, which is impossible; since, they say, there is no vacuum in nature. See *VACUUM*.

3. If Spinozism appear extravagant, when we consider

God as the subject of all the mutations, corruptions, and generations, in bodies, it will be found still worse, when we consider him as the subject of all the modifications of thinking. It is no small difficulty to unite extension and thinking in the same substance; since it is not an union like that of two metals, or of water and wine, that will serve the purpose: these last require only juxtaposition; whereas to combine thinking and extension, requires an identity. Thinking and extended are two attributes identified with the substance, and, consequently, they are identified with each other by the fundamental rule of all logic.

Again, when we say, that a man *denies this, affirms that, likes that, &c.* we make all those attributes fall on the substance of his mind, not on his thoughts, which are only accidents or modifications of it: if, therefore, what Spinoza advances be true, that men are modalities of God, it would be false to say, *Peter denies, likes, wills, &c.*; since, in reality, on this system it is, that God denies, wills, &c.; and, consequently, all the denominations which arise from the thoughts, desires, &c. of men, fall properly and physically on the substance of God. From whence it also follows, that God affirms and denies, loves and hates, wills and wills the same thing, at the same time, and under the same conditions; contrary to the great principle of reasoning, *opposita sunt quæ se neque de se invicem, neque de eodem tertio secundum idem, ad idem, eodem modo atque tempore verè affirmari possunt*; which must be false, if Spinozism be true; since it cannot be denied, but some men love and affirm what others hate and deny, under all the conditions expressed in the rule.

4. But if it be physically absurd to say, the same subject is modified at the same time with all the different thoughts of all men; it is horrible when we consider it in a moral light; since it will follow, that the infinite, the all-perfect Being, is not constant, is not the same one moment, but is eternally possessed even with contrary passions: all the uniformity in him in this respect, will be, that for one good and wise thought, he will have twenty foolish and wicked ones. He will not only be the efficient cause of all the errors, iniquities, and impurities of men, but also the passive subject of them, the *subjectum inhesionis*. He must be united with them in the closest manner that can be conceived, even by a penetrative union, or rather an identity, since the mode is not really distinct from the substance modified. Bayle, art. *Spinoza*.

SPINSTER, in *Law*, an addition usually given to all unmarried women, from the viscount's daughter downwards.

Yet Sir Edward Coke says, *generosa* is a good addition for a gentlewoman; and that, if such a person be named spinster in any original writ, appeal, or instrument, she may abate and quash the same.

Spelman says, that anciently, even queens used the distaff and spindle; whence spinster became a common appellation for all women.

SPINT, in *Commerce*, a corn measure of Germany. At Bremen, a last of corn, pease, or beans, contains 4 quarters, 40 scheffels, 160 viertels, or 640 spints; 50 scheffels answering to 101 bushels, Winchester measure. At Hamburg, a last of wheat or rye contains 3 wispels, 30 scheffels, 60 fasses, 120 kimterns, or 480 spints; and according to the standard measure of the fass, which is $21\frac{1}{2}$ inches in diameter, and $10\frac{1}{2}$ inches deep, Hamburg measure, its contents are 3872 Hamburg cubic inches, or 3213 English inches, 1 scheffel or two fasses = 3 bushels, Winchester measure nearly; and 1 last of Hamburg = $89\frac{1}{2}$ English bushels, or $11\frac{1}{3}$ English quarters.

SPINTHER, among the Romans, a kind of bracelet which the women, in the first ages of Rome, used to wear on the upper part of their left arm.

SPINTHERA, in *Mineralogy*, a mineral of greenish colour, which occurs crystallized in irregular dodecahedrons, composed of a double four-sided pyramid, obliquely truncated at the apexes. The crystals are small, and brightly shining; the fracture is lamellar. Its hardness is inferior to that of glass; it is translucent on the edges. It melts before the blowpipe without much difficulty. It has not been analysed. It was discovered by Haüy implanted in calcareous spar from Dauphiné. Aikin's Dict.

SPINUS, in the *Natural History of the Ancients*, the name of a fossil body of a very remarkable quality; for, according to the accounts of Theophrastus, and other authors of the greatest credit, it broke to pieces, and thrown in a heap exposed to the sun, it took fire and burnt, and that the more if moistened or sprinkled with water.

It seems to have been a substance nearly allied to what they call the *lapis thracicus*, but with this remarkable quality, both of them seem to have been of the class of the harder bitumens, and are wholly unknown to us. Some late writers have imagined, that the common black slate-stone, so frequent with us in the coal-pits, was the substance called by Theophrastus, and the ancients, by this name; but it had none of the qualities attributed to the spinus. Hill's Theophrastus, p. 35.

SPINUS, in *Ichthyology*, a species of the sparus, with a bifid tail, and the dorsal spine recumbent. It is found in the Indian seas.

SPINUS, the *Fringilla spinus* of Linnæus, in *Ornithology*, the name of a small bird, called by some *ligurinus*, and in English the *fskin*. Its head is black, and its neck and back green; the neck, however, has some slight admixture of a blackish tinge, and the roots of the back feathers have also some blackishness; its rump is of a greenish-yellow, as are also its breast and throat; its belly is white, and its tail is yellow underneath, with some brownish spots; the female is paler coloured than the male; and its throat, and its sides, under the wings, are whitish, with streaks of brown; the head and back are of a greenish ash-colour, marked with brown. It is common in Germany and England, which it visits at uncertain times, and is kept in cages for singing. In winter these birds fly in large flocks. In Suffex it is called the barley-bird, because it comes to them in the barley-feed time.

SPIO, in *Natural History*, a genus of the class Vermes, and order Mollusca. The generic character is as follows: Body projecting from a tube, jointed, and furnished with dorsal fibres; peduncles or feet rough with bristles, and placed towards the back; two feelers, which are long and simple; it has two oblong eyes. There are only two

Species.

* **SETICORNIS**. Feelers thin and striate. This species inhabits the ocean, principally where there is a clayey bottom; it is about three inches long; the tube is composed of agglutinated particles of earth, thin, erect, and thrice as long as the body. From this the animal projects its capillary white feelers in search of food, which consists of small marine worms; the body is whitish, with a tinge of green, with a red line down the middle of the back; the hind-part is of a sea-green; the fore-part is blackish-grey, with transverse white stræ; the head is pale.

FILICORNIS. Feelers thick and annulate. It inhabits the sea-shores about Greenland, and is an inch long. Body oblong, yellowish or reddish, with a cinereous line in the

middle, and at each end; the tube is fragile, erect, and greenish, from which it projects its feelers in search of *planaria*, and other small marine worms.

SPIPOLA, in *Ornithology*, the name of a small bird of the lark kind, of which there are, according to Aldrovand, three species, suspected by Mr. Ray to be only varieties of the *spinoletta*, or *tordino* of the Venetians.

Linnaeus makes two of these distinct species, under the titles of *alauda trivialis*, and *alauda pratensis*; the last of which is our tit-lark.

SPIRACLE. See **VENT**.

SPIRACULA, in the *History of Insects*, are little holes or pores placed singly on each side of every segment of the abdomen, through which the insect breathes; and if oil be applied so as to stop them up, it proves fatal to most of them.

SPIRÆA, in *Botany*, a name borrowed from Theophrastus, whose *σπιραία* is supposed to be one of the species of this pretty genus.—Linn. Gen. 253. Schreb. 341. Willd. Sp. Pl. v. 2. 1055. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 535. Ait. Hort. Kew. v. 3. 254. Pursh 341. Juss. 339. Lamarck Illustr. t. 439. Gærtn. t. 69.—Class and order, *Icosandria Pentagynia*. Nat. Ord. *Pomaceæ*, Linn. *Rosaceæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, flat at the base, in five acute segments, permanent. *Cor.* Petals five, roundish-oblong, inserted into the calyx. *Stam.* Filaments more than twenty, thread-shaped, inserted into the calyx, shorter than the corolla; anthers roundish. *Pistl.* Germens five or more; styles as many, thread-shaped, the length of the stamens; stigmas capitate. *Peric.* Capsules oblong, compressed, pointed, each of one cell and two valves. *Seeds* few, pointed, small, inserted into the inner margins of the valves.

Obf. *S. Filipendula* and *Ulmaria* have numerous germens and capsules; *S. Aruncus* is dioecious; *S. opulifolia* has only three germens and styles.

Ess. Ch. Calyx five-cleft. Petals five. Capsules superior, of two valves, with several seeds.

Seet. 1. *Stem shrubby.*

1. *S. laevigata*. Smooth-leaved Spiræa. Linn. Mant. 244. Willd. n. 1. Ait. n. 1. (*S. altaica*; Pall. Ross. v. 1. p. 1. 37. t. 23.)—Leaves obovato-lanceolate, entire, sessile, smooth. Clusters stalked, corymbose.—Native of Siberia. The English gardens are obliged to Dr. Solander for this shrub, which is quite hardy, flowering copiously in summer, and distinguished by its very smooth, willow-like, rather glaucous leaves. *Flowers* pure white, in clusters, collected into corymbose tufts at the ends of the branches. The leaves are deciduous in all the species.

2. *S. salicifolia*. Willow-leaved Spiræa. Linn. Sp. Pl. 700. Fl. Brit. n. 1. Engl. Bot. t. 1468. Ait. n. 2. Pursh n. 1. Pall. Ross. v. 1. p. 1. 36. t. 21, 22. (*S. Theophrasti fortè*; Ger. Em. 1601.)—Leaves ovato-lanceolate, bluntish, serrated, smooth. Clusters terminal, compound.—Native of mountain thickets, near water, in Siberia, Tartary, and North America, as well as in Scotland and the north of England. It is common in shrubberies, flowering in July. The stem is four or five feet high, erect, bushy. Leaves stalked, from one to two inches long, various in breadth, deeply serrated. *Flowers* pink, with a dark red calyx. In America there is a white variety.

3. *S. callosa*. Callous Spiræa. Thunb. Jap. 209. Willd. n. 3. (*S. japonica*; Linn. Suppl. 262.)—Leaves lanceolate, acute, serrated, rather villous. Stem downy. Panicle doubly compound, somewhat level-topped.—Native of Japan, flowering in June. Leaves longer and more acute than

than in the last, more villous than in the following, and not downy. The paniced *inflorescence* distinguishes it from both. *Flowers* red, on villous stalks.

4. *S. tomentosa*. Scarlet Spiræa. Linn. Sp. Pl. 701. Ait. n. 3. Pursh n. 2. "Schmidt Arb. v. 1. 52. t. 51." (*Ulmaria pentacarpos*, &c.; Pluk. Phyt. t. 321. f. 5.)—Leaves ovate, unequally ferrated; downy and white beneath. Clusters compound, downy.—Native of North America; a hardy shrub in our gardens, flowering towards autumn, and justly admired for its bright red *flowers*, and the white downiness of the backs of its *leaves*. In other respects it much resembles *S. salicifolia*.

5. *S. argentea*. Silvery Spiræa. Linn. Suppl. 261. Willd. n. 5.—Leaves wedge-shaped, furrowed, somewhat plaited; silky on both sides; ferrated at the extremity. Clusters compound. Capsules fringed.—Sent from New Granada by Mutis to Linnæus. The copious silvery *leaves*, about an inch long, render this a very elegant shrub. The *clusters* are numerous at the ends of the branches, but do not consist of many *flowers*. The *germens* and *capsules* are bordered with long hairs.

6. *S. alpina*. Alpine Small-leaved Spiræa. Pall. Roff. v. 1. p. 1. 35. t. 20. Willd. n. 6.—Leaves linear-lanceolate, partly toothed, very smooth. Flowers corymbose.—Native of cold woody mountains in Siberia, near the lake Baical. A small, spreading, branching *shrub*, whose bark splits into long threads. The *leaves* are hardly an inch long, and very narrow. *Flowers* white, in small downy *corymbs*, solitary at the end of each branch.

7. *S. hypericifolia*. St. John's-wort Spiræa, or Italian May; commonly called *Hypericum frutex*. Linn. Sp. Pl. 701. Ait. n. 4. Pursh n. 3. "Schmidt Arb. v. 1. 55. t. 56." Bocc. Mus. 137. t. 96. (*Pruno sylveltri affinis canadensis*; Pluk. Phyt. t. 218. f. 5.)—Leaves obovate, entire. Umbels sessile.—In dry swamps of Canada and New York, flowering in May. *Pursh*. This shrub, cultivated for near 200 years past in our English gardens, and asserted to be of American origin, is no less apparently wild on all the hills of Umbria, between Terni and Trevi, as Boccone long ago mentioned. (See Sm. Tour, ed. 2. v. 2. 322.) It is frequently called in England Italian May. The *leaves* are an inch long, resembling some species of *Hypericum*. *Flowers* white, copious and very pretty, in smooth lateral umbels.

8. *S. chamædrifolia*. Germander-leaved Spiræa. Linn. Sp. Pl. 701. Ait. n. 5. Pursh n. 4. Pall. Roff. v. 1. p. 1. 32. t. 15.—Leaves obovate, smooth, cut, and ferrated. *Corymbs* stalked.—Native of Siberia and Hungary. Hardy with us, flowering in June and July. The *leaves* are green, or slightly glaucous, on both sides, an inch, or rather more, in length. *Flowers* white, rather bigger than the last, nearly umbellate. *Branches* angular.

9. *S. ulmifolia*. Elm-leaved Spiræa. Scop. Carn. v. 1. 349. t. 22*. Willd. n. 9. Ait. n. 6. (*S. chamædrifolia*; Jacq. Hort. Vind. v. 2. 66. t. 140.)—Leaves ovate, smooth, doubly ferrated; glaucous beneath. *Corymbs* racemose, elongated, on long stalks.—Native of Carniola and Siberia. Cultivated for about 30 years past in our gardens, flowering in June. A shrub larger in all its parts than the foregoing, especially the *flowers*, which are rather racemose than corymbose. The *leaves* are an inch and a half long, on stalks one-third that length.

10. *S. betulifolia*. Birch-leaved Spiræa. Pall. Roff. v. 1. p. 1. 33. t. 16. Pursh n. 5.—Leaves broadly ovate, smooth, deeply ferrated, on short stalks. *Corymbs* compound, level-topped.—Native of Siberia; and, according to Mr. Pursh, of the mountains of Virginia, flowering from

May to July. He describes it as not above a foot high; the *flowers* tinged with red, and asserts it to be very distinct from the last, to which Willdenow refers Pallas's synonym. The *leaves* appear to be much broader than in the *ulmifolia*, with shorter thicker *footstalks*, and the *inflorescence* more compact.

11. *S. crenata*. Hawthorn-leaved Spiræa. Linn. Sp. Pl. 701. Ait. n. 7. Pall. Roff. v. 1. p. 1. 35. t. 19. (*Oxyacantha angustifolia non spinosa*; Barrel. Ic. t. 564.)—Leaves obovate, acute; toothed at the extremity. *Corymbs* lateral, crowded, stalked.—Native of Siberia, Tartary, Hungary, and Spain. Cultivated by Miller in 1739, and frequently met with in curious shrubberies, flowering in May. The *leaves* vary much in size and shape, but are always strongly toothed, or jagged, at the end. When small they are often three-ribbed, but that character is not so constant as to make a specific difference. *Flowers* white, in copious, short, lateral, leafless clusters. Willdenow suspects the Spanish variety may be a distinct species, but we find our garden plant so variable, that the line of distinction is scarcely to be drawn. A comparison of living specimens must decide the question.

12. *S. trilobata*. Three-lobed Spiræa. Linn. Mant. 2. 244. Willd. n. 11. Ait. n. 8. Pall. Roff. v. 1. p. 1. t. 17.—Leaves roundish, somewhat heart-shaped, bluntly lobed, toothed. Umbels terminal.—Native of mountains in Siberia. A hardy shrub with us, introduced by sir J. Banks in 1801, but not yet come into general culture. It flowers in May. The *leaves* are smooth, not unlike those of a gooseberry in shape. *Flowers* white, copious, and handsome.

13. *S. thalictroides*. Meadow-rue-leaved Spiræa. Willd. n. 12. Ait. n. 9. Pall. Roff. v. 1. p. 1. 34. t. 18.—Leaves obovate, obtuse, somewhat three-lobed. Umbels lateral, sessile.—Native of the alps of Dauria. Flowering at Kew in May. A pretty species, with small *leaves*, very glaucous beneath. *Flowers* white, smaller than the last, and lateral, not terminal.

14. *S. opulifolia*. Virginian Guelder-rose. Linn. Sp. Pl. 702. Ait. n. 10. Pursh n. 6. "Schmidt Arb. v. 1. 52. t. 52." (*Euonymus virginiana, ribesii folio, capsulis eleganter bullatis*; Comm. Hort. v. 1. 169. t. 87.)—Leaves ovate, three-lobed, ferrated, smooth. *Corymbs* terminal, dense, bracteated. Capsules polished, inflated.—On the banks of rivers, particularly among the mountains, from Canada to Carolina, flowering in June and July. Generally known by the name of Nine-bark. *Pursh*. Cultivated by bishop Compton, and now common in shrubberies, forming a small tree, with much resemblance to the Common Guelder-rose. *Flowers* white, somewhat like Hawthorn. *Capsules* tumid, smooth, of a shining brown. *Calyx* more or less downy.

15. *S. capitata*. Capitata Spiræa. Pursh n. 7.—"Leaves ovate, somewhat lobed, doubly toothed; reticulated and downy beneath. *Corymbs* terminal, dense, somewhat capitate, on very long stalks. *Calyx* downy."—Found by Mr. Menzies, on the north-west coast of America, flowering in June. Gathered also on the Columbia river by governor Lewis. *Pursh*.

16. *S. ariæfolia*. Beam-tree-leaved Spiræa.—Leaves elliptic-oblong, somewhat lobed, toothed; pale and villous beneath. Clusters compound, paniced, terminal, downy.—Gathered on the north-west coast of America, by Mr. Menzies, to whom we are obliged for specimens. It seems not noticed by Mr. Pursh. Perhaps this species ought, on account of its paniced very compound *inflorescence*, to be ranged near *salicifolia* and *tomentosa*. The *leaves* are lobed like

SPIRÆA.

like *Pyrus Aria*, but rather smaller, and villous, not cottony, beneath. The dried *flowers* look as if they had been reddish.

17. *S. difcolor*. Folded-leaved Spiræa. Pursh n. 8.—“Leaves ovate, lobed, toothed, somewhat plaited; snow-white and downy beneath. Panicles terminal, stalked, very much branched.”—On the banks of the Kookkooksky, gathered by governor Lewis, flowering in June and July. A shrub about five feet high. *Pursh*. Can this be the same species with our last? We have not had an opportunity of comparing specimens.

18. *S. forbifolia*. Service-tree-leaved Spiræa. Linn. Sp. Pl. 702. Ait. n. 11. Pursh n. 9. Pall. Ross. v. 1. p. 1. 34. t. 24, 25. (S. n. 51; Gmel. Sib. v. 3. 190. t. 40.)—Leaves pinnate; leaflets uniform, sharply serrated. Stem shrubby. Flowers paniced.—Native of Siberia and the north-west coast of America, flowering in July and August. Frequent in gardens, and distinguished by the elegance of its bright-green, finely serrated *leaves*, as well as its large panicles of cream-coloured *flowers*. The *root* creeps in some degree. The *stems* are three or four feet high, not very woody.

SECT. 2. *Stem herbaceous*.

19. *S. Aruncus*. Goat's-beard Spiræa. Linn. Sp. Pl. 702. Ait. n. 12. Pursh n. 10. Pall. Ross. v. 1. p. 1. 39. t. 26. (*Barba capri*; Fuchf. Hist. 181. B. capræ; Camer. Hort. 26. t. 9.)—Leaves doubly compound. Spikes paniced. Flowers dioecious.—Native of Siberia, Austria, Switzerland, the Pyrenées, and the mountains of North America. A hardy perennial in our gardens, of great elegance, about a yard high, with ample light-green *leaves*, and innumerable white feathery *flowers*, produced in June and July.

20. *S. Filipendula*. Common Dropwort Spiræa. Linn. Sp. Pl. 702. Willd. n. 16. Fl. Brit. n. 2. Engl. Bot. t. 284. Fl. Dan. t. 635. (*Filipendula*; Ger. Em. 1058. Camer. Epit. 608. Matth. Valgr. v. 2. 217.)—Leaves interruptedly pinnate; leaflets uniform, serrated, smooth. Stem herbaceous. Flowers cymose, with many styles.—Native of high chalky or gravelly pastures in England, and other parts of Europe, flowering in July. Commonly double in gardens. The *root* is perennial, furnished with oval woody knobs. *Stem* one or two feet high. *Leaflets* small, oblong, sharply cut. *Flowers* cream-coloured, with here and there a tinge of red.

21. *S. Ulmaria*. Meadow-sweet Spiræa. Linn. Sp. Pl. 702. Willd. n. 17. Fl. Brit. n. 3. Engl. Bot. t. 960. Curt. Lond. fasc. 5. t. 33. Fl. Dan. t. 547. (*Regina prati*; Ger. Em. 1043.)—Leaves interruptedly pinnate; downy beneath: the terminal leaflet lobed. Flowers cymose, with many styles.—Common in wet meadows, bogs, and the borders of rivers and pools throughout Europe, flowering in June and July. The *root* is fibrous, perennial. *Stems* three or four feet high. *Leaves* broad, serrated; white underneath. *Flowers* cream-coloured, copious, with a very sweet, but oppressive, fragrance. *Germs* twisted.

22. *S. digitata*. Fingered Spiræa. Willd. n. 18. (*S. palmata*; Linn. Suppl. 262. Pall. Ross. v. 1. p. 1. 40. t. 27.)—Leaves pinnate; downy beneath: the terminal leaflet largest, in seven deep lobes; side ones in five. Corymb compound, dense.—Native of moist mountainous situations, in the eastern part of Siberia. This has the habit of the last, but the palmate deeply divided *leaflets* abundantly distinguish it.

23. *S. lobata*. Palmate Red Spiræa. Jacq. Hort. Vind. v. 1. 38. t. 88. Willd. n. 19. Pursh n. 11.—Leaves pin-

nate, smooth: the terminal leaflet largest, seven-lobed: side ones three-lobed. Corymbs proliferous.—In fertile wet meadows of Virginia and Carolina, flowering in July and August. A beautiful perennial; *flowers* red, in large clusters. *Pursh*. The Linnæan herbarium shews that authors have here misapplied the reference to the *Supplementum*, which belongs to the last species.

24. *S. camtschatica*. Broad-leaved Siberian Spiræa. Pall. Ross. v. 1. p. 1. 41. t. 28. Willd. n. 20.—Leaves five-lobed, with auricles on the stalks. Corymbs proliferous. Stem somewhat hairy.—Native of Camtschatka and Beering's island. The *root* is perennial. *Leaves* very broad, smooth, with acute lobes. *Flowers* white.

25. *S. palmata*. Palmate Japan Spiræa. Thunb. Jap. 212. Willd. n. 21.—“Leaves palmate, serrated. Panicle repeatedly compound. Stem smooth.”—Native of Japan. The stalks of the *leaves* seem to have no auricles, and the *stem* is smooth; otherwise the description of this species bears some resemblance to the last. *Flowers* red or white.

26. *S. trifoliata*. Common Three-leaved Spiræa. Linn. Sp. Pl. 702. Ait. n. 16. Pursh n. 12. Curt. Mag. t. 489.—Leaves ternate, serrated, nearly equal. Stipulas linear. Flowers terminal, loosely paniced. Calyx tubular.—In shady woods and on bogs, chiefly in the mountainous parts of North America from Canada to Florida, flowering in June and July. *Pursh*. A hardy perennial in our gardens, of singular elegance, with large drooping *flowers*, whose *petals* are white, *calyx* deep red.

27. *S. stipulacea*. Auricled Three-leaved Spiræa. Willd. Enum. 542. Pursh n. 13.—Leaves ternate, serrated, nearly equal. Stipulas ovate, leafy, cut. Flowers terminal, loosely paniced. Calyx bell-shaped.—In the shady woods of Kentucky and Tennessee, flowering in June and July. *Pursh*. We received it from the choice garden of James Vere, esq. in August, 1814. The general appearance of this species is very like the last, but the very large *stipulas*, and perhaps the shorter greener *calyx*, distinguish it.

SPIRÆA, in *Gardening*, contains plants of the shrubby and herbaceous kinds, among which the species cultivated are, the willow-leaved spiræa (*S. falcifolia*); the scarlet-leaved spiræa (*S. tomentosa*); the hypericum-leaved spiræa (*S. hypericifolia*); the silver-leaved spiræa (*S. argentea*); the germander-leaved spiræa (*S. chamædrifolia*); the hawthorn-leaved spiræa (*S. crenata*); the three-lobe-leaved spiræa (*S. triloba*); the currant-leaved spiræa (*S. opulifolia*); the service-leaved spiræa (*S. forbifolia*); the goat's-beard spiræa (*S. aruncus*); the common dropwort spiræa (*S. filipendula*); the common meadow-sweet spiræa (*S. ulmaria*); and the three-leaved spiræa (*S. trifoliata*).

In the first species there are several varieties; as the flesh-coloured willow-leaved, the Alpine willow-leaved, the paniced willow-leaved, and the broad willow-leaved spirææ. The tough, straight, pliant, young shoots of this plant are sometimes used to top fishing-rods, &c.

The fifth species varies very much, with larger or smaller leaves, more or less cut, but more commonly quite entire and ovate-acute.

The eighth sort is commonly known in the nurseries by the name of Virginian guelder rose.

The eleventh sort is an elegant plant, which in gardens grows very luxuriantly, and has often double flowers.

In the twelfth sort there are varieties with double flowers, and with variegated leaves.

Method of Culture.—In all the shrubby sorts, this may be performed by suckers, layers, and cuttings. The suckers should be taken off in the autumn, and planted out where they are to remain, or in nursery-rows, to attain a

fuller growth. The first fort requires to be cleared of these suckers every two years at farthest. The layers should be put down in the autumn, or in the spring, and may be taken off and planted as above, in the autumn or spring following. All the forts may be raised in this way; but it is most proper for such forts as do not fend off suckers. The cuttings may be made from the shoots of the preceding summer, and be planted out in a shady border, in the early autumn. When they have become well rooted, they may be removed, and managed as the others. They succeed in this way with more difficulty than in either of the others.

All the herbaceous forts may be increased by seeds, or parting the roots. The seed may be sown in the autumn, or early in the spring, but the first is the better mode, on a bed of fine mould. When the plants appear, they should be kept clear from weeds till the autumn, when they may be planted where they are to remain, or in the nursery for a year or two. The roots should be parted in the autumn or spring, when the stems decay, before they shoot out new ones, being planted immediately where they are to grow. The double-flowered and striped varieties can only be preferred in this way.

They all afford variety and ornament in the shrubbery, and other parts of pleasure-grounds.

SPIRÆA, African, in *Botany*. See *DIOSMA*.

SPIRAL, in *Geometry*, a curve line of the circular kind, which, in its progress, recedes from its centre; as in winding from the vertex, down to the base of a cone.

It is called, from its inventor, *Archimedes's spire*, or *helix*, and is thus described: divide the periphery of a circle $A p A$ (*Plate XIV. Geometry, fig. 4.*) into any number of equal parts, by a continual bisection in the points p . Into the same number of parts divide the radius CA , and make CM equal to one part, Cm to two parts, &c. Then will the points, M, m, m , &c. be points in the spiral; which, connected, will give the spiral itself.

This is more particularly called the *first spiral*; and the space included between its centre and the point A , the *spiral space*.

The first spiral may be continued to a *second spiral*, by describing another circle with double the radius of the first; and the second may be continued to a *third*, by a third circle, &c.

Hence, 1. $A p$ is to the periphery, as Cm to the radius: wherefore, if the periphery be called p , the radius $AC = r$, $A p = x$, $p m = y$; then will $Cm = r - y$: consequently, as $p : r :: x : r - y$, we shall have $p r - p y = r x$.

2. If $Cm = y$, then will $r x = p y$; which equation the spiral has in common with the quadratrix of Dinostrates, and that of Tschirnhausen: and, therefore, $r^n x^m = p^n y^m$ will serve for infinite spirals and quadratrices. See *QUADRATRIX*.

The spiral line may be conceived to be thus generated: If a right line, as AB (*Plate XIV. Geometry, fig. 5.*) having one end fixed at B , be equally moved round, so as, with the other end A , to describe the periphery of a circle; and, at the same time, a point be conceived to move forward equally, from B towards A , in the right line AB , so as that the point describes that line, while the line generates the circle; then will the point, with its two motions, describe the curve $B, 1, 2, 3, 4, 5$, &c. which is called a spiral line; and the plain space contained between the spiral line and the right line BA , is called the spiral space.

Again, if the point B be conceived to move twice as slow as the line AB , so that it shall get but half way along BA , when that line shall have formed the circle; and if then you imagine a new revolution to be made of the line carrying the

point, so that they shall end their motion at last together, there will be formed a double spiral line, as in the figure: from the manner of which may be easily drawn these corollaries:

1. That the lines $B 12, B 11, B 10$, &c. making equal angles with the first and second spiral (as also $B 12, B 10, B 8$, &c.) are in arithmetical proportion.

2. The lines $B 7, B 10$, &c. drawn any how to the first spiral, are to one another as the arcs of the circle intercepted betwixt BA and those lines; because, whatever parts of the circumference the point A describes, as suppose 7 , the point B will also have run over 7 parts of the line AB .

3. Any lines drawn from B to the second spiral, as $B 18, B 22$, &c. are to each other as the aforesaid arcs, together with the whole periphery added on both sides: for at the same time that the point A runs over 12 , or the whole periphery, or perhaps 7 parts more, shall the point B have run over 12 , and 7 parts of the line AB , which is now supposed to be divided into 24 equal parts.

The area $CABDE$ of the spiral of Archimedes (*Plate XIV. Geometry, fig. 6.*) is equal to one-third part of the circle, described with the radius CE .

In like manner, the whole spiral area, generated by the ray drawn from the point C to the curve, when it makes two revolutions, is the third part of a space double of the circle described with the radius $2CD$; and the whole area, generated by the ray from the beginning of the motion, till after any number of revolutions, is equal to the third part of a space that is the same multiple of the circle described with the greatest ray, as the number of revolutions is of unit.

Any portion of the area of the spiral, terminated by the curve $Cm A$, and the right line CA , is equal to one-third of the sector CAG , terminated by the right lines CA and CG , the situation of the revolving ray, when the point that describes the curve sets out from C . See Maclaurin's Fluxions, Introd. p. 30, 31. See *QUADRATURE of the Spiral of Archimedes*.

SPIRAL, Logistic, or Logarithmic. See *LOGISTIC* and *QUADRATURE*.

SPIRAL of Pappus, a spiral formed on the surface of a sphere, by a motion analogous to that by which the spiral of Archimedes is described in plano.

This spiral is so called from its inventor Pappus. *Collect. Mathem. lib. ii. prop. 30.*

Thus, if C be the centre of the sphere (*fig. 7.*), $ARBA$ a great circle, P its pole; and while the quadrant PMA revolves about the pole P with an uniform motion, if a point proceeding from P move with a given velocity along the quadrant, it will trace upon the spherical surface the spiral PFa .

Now if we suppose the quadrant PMA to make a complete revolution in the same time that the point, which traces the spiral on the surface of the sphere, describes the quadrant, which is the case considered by Pappus; then the portion of the spherical surface terminated by the whole spiral, the circle $ARBA$, and the quadrant PMA , will be equal to the square of AB . In any other case, the area $PMA a FZP$ is to the square of the diameter AB , in the same proportion as the arc Aa is to the whole circumference $ARBA$. And this area is always to the spherical triangle PAa , as the inscribed square is to the circle. See Maclaurin's Fluxions, Introd. p. 31—33.

The portion of the spherical surface, terminated by the quadrant PMA , the arcs AR, FR , and the spiral PZF , admits of a perfect quadrature, when the ratio of the arc Aa to

As to the whole circumference can be assigned. See Mac-laurin, *ibid.* p. 33.

SPIRAL, Parabolic. See HELICOID.

SPIRAL, Proportional, is generated by supposing the radius to revolve equably, and a point from the circumference to move towards the centre with a motion decreasing in a geometric progression. See LOGISTIC.

From the nature of a decreasing geometric progression, it is easy to conceive that the radius CA (*fig. 8.*) may be continually divided; and although each successive division becomes shorter than the next preceding one, yet there must be an indefinite number of divisions or terms before the last of them becomes of no finite magnitude. Whence it follows, that this spiral winds continually round the centre, and does not fall into it till after an indefinite number of revolutions: and also that the number of revolutions decreases, or the number of the equal parts into which the circumference is divided increases.

It is also evident, that any proportional spiral cuts the intercepted radii at equal angles: for, if the divisions A d, d e, e f, f g, &c. of the circumference be very small, the several radii would be so close to one another, that the intercepted parts AD, DE, EF, FG, &c. of the spiral might be taken as right lines; and the triangles CAD, CDE, CEF, &c. would be similar, having equal angles at the point C. and the sides about those angles proportional: consequently, the angles at A, D, E, F, &c. being equal, the spiral must necessarily cut the radii at equal angles. Robertson's *Elem. of Nav.* book ii. p. 87.

Proportional spirals are such spiral lines as the rhumb lines on the terrestrial globe, which, because they make equal angles with every meridian, must also make equal angles with the meridians in the stereographic projection on the plane of the equator, and therefore will be, as Dr. Halley observes, proportional spirals about the polar point. From whence he demonstrates, that the meridian line is a scale of log. tangents of the half meridian complements of the latitudes. See RHUMB, LOXODROMY, and MERIDIONAL Parts.

SPIRAL, in Architecture and Sculpture, denotes a curve that ascends, winding about a cone, or spire, so that all the points of it continually approach the axis.

By this it is distinguished from the helix, which winds, after the same manner, around a cylinder. Ignorant architects confound the two, but the more knowing distinguish them carefully.

SPIRAL Pump. See ARCHIMEDES'S SCREW.

SPIRAL Stairs, in Building. See STAIRS.
